production increased significantly, possibly owing to increased dependance on imported copper concentrates, which may have had a higher selenium content.

According to shipment data compiled by the American Bureau of Metal Statistics (ABMS), demand for refined selenium declined by almost 7%, while world producer inventories of refined selenium rose by the same percentage. ABMS data reflect shipments and inventories from companies that accounted for about 75% of world production. The United States was the largest recipient of selenium, followed by the United Kingdom, Japan, Belgium, and the Netherlands. However, deliveries to European countries may not have reflected their ultimate point of consumption. In Europe, demand for selenium declined slightly, reportedly owing to the potential for a legislative ban on cadmium-base pigments. Conversely, a preference for glass containers for environmental reasons may have spurred a demand growth in this sector.

World production and consumption data for tellurium are limited. According to ABMS, which collected data from producers accounting for between 50% and 60% of estimated world production, production and shipments of refined tellurium declined sharply during 1990 and producer inventories fell slightly. However, supplies of tellurium were reported to be adequate, and it was likely that consumer and merchant inventories served to cushion demand.

More than 60 market economy countries reported mine production of copper and about 30 market economy countries reported electrolytic refined copper production from a total of more than 80 operating electrolytic refineries. However, only about 15 countries and 20 refineries reported recovery of primary selenium and about onehalf that number reported tellurium production. Several primary refiners of selenium also recovered selenium from scrap, though breakout of their primary and secondary production is not well documented. Several companies, including International Recoveries Inc. in the Philippines, Shinko Chemicals Co. Ltd. and Asia Bussei Zairyo in Japan, and Mineral and Chemical Products Ltd. in the United Kingdom, were believed to produce selenium exclusively from secondary materials.

OUTLOOK

Though world production of selenium fluctuated greatly over the previous 10

years, its overall trend was flat; selenium production did not keep pace with the growth in copper mine output. Similarly, demand for refined selenium was also relatively stable. However, a productiondemand imbalance existed, and a shortfall in production was met by a large drawdown of world inventories. According to ABMS data, by 1989, world inventories had fallen from their 1981 peak by almost 800 tons, more than 50%. In 1990, however, demand fell, production rose, and the slide in selenium inventories was halted. In recent years, major copper refiners throughout the world have been investing in new slimes treatment facilities. World capacity for refined selenium production has increased by more than 200 tons per year.

Demand for refined selenium declined in 1990 owing to environmental pressures and economic recession. Demand for selenium in its largest application, xerography, was expected to remain stable or even decline slightly as organic photoreceptors, particularly for color copying, gain market share. Pigment uses of selenium were also expected to experience weak demand owing to environmental constraints. Demand for use in glass manufacturing was expected to remain strong or even increase.

The U.S. Bureau of Mines forecasts a significant increase in world copper mine capacity for the next 5 years. Assuming that world demand for selenium remains stable and that new selenium refining capacity and increased mine production serve to maintain the 1990 level of refined selenium production, production of refined selenium is expected to meet or exceed world demand. Increased exports to China, which have become significant in recent years, and advances in solar and imaging technology could boost demand and lead to tight supplies.

Data on demand for and production of tellurium are incomplete. However, available data indicate that market economy country demand over the 1984-88 period was comparatively stable, averaging about 220 tonnes per year, but weakened in 1989 and 1990. World production of refined tellurium, according to ABMS data, has trended downward. Excess supply following a demand turndown in the early 1980's depressed prices and discouraged recovery

of tellurium. In 1990, production fell in excess to the decline in demand, and inventories fell slightly.

The near-term outlook is for the continued tight balance between the supply and demand for tellurium. The high price for tellurium is expected to moderate future demand for tellurium in traditional metallurgical applications and stimulate the substitution of alternative materials. Demand for highpurity tellurium for use in thermal imaging and optical storage devices is expected to grow but not have significant impact on overall demand. If new thin-film technologies stimulate the demand for tellurium in electronic applications, such as solar energy conversion or thermoelectric power generation, supply pressures could increase. Though no significant new tellurium capacity is expected, additional resources, such as the gold telluride ores found in Fiji and Colorado, are potential new sources of tellurium.

^eEstimated. ^pPreliminary. W Withheld to avoid disclosing company proprietary data.

Insofar as possible, data relate to refinery output only; thus, countries that produced selenium contained in copper ores, copper concentrates, blister copper and/or refinery residues, but did not recover refined selenium from these materials indigenously, were excluded to avoid double counting. Table includes data available through May 29, 1991.

²In addition to the countries listed, Australia and the U.S.S.R. produced refined selenium, but output is not reported, and available information is inadequate for formulation of reliable estimates of output levels. Australia is known to produce selenium in intermediate metallurgical products and has facilities to produce elemental selenium. In addition to having facilities for processing imported anode slimes for the recovery of selenium and precious metals, the United Kingdom has facilities for processing selenium scrap.

³Excludes secondary production. ⁴Reported figure.

⁵Incomplete; data shown is for primary production at Philippine Associated Smelting and Refining Corp.

⁶Data for fiscal year beginning Apr. 1 of year stated.

Insofar as possible, data relate to refinery output only; thus, countries that produced tellurium contained in copper ores, copper concentrates, blister copper and/or refinery residues, but did not recover refined tellurium, are excluded to avoid double counting. Table is not totaled because of the exclusion of data from major world producers, notably the U.S.S.R. and the United States. Table includes data available through May 29, 1991. In addition to the countries listed, Australia, Belgium, the Federal Republic of Germany, and the U.S.S.R. are known to produce refined tellurium, but output is not reported, and available information is inadequate for formulation of reliable estimates of output levels. Morever, the other major copper-refining nations such as Chile and Zambia may produce refined tellurium, but output in these nations is conjectural.

SILICON

By Joseph Gambogi

Mr. Gambogi, a physical scientist with more than 8 years of Government and industry experience, has been the commodity specialist for silicon since 1988. Domestic survey data and trade data were prepared by Robin Johnson, mineral data assistant.

ilicon (Si) is a light chemical element with both metallic and nonmetallic characteristics. In nature, silicon combines with oxygen and other elements to form silicates. Silicon in the form of silicates constitutes more than 25% of the Earth's crust. Silica is a silicate consisting entirely of silicon and oxygen. Silica (SiO₂) as quartz or quartzite is used to produce silicon-base products for the iron, steel, aluminum, and chemical industries.

The global silicon industry underwent further deterioration in 1990. Although demand was relatively strong, an abundance of supply caused prices to fall. Many producers were forced to curtail production and postpone expansion plans. Based on contained silicon, overall domestic production fell to 420,000 metric tons, while consumption increased to 585,000 metric tons. Imports of silicon products increased 38% compared with those of the previous year.

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on silicon that are consistent with international usage, will henceforth report data in kilograms and metric tons unless otherwise noted. For comparison to previous years data, metric tons can be converted into short tons by multiplying the published number by 1.10231.

DOMESTIC DATA COVERAGE

Domestic production data for the silicon commodity are developed by the U.S. Bureau of Mines by means of monthly and annual voluntary surveys. The "Silicon Alloys" survey canvassed all of the operations listed in table 2. The figures in table 1 represent 100% of the

production and shipments from these operations.

BACKGROUND

Definitions, Grades, and Specifications

Silicon metal and ferrosilicon are referred to by the approximate percentage of silicon contained in the material and by the maximum amount of trace impurities present. There are two standard grades of ferrosilicon, with one grade approximately 50% silicon and the other 75% silicon by weight. In addition to the standard grades of ferrosilicon are miscellaneous silicon alloys that contain silicon and other elemental alloys. The most common of these alloys are magnesium ferrosilicon and calcium silicon. However, other elemental additions include barium, boron, manganese, strontium, and titanium. Metallurgical-grade and polycrystalline silicon metal are referred to by their minimum silicon content and maximum impurity level. Typical impurities cited for metallurgical silicon metal are iron, calcium, and aluminum. Typical polysilicon impurities include carbon, boron, and phosphorus and are commonly measured at the parts per million and parts per billion levels.

The American Society for Testing and Materials (ASTM) has published standards for ferrosilicon and silicon metal. ASTM recommends that the producer furnish with each shipment an analysis showing the silicon content and, on request, also include aluminum, carbon, manganese, phosphorus, and sulfur contents. Semiconductor Equipment and Materials International (SEMI) has published standards for both polycrystalline and single crystal grades of silicon.

Products for Trade and Industry

Several grades of ferrosilicon are produced and sold in the United States. However, most of the ferrosilicon consumed domestically in 1990 was either 50%- or 75%-grade material, the majority being 50%-grade. The domestic silicon industry supplies nearly all of the 50%-grade material and about 70% of all ferrosilicon products. Miscellaneous silicon alloys consumed in the United States consist primary of magnesium ferrosilicon. Almost all ferrosilicon products are consumed by the iron and steel industries.

Metallurgical-grade silicon metal is used by the primary aluminum, secondary aluminum, and chemical industries. The products sold to these industries vary considerably in their specifications. The chemical and primary aluminum industries generally require more stringent specifications than those of the secondary aluminum industry. In addition, the chemical industry requires that the metal be ground into a fine powder rather than the lump form used by the aluminum industries.

Geology-Resources

The United States has an abundance of silica deposits for the production of ferrosilicon and silicon metal. For the production of these materials, 98% to 99% purity is preferred. However, trace amounts of aluminum and iron are also acceptable. Physically, the material should not contain fines and should not crumble easily.

Technology

Silicon metal and ferrosilicon are produced by the reduction of silica (SiO₂) to silicon (Si) in a submerged arc electric furnace. A typical charge consists of silica as beneficiated quartz or quartzite; coal, coke or charcoal as a reductant; wood

chips for porosity; and, when producing ferrosilicon, iron in the form of steel scrap or iron ore. During the furnace operation, raw materials are periodically charged into the top of the furnace, and the molten metal or alloy is periodically tapped at the bottom of the furnace and cast into chills or ingots. The material is then crushed to specific size requirements starting at about 20 centimeters down to 200 mesh.

Metallurgical-grade silicon metal is the starting material for high-purity silicon consumed by the electronics industry. First, silicon metal is used to produce an intermediate product such as silicon trichlorosilane (TCS). A vapor deposition process is then used to form a rod or boule of high-purity polycrystalline silicon (polysilicon) from the TCS. A single crystal boule is made from polysilicon by two methods. The Czochralski (CZ) method uses a seed crystal to grow a rod of single crystal silicon from a molten crucible of polysilicon. The Float Zone (FZ) method uses an induction coil to produce a molten zone within a rod of polysilicon. The coil starts at one end of the boule where a seed crystal starts the crystal growth. The coil moves slowly down the boule, allowing a single crystal to be formed. After being sliced into wafers. the silicon is used by the electronics industry to produce integrated circuits.

Byproducts and Coproducts

Silicon metal and ferrosilicon furnaces produce what is called a silica fume, silica dust, or microsilica. This material used to be considered of little or no value. However, microsilica is now used as an additive in a number of different products, including high-strength concrete. Research is ongoing to find additional uses for this material.

Economic Factors

Production of silicon metal or ferrosilicon is extremely power intensive, requiring a power input of about 8,000 kilowatt-hours (kW·h) per ton of 75%-grade and 12,000 kW·h per ton of silicon metal. Power costs represent approximately one-third of operating costs for silicon producers. Subsequently, most new producers of silicon products have been located where favorable electrical power availability and cost situations exist. Norway has traditionally been a major producer and exporter of silicon products because of its vast hydroelectric

power resources. More recently, Brazil, China, and Venezuela have emerged as major exporters of silicon products largely because of their low power costs.

ANNUAL REVIEW

Legislation and Government Programs

Amendments to the Clean Air Act were passed into law in November 1990. The new amendments were expected to have direct and indirect effects on the silicon industry. An indirect effect of the amendments was a predicted rise in the cost of electricity. The revised act limited the amount of sulfur dioxide emissions coal-base power utilities could produce. The cost of compliance incurred by the utilities was expected to be passed along to power consumers. The U.S. Bureau of Mines estimated that the requirements to limit sulfur dioxide emissions would increase the operational costs of certain silicon producers by up to 4.5 cents per pound. A more direct effect of the new amendments was that all ferroalloy producers were placed on a list of possible sources of toxic emissions subject to regulation by the Environmental Protection Agency. The impact of the toxic emissions regulation on the domestic silicon industry was not certain.

Under the authority of the Export Administration Act of 1979, the U.S. Department of Commerce (DOC) determined that foreign availability existed for certain types of high-purity polycrystalline silicon to controlled destinations, rendering existing controls to these destinations ineffective. Subsequently, export controls on certain grades of silicon to these destinations were removed.

Federal funding appropriated for photovoltaic research amounted to \$34.3 million in 1990 compared with \$35.5 million in 1989.

The U.S. Government provided partial funding for a consortium of semiconductor manufacturers known as Sematech. Sematech sponsored a number of programs aimed at improving silicon-base manufacturing technology.

Strategic Considerations

High-purity silicon is a strategic element of advanced electronic systems for commercial and military applications.

Although the United States is a leader in the development of these systems, many of the components and devices within these systems are provided from foreign sources. Recent studies indicate Japan leads the United States in its share of world semiconductor chip production.

Issues

Domestic producers of silicon metal filed for antidumping and countervailing duties against imports of silicon metal from Argentina, Brazil, and China. The imports included silicon metal containing at least 96.00% but less than 99.99% silicon content. Semiconductor-grade silicon metal was not part of the petition. The petitioners charged that imports from Brazil were dumped at 30% to 54% margins under fair market value, while Argentina and China were dumped at 52% to 106% and 123% margins, respectively. In response to the petition, investigations were begun by the U.S. International Trade Commission (USITC) and the DOC. Preliminary determinations made by the USITC and DOC concluded that the imports were sold at less than fair value and materially injured or threatened the domestic silicon industry, thereby warranting further investigation. Final USITC and DOC determinations were scheduled for 1991.1

Production

Overall gross production of silicon products decreased 6% compared with that of 1989, based on silicon content. Production of silicon increased 4%, while production of ferrosilicon and miscellaneous alloys decreased 9%. Ferrous scrap used in the production of these products was estimated to be 235,000 tons.

Although in absolute terms prices did not fall as far as they did in 1989, the continued price slide caused several producers to cut back or discontinue production. Several captive producers permanently closed their operations, and one independent producer filed for protection under chapter 11 of the U.S. Bankruptcy Code.

Owing to poor market conditions, American Alloys Inc., New Haven, WV, curtailed its production of silicon products. The company reduced its ferrosilicon production by temporarily shutting down individual furnaces throughout the latter half of 1990. In December, the company also idled its only silicon metal furnace for a maintenance overhaul.

TABLE 2

PRODUCERS OF SILICON ALLOYS AND/OR SILICON METAL IN THE
UNITED STATES IN 1990

Producer	Plant location	Product
Alabama Alloys Inc.	Dolomite, AL	FeSi.
American Alloys Inc.	New Haven, WV	FeSi and Si.
Applied Industrial Minerals Corp.	Bridgeport, AL	FeSi.
Dow Corning Corp.	Springfield, OR	Si.
Elkem Metals Co.	Alloy, WV	FeSi and Si.
Do.	Ashtabula, OH	FeSi.
Do.	Marietta, OH	Do.
Globe Metallurgical Inc.	Beverly, OH	FeSi and Si.
Do.	Selma, Al	Si.
Keokuk Ferro-Sil Inc.	Keokuk, IA	FeSi and silvery pig iron.
Reynolds Metals Co.	Sheffield, AL	Si.
Silicon Metaltech Inc.	Wenatchee, WA	FeSi and Si.
Simetco Inc.	Montgomery, AL	Si.
SKW Alloys Inc.	Calvert City, KY	FeSi.
Do.	Niagara Falls, NY	FeSi and Si.

Reynolds Metals opted to permanently close its silicon operations at its Listerville, AL, facility. However, the company continued to consume silicon for its magnesium production. After the closure, Reynolds met its requirements through open market purchases.

Union Carbide Chemicals and Plastics Co. sold its polysilicon operations to Advanced Silicon Materials Inc. The sale included two facilities in Moses Lake and Washougal, WA. The Moses Lake facility was one of the largest domestic producers of high-purity polysilicon in the world. The sale was not expected to affect production at the facility.

Globe Metallurgical Inc. cut its ferrosilicon and silicon metal production through a series of maintenance shutdowns. The shutdowns were at both the Beverly, OH, plant and the Selma, AL, plant.

Cominco American Resources Inc. stopped production of 50% ferrosilicon

at its Glenbrook Nickel operations in Riddle, OR. The company decided to meet its ferrosilicon requirements through open market purchases.

Early in 1990, Elkem Metals Co. idled one of its two 45-megawatt (MW) ferrosilicon furnaces at its Ashtabula, OH, facility for maintenance repairs. The company planned to reopen the furnace in June. However, a transformer failure delayed the startup of the furnace for the remainder of the year. The furnace had produced 50%-grade ferrosilicon the previous year. Elkem also overhauled a 32-MW silicon metal furnace at its Alloy. WV, facility. The overhaul was made midyear and lasted for several months. In December, Elkem stopped ferrosilicon production at its Alloy plant. The company planned to continue silicon metal production at Alloy and enhance the plant's hydroelectric power capabilities.

Silicon Metaltech Inc. filed for protection from its creditors under chapter 11 of the U.S. Bankruptcy Code. The company was formed in 1988 when it purchased the Wenatchee, WA, facility from the M.A. Hanna Corp.

Northwest Alloys Inc. did not produce ferrosilicon or silicon metal in 1990. Northwest consumed ferrosilicon in its magnesium operations and had produced ferrosilicon in previous years. The company decided to purchase its requirements in 1990.

Consumption and Uses

Apparent consumption of siliconcontaining ferroalloys and silicon metal was estimated to be 587,000 tons of contained silicon. Consumption of silicon metal was 195,000 tons, while consumption of ferrosilicon and miscellaneous silicon alloys was about 390,000 tons. Compared with that of 1989, consumption of silicon metal increased 13%, while consumption of ferrosilicon and other alloys increased 4%. Ferrosilicon and miscellaneous silicon alloys accounted for two-thirds of all the silicon materials consumed, based on silicon content.

The aluminum industry used silicon metal in the production of wrought and cast products, while ferrosilicon was used primarily as a deoxidizing and alloying agent in the production of iron and steel products. Metallurgical-grade silicon metal was also used as the basic raw material in the manufacturing of many chemical products and intermediates such as silicones and silanes. Silanes were used

in the production of high-purity silicon for semiconductor devices, solar cells (photovoltaic cells), and infrared detectors. The U.S. Bureau of Mines did not collect data on electronic grades of silicon.

Markets and Prices

Although demand for silicon products was relatively high in 1990, prices of silicon products continued the downward trend that began in 1989. The downward pressure in prices was brought about largely by low-priced imports from China, Eastern Europe, South America, and the U.S.S.R. Several domestic companies curtailed their production in early 1990. However, global production outpaced demand, resulting in a continued soft market. In response to low priced imports, domestic producers in the United States filed an antidumping petition with the DOC and USITC. The petition alleged imports from Argentina, Brazil, and China were sold at less than fair value and materially injured the domestic silicon industry.

Table 4 shows the average import price of 50%- and 75%-grade ferrosilicon as well as silicon metal. Prices are posted in cents per pound of contained silicon. The import price of 75%-grade ferrosilicon started the year at 38.0 to 40.0 cents per pound, peaked midyear at 41.8 to 43.3, then fell to 36.0 to 36.5 by yearend. Silicon metal followed a similar curve starting at 53.0 to 55.0, with a midyear high of 57.0 to 58.0 cents per pound. The import price of silicon metal ended the year at 54.0 to 57.0 cents per pound.

Foreign Trade

U.S. imports of silicon products increased significantly in 1990 compared with those of 1989. In particular, imports of ferrosilicon categorized as "55% to 80% silicon, other" increased 45% based on gross weight. However, the total value

¹Tariff effective Jan. 1, 1989.

for this category increased only 7%. Significant increases also occurred in ferrosilicon categorized as "Other," which included all ferrosilicon less than 55% silicon. Imports of "Other" ferrosilicon increased 40% by gross weight and 18% by total value. Overall imports of silicon metal products increased 54% based on gross weight. The U.S. net import reliance for ferrosilicon products jumped to 30% from 20% the previous year. The import reliance of silicon products was estimated to be 27% compared with 21% the previous year. The overall import reliance was estimated to be 29%.

U.S. exports of ferrosilicon increased 2% compared with that of 1989, based on gross weight. Meanwhile, the total value of ferrosilicon exports increased by 8%. In view of the soft global market, these figures demonstrate the domestic industry's trend toward higher value ferrosilicon products. Unlike ferrosilicon, silicon metal exports were affected by the soft global market. Although silicon metal exports increased 78% based on gross weight, the total value of these exports increased by only 10%.

World Review

During the past decade, the global industry has shifted a significant portion of its capacity from developed countries, such as the United States, to less developed nations with abundant resources. For example, producers in Brazil and China underwent huge capacity increases in the 1980's. However, in 1990, the market

was in a state of oversupply, and many producers were forced to postpone expansion programs and cut back production. Many Brazilian producers were affected by not only the slow silicon market but also the economic troubles of their own country. Meanwhile, Eastern Europe and the U.S.S.R. joined China as suppliers of inexpensive material to the United States and the European Community. In response to requests by their domestic industry, the European Commission investigated and took action against dumping of silicon products into their market.

Argentina.—Despite poor market conditions, Silarsa, a joint venture between Axel Johnson Ore & Co. HAB and Stein Ferroaleaciones Sacifa, entered the silicon market. Silarsa began production of silicon metal at a new facility at Mendoza. The facility was reported to have a capacity of 6,500 metric tons per year (mt/yr), and most of the production was expected to be exported.

Australia.—Simcoa Pty. took control of Barrack Silicon Pty. and announced a suspension of plans to double the capacity at the company's silicon metal facility in Kemerton. The Kemerton facility, which started production late in 1989, produced more than 30,000 metric tons of material in 1990.³

Brazil.—Several factors combined to make 1990 a difficult year for the Brazilian silicon industry. These factors included a soft international market, a

sharp increase in power rates, and a new economic policy by the Brazilian Government. As a result, many companies closed existing furnaces and halted plans for expansion. Companies that closed furnaces included Cia Industrial Fluminense, Cia Paulista de Ferro Ligas, Inonnibras, and RIMA Eletrometalurgica SA. Meanwhile, startups were delayed at Electrosiderúrgica Brasileira SA (Sibra) and Cia Paulista de Ferro-Ligas. Late in 1990, three Brazilian companies filed for "Concordata," which is similar to chapter 11 of the U.S. Bankruptcy Code.⁴

Owing to an inflation rate that reached almost 1,900% in 1989, the Brazilian Government instituted a new economic austerity plan in 1990. The new plan included the freezing of bank deposits, commodity prices, and wages. The plan's tight money policy had a detrimental effect on the domestic silicon industry by limiting bank loans that the industry used to help finance its export contracts. The Government also instituted a new 22% tax on electric power, and a 9.1% value added tax was placed on ferroallovs sold or exported. However, late in the year, the Government agreed to halve its tax on exports from the Minas Gerais State to 4.5%.5

In June, Cia Paulista de Ferro-Ligas stopped ferrosilicon production at its facility in Caxambu. The production capacity at Caxambu was estimated to be about 10,000 mt/yr.⁶

In mid-1990, Camargo Corrêa Metais halved its output of silicon metal. The cutback affected the company's plant in

the Para State, reducing output there from 32,000 mt/yr to 16,000 mt/yr.⁷

Electrosiderúrgica Brasileira SA (Sibra) announced it was constructing two 18-MW furnaces, but changed earlier plans to produce silicomanganese instead of ferrosilicon.⁸

Rima Electrometallurgia announced the closure of one of its three silicon metal furnaces in Minas Gerais. The company is one of the largest producers of silicon metal specializing in chemical-grade material. The closure reduced the company's silicon metal output from 24,000 mt/yr to 16,000 mt/yr.⁹

Late in the year, Electro Ila SA suspended plans to expand capacity at its Minas Gerais facility. The plant's capacity was estimated at close to 22,000 mt/yr of silicon metal. Ila og Lilleby Smelteverker increased its shareholding in Electro Ila from 49% to 75%. Metallur Mecanica SA was left with 25% of Electro Ila's shares. Elecro Ila produced 19,000 tons of metal in 1990 and marketed the material to Japan through Fesil KS. ¹⁰

In contrast to the rest of industry, Italmagnesio SA expanded its capacity in 1990. The company completed construction of a 24-megavolt-ampere (MV·A) ferrosilicon furnace. The furnace followed the completion earlier in the year of a 6-MV·A furnace. The new additions doubled the company's ferrosilicon capacity to 90,000 mt/yr. Late in 1990, Italmagnesio was granted \$90 million in finances by the Brazilian Government to help fund a series of projects, including the expansion of ferroalloy facilities, the building of hydroelectric facilities, and reforestation efforts.

Bhutan.—Marubeni Corp. signed an agreement as one of several partners in a joint venture called Bhutan Ferroalloys Ltd. The agreement called for plans to construct a 15,000-mt/yr ferrosilicon plant close to Bhutan's southern border with India. The company cited easy access to Asian markets, a nearby hydroelectric plant, and plentiful raw materials as reasons for constructing the plant at this location. ¹¹

China.—Once again China played a role in influencing the world market for ferrosilicon products. Although most of China's silicon products were sold in the Asian markets of Japan and Korea, China exported a significant quantity of material to the United States and European markets. Chinese ferrosilicon

exports to Japan increased significantly, while exports of silicon metal fell slightly. Chinese production of silicon metal was estimated to be 130,000 tons in 1990.

China's Hanway Ferroalloys completed construction of a new facility in the Yunnan Province. The facility included three 6-MV·A furnaces capable of producing more than 12,000 tons of 75%-grade ferrosilicon. The company intended to export 80% of its production.

Canada.—In October, Dow Corning Corp., Midland, MI, held a groundbreaking ceremony for its 6-MW silicon metal pilot plant in Manitoba. When completed, the facility was expected to produce 2,000 mt/yr of silicon metal for use within the Dow Corp. 12

European Community (EC).—In 1990, the EC took a series of actions to restrain dumping of silicon products into the European Community. Early in the year, the Commission completed a 19-month antidumping investigation of Norwegian ferrosilicon. However, in lieu of a punitive duty, the Commission accepted a proposal by Elkem AS for a minimum reference price. Later in the year, the Commission asked the main importers of Soviet material to abide by the same reference price. In August, the EC imposed a punitive duty on Chinese silicon imports into the EC. The duty was levied at 198 European Community Units (ECU's) per ton and made effective for a 5-year period. By yearend, the Commission decided to investigate dumping allegations of silicon metal imports from Brazil.¹³

Japan.—Imports of ferrosilicon into Japan increased significantly, rising from 407,000 tons in 1989 to about 494,000 tons in 1990. The rise in 1990 imports was attributed to the previous year's reliance on inventory built up in 1988. Chinese imports accounted for 158,000 tons of ferrosilicon imports. In April, Japan eliminated a 3% import duty on ferrosilicon. 14

Norway.—Norwegian producers of silicon metal and ferrosilicon were faced with a difficult world market. In accordance with agreements made with the EC, producers were prohibited from supplying ferrosilicon below a minimum reference price. Meanwhile, their market share was assaulted in Europe and North America by low priced imports of ferrosilicon and silicon metal from China,

Eastern Europe, and the U.S.S.R. Subsequently, producers cut back their production in 1990 and planned further cutbacks in 1991.

Elkem AS made several cutbacks in production. The company reduced output in three Norwegian plants: Bjolvefossen, Bremanger, and Thamshavn. Elkem also closed a furnace at its Icelandic plant. By shutting down one furnace at each plant during the fourth quarter of 1990, the company reduced its ferrosilicon output by about 20,000 mt/yr. Elkem also announced plans to close its Meraker facility. 15

In October, Fesil KS planned to cut ferrosilicon output by 20% by reducing output at its Halfslund, Rana Metall, and Finnfjord facilities. ¹⁶

Saudi Arabia.—United Gulf Industries Corp. announced plans to construct a 25,000-mt/yr ferrosilicon plant. The company planned to construct the plant in Jubail during the coming year. ¹⁷

Sweden.—Kemanord Industrikemi AB closed its 14,000-mt/yr silicon metal furnace at its Ljungaverk plant. Kemanord was the only remaining producer of silicon in Sweden. Vargon Alloys AB, the only producer of ferrosilicon in Sweden, cut production in the last quarter of 1990.¹⁸

Venezuela.—Many of the expansion programs planned in 1989 were put on hold in 1990. However, the estimated \$500 million Cefeca project was still underway. The Venezuelan Government, through the Corporacion Venezolana de Guayana (CVG), provided 20% of the funding. The balance of the funding was provided by Italmagnesio SA (8%), GT Administracion e Participacion SA (32%), and a group of private investors. 19

Current Research

With assistance from the Electrical Power Research Institute Inc. (EPRI), Dow Corning Corp. continued with its development of a new smelting process to produce silicon metal. Dow started construction of a 6-MW furnace, which will be used to test its new process for making silicon metal. The new furnace is based on direct current (DC) electric power with a closed furnace hood design. Commercial producers traditionally used alternating current (AC) submerged arc furnaces with open or partially open furnace hoods. If successful, the new furnace

was expected to help reduce the consumption of electrode materials and electrical power in silicon operations.

Researchers at the Westinghouse Science and Technology Center, Pittsburgh, PA, produced a rod of single crystal silicon with impurities of only a few parts per 100 trillion. Silicon, with this level of purity, was developed for infrared detection in the space, defense, and environmental industries.

Researchers at Motorola Inc., Schaumburg, IL, and TRW Inc., Redondo Beach, CA, developed a computer chip capable of detecting and correcting for errors within itself. The chip was developed for use in aircraft, missiles, and satellites.²⁰

IBM Corp. and Siemans announced they will jointly develop 64-megabit Dynamic Random Access Memory (DRAM) chips. The companies planned to market the chips by the mid-1990's. IBM also pursued agreements with Micron Technology and Cypress Semiconductor to develop a domestic source of 4-megabit DRAM chips based on IBM's design.²¹

OUTLOOK

Demand for silicon metal is driven by consumption in the aluminum and chemical industries. Consumption by these industries is expected to undergo slow growth during the next 5 years. The automotive sector will contribute to this growth through increased aluminum content within each vehicle as well as increased silicon content in individual aluminum castings. Consumption growth by the chemical industry is expected to be about 7% per year. The chemical industry consumes silicon metal to produce a wide variety of compounds such as silanes, silicone resins, and lubricants. However, specialty chemical products rather than traditional commodity products should be the driving force for consumption growth. Overall, consumption of silicon metal is expected to grow in excess of 5% per year for the next 5 years.

Ferrosilicon is consumed primarily by the iron and steel industries. The industries use ferrosilicon for both deoxidation of molten metal and as an alloying agent. The American Iron and Steel Institute studied the consumption of steel by industrialized countries and predicted an average decline of 0.1% per year from 1985 to 1995.²² Consequently, domestic ferrosilicon consumption is expected to decline during the next few years. The passage of the latest amendments to the Clean Air Act into law has reinforced predictions for decreased consumption. Other factors that could influence consumption of ferrosilicon by the steel industry include technological changes and trade agreements.

Although many production cutbacks were made by many silicon producers in 1990, it is anticipated that additional capacity will be required to meet the growth in silicon metal consumption during the next 10 years. Any new capacity will be required to meet the increasingly stringent quality requirements of the aluminum and chemical industries. Therefore, the conversion of older ferrosilicon furnaces is not likely. The location of any new capacity will be in regions with favorable power availability and cost, such as South America, Norway, the Middle East, and selected locations within North America.

Prices for silicon products fluctuate with market demand. Higher demand for silicon metal by the chemical industry would put upward pressure on silicon prices. Meanwhile, the increased presence of China, Eastern Europe, and the U.S.S.R. in the ferrosilicon market coupled with a lack of strong demand by the steel industry should inhibit any attempts to raise ferrosilicon prices.

SILVER

By Robert G. Reese, Jr.

Mr. Reese, a physical scientist with the Branch of Metals, has been the commodity specialist for silver for 9 years. Domestic survey data were prepared by Lisa Conley and Dwayne Penn, mineral data assistants; and international data tables were prepared by Virginia Woodson, international data coordinator.

omestic silver production increased for the fourth consecutive year despite a lower price, reflecting the importance of byproduct silver production. Owing to the fact that much of the byproduct silver can be produced at a very low cost, continued low prices had little impact on byproduct silver producers. However, near yearend, the Candelaria Mine, one of the largest domestic primary silver producers, was closed. Company officials attributed the closure to the low silver price.

The Government continued to reduce its silver holdings. The U.S. Department of the Treasury, as required by Public Law 100-440, the Treasury and Postal Service Appropriations Bill, disposed of approximately 78 metric tons of its silver stocks during fiscal year 1990. The quantity of silver held in the National Defense Stockpile (NDS) also declined from that of the previous year. The domestic silver price, as quoted by Handy & Harman, fell to a 15-year low in 1990. The annual average price, \$4.82 per troy ounce, marked the third consecutive year in which the average price had declined from that of the previous year. In December, the price fell below \$4.00 per troy ounce for the first time since February 1976.

The domestic apparent demand for refined silver declined in 1990. Apparent demand measures both the quantity of silver required by domestic manufacturers and the quantity of silver demanded by U.S. investors. The decline in apparent demand was attributed by many analysts primarily to lower investor demand. Handy & Harman, in its 1990 review, estimated world silver consumption at about 17,700 tons, a decrease of more than 200 tons from the revised 1989 figure.

DOMESTIC DATA COVERAGE

Domestic mine production data for silver were developed by the U.S. Bureau of

Mines from four separate, voluntary surveys of U.S. operations. Typical of these surveys was the lode mine production survey of copper, gold, lead, silver, and zinc. Of the 137 silver-producing lode mines to which a survey form was sent, 126 responded, accounting for an estimated 92% of the total U.S. mine production shown in tables 1, 2, 3, 4, 5, 6, and 7.

BACKGROUND

Silver has played an important role in peoples' lives since ancient times. Early people used silver for ornaments and utensils and as a substance that could be bartered for other goods and services. This concept of the "value" of silver eventually led to its use as the standard in monetary systems, such as that of the Roman Empire, and as a means of paying for international trade. Silver continued to be the standard for most currencies until the discovery of major silver deposits in Mexico and Peru. As more silver deposits were discovered in the 18th and 19th centuries, countries gradually abandoned silver as the standard for their currencies in favor of a gold standard.

Expanding industrial use of silver eventually led to the elimination of silver in U.S. coinage. In the early 1960's, the U.S. Department of the Treasury became a major supplier of silver to industrial consumers. The Treasury, however, had insufficient stocks both to meet industrial demand and to maintain an adequate supply of circulating silver coinage for a prolonged period. When the silver price reached \$1.29 per ounce, the value of the silver in a silver dollar equaled \$1 in currency. At silver prices greater than \$1.29, the silver in a silver dollar would have been worth more than \$1 in currency, and as a result, it could have been advantageous to melt silver dollars for their silver content, thereby decreasing the amount of circulating coinage. Similarly, if the silver price rose above \$1.38 per ounce, the silver in dimes, quarters, and half-dollars would have been worth more than the coin's face value. To avoid a possible meltdown of the circulating coinage, the Treasury attempted to control the silver price through increased silver sales and increased minting operations from 1964 to 1967. A reduced silver content half-dollar, along with silverless dimes and quarters, were introduced in 1965 to help maintain the supply of circulating coinage, and in 1967, the Treasury announced that all silver coins were being withdrawn from circulation.

Silver occurs as native metal, but is usually found combined with sulfur. Until the 16th century, the ratio of silver to gold produced in Europe was about 10:1. Most of the silver was obtained from the lead sulfide ore galena. With the discovery and exploitation in the 16th and 17th centuries of silver deposits in the Americas, silver production shifted away from Europe. As production increased in Bolivia, Mexico, and Peru, the world ratio of silver to gold production increased because silver was relatively more abundant than gold in the New World. Following the 1859 discovery of the Comstock Lode in Nevada, the United States was the world's leading silver producer from 1871 to about 1900. Mexico was the leading producer from 1900 to 1968. vielding to Canada from 1968 to 1976. In 1976, Mexico regained the position of the world's leading silver producer, a position that it held through 1990.

Definitions, Grades, and Specifications

The purity of silver in bullion, coinage, jewelry, or other items is usually expressed by its "fineness," or parts per thousand. Pure, or "fine," silver is 1,000 parts fine or 100.0% silver. Sterling silver is 925 fine, or 925 parts (92.5%) silver and 75 parts (7.5%) copper. Domestic coin silver is an alloy that was used in minting coinage until 1964 and

contained 900 parts silver and 100 parts copper. Commercial silver bullion ranges from 999 to 999.9 fine. For any fineness of silver bullion, the principal impurities are gold or copper. Doré silver is unrefined silver bullion generally containing a variable percentage of gold as an impurity. Silver for the NDS is required to be 999 fine; free of slag, dirt, or other foreign material; and in bars weighing approximately 31 kilograms.

Products for Trade and Industry

Refined silver is available in the form of bars, grain, sheet, strip and foil, wire, rod and tubing, powder, and flake. Bars produced at refineries generally weigh about 31 kilograms and are about 30.5 centimeters long by 12.7 centimeters wide and 10.2 centimeters thick. Grain silver is produced by pouring molten silver into water, creating irregularly shaped silver particles less than 1.3 centimeters across. Silver sheet and foil are available in widths of up to almost 2.1 meters and as thin as 0.01 millimeter. Generally, the thinner the sheet or foil, the narrower it is in width. Silver rod and wire can range from 5 centimeters in diameter to 0.1 millimeter in diameter. Openings in silver tubing can range from capillary size through 15 centimeters in diameter. Silver powders are generally powder-size (0.5 to 2 micrometers) spherical particles, although coarser sized particles can be produced.

Geology-Resources

About two-thirds of the world silver reserves and resources are contained in copper, lead, and zinc deposits. Ores in which silver or gold is the main component account for the remaining one-third of total world reserves and resources. U.S. silver resources are estimated to be about 190,000 tons. Total world silver resources are estimated to be about 780,000 tons.

The chief silver minerals found in U.S. reserves are native silver (Ag), argentite (Ag₂S), cerargyrite (AgC1), polybasite (Ag₁₆Sb₂S₁₁), proustite (Ag₃AsS₃), pyrargyrite (Ag₃SbS₄), and tetrahedrite {Cu₃(Sb, As) S₃}. Other ore minerals of silver are the tellurides, stromeyerite, and pearceite.

U.S. silver reserves are usually found associated with intermediate felsic rocks such as andesites and rhyolites, in veins ranging from a few centimeters to several meters in width. Ores from which silver is produced as a byproduct are usually found in copper porphyries, massive sulfide deposits, or in

copper-lead-zinc vein deposits. Historically, most of the U.S. silver production has been from the Rocky Mountain States. It is likely that if major new reserves are discovered, the deposits will be in this region.

Technology

Mining.—Silver is mined using well-established open pit and underground methods. Open pit mining consists of removing overburden, drilling and blasting the exposed ore, loading the broken ore, and hauling the ore to the processing plant. Overburden removal is done with draglines or bulldozers, depending on the depth of the ore body. The broken ore is loaded by either power shovels or front-end loaders, and the ore is shipped to the processing plant by truck, train, conveyor belt, or some combination of these transport modes, depending on the distance to the plant.

Underground mining of silver is generally done using one of several stope mining methods. Stope mining consists of the development of a series of horizontal workings, or stopes, into the ore body from a shaft or tunnel. The stopes are above each other and can be vertically separated by as much as 60 meters of ore. The ore between the stopes is removed through the use of explosives.

Beneficiation.—Current treatment of silver-containing base metal ores is almost entirely by a flotation process. The concentrates contain the silver along with the copper, lead, and zinc. The silver is recovered from intermediate products resulting from smelting the concentrates. In predominantly lead ores, silver is carried down with the lead in smelting and separated from it by the addition of zinc to the molten silver-lead mixture. The mixture is allowed to cool, and the virtually insoluble silverzinc alloy separates from the molten lead and rises to the surface where it is skimmed. In addition to the silver, this first crust contains some lead and any gold contained in the original ore. The zinc is distilled in a retort for reuse. The retort residue is roasted to recover the gold and silver as doré metal and the lead as litharge.

In predominantly copper ores, the silver is carried down with the copper in smelting. In the electrolytic refining of copper, the silver accumulates in the anode slime, from which it is recovered as silver bullion by smelting.

Gold and silver ores are generally treated by cyanidation. The ores are crushed by grinding in rod or ball mills and then leached with a dilute cyanide solution. Zinc dust is used to precipitate the gold and silver from the cyanide solution. The precipitate is melted in a furnace to produce a doré metal.

Silver bullion is generally refined using an electrolytic process. In the process, electricity is applied to a standard electrolytic cell in which the impure silver bullion is used as the anode, silver nitrate and nitric acid is used as the electrolyte, and either a pure silver strip or graphite is used as the cathode. Passage of an electrical current results in dissolution of silver in the anode and its subsequent deposition as silver crystals on the cathode. The silver crystals are periodically stripped from the cathode and collected, melted, and cast into bullion bars.

Economic Factors

Costs of mining silver ores vary greatly with depth, ground control problems, ventilation, width of vein, continuity of ore bodies, location, presence of byproduct metals, and the availability of electricity, water, labor, and equipment. Low-grade deposits can usually be mined profitably if sufficient quantities of other metals are contained in the ore. Accurate information on capital costs is difficult to obtain, not only because of variability in the factors enumerated above, but because of differences in accounting methods and definitions used by the mining industry. In general, the cost of mining silver ranges from less than about \$30 per kilogram (\$1.00 per troy ounce) to more than \$260 per kilogram (\$8.00 per troy ounce). Underground mining is, in general, more expensive than surface mining.

U.S. tax laws permit silver-producing companies a depletion allowance of 15% for domestic operations and 14% for foreign operations. There are no tariffs on the importation of silver ores, concentrates, doré, scrap, or refined bullion. Tariffs on semimanufactured silver can be as high as 27.5% ad valorem for countries receiving most-favored-nation classification and can be as high as 110% ad valorem for imports from those countries classified as non-most-favored-nation, depending on the item.

Operating Factors

Silver mining is, in general, no more hazardous than other mining, but because of the depths reached in the Coeur d'Alene district, rock bursts there are relatively common. Temperatures are uncomfortable at these depths, and air conditioning must be used in ventilation systems. Gains in productivity are difficult to achieve because the possibilities for mechanization are limited by the relatively narrow veins mined. In recent years, companies have attempted to increase productivity through modification of labor agreements to allow more flexibility in work assignments and compensation and by improved mining plans.

Although in most circumstances silver is not a toxic substance in other than very large doses, a standard has been established for worker exposure to airborne particulate silver. The Occupational Safety and Health Administration currently requires that the concentration of either silver metal or soluble silver compounds be less than 0.01 milligram per cubic meter of ambient air in workplaces.

Nearly all silver-bearing ores are processed after grinding by flotation or cyanidation. Pollution of downstream waters by fine solids from flotation plants is a problem that requires adequate ponding and retention of tailings. Disposal or stabilization of the accumulated tailings can be a problem at some mines. It can be partially solved in those deep mines where ground support is needed by pumping the tailings back into the mine. In cyanidation operations, extreme care must be exercised to avoid contamination of the ground water, nearby watercourses, or surrounding areas through losses of leach solution. As a result, the solution collection system for returning the leachant to the storage tanks and the system for monitoring water in the surrounding area must be adequate to prevent pollution.

Achieving adequate air pollution (sulfur dioxide) control and disposing of slag and other wastes (iron and silica) are the problems encountered in smelting silver ores. Refining presents little environmental concern because the bulk of noxious impurities are removed during the smelting step; however, spent solutions from electrolytic refining present a disposal problem because of toxic materials in the solutions.

ANNUAL REVIEW

Legislation and Government Programs

On July 16, the President signed Public Law 101-322, the Mount Rushmore Commemorative Coin Act, which authorized the U.S. Mint to produce 500,000 gold coins, 2.5 million silver coins, and 2.5 million copper-nickel-clad coins in honor of the

50th anniversary of the Mount Rushmore National Memorial. Each silver coin was to weigh 26.73 grams; consist of a 90% silver, 10% copper alloy; be legal tender; and have a \$1.00 face value. The silver for the coin was to be obtained from the NDS. Issuance of the coins was limited to calendar year 1991. The price of each silver coin was to include a \$7.00 surcharge, 50% of which was to be used to improve, enlarge, and renovate the memorial.

The 1992 Olympic Commemorative Coin Act, Public Law 101-406, was enacted on October 3. The law authorized the minting of not more than 500,000 gold coins, 4 million silver coins, and 6 million copper-nickel- clad coins. Each silver coin was to weigh 26.73 grams; consist of a 90% silver, 10% copper alloy; be legal tender; and have a \$1.00 face value. The silver for the coin was to be obtained from the NDS. No coins authorized by this act were to be minted after June 20, 1993. The price of each silver coin was to include a \$7.00 surcharge, all of which was to be paid to the United States Olympic Committee to support the training of U.S. athletes participating in the 1992 Olympic Games.

Production

Silver was produced from precious-metal ores at 118 lode mines and from base metal ores at 19 lode mines. In 1990, 18 mines each produced more than 30 tons of silver; their aggregated production equaled 76% of total domestic production. Silver was also produced at 16 placer operations. U.S. silver production in 1990, 2,170 tons, was the largest quantity produced in any year since 1941, when 2,211 tons was produced.

Alaska.—In its first full year of operation, the Greens Creek Mine achieved full production and operated at its designed capacity of 900 tons of ore per day. During the year, approximately 350,000 tons of ore was processed and more than 238 tons of silver was recovered.² In addition to silver, Greens Creek also produced gold, lead, and zinc. Exploration resulted in a significant increase in proven and probable reserves, which were estimated at about 6 million tons with an average silver grade of about 470 grams per ton. At yearend, Greens Creek employed 265 workers.

The Red Dog Mine completed its first full year of operation. Despite some initial problems, Cominco Ltd. reported that more than 900,000 tons of ore with an average content of 112 grams of silver per ton was processed at the mine.³

Idaho.—Hecla Mining Co. sold its 5% interest in the Coeur Mine to Coeur d'Alene Mines Corp. The sale, completed in the fourth quarter, increased Coeur d'Alene's holding in the mine to 45%. Other partners in the venture were ASARCO Incorporated, 50%, and Callahan Mining Corp., 5%. In 1990, the Coeur Mine reportedly produced about 66 tons of silver.⁴

Heap-leach operations at the DeLamar Mine were suspended in early 1990 owing to a ground stability problem. NERCO Minerals Co., owner of the mine, was able to stabilize the ground, and reportedly was assessing the situation at yearend. The heap-leach facility was constructed in 1987 to process DeLamar's low-grade ores and was expected to recover an additional 2 tons of gold and 44 tons of silver during its first 7 years of operation.

A project to increase DeLamar's mill capacity was begun in 1990 and completed in early 1991. Mill capacity was increased from 850,000 tons to 1.1 million tons per year. In addition to processing DeLamar ore, the mill will now be able to process ore from the nearby Stone Cabin Project. Stone Cabin, a gold-silver deposit, was under development by NERCO at yearend.

The mill capacity at the Galena Mine was increased through the addition of a lead-silver circuit. The new circuit allowed the treatment of lead-silver ore in addition to the mine's traditional silver-copper ore. For the year, the Galena Mine reportedly produced more than 95 tons of silver.⁵

Low silver prices were blamed for the closure of one of the six operating stopes at the Lucky Friday Mine in the fourth quarter. The closed stope reportedly contained the lowest grade ore. The need to close the stope occurred despite the cash-flow generated by the mine's byproduct copper, gold, lead, and zinc production and Hecla's reduction of operating costs. In 1990, Lucky Friday processed 134,000 tons of ore and recovered about 59 tons of silver.⁶ At yearend, the mine employed 173 workers.

Silver production at the Sunshine Mine was 165 tons, an increase of about 16 tons from the previous year. Continued declining silver prices combined with low prices for natural gas, Sunshine Mining Co.'s other principal product, resulted in the company reporting a net loss for the fifth consecutive year. As a result of the low prices, Sunshine developed a plan to restructure its debt during the summer. Included in the plan was the sale of its oil and gas assets and debt reduction. In early 1991, the sale of Sunshine's oil and gas proper-

ties was consummated, and the remainder of the plan was expected to be implemented.

The Thunder Mountain Mine, a small gold-silver heap-leach operation, was closed at yearend. Declining reserves and lower gold production were cited as reasons for the decision. The mine, in a federally designated wilderness area, was recognized throughout its operating life from 1986 to 1990 for its environmental stewardship. In 1990, the mine produced 183 kilograms of gold and 139 kilograms of silver. Work planned for 1991 included land reclamation and dismantling of the mine's plant and equipment.

A new heap-leach facility was commissioned at Hecla's Yellow Pine Mine. The new facility enabled the mine to resume gold and silver production near midyear. The decision to build the facility followed the termination of an ore processing agreement with Pioneer Metals Corp. in 1988. Although no commercial gold or silver production was reported during 1989, ore continued to be mined and stockpiled. Company officials expected identified oxide reserves to be depleted in 1991. The feasibility of mining a sulfide deposit on the property was being investigated.

Montana.—At the Basin Creek Mine, Pegasus Gold Inc. completed construction of a new leach pad. The new pad was expected to solve a number of operating problems encountered since the mine was acquired in late April 1989. However, owing in part to discontinuities in the ore and lower than expected ore grades, Pegasus decided to suspend mining operations near yearend. In the fourth quarter, Pegasus wrote off the carrying value of the mine. During the year, Basin Creek produced about 1 ton each of gold and silver. Although mining operations were suspended, leaching was expected to continue in 1991.

In September, Pegasus adopted a revised mining plan for the Montana Tunnels Mine. The new plan was expected to reduce the stripping ratio from 3.3:1 to 1.4:1. During 1990, 3.8 million tons of ore was treated. In addition to gold, lead, and zinc, the mine produced 37 tons of silver. ¹⁰

Construction of a new leach pad was completed at the Zortman/Landusky Mine. The new pad had a capacity of more than 54 million tons of ore. In 1990, 3 tons of gold and 20 tons of silver were recovered by heap leaching at Zortman/Landusky.¹¹

Asarco reported that the Troy Mine produced about 118 tons of silver. 12

Nevada.—USMX Inc. purchased the Alligator Ridge Mine from NERCO and

Kennecott Corp. near midyear. Prior to the sale, NERCO and Kennecott each held a 50% interest in the open pit heap-leach operation. Although identified reserves at the mine were exhausted in December 1989, leaching continued through 1990. USMX reportedly purchased other property along the Alligator Ridge geologic trend.

A new heap-leach facility began operation at the Battle Mountain Complex in early October. Battle Mountain Gold Co., which owned the complex, mined ore from three deposits, the Fortitude, the Labrador, and the Surprise. Ore from the Fortitude Mine was processed at the Fortitude mill, a carbon-in-pulp cyanide leach facility. Ore from the Labrador and Surprise Mines was in general a lower grade material than the ore mined at Fortitude and was leached at the new heap-leach facility. It was expected that unless new millable ore deposits were discovered, heap leaching would provide an increasing amount of the company's precious-metals production at the Battle Mountain Complex. The Fortitude Mine was expected to be depleted in 1993. The company reported that during 1990, 14 tons of silver and 8 tons of gold were produced by the Battle Mountain Complex.¹³

Mining operations were suspended at the Candelaria Mine in November. NERCO, the mine's owner, cited the low silver price as the reason for the closure. Reportedly, the silver price had declined to near Candelaria's cost of production. Although mining was suspended, leaching was expected to continue in 1991, with an expected silver output of approximately 62 tons. During 1990, Candelaria produced about 151 tons of silver, an increase of 15 tons from that of the previous year.¹⁴

At the McCoy/Cove Mines, operations at the 6,800-ton-per-day mill were halted for 3 months following the reoccurrence of bird deaths at the mill's tailings pond. Near mid-September, construction of a new milleffluent treatment facility was completed, and operations resumed. No additional bird kills were reported. Echo Bay Mines Ltd., owner and operator of the mines, cited an additional benefit provided by the new treatment facility. Following the startup of the new facility, the mill was able to resume using the correct amount of cyanide reagent, resulting in improved gold and silver recoveries. In 1990, the aggregated production from the McCoy and Cove deposits was about 8 tons of gold and 62 tons of silver.15

Silver production at the Paradise Peak Mine increased owing in part to the mining of the higher grade silver core of the ore body. During the year, about 1.3 million tons of ore was milled and an additional 700,000 tons was heap leached to produce 6 tons of gold and 170 tons of silver. ¹⁶

At its Rochester Mine, Coeur d'Alene Mines handled more than 6 million tons of ore. Heap leaching at the open pit mine resulted in the recovery of almost 2 tons of gold and about 149 tons of silver.¹⁷

Silver production at the Wind Mountain Mine increased by 60% to more than 17 tons. ¹⁸ Officials at Amax Gold Inc. attributed the increase primarily to improved productivity.

Homestake Mining Co. ceased operations at its Wood Gulch Mine following the depletion of minable ores. The open pit heap-leach operation produced gold and some byproduct silver. Reclamation of the mine site was begun and was expected to be completed in late 1992.

Other States.—A project begun by Cyprus Minerals Co. in 1989 to increase the milling capacity of the Bagdad Mine in northwestern Arizona was completed. A fifth grinding line was added to the existing mill, increasing the capacity of the sulfide ore concentrator by about 20,000 tons per day to about 69,000 tons per day. At its Sierrita Mine, also in Arizona, Cyprus reported improved productivity following the acquisition of new larger haul trucks and a power shovel.

At the White Pine Mine in Michigan, projects were begun to increase the mine's productivity and lower its operating costs. Metall Mining Corp., which acquired the mine in mid-1989, instituted a revised mining plan. As part of the new plan, additional headings were developed to increase production. Metall also began replacing some of White Pine's aging equipment. By yearend, 56 pieces of equipment, including drill jumbos, load-haul-dump units, and bolters, were replaced. This modernization program was expected to continue in 1991. For 1990, the White Pine Mine milled 4.6 million tons of ore and recovered 34 tons of silver. 19

At the Escalante Mine, in Iron County, UT, the milling of stockpiled ore was completed near midyear, and the mill was placed on care-and-maintenance status. Mining operations had been halted near the end of 1988 when the ore body was mined out. As part of its reclamation of the site, Hecla refilled a canal used for dewatering the mine, reseeded the surface area, and filled the access portal. In 1990, the mine recovered about 24 tons of silver.²⁰

Consumption and Uses

Apparent U.S. demand for silver in 1990, calculated as refinery production from primary materials and from old scrap plus net imports of refined bullion, was 4,006 tons. Included in the apparent demand calculation was the amount of silver absorbed by investors, as well as the amount of silver required by the domestic fabricating industry.

The most important use of silver is in photographic materials. Silver is used in the manufacture of film, photographic paper, photocopying paper, X-ray film, photooffset printing plates, and in some other minor light-sensitive products. Photographic materials are produced by depositing thin layers of silver salts, gelatin, and dyes onto a support material. Silver salts, although not extremely sensitive to light when first exposed to illumination, produce a greatly intensified image when subsequently treated with photographic chemical developers. The developer reduces a portion of each silver salt grain to metallic silver, depending on the intensity of the light to which the grain was exposed. The resulting gray to black metallic silver forms a negative image of the original object.

Silver is used in electrical and electronic products because of its high electrical and thermal conductivity and its resistance to corrosion. Silver has the highest thermal and electrical conductivities of any metal. Silver, in general, can be characterized as strongly resistant to atmospheric and ordinary oxidation and exceptionally resistant to corrosion by weak acids. Although silver commonly reacts with sulfur-containing atmospheric gases to form a sulfide tarnish, the tarnish itself offers little electrical resistance and does not prevent the use of silver as an electrical contact material. Pure silver is generally used in low- and mediumcurrent switching devices. In other applications where the device requires higher strength, more wear resistance, better resistance to arcing, or lower costs, silver is usually alloyed with another metal such as copper or palladium to produce the desired characteristics.

Batteries constitute another electrical use for silver. Silver batteries produce a highenergy output per unit size and weight, but are generally characterized by a short life and high per unit cost. Primarily because of the short life and high costs, the use of silver batteries has been confined to defense and space applications where battery weight, size, and reliability are major concerns. There is, however, a growing use for small silver-zinc button cells in such commercial applications as calculators and hearing aids.

The use of silver for decorative purposes can be divided into three main applications. Probably the oldest use of silver is its use in jewelry. Silver or a silver alloy, usually silver and copper, is flattened and shaped into objects that can be worn for personal adornment. Sterlingware, the second decorative use, consists of articles such as bowls and flatware that are often functional as well as decorative. Sterling silver is an alloy of silver (92.5%) and copper (7.5%). The third decorative use for silver is electroplated ware. Electroplated ware generally consists of the same types of objects produced as sterlingware, the difference being that electroplated ware is made by depositing a thin silver layer on a base metal object, whereas the sterlingware object is formed entirely of the silver-copper alloy. Because less silver is used in a piece of electroplated ware than is used in a similar piece of sterlingware, the price of the plated piece is less than the price of a corresponding sterlingware piece.

The refrigeration and air-conditioning industry uses silver in the form of brazing alloys because of the ability of silver brazing alloys to wet various base metals at temperatures below their melting points. In general, silver brazing alloys do not dissolve or attack steel in normal usage, are ductile, maintain their strength over a wide range of temperatures, and will join a variety of materials. Silver is added to some solders to improve their flow properties, corrosion resistance, and wettability.

Silver is also used in mirrors, catalysts, medicinals, dental amalgams, bearings, coins, medallions, and a variety of commemorative objects. Silver is used in mirrors because of its high reflectivity in the visible portion of the spectrum. Silver catalysts are used in oxidation reactions such as the production of formaldehyde from methanol and the conversion of ethylene to ethylene oxide. Medicinal compounds include the soluble salts, such as the nitrates and citrates, and insoluble compounds such as the oxides, halides, and proteinates. In dentistry, silver is an important component of amalgam fillings.

Stocks

Total accountable stocks at yearend 1990 had increased by about 500 tons over those of yearend 1989. Continued buildup of stocks held by futures exchanges more than

compensated for declines in industry and Government-held stocks and accounted for all of the increase in accountable stocks. Some analysts explained the continued stock buildup as a normal consequence of the slowdown in the U.S. economy combined with a lack of investor demand. A few analysts, however, pointed to the stock buildup as an indication that perhaps in industrialized countries such as the United States, silver was losing its status as a precious metal, and hence, the lack of investor demand.

The quantity of Government-held silver continued to decline. The U.S. Mint used NDS silver for various coinage programs, and a portion of excess Treasury Department stocks were sold through Government-sponsored auctions held in October 1989 and January, May, and July 1990. Since 1985, Government-held stocks have declined by more than 1,600 tons, almost all of which has been used in various Government coinage programs.

Markets and Prices

The domestic silver price, as quoted by Handy & Harman, decreased, continuing the declining trend of the previous 3 years. The price began the year at \$5.21 and was \$4.18 at yearend. Analysts attributed the continued weak price primarily to an abundant silver supply combined with a lack of investor demand. Silver prices declined steadily throughout the year except for a brief rally in August following Iraq's invasion of neighboring Kuwait. Notable was the brevity of the rally considering that the Iraq-Kuwait conflict continued through yearend. The price decline resumed in mid-August. In December, the price fell below \$4.00 per troy ounce for the first time since February 1976.

As with the domestic price, the London spot price decreased and followed a pattern similar to that of the Handy & Harman price. The U.S. dollar equivalent of the London spot price, as quoted in Metals Week, began 1990 at \$5.21 per troy ounce and ended the year at \$4.19. The low and high prices of \$3.95 and \$5.36 occurred on December 17 and February 20, respectively. The average for 1990 was \$4.83.

The amount of silver represented by the futures contracts traded on the Commodity Exchange Inc. (COMEX) decreased in 1990 to 608,635 metric tons. In the previous year, futures contracts representing 680,640 metric tons of silver had been traded on COMEX. At the Chicago Board of Trade,

the quantity of silver corresponding to the futures trading volume decreased from 8,295 tons in 1989 to 5,912 tons in 1990. Silver futures trading volume declined from 422 tons to 342 tons on the Mid-America Commodity Exchange.

Foreign Trade

U.S. silver exports increased in 1990 for the sixth consecutive year, probably owing in part to the lower domestic silver price and increased domestic production. The countries recording the largest increases in receipt of U.S. silver exports were Canada and Japan, with increases of about 208 tons and 359 tons, respectively. In the case of Canada, most of the increased shipments were in the form of silver-bearing waste and scrap materials. The increased shipments to Japan, however, were for the most part in the form of refined bullion. The largest decrease in U.S. silver exports from the previous year was in shipments of doré and precipitates to Switzerland—approximately 58 tons.

Although U.S. silver imports for consumption remained essentially the same as in 1989, the quantity of silver imported from Canada and Mexico declined by 70 tons and 424 tons, respectively. In the case of both countries, the decreases were in the form of refined bullion. However, increased shipments of 167 tons from Peru, 124 tons from Taiwan, and 126 tons from the United Kingdom were able to keep U.S. total silver imports essentially unchanged.

World Review

The data in table 13 were rated production capacity in mines as of December 31, 1990. Rated capacity was defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

A decline in Peruvian production was more than offset by increased silver production in Australia, Canada, and the United States. As a result, world silver production increased slightly in 1990. It was believed that, as in the United States, the increased silver production in Australia and Canada was attrib-

utable to increased byproduct production. In Australia, mining plans were modified at a number of mines to increase gold output in 1990, as a new Australian tax on gold production was to come into effect in 1991. Consequently, Australian silver production also increased. The lower Peruvian production was attributed to labor unrest and the country's economic problems.

Worldwide, gold continued to be the primary metals exploration target, although reported tight copper and zinc supplies were believed to have resulted in increased interest in these metals. As with gold, most copper and zinc deposits contain some silver that can be recovered as a byproduct. As in previous years, Oceania and countries bordering the Pacific Ocean continued to be the most active exploration areas.

In its 1990 review, Handy & Harman estimated world silver consumption at about 17,700 tons, a decrease of about 200 tons from the revised 1989 figure.²¹ Of the total, 16,900 tons was used in industrial applications, essentially unchanged from that of the previous year. The quantity of silver used for coinage decreased from that of about 1,100 tons in 1989 to about 800 tons in 1990.

Canada.—The Ansil Mine in Quebec completed its first full year of operation. The mine began commercial production in July 1989. In addition to copper, gold, and zinc, the mine recovered 10 tons of silver during 1990.²²

Construction of LAC Minerals Ltd.'s Bousquet No. 2 Mine was completed, and the mine commenced commercial operations on October 1. Ore from the mine was trucked to LAC's Est-Malartic mill, where copper, gold, and byproduct silver were recovered using flotation.

Production at the Dome Mine in Ontario declined. Lower ore grade was a contributing factor in the reduced production. Additionally, unionized workers struck the mine for about 6 months, from May to November, following the expiration of their contract. To reduce operating costs at Dome, Placer Dome Inc. reorganized the mine's operations, resulting in a significant reduction in the number of employees.

Silver production at the Equity Silver Mine in British Columbia was about 229 tons, an increase of about 11 tons from that of the previous year.²³ Improved recoveries and higher ore grades were cited as the reasons for the increased production. Production was expected to decline in each of the next 2 years owing in part to lower ore

grades and reserve depletion. The mine was expected to close in late 1992.

Workers at Brunswick Mining and Smelting Corp. Ltd.'s No. 12 Mine began a strike in early July. Issues included wages, work practices at the mine, and pension and health benefits. Near mid-July, the company began operating the mine at about 25% of its normal rate using staff personnel. At yearend, the strike remained unsettled.

At the Samatosum Mine, approximately 150,000 tons of ore was milled during the mine's first full year of operation. During 1990, the mine produced about 166 tons of silver.²⁴ Samatosum, an open pit mine in British Columbia, began commercial production in July 1989. In addition to silver, the mine also produced copper, gold, lead, and zinc.

Cominco Ltd. closed the Sullivan Mine at the end of January. Company officials attributed the decision to a combination of declining zinc prices, high operating costs resulting from the need for increased ground support at the mine's lower levels, and changes in the ore at these levels. In July, a new 27-month contract was negotiated with Sullivan's unionized workers. As part of the attempt to improve the mine's productivity, the new contract incorporated a new incentive plan. From August to November, the company made various improvement to the mine and mill. The mine was reopened in November, Employment at Sullivan declined from 727 at yearend 1989 to 655 at yearend 1990.25

At the Valley Mine in British Columbia, Highland Valley Copper Co. produced about 31 tons of silver, an increase of more than 9 tons from that of the previous year when operations were disrupted by a 15-week strike.²⁶ In February, the Bethlehem mill was permanently closed. Bethlehem, which last operated in 1989, was placed on standby that year following the opening of the Highland mill.

Other Countries.—Construction of a second roaster was completed at the El Indio Mine in Chile, and the construction of a third roaster was begun. The additional roasting capacity was expected to reduce the penalties imposed by smelters on some of El Indio's concentrates owing to its high arsenic content. In 1990, El Indio milled about 1 million tons of ore and recovered almost 7 tons of gold and 44 tons of silver.²⁷

The Real de Angeles Mine in Mexico increased its silver production to about 294 tons.²⁸ The increased production was attributed to mill modifications and an in-

crease in hauling capacity. About 5.4 million tons of ore with an average silver content of 59 grams per ton was milled at Real de Angles during the year.

At the Porgera Mine, in Papua New Guinea, construction of the underground mine and a new processing facility were completed in August. The processing plant had a capacity of 1,650 tons per day and began commercial production in early September. The plant used carbon-in-pulp technology to recover gold and silver. According to company reports, tailings from the operation were being stored so that they could be processed through a pressure oxidation circuit currently under construction to recover additional gold and silver. Construction of the pressure oxidation circuit was expected to be completed in late 1991.

OUTLOOK

The increasingly dominant component of domestic silver supply is its recovery as a byproduct of the processing of other nonferrous metals such as copper, gold, lead, and zinc. Most nonferrous ores contain some silver, which is either concentrated when the ore is processed or recovered with the principal product. Once it is concentrated or separated from the principal product, the additional cost to recover the silver is relatively minor. As a result, the revenue generated by the recovered silver is often an important component in many mines' finances, especially during periods of declining prices for the principal product.

A drop in the U.S. mine production of silver could have been expected given the

declining silver price and a U.S. economic recession. However, U.S. mine production did not decrease; instead, it increased for the fourth consecutive year in response to an increase in byproduct silver production. As a result of this relative independence of silver supply and price, it is expected that during the period 1991-93, domestic silver mine production will remain near 2,000 tons per year.

Worldwide, silver mine production is expected to remain near the 1990 level of 15,100 tons.

Future industrial demand for silver is harder to forecast owing to the lack of data. As in 1989, some analysts believed that the consumption of silver by domestic manufacturers increased, while other analysts believed that the consumption decreased. It is believed that during the period 1991-93, industrial silver demand will remain essentially unchanged from that of 1990. Worldwide, silver demand is expected to grow slightly as potential new markets are opened and countries such as those in Eastern Europe develop the means of earning the foreign exchange needed to purchase products containing silver.

Revised. W Withheld to avoid disclosing company proprietary data; included in "Other States."

Defined as refinery production from primary materials plus refinery production from old scrap plus imports of bullion minus exports of bullion. Represents not only the quantity of silver required by the domestic fabricating industry, some of which may be placed in stocks, but also the quantity of silver demanded by U.S. investors.

³Mine Safety and Health Administration.

²Includes Illinois, Kentucky, Michigan, New York, South Carolina, Tennessee, Washington, and States indicated by symbol "W."

³Data may not add to totals shown because of independent rounding.

¹Recoverable content of ores and concentrates produced unless otherwise specified. Table includes data available through June 21, 1991.

²In addition to the countries listed, Botswana produces silver (probably 1 kilogram or less per year) and Austria and Thailand may produce silver, but information is inadequate to make reliable estimates of output levels.

³Reported figure.

⁴Of total production, the following quantities, in kilograms, are identified as placer silver (the balance being silver content of other ores and concentrates): 1986—20 (estimated); 1987—20 (estimated); 1988—22 (estimated); 1989—22 (estimated); and 1990—22 (estimated).

⁵Smelter and/or refinery production.

⁶Less than 1/2 unit.

⁷Includes production from imported ores.

⁸Year beginning Apr. 1 of that stated.

SLAG-IRON AND STEEL

By Cheryl Cvetic Solomon

Ms. Solomon, a physical scientist with 5 years U.S. Bureau of Mines experience, has been the commodity specialist for iron and steel slag since 1990. Domestic survey data were prepared by Barbara McNair, mineral data assistant.

ron and steel slags are byproducts of the iron and steel industry and provide an important source of raw materials for construction and road building. Slags are used in road bases, asphalt concrete aggregates, concrete aggregates and products, glass manufacture, mineral wool, railroad ballast, sewage treatment, and soil conditioning.

In 1990, the Federal Environmental Protection Agency (EPA) permanently retained iron and steel slags in the Bevill amendment, or mining waste exclusion, under the Resource Conservation and Recovery Act (RCRA). Iron and steel slags are, therefore, not subject to Federal regulation as hazardous wastes.

Research during the year emphasized the use of granulated slag, particularly in cement. The Australasian Slag Association was formed in Sydney, Australia, to expand the already considerable use of slag in the Australian and Asian markets.

Domestic consumption of iron slag showed a moderate increase when compared with that of 1989, while the consumption of steel slag stayed at the increased level that it had reached in 1989.

DOMESTIC DATA COVERAGE

Data for sales, use, and transportation of iron and steel slag are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. processors. Of the 99 operations canvassed, 99 responded, representing 100% of the total sales or use quantity data shown in table 1. Value data had to be estimated for several operations using reports from prior years adjusted by industry trends.

BACKGROUND

Definitions, Grades, and Specifications

Slags are produced in many metallurgical operations, but this publication deals exclusively with iron slag and steel slag, produced during the ironmaking and steelmaking processes. Slag quantities are given in short tons except where otherwise indicated.

In the production of iron, the blast furnace is charged with iron ore, flux stone (limestone and/or dolomite), and coke for fuel. Two products are obtained from the furnace: molten iron and slag. The slag consists primarily of the silica and alumina from the original iron ore combined with calcium and magnesium oxides from the flux stone. It comes from the furnace as a liquid at temperatures of about 2,700°F, resembling a molten lava.

The blast furnace operation is a continuous process. The raw materials are fed into the top, and the products, molten iron and liquid slag, are drawn off at regular intervals throughout the entire day. The slag is usually run into iron ladles for conveyance to the cooling pit, or it may run straight into a cooling pit close to the furnace.

The density and porosity of the slag are affected by the conditions of cooling as well as by its chemical composition. Depending upon the manner in which the molten slag is cooled and solidified, three distinct types of blast furnace slag can be produced: air-cooled, expanded, and granulated.

Air-cooled slag is allowed to run into a pit adjacent to the furnace or is transported in large ladles and poured into a pit some distance away. Solidification takes place under the prevailing atmospheric conditions, after which cooling may be accelerated by water sprays on the solidified mass. After a pit has been filled and cooled sufficiently to be handled, the slag is dug, crushed, and screened to desired aggregate sizes.

Expanded slag is formed by controlled processing of molten blast furnace slag with water, or with water and other agents such as steam or compressed air, or both. The formation of gases and steam increases the cellular or vesicular nature of the slag, producing a lightweight product. Several methods of expanding the slag are employed involving the pouring of molten slag in open pits or the use of mechanical devices, one of which produces particles in pellet form. Expanded slag is a strong lightweight aggregate suitable for making lightweight concrete, either as building blocks or as structural elements for buildings, or for bridge decks, for example.

Granulated slag is produced when molten slag is cooled rapidly by means of high-pressure water jets, and it solidifies into a glassy, granular product. This is the most rapid cooling process, producing little or no crystallization. The granulated slag may be crushed and screened or pulverized for various applications.

When added to cement, granulated slag enhances the properties of ordinary cement. For example, it will increase the resultant concrete's durability in a marine environment, where concrete is subjected to sulfate attack.

The steel industry also produces steel slag during the steelmaking process. The manufacture of steel involves the removal from the iron of excess quantities of carbon and silicon by oxidation. Steel slag is composed of roughly 50% lime. The other

SLAG—IRON AND STEEL—1990

two main constituents are silica and iron oxide. Different types of steel slag are generated from the open hearth, basic oxygen, and electric arc furnaces.

Owing to skid resistant properties of both blast furnace and steel furnace slag, many State agencies or State departments of transportation have specified slag for use in any asphalt surface application having a high volume of traffic. The State of Illinois specifies the use of either blast furnace or steel furnace slag for road construction. In the Greater Chicago area, the use of steel furnace slag is presently specified in these applications. The State of Indiana presently specifies that at least 50% of the coarse aggregate portion of the asphalt mix be blast furnace slag.²

Industry Structure

In general, most slag processors operate under contracts of 3 to 10 years with steel companies. The services the slag processors typically offer to the steel mill industry are hauling and transport of the slag away from the mill site, processing of the slag, and recovery and distribution of metallics and nonmetallics. Because slag hauling and processing facilities are capital intensive, the slag processors usually try to negotiate a long-term initial contract with the steel company to recover the capital investment. Subsequent contracts may be shorter.

Depending upon the specific situation at the mill site, the slag processor may assume ownership of the slag at the point of discharge or process for a fee and/or market the finished product and pay royalties to the steel company on sales. Some steel companies may allow the processor to share in royalties on these sales. Although there are many variations in the way a particular slag processor and steel mill will set up their agreement, two possible options are considered here. The slag company may be paid to haul and transport the slag, process it, and market the finished product. The steel company, in turn, receives a royalty on the completed sale and a purchase discount on material recycled to the mill. Secondly, in a minority of the contracts, the slag processor takes ownership of the material and pays little or no royalties to the mill. In this situation, the slag processor would be assuming 100% of the site development and capital costs, including facilities for screening, metallic separation, and crushhaulers, to move the material around.

Technology

The slag pelletizer was developed by National Slag Ltd. in Hamilton, Ontario, as a means of bringing very high gas emission levels typical of the "pit foaming" process under control.3 Pelletized slag is produced by expanding molten blast furnace slag under water sprays and then passing the flow of this pyroplastic material over a spinning drum on which fins are mounted. The fins break up the slag, which then forms into pellets owing to surface tension. While previous expanding processes have been of the batch type, this is a continuous process so that gaseous emissions are effectively diluted by generation over a long period of time. Because of this rapid cooling, the pelletizer can be thought of as an "air granulator."

National Slag Ltd. now has licensed the process in many countries, including Australia, England, France, Japan, Sweden, and the United States. Currently, in Canada, about 400,000 metric tons of slag is pelletized annually and separately ground for use as a cementing material by the St. Lawrence Cement Co., Lafarge Canada Inc., and St. Mary's Cement. The pelletizers are installed near Hamilton, Ontario, where the major steel producers are.

Operating Factors

Until recently, in Canada and the United States, portland cement was relatively cheap, and there was no incentive for the ready-mixed concrete industry to use alternative cementing materials. Environmental concerns combined with high energy costs have forced cement companies to seek alternative cementing materials that can partially replace portland cement in concrete. In the construction industry, the search for less expensive types of binders has led to the utilization of ground granulated blast furnace slag, among other byproducts, to partially replace high energy consuming portland cement in concrete.

ANNUAL REVIEW

Legislation and Government Programs

screening, metallic separation, and crushing and heavy equipment, such as slag pot lished its final ruling concerning retaining

iron and steel slags permanently under the Bevill exclusion of RCRA until the EPA completed a required report to Congress and made a regulatory determination.5 As in the September, 25, 1989, proposal, the Agency evaluated the 20 mineral processing wastestreams by applying the high-volume and low-hazard criteria using a multistep process. The first step entailed applying the high-volume criteria to the available waste generation data. Mineral processing wastes generated above the volume criteria thresholds (an average rate of 45,000 metric tons per facility for nonliquid wastes) passed the high-volume criterion. In the second step, the Agency evaluated each of the 20 wastes with respect to the low-hazard criterion using the relevant waste characteristics. EPA considered a waste to pose a low hazard only if the waste passed both a toxicity test (Method 1312) and a pH test. Finally, the results of the first two steps were consolidated.

In July 1990, the EPA released its Report to Congress on Special Wastes From Mineral Processing (RTC).6 RCRA required the EPA Administrator to determine whether regulation of iron and steel slags as hazardous wastes under subtitle C, along with 19 other mineral processing wastes, was warranted. This was to be done within 6 months after publication of the report. The Agency accepted public comments until October 1990. These were to be used in the final regulatory determination. No comments were received opposing the RTC recommendation that regulation under subtitle C for those wastes is inappropriate, and the EPA was expected to conclude in 1991 that regulation under RCRA subtitle C is unwarranted for iron and steel slag wastes.

Production

American Aggregates, of Dayton, OH, a building material company with sand and gravel, limestone, and slag operations in the Michigan, Indiana, and Ohio area was acquired in February 1990 by CSR Australia. CSR Australia is a leading Australian building and construction materials company with operations in Australia, New Zealand, North America, and Europe. Construction materials include aggregates, sand, cement, premixed concrete, and asphalt.

C.J. Langenfelder & Son Inc., a general contracting company based in Balti-

more, MD, acquired the Maryland Slag Co. from the Arundel Corp. in September 1990. Langenfelder is involved in site and civil work, such as construction, roads, tunnels, and landfill. Arundel Corp. was to market the blast furnace slag products for Langenfelder.

Harsco Corp., of Camp Hill, PA, established a wholly owned subsidiary company to process slag and reclaim metal in Yugoslavia through its Heckett Div., based in Butler, PA. (See Yugoslavia in the World Review section of this report.)

In 1990, Koch Minerals Co., a division of Koch Industries of Wichita, KS, began the construction of a granulation facility to process all slag production from the Weirton Steel No. 1 blast furnace in Weirton, WV. Work was also begun on a facility to grind these granules into cement. Koch's grinding and granulation plant was to begin operations in 1991.

Koch Minerals was also contracted by USX to process slag at the USX Gary, IN, works in 1990. This included air-cooled and expanded slag from five furnaces. In addition, Koch signed an agreement to install a granulation plant at the USX No. 13 blast furnace and then to process the slag granules into cement. Koch planned to start up the granulation and grinding facilities by late 1991.

The Levy Co. of Portage, IN, was involved in many projects utilizing slag. Levy used 67,000 short tons of blast furnace slag to construct a breakwater for the Hammond Marina, Hammond, IN. Levy also completed construction of the Beta Steel slab finishing plant, in Portage, IN, in proximity to Bethlehem Steel. The project employed 40,000 cubic yards of concrete aggregate, 90% of which was pumped.

The Standard Slag Co., Eastern Div., based in Coraopolis, PA, supplied more than one-half million tons of slag for the new Greater Pittsburgh International Airport. Standard was using air-cooled slag coarse aggregate extensively to construct the airport. Slag was being used in runways, taxiways, bridges, and tunnels for the new landside and airside terminals. The entire project is expected to be completed by 1992.

Standard Slag also built a new plant at Browns Reserve in West Mifflin, PA, a slag bank where there is in excess of 16 million tons of blast furnace slag. It is estimated that 700 to 800 thousand tons of slag per year will be obtained from this reserve to keep up with the demand for slag. The slag was produced during the time period of the mid-1920's to the mid-1960's.

Based on American Iron and Steel Institute data, domestic production of iron and steel slag remained essentially unchanged. Sales and consumption of iron and steel slag, however, increased moderately when compared with the level of the previous year. The value of blast furnace slag increased compared with that of 1989, reflecting its use as a substitute for natural aggregates, which in certain geographic locations may be in short supply.

Consumption and Uses

Commercial use of slag reduces cost and landfill requirements for the iron and steel industry. Slag, in its use as a synthetic mineral fiber, has a unique costperformance relationship that makes it a preferred raw material in industrial applications and as a building material. Sales of slag products generally reflect demand from the construction industry. The Department of Commerce reported that value of new construction in 1990 declined slightly (2% decline estimated) compared with that of 1989. The value of highway and street construction increased from 1989 to 1990.

Air-cooled blast furnace slag continues to be the predominant form of iron slag processed in the United States, accounting for more than 90% of blast furnace slag sales in 1990. The most significant increase in 1990 in end use for air-cooled slag was as concrete aggregate. Air-cooled blast furnace slag is used in road base. asphaltic concrete aggregate, fill, mineral wool, and glass manufacture. (See table 5 for related data). Mineral wool is used in ceiling tile in commercial and residential buildings and in various thermal and acoustical insulation applications.8 Mineral wool exhibits low thermal shrinkage and high melting point, which makes it ideal as a fire-resistant material.

Granulated and expanded blast furnace slag accounted for the remainder of the iron slag that was sold or consumed in the United States. Consumption of combined expanded and granulated slag decreased by 15% from that of 1989 to 1,450,000 tons valued at \$26,448,000. Granulated slag was predominantly used in the manufacture of cement and expanded slag in the manufacture of lightweight concrete blocks.

Reported steel slag consumption increased slightly compared with that of 1989 (see table 6). It is reported by some slag companies that 90% of steel slag produced is being used. Steel slag used in asphaltic concrete and concrete aggregate increased moderately from that of 1989.

W Withheld to avoid disclosing company proprietary data; included in "Total and Undistributed."

Transportation

Most slag is used within about a 30-mile radius of its source. Transportation costs make slag uncompetitive with natural aggregates when transportation distances exceed about 30 miles. Some slag may be delivered over greater distances to areas that do not have other natural aggregates for use in construction and roadbuilding.

Of all the iron and steel slag products sold in 1990, 87% traveled by truck, with an average marketing range of 30 miles; 5% traveled by waterway, with an average range of 251 miles; and 3% traveled by rail, with an average range of 176 miles. The remaining 5% was used at the plant where it was processed (see table 4).

Markets and Prices

The average price, f.o.b. plant, for all iron blast furnace slag was about \$6.28 per ton, a slight increase over that of 1989 (see table 7). The price of air-cooled blast furnace slag increased from \$4.83 to \$5.14 per ton in 1990. Granulated and expanded slag price information was withheld to avoid disclosing company proprietary data. The unit value for steel slag decreased by 10% from that of 1989 to \$2.95 per ton.

Foreign Trade

Statistics developed by the U.S. Department of Commerce, Bureau of the Census, indicated that approximately 148,026 tons of granulated blast furnace slag was imported into the country during 1990. The breakdown was as follows: 137,006 tons from Belgium valued at \$1,243,002, 11,000 tons from Australia valued at \$89,622, and 20 tons from France valued at \$5,662. Japanese imports also reportedly entered into the country through the Port of Los Angeles, CA, and 100,000 tons of Canadian imports reportedly entered into the country primarily through Detroit, MI, Cleveland, OH, and Baltimore, MD. The Canadian imports may be, in fact, expanded or pelletized slag.

World Review

Australia.—The Australasian Slag Association, based in New South Wales, Australia, was formed in 1990 by a group of leading steel, cement, quarrying, and slag processing companies in Australia, Japan, New Zealand, Singapore, and the United Kingdom. The slag industry in Australia processes and markets approximately 4 million tons of slag per year. The association's goal is to increase public awareness of the properties and value of

slag products and thus to widen the use of slag.

Blue Circle Southern Cement of Sydney, Australia, grinds slag produced by Australian Steel Mill Services in ball mills for use in cement. Blue Circle used the blast furnace slag in the Sydney Harbour Tunnel to improve cement properties in the concrete subject to sulfate attack. Sydney Harbour Tunnel's submerged concrete tunnel segments were built in 1990. The segments contain approximately 200,000 tons of high-quality, sulfate-resistant concrete, made possible by the addition of blast furnace slag. Installation of the sections was planned for Sydney Harbour in 1991.

BHP Steel in Newcastle, Australia, contracted with Steelstone Pty. Ltd. to process and remove basic oxygen furnace slag for the next 10 years. Steelstone was first to recover metallics for recycling in steelmaking and the sinter plant and then to produce and market road construction aggregate. Steelstone is a joint venture of South Coast Equipment Pty. Ltd. of Port Kembla and the Slag Reduction Co. (SRC) of Rotherham, both of which specialize in steel mill services. Although the use of basic oxygen furnace slag as a roadmaking material is new to Australia. SRC has been turning processed and graded steel slag into coated roadstone

Not transported (used at plant site)	1,132
Total	24,149

since the 1930's. BHP began work on the slag utilization project in 1986. Between 200,000 and 250,000 tons of slag produced annually at the steelworks was expected to be absorbed by the process.

Steel Cement Ltd. was formed in 1989 by Independent Cement & Lime Pty. Ltd. (45%), Ube Industries Ltd. (26%), Adelaide Brighton Cement Investments Ltd. (20%), and AICIA Pty. Ltd. (9%) with the intent of using Australian granulated blast furnace slag in cement production and other areas. In 1990, Steel Cement shipped 11,000 tons of the granulated blast furnace slag to Hawaii to be used as fertilizer for cane fields as its first export.

South Africa, Republic of.—Iscor granulated 152,000 tons of slag at Pretoria Works for use in cement, 548,000 tons at Vandervijlpark (63% for cement), and 576,000 tons at Newcastle (37% for cement). The Republic of South Africa experienced a severe depression in the construction and mining industries in 1990 and did not use all of its available capacity for granulating slag. Iscor's steel slag production in Pretoria was 142,000 tons in Vanderbijlpark and 190,000 tons in Newcastle. The concept of utilizing blast furnace slag to produce cementitious material was first researched in the Republic of South Africa in the 1950's. After successful trials on Iscor slags, Building Binders Ltd. was formed to exploit this technology, and a plant was built in 1955 at Vanderbijlpark adjacent to the Iscor works. The business progressed rapidly and, in 1962, the three major South African cement companies-Pretoria Portland Cement, Blue Circle, and Anglo Alpha—acquired the shares of the company, and the name was changed to Slagment Ltd. Based on the success of this venture, a second plant was Withheld to avoid disclosing company proprietary data.

W Withheld to avoid disclosing company proprietary data.

built in 1966 at Pretoria. After this, Slagment increased production from the initial 65,000 tons per year to 600,000 tons per year. In 1985, the third plant was built near the Newcastle ironworks, and today the three plants have a production capacity of 1.5 million tons per year of cementitious slag material. The Newcastle plant was subsequently sold to one of Slagment's major customers, Natal Portland Cement, which now manufactures the product under license to Slagment.

U.S.S.R.—Approximately 88% of the slags produced in the U.S.S.R. is utilized. Blast furnace slags amounted to more than 41 million tons. Of that amount, about 25 million tons was granulated, 16 million tons was used as building stone, and 85,000 was used as mineral wool. Steel slags accounted for a little more than 9 million tons. Of these, 375,000 tons is used as slag-lime fertilizer and a little more than 7 million as building stone.9 Slag was used mainly in the production of cement, concrete, and in slag wool and in road construction and agriculture. According to U.S.S.R. economic indicators, including price, labor, and cost of production, slag industries were profitable.

The Cherepovets works in the U.S.S.R. produces granulated blast furnace slag. ¹⁰ The granulating complex processed slag from the Krivorozhstal steelworks. The granulators grind and crush the molten slag, as well as hydraulically transport, dewater, and collect the granulated slag from the blast furnace without the use of cinder cars.

United Kingdom.—Appleby Group, South Umberside, continued to increase its penetration into the cementitious market in spite of the recession in industry. The Group has made major inroads into the concrete, glass, and abrasives markets. Frodingham, the largest company in the Appleby Group, produced ground granulated blast furnace slag for use as a cement extender. It was the first such producer in the United Kingdom.

Appleby has invested in high-pressure roller crushers to increase production. The environmental concerns in the United Kingdom have pushed iron manufacturers toward production of granulated and away from air-cooled blast furnace slag. This trend is likely to continue.

Yugoslavia.—Harsco Corp., of Camp

Hill, PA, established a 100%-owned company for metal reclamation and slag processing in Yugoslavia through its Heckett Div. Designated Heckett Yugoslavia Ltd., the new company was one of the first U.S.-funded projects to begin operations in Yugoslavia since the liberalization of foreign investment laws by the Yugoslavian Government in 1989. The new company entered into a long-term contract for slag processing and metal recovery at the Metalurski Kombinat Smederevo (MKS) steel plant in Smederevo in the Republic of Serbia near Belgrade.

Current Research

Current research was dominated by that done on granulated blast furnace slag. A study at the Canada Centre for Mineral and Energy Technology (CAN-MET) of the Energy, Mines and Resources Canada reviewed the use of granulated blast furnace slag in concrete in Canada. Three areas were covered: mixture proportions and properties of fresh concrete incorporating slag, mechanical properties of concrete incorporating slag, and durability of concrete incorporating slag. The mixture proportions of granu-

lated blast furnace slag to be used in concrete depend upon the specific job. As an example, granulated slag would replace 25% to 50% by weight of cement if the goal were to conserve cement in concrete operations. However, if the purpose were to increase concrete durability, such as sulfate resistance, then the slag content would be at least 50% of the total cementitious material. Because each slag has a unique chemical composition, glass content, and fineness, it is necessary to perform exploratory investigations with the cement, aggregates, and chemical admixtures to be used in each specific project.

The mechanical properties of concrete incorporating slag are highlighted by the compressive strength development of slag concrete. Compressive strength development, as well, depends upon the type, fineness, activity index, and the proportions of slag used in concrete mixtures. Other factors that affect the performance of slag in concrete are the water-to-cementitious materials ratio and the type of cement used.

The increased durability of portland cement concrete incorporating slag results primarily from a finer pore structure and reduced contents of easily leached calcium hydroxide in the hardened cement paste. Also, the dilution of the reactive component of the portland cement by the replacement of cement by slag contributes to increased resistance of slag concretes to sulfate attack.

Several studies completed at CANMET in 1990 illustrate the above areas. The amount of slag replacing cement has been limited in the past by the relatively slow strength development of the slag. The studies have shown that, in slag concretes, strength development can be accelerated by the addition of alkali activators such as lime, sodium hydroxide, sodium carbonate, sodium silicate and, in general, salts of weak acids and strong bases. The purpose of the study was to formulate the proportioning of concrete mixtures made with ground-granulated blast furnace slag activated with sodium silicate and to determine their properties and durability.12 Six concrete mixtures were made using ground-granulated blast furnace slag, sodium silicate, lime, crushed limestone, natural sand, and a hydrocarbon air-entraining admixture. Among the conclusions, it was found that the sodium silicate-to-slag ratio was an important factor affecting the properties of fresh and hardened concrete and that the compressive strengths were comparable to or higher than those of portland cement concrete with equivalent water-to-cement ratio and workability.

In another study at CANMET, mechanical properties of slag, abrasion resistance, and chloride-ion permeability of concrete incorporating ground-granulated blast furnace slag from northern Ontario were investigated.¹³ Nine concrete mixtures were made with the water-tocementitious materials ratio of the mixtures ranging from 0.45 to 0.70. The percentage of slag used as a replacement by mass for the portland cement varied from 0% to 50%. Among other findings, the strength development characteristics of the slag concrete indicated that granulated blast furnace slag can be satisfactorily used as a partial replacement for portland cement in concrete.

Engineers at the Department of Civil Engineering ADFA in Australia investigated the possibility of using slagment (65% cement and 35% slag) instead of plain cement to manufacture structuralgrade concretes.14 The strength development of three grades of plain cement concretes, portland blast furnace slag concretes, and concretes in which 15% and 35% of slagment was replaced by fly ash (ternary blends) were tested. They found that low and medium-strength slagment concretes reaching 20 and 35 megapascals gave higher strength than those cast with plain cement. However, the addition of fly ash to slagment generally decreased concrete strength. In addition, the results suggest that the strength of the slagment concretes are less affected by lack of curing than the strength of the plain cement concretes.

Slag-blended cements have been used to improve the sulfate resistance of concrete in Europe for decades. However, they had not been widely used in North America because slags had limited availability. There were also concerns that not all slags performed equally because of variations in slag composition, reactivity, and fineness from different sources. In addition, until the 1970's in Canada and the United States, portland cement was not expensive, and there was no reason to find substitutes for it. Thus, in Canada in 1976, with higher energy costs renewing interest in slag, a research program was begun at McMaster University to monitor concrete and mortar specimens incorporating Canadian slag. Research continued at Trow Ltd. and then at the

University of Toronto, and the results of a 10-year study of slag exposure to sulfate solutions were published.¹⁵ The major finding was that replacement of a 50 percent by mass of normal portland cement by slag provided equivalent or better sulfate resistance than sulfate-resistant portland cement. Sulfate resistance was found to decrease with increasing slag aluminum oxide content and to improve with reduced slag permeability and reduced slag calcium hydroxide content, among other factors. The results of the study are based only on particular pelletized slags ground to a specific fineness.

Researchers at the University of Sherbrooke, Sherbrooke, Quebec, Canada, studied the microstructural development of a very high strength concrete containing 10% silica fume, 30% slag replacement for cement, and a high-range water-reducing admixture.16 Chemical and mineral additives traditionally have been used to improve the properties of fresh and hardened concrete and to reduce costs by replacing cement with low-cost industrial byproducts. The concrete displayed high early strength and reached 94 MPa at 28 days. Past experience has shown them to be very efficient components in the production of very high strength concrete. The benefits of blended elements incorporating slag for high-strength concrete production have been illustrated during the construction of Nova Scotia Plaza.¹⁷

Portland cement containing 50% to 80% blast furnace slag has higher resistance to seawater attack and to alkalisilica reactions and a better development of strengths than portland cement. The Laboratory of Metal Engineering and Mineral Geochemistry, Ecole Superieure Energie et Materiaux, Universite d'Orleans, France, investigated the influence of the nature of solid and aqueous solutions on the composition of the hydrated slag. 18 To understand the properties of cement and concrete containing slag powders or sands, the researchers determine the structure, composition, and origin of the hydrated layers grown after different reaction times. Two synthetic glassy slags with high aluminum and magnesium contents were hydrated at 40° C at time periods ranging from 4 hours to 150 days in water and alkaline solutions. Glassy slags in alkali media were more highly reactive than in water.

Researchers at the Regional Research Laboratory in Assam, India, have investigated the activation of low-lime, high-

alumina granulated blast furnace slag by anhydrite to prepare supersulfated slag cement.¹⁹ The latent hydraulic property of granulated blast furnace slag is advantageously used in making various cementitious binders by activating it with different activators, such as ordinary portland cement. The hydraulic activity of a slag depends mainly on its glassy phase content and chemical composition. In general, the higher the glassy phase, the lime and alumina contents, the higher is the hydraulic property of the slag. Ordinary portland cement clinker (commercial grade) and slag procured from the Rourkela steel plant were ground separately in a laboratory ball mill. The researchers concluded that the optimum quantity of anhydrite required to make supersulfated slag cement from a low-lime (26%), high-alumina (27%) Indian blast furnace slag is in the range of 15% to 20%. The enhancement of strength characteristics in the latter stages of hydration was attributed to the formation of calciumsilicate hydrates.

The King Fahd University of Petroleum and Minerals has investigated the long-term corrosion-resisting characteristics of concrete incorporating slags or pozzolans.²⁰ They investigated the corrosion-resisting characteristics of concrete samples made with a blast furnace slag cement, two Class F fly ashes, a natural pozzolan, and a preblended portland-fly ash cement. Specimens were immersed in 5% sodium chloride solution for a period of more than 5 years, and the corrosion activity was evaluated by monitoring the half-cell potentials and measuring the corrosion rate of embedded steel using a linear polarization resistance technique. The investigators concluded that the corrosion rate of steel in concrete made with blast furnace slag cement is lower than in the other concretes tested.

Investigators at the Building Research Station have studied the hydration behavior of refractory aluminous cement and ground-granulated blast furnace slag over a range of temperatures.²¹ Commercial high-alumina cements (HAC) show a reduction in compressive strength when kept in a hot and humid atmosphere over a prolonged period of time. It has been claimed that the strength loss suffered by HAC under hot and humid conditions can be counteracted by the addition of sufficient quantities of ground-granulated blast furnace slag to the cement. When kept in hot water over a long period of

time, the 1:1 cement plus slag mixture has not shown any reduction in strength. The researchers concluded that there are chemical interactions between the cement and the granulated blast furnace slag that form sulfate hydrates and accompanying gel material. These inhibit the formation of the hydrate phase that is responsible for reduction in strength of HAC concrete.

Ground-granulated blast furnace slag is recognized as giving specific qualities to the composite-cement concrete making it superior to concrete made from portland cement alone. The Department of Mechanical and Process Engineering at the University of Sheffield, England, studied the engineering properties of slag concrete when 50% to 70% by weight of portland cement was replaced by slag.²² The study emphasized that adequate drying should be an essential specification when slag is incorporated in concrete. Prolonged drying of inadequately cured slag concrete can adversely influence its longterm durability owing to internal microcracking and loss of elastic modulus.

The U.S.S.R. studied the reduction of dust and gas emissions from slag forming mixtures used in continuous casting.²³ Introduction of effective means of recovering waste products was investigated. It was discovered that the basic components of the gas emissions are the flourine and carbon compounds, the quantity of which, depending upon the mixture, composes from 1.8 to 10.4 milligrams per gram of mixture. When using granulated slag, the dust emissions are insignificant.

OUTLOOK

The use of granulated slag is expected to increase owing to environmental and cost considerations. Using granulated slag reduces energy costs that would be higher when using portland cement. As more companies decide to granulate slag, more slag may be used in cement, and less may be available for use as an aggregate in building and construction. Granulated slag production capacity may exceed demand as the amount of slag consumed approaches an upper limit for slag use in cement. On the other hand, in some areas of the country, there may be shortages of blast furnace slag because of blast furnace shutdowns. There may also be shortages in steel slag as a result of an expected downturn in the steel industry in 1991.

The slag industry is expected to pursue

markets in traditional areas such as building and road maintenance and resurfacing as well as to seek nontraditional niches. The use of slag and fly ash as a substitute for open graded fill is one such nontraditional area. Slag used in ways other than as replacement for natural aggregates will represent a new area for slag to be used in the future. Slag industry demand, both for cement and aggregate end use, depends upon the construction industry, which in turn depends on general economic conditions.

Events of the past few years have indicated that there continues to be foreign interest in acquiring U.S. slag companies and that the total number of U.S. slag companies may decrease as consolidation occurs. Downstream integration of the industry continues, with increased emphasis in the United States in marketing slag in higher value end uses such as in cement. Iron slag processors are increasingly part of larger companies having captive markets in the aggregate, cement, and construction markets.

SODA ASH

By Dennis S. Kostick

Mr. Kostick, a physical scientist with 12 years of U.S. Bureau of Mines experience, has been the commodity specialist for soda ash since 1979. Domestic survey data were prepared by Carleen Militello, mineral data assistant; and international data tables were prepared by William Zajac, Chief, Section of International Data.

eginning with this report, all data will be reported in metric units to comply with Public Law 100-418 of August 23, 1988. This Federal law required all Federal agencies to use the metric system of measurement by the end of fiscal year 1992. Although the use of the metric measurement standards was authorized by law since 1866 (Act of July 28, 1866; 14 Stat. 339) and the United States was an original signatory party to the 1875 Treaty of the Meter (20 Stat. 709), the United States has been the only industrially developed nation that has not universally converted to the metric system from the English system of measurements. While foreign trade of soda ash increases and foreign participation in U.S. joint ventures continues, communicating information with an international standard of measurement becomes more important.

DOMESTIC DATA COVERAGE

Domestic production data for soda ash are developed by the U.S. Bureau of Mines from monthly, quarterly, and annual voluntary surveys of U.S. operations. Of the six soda ash operations to which a survey request was sent, all responded, representing 100% of the total production data shown in this report.

Soda ash consumption by end use was collected quarterly from the industry. Trade statistics are obtained from the U.S. Department of Commerce, Bureau

of the Census. The export data collected by the Census Bureau may not correspond to the export data provided by the soda ash producers in the quarterly survey of soda ash sales. This discrepancy between the export data is because Census data reports the transaction on the date the cargo physically departed from the U.S. port whereas soda ash producers consider a shipment as exported when it leaves the plant. Overland transit time between the plant and port and any carryover export inventory are not taken into consideration.

Soda ash, also known chemically as sodium carbonate, is the 11th largest inorganic chemical in terms of production of all domestic inorganic and organic chemicals, excluding petrochemical feedstocks. Although soda ash is not a common

household term, it is used in many consumer products found in virtually every home—glass, soap and detergents, paper, textiles, and food. The United States is the world's largest soda ashproducing nation, with the world's largest natural deposit of trona, the ore from which soda ash is refined. Because the majority of world output is made synthetically, which usually is more expensive to manufacture, U.S. natural soda ash is extremely competitive in world markets.

BACKGROUND

In 1990, soda ash represented about 2.2% of the total \$38 billion nonfuel mineral industry that was surveyed by the U.S. Bureau of Mines. The average U.S. citizen consumes about 18,140 kilograms (40,000 pounds) of new minerals in the form of consumer goods each year. Based on the 1990 U.S. population of almost 250 million, the 1990 per capita consumption of soda ash was 26 kg (58 lbs), compared with copper, 8 kg (18 lbs); aluminum, 17 kg (38 lbs); salt, 156 kg (345 lbs); cement, 328 kg (724 lbs); and iron and steel, 348 kg (767 lbs). If an infant were born in 1988, he or she would require 1,940 kg (4,344 lbs) of soda ash in his or her lifetime, based on an average life expectancy rate of 74.9 years.

Natural soda ash was probably first obtained as evaporite incrustations along the edges of alkaline lakes in Lower Egypt. It was used about 3,500 B.C. to make ornamental glassware, as evidenced by many of the early Egyptian glass artifacts. The Egyptians also mixed lime and soda ash to make caustic soda. The caustic soda was combined with silicate minerals obtained from the Sinai Desert. This made a soluble silica, which was added to aluminum-rich Nile River silt, producing a silica-aluminate cement mortar with superior bonding properties. In the Old Testament, it was referred to as neter but has also been known as natrium, kali, trona, and natron. Until the 18th century, soda ash was obtained mainly by burning seaweeds and marine plants, leaching the soluble material from the ashes, and evaporating the solutions to dryness. About 12 metric tons (13 short tons) of ash yielded 1 metric ton of sodium carbonate and 14 kilograms (30 pounds) of iodine as a byproduct. The final material was very impure but could be used in the manufacture of glass and soap and detergents. Pliny, a Roman historian, listed soda ash in the manufacture of glass, as a medicine for colic pains and skin eruptions, and for making bread in the first century A.D.

In 1791, Nicolas Leblanc, a French chemist, developed a process for making soda ash from "salt cake" (from salt and sulfuric acid), coal, and limestone. The French Revolution interfered with its development, and Leblanc's patent and factory were confiscated, with him receiving only token compensation. Napoleon returned his factory to him, but Leblanc was not able to raise enough capital to reopen it, and he committed suicide in 1806. More than 30 years passed before the process first became successful in Liverpool, England. The process was not used successfully in the United States except during a short period from July 1884 to January 1885 at Laramie, WY.

Ernest and Alfred Solvay developed an improved method for making soda ash from salt, coke, and limestone, with ammonia as a catalyst, in the early 1860's. That process was first used in the United States in 1884 at Syracuse, NY, in a plant that continued to produce soda ash until 1986. It was the first of about 17 synthetic Solvay plants that was in operation by 1939 in the United States and, ironically, the last one to close. The Solvay process gained in popularity over the years and is now the basic method used throughout the world for making synthetic soda ash.

The site of the first commercial production of natural soda ash in the United States was from two deposits known as the Soda Lakes near the present town of Fallon, NV. Asa L. Kenyon acquired title to Little Soda Lake in 1855 and sold it to Higgins and Duffy in 1868, when the first 270 metric tons (300 short tons) of natural soda ash was produced. Production of adjacent Big Soda Lake began in 1875 and reached its peak in 1887. The brines became diluted as the lake levels rose in 1907 because regional dam construction affected the local water table.

Searles Lake in California was originally mined for borax as early as 1874. Soda ash production began in 1926 by the West End Chemical Co. American Potash Corp., formerly the American Trona Corp., was the second company to produce soda ash in 1931.

Definitions, Grades, and Specifications

The following terms are used in the soda ash industry:

Ammonia-Soda Process.—Also known as the Solvay process and lime-soda process.

Dense Soda Ash.—Has a bulk density of 0.96 to 1.06 grams per cubic centimeter (60 to 66 pounds per cubic foot). It is produced by hydrating light soda ash followed by dehydration through calcination to produce denser crystals. In eastern Europe, dense ash is made by compressing light ash between rollers to increase the density followed by screening.

Light Soda Ash.—Has a bulk density of 0.51 to 0.62 gram per cubic centimeter (32 to 39 pounds per cubic foot). It is produced by calcining the sodium sesquicarbonate precipitate recovered from the carbonation towers or vacuum crystallizers.

Natural Soda Ash.—Soda ash produced from trona ore, sodium carbonate-bearing brines, or surface mineralization.

Soda Ash.—Synonymous with sodium carbonate. It is a general term that can apply to soda ash produced from natural sources or from various chemical processes.

Sodium Sesquicarbonate.—Can refer to the name for the chemical composition of trona or the chemical process that produces a light- to intermediate-grade of soda ash having an average bulk density of 0.8 gram per cubic centimeter (50 pounds per cubic foot).

Synthetic Soda Ash.—Term for soda ash produced from one of several chemical processes, such as the Solvay process.

Trona.—The principal ore from which soda ash is made. It is composed of sodium carbonate, sodium bicarbonate, and water. The monoclinic crystals are prismatic to tabular with colors ranging from translucent (spar variety) to shades of brown, which vary depending on the amounts of contained organic matter. Trona has a specific gravity of 2.17 with a hardness of 2.5 to 3 on the Mohs' scale. About 1.8 tons of trona is required to produce 1 ton of soda ash.

The terms "soda ash" and "sodium carbonate" are used interchangeably. The material manufactured from Wyoming

trona normally contains more than 99.8% sodium carbonate, and the sodium chloride content ranges between 0.01% to 0.02%. The amount of iron is less than 10 parts per million. Searles Lake brines are processed to yield a product of similar high quality with salt and sodium sulfate as the principal trace impurities. The average material produced by a Solvay soda ash plant is about equal to the natural product in sodium carbonate content, but often contains a larger quantity of salt. Dense soda ash, because of its greater bulk density, may command a higher price than the light variety and is preferred for glass manufacture because the light soda ash leads to frothing in the glass melt. Light soda ash is preferred by many chemical and detergent industries because it dissolves more readily. Sodium sesquicarbonate has an intermediate bulk density and is used in some detergent and bath salts.

Typical official specifications for soda ash include American National Standard K60, 11-1956 (R1969) "Standard Specifications for Soda Ash," which appears as the American Society for Testing and Materials (ASTM) Designation D458-74 (Reapproved 1979); and British Standard (BS) 3674: 1963 "Specification for Sodium Carbonate (Technical Grades)." The British Standard specifies, among other requirements, not less than 57.25% Na₂O and not more than 0.005% Fe₂O₃; the ASTM, a minimum of 99.16%

Na₂CO₃. Both standards specify methods of testing.

Industry Structure

The U.S. soda ash industry is composed of six companies, five in Wyoming and one in California. All produce natural soda ash only, either from sodium carbonate-rich brines or from underground mining of trona ore. Foreign investment in U.S. soda ash operations has risen from 10% of capacity in 1981, when Société Nationale Elf Aquitaine of France bought Texasgulf Chemical Co., to 37% in 1990. Five of the six U.S. companies have either Australian, French, Japanese, or Korean partners. FMC Wyoming Corp. remains the only U.S. producer without any foreign ownership.

Geology-Resources

The definitions of resources, reserves, and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals." Briefly, "resources" describe the quantity of ore present, regardless of grade or ease of extraction. The "reserves" are the portion of the resource that are economic to mine using the current technology and value of the commodity.

There are more than 60 identified natural sodium carbonate deposits in the world, the largest of which is the trona deposit in southwest Wyoming. Although

several of these deposits have been quantified, most are economically insignificant or too remote to be commercially developed. Table 4 lists the countries with known soda ash deposits. All soda ash deposits can be classified in one of five modes of occurrences. In decreasing order of economic importance, they are: buried, surface or subsurface brines, crystalline shoreline or bottom crusts, shallow lake bottom crystals, and surface efflores-

The trona found in the Green River Formation in southwest Wyoming is an excellent example of a buried trona deposit. The Wilkins Peak Member contains 42 beds of trona, 25 of which have a thickness of 0.91 meters (3 feet) or more. Eleven of these exceed 1.83 meters (6 feet) in thickness covering an area more than 3,100 square kilometers (1,200 square miles). The trona beds were deposited about 50 million years ago in the early to middle Eocene epoch in an ancient freshwater lake, named "Lake Gosiute" by Clarence King in 1878. The sodium and carbonate constituents of trona owe their respective origins to the leaching of the extensive pyroxeneandesite volcanic ash layers and the seasonal influxes of carbonate-rich sediments into the local depositional basin. In addition, subterranean thermal springs contributed a significant quantity of dissolved alkaline carbonates as well as sodium, calcium, silica, and bicarbonate ions. Trona can precipitate only in the

Natural soda ash only for 1980, and 1987 and thereafter: natural and synthetic from yearend 1981-86.

Also known as apparent consumption (production + imports-exports ± stock changes) and is equal to "Total U.S. primary demand."

Also known as apparent consumption (production + imports-exports ± stock changes) and is equal to "Total U.S. primary demand."

Estimated consumption for 1980-86 was based on industry sources; reported consumption 1987 and thereafter were from quantitative and qualitative quarterly surveys of producers' sales. Other end-use categories were incorporated in the survey.

Includes soda ash used in petroleum and metal refining, leather tanning, enamels, etc. Also includes data in categories indicated by "NA."

Because end-use data prior to 1987 were estimated, industrial demand and U.S. primary demand calculations (both based on production, trade, and inventory data) were assumed to be equal to total U.S. because enu-use data prior to 1767 were estimated, industrial demand and 0.5. primary demand calculations tooth based on production, trade, and inventory data) were assumed to be equal to total 0.5. consumption. Beginning with 1987, reported consumption data by end use often disagreed with derived apparent consumption calculations that necessitated including an "Undistributed" category to account for the discrepancies. These discrepancies are because of the fluctuating balance of inventory in transit from plants to domestic or export destinations.

National may not add to totals because or independent rounding.

*Values are the combined total revenue of California and Wyoming natural, bulk, dense soda ash sold on an f.o.b. plant basis, at list prices, spot prices, discount, long-term contracts, and for export, divided

Note.—There are at least 62 identified natural sodium carbonate deposits in the world, some of which have been quantified. The countries and number of deposits include Australia (1), Bolivia (2), Botswana (1), Brazil (1), Canada (3), Chad (9), China (9), Egypt (1), Ethiopia (1), India (2), Kenya (3), Mexico (1), Namibia (1), Niger (1), Pakistan (1), the Republic of South Africa (1), Tanzania (5), Turkey (1), Uganda (1), the U.S.S.R. (4), the United States (20), and Venezuela (1).

presence of abundant carbon dioxide, which probably was supplied from the atmosphere and/or the biogenic decay of Eocene plant and aquatic remains. For 4 million years, Lake Gosiute went through many stages of filling and evaporation, thereby depositing more than 42 beds of trona on the lake bottom along

with repetitive beds of marlstone, limestone, oil shale, and sandstone-mudstone. The decrease of the inflow to the lake was probably in response to climatic changes that resulted in the final evaporation of the waters. The former Lake Gosiute is the present Green River Basin.

Assuming 1.8 tons of trona yields

approximately 1 ton of soda ash, about 47 billion metric tons (52 billion short tons) of identified soda ash resources could be obtained from the 56 billion metric tons (62 billion short tons) of bedded trona and the 47 billion metric tons (52 billion short tons) of interbedded or intermixed trona and halite that are in beds greater than 1.22 meters (4 feet) thick. Approximately 34 billion metric tons (37 billion short tons) of reserve base soda ash could be obtained from the 36 billion metric tons (40 billion short tons) of halitefree trona and the 25 billion metric tons (27 billion short tons) of interbedded or intermixed trona and halite in beds more than 1.83 meters (6 feet) thick. Although about 15 million metric tons (16 million short tons) of trona is presently being mined annually, with these minable reserves, Wyoming could supply all domestic requirements for more than 3,100 years at the 1990 demand level. As technology improves in the future, mining of the subeconomic grades of ore would further extend the life of the trona deposit to more than 5,100 years. With Wyoming reserves estimated at 20 billion metric tons (22 billion short tons), the United States, through this one deposit, could supply the world all the soda ash to meet the current demand levels for about 630 years.

The U.S. Government established a Known Sodium Leasing Area (KSLA) in Wyoming within the perimeter of the trona depositional basin. The trona within the KSLA is subject to Federal and State leasing regulations and private lease agreements. Although most of the leasable trona averages 93% sodium sesquicarbonate, several areas contain lower grade trona because of local depositional contamination along the lake margins, thereby reducing the reserve estimates of that particular area.

A series of Pleistocene playa lakes rich in evaporate minerals found in California compose the second largest reserves of sodium carbonate in the United States. Subsurface sodium carbonate-bearing brines and crystalline material compose the resource at Searles Lake, which is almost dry playa 15 kilometers (9 miles) long by 11 kilometers (7 miles) wide with an area of about 104 square kilometers (40 square miles). Surface sodium-bearing crystalline minerals predominate at Owens Lake, which was first mined in 1885 by the Inyo Development Co. Both deposits have combined reserves of about

¹The reserve base includes demonstrated resources that are currently economic (reserves), marginally economic (marginal reserves), and some of those that are currently subeconomic (subeconomic resources).

²Represents only the quantity recoverable based on an average rate of 60% extraction efficiency from room and pillar, longwall, and shortwall methods of underground mining. This extraction rate does not apply to brines or surface evaporite lake beds. Solution mining of trona and nahcolite is estimated to have a 30% extraction efficiency rate.

³The sodium carbonate content of nahcolite reserves and reserve base are 0.8 billion short tons and 1.26 billion short tons, respectively. The sodium carbonate content of dawsonite reserves and reserve base are 1.82 billion short tons, and 3.0 billion short tons, respectively.
⁴Data may not add to totals shown because of independent rounding.

⁵Annual leaching of volcanic rocks replenishes the resources at Lake Magadi.

817 million metric tons (900 million short tons).

Two potential sources of soda ash nahcolite (natural sodium bicarbonate) and dawsonite (sodium-aluminumcarbonate)—are associated with oil shale in the Piceance Creek basin in northwest Colorado. Identified resources of 29 billion metric tons (32 billion short tons) of nahcolite and 17 billion metric tons (19 billion short tons) of dawsonite, equivalent to 18 billion metric tons and 6 billion metric tons (20 billion short tons and 7 billion short tons), respectively, of sodium carbonate resources, would be available as a byproduct of oil shale processing or as single mineral extraction. These deposits were formed in middle Eocene time with the nahcolite occurring as aggregates (62%), disseminated crystals (24%), and impure beds (14%).

The only other commercial natural soda ash deposit in the Western Hemisphere, excluding those in the United States, occurs at Lake Texcoco, near Mexico City, Mexico. Two caliche layers at a depth of 46 meters (150 feet) act as a filter and reservoir for the sodium carbonate-rich brine resource. With an average concentration of about 7% sodium carbonate, the resource contains about 180 million metric tons (200 million short tons) of available soda ash.

The Rift Valley of eastern Africa has several alkaline lakes resembling those of California. Only Lake Magadi in Kenya is presently in production. The soda ash reserves of these lakes are renewed annually from natural active volcanic sources. Other African countries that may become future suppliers of soda ash are Chad, Ethiopia, Niger, the Republic of South Africa, Tanzania, and Uganda. Botswana is developing its Sua Pan salt and soda ash deposit, and final completion of the project is scheduled for 1991. Elsewhere, deposits of natural soda ash occur in Bolivia, Brazil, Canada, India, Pakistan, the U.S.S.R., and Venezuela. Plans are underway to develop deposits in China at Xilin Gol and in the Wulan Buh desert area. A trona deposit in Turkey near Beypazari is also under consideration for development.

Technology

Soda ash from Wyoming trona is mined, crushed, dried, dissolved, filtered, recrystallized, and redried. In California, soda ash from sodium carbonate-bearing brines is solution mined, carbonated, filtered, dried, decomposed, bleached, and recrystallized to dense soda ash.

Exploration.—Because of the scarcity of economic soda ash deposits in the world, many nations continue to search for new prospects. Smaller and less well known deposits are often reevaluated by different groups at different times and with usually the same results. As new techniques of exploring are developed and used, such as Landsat satellite remote sensing imagery and side-scanning radar, new deposits may be discovered.

In the United States, exploring for soda ash continues. An area near the junction of the Black's Fork and Green River in southwest Wyoming has potential. In Oregon, a few companies have expressed interest in evaluating the sodium carbonate deposits at Summer Lake and Abert Lake, which are near several pulp and paper manufacturers. These manufacturers have traditionally obtained their soda ash and caustic soda pulp-bleaching chemicals from Wyoming and Washington producers, respectively. As soda ash and caustic soda prices increase and overland transportation costs rise, these Oregon deposits may have commercial significance because their locations are nearer to the pulp markets.

Mining.—Commercial mining of Wyoming trona began in 1948. Between 1950 and 1990, more than 209 million metric tons (230 million short tons) of trona (equal to about 124 million metric tons or 137 million short tons of soda ash) have been mined. Only about 0.6% of the 36 million metric tons (40 million short tons) of halite-free trona reserve base has been used since mining began.

Underground mining of Wyoming trona is similar to coal mining, except that trona is a harder mineral than coal. The five present Wyoming soda ash producers use room-and-pillar, longwall, shortwall, and solution-mining techniques individually or in combination. The room-and-pillar method has an ore extraction efficiency rate of about 45% (55% of ore remains as pillars for structural integrity), the longwall and shortwall methods each have efficiency rates of about 75%, and solution mining has an efficiency rate of about 30%. These rates are important when calculating the amount of reserves that are minable. Based on the types of mining techniques, the author used a 60% average extraction efficiency rate to calculate reserves (remaining 40% stays in place as pillars for structural integrity and unavailable for present extraction). The ore is undercut, drilled, blasted, mucked, crushed, and transported to the surface by wellestablished methods and various state-ofthe-art mining equipment. The conventional blasting method using prilled ammonium nitrate and fuel oil (ANFO) is a standard and reliable method. Continuous mining uses vehicles equipped with a rotating cylindrical cutter. Continuous miners are used by T.g. Soda Ash Inc. in its shortwall technique. The longwall technique was used by General Chemical Corp. and is now used by FMC. Adopted from coal mining use, the longwall method uses a special track-mounted shearer that moves in front of a hydraulic-operated roof support system.

FMC has pioneered the use of solution mining to dissolve and recover deeply buried trona. Using an array of injection and recovery wells, a solvent (dilute sodium hydroxide) is introduced under pressure to dissolve the underlying trona. This technique has had moderate success since its first commercial debut in 1985. Beginning in 1990, FMC used the majority of the output from its solution mining for manufacture of caustic soda, from which some sodium cyanide was produced.

To reduce mining costs and maintain their competitiveness in the world, many Wyoming soda ash companies implemented continuous belt and mobile track conveyor systems to transport trona underground more efficiently. This new haulage system has replaced ore-carrying shuttle cars, reduced the mine work force, and increased the quantity of ore mined per shift. Companies have also been considering eliminating conventional mining but retaining other mining methods sometime in the foreseeable future to further reduce labor, safety, and other operating costs.

Subterranean brines between 15 and 107 meters (50 and 350 feet) below the surface at Searles Lake in California are extracted using an array of injection and recovery well drilled down to specific depths where mineral concentrations favor maximum extraction. The Argus plant of Kerr-McGee Chemical Corp. uses sodium carbonate-rich brines found in the Mixed Layer zone 67 meters to 95 meters (220 feet to 310 feet) below the surface. Solar concentration ponds are used to aerate and concentrate the brine to improve processing efficiency.

Processing.—Crushed trona is calcined in a rotary kiln at 163° to 204° C (325° to 400° F) to dissociate the ore by the monohydrate process, which produces only dense soda ash with carbon dioxide and water as byproducts. The calcined material is combined with water to dissolve the soda ash and to allow separating and discarding of the insoluble material such as shale and shortite by settling and/or filtration. The waste material is piped in a slurry to containment basins, also known as tailing ponds. The resulting clear liquid is concentrated as necessary by triple-effect evaporators or mechanical vapor recompression crystallizers, and the dissolved soda ash precipitates as crystals of sodium carbonate monohydrate, Na₂CO₃·H₂O. The crystallization temperature is about 100°C (212°F), which is below the transition temperature of monohydrate to anhydrous soda ash. Other dissolved impurities, such as sodium chloride or sodium sulfate, remain in solution. The crystals and liquor are separated by centrifugation. The sodium carbonate monohydrate crystals are calcined a second time at 300°F to remove water of crystallization. The resultant finished product is cooled, screened, and shipped by rail or truck in bags or bulk.

An alternate method of soda ash production from trona is the sesquicarbonate process. Crushed trona is first dissolved and filtered to remove insoluble impurities. The liquor is evaporated in vacuum crystallizers, and the sodium sesquicarbonate precipitate is cooled to 38° C (100° F) and centrifuged to produce a pure product, which has uses as such. The sesquicarbonate can be further calcined at 204° C (400° F) to produce anhydrous soda ash of light to intermediate density.

The complex brines of the lower level of Searles Lake are first treated with carbon dioxide gas in carbonation towers to convert the sodium carbonate in solution to sodium bicarbonate, which will precipitate under these conditions. The sodium bicarbonate is separated from the remainder of the brine by settling and filtration and is then calcined to convert the product back to soda ash. The decarbonated brine is cooled to recover borax and Glauber's salt. A second dissolving, precipitating with carbon dioxide, filtering, and calcining the light soda ash to dense soda ash refines the product to better than 99% sodium carbonate.

At Owens Lake in California, crude soda ash has been mined and processed by Lake Minerals Corp. by simply digging perimeter channels allowing the interstitial fluids to drain. The surface was tilled to promote evaporation to reduce moisture content, followed by harvesting with front-end loaders.

At Lake Magadi, Kenya, crude trona is dredged from surface crusts, crushed, washed, and calcined to convert the sodium sesquicarbonate to soda ash. At Lake Texcoco in Mexico, underground brines are recovered and sent to a surface spiral concentrator to promote the solar concentration of the sodium carbonate in solution. On the Kola Peninsula in the U.S.S.R., soda ash is recovered from processing nepheline-bearing rocks. Nepheline, a sodium-potassium-aluminum silicate, is calcined in rotary kilns to yield alumina, potash, and soda ash. The alumina content of the rocks is about onehalf of bauxite, but the mining and processing produces byproduct soda ash. The Petukhi and Tanatar (Mikhaylovskiy) natural soda ash lakes in Altay Krav of West Siberia provide some source of natural product.

Synthetic soda ash using the Solvay process uses salt and limestone as raw materials. A purified sodium chloride brine is saturated with ammonia and carbon dioxide gas to produce ammonium bicarbonate, which reacts with the salt to form sodium bicarbonate and ammonium chloride. The sodium bicarbonate is calcined at 177° to 218° C (350° to 425° F) to light soda ash, and the gases produced are recycled back to the liquid phase. The liquid containing ammonium chloride is reacted with milk of lime to recover the ammonia and to produce byproduct calcium chloride. Limestone and coke are required to make the milk of lime. Dense soda ash is produced by hydrating light ash to produce larger sodium carbonate monohydrate crystals. The crystals are dehydrated in dryers to change the bulk density. To produce 1.0 ton of synthetic soda ash requires about 2.8 tons of steam, 1.7 tons of salt, 1.4 tons of limestone, 0.6 ton of coal for the boilers, and about 0.2 ton of coal for the dryers. Disposition of effluent streams containing high concentrations of calcium chloride and sodium chloride is a major problem for all Solvay soda ash plants. The Solvay process discharges about 1.7 tons of waste products.

Other chemical processes can produce

synthetic soda ash. The Japanese ammonium chloride coproduction process, a variation of the Solvay process, converts all the sodium content of the salt into soda ash, whereas the Solvay process converts only about 70% of the sodium. The Japanese process also produces byproduct ammonium chloride that can be used as a fertilizer for growing rice in wetlands. The New Asahi process was also developed in Japan and uses less energy than the traditional Solvay process. An electrolysis-free process to produce vinyl chloride monomer with coproduct soda ash was developed in the Netherlands but has not been in commercial operation. The method yields soda ash instead of caustic soda and uses steam and carbon dioxide instead of electricity. The energy consumption is reported to be one-half that of the Solvay process.

Recycling.—There is no recycling of soda ash by producers; however, many glass container manufacturers are using cullet glass, thereby reducing soda ash consumption.

Byproducts and Coproducts

Borax, potassium chloride, sodium chloride, and sodium sulfate are produced as coproducts with soda ash by North American Chemical Co. in California. In Wyoming, only value added products, such as sodium bicarbonate, sodium hydroxide (caustic soda), sodium sesquicarbonate, and sodium tripolyphosphate, are produced from trona ore. Soda ashbearing purge liquors and waste streams, normally considered waste byproducts, have been sold to powerplants for fluegas desulfurization because of their sodium carbonate content.

Substitutes

Sodium hydroxide can be substituted for soda ash in some applications, but usually only at a higher cost and when available. About 1.3 tons of soda ash must be used to have the same chemical effect as 1.0 ton of caustic soda. Soda ash is usually shipped in dry, bulk form whereas caustic soda is transported as a liquid in various-sized closed containers.

An alternate source of soda ash is nahcolite, natural-occurring sodium bicarbonate found in a vast deposit in Colorado. The nahcolite could be converted to soda ash by calcination.

Economic Factors

Prices.—The list prices of natural and synthetic soda ash historically were identical until the mid-1970's, when higher energy costs and costs to implement the controls imposed by antipollution legislation caused the synthetic soda ash price to increase compared with that of the natural material. New natural soda ash producers came on-stream in 1976 and 1982 and contributed to slight changes in price-value trends. Changes in the domestic demand pattern also affected average annual values, especially after 1980, when domestic demand declined.

The list prices quoted in trade journals or by producers differ from the annual average values reported to and by the U.S. Bureau of Mines. The values are the combined total revenue of California and Wyoming natural bulk, dense soda ash sold on an f.o.b. plant basis at list prices, spot prices, discount, long-term contracts, and for export, divided by the quantity of soda ash sold. This value may or may not necessarily correspond to the posted list prices.

Tariffs.—The United States has a 1.2% ad valorem tariff on imports of soda ash from countries having most favored nation (MFN) status. There is an 8.5% ad valorem tariff on imports from non-MFN sources.

Many nations levy import tariffs or antidumping duties of varying percentages on U.S. soda ash. In Western Europe, an antidumping duty of 67.5 European Currency Units (about \$67.13 per ton) had been imposed on U.S. soda ash sold on the continent; however, the duty was rescinded in late 1990. Import tariffs in some other countries are the Republic of South Korea, 15%; Taiwan, 12.5%; Thailand. 10%; Indonesia, 5%; Japan, 3.9%; and Malaysia, 2%. Some of these duties will decline over time.

Taxes.—The total effective tax rate on the Wyoming trona industry is about 12.64% and comes from two major taxes. The trona severance tax of 5.5% is a State excise tax on minerals as they are removed from the ground and are applied as a percentage of assessed valuation. The collected taxes are disbursed to the Permanent Wyoming Mineral Trust Fund (2.0%), the General Fund (2.0%), and the Capital Facilities Revenue Account (1.5%). The property, or ad valorem, tax is about 7.14% of the assessed value of

¹Values are the combined total revenue of California and Wyoming natural soda ash sold at list prices, spot prices, discount, long-term contracts, and for export, divided by the quantity of soda ash sold on a bulk, f.o.b. basis. The average annual value may not necessarily correspond to posted list prices for soda ash.

From final 1990 implicit price deflators for gross national product, by the Council of Economic Advisors. Based on 1982=100.

trona produced from the mines. The ad valorem taxes on trona are higher than any other Wyoming minerals, including oil, gas, and coal. Other ad valorem taxes are placed on the assessed value of real property (buildings and equipment) and State sales and use taxes on equipment and facilities.

Royalties. - Soda ash mined on Federal lands is subject to the Mineral Leasing Act of 1920, which provides royalty payments to the U.S. Government. The Federal royalty is 5% of the quantity or gross value of the output of the product at the point of shipment to market. Each Federal lease also has other costs, such as bonds, acreage rental fees, sodium prospecting permit application fees, and permit bonds.

In Wyoming, the soda ash deposit

within the KSLA is under the jurisdiction of the U.S. Government (administered by the Bureau of Land Management), the State, and the Union Pacific Railroad, which was given alternate 1-square-mile sections north and south of the railway it constructed in the 1860's. Of the approximately 915,000 total acres of sodium mineral estate, the Federal ownership is 55.7%, Union Pacific, 38.1%; and the State, 6.2%. Sixteen lessees hold 53 active and inactive Federal leases, having a total of 75,783 acres. To prevent a possible land monopoly, no lessee may hold more than 15,360 acres of Federal land but may lease more private or State land. The State royalty rate is tied to the Federal rate of 5%; however, the private royalty rate varies. One-half of all Federal royalties collected by the Minerals

Management Service is disbursed back to Wyoming for various State and local programs.

In California, the Federal Government maintains 33 sodium mineral leases having 26,799 acres. The major lessee is North American Chemical, which produces soda ash, sodium sulfate, and salt on its sodium leases on Searles Lake.

Depletion Provisions.—The mineral depletion allowance granted to the mining industry through legislation passed by the U.S. Government has been an important inducement for companies willing to accept the risk and high cost of mining development. The concept of depletion allowances for minerals is similar to the depreciation of other assets. Although cost depletion and percentage depletion are two methods used to compute depletion deductions, most companies prefer to use the latter. About 100 mineral categories are entitled to percentage depletion. The rates range between 5% and 22% of the gross income from the mineral property, depending on the mineral and location (foreign or domestic), and are subject to a limitation of 50% of the net income from the property. The significance of percentage depletion is that the deduction is based on the quantity of the first marketable product (soda ash and not trona) and not necessarily on the amount invested. The mineral depletion allowance for soda ash is 14% for U.S. companies mining from domestic or foreign sources.

Operating Factors

Operating factors are different for mining companies than for manufacturing facilities engaged in producing natural soda ash and synthetic soda ash, respectively. The shift in U.S. soda ash production from synthetic to natural has been caused by higher costs attributed to the greater energy and labor requirements of the Solvay process and to environmental regulations. Within the natural soda ash industry, the operating factors vary for producing the commodity from brines and from trong ore.

Environmental Requirements.—U.S. natural soda ash facilities do not have difficult problems disposing of effluents. Residual insoluble material is piped to surface tailing ponds and allowed to settle. Some soda ash in solution that is not economically recoverable from processing

is discharged and is converted to sodium decahydrate in the ponds and precipitates on the bottom of ponds to become an additional source of soda ash if needed. For example. FMC has been dredging some of its sodium decahydrate, which has been accumulating since 1950. Some pond water is recirculated into the mines and used as drilling and cutting coolant. Because of changes in environmental legislation in Wyoming, Tenneco Minerals Co. has begun discharging its waste material into abandoned sections of its underground mine, thereby using less surface area on the surface for tailing ponds. The expense of underground discharge is partially offset with the reduction in costs of constructing and maintaining surface tailing ponds.

The alkaline surface ponds, with a pH up to 10.5, have posed some problems for migratory fowl that land on the ponds. The alkaline solutions strip the insulative natural oils from the feathers, thereby increasing the vulnerability of the birds to death from hypothermia. Also, birds have drowned because of the weight of sodium decahydrate that crystallizes on them when the temperature falls below 4° C (40° F). All trona producers have established a rehabilitation program to recover and release contaminated birds and to minimize the mortality and morbidity rate.

Land surrounding trona operations in Wyoming is relatively undeveloped, and the influx of large numbers of workers has caused great strain on the local facilities for housing, schools, shopping, and entertainment. Soda ash companies have provided financial assistance to aid local government in handling any overloads caused by the migration of their employees and families into the community. The companies have given financial aid to employees purchasing homes in the surrounding communities and other fringe benefits such as low-cost transportation to and from work.

Toxicity.—Although soda ash is not considered a highly toxic substance, contact with the eyes may be injurious, and prolonged contact with the skin may cause irritation, especially to those who have allergic reactions to alkaline materials. It has also been found to be corrosive to the stomach lining if ingested. It has an acute oral lethal dose (LD50) of 2.8 grams per kilogram (when tested on a rat) and a primary skin irritation index (PSII) of 2.54 (when tested on a rabbit).

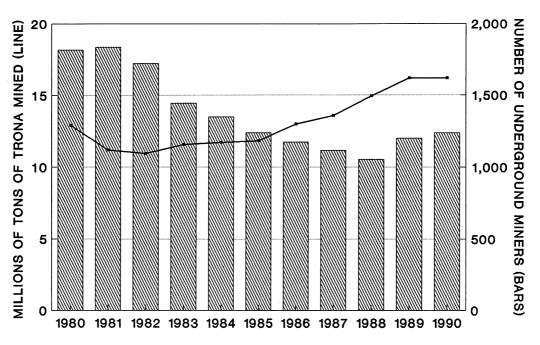

Simultaneous exposure to soda ash and lime dusts should be minimized because in the presence of moisture, as from perspiration, the two materials combine to form caustic soda, which is very harmful. Soda ash is not flammable, and the dust is not explosive.

Employment.—According to the Wyoming Office of the State Inspector of Mines, the Wyoming soda ash industry in 1980 employed 3,931 people, of which 1.817 were underground workers, to produce 11.7 million metric tons (12.9) million short tons) of trona. In 1990, 3,047 people were employed, of which 1,237 underground workers produced 14.7 million metric tons (16.2 million short tons) of ore. From 1980 through 1990, the underground work force was reduced about 32%, while the quantity of trona increased 25%. This represented an 84% increase in the amount of ore mined per person per year; 6,439 metric tons in 1980 and 11,884 metric tons in 1990.

Energy Requirements.—Natural soda ash plants consume considerably less energy per unit of product produced than do synthetic soda ash facilities. As the cost of energy has increased since the 1973 energy crisis, the differential in production costs between natural and synthetic soda ash has become greater. This is one of the major reasons why U.S. natural soda ash has maintained its competitiveness in the world market.

An early U.S. Bureau of Mines energy study using 1973 data indicated that 15.8 million British thermal units (Btu) was required to produce 1 ton of synthetic soda ash, whereas the energy requirement to produce the same quantity from trona was 7.2 million Btu. The domestic soda ash industry has reduced its energy requirements significantly since 1973 by replacing gas-fired dryers with steam-tube units and installing mechanical vapor recompression units to replace tripleeffect evaporators. The industry has also converted to coal exclusively or combined with other fuel sources. Plants operated by T.g. and Tenneco and the Argus plant operated by North American Chemical use coal only. As a result of these energy saving measures, the Wyoming soda ash industry lowered its energy requirement to a range of from 4.5 to 6 million Btu, depending on the individual producer. An estimated one-half of the energy consumed in natural soda ash refining using

FIGURE 1
TONS OF WYOMING TRONA MINED VERSUS NUMBER OF UNDERGROUND MINERS

Source: State Inspector of Mines of Wyoming.

triple-effect evaporators is for evaporating, one-third is for calcining, and the remainder, for drying.

These energy requirements exclude the amount of energy needed to ship soda ash to foreign markets. Although it has been estimated that it would take about 2.9 million Btu of additional energy to transport soda ash by rail and by ship to western Europe, natural soda ash production requires less energy than the Solvay process or any other synthetic technique.

Transportation.—The western geographic locations of the domestic natural soda ash industry often pose problems because of the great shipping distance to most foreign customers. Even within the United States, the majority of domestic consumption is in the Midwest and east of the Mississippi River. Overland and ocean transportation rates become important factors in the delivered price of soda ash and must be considered seriously in negotiations with foreign consumers who often have alternate supply sources. Bulk freight rates can usually be reduced by shipping in larger volumes, such as in 7,500-ton units.

The railroad is the dominant mode of transportation for the shipment of soda ash. In Wyoming, the Union Pacific Railroad provides the main service to the industry. All bulk soda ash that is railed is carried in covered hopper cars, each handling about 98 tons. Although the railroad companies make their cars available, most soda ash companies have their own sizable fleet.

Beginning in 1985, soda ash was shipped in large quantities by truck. Bonneville Transloaders Inc. trucked soda ash from Green River to the Burlington Northern Railroad's line at Shoshoni, WY. Of the approximately 8.4 million metric tons (9.2 million short tons) of soda ash produced in Wyoming, Bonneville trucks about 770,000 metric tons (850,000 short tons) out of Green River. Other trucking companies have started similar operations with the Southern Pacific (shipping more than 227,000 metric tons or 250,000 short tons per year) and Denver Rio Grande railroads to compete with Union Pacific.

The railroads have been involved in establishing soda ash bulkloading terminals at ports to handle large volumes of

material for export. Kansas City Southern Railroad's terminal at Port Arthur, TX, has a railcar unloading capacity of about 1,000 tons per hour. Material is conveyed to a shiploader spout for transfer to bulk cargo ocean vessels. Port Arthur was the third largest port of the 23 ports that shipped soda ash in 1990, most of which was shipped to South America. Longview, WA (out of the Portland, OR, customs district), has a bulkloading terminal, which transferred the most soda ash, 55%, in 1990.

ANNUAL REVIEW

Issues

The major issues in 1990 that affected the U.S. soda ash industry were the global environmental consciousness toward certain chlorine-base chemicals that altered the international chloralkali supplydemand balance; the elimination of the antidumping duties on imports of U.S. soda ash in Europe; and the movement by some domestic soda ash producers to make higher value added downstream products that use soda ash as feedstock.

The world supply and demand balance between chlorine and caustic soda historically has fluctuated. When chlorine demand was low, the availability of coproduct caustic soda was also low, which often resulted in higher prices for caustic when the market for caustic soda was strong. Some consumers temporarily switched to lower priced soda ash that was in abundant supply. This conversion usually was always a short-term cycle because the balance between the chlorine and caustic soda markets ultimately became stabilized. The present cycle of reduced supplies and higher prices, however, has lasted longer than many analysts forecasted based on previous experiences.

Major market sectors that use chlorine in products or in a process have been under pressure to reduce or eliminate chlorine use. Chlorine-base compounds such as those used in chlorofluorocarbons (CFC's) have been associated with stratospheric ozone depletion and contributing to global warming. In paper bleaching, discharges of chlorine chemicals from various pulp mills were found to contain trace amounts of carcinogenic dioxin (2,3,7,8-TCDD) and furan (2,3,7,8-TCDF).

The elimination of the antidumping duties on U.S. soda ash entering Europe raised hope for future export sales to that continent. The timing of this action was fortuitous; U.S. exports to China had drastically declined, and the U.S. soda ash industry needed replacement markets. Other important issues confronting the growth of U.S. soda ash are the political events in Eastern Europe and the reunification of the Federal Republic of Germany, both areas that have tremendous potential for increased soda ash consumption. The export opportunities are encouraging, pending a favorable resolution to the political and economic problems.

Historically, the main product produced at each soda ash plant was exclusively soda ash, which usually was sold as a raw material for other companies to make different downstream products. FMC had been producing sodium phosphates, and Rhône Poulenc had been making sodium bicarbonate, but it was apparent that many other sodium-base commodities could be made from the resource. Soda ash values between 1984 and 1988 were virtually flat because of stagnant market conditions and oversupply. In 1990, FMC, Tenneco, and

Texasgulf made plans to produce higher value added products derived from soda ash to increase corporate revenue.

Production

U.S. production of natural soda ash from California and Wyoming reached a record 9.156 million tons. About 112,000 tons of soda ash equivalent from soda liquors and mine waters was included in the total and used primarily for neutralizing powerplant process water. The liquors represent a growing market for soda ash producers and provide additional revenue.

In February, Tenneco Minerals Co. and Asahi Glass Co. of Japan formed a joint venture named Tenneco Soda Ash Joint Venture. The new \$100 million project will add 544,000 tons (600,000 short tons) of annual soda ash capacity to Tenneco's 1.13-million-ton-per-year (1.25 million short tons) facility by late 1992. Asahi will receive 20% ownership of the combined 1.67-million-ton-per-year (1.85 million short tons) operation or about 335,000 tons (370,000 short tons). This output will be exported to Japan or other areas served by Asahi. 1

On September 19, 1990, Tenneco announced plans to process an additional 1.36 million tons (1.5 million short tons) of trona into calcined trona, which can be used to produce several other sodium carbonate-base products such as soda ash, sodium sulfite, and caustic soda.² Calcining converts trona into an unrefined sodium carbonate product with some residual insoluble impurities. Because Tenneco's ore grade exceeds 93% compared with an industry average of about 89%, its calcinate contains less impurities. Calcined trona can be shipped more economically to greater distances than regular trona because the water content and other volatiles have been removed. At the customers location, the trona could be converted to caustic soda with the addition of lime and the insoluble impurities disposed to landfills.

T.g. and Atochem North America Inc., both subsidiaries of Société Nationalé Elf Aquitaine of France, formed a joint venture in August to make chemical caustic soda at T.g.'s Granger, WY, facility.³ The plant will have an annual production capacity of 91,000 metric tons (100,000 short tons) with startup scheduled for early 1992. The company will use available sodium carbonate-rich mine water to produce the caustic soda. Atochem has

a chloralkali facility in Tacoma, WA, that produces electrolytic caustic soda and coproduct chlorine.

FMC commissioned its 65,000-ton-peryear caustic soda plant at Green River, WY, in March. A major portion of the caustic soda was to be used captively to make sodium cyanide for FMC's precious-metals operations in Nevada. The sodium cyanide plant, which has a capacity of 27 million kilograms (60 million pounds) per year, was operable in November. The company also brought on-stream a 60.000-ton-per-year sodium bicarbonate facility that used sodium sesquicarbonate as the raw material because it required one-third less carbon dioxide for conversion to sodium bicarbonate.4

The Kerr-McGee Chemical facility in California was sold November 30 for a reported \$210 million to North American Chemical, a company formed by a consortium led by D. George Harris and Associates. Oriental Chemical Industries of the Republic of South Korea, which was one of the investors, owns about 27% of the venture and has a synthetic soda ash plant at Inchon, Korea. In addition to soda ash produced at the Argus plant, North American will continue to produce various boron, potassium, and sodium products from its Trona and Westend facilities on Searles Lake.

Consumption and Uses

U.S. apparent consumption in 1990 increased 5% compared with that of the previous year, whereas reported consumption rose only 1%. The discrepancy between the two was attributed to disagreement between the sources of export data used to derive consumption statistics. The two sources were the Bureau of the Census, which reports exports upon departure from the U.S. port, and the soda ash producers, which consider a shipment as exported when their export association, the American Natural Soda Ash Corp., takes charge at the California or Wyoming plant sites. Transit times between the plant and port and carryover export inventories contribute to the discrepancy between reported and apparent consumption.

Based on reported industry sales, the manufacture of glass represented about 49% of domestic soda ash consumption, with the container sector composing 60% of this end use; flat, 27%; fiber, 7%; and specialty, 6%. The other end uses include

chemicals (primarily sodium bicarbonate, sodium chromates, sodium phosphates, and sodium silicates), 24%; soap and detergents, 13%; distributors, 6%; flue gas desulfurization, 3%; pulp and paper and miscellaneous, 2% each; and water treatment, 1%.

U.S. reported consumption of soda ash increased in the chemical, soap and detergent, and pulp and paper sectors in 1990. The rise in demand was because of greater substitution of high-priced caustic soda for less expensive soda ash by chemical consumers in the pulp and paper, chemical, and alumina industries.

Less soda ash was used in glass because of the increased use of recycled cullet. Sales to the flat glass sector declined, mainly due to the downturn in the national economy that adversely affected the building construction and automobile industries. The industrial building construction industry consumes about 57% of all flat glass made, whereas the automotive glass sector used 25%. The remainder went to specialty flat glass products.

The third largest use of soda ash is in detergents. It is used as a builder to emulsify oil stains, reduce the redeposition of dirt during washing and rinsing, provide alkalinity for cleaning, and soften laundry water. In addition, soda ash is a component of sodium tripolyphosphate (STPP), another major builder in detergent formulations, but soda ash consumption has been decreasing because phosphatic detergents contribute to the environmental problems of eutrophication. Many regions of the Nation have adopted phosphate limitations or bans. These areas represent about 33% of the U.S. population. In response to the environmental issue, detergent manufacturers began reformulating their detergents to make compact and superconcentrated products. These reformulations require sodium silicates and synthetic zeolites, which are made from soda ash. Liquid detergents, which do not contain any soda ash, compete with powdered detergents and command 40% of the household laundry detergent market, up from only 15% in 1978.

Stocks

Yearend stocks of dense soda ash in plant silos, warehouses, terminals, and on teamtracks amounted to 286,610 tons. Producers indicate that a potential supply problem could exist when inventories

¹Includes soda ash equivalent from soda liquors, purge liquors, and mine water, sold to powerplants for water treatment: 63,469 tons in 1987, 73,365 tons in 1988, 95,027 tons in 1989, and 111,894 tons in 1990.

²Data are from the Bureau of the Census and may vary from the quantity reported by the producer/importer. Actual imports are proprietary data but have been distributed into appropriate end-use categories and included in "Total domestic reported consumption."

³Reported consumption data do not agree with apparent consumption data shown in tables 1 and 3 because of dissimilar sources of export data. The data vary because of different reporting periods, overland transit times between plant and port, and carryover export inventory.

⁴As reported by producers. Includes Canada. Data may not necessarily agree with that reported by the Bureau of the Census for the same periods.

periods.

Revised from monthly Mineral Industry Surveys data because of 181 metric tons (200 short tons) of misreported export data in first quarter 1989.

Represents soda ash from domestic origin (production and inventory changes) and imports, and for exports.

⁷In monthly Mineral Industry Surveys reports, "Total Industry Sales" for 1987 were erroneously reported as 8,088,423 metric tons (8,915,951 short tons). The misreported figure deducted imports, which already had been included in specific end uses under "Total domestic reported consumption."

consumption."

⁸An extra 23,548 metric tons (25,957 short tons) of coproducer sales is included in total, but specific end-use breakout is unknown.

fall below 180,000 tons. Most consumers of soda ash do not have storage facilities to accommodate large quantities of soda ash and must rely on suppliers to provide the material on a timely basis.

Markets and Prices

There are essentially two markets for soda ash—domestic and export. In the domestic market, the large volume buyers of soda ash are primarily the major glass container manufacturers, whose purchases are seasonal (more beverage containers made in second and third quarters for summertime beverage consumption). Soda ash sales to the flat glass sector are usually dependent on the state

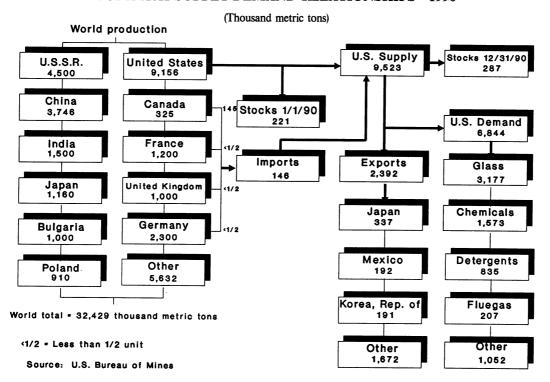

of the economy because the largest use of flat glass is in automobile manufacture and residential housing and commercial building construction. These two major industrial sectors are especially sensitive to changing economic conditions. If construction starts and automobile sales are up, soda ash sales will proportionally follow. Although there were not any increases in the list price during 1990, the soda ash industry was successful in increasing the off-list price of some contracts. The result was that the annual soda ash value increased to \$91.33 per metric ton (\$82.85 per short ton) for bulk. dense, natural soda ash, f.o.b. Green River, WY, and Searles Valley, CA.

FIGURE 2
SODA ASH SUPPLY-DEMAND RELATIONSHIPS—1990

Foreign Trade

Exports of U.S. soda ash have increased every year since 1976, growing more than 325% between 1976 and 1989, when exports reached a record high of 2.65 million tons or about 29% of production. In 1990, however, exports decreased to 2.39 million tons because of the dropoff in export sales to China. China had been the largest consumer of U.S. exports, but its national determination to become self-sufficient in production reduced its import requirements. U.S. exports to 53 countries, on a regional basis, were as follows: Asia, 49%; South

America, 16%; North America, 14%; Africa, 7%; Europe, 6%; Oceania, 4%; the Middle East, 2%; and the Caribbean, 1%. Exports to Central America were less than 0.5%.

Section 1205 of the Omnibus Trade and Competitiveness Act of 1988 required the United States to adopt an international nomenclature and metric units for reporting trade information. On January 1, 1989, the Harmonized Commodity Description and Coding System (HS) replaced the Tariff Schedule of the United States, Annotated for import data and Schedule B for exports. The new

code numbers for soda ash are listed in the appropriate trade tables in this report.

The antidumping directorate of the European Community Commission (ECC) ruled in October that the six West European synthetic soda ash producers collectively prevented the United States from entering the European market in the early 1980's. The companies were Solvay et Cie of Belgium, Akzo N.V. of the Netherlands, Imperial Chemical Industries PLC (ICI) of England, Rhône-Poulenc S.A. of France, and Chemische Fabrik Kalk and Matthes and Weber G.m.b.H. of the Federal Republic of

TABLE 8

Germany. The combined output of these producers represented about 20% of world soda ash production. The duty of 67.5 European Currency Units (ECU's), about \$67.13 per short ton, was rescinded. ECC investigators also ruled in December that the U.S. export association would not be able to represent the U.S. producers in Europe. European soda ash consumers would prefer to have an alternate source of soda ash, namely the United States. With two Wyoming soda ash plants coowned by French companies and others that have European subsidiaries, the U.S. soda ash industry is hopeful that the investigation will result in reduced or eliminated duties, which could increase U.S. export sales to Europe.

The commission also fined Solvay and ICI a total of \$64 million (ECU 47 million) for illegal pricing arrangements and

market sharing in the early 1980's. These were the largest fines ever imposed on individual companies found violating ECC competition laws.⁷

World Review

Industry Structure.—The developed nations are generally the largest consumers of soda ash. Although the production and consumption quantities vary among the countries, the end-use patterns are basically the same (e.g., glass, chemicals, and detergents are the major sectors). Although the United States is the largest soda ash-producing country in the world, foreign ownership in the U.S. soda ash industry is presently 30% of name-plate capacity.

Eleven countries have the capability to produce more than 1 million tons annually. The major ones include, in

TABLE 11 U.S. IMPORTS FOR CONSUMPTION OF SODA ASH

Year	Disodium carbonate ¹						
	Quantity (metric tons)	Value ² (thousands)					
1986 ³	96,130	\$15,023					
1987 ³	136,171	18,334					
1988 ³	120,609	15,999					
1989	128,790	17,396					
1990	145,534	20,495					

¹Beginning in 1989, import data were reclassified under the Harmonized Commodity Description and Coding System (HS Code No. 2836200000). Prior years were classified under the Tariff Schedule of the United States, Annotated, TSUSA No. 4208400 (calcined) and No. 4208600 (hydrated and sesquicarbonate). ²C.i.f. value at U.S. ports.

descending order, the United States, the U.S.S.R., China, the Federal Republic of Germany, France, Bulgaria, and India. Most of these countries have large populations that require consumer products made with soda ash. The lesser developed nations tend to have greater soda ash demand and higher rates of growth as soda ash-consuming industries are developed.

Capacity.—World soda ash production capacity is about 34.8 million tons divided among 35 countries. Approximately 70% of world capacity is synthetic soda ash. 30% natural. The United States represents 28% of world capacity and 94% of the total natural capacity.

The largest soda ash company in the world, excluding State-owned facilities, is Solvay et Cie of Belgium. It operates nine plants in seven countries and has a combined annual capacity of more than 4 million tons. FMC of the United States is the second largest with 2.59 million metric tons (2.85 million short tons) of capacity.

Botswana.—Soda Ash Botswana, the venture formed by the Botswana Government and African Explosives and Chemical Industries with its partners, the Anglo American Corp. and De Beers Holdings. commenced limited brine production at yearend. A wellfield containing 40 wells covering 200 square kilometers was developed to supply the newly constructed soda ash refinery. The wells are sunk to depths of about 35 meters. Approximatelv 20.000 tons of refined soda ash was expected to be produced by March 1991.8

Jordan.—Arab Potash Co. awarded contracts to Fluor Daniel, MDPA, and Batelle Europe to do feasibility studies of expanding the Dead Sea chemical works. Arab Potash had the intention to produce chlorine, phosphoric acid, potassium sulfate, sodium tripolyphosphate, and soda ash.9

Saudi Arabia.—Plans were announced by International Chemical Industries and Trading Co. Ltd. to construct a 250,000-ton-per-year synthetic soda ash plant at Jubail, near the Persian Gulf coast. One-half of the plant's production was slated for domestic consumption and the remainder for export to other Middle Eastern countries. The \$240 million facility was scheduled to come on-stream by 1994 using Akzo Salt and Basic Chemicals International BV ammonia-soda technology, 10

Turkey.—Etibank, the state mining agency, received bids from seven foreign consulting and engineering companies for planning work on a \$500 million trona project. The deposit is in Beypazari near Ankara.11

OUTLOOK

World soda ash production has grown about 2.5% per year since 1970. Assuming that world production is equal to world demand (worldwide inventories are insignificant compared with output levels), world production would reach 41.1 million tons by the year 2000, based on the growth rate trend between 1970 and 1990 shown in figure 3. The environmental, energy, and economic issues of the 1980's reduced the international growth rate of soda ash to about 1.2% per annum. These issues, which will continue to be of greater importance during the 1990's, affect the overall supply and demand balance of soda ash than those events of the 1970's. Using a growth rate of 1.2% per year, world soda ash production by the year 2000 could reach 36.4 million tons, which is a conservative forecast as noted in figure 4. Developed nations, where soda ash consumption is mature and growth rates are proportional to population changes, are more concerned about environmental quality, energy efficiency, recycling, and

²The majority was bagged and transshipped to China.

eEstimated. rRevised.

 $^{^{1}\}text{Table}$ includes data available through Apr. 26, 1991. Synthetic unless otherwise specified. $^{2}\text{Reported}$ figure.

³Production for sale only; excludes output consumed by producers.

⁴Revised to zero.

⁵Natural only.

⁶ Includes natural and synthetic. In 1988 and 1989, Mexico produced an estimated 180,000 metric tons per year of natural soda ash. The new series listed is as reported by Asociacin Nacional de la Industria

Qumica, beginning with 1986.

7 Excludes potash for 1986-87.

⁸Natural and synthetic for 1986, natural only thereafter.

FIGURE 3
U.S. AND WORLD SODA ASH PRODUCTION GROWTH RATES

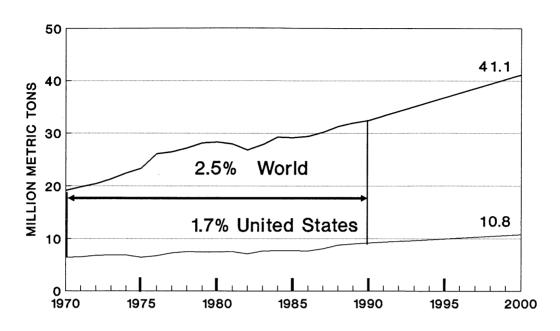

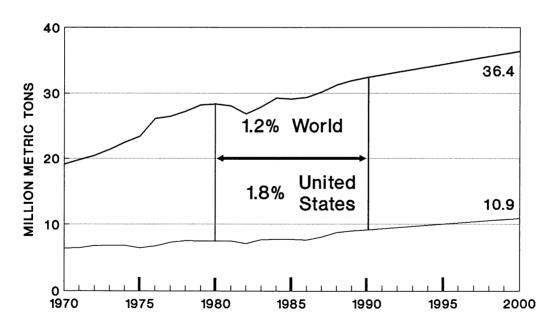

FIGURE 4
U.S. AND WORLD SODA ASH PRODUCTION GROWTH RATES

and consumer preferences—all of which have an adverse affect on soda ash usage. Developing countries still have a greater demand for soda ash but often have less hard currency to purchase all their requirements.

The U.S. annual growth rate for domestic production since 1970 has been

about 1.7% per annum. The 1973 energy crisis and subsequent higher fuel costs changed the operating factors between competing natural and synthetic soda ash industries. U.S. production was close to what was forecast for 1990 in the 1985 "Mineral Facts and Problems." The export market grew greater than anticipated,

mainly through the efforts of the industry's export association, and raised total industry sales despite periods of stagnant domestic sales.

Domestic production is forecast to grow at 1.8% per year and reach 10.9 million tons by the year 2000, as indicated in figure 4. This growth rate, based

on the trend between 1980 and 1990, is similar to the 21-year pattern from 1970 through 1990.

Exports

The outlook for soda ash is excellent. Export opportunities to the Middle East and Western and Eastern Europe are very favorable. With the removal of the ECC antidumping tariffs on U.S. soda ash, more soda ash will be exported to Western Europe in the near future. The changes in the political situation in the U.S.S.R. and Eastern Europe may also lead to more U.S. exports to meet the growing demand for consumer products in those areas. The limiting factor, however, may be the lack of available hard currency and the internal manufacturing capabilities of the industries that use soda ash.

The future of reestablishing U.S. exports to China is uncertain. China has been debottlenecking several synthetic soda ash plants and constructing new ones, but production has not kept pace with demand. China was forced to reduce its soda ash consumption by limiting imports because of economic problems. Bulgaria had supplied some of China's requirements; future shipments could be curtailed to satisfy Eastern Europe's needs, thereby reducing Bulgaria's level of exports. This could allow the United States the opportunity to continue to supply China, pending the availability of U.S. product. Despite these obstacles, total U.S. exports could grow by at least 400,000 tons in the next several years.

Glass

Although glass is the largest end use of soda ash, domestic consumption in the glass container sector is declining because of (1) the increasing use of cullet (2) the national interest in recycling, and (3) the continuing competition with polyethylene terephthalate (PET) plastic containers.

Glass container shipments were less in 1990 than in previous years. The public's perception that glass is completely recyclable compared with plastics will raise the quantity of cullet now being consumed. Aside from the problems with plastics' recyclability, the public also is concerned about the dioxin emissions from incineration of polyvinyl chloride (PVC) bottles. Flat glass consumption was also down because of adverse

economic conditons affecting housing starts and automobile sales. This situation is temporary because interest rates will decline for home mortgage loans.

Municipal landfills are a growing national problem. Glass reportedly accounts for 8.4% of disposable household waste. The U.S. Environmental Protection Agency has a goal of reducing the Nation's waste by 25% by 1992. It is probable that new taxes will be placed on items manufactured at the source of production to encourage greater use of recycled products. Rebates would be given for every ton of recycled material utilized.

Chemicals

The global chloralkali supply and demand imbalance will continue to be an important topic for the next few years. The demand for PVC products will govern chlorine supplies and the availability and price of coproduct caustic soda. Chemical caustic soda produced by the lime-soda process will satisfy part of the projected caustic soda shortages. For foreign shortages, trona deposits outside the United States will be evaluated as potential natural sources to produce chemical caustic soda.

Soap and Detergents

About 10 million tons of laundry detergents is consumed annually in the world. Most detergents are composed of many active and inert chemical ingredients. Household liquid detergents and phosphate-free detergents are considered environmentally safe products. More soda ash has been added as a phosphate-replacement builder in various detergent formulations to meet regional phosphate discharge requirements.

The environmental movement in Europe has also prompted foreign detergent manufacturers to consider changing formulations to reduce phosphate content. In the Federal Republic of Germany, consumption of phosphates in detergents dropped from 276,000 tons in 1975 to 80,000 tons in 1987. The quantity of packaging waste discarded to landfills prompted detergent manufacturers to test market compact and superconcentrated products in different regions. Whatever amount of soda ash lost due to reformulation could be partially offset from the use of soda ash in synthetic zeolites and sodium silicates in the new formulations. Consumer preferences also may determine the preferred detergent and format (i.e., liquid versus powdered, unit dose packets versus bulk). Depending on the choice, the growth of future soda ash sales is optimistic.

Pulp and Paper

Although the U.S. pulp industry is growing at about 2.75% per year, changes are taking place to alter the pulp-and-papermaking processes. Pulp mills are striving to address the environmental issues regarding dioxins and furans, improve productivity, reduce costs, and improve paper quality. One solution is alkaline paper sizing, which produces alkaline-based paper rather than acid-based. The conversion is not being implemented as fast as the environmental issue is mounting. Other alternatives include substituting certain pulping chemicals.

Dioxins, created from chlorine molecules introduced in the paper-bleaching process, have been detected in bleached paper products as reported in a study of the 104 kraft-pulp mills in the United States. To avert the public's reaction to the issue, the industry began investigating substituting chlorine-base chemicals for nonchlorine pulping and bleaching agents, such as oxygen and hydrogen peroxide. About 1.8 million tons of chlorine is used in pulp bleaching annually. Industry sources estimate a 25% to 30% reduction in chlorine consumption by 1995. If this forecast is accurate, coproduct caustic soda, which is used to delignify wood pulp, could be in short supply. This situation could result in additional quantities of soda ash being used instead of caustic soda, although it would take 1.3 tons of soda ash to have the same chemical effect of 1.0 ton of caustic soda. FMC, Tenneco, and T.g. have made announcements to produce caustic soda from their Wyoming soda ash operations. Although the majority of the output is for captive needs, the opportunity will demonstrate the economic feasibility of producing caustic soda from nonsalt feedstocks. Soda ash consumption in the pulp and paper sector could increase during the next few years depending on the strength of chlorine demand, which is influenced by the strength of PVC sales.

Flue Gas Desulfurization

The Clean Air Act, as amended by Public Law 101-549, will require the

Nation's powerplants to reduce emissions of sulfur and nitrogen compounds produced from burning fossil fuels. Although most high-sulfur coal is used in Eastern powerplants where inexpensive calcium-base compounds are located, sodium-base sulfur dioxide removal agents, such as trona and nahcolite, have opportunities for commercial development in the West.

In 1990, approximately one-quarter million tons of soda ash was used for reducing harmful stackgas emissions in the West and Midwest. Transportation costs will reduce the competitiveness of sodium minerals in the East in the future: however, the concern regarding water quality and quantity will be major issues in the Western United States in the 1990's. Several wet-scrubbing utility plants, which use tremendous amounts of water, are evaluating the economics of replacing traditional wet-scrubbing systems using lime with dry-injection technologies using calcium- and sodium-base agents. The addition of some sodium minerals removes additional sulfur and a substantial amount of the nitrogen materials. Eastern powerplants will probably use low-sulfur coal rather than use trona or nahcolite resources found in the West. When Western powerplants retrofit older facilities with dry-injection scrubbing equipment to conserve water, demand for soda ash will increase.

Soda Ash Industry

Although the outlook for the U.S. soda ash industry is very good, the structure of the industry continues to change as foreign participation increases. The United States will remain an important supply source of inexpensive natural soda ash for international consumption. However, a growing percentage will be shipped by the foreign partners of the U.S. resource—primarily Australia, France, Japan, and the Republic of Korea. More shares of the U.S. soda ash industry are available for joint venture at the present time. It is unlikely that any new grassroots operation will be constructed in the United States for the remainder of this century.

SODIUM SULFATE

By Dennis S. Kostick

Mr. Kostick, a physical scientist with 12 years of U.S. Bureau of Mines experience, has been the commodity specialist for sodium sulfate since 1979. Domestic survey data were prepared by Carleen Militello, mineral data assistant; and international data tables were prepared by William Zajac, Chief, Section, International Minerals.

odium sulfate is produced from natural sources or recovered as a byproduct from various manufacturing processes and has several important and useful applications in various consumer products. In a survey of the top 50 basic organic and inorganic chemicals made in the United States, sodium sulfate ranked 48th in terms of quantity produced.¹

Beginning with this report, all data will be reported in metric units to comply with Public Law 100-418 of August 23, 1988. This Federal law required all Federal agencies to use the metric system of measurement by the end of fiscal year 1992. Although the use of the metric measurement standards was authorized by law since 1866 (Act of July 28, 1866; 14 Statute 339) and the United States was an original signatory party to the 1875 Treaty of the Meter (20 Statute 709), the United States has been the only industrially developed nation that has not universally converted to the metric system from the English system of measurements. As foreign trade of soda ash increases and foreign participation in U.S. joint mining ventures continues, communicating information with an international standard of measurement becomes more important.

DOMESTIC DATA COVERAGE

Domestic production and inventory data for natural sodium sulfate are developed by the U.S. Bureau of Mines from monthly and annual surveys of U.S. operations. Of the three natural sodium sulfate operations to which a survey request was sent, all responded, representing 100% of the natural sodium sulfate data used in this report.

Synthetic, also known as byproduct, sodium sulfate data were collected by the

U.S. Department of Commerce, Bureau of the Census, from monthly and annual surveys (aggregate data published in Current Industrial Reports, Inorganic Chemicals, M28A and MA28A) of companies engaged in recovering and selling byproduct sodium sulfate. Any revised Census Bureau data have been included using most recent Census Bureau statistics. These data are aggregated with U.S. Bureau of Mines natural sodium sulfate data and included in several tables.

BACKGROUND

Natural sodium sulfate was known to have been used as a medicine as early as the 16th century. It was first accurately described in 1658 by Johann Rudolf Glauber, a German chemist whose name is still associated with the hydrated crystal, Glauber's salt ($Na_2SO_4 \cdot 10H_2O$), and the anhydrous mixed sulfate, Glauberite ($Na_2SO_4 \cdot CaSO_4$).

Glauber and other researchers prepared sodium sulfate by reacting common salt with sulfuric acid. The invention of the Kraft process for making pulp and paper in 1880 provided the first major industrial market for sodium sulfate.

Definitions, Grades, and Specifications

The following terms are used in the sodium sulfate industry:

Anhydrous Sodium Sulfate.—Refined sodium sulfate or the mineral thenardite (Na₂SO₄). Named for the French chemist, Louis Jacques Thenard, thenardite is a colorless to white mineral with a specific gravity of 2.67 and a hardness of 2.5 to 3. Because of its whiteness and purity, it is used in detergents, pharmaceuticals, dyestuffs, glass, and ceramic glazes.

Commercial grade material has a bulk density of about 1.23 grams per cubic centimeter (77 pounds per cubic foot).

Byproduct Sodium Sulfate.—Synonymous with synthetic sodium sulfate. It is recovered as a byproduct from various chemical and textile manufacturing processes.

Glauber's Salt.—Same as the mineral mirabilite (Latin "sal mirabile" or "wonderful salt"), sodium sulfate decahydrate (Na₂SO₄·10H₂O). The mineral contains 55.9% water of crystallization and forms opaque to colorless needlelike crystals.

High Purity.—Refers to anhydrous sodium sulfate with a purity of 99% or greater. Usually sold to detergent, glass, and textile industries.

Low Purity.—Some processes occasionally produce sodium sulfate that does not meet certain physical or color specifications required by certain consumers despite being a chemically pure product. This grade of sodium sulfate is generally sold to sectors that are not as concerned about whiteness or particle size, such as the pulp and paper industry, at reduced prices.

Natural Sodium Sulfate.—Sodium sulfate obtained from mining crystalline sodium sulfate-bearing minerals or from sodium sulfate-bearing brines.

Salt Cake.—Normally refers to impure sodium sulfate containing 90% to 99% Na₂SO₄. Because of its impurity or possible discoloration, it usually is sold only to the pulp and paper industry.

Synthetic Sodium Sulfate.—Same as byproduct sodium sulfate.

Sodium sulfate made from natural brine usually contains less than 0.5% total impurities, but that produced as a byproduct of other manufacturing may contain much larger quantities. The

material meeting U.S. Pharmacopeia (U.S.P.) specifications and that intended for glassmaking must contain at least 99% sodium sulfate. In addition, glassmakers' grade must be low in iron and heavy metals. Technical grades of sodium sulfate may have from 2% to 6% impurities. Purchases of detergent or rayon-grade sodium sulfate are based primarily on whiteness. Its sodium chloride content may be between 1.5% and 2.0%, and its iron content between 60 and 100 parts per million.

Industry Structure

Three companies produced natural sodium sulfate from a total of three plants in California, Texas, and Utah. The domestic natural sodium sulfate industry supplied about one-half of the total output of U.S. sodium sulfate. Because of the location of these plants, most natural sodium sulfate is marketed in the West and southern gulf areas. Byproduct material was supplied by 15 companies operating 16 plants primarily in the Midwest and Mid-Atlantic regions. Total rated production capacity in 1990 was 836,000 tons, and the industry operated at 80% of this capacity.

Geology-Resources

Sodium is the sixth most abundant element in the Earth's crust. Sodium sulfatebearing mineral deposits are geologically young, mainly of post-glacial age. Sodium sulfate is widespread in occurrence and is a common component of seawater and many saline or alkaline lakes. Economic reserves of natural sodium sulfate are estimated at 3.3 billion tons worldwide. With world production of natural sodium sulfate averaging about 2.6 million tons per year, supplies are sufficient to meet anticipated demand for several centuries. The quantity of synthetic sodium sulfate is dependent on the longevity of the manufacturing firms recovering byproduct sulfate.

Surface depressions or lakes that have no outlets and are fed by spring waters flowing over volcanic rocks containing sulfide minerals often vield soluble sulfide salts that are oxidized by contact with the air to produce sulfates. Some minerals over which the spring water may flow contain the sulfates directly, such as bentonite or gypsum. When an inland lake of this type evaporates and becomes highly concentrated in salts, one of the first salts to precipitate would be mirabilite, also known as Glauber's salt, which has very poor solubility at low temperatures. During seasonal temperature variations, the sulfate will precipitate preferentially to the lake bottom.

Thenardite and mirabilite are the only sodium sulfate minerals that are commercially important. Many economic deposits of sodium sulfate are in the form of crystalline beds of mirabilite such as those found in Canada and the U.S.S.R., which has the world's largest sodium sulfate resource in the Kara-Bogaz-Gol Gulf. Because mirabilite converts to thenardite when exposed to air, its outer surface may develop a thenardite crust. Some buried sedimentary formations contain very large deposits of thenardite and glauberite. such as the deposit in Villarrubia de Santiago in Spain.

Sodium sulfate is also found dissolved in underground brines in California, Texas, and other parts of the world. The sulfate is usually converted to mirabilite when extracted from the brine by mechanical refrigeration techniques.

Technology

The technology to mine and process natural sodium sulfate involves mechanical refrigeration or natural chilling to induce crystallization followed by dissolution, filtration, evaporation, and drving. Recovery of byproduct sodium sulfate from chemical processes involves various techniques.

Mining.—Sodium sulfate is extracted from the upper level of the Searles Lake brine in California and is treated separately from the carbonate-rich lower level and mixed layer brines. The subterranean sodium sulfate-bearing brines in western Texas are the simplest of the domestic brine deposits. Mechanical refrigeration is used to extract Glauber's salt crystals from the brine. The Great Salt Lake in Utah also contains valuable quantities of sodium sulfate. Brine from the most concentrated northwest segment of the lake is pumped into solar evaporation ponds on the eastern shore of the lake where sodium chloride first precipitates as the water evaporates. Sodium sulfate crystals precipitate in a fairly pure state when winter weather cools the brine to -1° to 4° C (30° to 40° F). The crystals are picked up by large earth-moving machinery and stored outdoors until further processing to anhydrous sodium sulfate can take place.

Processing.—At Searles Lake, the brine is first cooled at about 16° C (60° F) to precipitate borax crystals, which are removed from the system for subsequentfurther processing and sale. A second cooling to about 4°C (40°F) precipitates the sodium sulfate in the form of Glauber's salt. These crystals are separated from the brine on a rotating drum filter. They are then redissolved in fresh

¹Includes natural and synthetic. Total production data for synthetic sodium sulfate, obtained from the Bureau of the Census, was revised in Dec. 1990 M28A Inorganic Chemicals, Current Industrial Report.

The value for synthetic sodium sulfate is based upon the average value for natural sodium sulfate.

water in a vacuum crystallizer. After the second separation and drying, the crystals are about 98.2% sodium sulfate. Additional treatment can obtain a 99.3% purity. Major impurities remaining are sodium chloride, sodium carbonate, and boron.

In Texas, after the crystals are processed in rotary drum vacuum filters and washed, they are melted and dehydrated using mechanical vapor recompression evaporators, which are more energy efficient than triple effect evaporators or submerged gas burners. Final classifying, centrifuging, drying in rotary kilns, and screening converts the Glauber's salt to marketable anhydrous sodium sulfate of 99.7% purity.

Purification and dehydration procedures at the facility on the Great Salt Lake are similar to those of other sodium sulfate plants. The final product

results in a purity between 99.5% to 99.7%.

Sodium sulfate is also produced as a byproduct of the production of ascorbic acid, boric acid, cellulose, chromium chemicals, lithium carbonate, rayon, resorcinol, and silica pigments. It is also recovered from certain flue gas desulfurization operations. The Mannheim and Hargreaves furnace processes also produce byproduct sodium sulfate. In the Mannheim furnace, salt and sulfuric acid are reacted to form hydrogen chloride (HCl) and sodium sulfate. The Hargreaves furnace produces HCl and sodium sulfate by the reaction of sulfur dioxide, sodium chloride, air, and water. The Mannheim process is the major method used in Europe, but its use in the United States has decreased considerably since less expensive methods to produce HCl became available.

Recycling.—Because of environmental concerns regarding sulfur emissions from pulp and paper mills, many Kraft pulpers were installing pollution abatement equipment to reduce sulfur losses in the pulping process. This will result in more sodium sulfate being recycled and less used in batch makeup solutions.

Byproducts and Coproducts

The brines of Searles Lake in California contain sodium sulfate as well as coproduct borax, potassium chloride, sodium chloride, and soda ash. The Great Salt Lake in Utah is a source of magnesium compounds, potassium sulfate, sodium chloride, as well as sodium sulfate. The brines in Texas do not yield any secondary products.

Some manufacturers of ascorbic acid, boric acid, cellulose, chromium chemicals,

²Ozark's Brownfield plant, owned by Atochem North America (formerly Pennwalt), was placed on standby in Sept. 1987; 64,000 tons of capacity is not included in total industry capacity.

TABLE 3
WORLD NATURAL SODIUM SULFATE RESERVES AND RESERVE BASE

¹The reserve base includes demonstrated resources that are currently economic (reserves), marginally economic (marginal reserves), and some of those that are currently subeconomic (subeconomic resources). These definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals."

NOTE.—Resources of sodium sulfate are known to also exist in Antarctica, Argentina, Chile, India, Iran, Italy, Mongolia, Romania, the Republic of South Africa, and Turkey. Production of synthetic sodium sulfate is dependent on the supply and demand of the primary product.

²Data do not add to total shown because of independent rounding.

lithium carbonate, rayon, resorcinol, and silica pigments produce sodium sulfate as a byproduct of the process. The sodium sulfate is considered a waste product but has marketability.

Economic Factors

Prices.—Producers of natural sodium sulfate tend to market and sell most of their own product, but most synthetic producers use major chemical distributors or chemical supply companies as sales agents. The principal product made and sold by the synthetic sodium sulfate producer is the primary economic factor. Because sodium sulfate is considered a waste product, it will be sold at a price that ensures prompt sales. This practice tends to set the rates at which the natural product can be sold.

The list prices quoted in trade journals or by producers of all grades of sodium sulfate differ from the annual average values reported by the U.S. Bureau of Mines. The value represents the combined

²From final 1990 implicit price deflators for gross national product, by the Council of Economic Advisors. Based on 1982=100.

amount of total revenue of domestic natural sodium sulfate sold at list prices, spot prices, long-term contracts, discounts, and export divided by the aggregated quantity of sodium sulfate sold. The published value does not necessarily correspond to the posted list price.

Tariffs.—Import tariffs serve to protect the interests of domestic producers for particular products. For sodium sulfate, a 32.5-cent-per-ton tariff is imposed on imported anhydrous sodium sulfate from countries having most favored nation (MFN) status and \$2.95 per ton from those with non-MFN status. There are no import tariffs on imported salt cake, regardless of the country of origin.

Royalties.—Sodium sulfate mined on Federal lands is subject to the Mineral Leasing Act of 1920, which provides for royalty payments to the U.S. Government. The royalty is 5% of the quantity

or gross value of the output of the product at the point of shipment to market. Each Federal lease also has other costs, such as bonds, acreage rental fees, sodium prospecting permit application fees, and permit bonds. The Searles Lake sodium sulfate deposit is the only resource with active operations that has any Federal leases. Because of the variety of the brine constituents, the operator has a commingling agreement with the U.S. Government to compute royalties.

Depletion Provisions.—Legislation passed by the U.S. Government provides an allowance for the depletion of natural resources, notably timber and minerals. The depletion allowance is an important inducement for companies willing to accept the risk and high cost of mining development. The concept of depletion allowances for minerals is similar to the depreciation of other assets. Although cost depletion and percentage depletion are two methods used to compute depletion deductions, most companies prefer to use the latter. About 100 mineral categories are entitled to percentage depletion. The rates range between 5% and 22% of the gross income from the mineral property, depending on the mineral and location (foreign or domestic), and are subject to a limitation of 50% of the net income of the property. The mineral depletion allowance for natural sodium sulfate is 14% for U.S. companies mining from domestic or foreign sources.

Operating Factors

Operating factors are different for mining companies producing natural sodium sulfate compared with manufacturing facilities recovering byproduct sodium sulfate. The quantity of synthetic sodium sulfate recovered is directly associated with the production capabilities of the primary industry (e.g., rayon, lithium carbonate, etc.) and the sulfate recovery rates.

Environmental Requirements.—Land usage may become a problem when sodium sulfate is obtained by solar evaporation, as in the case of the Great Salt Lake brines. Large areas of relatively flat land are required to allow for adequate concentration and evaporation. When land values are high, the capital required for land acquisition may increase operating costs. Disposal of the waste liquors

from which sodium sulfate was extracted may develop into a major groundwater discharge problem in some areas. Reinjection of spent solutions into underground source strata is expensive but often is the only acceptable method of disposal.

Because sodium sulfate is water-soluble, most releases of sodium sulfate to the environment affect water quality rather than air or land quality. These releases are mainly from Kraft pulp mills, which typically discharge between 5 to 15 million kilograms (11 to 33 million pounds) of sodium sulfate per year per site. The resulting drinking water concentrations have been estimated as high as 38.8 milligrams per liter, which is significantly below the maximum concentration level of 250 milligrams per liter set by the National Secondary Drinking Water Standard.

Problems associated with chemical effluents discharged from manufacturing plants that recover sodium sulfate have also caused environmental concerns not attributed to sodium sulfate. The second largest byproduct sodium sulfate facility in the United States at Front Royal, VA, owned by Avtex Fibers Inc., was closed in late 1989 by Federal and State regulatory agencies because of contaminated water discharges containing carbon disulfide and polychlorinated biphenyls (PCB's). These toxic chemicals were produced from rayon manufacture, not sodium sulfate recovery.

Toxicity.—Sodium sulfate was deleted in early 1989 from the list of toxic chemicals under section 313 of Title III of the Superfund Amendments and Reauthorization Act of 1986. The U.S. Environmental Protection Agency determined that there was no evidence that sodium sulfate caused, or could reasonably be anticipated to cause, adverse human health or environmental effects as specified in the act.

Employment.—According to the Bureau of Labor Statistics and industry sources, approximately 300 persons are employed in mining and processing natural sodium sulfate in the United States. No data are available on the number of personnel employed in recovering byproduct sodium sulfate.

Energy Requirements.—The energy requirements to mine natural sodium sulfate are minimal compared with the amount of energy required to process it.

SODIUM SULFATE—1990 1065

An early U.S. Bureau of Mines energy survey reported that 4.5 million British thermal units (Btu's) were required to produce 1 ton of natural sodium sulfate. With the interest in conserving energy, some technical improvements, such as the installation of mechanical vapor recompression crystallizers, have reduced the overall energy requirement to slightly less than 2 million Btu's per ton of sulfate produced.

Transportation.—All natural sodium sulfate is shipped in bulk or in bags by either rail or truck. The mode of transportation depends on the location of the customer, quantity purchased, and difference in freight rates. Because of the location of the natural producers in the West and Southwest, very little natural sodium sulfate is shipped to the East because transportation rates reduce its competitiveness with synthetic sodium sulfate. Consumers in the Midwest and East tend to rely on synthetic sodium sulfate produced in various Midwest and Southern locations.

ANNUAL REVIEW

U.S. production of sodium sulfate decreased about 3% in 1990, but overall domestic apparent consumption declined more than 9%. The downturn in production was attributed to depressed economic conditions that affected some of the industries that recover byproduct sodium sulfate and the effects of the shutdown of Avtex Fibers Inc. the previous year. Although the United States is one of the largest producers in the world of natural and synthetic sodium sulfate, its share has decreased from 23% of world production total in 1980 to 13% in 1990.

Issues

The soap and detergent industry, the largest consumer of sodium sulfate, began reformulating powdered home laundry detergents that substantially reduced the quanity of sodium sulfate used as filler. The growing national environmental awareness regarding the volume of

packaging material discarded to landfills prompted certain detergent manufacturers to begin making superconcentrated or compact products that are packaged in smaller containers. This reduction in package size will minimize the amount of landfill waste but will also reduce the quantity of sodium sulfate used in powdered detergents.

The use of superconcentrates also has had a psychological affect on some of the public. Consumers traditionally have believed that adding more than the recommended quantity of powdered detergent to a washload would make clothes more cleaner. Although the technology to make superconcentrated detergents has existed for several years, detergent manufacturers could not counter the consumers' long-standing belief that "more is better." Interest in the environment has made it possible for detergent manufacturers to invoke this change in perception.

Sodium sulfate consumption by the pulp and paper industry remained firm despite all the publicity regarding the

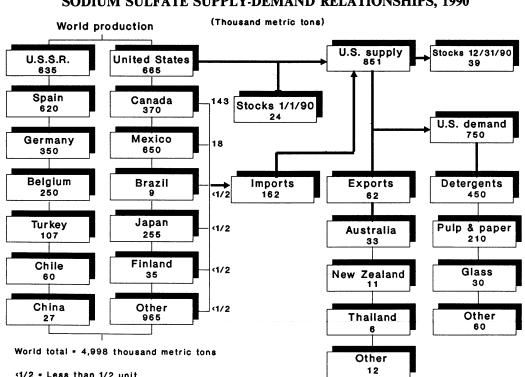

FIGURE 2
SODIUM SULFATE SUPPLY-DEMAND RELATIONSHIPS, 1990

environmental effects of discharged pulp bleaching chemicals.

Production

U.S. production of sodium sulfate decreased about 3% in 1990 primarily because of the closure in 1989 of Avtex Fibers Inc., a rayon manufacturer in Front Royal, VA, that recovered byproduct sodium sulfate. Avtex was the second largest synthetic sodium sulfate producer in the United States with an annual production capacity of 77,000 tons.

North American Chemical Co., a company formed by a group of investors led by D. George Harris and Associates, purchased the Kerr-McGee Chemical Corp. sodium sulfate operation at Searles Lake

in Trona, CA, for a reported \$210 million in November 1990.² Oriental Chemical Industries of the Republic of Korea was one of the investors that acquired about 27% of the operation. In addition to sodium sulfate, the operation produces soda ash, salt, and various boron and potassium compounds. Harris and Associates was affiliated with Great Salt Lake Minerals and Chemicals Corp., which also produced natural sodium sulfate in Utah.

The United States was the largest producer of total sodium sulfate, representing about 13% of the world total, followed by Mexico and the U.S.S.R. with about 13% each; Spain, 12%; and Canada, 7%. These five countries accounted for approximately 58% of the

world's output of total sodium sulfate, based on obtainable production data.

Consumption and Uses

Domestic consumption of sodium sulfate decreased about 9% because of environmental considerations, rather than economic conditions, affecting users of sodium sulfate. Imports for consumption of anhydrous sodium sulfate, primarily from Canada and Mexico, also declined.

About 60% of the total sodium sulfate consumed in the United States is for use as a filler in powdered laundry detergents. Many areas in the country have adopted phosphate bans or limitations because phosphatic detergents contribute to the environmental problems of eutrophication. The affected areas represent about

Estimated using data from "Chemical Profile" issues on sodium sulfate by Chemical Marketing Reporter for 1980, 1983, 1986, and 1989. Revised.

¹Natural and synthetic except where noted. Synthetic sodium sulfate data obtained from the Bureau of the Census are revised periodically and may differ from previous published reports by the U.S. Bureau of Mines. World production data also are periodically revised on receipt of updated information.

²Natural sodium sulfate only.

³Includes ceramics, chemicals (potassium sulfate, sodium hyposulfite, sodium sulfide, sodium silicate, and sodium aluminum sulfate), feed supplements, printing inks, sulfonated oils, textile dyeing, veterinary medicines, and viscose sponges.

Dollars per ton for natural sodium sulfate, f.o.b. mine or plant.

⁵Although data from 1990 and thereafter will be published in metric units, historical values based on short tons will continue to be published for reference.

West, same basis	90.00- 99.00	

Sources: Chemical Marketing Reporter. Current Prices of Chemicals and Related Materials. v. 237, No. 1, Jan. 1, 1990, p. 39; and v. 238, No. 27, Dec. 31, 1990, p. 31.

33% of the U.S. population. In response to this environmental issue, detergent manufacturers continued reformulating their detergents by switching from sodium tripolyphosphate (STPP) to tetrasodium pyrophosphate, which has the same building power as STPP but requires less to be used, thereby reducing the amount of phosphate released into the environment. These reformulations used more sodium sulfate as filler, which was beneficial to the sodium sulfate industry.

Sodium sulfate consumption increased in the Kraft pulping industry because of the rise in demand for paper products and the high prices of caustic soda, which is an alternative to sodium sulfate when prices and availability are favorable. Kraft pulping represented about 83% of the domestic pulp market in 1990. Public

awareness about the environmental issue of nondegradable plastic packaging made many people prefer brown paper grocery bags (produced by the Kraft process), which degrade in landfills much more readily than plastic bags. Kraft pulping represents about 28% of the total demand for sodium sulfate.

Stocks

Yearend inventories of natural sodium sulfate stored by the three producers were 39,150 tons, which was a 63% increase over that of the previous year. The material stockpiled was anhydrous sodium sulfate. Synthetic sodium sulfate was marketed mainly through major chemical distributors, which have separate storage facilities from the producers.

Markets and Prices

A tightness in supply owing to Avtex Fiber's closure in 1989 caused the prices of available bulk and bagged sodium sulfate to increase. The average value rose from \$91.55 per metric ton (\$83.05 per short ton) in 1989 to \$96.63 per metric ton (\$87.66 per short ton) for bulk sodium sulfate, f.o.b. mine or plant. Kerr McGee Chemical Corp. (purchased by North American Chemical Co. later in the year) raised its bulk list price \$5 per ton to \$122 in April. Ozark Mahoning increased its list price by \$5 to \$105 per ton also in April.³ Prior Chemical Corp. and Ashland Chemical Inc., two major chemical distributors, raised the bulk list price of byproduct sodium sulfate by \$5 in February and saltcake prices by \$10 later in the year.

Foreign Trade

Canada and Mexico represented about 89% and 11%, respectively, of total U.S. imports of sodium sulfate. Although the United States had a net import reliance of about 13%, most imports were less expensive to consumers than products from domestic sources, especially when overland shipping costs are considered.

U.S. exports of 62,000 tons were virtually the same in 1990 when compared with those of the previous year. About 53% of the total quantity was shipped to Australia; New Zealand received 17%; Thailand, 10%; and Colombia, 7%. Most was in the form of low-purity salt cake.

World Review

Industry Structure.—Approximately 52% of the world sodium sulfate production in 1990 was from natural sources; the remainder was represented by synthetic sodium sulfate recovered from various chemical and manufacturing processes. Although the U.S. Bureau of Mines collects or estimates data from 28 sodium sulfate-producing countries, other countries are known or assumed to have produced synthetic sodium sulfate, but production statistics are not reported, and available information is inadequate to make reliable estimates of output.

Capacity.—The data in table 2 are rated capacities for domestic natural operations and byproduct recovering facilities in 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a

eEstimated. Revised.

Estimated. ¹Revised.

Table includes data available through Apr. 19, 1991.

In addition to the countries listed, China, Norway, Poland, Romania, and Switzerland are known or are assumed to have produced synthetic sodium sulfate, and other unlisted countries may have produced this commodity, but production figures are not reported, and general information is not adequate for the formulation of reliable estimates of output levels.

Natural mine output, excluding byproduct output from the nitrate industry, which is reported separately under "Synthetic" in this table.

Byproduct sodium sulfate is known to be recovered but reliable data are not available; not included under "Synthetic."

Series revised to show output as reported in the Annuario Estadstico de la Industria Química Mexicana, 1990 edition.

Reported as concentrate. Run-of-mine production reported as, in metric tons: 1986—160,992; 1987—285,182; 1988—290,579; 1989—290,000 (estimated); and 1990—290,000 (estimated).

Conjectural estimates based on 1968 information on natural sodium sulfate and general economic conditions.

Conjectural estimates based on 1968 information on natural sodium sulfate and general economic conditions. Reported figure.

Byproduct of nitrate industry.

10 Quantities of synthetic sodium sulfate credited to Spain are reported in official sources in such a way as to indicate that they are in addition to the quantities reported as mined (listed under "Natural" in

this table), but some duplication may exist.

Derived approximate figures, data presented are the difference between reported total sodium sulfate production (natural and synthetic not differentiated) and reported natural sodium sulfate sold by producers

sodium sulfate-bearing brines. Refinery capacity for natural sodium sulfate pertains to the total amount of anhydrous sodium sulfate that the plant is capable of processing from the ore. Synthetic sodium sulfate-refining capacity is dependent on the production capabilities of the primary industry and the sodium sulfate recovery rates.

Canada.—Tonolli Canada Ltd. of Mississauga, Ontario, announced plans to recover sodium sulfate at its battery recycling operation. About 7,000 tons per vear of high-purity sodium sulfate would be produced from spent sulfuric acid from the batteries.

Norway.—After the acquisition of Stora Kemi and Rana Kjemi in 1989, Eka Nobel commenced production at its new sodium sulfate facility at Mo i Rana. The plant has an annual production capacity of 25,000 tons. Access to inexpensive electrical energy was one important reason to construct the facility.4

OUTLOOK

Sodium sulfate production and consumption declined 36% and 33%, respectively, from those of 1980 to 1990. The decreases were because of changes in the recovery operations of consuming industries mandated by environmental legislation requiring reductions in sulfate emissions and declining use of sodium sulfate in powdered laundry detergents. Although production has been relatively flat since about 1982, domestic consumption of sodium sulfate has fluctuated primarily due to detergent reformulations that contain reduced quantities of sodium sulfate. U.S. consumption is expected to decline further, or least optimistically remain flat, in the next few years.

Less expensive imports from neighboring countries will continue to serve an important part of the needs of the domestic detergent and pulp and paper industries.

Foreign producers dependent on sales to the United States may, however, encounter financial strain as domestic markets shrink. Canada, and possibly Mexico. may be affected by the declining demand for sodium sulfate within the United States. This could allow for more U.S. product to be produced and consumed within the United States.

Detergents

The use of sodium sulfate as a filler appears to have peaked in 1989. In 1990, major detergent manufacturers began reformulating to make superconcentrated detergent products rather than the traditional large boxes filled with bulk detergents containing up to 20% sodium sulfate as filler. This sudden change, initiated by environmental considerations, will further reduce sales of sodium sulfate in the near future unless consumers do not purchase the moreexpensive superconcentrate detergents because of the higher cost. In addition, liquid laundry detergents that do not contain any sodium sulfate make up about 40% of the home laundry market.

Pulp and Paper

The economic recession that began in late-1990 had a slight affect on sodium sulfate sales to the pulp and paper sector. resulting in reduced sodium sulfate consumption. Environmental concerns regarding sulfur emissions prompted many Kraft pulpers to install pollution control equipment to reduce sulfur losses in the pulping process. One procedure using bipolar membranes recycles sodium sulfate and converts it to sulfuric acid and caustic soda, which was in short supply and expensive. The technology, developed by Allied-Signal Inc., has application in many pulp mills throughout the world.⁵ Widescale use of this process may adversely affect the demand for sodium sulfate in the near future.

The paper industry has responded to the growing international environmental awareness by implementing alternate pulp bleaching technology. The pulp producers have been investigated for discharging carcinogenic wastewater effluents that contain certain dioxins and furans into the environment. Oxygenbased chemicals, such as sodium chlorate and hydrogen peroxide that are environmentally safe, are alternative pulp bleaching chemicals that may lessen the need for additional makeup sodium sulfate because the process generates byproduct sodium sulfate in the pulp liquor. Losses in sodium sulfate consumption may be partially offset by gains in sodium sulfate sales if the prices of caustic soda, which is an alternate pulping chemical, continues to increase, as many industry analysts forecast.

CRUSHED STONE

By Valentin V. Tepordei

Mr. Tepordei, a geological engineer with more than 20 years industry experience, has been the crushed stone commodity specialist with the U.S. Bureau of Mines since 1981. Domestic survey data were prepared by the crushed and broken stone survey staff of the Branch of Data Collection and Coordination.

rushed stone is one of the most accessible natural resources and a major basic raw material used by a wide range of industries from construction to agriculture, chemicals, and complex industrial processes. Despite the relative low-value of its basic products, the crushed stone industry is a major contributor to and an indicator of the economic well-being of the Nation.

A total of 1.2 billion short tons of crushed stone was estimated to have been produced for consumption in the United States in 1990, a slight increase compared with the 1989 total. This tonnage represents the fourth consecutive year of production of more than 1.2 billion tons, indicating a continuation of the strong demand for construction aggregates. About three-quarters of the crushed stone production continued to be limestone and dolomite, followed by granite, traprock, sandstone and quartzite, miscellaneous stone, marble, shell, calcareous marl, volcanic cinder and scoria, and slate, in order of volume.

Foreign trade of crushed stone remained relatively minor. Exports increased 30.8% to 5.1 million tons, while value increased 77.3% to \$41.4 million. Imports of crushed stone, including calcium carbonate, increased 14.1% to 5 million tons, while the value decreased 4.2% to \$35.3 million. Domestic apparent consumption of crushed stone was 1.2 billion tons.

The implementation of the provisions of the amended Federal Water Pollution Control Act of 1977, the Clean Water Act, Section 404, dealing with "wetlands" and the establishment of a "no net loss of wetlands" policy constitutes one of the major areas of concern to the crushed stone industry. The new regulatory requirements being proposed by the Occupational Safety and Health Administration (OSHA) continue to be the other areas of concern

for the industry. They include the revised asbestos standards governing occupational exposure to nonasbestiform varieties of actinolite, tremolite, and anthophyllite minerals and the final promulgation of the permissible exposure limit for crystalline silica measured as respirable silica.

DOMESTIC DATA COVERAGE

Domestic production data for crushed stone are developed by the U.S. Bureau of Mines from voluntary surveys of U.S. producers. Full surveys of crushed stone producers are conducted for odd-numbered years only. For even-numbered years, only annual estimates for each State are generated based on information provided by the new quarterly sample survey of crushed stone and sand and gravel producers. This survey provides production estimates by quarters for each State and the nine geographic regions. The sample survey canvasses most of the large companies in each State, accounting for up to 80% of the State's total tonnage. The results of this survey are published each quarter in a separate publication, the Quarterly Mineral Industry Survey.

BACKGROUND

Crushed stone is a term applied to rock that has been broken and/or crushed after quarrying. It is a low-value product characterized by its "place value," a term that describes the importance of the location of the geologic deposit in reference to the market. Stone in its multitude of forms represents a very significant part of the Earth's crust. As one of the most accessible natural resources, it has been used since

the earliest days of our civilization. First used as a tool or weapon, it was then used as a construction material, and later, in its crushed form, as one of the basic raw materials for a wide variety of uses, ranging from agriculture and chemicals to complex industrial processes.

The beginnings of the crushed stone industry are difficult to trace, but it is known that the Greeks, and later the Romans, the first great road builders, used limestone and lime extensively. In the 19th century, the mining of crushed stone was labor intensive. Workers with sledge hammers and shovels used their muscles to work the quarries and produce crushed stone that was used mostly for road and railroad construction.² The modern crushed stone industry began in England in about 1815 and expanded rapidly after the invention of the mechanical rock crusher in 1858.3 Today's crushed stone industry is vastly different. It evolved from a labor-intensive to a capital-intensive industry where the labor force mostly directs and controls sophisticated and powerful equipment operating in the quarries.

In the United States, railroad ballast was the principal market for the crushed stone industry during the last half of the 19th century. Passage of the Federal Aid Highway Act in 1916 acknowledged the national importance of highways, and subsequent highway construction created a new and significantly larger market. The crushed stone industry grew tremendously, especially in the second half of this century. Production increased from 130 million tons in 1928 to a high of 1.25 billion tons in 1988, mainly owing to rapidly increasing demand for highway, railroad, and other construction work. Today the volume of crushed and broken stone produced is greater than that of any other mineral mined in the United States. The United States is, in general, self-sufficient in crushed stone, producing enough

eEstimated.

to meet most of the domestic needs. Small quantities of crushed stone, used mostly as construction aggregates, are being imported by water from the Bahamas, Canada, Mexico, and to a smaller extent from Scotland, the United Kingdom.

Most of crushed stone is used for construction purposes, mainly as aggregate with or without a binder. Road base or road surfacing material, macadam, riprap, and railroad ballast are the major uses without a binder. Aggregate for cement and bituminous concrete in highway and road construction and repair and in residential and nonresidential construction are the major uses for aggregates with a binder. Other uses include cement and lime manufacture, agriculture, metallurgical flux, and fillers and extenders.

Although crushed stone resources are widespread and in adequate supply in most parts of the United States, local shortages exist. Land use conflicts and environmental problems associated with rapid urban expansion are major factors contributing to these shortages. Demand pressures, land use regulations, and the cost of meeting environmental and reclamation requirements are factors that will cause a rising price trend. Larger operations with more efficient equipment, more automation, and better planning and design will be the trend of the industry in the future.

Definitions, Grades, and Specifications

Crushed and broken stone is a term applied to rock that has been broken and/or crushed into smaller, irregular fragments or ground to specified particle sizes. Crushed stone is also classified by kind of stone, including limestone, dolomite, marble, shell, granite, traprock, sand-

stone, quartzite, slate, volcanic cinder and scoria, and miscellaneous stone. The terminology used by the crushed stone industry is not always consistent with mineralogical definitions. Limestone and dolomite are rocks composed, respectively, of the minerals calcite, CaCO₃, and dolomite, CaMg (CO₃)₂; however, they are usually called limestone by the industry, and intermediate varieties are seldom distinguished. Some deposits of limestone consist chiefly of the mineral aragonite. which has the same composition as calcite. but has a different crystal structure. Marble may include any calcareous rock that will accept a polish. Marl is calcitic and contains varying amounts of shale or clay. Granite includes the coarser grained igneous rocks such as true granite and syenite. Gneisses, although metamorphic rocks, are usually included with granite. Quartzite is a well-cemented sandstone that is indurated to the extent that, when fractured, it breaks across the grain. Traprock includes all dense, dark, and fine-grained igneous rocks such as basalt, diabase, and gabbro.

Crushed stone in its different rock types and particle sizes is used in a wide variety of applications in many industries, including construction, chemical, metallurgical, and agriculture. For the purpose of collecting and disseminating production information, the U.S. Bureau of Mines generally accepts the rock type classification and the principal end uses and their definitions as reported by the crushed stone producers.

Specifications for crushed stone are numerous because of the large number and the variety of uses, the diversity of stone types, and the variations in physical and chemical requirements for different uses. Various national specifications and

tests exist for crushed stone products, but the most active organizations in preparing and reviewing them are the American Society for Testing and Materials (ASTM)4 and the American Association of State Highway and Transportation Officials. For construction aggregates, these are regarded by industry as guide or reference specifications. State specifications are often much more stringent and vary from State to State. The most common specifications and tests relate primarily to gradation, but soundness, shape, abrasion resistance, porosity, chemical compatibility, and content of soft particles are also important.⁵ Specifications for construction aggregates are written by commercial users; government agencies, including Federal, State, county, and city construction and highway departments; and the ASTM. Problems arise for the producers of construction aggregates when their product is sold or used in several different cities, counties, or States, many of which may have different specifications. Some progress is being made toward the standardization of aggregate sizes for similar requirements. A need exists for a more active interchange of data and experience among aggregate consumers and producers.

Specifications for limestone used in portland cement manufacture require a content of more than 75% calcium carbonate (CaCO₃) and less than 3% magnesium carbonate (MgCO₃). For white portland cement, the iron content of the raw materials should be very low, less than 0.01%. Because raw materials are finely ground for processing, chert nodules or coarse quartz grains are undesirable. Limestone for lime manufacture should contain more than 90% calcium carbonate, often more than 97% or 98%; less

¹Does not include American Samoa, Guam, Puerto Rico, and the U.S. Virgin Islands.

²One metric ton is equal to 1,000 kilograms or 2,204.62 pounds. To convert short tons into metric tons, multiply short tons by 0.907185. ³Excludes precipitated calcium carbonate.

than 5% magnesium carbonate; and less than 3% of other impurities. For lime produced in vertical kilns, 5- to 8-inch stone is recommended, while in rotary kilns 3/8- to 21/2-inch stone may be used. Limestone and dolomite should be sufficiently hard so as not to decrepitate when heated. High-magnesium lime made from dolomite should contain more than 40% magnesium carbonate.

Specifications for the use of limestone or dolomite as fluxstone vary with the pyrometallurgical process, the kind of ore processed, and the final use of the slag; silica content should not exceed 2% to 5%, magnesia content should be less than 4% to 15%, and sulfur less than 0.1%. Size specifications also vary and include ranges from 1 to 4 inches, 2 to 4 inches, and 3 to 6 inches. The limestone or dolomite used for glassmaking should contain at least 98% CaCO₃ or MgCO₃, respectively, and less than 0.05% to 0.02% iron oxide. Size specifications vary with the manufacturer and the kind of glass being produced, but uniformity is a major requirement; usually 100% of the material should pass a No. 10 sieve (2 millimeters) and 96% to 100% should be retained on a No. 100 sieve (0.15 millimeters).

Requirements for agricultural limestone are not very rigid and depend on the specific use: as direct application to soil, as filler and conditioner for fertilizers, in animal mineral feeds, or as poultry grit. In all of these applications, CaCO₃ or MgCO₃ equivalent or content is of major significance. Many individualized specifications exist for a wide variety of industrial applications, mostly pulverized limestone for rock dusting, or as asphalt, plastic, rubber, paper, or paint fillers or extenders.⁶

Products for Trade and Industry

The ultimate use of crushed stone determines the specification for particle size and gradation, shape, rock type, and chemical composition. Crushed stone can be used without any binder for a variety of construction or industrial applications or it may be mixed with a matrix binding cement. The most common use of crushed stone for construction purposes is as aggregate without a binder, including road base or road surfacing material, macadam, riprap, railroad ballast, filter stone, etc. The second largest use of crushed stone is as aggregate for cement and bituminous concrete in a variety of forms and applications in residential and nonresidential construction, highway and road construction and repair, airports, dams, sewers, and foundations. Sized crushed stone is used to make asphaltic concrete aggregate and road bases. Broken surfaces adhere to the hot asphaltic mixture better than rounded surfaces do and provide interlocking surfaces that tend to strengthen the asphaltic concrete. Broken particles pack better and tend to move less under load than rounded particles do and, therefore, make better road bases for highway and road construction. This is essential because bases and asphaltic concrete tend to flow when placed under great or long duration stresses. Other uses include limestone for cement and lime manufacturing and as agricultural limestone used as direct application to soil, as filler and conditioner for fertilizers, in animal mineral feeds, or as poultry grit. Smaller amounts of crushed stone are used for a wide variety of applications ranging from metallurgical fluxing of antimony, copper, iron, lead, and zinc to the manufacture of glass, ceramic pottery, paper, and as fillers and extenders in asphalt, paint, rubber, and plastics.

A growing amount of limestone is being used in the removal of sulfur oxides from stack gases, primarily from coal burning electric generating stations, and for mine dusting to enhance mine safety by reducing the explosion risk of highly combustible coal dust.

Industry Structure

Because of the low unit value, crushed stone is usually produced near the point of use; therefore, the industry is concentrated mostly in or nearby large, rapidly expanding urban areas. Crushed stone is produced in every State except Delaware, with more than 75% of the national total coming from two major geographic regions, the South and Midwest. The largest quarries tend to be concentrated in the States with the largest populations and largest productions of crushed stone.⁷

Although limestone is produced in all States except Delaware, Louisiana, New Hampshire, and North Dakota, the major producing States are east of the Rockies. Crushed marble is produced mostly in the eastern part of the United States in Alabama, Georgia, and Pennsylvania. Crushed granite is produced primarily in Appalachia, with Georgia, North Carolina, South Carolina, and Virginia being the largest producing States. Crushed trap-

rock is produced mainly in the northeast and the Pacific Coast States, with California, Connecticut, Massachusetts, New Jersey, Oregon, and Washington the largest producing States. Crushed sandstone and quartzite are produced in 31 States led by Arkansas, California, and Pennsylvania. Most crushed slate is produced in the Eastern part of the United States, mainly in Arkansas, Georgia, and Virginia. Shell, primarily oyster residue, is produced by dredging along the gulf coast. Volcanic cinder is produced in the West, mainly in Arizona, California, and New Mexico.

On the basis of tonnage, the crushed stone industry is the largest nonfuel mineral industry in the United States. The industry is widespread and has a large variation in operation size, kind of stone, and size of material produced. The individual companies range in size from small independent producers with 1 quarry to large diversified corporations with 50 or more crushed stone operations.

In 1989, the last year when a complete survey of the crushed stone producers was conducted, 1,716 companies produced crushed stone from about 3,416 active quarries. Individual crushed stone quarries range in size from those producing between 1 and 11 million tons annually to those reporting less than 50,000 tons per year. However, most of the tonnage comes from large operations. In 1989, for example, 86 operations each reporting production of more than 2 million tons per year represented only 2.3% of the total number of operations but accounted for 22% of total crushed stone production. The large operations are owned or operated by a small number of companies. In 1989, the combined production of the top 10 producers operating 477 quarries accounted for 27.8% of the total output of crushed stone in the United States. The 10 leading producers were Vulcan Materials Co., Beazer USA Inc., Martin Marietta Aggregates, Tarmac America Inc., Dravo Corp., General Dynamics Corp., The Rogers Group Inc., Lone Star Industries Inc., Genstar Stone Products Inc., and Florida Rock Industries Inc.

In the past several years, significant changes in the structure of the crushed stone industry have occurred, caused primarily by mergers and acquisitions. An established and well-managed company with significant reserves in the ground becomes a potential target of larger companies trying to lockup sufficient reserves or

CRUSHED STONE—1990 1077

expand into the aggregate business. Some of the recent acquisitions were made by foreign companies or were associated with the influx of foreign capital. Two of the top five crushed stone-producing companies in 1989 are subsidiaries of foreign companies.

The United States is the largest producer of crushed and broken stone among the market economy countries. Other major producing countries are Australia, Canada, France, the Federal Republic of Germany, Japan, and the United Kingdom. Some information about the production of crushed stone in foreign countries may be found in the U.S. Bureau of Mines Minerals Yearbook Volume III, Area Reports: International. For nonreporting countries, estimates of crushed stone outputs can be based on indirect sources such as the level of cement consumption.

Geology-Resources

Bedrock deposits are classified on the basis of their origin into sedimentary, igneous, and metamorphic rocks. Sedimentary rocks were produced from the consolidation of loose sediments through chemical or mechanical sedimentation. Limestone, which is primarily calcium carbonate (CaCO₃), and dolomite, which is calcium-magnesium carbonate (CaMg(CO₃)₂), are the most common sedimentary rocks produced through chemical or biochemical sedimentation. Limestone and dolomite formations are widespread in the United States, with most of the deposits being of Paleozoic age, with a few of Mesozoic and Tertiary age. Most States have adequate reserves for use in construction and other applications that do not require chemically pure stone.8 High-calcium limestone and high-purity dolomite make up only a small fraction of all limestone and dolomite formations, and they occur in restricted areas, mostly in the eastern part of the United States, with some formations in the Western States as well.9 High-purity dolomite deposits are more limited in occurrence than the high-calcium limestone. Of the clastic sedimentary rocks that are produced through mechanical sedimentation, only sandstones, rocks consisting predominantly of cemented sand-size particles, are, to a limited extent, used as crushed stone.

Igneous rocks, rocks that solidify from molten volcanic magma, are classified as intrusive and extrusive rocks. Intrusive or plutonic rocks are those that were formed

deep beneath the ground surface, are coarse grained, and include granite, diorite, and gabbro as rock types. Extrusive or volcanic rocks are igneous rocks that were formed from molten volcanic magma at the Earth's surface, are fine grained, and include andesite, rhyolite, and basalt. Plutonic and volcanic rocks are further subdivided on the basis of mineralogy in light-colored igneous rocks with high-silica content that includes granite, diorite, rhyolite, and andesite, and dark-colored igneous rocks low in silica content that include gabbro, diabase, and basalt, commonly called traprock. Granite and traprock are the most common igneous rock-types used as crushed stone. Granite occurs primarily in the eastern part of the United States from Maine to Georgia, along the Appalachian Range where major producing States are located. It also occurs in Arkansas, Minnesota, Missouri, Oklahoma, Texas, and Wisconsin and in all Western States except Utah. Most of the traprock occurs in California, Hawaii. Idaho, Oregon, and Washington in the West; in Connecticut, Maryland, Massachusetts, New Jersey, New York, North Carolina, Pennsylvania, and Virginia in the East; and to a smaller extent in Minnesota and Texas.

Metamorphic rocks are formed from preexisting rocks through mineralogical, chemical, and structural changes produced by high heat and pressure. The metamorphic rocks include gneisses, marbles, quartzite, slates, and schists. Marble, quartzite, and slate are the major types of metamorphic rocks used to some extent as crushed stone. Marble occurs primarily in Alabama, Georgia, New York, Vermont, and Virginia in the East and in California and Texas in the West.

A comprehensive report showing geologic occurrences of potential sources of crushed stone and sand and gravel of the conterminous United States for use as natural aggregates was published by the U.S. Geological Survey.¹⁰

On the basis of geologic evidence, stone resources of the United States and the world are sufficient to meet demands, although not always precisely where needed. Reserves, which are measurable amounts of crushed stone that can be produced profitably with current technology under existing economic and political conditions, are controlled mostly by land use and/or environmental constraints. The actual volume of stone available is so vast as to preclude the necessity of measure-

ment on a large scale. The local shortages that occasionally exist are caused less by a lack of stone than by urban encroachment or zoning regulations that force closure of operating quarries or prevent the development of new ones.

Technology

Major technological developments have been instrumental in maintaining adequate production at relatively stable real costs in the crushed stone industry. Equipment manufacturers usually conduct most of the research related to improvements in the mining and processing of crushed stone operations. Larger, more efficient equipment is being developed and improved constantly. The use of computerized control systems in plant operation and quality control has increased significantly in recent years. Automatic controls. along with monitoring by closed-circuit television coordinated with automated counting and recording and radio communications systems, have been installed in many of the larger and newer operations. Automated plants have significantly improved operating efficiency and produce the optimal product mixture to fit market requirements at lower cost.

As part of the national drive to reduce air pollution, significant progress is being made toward the desulfurization of stack gases resulting from coal burning electric generating stations and some industrial installations.¹¹ Limestone and lime are used as chemically reactive agents in most of the dry- or wet-scrubbing processes as well as in the treatment of acidified waters, specifically lakes and streams.

Exploration.—A large number of geologic formations that have economic potential as a source of crushed stone have been mapped and described in the literature over the years. Consequently, detailed exploration and development work for any new crushed stone operation will most probably be done on one of these formations. However, in the event that a new stone deposit is discovered, more exploration and evaluation work would be required before development. Preliminary examination can establish the extent and nature of the deposit. This is followed by a detailed exploration program aimed at obtaining reasonably accurate information about the quality of the available material, including the kind of stone, its chemical composition and degree of ce-

1078

mentation, and the degree of uniformity throughout the deposit. Also, the nature and the amount of waste material and the economic feasibility of its removal, processing, and marketing must be studied. In most cases, an environmental impact study is required by local or State agencies.

If the raw material cost and quality are proven to be adequate and sufficient reserves are demonstrated, the development stage of the operation can be started. Economic feasibility and marketing studies include analysis of the availability of power and water supply; mining and processing costs and requirements; the condition of nearby roads and highways and the proximity of rail haulage; the cost of compliance with local, State, and Federal regulations; and the proximity and density of local population, as well as its attitude toward such a project.

Mining.—Most crushed and broken stone is mined from open quarries; however, in many areas, factors favoring large-scale production by underground mining are becoming more frequent and more prominent.

Surface mining equipment varies with the kind of stone mined, the production capacity needed, the size and shape of the deposit, estimated life of the operation, location of the deposit with respect to urban centers, and other important factors. Ordinarily, drilling is done with tricone rotary drills, long-hole percussion drills, and churn drills. Blasting in smaller operations may still be done with dynamite, but in most medium- to large-size operations ammonium nitrate-fuel oil (AN-FO) mixtures, which are much lower in cost, are used.

Underground operations are becoming more common, especially for limestone mining in the central and eastern parts of the United States, as the advantages of such operations are increasingly recognized by the producers. By operating underground, a variety of problems usually connected with surface mining such as environmental impacts and community acceptance are significantly reduced. Underground room-and-pillar mines can be operated on a year-round basis, do not require extensive removal of overburden, and produce a minimum of environmental disturbance. The need for less surface space is also an important factor in areas of high land costs. Subsidence has not been a problem in areas mined, and the conventional practice has been to leave 12% to 15% of pillar areas and 6 to 8 feet of stone in the mined roof. A specific advantage of underground quarries is the creation of valuable storage facilities. In many cases, the value of the sale or rental of the storage space may exceed the value of the stone mine. Thus, the incentives for producing stone from underground mines can be enhanced by the economic advantages of subsequent use of the excavated areas.

Loading and hauling equipment has grown larger as increased demand for stone has made higher production capacities necessary. Track-mounted equipment is still used extensively, but hydraulic, tire-mounted hauling equipment is predominant.

Processing.—Processing plants have become larger and more efficient, in part because of an increase in the use of computerized control systems. Programmable controllers and/or computers are viewed today as valuable tools that improve operating efficiency and product quality. Primary crushing is often done at or near the pit, usually by jaw or gyratory crushers, but impact and other special types of crushers are also used for nonabrasive stone or stone that tends to clog conventional crushers. The cost effectiveness of permanent crushing installations can be limited because the raw material moves away from the primary stage. It becomes increasingly expensive to haul material from the production face to the crushing plant. Improved crusher technology and increased capacity toward greater equipment mobility are accelerating the use of in-pit movable primary crushers. There is an increased interest in the use of portable crushers ranging in size from 500 tons per hour up to 5,000 tons per hour. For secondary crushing, a variety of comminution equipment is used, depending on plant size, rock type, and kind of material being produced. Cone crushers and gyratory crushers are the most common types used, but impact crushers, including hammer mills, and roll crushers are often used. Belt conveyors are being used extensively to haul material within the quarry because they provide continuous operation, low maintenance costs, low work force requirements, and reduced noise levels. Conveying systems are often associated with in-pit crushers and consist of several portable units and a stationary field conveyor. The portable conveyors, usually in 100- to 200-foot lengths, make the connection between the portable crusher and the field conveyor and provide a good range of motion. The increased use of conveyors reduces significantly the use of haul trucks in quarries.

Screening is the single most important part of the processing cycle of crushed stone particles. A wide variety of screen types exists, and their selection is a function of the material processed as well as the final product required. Inclined vibratory screens are most commonly used in stationary installations, while horizontal screens are used extensively in portable plants. For screening large sizes of crushed stone, grizzly bars, rod decks, and heavy punched steel or plastic plates are used; for smaller sizes, woven wire, welded wire cloth, rubber, or plastic screens are used.

Processed crushed stone is usually stored in open areas except for relatively small quantities that go to the load-out bins. In the more efficient plants, the crushed stone is transported from the storage piles on belt conveyors through tunnels installed under the piles, thus facilitating the blending of any desired mixture of sizes from different piles.

Recycling.—As the Nation moves into an age of increased environmental consciousness, recycling of old concrete and asphalt, used mostly in pavements, is increasing. Local scarcity or high cost of construction aggregates in some areas as well as waste disposal problems are making recycling more attractive economically. In some States, limited recycling, especially in road construction, is either encouraged or required by law. The best utilization for recycled cement concrete is as road base material, because the matrix of concrete cannot be converted back to cement, and also because of the lower strength of concrete compared with that of natural aggregates. Sound crushed concrete can make good coarse aggregate, but the fines produced in crushing the concrete have a higher absorption, are more friable, and will require a higher amount of asphalt in asphaltic concrete and a higher amount of mixing water in portland cement.12

The amount of asphalt roads recycled is significantly larger than that of concrete roads, mainly because asphalt can be rejuvenated with oil additives and used in pavements, significantly reducing the cost of the finished road. Experience has shown that about 35% of crushed asphalt pavement can be recycled into new asphalt

mixtures. Proper testing under engineering supervision in all construction projects using recycled materials as aggregates should be performed to ensure that the technical specifications are met.

Byproducts and Coproducts

Clay of good quality is sometimes encountered in limestone overburden and is mined as a coproduct. Gypsum is often encountered beneath beds of limestone and is mined as a coproduct. Amphibolite rock often occurs as formations paralleling spodumene-bearing pegmatitic dikes and is mined concurrently with these, notably in North Carolina. This coproduct of lithium mining is marketed primarily as roadstone. Stone is also mined in conjunction with many metallic ores and nonmetallic minerals, but seldom does a market exist for it.

Economic Factors

Crushed stone is a high-volume, lowvalue commodity. The industry is highly competitive and is characterized by thousands of operations serving local or regional markets, largely because stone is an abundant mineral. Production costs are determined mainly by the cost of labor, equipment, energy, and water, in addition to the costs of compliance with environmental and safety regulations. These costs vary depending on geographic location, the nature of the deposit, and the number and type of products produced. Despite having one of the lowest average per ton values of all mineral commodities, the constant dollar price of crushed stone has changed relatively little over the past 20 years. As a result of rising costs of labor. energy, and mining and processing equipment, the average unit price of crushed stone increased from \$1.58 per ton, f.o.b. plant, in 1970 to \$4.39 in 1990. However, the unit price in constant 1982 dollars fluctuated between \$3.48 and \$3.91 per ton for the same period. Increased productivity achieved through increased use of automation and more efficient equipment was mainly responsible for maintaining the prices at this level.

The delivered price of the product, in addition to quality, is a particularly important element in any major transaction because of the low unit value of crushed stone, and therefore, producers that are closest to markets have a significant advantage. Sophisticated equipment backed

by technical knowledge combined with solid sales expertise are becoming very important. For this reason, large companies are better able to compete in the crushed stone business, especially when there is a need for a wide variety of products. Smaller, less efficient operations become less economical as operating costs, as well as costs associated with meeting various Federal, State, and local regulations, continue to increase. The only alternatives these producers have are to supply local markets with a limited number of products. The gradual trend toward larger operations has continued. mostly because the stone industry is capital intensive, and it is becoming less economical to operate small quarries. The viability of small operations is dependent on the demand in the local markets, mining costs, and the degree of processing required to supply the final product.

A 5% depletion allowance based on gross income is allowed for crushed stone used in construction, including aggregates. The depletion allowance for chemical and metallurgical crushed stone is 14%.

Operating Factors

Many States, counties, and cities in the United States have zoning laws, and land within each governmental unit is usually zoned to indicate acceptable land uses. If mining is permitted in a zone and a crushed stone company owns or leases land within that zone, the company may apply for a use permit or its equivalent to begin an operation. If the parcels to be quarried are on lands under both city and county jurisdiction, permits usually must be obtained from each. An acceptable reclamation plan that meets the guidelines or regulations of the appropriate governmental agency must also be approved. Environmental concerns such as noise. dust, beautification, and storage of wastes must be accounted for in a manner satisfactory to the governmental entity involved. Wastewater discharge requirements must be planned for and met. If the deposit to be worked is on land controlled by a State or Federal agency, that agency's requirements must also be satisfied.

In most States, permits for crushed stone operations require an Environmental Impact Report (EIR) or Environment Impact Statement (EIS). A reclamation plan and a use permit application may also be required, with considerable overlap of subject matter with the EIS. A

complete EIS may cover all the problem areas at once and facilitate acceptance.

Environmental Requirements.—Many of the environmental problems facing crushed stone producers arise because a great number of stone quarries and processing plants are located in suburban areas near the major crushed stone markets. Major environmental considerations that must be dealt with in mining and processing of crushed stone are emission of particulate matter into the air, discharge of processing water, noise abatement, and employee and public health and safety. Air pollution constitutes a major problem in processing plants, especially in the drying and packaging stages of fine particle products such as limestone used as fillers or extenders. Both wet and dry methods of dust control are used. The most important water pollutant is clay in suspension that results from washing and screening crushed stone. Because of the large quantities of water used to process stone and the need for compliance with often stringent regulations, the treatment of discharge water by crushed stone pro-

ducers is becoming a necessity that may require sophisticated and expensive processing methods. Significant progress has been made in reducing noise pollution both inside and outside of the quarries, including noise and vibration produced by blasting and movement of heavy trucks. Therefore, the industry must be concerned first about any practices that can affect the community environment. An effective effort must be made to reduce noise, air, and water pollution and to improve the overall appearance of the operating mine, processing plant, and transportation facilities. Second, the industry and community must recognize the time and costs required to protect the environment and the importance of agreeing on fair and realistic environmental standards. Because crushed stone is a local industry, the effect of supply deficiencies and cost of material will affect the local community first. Undue delay and unreasonably high cost can strongly affect the movement of crushed stone into the marketplace. Also, stringent controls by the local governments that prevent permits being issued to operators can have adverse economic effects on the communities around them. These conditions can make it difficult to assess the timing and even the possibility of plants going on-stream and can therefore affect the supply of crushed stone into the marketplace.

Although much progress is being made through premining planning, the crushed stone industry continues to have problems with environmental controls, land use conflicts, and reclamation practices. Many of these problems are acute because extraction areas and plants must be reasonably near to consumers who are largely in metropolitan areas.

Transportation.—Transportation is a major factor in the delivered price of crushed stone. The cost of moving crushed stone from the plant to the market often equals or exceeds the sales price of the product at the plant. Because of the high cost of transportation and the large quantities of bulk material that have to be shipped, crushed stone is usually marketed locally. The high cost of transportation is responsible for the wide dispersion of quarries around the country, usually located near highly populated areas.

However, increasing land values combined with local environmental concerns are moving crushed stone quarries farther from the end-use locations, increasing the price of delivered material. Economies of scale, which might be realized if fewer, larger operations served larger marketing areas, would probably not offset the increased transportation costs.

Truck haulage is the main form of transportation used in the crushed stone industry, despite the fact that it is the most expensive mode of transportation on a cost-per-ton-per-mile basis. Many producers have their own truck fleets and deliver their own raw materials and products. A significant and increasing amount of crushed stone, however, is being hauled by independent truckers because of the cost of maintaining a truck fleet, particularly when the market is highly variable. Rail and water transportation combined account for about 7% to 10% of total crushed stone shipments. In recent years, an increased amount of crushed stone is being shipped into the United States by water from Bermuda, Canada, Mexico, and the United Kingdom, using large oceangoing vessels. Some of them are selfunloading vessels.

ANNUAL REVIEW

In 1990, the crushed stone industry reached the second highest production level ever recorded and the fourth consecutive year of production of more than 1.2 billion tons. This high level of production indicate a continuation of the strong demand for construction aggregates. Production increased significantly in the first quarter of 1990, compared with the same period of 1989, decreased slightly in the second and third quarters, and increased again in the fourth quarter.

Legislation and Government Programs

On November 15, 1990, the U.S. Congress enacted the 1990 Amendments to the Clean Air Act of 1970 (Public Law 101-549). Most of the regulatory programs and air quality standards established by the original Clean Air Act of 1970 were revised and new provisions were promulgated. The new clean air law contains eleven parts covering: National Ambient Air Quality Standards; Mobile Sources; Hazardous Air Pollutants; Acid Rain Control; and Stratospheric Ozone Protection. The new law will be implemented through rules written by the Environmental Protection Agency (EPA) and laws

passed by the States. The standard for measuring the amount of solid or liquid "particulate" matter suspended in the atmosphere (PM-10) and the designation of PM-10 noncompliance areas, the new system of operating permits, and the enforcement and review of air pollutant emission factors are areas that will have an impact on the crushed stone industry.

On October 28, 1990, the U.S. Congress approved the Department of Transportation's Appropriation bill that increased funding for the Federal highway and airport programs. The Federal Highway Program increased from a total of \$13.5 billion in the fiscal year 1990 to \$16 billion in fiscal year 1991. The Airport Improvement Program increased from \$1.4 billion in fiscal year 1990 to \$1.8 billion in fiscal year 1991. The U.S. Congress also approved the Omnibus Budget Reconciliation Act of 1990, which increased the Federal motor fuels taxes by 5 cents, divided 50-50 between the General Revenue Fund and the Highway Trust Fund.

On February 7, 1990, the EPA and the U.S. Army Corps of Engineers (USACE) signed a revised Memorandum of Agreement (MOA) intended to clarify the policies and procedures to be used by their field personnel in determining compliance with the provisions of the section 404 of the amended Federal Water Pollution Control Act of 1977, the Clean Water Act, dealing with "wetlands." A Wetland Delineation Manual developed by the EPA, the USACE, the U.S. Department of Agriculture, and the U.S. Fish and Wildlife Service was published with the intent to bring consistency to the definition process of wetlands for Federal regulatory purposes.

On February 12, 1990, OSHA issued a notice of proposed supplemental rulemaking on its standards, issued June 17, 1986, governing Occupational Exposure to Asbestos, Tremolite, Anthophyllite, and Actinolite (AT&A)13 for industry in general and the construction industry in particular. An administrative stay of enforcement of the standards was extended until November 1990 to provide time to complete this supplemental rulemaking. The former asbestos standard remains in effect for the extent of the stay. Based on available information, OSHA believes that there is insufficient evidence to conclude that exposure to nonasbestiform AT&A mineral fragments presents a risk similar in magnitude or type to fibers of their asbestiform counterparts. Therefore,

CRUSHED STONE—1990 1081

OSHA proposed that nonasbestiform AT&A minerals should no longer be regulated in the same way as asbestos, either under the 1972 asbestos standard or under the revised asbestos standard. Public hearings on the proposed supplemental rulemaking were held on May 8, 1990, at the Labor Department, in Washington, DC. After reviewing the notice of proposed rulemaking regarding the Occupational Exposure to Asbestos, Tremolite, Anthophyllite, and Actinolite, the Department of the Interior informed OSHA that it "recommends that OSHA deal with asbestos and AT&A as separate issues, introduce a mineralogical definition of asbestos into the asbestos regulation, and initiate a separate rulemaking for AT&A because of the potential impact on the mining and minerals industries, the uncertainty in the health risks, and the lack of exposure data and health studies in the consuming industries."14

Issues

The implementation of the provisions of the amended Federal Water Pollution Control Act of 1977, the Clean Water Act, Section 404, dealing with "wetlands" and the establishment of a "no net loss of wetlands" policy constitutes one of the major areas of concern to the crushed stone industry. There is a significant amount of uncertainty regarding the process of designating some lands as wetlands, and whether the current exemptions to the Clean Water Act Section 404 permit program will be maintained in the future. The many criticisms of the current wetland regulatory process include the following: it fails to cover activities that are destructive to wetlands; it ignores basic, fundamental rights of private property owners; and covers privately owned lands that provide minimal wetland functions and values. Several bills were introduced in the 102nd Congress to replace the current Section 404 of the Federal Water Pollution Control Act. The new proposed bills plan to provide a concise and structured program for the delineation of wetlands based upon their functions and values, and will balance the need for effective protection of the Nation's important wetlands with the need for essential community growth and the constitutional rights of landowners.

The regulatory requirements being proposed by the Occupational Safety and Health Administration (OSHA) continue

to be the other areas of concern for the industry. They include the revised asbestos standards governing occupational exposure to nonasbestiform varieties of actinolite, tremolite, and anthophyllite minerals, and the final promulgation of the permissible exposure limit for crystalline silica measured as respirable silica. The revised OSHA regulations for airborne asbestos standards, if implemented, are expected to have a significant impact on the aggregates and the construction industries that could include increased mining and construction costs and disruption of the supply of aggregates in most areas.

Although progress is being made toward better cooperation between the aggregates industry and the local communities in most parts of the country, problems still exist in other areas. An attempt was made in 1990 in Colorado to amend the State constitution and prohibit surface mining of aggregates in the Front Range mountains within view of six major cities, Colorado Springs, Denver, Manitou Springs, Boulder, Pueblo, and Fort Collins, and in various other parts of the State. The amendment would have allowed local governments to adopt and enforce their own reclamation and bonding requirements for aggregate mines. The proposed amendment was challenged in the State Supreme Court and due to the delay caused by the challenge, backers of the amendment could not gather in time the number of signatures required to place the issue on the November 1990 ballot. Backers of the proposed amendment plan to have it included in the Colorado's 1992 general elections.

Production

A total of 1.2 billion short tons of crushed stone was estimated to have been produced for consumption in the United States in 1990, a 0.7% increase compared with the 1989 total. This tonnage was the second largest production ever recorded in the United States and the fourth consecutive year of production over 1.2 billion tons. It is estimated that about three-quarters of the crushed stone production continued to be limestone and dolomite, followed by granite, traprock, sandstone and quartzite, miscellaneous stone, marble, shell, calcareous marl, volcanic cinder and scoria, and slate, in order of volume. Production information by kind of stone is available only for odd-numbered years when full surveys of crushed stone producers are conducted by the U.S. Bureau of Mines.

The production estimates indicate that in 1990 the output of crushed stone increased in all geographic regions except New England, Mountain, and the Pacific regions. The South Atlantic region continued to lead the Nation in the production of crushed stone with an estimated 311 million tons or 25.4% of the U.S. total, followed by the East North Central region with 218 million tons or 17.8%, and the Middle Atlantic region with 157 million tons or 12.8%.

A comparison of the reported 1989 and estimated 1990 production for consumption data indicates that the largest increases occurred in the West North Central region, 8.9%; East South Central region, 6.0%; and East North Central region, 3.0%. The largest decreases in the production for consumption occurred in the Pacific region, -17.0%; New England regions, -11.5%; and South Atlantic region, -1.8%. The estimated production for consumption by quarters for 1990 indicates that most of the crushed stone in the United States was produced in the third quarter of 1990, followed by the second quarter and the fourth quarter.

Crushed stone was produced in every State except Delaware. The 10 leading States in the production of crushed stone, in decreasing order of volume, were Pennsylvania, Texas, Florida, Illinois, Virginia, Tennessee, Missouri, Georgia, North Carolina, and Kentucky. Their combined production represented 52.2% of the national total.

Changes in ownership, acquisitions by foreign or domestic companies, and mergers continued in the crushed stone industry. In January 1990, Colonial Sugar Refineries (CSR) Ltd. of Sydney, Australia, completed the acquisition of ARC America Corp. of Newport Beach, CA, and all its subsidiaries. The transaction included American Aggregates Co. of Greenville, OH, Associated Sand and Gravel Co. of Everett, WA, and WMK Co. of Las Vegas, NV, as well as Hydro Conduit, a large producer of concrete pipes with operations in Florida and most of the Western States. The acquisition added 48 aggregates operations located in six States and 40 concrete pipe plants in 20 States to CSR holdings. CSR owns Rinker Materials Corp. of West Palm Beach, FL, since 1988.

In midyear, C. H. Beazer PLC, of Bath, United Kingdom, reorganized its

American subsidiaries in two separate companies. All Beazer operations located west of the Mississippi, including Gifford-Hill & Co. operations, became Beazer West Inc. of Dallas, TX, while Beazer Materials and Services of Pittsburgh, PA, and all its operations east of the Mississippi became Beazer East Inc.

The Rogers Group Inc. of Nashville. TN, acquired the assets of Billy Holloway Ag-gregates of Louisville, KY, that included two quarries at Avoca and Fern Creek, TN. In addition, the new Rogers Group affiliate, Billy Holloway Ready Mix of Louisville, KY, and American Builders Supply, of Louisville, KY, an affiliate of Sibo Services Inc. of Louisville, KY, formed a joint venture that will operate under the name of American Builders Supply, a Rogers Group company. Sibo Services Inc. is a holding company with assets in aggregates and concrete in Kentucky and Indiana, a subsidiary of Sibo Gruppe, Dyckerhoff Cement Co., Hans Sievert A.G. & Co., Oppermann Sand and Gravel, and Homann Co., all of Germany.

¹Includes "Limestone and/or dolomite," reported with no distinction between the two.

¹Includes volcanic cinder and scoria.

²Data may not add to totals shown because of independent rounding.

³To avoid disclosing company proprietary data, certain State totals do not include estimates for all kinds of stone produced within the State; the amount not shown has been included with U.S. total.

eEstimated.

Cements Francais of Paris, France, acquired most of the Midwest Portland Cement Co., of Uniontown, PA, operations that included two crushed stone quarries in Ohio, one ready-mix plant in Toledo, OH, and a concrete block plant in Bessemer, OH.

Inspiration Resources Corp. of New York, NY, acquired Rogue Aggregates Inc., and LTM Inc., of Medford, OR. Rogue Aggregates has three crushed stone and sand and gravel operations, while LTM is an aggregates, ready-mix concrete, and asphalt producer. Inspiration Resources is a diversified natural resources company that operates base and preciousmetal mines as well as coal mines, and also produces construction materials.

In June, Martin Marietta Aggregates of Bethesda, MD, acquired McKee Quarries, Inc., of Greenwood, MO, and its two limestone quarries located near Kansas City, MO.

Vulcan Materials Co. of Birmingham AL, completed the acquisition of Reed Crushed Stone Co. of Paducah, KY, and two subsidiary companies, Reed Terminal Co. and BRT Transfer Terminal Inc. Reed Crushed Stone quarry is one of the largest quarry in the United States.

Consumption and Uses

Crushed stone production reported to the U.S. Bureau of Mines is material that was either sold or used by producers. Stockpiled production is not reported. Therefore, the "sold or used" tonnage represents the amount of production released for domestic consumption or export in a given year. Because some of the crushed stone producers did not report a breakdown by end use, their total production is reported under "Other unspecified uses, actual." The estimated production of nonrespondents is reported under "Other unspecified uses, estimated." Production information by uses of stone is available only for odd-numbered years when full surveys of crushed stone producers are conducted by the U.S. Bureau of Mines.

Prices

Compared with the actual prices of 1989, the 1990 estimated average unit price for all crushed stone increased 4.3% to \$4.58. Over a 20-year period, the average unit price of crushed stone increased from \$1.72 per ton, f.o.b. plant, in 1972, to \$4.58 in 1990. However, the unit price in constant 1982 dollars fluctuated between

¹To avoid disclosing company proprietary data, certain State totals do not include all kinds of stone produced within the State; the portion not shown has been inluded with "Other."

²Data may not add to totals shown because of independent rounding.

¹Data may not add to totals shown because of independent rounding

a low \$3.48 per ton in 1990 and a high of \$3.91 in 1987 (see table 2). Price information by kind of stone and uses is available only for odd-numbered years, when full surveys of crushed stone producers are conducted by the U.S. Bureau of Mines.

Foreign Trade

The widespread distribution of domestic crushed stone deposits and the high cost of transportation limits foreign trade mostly to local transactions across international boundaries. U.S. imports and exports are small, representing less than 0.5% of the domestic consumption. However, shipments of crushed stone by water from Canada and Mexico are increasing.

Exports.—Exports of crushed stone increased 30.1% to 5.1 million tons compared with those of 1989, while value increased 39.5% to \$32.6 million. About 74% of the exported crushed stone was limestone, Canada being the major destination with over 99% of the total.

Imports.—Imports of crushed stone increased 14.1% to 5 million tons compared with those of 1989, while the value decreased 4.2% to \$35.3 million. About 91% of this tonnage was limestone, 35% of which came from Mexico, 34% from Canada, and 20% from the Bahamas.

Imports of natural calcium carbonate fines decreased 17.5% to 3,300 tons, while

the value decreased 70% to \$864,000. About 59% of processed calcium carbonate was imported from France and 25% from Switzerland.

Shipments of crushed stone from the Bahamas, Canada, and Mexico into the United States continued in 1989. The imported crushed stone, used mostly as construction aggregates or for cement manufacturing, was shipped to Florida, Louisiana, New York, North Carolina, Pennsylvania, South Carolina, and Texas. This trend is expected to continue and the volume of imports to increase.

World Review

Canada.—The 1989 production of stone in Canada was 118 million metric tons, a decrease of 1.7% over the revised 1988 total, valued at \$662 million. About 99% of this output was crushed stone. The Province of Ontario continued to be the largest producer of stone, with 58.3 million tons valued at \$330 million, followed by Quebec with 42.6 million tons valued at \$230 million. The two Provinces accounted for 88% of the total stone production. Preliminary estimates for 1990 stone production indicate a decrease of 5% to 112 million tons valued at \$651 million. The Provinces of Ontario and Ouebec continued to be the largest producers of stone with about 85% of the total output.

United Kingdom.—The 1989 produc-

tion of crushed stone in Great Britain (Northern Ireland not included) reached a record-high level of 193 million tons, as reported by the British Aggregate Construction Materials Industries Association (BACMI). Of this total, 170 million tons was used for construction purposes. About 67% of the total output of crushed stone was limestone and dolomite. South West and East Midlands were the largest crushed stone-producing regions, followed by Wales and Scotland. Preliminary estimates made by BACMI indicate that a total of 185 million tons of crushed stone was produced in 1990, a 4% decrease compared with that of 1989.

Current Research

The 5-year Strategic Highway Research Program (SHRP) that will conclude in 1992 passed its midpoint this year. The program made significant progress toward its main goal of improving the Nation's highways through the use of high-performance technology. SHRP's mission is to produce usable research results targeted toward technical areas where there is potential for rapid progress that could yield significant cost savings. SHRP was conceived as a research program with the following distinguished characteristics: an accelerated research activity to be conducted during the short 5-year life of the program; a dollar-driven and performance-oriented program; management-

directed activities determined by management imperatives; and a productoriented program designed to develop better and more useful highway technology for immediate practical application. ¹⁵ SHRP's research activities account today for more than one-quarter of all highway research conducted in the United States by the Federal agencies, the States, and the private industry.

SHRP's four areas of research are asphalt, concrete and structures, highway operations, and long-term pavement performance. The broad objective of SHRP's research program in the asphalt area is to improve the long-term durability and cost-effectiveness of the Nation's annual \$10 billion-plus investment in asphalt pavements. Preliminary drafts of the performance-based specifications for asphalt

²Includes Aruba, Belize, Dominican Republic, Haiti, and Jamaica.

³Includes Argentina, Brazil, Chile, and Ecuador.

and asphalt binders were released for discussion in 1990. The report indicates that "the chemical and physical properties of the asphalt binder determine, to an important degree, the level of performance achieved by the asphalt pavement."16 Accordingly, chemical analysis of the asphalt yields a large amount of information on how the asphalt will perform as a binder in payement. An initial draft of specifications for asphalt-aggregate mixture was also released in an effort to generate input from users and producers. "The specifications address five pavement performance characteristics—aging, fatigue cracking, moisture sensitivity, permanent deformation, and low-temperature cracking. Applying mixture and binder specifications in the design of specific highways will enable designers to account for severe traffic and climatic conditions. The result will be more durable and economical pavements."17

The concrete and structure program includes research in the area of improved concrete materials and corrosion of steel in concrete structures. Tables that provide guidance for curing concrete, developed by the Pennsylvania State University, and a new test for selection differences between concrete and the environment in which the concrete will be placed are some of the emerging products from the concrete program. A new test for control of freezethaw damage was developed as an alternative to the standard ASTM C-666B test, as well as a fiber-optic air meter, a portable, battery-operated device for measurement on-site of air voids in fresh concrete. All new products and methods will be pilot-tested by State highway agencies around the country in the coming year.

Highway maintenance problems and their high costs are addressed by SHRP's highway operations research program, while SHRP's long-term pavement performance (LTPP) program is measuring pavement performance in different climate, traffic, and subgrade conditions.

A Midcourse Assessment meeting organized by SHRP in Denver, CO, on August 1-3, 1990, was attended by more than 400 representatives of State highway agencies, research organizations, and the industry. SHRP's activities and progress of the research program were examined by the participants, and specific recommendations were made regarding the direction of the program.¹⁸

The mining industry uses annually very large quantities of explosives to fragment

rock.¹⁹ Blasting techniques continue to evolve as new explosives and initiation systems are developed. The U.S. Bureau of Mines, working with Sandia National Laboratory, is developing new computerized blasting designs for better control of rock fragmentation in the mining industry. Mining companies could achieve significant savings in mining costs if blasts can be designed to produce desired size and motion of the blasted material without extensive trial and error. Blasting experiments at one-tenth to full scale were used to examine the effects of various blast parameters on fragment size. From these tests, researchers developed prediction equations that relate design parameters to resulting fragment size distribution. The predictions are accurate to within 16% for massive and relatively unjointed rock. For highly bedded and jointed rock, an additional factor to account for these planar features must be included in the prediction. Because about one-half of the U.S. mineral production is crushed stone, initial tests concentrated on limestone and other rocks with similar properties. Future tests will focus on hard rock such as granite.

The Bureau's Automation in Mining Research Program is pursuing development of systems and technologies required for computer-assisted mining systems.²⁰ Such systems will enable relocation of workers to a safe work environment that will significantly reduce or eliminate human casualties that result especially from working in underground mines. The Bureau's research program is directed specifically at the automation of present-day underground equipment. Projects under Bureau's Automation in Mining Research Program address: guidance technology for navigation of autonomous mining vehicles; expert systems for reducing mining machines downtime caused by electrical, mechanical, or hydraulic failures; intelligent control systems for autonomous mining; and natural language processing and computer graphics for worker-machine interface.

For a long time, good base design and good drainage under pavements was the accepted rule among pavement designers. The development of "rational" methods of pavement design in the 1950's and 1960's led to the belief that pavements could be built strong enough to resist damage without the benefits of good drainage. ²¹ That rationale led the designers to increase the thickness and strength of pavements, while reducing drainage capa-

bilities (capacity) of the base and subbase layers. The bases became also denser and stronger in order to be able to carry heavier loads during the construction and especially after the completion of the roads. Over the years, the inadequate drainage of pavement structures was identified as one of the primary cause of pavement distress and failure in today's highways.

Today, a different design approach is emerging. Rather than using impermeable dense-graded materials, several States started to use open-graded permeable bases that allow moisture to rapidly drain through the base and out from beneath the pavement structure. Permeable bases usually consist of open-graded crushed aggregate with very limited amount of fines and a longitudinal edge-drain system that collects the water from the permeable base. The permeable bases are used mostly under portland cement concrete pavements, but their use under asphaltic concrete pavement is increasing. There are two kind of permeable bases in use: the untreated or unbound permeable bases that are dense-graded aggregate material with reduced amount of fines, and the treated or bound with either asphaltic concrete or portland concrete bases. A good number of States are using the permeable base design method for some time, with California, Michigan, New Jersey, and Pennsylvania being the most advanced States. Performance data indicate that properly designed and constructed permeable bases virtually eliminate pumping, faulting, and cracking of pavements. Studies of pavements constructed on permeable bases in California suggest a minimum service life increase of 33% and 50%, respectively, for asphalt concrete and portland cement concrete pavements constructed on permeable bases.22

For the existing roads built on densegraded bases, a patented process for installing transverse drains under the joints of concrete pavements is being tested in Wisconsin.²³ The drains effectively remove free water from dense-graded bases under the pavement joints, reducing or eliminating the pumping of fines and faulting of joints under heavy traffic. Drainage Technologies Inc., of Oconomowoc, WI, is the patent holder for the new drainage system.

Following the suggestion of the National Pavement Association (NAPA), and in cooperation with AASHTO, and the Federal Highway Administration (FHWA), a 14-day study tour of six Eu-

ropean countries was organized in September 1990. Representatives of AASHTO, FHWA, NAPA, Strategic Highway Research Program, The Asphalt Institute, and the Transportation Research Board visited Denmark, France, the Federal Republic of Germany, Italy, Sweden, and the United Kingdom. The objective of the tour was to exchange ideas and experiences with European highway agencies and construction industry representatives regarding the design, production, and maintenance of asphalt pavements. The group members concluded that there was "a lot to learn from Europe about asphalt pavements and about pavement philosophy in general. European pavements are better than ours. The Europeans invest more in research, development, and deployment of new pavement technology. They build their pavement foundations better. They use innovative surfaces, such as Stone Mastic Asphalt, and mix in additives to a greater extent and with better results. And, the Europeans maintain their pavements to get the maximum life out of them."24 A report summarizing the findings of the study group that also provided a plan for applying these finding in the United States was published by AASHTO.

Technology

A steep-incline, high-capacity conveyor capable of operating uphill or downhill at angles of up to 70° on short or very long lifts was produced by Huwood, a United Kingdom conveyor manufacturer.²⁵ A troughed conveyor belt runs in parallel with a chain conveyor system. Attached to the chain are paddles shaped to the profile of the belt trough that propel the material and the belt up or down the incline. A single drive is used on the chain conveyor that allows the troughed belt to be manufactured from flexible, abrasion resistant, low-tensile material. The rated operation capacity of the conveyor is 10,000 tons per hour. The conveyor will accommodate irregular-sized material, large lumps of fines, and abrasive as well as sticky or frozen materials. The conveyor is said to offer substantial cost benefits for bulk material transportation, especially in surface mine operations and stockvards.

Significant changes are taking place in the design and the use of conveyor systems and their accessories. Stationary or selfpropelled conveyors are replacing in quarry and pit haul trucks because they provide increased productivity by moving large volumes of materials at a faster speed and lower cost. A new computerized designing method for belt conveyor systems was developed by Don Suverkrup and John Cloes, mechanical engineering consultants of Bakersfield, CA.²⁶ Their computer program provides an improved method for producing the proper design of belt conveyors and accessories at a low cost. A review of the latest developments in conveyor systems and their accessories as well as their use was published by Rock Products.²⁷

As the supply of aggregates from landbased resources becomes more restricted. European sand and gravel producers are placing more emphasis on offshore dredging of sand and gravel. To satisfy increased requirements for greater consistency of the products supplied, more sophisticated mining and processing methods are being used. For years, a common practice for offshore dredging was to do some onboard vessel screening of the dredged material. Recently, based on increased environmental concerns, some United Kingdom licenses started to prohibit onboard screening of dredged aggregates. To overcome this restriction, new excavating methods are being tested that will be more selective regarding the material being dredged. The USP RoxAnn seabed classification system is a device that improves the efficiency of trailer-suction dredges.²⁸ The device works through reflected hydroacoustic signals that are able to determine the type of aggregate present in the seabed before the material is excavated. The dredging is therefore adjusted according with the information provided by the device.

Self-unloading vessels were created first and continue to thrive in the Great Lakes area. However, a new market for oceangoing self-unloaders transporting aggregates, cement, and other free-flowing, dry-bulk commodities is developing. The main advantages provided by such vessels for transporting low-value/high-volume commodities are reduced handling costs, improved turnaround time, and capability to supply ports that are not equipped with high capacity unloaders. These kinds of vessels are most cost effective if they perform short hauls and operate often and therefore make full use of the installed equipment, but some are being used for long ocean hauls. Some new developments in the use of self-unloaders as well as reviews of some operations were published by Bulk International Journal.²⁹

OUTLOOK

The demand for crushed stone in 1991 is expected to be about 1.1 billion tons, a 10% decrease compared with the estimated total for 1990. The slowdown of the economy that affected the construction industry in the second half of 1990 is expected to have an impact on the demand for crushed stone in the first half of 1991. Gradual increases in demand for construction aggregates are anticipated after 1991, based on an increased volume of work on the infrastructure expected to occur following the passage of the Surface Transportation Assistance Act of 1991. It is estimated that the demand for crushed stone will reach 1.4 billion tons in 1995. The projected increases will be influenced by construction activity primarly in the public construction sector.

The release of the Department of Transportation comprehensive report on national transportation policy entitled "Moving America, New Directions, New Opportunities"30 indicates that a significant increase in the volume of work on the infrastructure should be expected in the next 5 to 10 years. The value of public construction work as part of the gross national product has declined constantly from about 3% in the 1950's and 1960's to less than 2% in the 1980's. If this trend begins to reverse in the 1990's, a significant increase in spending for public construction work is expected that will dramatically alter above forecasts.

Crushed stone f.o.b. prices are not expected to increase significantly, even if the demand for construction aggregates will rise over forecasts. However, the delivered prices of crushed stone are expected to increase, especially in and near metropolitan areas, mainly because more aggregates are transported from distant sources.

DIMENSION STONE

By Harold A. Taylor, Jr.

Mr. Taylor, a physical scientist with 25 years of industry, Federal Government, and U.S. Bureau of Mines experience, has been the commodity specialist for dimension stone since 1981. Domestic survey data were prepared by Chris Lindsay, mineral data assistant.

roduction of dimension stone increased slightly to 1.19 million short tons valued at \$210 million. More than one-half of the dimension stone produced was granite. Limestone, marble, sandstone, and slate were also produced.

Exports of dimension stone increased 23% in value to \$43 million. The value of dimension stone imports for consumption decreased slightly to \$524 million, equivalent to 250% of the value of domestic production.

DOMESTIC DATA COVERAGE

Domestic production data for dimension stone are developed by the U.S. Bureau of Mines from voluntary surveys of U.S. producers of rough and finished dimension stone. The survey of dimension stone producers was not conducted in 1990. A sample survey based on the first 9 months of data was used to generate State annual preliminary estimates. Of the 368 dimension stone operations surveyed for 1989 and 1988, including those that were idle, 317, or 72%, responded, representing 96% of the estimated value shown in table 1. The final 1988 data are based on data from the 1989 survey, and updated 1988 preliminary data for nonrespondents were estimated using preliminary production reports, adjusted prior years production levels, and employment data.

BACKGROUND

Definitions, Grades, and Specifications

Dimension stone is a natural rock material that has been selected, trimmed, or cut to specified or indicated shapes or sizes, with or without one or more me-

chanically dressed surfaces. This includes rough stone, rubble, ashlar, blocks, panel, and curvilinear shapes. Finished surface requirements may vary from a controlled fractured surface to ground and polished. The most prominent required qualities of dimension stone are strength, toughness, hardness, and resistance to environmental damage. Color and grain structure contribute largely to price and marketability. The principal types of dimension stone used in construction are granite, marble, limestone, sandstone, and slate.

Stone classification by type in the dimension stone industry is somewhat ambiguous and does not correspond in some respects with the same terms used in mineralogical rock descriptions. The U.S Bureau of Mines generally accepts the classification reported by producers. Granite includes all feldspathic crystalline rocks of predominantly interlocking texture with mineral grains visible to the naked eye; these include igneous and metamorphic rocks, including quartz diorites, syenites, quartz porphyries, gabbros, anorthosites, and gneisses. White, gray, black, pink, and red are the common colors for granite. but greens, browns, and other shades are produced in some localities.

Limestone includes dolomitic types as well as calcitic. The latter contain less than

5% magnesium carbonate (MgCO₃). Dolomitic limestone contains 5% to 40% MgCO₃. Marble is a recrystallized (metamorphosed) limestone containing grains of calcite or dolomite or both. In commercial usage, it is any calcareous crystalline rock or serpentine, a hydrous magnesium silicate, capable of taking a polish. Travertine is a type of marble similar to onyx except that it is precipitated from warm or hot water; it has a banded cellular structure and contains cavities up to onehalf inch in width that are lined with microstalactites. Dark green serpentines are classified as marble in the industry because they are often crisscrossed with marblelike veinlets of lighter materials, chiefly calcite or dolomite, and because of their ability to take a high polish.

Commercial sandstone is a sedimentary rock consisting mostly of quartz, sometimes with feldspar, or rock fragments of clastic texture bonded by silica, clay, calcite, or iron oxide. Bluestone is a dense, hard, fine-grained feldspatic sandstone that splits easily along a plane into thin, smooth slabs. It is commonly dark or slate gray in color, and its name no longer has color significance. Brownstone is a feldspathic sandstone of brown reddish-brown color caused by abundant interstitial iron oxide. Flagstone may be either a sand-

stone or a slate that splits into large, thin slabs.

Quartzite is a metamorphic equivalent of sandstone that has been firmly cemented by secondary silica or by recrystallization so that it is essentially homogeneous and fractures through rather than around the original sand grains.

Slate is a fine-grained metamorphic rock derived from shale, siltstone, or claystone. It has prominent cleavage that is oriented independently from the original sedimentary bedding. Mineral constituents are quartz, mica, sericite, or chlorite with assorted minor accessories. Shale is composed mostly of original clay minerals, and cleavage is parallel to the bedding.

Traprock is a commercial term for all dark, igneous rocks too fine in grain size to be called black granite. In addition to extrusive flow rocks such as basalt, andesite, or dacite, traprock includes intrusive igneous rocks such as diabase, diorites, gabbros, pyroxenites, amphibolites, and peridotites.

Miscellaneous stones used for dimension purposes include schist, scoria, soapstone, wollastonite, argillite, and many others.

Geology-Resources

Domestic resources of most types of dimension stone used in construction are practically unlimited. There is considerable interstate transportation of certain types of stone such as Indiana limestone, Georgia marble and granite, and Vermont granite, marble, and slate. A lack of deposits of certain specific varieties of dimension stone especially noted for their aesthetic qualities in architecture and artifact manufacture is an important cause of importation of these varieties; for example, brightly colored marbles from Italy.

Technology

Mining.—Present mining methods range from antiquated and very inefficient to modern and technically superior. Quarrying methods include use of various combinations of diamond saws, wire saws, diamond wire saws, chain saws, channeling machines, drilling machines, wedges, and broaching tools. The choice of equipment depends on the type of dimension stone, size, and shape of deposit, production capacity, labor costs, economics, and management investment attitudes.

Little blasting is done in the mining of

dimension stone. Blocks cut from the face are sawed or split into smaller or thinner blocks for ease in transportation and handling and taken to processing plants, often at the quarry site, for final cutting and finishing operations.

Processing.—Stone-sawing equipment includes large circular saws 10 feet or more in diameter, some with diamond inserts and some using other abrasives; diamond circular saws of smaller size and reciprocating diamond-bladed or loose-abrasive gang saws for multiple cuts. Various types of diamond and other equipment are used for smoothing, polishing, edging, and decorating the finished stone products.

Economic Factors

The current import duties (tariffs) are shown in table 2.

The depletion allowance for dimension stone is 14%. Dimension stone quarries are generally in mountainous or hilly areas remote from areas of dense population. Because land use for other purposes is limited, the cost of land is reasonable.

Transportation costs for dimension stone are high because of its weight and because special handling methods are required to prevent damage to the finished stone. A single stone panel broken in transit not only results in the loss of the many employee-hours of skilled labor required to produce it, but also can cause construction delays that are even more costly. Nevertheless, dimension stone is routinely shipped long distances by motor and rail freight, and special domestic varieties are shipped by ocean freight to foreign countries.

Operating Factors

Environmental requirements vary from State to State and are often a cause of conflict between State or local governments and the quarry operators.

Stone primary and waste products are not toxic, nor are the supplies utilized in their production. However, sufficient exposure to silica-rich stone dust can cause silicosis.

The approximate number of employees in the dimension stone industry by stone kind are granite, 9,600; limestone, 1,100; marble, 1,500; slate, 950; and sandstone and other dimension stone, 850. Of the total 14,000, about 3,100 are employed in quarrying and approximately 10,900 in

finishing operations. Major States for employment were Georgia with 2,100 employees, Vermont with 1,700, Minnesota with 1,250, North Carolina with 850, Texas with 700, and Indiana with 650.

Fuel is used to power quarrying equipment, and electricity is used for sawing and finishing. Water is used in some quarries to cool equipment such as chain saws and in sawing and finishing plants to cool the equipment; water consumption is relatively minimal in all instances.

ANNUAL REVIEW

Production

Dimension stone was produced by 176 companies at 288 quarries in 34 States. Leading States, in order of tonnage, were Indiana, Georgia, and Vermont, producing together 37% of the Nation's total. Of the total production, 53% was granite, 27% was limestone, 11% was sandstone, 3% was slate, 2% was marble, and the remaining 4% was miscellaneous stone. Miscellaneous stone included argillite, schist, soapstone, and traprock (basalt). Leading producing companies in terms of tonnage were Cold Spring Granite Co., principally in California, Minnesota, South Dakota, and Texas; Rock of Ages Corp. in New Hampshire and Vermont; and Fletcher Granite Co. Inc. in Massachusetts and New Hampshire (1988-89).

Granite.—Dimension granite includes all coarse-grained igneous rocks. Production decreased 4% to 634,000 tons and decreased slightly in value to \$116.2 million. Granite was produced by 62 companies at 114 quarries in 22 States. Georgia continued to be the leading State, producing 21% of the U.S. total, followed by Vermont and Massachusetts. These three States together produced about 46% of the U.S. total. Cold Spring Granite, Rock of Ages, and Fletcher Granite Co. were the leading producers and accounted for 44% of U.S. production.

Orex Corp. is beginning to quarry a true black granite at a site north of Whitehall, NY. The stone has the coloring and appearance of a good South African or Indian black granite. The United States has imported large quantities of this expensive premium dimension stone for many years. If a large quarry can be opened, a significant shift to domestic

sourcing would result. The quarry is on the site of an old graphite mine. Sample rough blocks are being sent to Vermont for finishing.

The Rock of Ages Corp. of Barre, VT, in partnership with Dakota Granite Co., has acquired two mahogany granite quarries in South Dakota. The purchased

quarries, along with equipment and inventories, used to belong to Field Enterprises. Ownership of the new firm, titled Whetstone Granite Co., will be split even-

²Includes data for Alabama, Arizona, Arkanasas (1989, 1990), Idaho, Illinois, Kansas, Michigan, Missouri, Montana, New Mexico, South Carolina, and Washington, and data that is withheld.

³Data may not add to totals shown because of independent rounding.

Estimated. ^rRevised. W Withheld to avoid disclosing company proprietary data, included with "Other."

^lIncludes California, Connecticut, Colorado, Maryland, Minnesota, Missouri, New York, Rhode Island, South Carolina, Texas, Virginia, Washington, and data indicated by symbol W.

ly. Dakota Granite Co. will oversee the operations because it is nearby.

Limestone.—Dimension limestone includes bituminous, dolomitic, and siliceous limestones. Indiana, the leading State, produced 195,000 tons in 1990 compared with 198,531 tons in 1989 and 197,894 tons in 1988. Wisconsin, usually the second or third largest producer, totaled 37,636 tons valued at \$1,642,700 in 1989 and 37,976 tons valued at \$1,804,000 in 1988.

Marble.—The Colorado Yule Marble Co. reopened the old Yule white marble quarry in mid-1990. The company began by producing rough block to sell to other firms with finishing facilities. Colorado Marble from this quarry, closed for 50 years, was used in the Lincoln Memorial and the Tomb of the Unknown Soldier, as well as in the Colorado State capitol. The quarry was leased from Vermont Marble Co. The firm was thinking of building a finishing plant, but probably at some distance from the quarry.

Consumption and Uses

Dimension stone was marketed over wide areas. Industry stockpiles were not monitored, and production during the year was assumed to equal consumption.

Consumption of domestic dimension stone increased slightly to 1.19 million tons valued at \$209.7 million in 1990 compared with 1.24 million tons valued at \$211.0 million (revised) in 1989 and 1.16 million tons valued at \$207.8 million in 1988.

Consumption of domestic granite increased to 614,000 tons valued at \$109.5 million in 1990 compared with 661,500 tons valued at \$116.9 million in 1989 and 654,000 tons valued at \$118.9 million in 1988.

Domestic limestone consumption was 326,000 tons valued at \$45.0 million in 1990 compared with 334,200 tons valued at \$42.5 million (revised) in 1989 and 320,500 tons valued at \$42.3 million in 1988.

Domestic marble consumption, including travertine, totaled 23,000 tons valued at \$20.0 million in 1990 compared with

24,280 tons valued at \$21.4 million in 1989 and 20,080 tons valued at \$21.8 million in 1988.

The Carrara marble used as a cladding on the Amoco Building in Chicago is being removed because of weather-related deterioration and will be recycled. The thin-cut stone lost much of its strength after weather-induced warping. This deterioration is expected to continue, so some other use had to be sought. The warping eliminates most possible uses. As a result, 1,000 tons of the 6,000-ton total will be crushed and used as decorative landscaping gravel at Governors State University. An additional 500 tons will be given to an agency for the handicapped to be carved into souvenir items such as bookends, and the balance will be stored until Amoco needs landscaping gravel for its own purposes.

The marble cladding had bowed enough from freeze-thaw to become noticeable a few years ago. Many panels bowed outward more than one-half inch. Some of the panels cracked, and some even fell to the ground, posing a danger to passers-by.

¹Includes rubble, rough blocks for building and construction, irregular shaped stone, and monumental.

²Includes stone used in dressed ashlars and partially squared pieces and a small amount used in flagging, and unspecified uses.

³Data may not add to totals shown because of independent rounding.

¹Includes rubble.

²Includes uses not specified.

³Includes curbing and unspecified uses.

⁴Data do not add to total shown because of independent rounding.

¹Includes a minor amount of slate used for billiard tabletops, blackboards, and unspecified uses.

Prices

The average price for dimension stone increased to \$165 per ton, up slightly from \$170 in 1989.

Foreign Trade

Exports.—Exports of dimension stone, about 40% of which was granite, increased 23% in value.

Imports.—Imports for consumption of dimension stone decreased slightly in value to \$524 million, mostly because of decreases in imports of several major categories of dimension stone, particularly marble slabs. Imports of dressed marble slabs, mostly from Italy, decreased 21% to \$147 million. Imports of dressed granite increased 10%. On a value basis, marble accounted for 45% of imports, followed by granite, 37%.

World Review

Some production of dimension stone occurred in most countries of the world. As usual, Italy produced about one-half of the world's total. Other significant producers were Brazil, China, Finland, India, Norway, Portugal, Spain, Sweden, Turkey, and the United States.

China.—The U.S. Bureau of Mines dimension stone specialist authored a pithy article on recent developments in the Chinese dimension granite industry. According to published numbers of Chinese origin, Chinese production is three times U.S. production or 30% to 40% more than Italian production. Chinese firms have imported more than 200 stone-finishing production lines from Europe in recent years. The decisionmakers for dimension stone exports are the autonomous offices of two Government-owned firms in each Province. Although the Chinese have problems with quality control, they usually offset this by selling at one-half the market price. Chinese exports of dimension stone are rapidly growing, especially to major markets in Japan and the United States.1

Germany, Federal Republic of.—The major dimension stone operations in what was formerly East Germany, now owned by four firms, were described in a recent review. Vereingte Thringische Schiefergruben GmbH produces a dark slate that is heavily used locally. The firm exported about 40% of its dimension slate product output in 1989, mainly to the western part of Germany. Elbe Naturstein GmbH and its recent offshoot, Schsische Sandsteinwerke GmbH, have 23 quarries that pro-

duce a variety of stone. Elbe Naturstein is going to concentrate on its tavertine and limestone quarries in Thuringia, its marble and schist quarries near Plauen, and its Meissen granite quarries in Saxony. The firm exports a small proportion of its output to Western Europe. Schsische Sandsteinwerke GmbH is going to concentrate on its five sandstone quarries near Dresden. Lausitzer Granit GmbH operates three granite quarries and two dolerite quarries north of Dresden and is likely to be broken up, some of it being returned to the original owners and some being sold off.²

The prospects of most of these firms are fairly decent, particularly if a hoped-for building boom occurs. The slate producer probably has the best prospects because it is used to selling in Western markets and because it is the least behind technically.

Ireland.—Prospects for the Irish dimension marble and slate industries were recently described. The famous Connemara marble is no longer quarried, and the tourist trade items still being made are drawing on stockpiled material. A trade association is trying to encourage the industry. Connemara Marble Industries Ltd. is trying to resume production but is involved in a dispute with the national Government over the mining lease.

Marble merely cut by sawing or otherwise.

Source: U.S. Bureau of the Census as modified by U.S. Bureau of Mines.

A new joint venture is trying to reopen a slate quarry in Company Tipperary. This will be a reappearance of the Killaloe slate of the 1800's. One of the partners is the Welsh slate-producing Penrhyn Quarries subsidiary of Alfred McAlpine PLC. The blue-gray slate will be made into roofing and other slate products mostly for the domestic market, but also to be exported to other English-speaking countries, particularly Scotland. The plant and infrastructure will have to be built from scratch. and the total investment may reach \$2 millon. Good progress was being made by vearend.3

European quarries of granite. About 80% to 90% of the granite gets exported in the form of rough block to the Federal Republic of Germany and Italy also to other destinations of lesser importance. However, Swedish exporters are having some difficulty providing the large, rough blocks that are easier to process in present state-of-the-art equipment. They are encountering increasing competition not only from Finland and Norway but also from Brazil, Canada, China, and Saudi Arabia. An unusually high proportion of the rough block is lost as waste in processing the rough blocks.

The largest dimension stone producer, Sweden.—Sweden is one of the major | Emmaboda Granit AB, operates 10 quarries and has a production capacity of about 50,000 tons per year. The firm has been 49% owned by Deutche Steinindustri AG since 1988. The Barap gneiss is the most important product, accounting for about one-half of the firm's production capacity. Domestic markets are served by a finishing plant at the town of Emmaboda.

The second largest producer is the Nilsten firm in Vastervik. AB Broderna Wallins Granitindustrier operates three quarries, two of which produce red granites, including the one that produces Red Vanga. About 80% of this firm's granite is exported to Italy and 10% to Germany. It has plans to open a new quarry for a yellowish granite.4

OUTLOOK

Projected demand for dimension granite totaled 1.7 million tons for 1995 and 2.5 million tons for the year 2000. Demand for dimension marble totaled 750,000 tons for 1995 and 1.1 million tons for the year 2000. Demand for dimension limestone totaled 350,000 tons for 1995 and 390,000 tons for the year 2000, while demand for slate ought to be 55,000 tons in 1995 and 57,000 tons in the year 2000. This relatively slow rate reflects a major drop in the market for building stone in 1989-91 and a welcome major recovery later in the 1990's.

Certain segments will continue to grow rapidly, such as the uses in kitchens and bathrooms. The supply will be adequate and is likely to shift in favor of domestic producers.

STRONTIUM

By Joyce A. Ober

Mrs. Ober, a physical scientist with 13 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for strontium since 1986. Domestic survey data were prepared by Maureen Nash Riley, mineral data assistant; and the international production table was prepared by Virginia A. Woodson, international data coordinator.

he largest consumption of strontium compounds domestically and internationally was in the production of color television picture tube faceplate glass. Strontium carbonate, produced by processing the mineral celestite, was the most important strontium compound produced. Chemical Products Corp. (CPC) of Cartersville, GA, was the only U.S. producer of strontium compounds from celestite. CPC produced compounds from imported material because there were no active celestite mines in the United States.

Strontium occurs commonly in nature. averaging 0.034% of all igneous rock; however, only two minerals, celestite and strontianite, contain strontium in sufficient quantities to make its recovery practical. Of the two, only celestite has been found to occur in deposits of sufficient size to make development of mining facilities currently attractive. Celestite, the most common strontium mineral, consists primarily of strontium sulfate. Strontianite, the second most common mineral, consists primarily of strontium carbonate. Strontianite would be the more useful of the two common minerals because strontium is used most commonly in the carbonate form, but few deposits have been discovered that are suitable for development.

DOMESTIC DATA COVERAGE

The sole U.S. strontium carbonate producer voluntarily provided domestic production data to the U.S. Bureau of Mines. Production and stock data, however, were withheld from publication to avoid disclosing company proprietary data.

The Bureau also estimated the distribution of strontium compounds by end

use. Of the 10 operations to which a survey request was sent, 8 responded. The information collected from this survey represents about 100% of the end-use data shown in table 2. Consumption for the nonrespondents was estimated using reported prior-year consumption levels.

ANNUAL REVIEW

Issues

The Government of Mexico requested a waiver of the competitive need limit for strontium carbonate. Under the General System of Preferences, Mexican strontium carbonate entered the U.S. duty free. A tariff was assessed against imports of strontium carbonate from Mexico when those imports represented more than 50% of total strontium carbonate imports.

The duty free status was revoked in July 1990. The waiver was expected to be approved because there was no opposition from the domestic strontium carbonate producer, and the consumers favored the proposal.

Production

Although there have been no active celestite mines in the United States since 1959, celestite deposits have been identified nationwide. During World War II, domestic mining of celestite resources occurred in California and Texas. U.S. celestite mines had at that time been inactive since World War I, and all demand for strontium minerals was met from foreign sources.

Strontium carbonate, the most important strontium compound by far, was produced in 1990 by one company in the United States. CPC was the only company

¹The strontium content of celestite is 43.88%, which was used to convert units to celestite.

²Export data are obtained from the Journal of Commerce Port Import/Export Reporting Service.

³Excludes China and the U.S.S.R.

that produced strontium chemicals from celestite. The majority of the celestite CPC used was imported from Mexico. CPC utilizes the black ash method of strontium carbonate production at its facility. The black ash method and the soda ash method are the two most common recovery techniques. The black ash method, known alternatively as the calcining method, produces chemical-grade strontium carbonate, which contains at least 98% strontium carbonate. The soda ash or direct conversion method produces technical-grade strontium carbonate, containing at least 97% strontium carbonate.

The black ash method received its name because the first step in the procedure involves mixing the crushed and screened celestite with powdered coal, making a black mixture. The mixture is then heated to about 1,100 °C, expelling oxygen in the form of carbon dioxide from the insoluble strontium sulfate to form water-soluble strontium sulfide.

Strontium sulfide is dissolved in water, and the resulting solution filtered. Carbon dioxide then passes through the solution or soda ash is added. Either compound provides the necessary carbon and oxygen for strontium carbonate to form and precipitate from the solution. The precipitated strontium carbonate is then removed from the solution by filtering and is dried, ground, and packaged. The sulfur released in the process is either recovered as elemental sulfur or in other byproduct sulfur compounds.

In the soda ash method, ground celestite is washed and most of the water removed. The thickened mixture is then mixed with soda ash and treated with steam for 1 to 3 hours. During this time, celestite and soda ash react to form strontium carbonate and sodium sulfate. Sodium sulfate is water soluble, making it possible to separate the insoluble strontium carbonate by centrifuging. Although the soda ash method is a simpler process, the lower grade of the product causes it to be the less preferred method of recoverv. The black ash method is the most common method of strontium carbonate production, and new production facilities usually use black ash technology.

CPC purchased the strontium nitrate production facilities from FMC Corp. in Modesto, CA, when that company discontinued production of carbonate and nitrate in 1984. The company moved the equipment to Cartersville and now is also the sole U.S. producer of strontium nitrate.

There are several U.S. companies that produced strontium compounds from strontium carbonate. Mallinkrodt Inc. of St. Louis, MO, produced strontium chloride, and Mineral Pigments Corp. of Beltsville, MD, produced strontium chromate. A few other companies produced downstream strontium compounds, but on a very small scale.

Domestic strontium deposits were operated in 1944 near Blanket, in Brown County, TX; in Nolan County, TX; in the Fish Mountains in Imperial County, CA; and near Ludlow, CA.¹ At that time, the major use for strontium chemicals was for pyrotechnic applications such as signal flares and tracer bullets required for military applications. Immediately following the World War II, this demand disappeared, causing domestic production of celestite to decrease quickly and eventually disappear.

Resources in the United States have been estimated at 3.2 million metric tons, with an identified reserve base of 1.4 million tons. The reserve figure includes material containing no more than 60% strontium sulfate, which is much too low grade to meet today's rigid specifications. In addition to deposits operated in the early 1940's, celestite has been discovered in Arizona, Arkansas, Kentucky, Michigan, Missouri, New York, Ohio, Pennsylvania, Tennessee, Utah, and Washington.²

Consumption and Uses

Approximately 80% of all strontium was consumed in ceramics and glass manufacture, primarily in television faceplate glass and ceramic ferrite magnets, and in smaller amounts in other ceramic and glass applications. In the past 20 years, color television production has become the major consumer of strontium. Because of unique properties that strontium compounds possess, technologies have developed that take advantage of those properties for specific applications. All color televisions and other devices containing color cathode-ray tubes sold in the United States were required by law to contain strontium in the faceplate glass of the picture tube. Strontium blocks X-rays better than barium, which was previously used, and although lead is a better X-ray barrier than strontium, it causes a browning of the glass, which makes its use undesirable. Major manufacturers of television picture tube glass incorporate about 8%, by weight, strontium oxide in their glass faceplate material. The strontium is added to the glass melt in the form of strontium carbonate, and during processing, it is converted to strontium oxide. In addition to blocking X-rays, the strontium improves the appearance of the glass, increasing the brilliance and improving the quality of the picture.

Trends in television production show a shift to larger, flatter tubes that require thicker glass, and therefore, more strontium. Although the television industry in the United States is considered mature, there is a continuing demand for replacement televisions as well as additional sets in large numbers of households. The trend to personal computers and sophisticated, computerized instrumentation increased the demand for strontium in color monitors for these devices.

Permanent ceramic magnets were another large end use for strontium compounds in the form of strontium ferrite. When these magnets were first developed, they were used primarily as magnetic closures for refrigerator doors. Applications have expanded to include extensive use in small direct current (dc) motors, especially for automotive applications such as windshield-wiper motors, as well as loudspeakers, other electronic equipment, toys, and magnetically attached decorative items.

Strontium ferrites are used in permanent ceramic magnets because they have high coercive force, high thermal and electrical resistivity, and are chemically inert. They retain their magnetism well, are not adversely affected by electrical currents or high temperatures, and do not react with most chemical solvents. Other properties that make the strontium magnets more attractive for specific applications are their resistance to demagnetization and lower density, making them more desirable in applications where weight is a factor.

Barium or lead can replace the strontium in ferrite magnets, but strontium ferrites have been found to possess the best combination of properties necessary for superior magnets.

One of the most consistent and continuing applications for strontium has been in pyrotechnic devices. Strontium burns with a brilliant red flame, and no other material has been found to be better in this application.

The strontium compound used most frequently in pyrotechnic devices was strontium nitrate. Some strontium compounds

1108

are slightly hygroscopic, but strontium nitrate takes on very little water and imparts the desired brilliant red. Strontium carbonate, strontium oxalate, strontium sulfate, and strontium chlorate can be used in pyrotechnic applications, but strontium nitrate was used in significantly larger quantities than any of these.

Pyrotechnic devices were used in military and nonmilitary applications. Military pyrotechnic applications that contained strontium included tracer ammunition, military flares, and marine distress signals. Nonmilitary applications included warning devices and fireworks.

Strontium was used to remove lead impurities during the electrolytic production of zinc. Zinc used in diecasting alloys is required to contain less than 9.003% lead. Addition of strontium carbonate in sulfuric acid to the electrolyte reduced the lead content of the electrolyte and of the zinc that is deposited on the cathode.

The addition of strontium chromate to paint creates a coating that is resistant to corrosion. It is an effective coating for aluminum, most notably on aircraft fuselages and ships. These paints are used to some degree on aluminum packaging to prevent package corrosion. The nitrate and chloride contents of strontium chromate paint pigment are very strictly controlled to prevent corrosion.

Consumption of metallic strontium was still a very limited factor in total strontium consumption. Small amounts of strontium are added to molten aluminum to improve the castability of the metal, making it much more suitable for casting items that have been traditionally made from steel. The addition of strontium to the melt improves the machinability of the casting. The use of cast aluminum parts is currently gaining popularity in the automotive industry. Aluminum parts were impractical before modification techniques were developed. The reduction in the weight of the automobile by using cast aluminum parts instead of steel helps to improve energy efficiency of the cars incorporating these parts.

At the present time, other strontium end uses consume only small amounts of strontium and strontium compounds. As mentioned previously, the presence of strontium in glass applications improves the brilliance of the glass. It also improves the quality of certain ceramic glazes as well as eliminates the toxicity that may be present in glazes containing lead or barium. One high-tech strontium ceramic is strontium titanate, which is sometimes used as substrate material for semiconductors and also in some optical and piezoelectric applications.

Strontium chloride was used in toothpaste for sensitive teeth. For this application, impurities must be strictly controlled, with limits for some of them in the parts per million range.

Strontium phosphate was used in the manufacture of fluorescent lights, and the entire range of strontium chemicals was used in analytical chemistry laboratories.

Prices

The average customs value for celestite imported from Mexico was about \$80 per ton (\$73 per short ton). Mexico was the source of 89% of all celestite imports in 1990. Another 10%, valued at \$190 per ton (\$172 per short ton), was imported from Spain. Average value for total strontium imports was about \$85 per ton (\$77 per short ton). This value was slightly higher than the average customs value reported for 1989. Values of imported strontium compounds varied according to the type of compound and the country of origin.

Foreign Trade

According to the Port Import/Export Reporting Service of The Journal of Commerce, U.S. exports of strontium compounds were about 2,200 tons, a 58% decrease from the exports reported from the same source in 1989. Of these exports, 98% was strontium carbonate that went to Taiwan. Other reported strontium exports were chloride, chromate, ferrite, nitrate, and peroxide, all in relatively small quantities.

The Bureau of the Census began using the Harmonized Tariff Schedule in 1989 to identify material passing through U.S. customs. This system makes classification codes for imports and exports consistent internationally. With the adoption of the new codes, imports and export codes for strontium changed, and some formerly listed details are no longer available. Trade information for strontium metal was grouped with barium under a classification of other alkaline earth metals, making specific information concerning strontium unavailable. Strontium chromate data were eliminated. Other strontium compounds experienced changes in classification numbers, and the grouping of compounds differed.

According to reports from the Bureau of the Census, imports of celestite increased 90% from the levels reported in 1989. Nearly all of it was from Mexico and a small amount from Spain.

Mexico continued to grow in importance as a source for imported strontium compounds; the Federal Republic of Germany was second. Imports of strontium carbonate were virtually the same as in 1989; with imports from Mexico becoming a larger percentage of total imports. Strontium carbonate from the Republic of Germany continued to decrease as Mexico took over more of that market. Imports of strontium nitrate nearly tripled for the second consecutive year.

World Review

In almost all instances, celestite deposits occur in remote, undeveloped locations far from population centers in areas where inexpensive labor is available for mining. Huge deposits of high-grade celestite have been discovered throughout the world. Strontium commonly

occurs with barium and calcium, two elements with properties very similar to strontium, thus making separation difficult. Because removing many impurities from celestite is difficult and energy intensive, current strontium chemical producers require material to contain at least 90% strontium sulfate. Most of the currently operating celestite facilities can produce sufficient supplies with only

minimal processing necessary to achieve acceptable specifications. Hand sorting and some washing are all that are necessary at many strontium mines; only a few operations use froth flotation or gravity separation to beneficiate their ore.

Detailed information on most world resources is not readily available. Many of the large deposits are in remote, sparsely inhabited areas, and very little formal

exploration has been done. Other deposits may be well identified but are in countries from which specific mineral information is not easily obtained.

Capacity.— The data in table 5 are annual rated capacity for chemical processing plants as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Two types of strontium capacity exist, ore production capacity and compound production capacity. Strontium compound capacity was deemed the more important for several reasons. Essentially, all strontium is consumed in compound form, primarily as the carbonate and to a lesser extent as the nitrate. Strontium carbonate is also the intermediate product in production of downstream compounds. At least 12 countries mined celestite in 1989. Virtually all of the celestite mined annually is consumed in the production of strontium carbonate and other strontium compounds. Very little strontium was consumed directly in the mineral form.

Listing both ore and compound production capacity could be misleading, possibly resulting in double-counting of strontium capacity. Because most ore is produced for market by means of very simple sorting and beneficiation techniques, capacity can easily be raised to meet increased demand. Strontium carbonate production capacity is the limiting factor in strontium production, requiring complicated and sophisticated processing facilities. Therefore, strontium carbonate production capacity, reported in terms of contained strontium, was selected for tabulation. Construction to expand strontium carbonate capacity has increased because of the continued growth in international sales of color television sets. Capacity information was compiled from published reports.

Algeria.—Celestite was mined in Algeria from a surface deposit near Beni Mansour. Estimated reserves were more

than 1 million short tons. The deposit was mined by Enterprise des Produits Nonferreux et des Substances Utiles (ENOF) and was controlled by L'Enterprise Nationale de Developpement Minière (Edemines), a division of Société Nationale de Recherches et d'Exploitations Minières (SONAREM). No strontium has been exported in recent years, but in the past, up to 3,600 tons per year has been exported to nations in Eastern Europe and the Federal Republic of Germany. Although the celestite was relatively low grade, only about 70% strontium sulfate, it contained low concentrations of barite, silicate, gypsum, and iron, making it possible to concentrate the ore to acceptable levels using only gravity separation. The deposit has not been fully exploited, but there is interest in further development.³

Argentina.—Celestite mining was controlled by the Argentine Mining Union at the San Juan Mine in the Province of

Mendoza. Celestite has been identified at several other small mines, the Maria Del Carmen and Don Luis Mines also in Mendoza Province and the Rayoso, Julio, Cerro Partido, and Llao Llao Mines in the Province of Neuquen. It is unlikely that any production was carried out on a regular basis at these mines. Most Argentine production was exported to Brazil.⁴

Canada.—Canada has produced celestite ore in the past from the McRae deposit, also known as the old Kaiser Celestite Mining Ltd. mine. It is at Enon. Cape Breton County, Nova Scotia. Mineral rights were acquired by Timminco Metals, a division of Timminco Ltd. Toronto. Exploration identified reserves of more than 1 million tons of celestite, with grades ranging from 60% to 65% strontium sulfate. Reopening the mine has been considered, but the low grade of the ore makes economic feasibility questionable. Other strontium deposits have been identified in British Columbia, Newfoundland, and Ontario.⁵ but none as significant as the deposit in Nova Scotia. Timminco Metals was the largest producer of strontium metal in the world and the only producer of strontium metal in North America. The company operated a processing facility in Westmeath, Ontario. The strontium production facilities in Westmeath and facilities in Haley, Ontario, produce strontium metal by the aluminothermic reduction of strontium oxide.

China.—Celestite was mined in China almost exclusively for domestic consumption. An ore-dressing facility at the Nanjing Mine in Jiang Su Province has a capacity of 10,000 tons per year. The Nanjing deposit is reported to be high grade and close enough to the surface for open pit mining.⁶ Past import data indicated that strontium chemical plants must exist, but no specific details were available. Reports indicated that Japan imports strontium carbonate from China and that strontium carbonate from China has also been reported in the United States.

Cyprus.—Celestite mining began in Cyprus in 1985 at Vassliko, near Limassol, in southern Cyprus. The mine was operated by Hellenic Mining Co. Ltd. The ore averaged about 54% strontium sulfate and, therefore, required concentration to make it marketable. The ore

was beneficiated through a flotation process to reach 94% strontium sulfate. The reserves have been determined to be 200,000 tons of celestite. No mining has occurred for the past 3 years.

Germany, Federal Republic of.—Kali-Chemie AG of Hannover produced strontium carbonate from imported celestite at its plant at Bad Hoenningen. The major western European producer used the black ash method in the production facilities. Plant capacity is estimated to be 15,000 tons per year. Kali-Chemie imported most of its celestite from Spain and Turkey; it exported 80% to 90% of the production, most of which goes to the United States and the Republic of Korea. Kali-Chemie also produced strontium hydroxide and strontium nitrate. The nitrate was produced by its Italian subsidiary, Societa Bario e Derivati SpA, in Massa.8

Iran.—One of the world's largest celestite deposits is in the northwestern part of the Dasht-e-Kavir salt desert. The deposit was mined by Iran Strontium Co., a subsidiary of Cherkate Sahami Sanati Va Maadani Irani (Simiran). Average strontium sulfate values for the deposit were reported at more than 91%, but there were unfavorably high levels of barium sulfate and calcium sulfate. Proven reserves total 1.8 million tons of celestite, 430,000 tons of which has no overburden. Most of the celestite produced from this deposit is believed to go to the U.S.S.R.

Italy.—Mining has been done by Minera Chimica Farnesiana SpA in Tarquinia, near Rome. Most production of this 75% strontium sulfate and 5% barium sulfate product was sold domestically. Annual production capacity at the mine was 7,300 tons per year, but production ceased in 1988. Some of the processed ore has been exported to the U.S.S.R. in the past. Other deposits are known to exist in the interior of Sicily, although none are presently being mined. Societa Bario e Derivati, a subsidiary of Kali-Chemie AG of the Federal Republic of Germany, produced strontium nitrate at Massa. Production and capacity figures were not available, but it was known that most of the production is exported to the United States. 10

Japan.—No celestite was mined in Japan, but that country was the largest consumer of strontium carbonate in the

²Production was entirely from imported celestite.

³Includes strontium nitrate production capacity.

⁴Strontium carbonate production capacity existed in these countries, but specific data were not available.

^eEstimated. ^rRevised.

world, mostly due to its large television and electronics industry. Four companies produce strontium carbonate from imported celestite. Honjo Chemical Corp. operated a production facility for 18,000 tons per year of carbonate at Neyagawa in Osaka using celestite from Spain and China. Sakai Chemical Industries Co. also produced strontium carbonate, by the black ash method, in Osaka at a 12,000-ton-per-year plant using Chinese, Mexican, and Spanish celestite. Japan Special Chemicals (Nihon Tokushu Kasei) and Dowa Chemicals also produced strontium carbonate, but on a much smaller scale. The total capacity for both companies was only about 1,100 tons per year. These two companies used celestite from Spain.¹¹

Korea, Republic of.—Although celestite deposits have not been identified in Korea, its growing electronics and television industry prompted a European company to form a joint venture with a Korean firm. Kali-Chemie and Samsung Corning Ltd., Korea, formed Daehan Specialty Chemicals Co. Ltd. to build a strontium carbonate and barium carbonate plant. The plant began operation in 1990 with a production capacity of 40,000 tons per year of strontium carbonate and barium carbonate, combined. The production will be targeted to the growing television industry in that

country. The black ash method will be used. 12

Mexico.—Two companies announced plans to build production facilities in the North. CPC planned to build a strontium carbonate plant in Reinosa, Tamaulipas, close to the U.S. border. Capacity should be about 22,000 tons per year.¹³ Quimica Dinámica SA de CV, a Monterrey company that currently produces 8,000 tons of strontium carbonate, formed a joint venture with an unnamed Japanese company to create Cistron Mexicana SA de CV. The new company is expected to build a strontium carbonate plant initially designed to produce 30,000 tons per year, with a possible doubling of capacity in a second phase of construction.¹⁴

Strontium carbonate production has been a recent development in Mexico. This is a very attractive location for additional production facilities because of the huge celestite resources in the country. After a major U.S. strontium carbonate and strontium nitrate producer (FMC Corp.) closed its plant in 1984, Cia. Minera La Valenciana SA (CMV) bought the strontium carbonate processing equipment from the FMC plant in California. The plant, which utilized the soda ash method of carbonate production and was converted to the black ash method, was relocated to Torreón in Coahuila State, near a company-operated mine. The plant capacity is 50,000 tons per year. Shipments from the plant, targeted for the television and electronics industry in the Far East, commenced in May 1987. Sales y Oxidos (SYOSA), 49% owned by Kali-Chemie, built a new strontium carbonate plant near Monterrey with the capacity of 15,000 tons per year. The company's old strontium carbonate operation will be converted to produce barium carbonate. SYOSA, which produced carbonate by the black ash method from celestite it mines nearby, marketed its production in the United States. 15

Mexico was one of the world's largest producers of celestite in 1990. The most recent Directory of Mexican Non-Metallic Minerals Trust lists 11 companies currently mining celestite. CMV mined celestite from the San Agustín deposit near Torreón, and Compañía Minera Ocampo SA mined a deposit near Saltillo in Nuevo Leon State, as well as some small production in Hidalgo, Aguascalientes, and Chihuahua States. Reserves of the San Augustín Mine alone have been estimated at more than 725,000 tons. SYOSA mines west of Monterrey. Other small operations occur in Coahuila, Aguascalientes, Chihuahua, and Nuevo Leon. Mexican celestite is primarily high grade, and only hand sorting is required to achieve at least 92% strontium sulfate with low barium content. Abandoned mines and easily identified deposits that have not yet been developed are common throughout a large area in northern Mexico. Reserves are believed to be vast, but these deposits have not been extensively explored. 16

Pakistan.—All mines in Pakistan are the property of Provincial governments and are operated by private companies for the governments. Recent celestite production figures have been reported for two active mines, one near Dawood Khail and one near Karachi. 17 Tawakkal Mineral Exports Corp. recovered celestite from these mines in the Dadu District of Sind Province. No beneficiation was necessary to produce 94% strontium sulfate. Reserves of celestite have not been quantified at this location. 18 Other deposits, with 500,000 tons of reported reserves, have been identified in the Punjab Province. 19

Spain.—Spain was another of the largest celestite producers worldwide. Celestite was produced from the Montevive deposit, which was operated by Herederos

¹Table includes data available through May 24, 1991.

²In addition to the countries listed, China, Poland, and the U.S.S.R. produce strontium minerals, but output is not reported quantitatively, and available information is inadequate to make reliable estimates of output levels.

³Data are for year beginning Mar. 21 of that stated.

de Aurelio Farjardo Vilches, with sales and marketing handled by Bruno SA. Selective mining and hand sorting was all that was necessary to produce ore grades of more than 92% strontium sulfate. although a concentration plant has been constructed. Reserves are believed to be at least 2 million tons. Most Spanish production is exported to Japan, some remains in Spain, and the rest is exported to the Federal Republic of Germany.²⁰ Promotora de Industria del Sur (Proinsur SA) produced strontium carbonate and strontium nitrate at a combined facility near Granada. The plant has a theoretical design capacity of 8,000 tons per year of carbonate, but has never reached this capacity. Strontium carbonate was produced by the soda ash method. The plant also has a production capacity of about 3,000 tons per year of nitrate, which has not yet been fully utilized.²¹

Turkey.—Turkey competes with Mexico, Spain, and Iran in claiming the world's largest strontium reserves. Barit Maden Turk AS produced celestite from a mine near Sivas. Run-of-mine ore was gravity separated to produce a concentrate with a minimum of 95% strontium sulfate. Because of the harsh climate in the region, the mine can only be operated on a seasonal basis, from May to October. Another mine near Sivas was formerly operated by Bilfer Madencilik AS, which reestablished concessions for future celestite mining. Identified reserves have been placed at 550,000 tons, and further reserve potential is estimated to be greater than 2 million tons. Turkish celestite was primarily exported to the Federal Republic of Germany.²²

U.S.S.R.—Very little is known about Soviet production of strontium minerals. Deposits are known in the Karakum Desert, Zaunguz Plateau; Permian deposits near Bashkir; caprocks of the Romy and Isachkov salt domes; Pinega area, Archangel Province; Yakutsk, eastern Siberia; and in Turkestan from eastern Fergana to the shores of the Caspian Sea, and from southeastern Bucharia to the shores of the Sea of Aral. Reserves are believed to be very large, but the ore grade is probably not high.²³ No details are available concerning the production of strontium carbonate in the U.S.S.R. except that there is production, probably from domestic celestite as well as from imports from Iran and Turkey.

United Kingdom.—Celestite deposits, which occur in the Bristol area, were mined by Bristol Minerals Co. Ltd. The ore is crushed, washed, and graded to achieve a product with 95% strontium sulfate. Reserve estimates vary from 100,000 to 500,000 tons. The British deposits continue to be encroached upon by large-scale housing developments, limiting possible exploitation of the minerals to the near future. This was one of the few sites where celestite deposits are not in remote locations.²⁴

Current Research

Strontium-90, a radioactive isotope of strontium, is a component of nuclear waste from reactors and nuclear fallout. It presents special problems for waste disposal and storage because it generates a significant amount of heat as it decays. When released into the atmosphere through nuclear testing or accidents, it easily enters the food supply in milk and vegetables because it is so similar chemically to calcium. Scientists at Argonne National Laboratory have developed a process for removing strontium-90 from liquid nuclear waste.

The method known as SREX dissolves more than 99.999% of the strontium-90 from the waste stream in a special solvent. Pure strontium-90 is then removed from the solvent with water or dilute acid. The recovered strontium-90 could be used in radio-isotopic thermal generators that are used in devices such as harbor markers, which require long-lasting, unattended power supplies.²⁵

OUTLOOK

The future continues to look bright for the strontium industry for the near term, although if both planned operations in Mexico are actually accomplished, a serious oversupply situation could occur. Continued growth is expected in the color television industry, and larger screens are expected to increase in popularity. Demand for strontium carbonate for television application should expand likewise. Other markets will probably continue at their current, slower rate. Development of a technology to produce an affordable flat television display could severely reduce the demand for strontium carbonate. Although a high-quality, large, flat screen is not yet available, small models are, and research continues to perfect the technology. The question remains whether a new display system can be developed that will be economically attractive to the general public. Initial devices are expected to find application in military hardware and other sophisticated medical and scientific instrumentation. Flat screen display systems may eventually replace cathode-ray tubes, and, at that point, strontium producers may experience a serious setback.

SULFUR

By David E. Morse

Mr. Morse, a physical scientist with 14 years U.S. Bureau of Mines experience, has been the commodity specialist for sulfur since 1981. Domestic survey data were prepared by Jessie G. Austin, mineral data assistant; and the international data table was prepared by Harold D. Willis, international data coordinator.

ulfur, through its major derivative sulfuric acid, ranks as one of the more important elements utilized by humanity as an industrial raw material. It is of prime importance to every sector of the world's industrial and fertilizer complexes. Sulfuric acid consumption has been regarded as one of the best indexes of a nation's industrial development.

The United States retained its position as the world's foremost producer and consumer of sulfur and sulfuric acid in 1990. Production from U.S. Frasch mines decreased slightly to about 3.7 million metric tons. Erection began on the structures to develop a major salt dome discovery on Federal lease block Main Pass 299 in the Gulf of Mexico, which had been acquired from the U.S. Department of the Interior in 1988. Main Pass 299 was the first new domestic Frasch mine to be built in more than 20 years.

Production of recovered elemental sulfur, a nondiscretionary byproduct of petroleum refining and natural gas processing, continued to increase and set a record-high production standard. Recovered elemental sulfur shipments to domestic consumers were greater than Frasch shipments. Recovered sulfur exports, primarily from California where sulfur supplies exceeded local demands, were higher than Frasch sulfur exports.

Byproduct sulfuric acid from the Nation's nonferrous smelters and roasters, essentially mandated by laws concerning sulfur dioxide (SO₂) emissions, supplied a significant quantity of sulfuric acid to the domestic merchant acid market. Marketing sulfuric acid continued to be difficult for some producers because smelters were near western copper mines and far from major sulfuric acid markets.

Total world production of sulfur in all forms decreased slightly compared

with that of 1989; Frasch sulfur output decreased because of a United Nation's trade embargo against Iraq that affected Iraqi output and reduced output in the United States and the U.S.S.R. Recovered elemental production increased in Asia and North America, decreased slightly in Western Europe because of declining production from gas plants, and held at a reduced level in Eastern Europe because of continuing technical problems at gas processing facilities in the U.S.S.R. Nearly five-eighths of the world's elemental sulfur production came from recovered sources; the quantity of sulfur supplied from these sources was dependent on the world demand for fuels and petroleum products, not on the demand for sulfur.

World consumption decreased slightly despite an increase in fertilizer manufacture use, especially in the fertilizer-producing countries of North Africa. Consumption for a myriad of industrial uses continued to be pressured by environmental constraints placed on the products produced or effluents from the chemical processes utilizing sulfur or its major derivative, sulfuric acid.

World trade of elemental sulfur increased by an estimated 1 million metric tons, but was about 1.8 million tons less than the quantity traded in 1988. Although individual country sulfur inventories showed important variations from yearend 1989, total world producers' stocks of elemental sulfur were reduced by about 1 million tons, a return to the annual decreases that had been characteristic of the 1980's.

DOMESTIC DATA COVERAGE

Domestic production data for sulfur are developed by the U.S. Bureau of

Mines from four separate, voluntary surveys of U.S. operations. Typical of these surveys is the "Elemental Sulfur" survey. Of the 173 operations to which a survey request was sent, 172 responded, representing 99.99% of the total production shown in tables 1 and 2. The production of the nonrespondent was estimated using prior production histories adjusted to reflect trends in output of its primary products.

BACKGROUND

Sulfur, known as brimstone, "the stone that burns," was used in small quantities for thousands of years. Ancients were probably first drawn to native sulfur by its bright yellow color and pungent odor. Early humanity used sulfur as a colorant for cave drawings, as a fumigant, for medicinal purposes, and as incense. As early as 2000 B.C., the Egyptians used sulfur in the bleaching of linen textiles. In the Odyssey, Homer refers to its use as a fumigant. During the Peloponnesian War, fifth century B.C., the Greeks employed the burning of a sulfur-pitch mixture to generate suffocating gases. The Romans combined brimstone with tar, pitch, and other combustible materials to produce the first incendiary weapons. Muslims during the "Golden Age of Arabic Science," from about A.D. 700, developed alchemy and were probably the first producers of sulfuric acid. Sulfur is a necessary ingredient in gunpowder. which was developed as a pyrotechnic in China by the 10th century. Gunpowder's introduction into Europe led to its use in warfare in the 14th century and made sulfur an important mineral commodity for the first time.

However, it was not until the birth of the science of chemistry in the 1700's and the growth of chemical industries

Estimated. Revised.

in the 1800's that sulfur became of major importance to the world outside of its use in warfare. Early chemists soon recognized the importance of sulfuric acid as the cheapest and most versatile of the mineral acids, and it rapidly became the most common acid in the chemical industry.

Sulfur is one of the few elements that occurs in the native, or elemental, state, It also occurs combined with iron and base metals as sulfide minerals and with the alkali metals and alkali earths as sulfate minerals. In petroleum, sulfur is found in a variety of complex organic compounds and in natural gas as hydrogen sulfide (H₂S) gas. In coal, sulfur occurs in complex organic compounds

and as "coal brasses" (pyrites-marcasite). Commercial production of sulfur in the United States is accomplished by a variety of methods dictated by the source of sulfur.

Definitions, Grades, and **Specifications**

Native Sulfur.—Sulfur occurring in nature in the elemental form.

Pyrites.—Iron sulfide minerals that include pyrite, marcasite, and pyrrhotite.

Sulfur Ore.—Unprocessed ore containing native sulfur.

Elemental Sulfur.—Processed sulfur in the elemental form produced from native sulfur or combined sulfur sources. generally with a minimum sulfur content of 99.5%.

Frasch Sulfur.—Elemental sulfur produced from native sulfur sources by the Frasch mining process.

Recovered Sulfur.—Elemental sulfur produced from combined sulfur sources by whatever method.

Crude Sulfur.—Commercial nomenclature for elemental sulfur.

Brimstone.—Synonymous with crude

Broken Sulfur.—Solid crude sulfur crushed to minus 8-inch size.

Slated Sulfur.—Solid crude sulfur in the form of slatelike lumps produced by allowing molten sulfur to solidify on water-cooled, moving belt.

Prilled Sulfur.—Solid crude sulfur in the form of pellets produced by cooling molten sulfur with air or water.

Bright Sulfur.—Crude sulfur free of discoloring impurities and bright yellow in color.

Dark Sulfur.—Crude sulfur discolored by minor quantities of hydrocarbons ranging up to 0.3% carbon content.

Sulfuric Acid.—Sulfuric acid of commerce produced from all sources of sulfur, generally reported in terms of 100% H₂SO₄ with a 32.69% sulfur content.

Products for Trade and Industry

Elemental sulfur of commerce, sometimes called crude sulfur or brimstone, may be marketed in either the liquid or the solid phase, generally with a minimum sulfur content of 99.55%. Most elemental sulfur marketed in North America is sold as liquid sulfur. In worldwide commerce, sulfur is shipped either as broken sulfur or formed sulfur. Formed sulfur-prills, slates and pastilles—is generally preferred to broken sulfur because it is less prone to dusting and the release of fugitive dust at terminals where sulfur is stored and

FIGURE 1
TRENDS IN THE SULFUR INDUSTRY IN THE UNITED STATES

transferred from one transportation mode to another. Sulfuric acid may be sold at various strengths, usually depending on the requirements of the consumer. The acid is generally marketed on a 100% basis, but is normally shipped at 66° Baume (93% $\rm H_2SO_4$), as 98% acid, or as 20% to 22% fuming oleum, which is sulfur trioxide dissolved in sulfuric acid.

Industry Structure

Over the centuries, many fundamental changes have occurred in the sources of sulfur supply. Early civilizations obtained their meager requirements from native sulfur deposits in or around volcanoes. The increase in demand for sulfur in the late 1700's and early 1800's was largely satisfied from extensive native sulfur deposits in Sicily. Monopolistic practices by the owners of sulfur-mining facilities in Sicily, which led to exorbitant sulfur prices, caused consumers to adopt iron pyrites as the second major sulfur source during the mid- to late-19th century. The development in 1895 of the Frasch process for mining the large native deposits associated with salt domes in Louisiana and Texas brought a new and important source of sulfur to the United States and world markets. Frasch sulfur and pyrites maintained their joint predominance as world sulfur sources through the mid-1970's.

With small beginnings in the 1930's and increasing significantly from the 1950's onward, environmentally mandated or involuntary sulfur from natural gas processing and petroleum refining grew to surpass Frasch sulfur and pyrites as the world's major source of sulfur. In addition, increasing quantities of byproduct sulfuric acid from smelting operations have been produced to comply with pollution control laws and environmental regulations worldwide.

Sulfur in its various forms is produced worldwide, with no single nation predominating as a producer or supplier to world markets. In 1990, world sulfur production and consumption amounted to 57.7 and 58.9 million tons, respectively. The United States and the U.S.S.R. were the world's largest producers; both nations, however, were net importers of sulfur. Canada and Poland, respectively, the third and fourth largest world producers, ranked

first and second among the world's exporting nations. China, the world's fifth largest producer and largest pyrites producer, was the third largest sulfur consumer; China, however, satisfied most of its sulfur requirements from internal sources.

Geology-Resources

Sulfur is widely distributed in nature, constituting 0.060% of the Earth's crust. Sulfur combines with most other elements, except the inert gases and nitrogen. Practically all plant and animal life on Earth contains some sulfur. Only a very small portion of the world's sulfur resources occurs in sufficiently concentrated quantities to justify commercial extraction by mining or other recovery methods. Sulfur is one of the few substances found in the elemental form: it also occurs combined with other elements as sulfides, sulfates, or organic compounds in sedimentary, metamorphic, and igneous rocks, as well as in all fossil fuels. By type, sulfur deposits are classified as follows:

Native (Elemental) Sulfur Deposits.— These include deposits (1) in anhydritelimestone cap-rock on the top and flanks of salt domes, (2) in bedded anhydritegypsum evaporite basin formations, and (3) in unconsolidated volcanic deposits. In salt dome cap-rock and evaporite beds, the sulfur is believed to have been formed by hydrocarbon reduction of anhydrite, assisted by bacterial action. Volcanic sulfur was produced by the reaction between escaping hydrogen sulfide and sulfur dioxide.

Large deposits over salt domes are mined in the gulf coast regions of the United States and Mexico. Extensive deposits in evaporites are mined in west Texas, Iraq, Poland, and the U.S.S.R. Together, these deposits are by far the principle source of mined elemental sulfur, generally extracted by the Frasch hotwater process. Most volcanic sulfur occurrences are in the circum-Pacific belt. Volcanic sulfur deposits are locally important, but furnish only a minor portion of the world's sulfur supply.

Sulfide Deposits.—These include deposits of (1) ferrous sulfides (pyrite, marcasite, and pyrrhotite) that, while they may contain minor quantities of nonferrous metals, are generally mined

and processed for their sulfur content and (2) nonferrous metal sulfides, which are mined for their metal content and in the processing produce sulfur in the form of sulfuric acid. In order of importance from the quantity of acid produced, sulfide minerals of copper, lead, zinc, molybdenum, nickel, mercury, arsenic, antimony, and silver are the most noted in the nonferrous sulfide group.

Sulfate Deposits.—These include bedded deposits of anhydrite and gypsum. Although they are mined on a large scale worldwide for their mineral content, they represent one of the world's largest, yet virtually untapped, sulfur resource. Existing technology can recover elemental sulfur from these sources, but the economics are presently unfavorable.

Natural Gas.—Hydrogen sulfide occurs as a component of natural gas in many parts of the world. To market this "sour" natural gas, the hydrogen sulfide must be removed and, consequently, as additional sour natural gasfields have been brought into production, elemental sulfur recovered from these fields has become a major source of world sulfur supply. Major deposits of sour natural gas occur in western Canada, the Near East, and the U.S.S.R.; substantial deposits occur in the mountain and gulf coast regions of the United States, in Mexico, France, the Federal Republic of Germany, and Venezuela.

Petroleum and Tar Sands.—Complex organic sulfur compounds occur as a component of petroleum and tar sands in a wide range of concentrations. In the refining of petroleum or bitumen from tar sands, a portion of the sulfur is removed and recovered in the elemental form. Because of environmental concerns, the portion of contained sulfur removed continues to increase annually. The vast petroleum reserves of the Near East contain high percentages of sulfur, as do many of the recent discoveries in Mexico and off the U.S. west coast. Additionally, Canadian tar sands constitute a major sulfur resource.

Coal and Oil Shale.—Sulfur occurs as pyrites or complex organosulfur compounds in varying concentrations

in both coal and oil shales. Although little sulfur is produced from these vast resources at present, the potential for large-scale output exists in the United States and in the rest of the world.

Economic Factors

During the past 20 years, world sulfur price leadership has shifted from dominance by the U.S. Frasch producers to the Canadian exporters. The transfer was aided in the 1980's by Canada's ability to export most of its production from the Port of Vancouver and by its willingness to ship large volumes of sulfur from vatted stocks. The maturation of Sultran Ltd., dealing almost exclusively with sulfur destined for the offshore market, into a well-organized and skilled transportation arm of the Canadian sulfur industry aided immeasurably in Canada's ascension to world price leadership.

In the United States, the quoted liquid Frasch sulfur price, f.o.b. terminal Tampa, FL, is the bench-mark price. Recovered sulfur producers, in many cases, consider the economic desirability of producing sulfur subordinate to the necessity of producing it. As a result, domestic recovered elemental sulfur producers normally offer sulfur at a price \$5 to \$15 per ton below the Tampa quote to ensure prompt sale and reduce storage costs. This marketing strategy has resulted in restricting Frasch sulfur sales from many market areas that they formerly served.

During the 1980's, the sulfur price showed a significant degree of volatility compared with its prior history (see figure 1). The worldwide recession of 1982 and the U.S. Department of Agriculture Payment In Kind program in 1983 reduced world sulfur production and demand. Tampa prices fell from \$147.50 per long ton to \$122.50 from mid-1982 to yearend 1983. Vancouver, British Columbia, export prices were down from \$127.50 in mid-1981 to \$85.50 in December 1983. Prices escalated rapidly in 1984 because of a tremendous increase in demand in the United States and worldwide. The quoted Frasch price at Tampa, FL, increased \$25 per long ton during the year, and the spot price from Vancouver, British Columbia, jumped \$60 per ton. A downward spiral began in mid-1986 because of a slight softening in demand and increased competition for world markets. The Tampa price decreased \$20 from August 1986 to September 1987, and Vancouver prices were off about \$37 during the same time period. Tampa prices were stable for about 1 year and then increased \$12.50 per long ton during the latter part of 1988. Vancouver prices declined another \$2 to \$3 per ton in late 1987 and held steady until the latter part of 1988 when they rose about \$10 per ton. In 1989, the posted price for liquid sulfur, exterminal Tampa, FL, began the year at \$142, decreased to \$138 per long ton in June, fell to \$130 in July. and dropped an additional \$12.50 per long ton in September to \$117.50. Spot prices and contract prices for sulfur, f.o.b. Vancouver, British Columbia, Canada, were \$100 to \$108 per metric ton during the first half of the year; Vancouver spot prices decreased to \$90 per ton in July, fell further to about \$80 per ton well before the end of the third-quarter, and remained at that level through the fourth-quarter.

Domestic and international sulfur price quotations increased steadily and substantially during 1990. The posted liquid Frasch price at Tampa, FL, was raised on three occasions, ending the year at \$140 per long ton. Vancouver, British Columbia, solid sulfur spot price indications at the end of 1990 were in the mid-\$90 per metric ton range.

ANNUAL REVIEW

Production

Frasch.—Native sulfur associated with the cap-rock of salt domes and in sedimentary deposits is mined by the Frasch hotwater method, in which the native sulfur is melted underground and brought to the surface by compressed air. In January 1990, the United States had five Frasch mines operating in Texas and Louisiana. Mines in Louisiana were Freeport Sulphur Co. at Garden Island Bay on the Mississippi River Delta and Grand Isle and Caminada Pass, 7 miles and 9 miles, respectively, offshore in the Gulf of Mexico. Mines in Texas were Pennzoil Sulphur Co. at Culberson and Texasgulf Inc. (TG) at Boling Dome in Wharton County. At yearend, the Frasch mining industry was operating at about

1988	85.95	93.18
1989	86.62	90.19
1990	80.14	80.14

Based on the average reported prices for elemental sulfur (Frasch and recovered), f.o.b. mine and/or plant, these prices reflect essentially 90% of the shipments of sulfur in all forms during 1971-90.

90% of rated capacity.

In December 1988, Freeport McMo-Ran Resource Partners, operator for a consortium that included the IMC Fertilizer Group Inc. and Felmont Oil Co., reported a geologic reserve of 50 million long tons of sulfur on its Federal lease block. Main Pass 299, which is offshore in the Gulf of Mexico 17 miles from the mouth of the Mississippi River. The announcement was based on the results of five exploratory holes. Additional drilling in 1989 that delineated the size of the salt dome deposit brought the total reserve to 67 million long tons, which made Main Pass 299 the second largest domestic sulfur deposit yet discovered. Freeport McMoRan began erecting the offshore platform for the mine in 1990. The company planned to ready Main Pass 299 for production by late 1991 or early 1992, which would require an investment of more than \$550 million. Pennzoil performed exploratory drilling operations on offshore Federal leases that it had acquired in 1988.

Frasch sulfur output decreased

160,000 tons from the quantity produced in 1989. Total shipments to domestic and overseas consumers decreased by more than 100,000 tons. Frasch sulfur accounted for 32% of domestic production in 1990. Approximately 91% of Frasch sulfur shipments was for domestic consumption and 9% for export. The total value of Frasch sulfur shipments decreased by more than \$40 million.

Recovered.—Recovered elemental sulfur, a nondiscretionary byproduct from petroleum refining, natural gas processing, and coking plants, was produced primarily to comply with environmental regulations that were applicable directly to emissions from the processing facility or indirectly by restricting the sulfur content of the fuels sold or used by the facility. Fuel processing plants accounted for 57% of the total domestic output of sulfur in all forms compared with 56% in 1989. Production and shipments reached alltime high levels owing to record production from the Nation's petroleum refineries. Production and shipments from natural gas processing plants declined primarily because of lengthy maintenance periods at two of the largest facilities. Recovered elemental sulfur was produced by 58 companies at 151 plants in 26 States, 1 plant in Puerto Rico, and 1 plant in the U.S. Virgin Islands.

Most of these plants were of relatively small size, with only 15 reporting an annual production exceeding 100,000 tons. By source, 64% was produced at 84 refineries or satellite plants treating refinery gases and 3 coking plants. The remainder was produced by 27 companies at 64 natural gas treatment plants. The five largest recovered-sulfur producers in 1990 were Chevron U.S.A. Inc., Exxon Co. U.S.A., Shell Oil Co., Standard Oil Co. (Indiana), and Star Enterprise. The 51 plants owned by these companies accounted for 57% of recovered elemental sulfur output during the year.

Byproduct Sulfuric Acid.—Byproduct sulfuric acid at copper, lead, molybdenum, and zinc roasters and smelters amounted to 11% of the total domestic production of sulfur in all forms. Seven acid plants operated in conjunction with copper smelters, and eight were accessories to lead, molybdenum, and zinc smelting and roasting operations. The five largest acid plants accounted for 73% of the output, and production in

five States was 89% of the total. The five largest producers of byproduct sulfuric acid were ASARCO Incorporated, Cyprus Miami Mining Corp., Kennecott, Magma Copper Co., and Phelps Dodge Corp. Their eight plants produced 87% of the 1990 total.

Pyrites, Hydrogen Sulfide, and Sulfur Dioxide.—The total sulfur contained in these products did not constitute a significant portion of total domestic sulfur production.

Consumptiom and Uses

Domestic consumption of sulfur in all forms continued the strong performance exhibited in 1988 and 1989. In 1990, 80% of the sulfur consumed was obtained from domestic sources compared with 82% in 1989 and 84% in 1988. The sources of supply were domestic recovered elemental sulfur, 45%; domestic Frasch sulfur, 25%; and combined domestic byproduct sulfuric acid, pyrites, hydrogen sulfide, and sulfur dioxide, 10%. The remaining 20% was supplied by imports of Frasch and recovered elemental sulfur.

The U.S. Bureau of Mines collected end-use data on sulfur and sulfuric acid according to the Standard Industrial

Classification of industrial activities. Shipments by end use of elemental sulfur were reported by 60 companies, and shipments of sulfuric acid were reported by 53 companies. Shipments of both elemental sulfur and sulfuric acid were reported by seven companies.

Sulfur differs from most other major mineral commodities in that its primary use is as a chemical reagent rather than a component of a finished product. Its predominant use as a chemical reagent generally required that it first be converted to an intermediate chemical product prior to its initial use by industry. The largest sulfur end use, sulfuric acid, represented 86% of shipments for domestic consumption.

Some identified sulfur end uses were tabulated in the "Unidentified" category because these data were proprietary. Data collected from companies that did not identify shipment by end use were also tabulated as "Unidentified." Although there is no support-

ing data, it could be reasonably assumed that a significant portion of the sulfur in the "Unidentified" category was shipped to sulfuric acid producers or was exported. The difference between exports reported in the canvass and exports of 0.97 million tons reported by the Bureau of the Census may have been caused by differences in accounting between company records and compilations by the Census Bureau or by sales to other parties that exported sulfur and were not included in the U.S. Bureau of Mines canvass.

Sulfuric acid, because of its desirable properties, retained its position, both domestically and worldwide, as the most universally used mineral acid and the largest volume inorganic chemical in terms of the quantity produced and consumed. U.S. shipments of sulfuric acid (100% basis) increased by more than 100,000 tons in 1990 because of continued high demand for the production of phosphoric acid, the largest

single end use. Sulfuric acid demand for copper ore leaching, the second largest end use, increased 158,000 tons to about 2 million tons because solvent extraction-electrowinning (SX-EW) operations could produce high-purity copper at a significantly lower cost than by conventional smelting methods. Reported shipments of sulfuric acid for petroleum refining and other petroleum and coal products decreased significantly from those of 1990.

According to the 1990 canvass reports, company receipt of spent or contaminated sulfuric acid for reclaiming totaled 2.6 million tons. The largest source of this spent acid continued to be the petroleum refining industry, which accounted for 55% of the total returned. About 1.0 million tons of spent acid was reclaimed from plastic and synthetic materials producers. The remaining reclaimed acid was from manufacturers of soaps and detergents, steel, industrial organic chemicals, inorganic chemicals, other chemical products, storage batteries, explosives, agricultural chemicals, and some unidentified sources.

The largest use of sulfur in all forms, for agricultural purposes, increased slightly from 9.1 million tons in 1989 to about 9.2 million tons. The quantity of sulfur needed to manufacture exported agricultural chemicals decreased by more than 150,000 tons to 4.5 million tons, indicating that consumption for domestic purposes, especially for phosphatic fertilizers, increased by more than 250,000 tons.

Stocks

Yearend inventories held by Frasch and recovered elemental sulfur producers increased 9% from those of 1989, but remained well below historical levels. Combined yearend stocks amounted to approximately a 50-day supply compared with a 45-day supply in 1989, a 38-day supply in 1988, and an 82-day supply in 1987, based on domestic and export demands for Frasch and recovered sulfur.

Markets and Prices

The posted price for liquid sulfur, exterminal Tampa, FL, began the year at \$123 and increased to \$128 per long ton in May because of the continued strong showing of the Florida phosphate industry. Canadian sulfur exporters, encouraged by first half 1990 sales, expected to recoup part of their 1989

price concessions in the second half of the year. While international buyers of sulfur were resisting Canadian price ideas, Iraq invaded Kuwait in early August. The United Nations Security Council called for all member nations to embargo trade with Iraq, which essentially removed the annual 1.5- to 1.7-million-ton Iraq-Kuwait sulfur exports from international commerce. Sulfur consumers, who had been resisting Canadian pricing, settled shortly after the Iraqi takeover of Kuwait. The posted price, Tampa, FL, was increased \$6 per long ton in September and an additional \$6 per long ton in December. ending the year at \$140 per long ton.

On the basis of total shipments and value reported to the U.S. Bureau of Mines, the average value of shipments of Frasch sulfur, f.o.b. mine, for domestic consumption and exports combined decreased from \$100.18 to \$91.17 per ton. The average value, f.o.b. plant, for shipments of recovered elemental sulfur varied widely by geographic region: lowest in the Rocky Mountain States, higher on the west coast, somewhat higher in the midcontinent, and near the values for Frasch sulfur in the East and South. The disproportionately low average value for Wyoming distorted the average calculation for all recovered elemental sulfur shipments.

Foreign Trade

Exports of elemental sulfur from the United States, including the U.S. Virgin Islands, decreased 5% in quantity, but increased slightly in value. According to the Bureau of the Census, exports from the west coast were 550,000 tons or 57% of total U.S. exports.

The United States continued to be a net importer of sulfur; imports exceeded exports by more than 1.6 million tons in 1989. Frasch sulfur from Mexico and recovered elemental sulfur from Canada, both delivered to U.S. terminals and consumers in the liquid phase, continued to furnish nearly all U.S. sulfur import requirements. Total elemental sulfur imports increased 14% in quantity; imports by rail from Canada increased 24%, while waterborne shipments from Mexico were slightly higher than those in 1989.

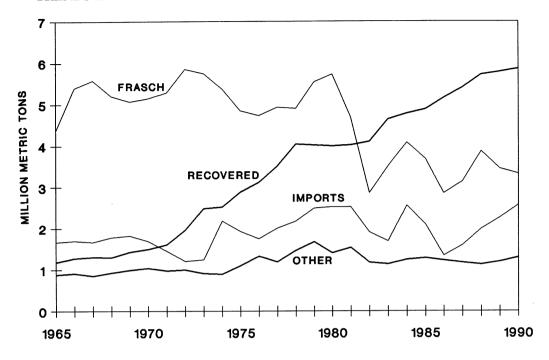

The United States also had significant trade in sulfuric acid. Sulfuric acid exports increased slightly from those of 1989. Imports, which were significantly

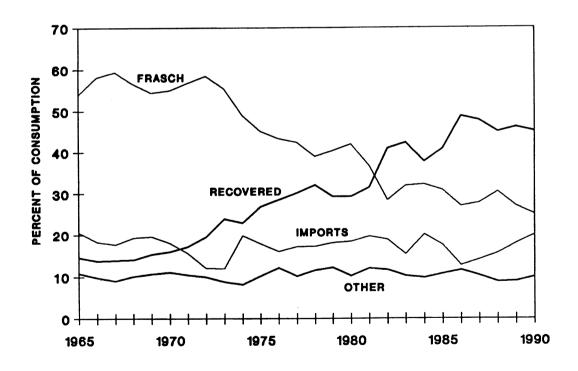

¹ Crude sulfur or sulfur content.

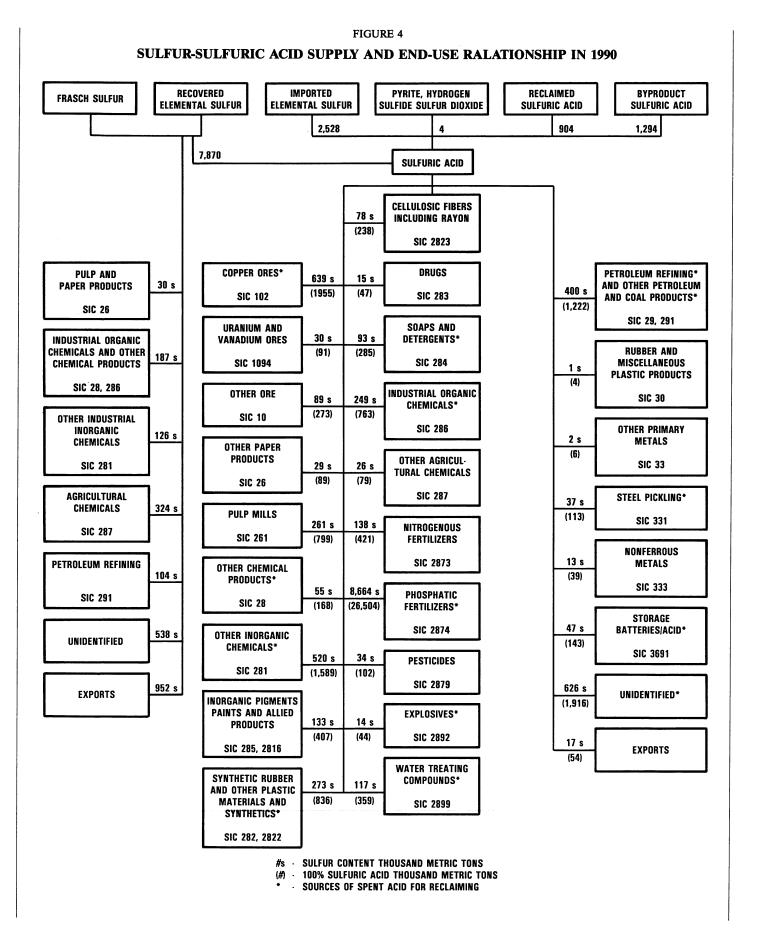

²Includes Puerto Rico and the Virgin Islands.

³ Includes consumption of hydrogen sulfide, liquid sulfur dioxide, and data indicated by symbol W.

FIGURE 3
TRENDS IN THE CONSUMPTION OF SULFUR IN THE UNITED STATES

greater than exports, were mostly by rail from Canada. The tonnage increased 35% from the quantity reported in 1989; the value of imported sulfuric acid, however, increased by 45%. Approximately 520,000 tons of acid was imported into the Tampa, FL, area, which more than doubled the Tampa acid imports of the previous year. Two sulfuric acid terminals had been established there in 1989.

World Review

Industry Structure.—In 1990, the sulfur industry was divided into two sectors, discretionary and nondiscretionary. In one, the mining of sulfur or pyrites was the sole objective; this voluntary production of native sulfur or pyrites was based on the orderly mining

of discrete deposits, with the objective of obtaining as nearly a complete recovery of the resource as economic conditions permit. In the other, sulfur or sulfuric acid was recovered as an involuntary byproduct, the quantity of output subject to demand for the primary product irrespective of sulfur demand. In 1990, involuntary sources represented about 65% of the elemental sulfur produced worldwide, and the combination of recovered elemental sulfur and byproduct sulfuric acid equaled more than 58% of total world production of sulfur in all forms.

Large quantities of Frasch sulfur were produced from mines in only five countries: Iraq, Mexico, Poland, the U.S.S.R, and the United States. Poland and the U.S.S.R. also produced signif-

lic of South Africa and an important source in Scandinavia and the U.S.S.R. Recovered elemental sulfur was the predominant sulfur source in Canada, France, the Federal Republic of Germany, Kuwait, Saudi Arabia, and the United States. Additionally, recovered elemental sulfur was an important source in Iran, Iraq, Japan, and the

U.S.S.R.

icant quantities of native sulfur using

conventional mining techniques; small

quantities of native sulfur were pro-

duced in Asia, Europe, and South

America. Pyrites were the prime sulfur

source in China, Spain, and the Repub-

International sulfur trade was dominated by a limited number of exporting countries; exports from Canada, Poland, Saudi Arabia, Mexico, the United States, the Federal Republic of Germany, Iraq, and France, in descending order of the quantity shipped, accounted for 90% of sulfur trade in 1990. Major sulfur importers in 1990 were the United States, Morocco, India, the U.S.S.R., Tunisia, Brazil, the United Kingdom, France, and Jordan, in descending order of importance.

Capacity.—The data in table 21 are rated capacity for Frasch mines, elemental sulfur mining facilities and attendant beneficiation plants, pyrites mines and plants, sulfur and/or sulfuric acid recovery units associated with petroleum refineries, natural gas processing plants, metal smelting operations, electric powerplants, and coke ovens as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the facility, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with a minimum of capital expenditure. Rated capacity is not equivalent to engineering (design) capacity of installed equipment.

Frasch mines operate continuously, and capacity is related to the quantity of superheated water that can be injected into the associated sulfur deposit. The nature of Frasch mining

makes capacity quite variable over time and depends on the number of "steaming wells," water injection rates, water losses from the formation, location of wells within the deposit, and length of time that the deposit has been worked. The rated capacity or realizable capacity of a Frasch mine generally decreases as the deposit becomes depleted.

Petroleum refineries—large, very costly, and complex processing facilities designed to produce a spectrum of fuels and petrochemical products—operate continuously. Sulfur recovery units make up only a small segment of these facilities; because sulfur recovery is mandated by environmental considerations, the installed sulfur recovery capacity at petroleum refineries generally exceeds the expected sulfur production. To ensure that the loss of a sulfur recovery unit does not require the shutdown of the entire refinery, multiple sulfur recovery units, each capable of servicing the petroleum refinery, are installed. The quantity of sulfur recovered by domestic petroleum refineries in the United States during 1990 was

equal to slightly more than 50% of the installed engineering capacity. Rated capacity for petroleum refineries is assumed to be 50% of installed engineering capacity.

Natural gas processing plants may be installed to service gasfields and/or oil-fields that contain significant quantities of associated gas. Gas plants are designed to accommodate the natural gas from a specific field that may contain, in addition to methane, which is sold as pipeline gas, varying amounts of nitrogen, carbon dioxide, helium,

condensable hydrocarbon liquids, and poisonous hydrogen sulfide. The poisonous nature of hydrogen sulfide makes its removal from pipeline gas imperative. Sulfur removal and recovery plants in natural gas facilities vary in size from small units rated at 5 to 10 tons per day to multiple-train plants capable of recovering thousands of tons per day. In general, sulfur recovery rates from gasfields approximate installed engineering capacity, based on a 340- to 345-day-per-year operation of all units, in the first 7 years of operation. In succeeding years, sulfur recovery declines steadily because the gas apparently becomes "sweeter" over time and because gas flow rates drop as the field is depleted. Rated capacity for gas processing plants is based on the age of the plant and its recent production history.

Rated capacity for plants operating in conjunction with metal smelters, powerplants, and coking operations is assumed to approximate engineering capacity. Where information on design capacity is unknown, rated capacity was estimated to be equal to the greatest output recorded by a plant or country in the past 5 years. World rated sulfur annual production capacity is significantly lower than the installed world engineering capacity of approximately 91 million tons.

Canada.—Shipments of sulfur in all forms were about 7.9 million tons, or 1 million tons greater than production. Elemental sulfur exports increased from 5.8 million tons in 1989 to 6.3 million tons in 1990; offshore exports from Vancouver, British Columbia, increased from 4.65 million tons in 1989 to about 4.85 million tons; Canada remained the world's largest sulfur exporting country.

Natural gas processing plants in Alberta continued to supply the major share of Canadian sulfur production. In Alberta, gas-recovered sulfur output increased slightly to 4.77 million tons. Sulfur production from gas plants in British Columbia increased to a record high of more than 412,000 tons.

leum Ltd., and Shell Canada Ltd. began test operations on the Bearberry, Alberta, demonstration project to develop the capability to extract sulfur from the field's ultrasour gas (90% H₂S). A 200-ton-per-day pilot plant was completed in late 1990, and a 5-year study was planned by the developers. The sulfur resource at Bearberry was estimated to be between 70 and 100 million tons.

Shell Canada received approval for its plan to develop the Caroline gascondensate field near Sundre, Alberta. The Caroline field has been estimated to contain about 2 trillion cubic feet of sour natural gas (30% to 35% H₂S), and development of the field was expected to be completed during 1993.

Iraq.—Sulfur production and exports were adversely affected by the United Nation's trade embargo that was instituted after Iraq invaded Kuwait in early August.

Mexico.—Frasch sulfur production decreased slightly from that of 1989.

Efforts continued to expand production from the recently commissioned Otapan Mine, and exploration for new resources continued. Sulfur imports from Canada and the U.S. west coast were about 490,000 tons, which did not appear in official Mexican trade statistics.

Morocco.—Morocco was a major world importer of elemental sulfur because of consumption at its phosphate fertilizer facilities at Safi and Jorf Lasfar. Imports increased from 0.96 million tons in 1989 to approximately 2.38 million tons in 1990. A major dispute concerning phosphoric acid prices and exports to India in 1989 had curtailed phosphoric acid production and the need for sulfur imports.

Poland—Sulfur exports increased from 3.65 million tons in 1989 to 3.81 million tons. Approximately 1.5 million tons was shipped to Eastern Europe and 0.7 million tons to Western Europe; most of the remainder was shipped to Brazil, India, Morocco, and

Tunisia.

Poland was the largest world producer of native sulfur, with major mines at Jeziorko, Grzybow, and Machow. The Machow open pit mine continued to operate with an ever increasing overburden to sulfur ore stripping ratio; because of the social, political, and economic restructuring that began in Poland during 1990, Machow may have a limited life. The construction of the new Osiek Mine was delayed for environmental reasons. The mine should come on-stream in two phases, one in 1992 and the second in 1993.

Saudi Arabia.—Sulfur production from natural gas processing plants and oil refineries increased slightly. Exports increased substantially from 939,000 tons in 1989 to 1.61 million tons. India, Morocco, and Tunisia received about three-fourths of Saudi sulfur exports.

U.S.S.R.—Production of sulfur in all forms decreased substantially. Technical problems and environmental con-

cerns continued to restrict the output from Astrakhan natural gas processing facility to 25% of capacity. Although construction on the second phase to double the size of the Astrakhan facility was complete, the second phase was not commissioned because of the problems plaguing the first phase. The first of three gas processing plants at the Tengiz oil-gas-condensate field near the northeast shore of the Caspian Sea was completed; each plant had a design annual sulfur capacity of 450,000 tons.

OUTLOOK

World sulfur demand, from 1991 to the year 2000, is forecast to increase at an annual rate of 1.4% to 1.8% per year. World demand is projected to attain 63.5 million tons in 1995 and increase to more than 70 million tons in the year 2000. In the short term, U.S. sulfur demand is forecast to decline from 13.1 million tons consumed in 1990; demand will probably decrease to 12.4 million tons in 1991 and increase only marginally thereafter. U.S. sulfur demand is forecast to be 12.5 million tons in 1995 and reach 13.2 million tons in the year 2000.

Agriculture is by far the most important of the sulfur end-use categories. accounting for more than 70% of U.S. demand and 57% of world consumption. The principal individual requirement is for the manufacture of phosphatic fertilizers, in which sulfuric acid is the essential intermediate chemical product. The production of phosphoric acid by the wet acid process involves the acidulation of phosphate rock with sulfuric acid. The phosphoric acid is primarily an intermediate product that is used to manufacture a spectrum of high-grade fertilizers; the acid itself may also be used for direct application to soil to supply the needed plant nutrition. Other fertilizers that require sulfuric acid in their production, but in comparably lower quantities, include ammonium and potassium sulfates and single super phosphate, which is produced by the partial acidulation of phosphate rock to form a lower analysis fertilizer, on a nutrient basis, than is produced from phosphoric acid. Nonfertilizer sulfur uses in agriculture include direct application of sulfur and

sulfuric acid to soils, pesticide manufacture, and for animal feed supplements. More than 90% of U.S. agricultural sulfur demand and about 80% of world agricultural sulfur consumption was for the manufacture of phosphoric acid in 1990.

World demand for phosphate fertilizers is forecast to increase at an annual rate of slightly less than 2% for the remainder of the century. It is assumed that 90% of the growth will be for the production of phosphoric acid to produce high-analysis fertilizers, which will

directly affect world sulfur demand. Consumption of sulfur for phosphate fertilizer manufacture in the United States is divided into two main components: (1) demand for phosphate fertilizers consumed by domestic farmers and (2) demand for exported phosphate fertilizers. In 1990, 4.5 million tons of sulfur was required to manufacture the phosphatic fertilizers exported from the United States compared with 3.91 million tons of sulfur for domestic phosphoric fertilizer use. Sulfur demand for domestically consumed phosphates is forecast to increase to about 4.8 million tons by 1995 and remain relatively stable thereafter. The export component is not expected to repeat the strong performance of 1990 until sometime after 1995, if at all during the 1990's, because of increasing foreign competition in world markets. U.S. sulfur consumption for agricultural purposes could drop significantly if domestic phosphate fertilizers' producers are not able to compete successfully in the international arena.

The broad spectrum industrial or nonagricultural sulfur use category accounted for about 30% of U.S. sulfur consumption and more than 43% of world sulfur demand. While significant variations in demand for the diverse elements within this broad category are expected in the United States and other geographic areas, world industrial demand is expected to average a 1% to 1.2% increase annually through the remainder of the century, reaching 28 million tons in the year 2000.

The necessity for the removal of sulfur from solid, liquid, and gaseous effluents for environmental protection has caused the production of sulfur and sulfur compounds from these sources to exceed production from primary sources of supply. The long-term prospect is that 85% or more of the world sulfur supply will come from environmentally regulated sources and that output from these sources will be produced regardless of world sulfur demand. As a result, it is probable that, after the turn of the century, no new operation that produces sulfur as its primary product will be developed, except where it may be deemed necessary for political or social reasons.

In 1980, voluntary sources of production, Frasch, native sulfur, and pyrites, accounted for 50% of world output of about 55 million tons. In 1990,

these same sources supplied only 37% of world production of 57.7 million tons. Not only did the voluntary producers share of production decrease, the volume of output fell by 3.62 million tons or more than 15%; U.S. Frasch production accounted for most of the drop, plunging from 6.39 million tons to 3.73 million tons. Additionally, world sulfur stocks fell from about 27 million tons to about 9 million tons during the period 1980-90; more than 17 million tons was removed from vatted Canadian stocks, which had been built during the 1970's at natural gas processing plants.

It is anticipated that, in the short term, world sulfur demand will surpass output and that stocks will continue to decline. A temporary severe shortage could develop by 1992. Any sulfur shortage would be of short duration because of the size and number of new production facilities planned or under development.

In Canada, projects nearing completion should raise output from existing gas plants 400,000 to 500,000 tons by

1992. The development of the Caroline gasfield should increase Canadian capacity by 1.2 million tons in 1993. The development of the Osiek Mine in Poland should result in a net increase in Polish sulfur output of 100,000 tons by 1993. The new associated gas processing facility at Tengiz (Tengiz I-1990, Tengiz II-1992, Tengiz III–1993) should be capable of producing 1.2 million tons per year by 1993. If the technical problems with Astrakhan I can be remedied, both Astrakhan I and II should be on-stream by yearend 1992, producing 4 million tons per year compared with the estimated 700,000 tons produced at Astrakhan in 1989. Freeport McMoRan plans to have its new Main Pass 299 mine on-stream by early 1992 and be producing at a rate of more than 2 million tons per year by early 1993, increasing U.S. Frasch capability 1 million tons compared with that of 1990. Net additions to world production from expansions and new facilities at oil refineries and gas processing plants should amount to several hundred thousand tons. A worldwide

Sulfur in all forms.

²The difference between total U.S. distribution of supply and total U.S. supply.

sulfur surplus will probably develop in 1993, a surplus that could persist for much of the remainder of the century. World sulfur production will likely attain a level of 68 million tons in 1995 and exceed 72 million tons in the year 2000.

^eEstimated. ^rRevised. W Withheld to avoid disclosing company proprietary data; included with "Byproduct: Unspecified sources." ¹Table includes data available through May 17, 1991.

³ The term "source" reflects both the means of collecting sulfur and the type of raw material. Sources listed include the following: (1) Frasch recovery; (2) native, comprising all production of elemental sulfur by traditional mining methods (thereby excluding Frasch); (3) pyrites (whether or not the sulfur is recovered in the elemental form or as acid); (4) byproduct recovery, either as elemental sulfur or as sulfur compounds from coal gasification, metallurgical operations, including associated coal processing, crude oil and natural gas extraction, petroleum refining, tar sand cleaning, and processing of spent oxide from stack-gas scrubbers; and (5) recovery from the processing of mined gypsum. Recovery of sulfur in the form of sulfuric acid from artificial gypsum produced as a byproduct of phosphatic fertilizer production is excluded because to include it would result in double counting. It should be noted that production of Frasch sulfur, other native sulfur, pyrites-derived sulfur, mined gypsum-derived sulfur, byproduct sulfur from extraction of crude oil and natural gas, and recovery from tar sands are all credited to the country of origin of the extracted raw material; in contrast, byproduct recovery from metallurgical operations, petroleum refineries, and spent oxides is credited to the nation where the recovery takes place, which in some instances is not the original source country of the crude product from which the sulfur is extracted.

 $^{^2}$ In addition to the countries listed, a number of nations may produce limited quantities of either elemental sulfur or compounds (chiefly H_2S or SO_2) as a byproduct of petroleum, natural gas, and/or metallurgical operations, but output, if any, is not quantitatively reported, and no basis is available for the formulation of reliable estimates of output. Countries not listed in this table that may recover byproduct sulfur from oil refining include Albania, Bangladesh, Brunei, Burma, Costa Rica, Guatemala, Honduras, Jamaica, Malaysia, Nicaragua, Paraguay, and the Republic of Yemen. Albania and Burma may also produce byproduct sulfur from crude oil and natural gas extraction. No complete listing of other nations that may produce byproduct sulfur from metallurgical operations (including processing of coal for metallurgical use) can be compiled, but the total of such output is considered as small. Nations listed in the table that may have production from sources other than those listed are identified by individual footnotes.

Data may not add to totals shown because of independent rounding.

⁵ Reported figure.

⁶ In addition, may produce limited quantities of byproduct sulfur from oil refining.

⁷ Includes only the elemental sulfur equivalent of sulfuric acid produced as a byproduct from metallurgical furnaces; additional output may be included under "Byproduct: Unspecified sources."

⁸ Includes recovery from gypsum, if any.

⁹Less than 1/2 unit.

¹⁰ Official Polish sources report total Frasch and native mined elemental sulfur output annually, undifferentiated; this figure has been divided between Frasch and other native sulfur on the basis of information obtained from supplementary sources.

¹¹ Estimates for 1986–90 include byproduct production from synthetic fuels.

TALC AND PYROPHYLLITE

By Robert L. Virta

Mr. Virta, a physical scientist with 15 years of U.S. Bureau of Mines experience, has been the commodity specialist for talc and pyrophyllite since 1986. Domestic survey data were prepared by Linder Roberts, mineral data assistant; and international data tables were prepared by William Zajac, Chief, Section, International Data.

omestic production of talc and pyrophyllite increased slightly from that of 1989 to 1,267,167 metric tons. Sales of crude and processed talc decreased 4% to 1,021,004 tons in tonnage and decreased 3% in value. Sales of pyrophyllite increased slightly. Imports for consumption decreased 17% in tonnage to 65,099 tons and decreased 9% in value to \$11,056,000. Exports decreased 25% in tonnage to 238,000 tons and increased 14% in value to \$32,909,000. During the past 10 years, talc and pyrophyllite production averaged 1,075,000 tons; sales, 972,000 tons; domestic consumption, 948,000 tons; exports, 242,000 tons; and imports, 49,000 tons. The major use for talc was in ceramics, which accounted for 28% of the domestic consumption, followed by paint, 18%; paper, 17%; roofing, 11%; plastics, 6%; and other, 20%. The major use for pyrophyllite was in ceramics, followed by refractories, insecticides, paint, plastics, and rubber.

DOMESTIC DATA COVERAGE

Domestic production and sales data for talc and pyrophyllite are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. mines and mills. Survey forms were sent to 18 companies that operated 52 mines and mills. Seventeen companies that account for approximately 99% of the domestic production responded to the survey. Production data for the nonrespondent were estimated from reported prior-year production levels adjusted by trends in employment and other guidelines.

ANNUAL REVIEW

Legislation and Government Programs

The Occupational Safety and Health Administration (OSHA) extended an administrative stay on its 1986 regulation governing worker exposure to the nonasbestiform varieties of actinolite, anthophyllite, and tremolite through August 31, 1991. During the stay, OSHA continued to analyze the impact of using the asbestos standard to regulate the nonasbestiform varieties of the minerals. An exposure limit of two fibers per cubic centimeter will remain in effect during the stay.¹

The Mine Safety and Health Administration (MSHA) continued to review its proposed revisions to its air quality, chemical substances, and respiratory pro-

¹Data may not add to totals shown because of independent rounding.

²Does not include value for pyrophyllite.

Excludes powders—talcum (in package), face, and compact.
 Production, plus imports, minus exports, plus adjustments in Government and industry stock. Does not include imported pyrophyllite.

tection standards. The proposed permissible 8-hour time weighted average exposure limit is 2.5 milligrams per cubic meter for talc (containing no asbestos), 3 milligrams per cubic meter for respirable soapstone, and 6 milligrams per cubic meter for total soapstone dust. The nonasbestiform varieties of tremolite, anthophyllite, and actinolite would be covered under the proposed respirable mine dust standard.²

MSHA issued a proposed rule that would create a hazard communication standard. Mine operators would be required to provide information to their employees concerning any hazards that chemicals, including talc, produced or used on the premises through labeling, material safety data sheets, and employee training.³

Issues

The health risk posed by nonasbestiform varieties of tremolite, anthophyllite, and actinolite continued to be a concern for a portion of the talc industry. OSHA is evaluating whether to regulate the nonasbestiform amphiboles as asbestos, regulate nonasbestiform amphiboles under a separate standard, or not to regulate nonasbestiform amphiboles.

Production

Talc.—Thirteen companies operating 22 mines in 10 States produced talc, soapstone, and steatite. These companies generally were structured to cover all aspects of talc mining, from mining to processing. Only a few companies hired custom grinders to mill the ore. The largest of the domestic producers were Cyprus Industrial Minerals Co. Inc., Dal Minerals, Gouverneur Talc Co., Montana Talc Co., and Pfizer Inc. The major producing deposits were in Montana, New York, Texas, and Vermont.

Commercial talc production was from deposits that were formed through hydrothermal alteration of ultrabasic rocks and low-grade metamorphism of siliceous dolomites. They generally occur as lenses or pods in the country rock. Magnesite, quartz, chlorite, magnetite, serpentine, anthophyllite, tremolite, dolomite, and actinolite may be present as accessory minerals.

Most of the domestic talc production was from open pit mining operations. Underground mining was used only

when a large waste rock to ore ratio made open pit mining uneconomical. Typically, overburden was removed, and blasting was used to fracture the ore. The companies then used selective mining and manual or automated sorting to produce a high-grade feed for the mill. Jaw crushers were used to reduce the size of the mill feed, and ball mills or roller mills were used to produce the final product. Fluid-energy mills or pulverizing mills were used for ultrafine grinding of the talc ore. In a few instances, the ore was calcined prior to milling to increase its whiteness.

Flotation processes were used when the desired product purity was not obtained by using conventional processing. The milled ore was chemically treated, passed through rougher and cleaner cells to separate the talc from the gangue material, dried in a flash dryer, and ground in a pulverizer. Ore composition, reagent type, pulp density, pH of the flotation system, and residence time in the flotation circuits determined flotation efficiency.

Cyprus Industrial Minerals Co. announced that it would close its Hammondsville mine. The decision to close the underground mine, which has operated for about 40 years, was made for safety and economic reasons.⁴

U.S. mine production of crude talc increased slightly in tonnage and 12% in value. Mines that operated in Montana, New York, Texas, and Vermont accounted for 96% of domestic talc production. Montana led all States in the tonnage and value of talc produced.

Pyrophyllite.—Pyrophyllite was pro-

duced by three companies operating four mines in two States. Production was from hydrothermally altered volcanic deposits of acidic composition. The deposits consisted of pyrophyllite with sericite, andalusite, and/or quartz as accessory minerals. After removing the overburden, the ore was either stripped using dozers and scrapers or extracted using conventional open pit mining techniques. The ore was dried, and then jaw crushers and gyratory crushers were used to reduce the size of the mill feed. Ball, pebble, or roller mills were used to produce the final product.

U.S. mine production of crude pyrophyllite increased slightly in tonnage. North Carolina accounted for most of the domestic production.

Consumption and Uses

Talc.—Talc was used in a wide variety of products because of its softness (1 on the Mohs scale), purity, fragrance retention, whiteness, luster, moisture content, oil and grease adsorption, chemical inertness, low electrical conductivity, high dielectric strength, and high thermal conductivity. These properties were not universal to all talcose materials because of differences in their mineralogical composition and particle shape. Mineral content was extremely important because it determined the end use for the material. Generally, only two or three of these properties were critical for any one application.

Talc was used as a filler in polypropylene compounds. It served to improve the modulus and impact strengths of the product, improve the stability of the

product under ultraviolet light, and reduce the price of the final product. Products had higher modulus and impact strengths, higher deflection temperatures under load, and lower coefficient of thermal expansion when finely ground talc was used with high crystallinity polypropylene.⁵

Domestic producers reported that overall sales (including direct exports) declined 4% in tonnage to 1,021,004 tons and 3% in value to \$110,584,808 in 1990. The major consumer of talc was the construction industry, with applications in ceramic tiles and sanitaryware, joint compounds, paint, plastics, and roofing. The end-use distribution was ceramics, 28%; paint, 18%; paper. 16%; roofing, 11%; plastics, 6%; cosmetics, 4%; and insecticides, refractories, rubber, and other, 17%. The greatest decrease in demand was in ceramics, cosmetics, and plastics applications. Some decline was expected due to a sluggish U.S. economy, but it is doubtful that the entire decrease can be attributed to a sluggish economy. It is likely that some sales to the ceramic, cosmetic, and plastic industries were reported under the "Other" category, which increased in 1990. More than 90% of the companies responded to the end-use portion of the 1990 annual representing approximately 95% of the data in table 3.

Pyrophyllite.—Pyrophyllite, being different in composition from talc, did not have the same applications as talc. Properties such as softness (1 to 2 on the Mohs scale), whiteness, chemical inertness, high melting point, low electrical conductivity, and high dielectric strength made pyrophyllitic materials useful for ceramics and refractories.

U.S. consumption of pyrophyllite increased slightly in tonnage in 1989. The largest portion of domestically produced ground pyrophyllite was used in ceramics, followed by refractories, insecticides, paint, plastics, and rubber. The end-use distribution did not change significantly from previous years.

Markets and Prices

Talc prices varied depending on the quality and on the degree and method of processing. The unit value of crude talc was \$25 per ton. The average unit value of processed talc was \$108 per ton. The average unit values of crude

and processed pyrophyllite were higher in 1990 than in 1989. Unit values for imported crude and ground talc ranged from \$33 per ton to \$410 per ton for quantities greater than 100 tons. The average unit value for all imported talc was \$170 per ton. Unit values for exported talc ranged from \$16 per ton to \$1,576 per ton for quantities greater than 100 tons and averaged \$138 per ton for all exports.

Prices, quoted by the American Paint & Coatings Journal, December 26, 1990, in U.S. dollars per metric ton for paint-grade talc in carload lots ranged from \$99 to \$243. Approximate equivalents, in dollars per metric ton, of price ranges quoted in Industrial Minerals (London), December 1990, for talc, c.i.f. main European ports, ranged from \$165 to \$336.

Foreign Trade

Talc exports decreased 25% in tonnage and increased 14% in value. Mexico remained the largest importer of talc, followed by Canada, Japan, and Belgium-Luxembourg. Talc imports decreased 17% in tonnage and 9% in value. Australia and Canada provided 82% of all talc imports.

World Review

The United States remained the world's largest talc producer, and Japan

remained the largest pyrophyllite producer. China, Japan, and the United States accounted for 43% of the world's tale and pyrophyllite production.

The production and consumption of

talc in Australia and East Asia was reviewed. The paper focussed on high-quality deposits in Australia, China, and the Republic of Korea, whose producers account for approximately one-third of the world's talc production. The region possesses large reserves, high-quality deposits, and a good location with regard to growing markets, although technological deficiencies and supply reliability are weaknesses of the industry.⁶

Capacity.—The data in table 6 are annual rated capacity for mines and refineries as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Australia.—South Australia supplied most of the talc for Australia's domestic demands despite accounting for only 9% of Australia's total production. Production comes primarily from the Mount Fitton deposit, 470 miles north of Adelaide. The Mount Fitton deposit was formed through the hydrothermal alteration of dolomite and marble rocks. It is 10 to 15 meters wide, 20 meters high, and several hundred meters long. Conventional open pit methods are used to mine the deposit. Approximately 70% of production is used in pharmaceutical and paint products.⁷

Ireland.—Ivernia West PLC acquired a major shareholding in Talc Technology Ltd., owner of the Westport talc deposit. The talc deposit is composed of 50% talc, 33% breunerite, 10% antigorite, 2% dolomite, and 5% magnesite and contains approximately 5.5 million tons of talc. If development permits are approved, the mine production initially will be 40,000 tons per year.⁸

Sweden.—Handöls Taljstens AB, now under private ownership, produces approximately 20,000 tons of talc-

chlorite for animal feed, roofing, plastics, and fertilizers. Research is being conducted to separate talc from chlorite through flotation processing. The processed talc will be suitable for paper applications. Primary tests indicate that the talc can be upgraded from 60% talc

to 97% talc with a brightness of 92% to 93%.9

Venezuela.—A talc deposit was discovered on Margarita Island, off the coast of Venezuela. Further investigations are being carried on the commercial viability of the deposit. Venezuela currently does not produce talc. 10

Current Research

The flotation process can be better controlled with the use of on-line monitoring. On-line processing enables the operator to immediately detect changes in the operation and make the necessary adjustments to ensure a constant product quality. X-ray fluoresence is used to determine elemental compositions of the flotation slurry at various stages in the flotation process. Greater control is obtained when coupled with on-line brightness determinations. ¹¹

The use of column flotation to process industrial minerals was reviewed. The paper discussed the processing of andalusite, chromite ore, fluorite, graphite, manganese oxide ore, phosphate ore, potash, and talc. A talc ore composed of 50% talc and ground to 80% less than 45 micrometers was upgraded to 73% talc by using two stages of column flotation. This result is a 6% improvement over conventional flotation using five stages. A Korean talc ore composed of 73% talc and ground to less than 45 micrometers was upgraded to 83% by using a single stage of column flotation. Recovery of the same ore using three stages of conventional flotation was 45% to 65%.12

OUTLOOK

The average annual growth in domestic demand for talc and pyrophyllite was 1.2% between 1981 and 1990. Demand averaged between 900,000 and 1,000,000 tons per year for this period. Relative increases and decreases in demand have been the result of minor market fluctuations rather than long-term trends. Demand for talc and pyrophyllite is expected to continue to fluctuate around 1 million tons per year in the near future.

Ceramics will continue to be the major domestic end use for talc, followed by consumption in paint, paper, plastics, roofing, and cosmetics, in de-

scending order. For pyrophyllite, the major domestic end uses will continue to be in ceramics and refractories.

¹ Table includes data available through May 14, 1991.

² In addition to the countries listed, Czechoslovakia and Turkey produce talc, but information is inadequate to make reliable estimates of output levels.

³ Total of beneficiated production, salable direct shipping production, and that consumed by producers.

Reported figure.
 Data based on Nepalese fiscal year beginning mid-July of year stated.

THALLIUM

By Thomas O. Llewellyn

Mr. Llewellyn, a physical scientist with the U.S. Bureau of Mines, has been the commodity specialist for thallium since 1987. Domestic survey data were prepared by Eraina C. Dixon, mineral data assistant.

n 1990, domestic demand for thallium metal was met by import. Thallium is a trace element with an estimated average abundance of 2.2 parts per million in zinc sulfide ores and is a byproduct recovered from flue dust and residues collected in the smelting of zinc as well as copper and lead. There are a number of rare thallium minerals found in nature that have no commercial importance as sources of thallium metal.

PRODUCTION

Although thallium was contained in ores mined or processed in the United States, it was not recovered domestically as a marketable product in 1990.

CONSUMPTION AND USES

Based on import data and discussions with metal traders, the domestic consumption of thallium in 1990 was estimated to be 700 kilograms, about 26% lower than that of 1989.

Thallium was used in superconductivity research, gamma radiation-detection equipment, additives for changing the refractive index and density of glass, low-temperature mercury-thallium alloy switches, high-density liquids, alloys, photosensitive devices, and radioactive isotopes for cardiovascular diagnostic procedures. It appears that all foreign countries have stopped using thallium sulfate as an ingredient in rodenticide because of its high toxicity to humans.

MARKETS AND PRICES

Thallium metal was sold at various | Source: Bureau of the Census.

prices during the year according to its purity. Metal traders reported that the average price of thallium metal in 100kilogram lots was \$190 per kilogram for 99.99%-pure thallium metal. The average value per kilogram of unwrought thallium metal and waste and scrap imported into the United States was estimated to be about \$137 per kilogram.

FOREIGN TRADE

In 1990, thallium materials were imported only from Belgium. Effective January 1, 1990, the import duty for unwrought thallium and waste and scrap (Harmonized Code 8112.91.6000) was 5.5% ad valorem for most favored nations (MFN) and 25% ad valorem for non-MFN.

Thallium producers are granted a depletion allowance of 14% on both domestic and foreign production.

TABLE 1

RESERVES

World production data for thallium were not available. The U.S. reserves in zinc ores were estimated to be about 32,000 kilograms. Rest-of-the-world reserves were estimated to be 345,000 kilograms of thallium.

CURRENT RESEARCH

The first patent in the United States for high-temperature superconductor compound formulations, based on thallium, was granted in 1989 to International Business Machines Corp., Armonk, NY.1 In 1990, researchers at the University of Arkansas, Fayettesville, AR, who were regarded as the discoverers of thallium-base superconductors were notified by the U.S. Patent Office that a patent would be issued for their thalliumbase superconductor formulations discovered in 1988.2 On June 27, 1990, E.I. du Pont de Nemours & Co., Wilmington, DE, received a U.S. patent for a high-temperature superconducting material containing thallium, barium, copper, and oxygen.3

TOXICITY

Thallium metal and its compounds are highly toxic; they should be handled with extreme care and require the use of rubber gloves. It can be absorbed into the human body by skin contact, ingestion, or by inhaling dust or fumes. The element is not quickly eliminated from the body; therefore, absorption of subtoxic quantities eventually may accumulate to a toxic level.

OUTLOOK

The United States is not expected to resume recovery of metal thallium within the next 2 to 5 years. The toxicity of thallium is the factor that was expected to continue to influence domestic dependence on foreign sources for its supply.

THORIUM

By James B. Hedrick

Mr. James B. Hedrick, a geologist and physical scientist with the Federal Government for 13 years, has been the commodity specialist for thorium since 1982. Domestic survey data were prepared by Mr. Kevin Bacon, mineral data assistant; and international data tables were prepared by Mr. Harold Willis, international data coordinator.

omestic consumption of refined thorium products increased. Thorium was recovered primarily from the rareearth ore monazite, a byproduct of processing heavy-mineral sands for titanium and zirconium minerals or tin minerals. Thorium was recovered as a byproduct during processing for the rare-earth elements. Only a small portion of the thorium produced worldwide is used: most is discarded as waste. Major monazite-producing countries were Australia, Brazil, China, India, Malaysia, the Republic of South Africa, Thailand, and the United States. None of the domestically produced monazite was refined in the United States. Essentially all of the thorium compounds and alloys used by the domestic industry were derived from either imports or U.S. Government stocks.

Limited demand for thorium, relative to the rare earths, continued to create an extensive world oversupply of thorium residues. Excess thorium, not designated for commercial use, was either stored for potential use as a nuclear fuel or disposed of as a radioactive waste. Major nonenergy uses were refractory applications and lighting applications. The only domestic thorium-fueled commercial reactor discontinued operation in late 1989 and was decommissioned during 1990.

Thorium's natural radioactivity represented a significant problem to those companies involved in its mining, processing, and use.

DOMESTIC DATA COVERAGE

Domestic mine production data for thorium-bearing monazite are developed by the U.S. Bureau of Mines from a vol-

untary survey of U.S. operations. This is the "Rare Earths, Thorium, and Scandium" survey. The one mine to which a survey form was sent responded, representing 100% of mine production. Mine production data for thorium are withheld to avoid disclosing company proprietary data. Statistics on domestic thorium consumption are developed by surveying various processors and end users, evaluating import-export data, and analyzing Government stockpile shipments.

LEGISLATION AND GOVERNMENT **PROGRAMS**

The calendar year 1990 included the U.S. Government fiscal years for 1990 and 1991. Public Law 101-189, the National Defense Authorization Act for Fiscal

entation of the Harmonized Tariff System begun in Jan. 1989, import and export catagories for 1989 and later are not necessarily comparable to those of previous years.

³All domestically consumed thorium was derived from imported metals, alloys, and compounds; monazite containing thorium has been imported annually but has not recently been used to produce thorium products. Source: Rhône-Poulenc, Inc.

Data withheld by company.

Years 1990 and 1991, continued the authorization for disposal of all stocks of thorium nitrate in excess of the National Defense Stockpile (NDS) goal of 272,155 kilograms (600,000 pounds). Thorium nitrate in excess to goal at yearend 1990 was 2,946,185 kilograms (6,495,225 pounds).

The National Defense Authorization Act also legislated a limit of \$180 million on the value of materials disposed of during each fiscal year.

PRODUCTION

Associated Minerals (USA) Ltd., a wholly owned subsidiary of the Australian-based firm Renison Goldfields Consolidated Ltd. operated a dredging operation at Green Cove Springs, FL. Associated Minerals was the principal producer of thorium-containing monazite in the United States. Monazite produced by Associated Minerals was a byproduct of processing mineral sands for titanium and zirconium minerals

Imperial Mining Co., a minor producer of byproduct monazite and xenotime, closed its operations at midyear. The Marion, NC, mine was primarily an in-

dustrial sand and gravel and gold producer. The operation closed reportedly as a result of Imperial's failure to obtain State permitting for a closed cyanide leach system for gold recovery.

CONSUMPTION AND USES

Domestic thorium producers reported consumption of an estimated 65.5 metric tons of thorium oxide equivalent in 1990, an increase of 8.3 tons from the 1989 level. Nonenergy uses accounted for all of the total consumption. The increase was the result of higher demand in lighting applications. The approximate distribution of thorium by end use, based on data supplied by producer, processors, and several consumers, was as follows: refractory applications, 70%; lamp mantles and lighting, 26%; metallurgical applications, 1%; welding electrodes and other applications, 3%.

Thorium oxide (thoria) has the highest melting point of all metal oxides, 3,300°C, a property that contributed to its use in several refractory applications. Applications included high-temperature ceramics,

investment molds, and crucibles.

Thorium nitrate was used in the manufacture of mantles for incandescent "camping" lanterns and in natural gas and oil lamps. Thorium mantles provide an intense white light that is adjusted to the yellow region of the visible spectrum by a small addition of cerium. The lamp mantle was thorium's first commercial use in the 1890's.

Thorium nitrate was also used to produce thoriated tungsten welding electrodes. Thoriated tungsten electrodes were used to join stainless steels, nickel alloys, and other alloys that require a continuous and stable arc to achieve precision welds.

The nitrate form was also used to produce thoriated tungsten elements used in the negative pole of magnetron tubes. Thorium was used because of its ability to emit electrons at relatively low temperatures when heated in a vacuum. Magnetron tubes were used to emit electrons at microwave frequencies to heat food in microwave ovens and in tracking radar and communication radar.

Thorium was used in other types of electron-emitting tubes, elements in special use light bulbs, high-refractivity glass, radiation detectors, computer memory components, catalysts, photoconductive

TABLE 2 U.S. COMPANIES WITH THORIUM PROCESSING AND FABRICATING CAPACITY

Company	Plant location	Operations and and

films, target materials for X-ray tubes, and fuel-cell elements. Thorium fluoride was used in the manufacture of carbon arc lamps. Carbon arc lamps were used in searchlights, movie projectors, and cinematography lighting.

Most thorium used in metallurgical applications was alloyed with magnesium. Magnesium-thorium alloys used by the aerospace industry are lightweight and have high-strength and excellent creep resistance at elevated temperatures. Small quantities of thorium were used in dispersion-hardened nickel alloys for high-strength, high-temperature applications.

Thorium was used as a nuclear fuel in the thorium-232/uranium-233 fuel cycle. Only a few foreign-based nuclear reactors continue to operate with this fuel cycle.

STOCKS

Government stocks of thorium nitrate in the NDS were 3,219,457 kilograms (7,097,687 pounds) on December 31, 1990. The NDS goal at yearend was 272,155 kilograms of thorium nitrate (600,000 pounds). Stocks in excess of goal were authorized for disposal.

The U.S. Department of Energy's inventory at yearend was 2,268,322 kilograms of thorium oxide equivalent contained in ore, metal, and various compounds.

PRICES

The price range of Australian monazite (minimum 55% rare-earth oxide, including thoria, f.o.b.),1 as quoted in Australian dollars (A\$),2 increased from A\$780 to A\$880 per ton at yearend 1989 to A\$800 to A\$900 per ton at yearend 1990. Changes in the United States-Australia foreign exchange rate in 1990, resulting from a slightly weaker Australian dollar. caused the corresponding U.S. dollar to be up \$0.03 against the Australian dollar at yearend. The U.S. price range, converted from Australian dollars, increased slightly from US\$616 to US\$6953 per ton in 1989 to US\$618 to US\$6954 per ton in 1990.

Thorium prices quoted by Magnesium Elektron, Flemington, NJ, at yearend 1990 were \$87.29 per pound for thorium hardener (80% Mg-20% Th) in single drum quantities and \$16.26 per pound

for thorium-containing HZ-32 magnesium alloy ingot.

WORLD REVIEW

Australia

Rhône-Poulenc SA of France abandoned its plans to build a \$150 million rare-earth and thorium separation plant at Pinjarra, Western Australia. Environmental concerns related to the disposal of naturally radioactive thorium halted the project in 1988. Rhône-Poulenc reported that the primary problem in securing project approval was the Australian Government's lack of strict environmental regulations: allowing opposition a free range of targets.⁵

Renison Goldfields continued development of its Eneabba West mineral sands deposit in Western Australia. Production from the mine, including thorium-containing monazite, is expected in 1991.

Brazil

Production of thorium-containing monazite concentrates in 1988 was 2,817 tons: 2,038 tons from the State of Rio de Janerio, a decrease from the 1987 production of 3,271 tons; 779 tons from the State of Bahia, a decrease from the 884 tons of monazite produced in 1987; and no production from the State of Espírito Santo, down from 177 tons in 1987.

Measured reserves of monazite increased to 48,281 tons in 1988 from 36,806 tons in 1987. Estimated thorium content of the 1988 reserves was 3,138 tons of thorium oxide equivalent. The increase in reserves was the result of additional tonnages added from the Sao Joao da Barra deposit in the State of Rio de Janeiro. Additional monazite reserves were in the States of Bahia, Espírito Santo, and Minas Gerais.⁶

Japan

Imports of Malaysian ilmenite were suspended because of unacceptable radiation levels from thorium and uranium in the concentrate. The radioactivity was traced to other mineral sands in the concentrate, primarily monazite, zircon, and xenotime. The Malaysia Chamber of Mines is negotiating to resume shipments, claiming that the radiation levels are with in acceptable limits.

OUTLOOK

The nonenergy uses of thorium are expected to decrease. Industry users continue to search for suitable substitutes, and the long-term outlook for demand is for a significant decline. Because of its natural radioactivity, new applications for thorium are not being developed, the result of high costs associated with handling, storing, monitoring, and disposal. The current trend to safeguard the environment is expected to continue, and additional regulations to control thorium's use are expected. Laws banning certain applications of other hazardous materials, including asbestos, mercury, and lead, have recently been enacted.

Thorium's domestic use in energy applications dropped to zero in 1990. The only domestic thorium-fueled reactor was decommissioned during the year, and no short-term domestic use as a nuclear fuel is foreseen. The long-term outlook for thorium in domestic energy applications is dismal: uranium is expected to remain the only nuclear fuel used by the domestic industry.

Table includes data available through Apr. 23, 1991.

In addition to the countries listed, China, Indonesia, North Korea, the Republic of Korea, Nigeria, and the U.S.S.R. may produce monazite, but output, if any, is not reported quantitatively, and available general information is inadequate for formulation of reliable estimates

TIN

By James F. Carlin, Jr.

Mr. Carlin, a physical scientist with the Branch of Metals, has been the commodity specialist for tin for 11 years. Domestic survey data were prepared by Elsie Isaac, mineral data assistant; and international data tables were prepared by William L. Zajac, Chief, Section of International Data.

in was one of the earliest metals known to humankind. Tin occurs in nature mostly as the oxide mineral cassiterite. Tin metal is commonly used as a protective coating or as an alloy with other metals. It finds applications in products and processes as diverse as tin cans, solder for electronics, tin chemicals, bronze fittings, and flat-glass production. Its strategic importance is exemplified by the fact that it is the largest dollar-volume holding of all metals in the National Defense Stockpile (NDS).

In 1990, for the 10th consecutive year, there was an excess of tin on the world market. Excess stocks were believed to have increased somewhat to about 45,000 metric tons of tin at yearend. Legal conflicts that had continued for 4 years, pitting tin dealers and banks against the London Metal Exchange (LME) and the International Tin Council (ITC), connected to the 1985 "tin crisis," ended as all parties agreed to a settlement.

The price of tin remained in a fairly narrow band throughout the year and at a level that was low by historical standards. World tin mine output declined as continued low tin prices caused numerous mines to close. In the United States, there was increased interest in the recycling of used tin cans largely because of dwindling landfill space. The opening of several new detinning facilities stimulated recycling activity. Despite the adoption of terms of reference for a proposed International Tin Study Group (ITSG), no action was taken to bring the group into realization.

DOMESTIC DATA COVERAGE

Domestic consumption data for tin are developed by the Bureau of Mines from a voluntary survey of U.S. tin users. Of the

318 consumers to which a survey request was sent, 318 responded.

BACKGROUND

Definitions, Grades, and Specifications

Primary or virgin tin metal is cast and sold as bars, ingots, pigs, and slabs in weights of 50 kilograms or less. Most of the tin metal imported into the United States is in the form of 45-kilogram pigs. During 1982-84, the American Society of Testing and Materials (ASTM) Pig Tin Task Group developed a new specification for grade-A tin, calling for 99.85% minimum tin content and 0.030% maximum bismuth content. This specification bore the code B-336-90. In 1990, the American Tin Traders Association modified the silver content of tin to be 0.01% maximum. This action was taken to limit some tin metal that was being imported into the United States with high silver content, which was thought to be detrimental to the electronic soldering industry.

Products for Trade and Industry

Tin is rarely used in its pure form, but is usually alloyed with other metals. Bronze, developed in the fourth millennium B.C., traditionally was a copper-base alloy containing about 10% to 15% tin to harden the copper. Today, the term "bronze" is seldom used without a modifier because it is applied also to some copper-base alloys containing no tin. The most important tin bronzes are the phosphor bronzes, containing up to 12% tin with small additions of phosphorus, and the gun metals, which are tin bronze casting alloys containing from 1% to 6% zinc. Brass, another old and important alloy, is primarily an alloy of copper and zinc, but often tin is a component.

There are numerous solder compositions, typical of which are tin-silver solder (95% tin, 5% silver), antimony-tin solder (95% tin, 5% antimony), and soft solders (ranging from 1% to 70% tin, with the remainder essentially lead).

Tin-base babbitt is an alloy containing antimony and copper, used for lining bearings. Lead-base babbitt metal contains 1% to 10% tin.

Compositions for tin foil and "white metal" vary with the producer. Most foil now is a tin-lead alloy. Some foil is made from relatively pure tin, or tin containing small amounts of copper or antimony hardener. White metals, such as britannia metal, jewelers metal, and pewter, are tin alloys, normally hardened with antimony. Pewter may have a wide range of composition, but high-grade pewter contains 90% to 95% tin, with 1% to 2% copper and the remainder antimony. Copper and antimony serve as hardeners.

Tinplate is a thin-gauge steel sheet product that has a very thin tin coating on both surfaces; the steel thickness and the weight of surface tin coating vary according to end-use requirements. Terneplate is sheet steel coated on both surfaces with tin-lead alloy.

Tinplate is commonly shipped as coil, solder as ingot, bronze as strip or plate, and brass as any of these forms. Each of these semifinished products is then used to fabricate a wide variety of end-use items. Brass and bronze are also produced in cast forms. Tin usually becomes a very small, but essential, part of the end-use item's weight or cost.

Industry Structure

At least 35 countries mine or smelt tin. Virtually every continent has an important tin-mining country. Most operations are privately owned, but many are publicly owned. A similar situation exists in the tin-smelting industry.

In the major Southeast Asian tinproducing countries, small, labor-intensive, high-unit-cost mines, such as gravelpump mines, produce a significant proportion of total output. In these same countries, massive, expensive dredges also are used. Large, privately owned mining enterprises operate in Southeast Asia, but many of the operations are also Government-owned. The four largest tin mining companies in the market economy countries are Paranapanema in Brazil, the Malaysian Mining Corp., P.T. Timah in Indonesia, and Corporación Minera de Bolivia (COMIBOL).

An agreement establishing the Association of Tin Producing Countries (ATPC) came into force on August 16, 1983. The five charter members were Bolivia, Indonesia, Malaysia, Thailand, and Zaire. Australia and Nigeria joined later. The stated objectives of the ATPC were to obtain fair returns for tin producers and

adequate and stable supplies at reasonable prices for tin consumers, to facilitate cooperation in the marketing of tin, and to enhance the growth of tin use. Members stated that they viewed the ATPC as complementary and supportive of the activities of the ITC. The Tin Council was an association of leading world tin producer and user countries that attempted to stabilize tin prices and supply-demand from 1956 until its demise in 1989. In recent years, the most visible activity of the ATPC has been to attempt to reduce the world oversupply of tin through a series of supply rationalization schemes. These programs have essentially featured export-control limits placed on the seven member countries. While these programs have succeeded in drastically reducing the huge tin oversupply, they have not eliminated it largely because major producers like Brazil and China were not bound by the guidelines of the programs.

U.S. mine production of tin has been negligible for many decades. Small quantities of tin concentrates are produced from placer deposits in Alaska, and small quantities were once produced in several Western States.

In recent decades, the only tin smelter in the United States was the Texas City, TX, facility of TexTin Corp. In recent years, this smelter treated tin concentrates imported from Bolivia and Peru, as well as some domestic tin concentrates and some accumulated secondary residues. In 1989, owing to continued low tin prices and difficulties in obtaining feedstocks, TexTin ceased tin production and converted its equipment to process secondary copper.

The tinplate-producing industry is quite concentrated, comprising only seven major steel firms. The solder-producing industry is considerably more dispersed, but most of the tonnage is account-

The London Metal Exchange resumed trading as of June 1, 1989.

ed for by a relatively few soldermaking firms. During the past decade, both the tinplate and the solder industries have undergone considerable consolidation. In the tin chemical field, while there are a number of companies, one firm dominates.

The other domestic tin-using industries are diverse, such as the brass, bronze, solder, and flat-glass industries, and are represented by hundreds of firms and plants. Most are located in the East and Midwest.

Geology-Resources

Tin is a relatively scarce element; its average abundance in the Earth's crust is about 2 parts per million (ppm), compared with 94 ppm for zinc, 63 ppm for copper, and 12 ppm for lead. Tin is preferentially concentrated by magmatic differentiation processes and shows a worldwide affinity for granitic rocks or their extrusive equivalents. The principal deposits are scattered irregularly along a belt surrounding the Pacific Ocean. Most of the world's tin is produced from placer deposits; about one-half of placer tin comes from Southeast Asia.¹

The only mineral of commercial importance as a source of tin is cassiterite (SnO₂), although small quantities of tin are recovered from the complex sulfides stannite, cylindrite, franckeite, canfiel-dite, and teallite. Cassiterite has a high specific gravity (6.8 to 7.1), a Mohs' scale hardness of 6 to 7, and is usually a dark-brown or black color with an adamantine luster.

Because cassiterite is both heavy and chemically inactive, it is concentrated in residual (eluvial) placers that form over or adjacent to bedrock source areas where weathering and erosional processes remove lighter rock materials and gravity assists in downslope movement of heavy minerals released by weathering. The richest placers are stream deposits (alluvial placers) found where flowing water has concentrated heavy minerals generally derived from residual placers. Ocean beach sands may also contain placer accumulations of tin; such placers are mined offshore in Indonesia and Thailand. No extensive tin placer deposits have been found in the conterminous United States.

Technology

Exploration.— Historically, prospect-

ing for tin has been carried out by the time-honored methods of panning, drilling, and pitting. As rich deposits were exhausted and the costs of exploration rose, the search for tin required more sophisticated methods. Geophysical and geochemical analyses have been employed to cover large areas more rapidly, isolating areas of possible tin deposits so that drilling can be more effective and less costly.

Mining.—Principal methods for mining placer deposits are bucket-line dredging and gravel-pump operations, although hydraulicking and various open pit methods are also used. The bucket-line dredges used are floating dredges similar to those used to mine other placer deposits. The ore is excavated and transported by buckets to the interior of the dredges, washed on screens, and concentrated in jigs and on shaking tables. Tailings are discharged at the rear of the dredges to fill in the mined pond, and the crude tin concentrate is sent to the dressing shed for final concentration.

Although gravel-pump and hydraulic mining both use water jets to break up the tin-bearing material, the methods of conveying the material to the launders differ. In gravel-pump mining, a pump is used, whereas hydraulicking employs the pressure developed by a natural head of water. In each method, the material is washed through a riffled launder, called a palong in Malaysia, where the cassiterite is collected by the riffles and the waste is washed away.

In open pit operations, the material is excavated by power shovels and transported on a conveyor belt to the washing plant for treatment.

Vein tin deposits are mined by methods similar to those used in the hard-rock mining of other nonferrous ores. Access to the ore bodies is by adits and shafts. The ore is broken by conventional drilling and blasting and transported from the mine to a concentrator for treatment.

Processing.—The crude tin concentrate from placer mining is further upgraded by washing, tabling, and magnetic or electrostatic separation. The final product is virtually pure cassiterite.

Tin ore from lode deposits is reduced to the necessary size by conventional crushing and grinding. The ore is concentrated by gravity methods involving screening, classification, jigging, and tabling. The

gravity concentrate is usually of lower grade than placer concentrate owing to associated sulfide minerals. The sulfide minerals are removed by flotation or magnetic separation, with or without roasting, to produce a second-stage concentrate.

Cassiterite in placer deposits is fairly coarse grained, and recoveries range from 90% for gravel-pump mines to 95% for dredging operations. However, the cassiterite in vein deposits is very fine grained and is difficult to recover by gravity concentration. Cassiterite ore at mines in Australia, Bolivia, the Republic of South Africa, and the United Kingdom are floated, but recoveries are seldom above 70%. Recovery of the tin content in Bolivia is reportedly as low as 50%.

Cassiterite is reduced to tin by heating with carbon at 1,200° to 1,300° C. The almost pure cassiterite concentrate from placer deposits is smelted directly. Other concentrates, particularly from Bolivia, contain impurities that must be removed before smelting. This is usually done by roasting the tin concentrates with or without fluxes, followed by acid leaching. During roasting, most of the sulfur and arsenic are removed as oxides. Bismuth, copper, iron, and zinc oxides are removed by leaching the roasted concentrate with sodium carbonate or sulfate and leaching with water. Antimony, bismuth, lead, and silver may be removed by a chloridizing roast, followed by an acid leach.

In modern tin-smelting plants, reverberatory furnaces are used to smelt primary tin concentrate and to resmelt the slag for additional tin recovery. Although blast and electric furnaces are also used to smelt tin concentrate, reverberatories are often preferred because of better control, cleaner slags, and superior efficiency in smelting finely divided materials. Electric furnaces are often favored for energy-saving reasons, especially for smaller smelters.

Tin smelting is a batch operation. A typical charge consists of cassiterite concentrate, a carbon reducing agent, and limestone and silica fluxes. From 10 to 12 hours is required to smelt a charge. When smelting is complete, the molten batch is tapped into a settler, from which the slag overflows into cast-iron pots. The molten tin from the bottom of the settler is cast into slabs or pigs for refining.²

The slag, containing 10% to 25% tin, is resmelted to yield a slag containing less than 1% tin.

Heat treatment is the most widely used refining method and consists of heating the tin from smelters on an inclined hearth to a temperature slightly above the melting point of pure tin, but below the melting points of the impurities. Thus, the comparatively pure tin melts and flows into a kettle, leaving impurities such as iron and copper in a dross residue that is re-treated to recover the contained tin.

The molten tin is then stirred with green wood, which produces a strong boiling action. During the stirring, the metal impurities and part of the tin are oxidized and form an oxide dross that is skimmed off. Sometimes tossing is used instead of stirring. In this operation, hand ladles of molten tin are dipped from and poured back into the kettles, exposing the tin to the oxidizing action of the air. After refining has been completed, the tin is cast into pigs for marketing.

Recycling.—The only form of tin recycling in which free tin is produced is detinning. In recent decades most detinning has been conducted on new, flat tinplate scrap, mostly from tin mills or canmaking plants. In the detinning of flat tinplate, generally the tinplate scrap is treated with a hot solution of caustic soda in the presence of an oxidizing agent to dissolve the tin as sodium stannate. The base steel is then washed and compacted into bales for shipment. The tin may be recovered from the stannate solution as metal, sodium stannate crystals, or tin oxide. Because of advantages in processing costs and production of a high-purity metal, the common practice is electrolysis of the stannate solution to yield metallic tin. The refined tin averages as high as 99.99% purity, with antimony, iron, and lead as common impurities.

Until recent years, the detinning of used tin cans was not performed on an economic, high-volume basis because cans were often in a crushed condition and had enamel coatings and food particles attached that made effective detinning impossible. However, in the late 1980's, techniques were developed to detin these used tin cans. The most common method is to shred the cans into small popcorn-sized pieces and then proceed with the caustic soda treatment.

Most scrap tin is alloyed tin (such as solder, brass-bronze, or babbitt) that is recycled in its own alloy industry. These producers refine out undesired elements from the scrap charge or may use addi

tions to build up desired elements.

Byproducts and Coproducts

In some tin placer deposits, large amounts of columbium, tantalum, and rare-earth minerals are associated with the cassiterite. Some lode tin deposits contain numerous other materials such as copper, lead, silver, and zinc, usually in the form of sulfides.

Tin has been recovered as a coproduct of molybdenum mining at the Climax lode mine in Colorado. Small quantities have been produced as a coproduct of placer gold-mining or tailings-cleanup operations in Alaska or South Dakota. It has been produced as a byproduct of lead-zinc mining in Ontario and British Columbia, Canada.

In some major tin-producing countries, such as Malaysia and Thailand, tantalum contained in tin smelter slags is a major source of tantalum supply.

Substitutes

Alternative materials, often less costly. have been a significant factor in the downward trend in domestic tin consumption over the past two decades. Aluminum and chromium-coated tin-free steel were two materials used to replace tinplate in beverage cans over the past two decades. Other substitutes for tinplate include enameled steel, glass, paper, and plastics. Nonmetallic materials, aluminum, copper, and galvanized steel have largely replaced terneplate for roofing and both tinplate and terneplate for other construction. In general, no satisfactory substitutes have been found for tin in solder, although lowering the tin content of the solder may be possible in some applications. Aluminum alloys, other copper-base alloys, and plastics could be substituted for some bronzes. Low-tin aluminum-, copper-, or lead-base bearing alloys and roller or ball bearings may be substituted for babbitt metal. Other chemicals may replace some tin chemical compounds for use as fungicides, biocides, marine antifouling paints, or polyvinyl chloride stabilizers.

ANNUAL REVIEW

Legislation and Government Programs

The NDS continued in its second year

of being managed by the Secretary of Defense, with day-to-day operations guided by the Defense Logistics Agency (DLA).

The DLA sold 2,145 tons of tin from the stockpile in 1990. Through June 30, disposals were payment materials in support of the ferroalloy upgrading program (this tin swap program started April 11. 1984); after June 30, disposals were direct sales to the marketplace. Direct sales to the public (primarily dealers and industrial users) were held each day, with orders for lots of 5 tons or more being accepted daily between 1:00 p.m. and 3:00 p.m. at the price set by the DLA for that day. Pickup points for the stockpile tin were Point Pleasant, WV; Curtis Bay, MD; Hammond, IN; and Stockton, CA. The DLA had authority from Congress to dispose of about 7,000 tons of tin in fiscal 1990 and a further 7,000 tons in fiscal 1991. At yearend 1990, the NDS inventory was 168,496 tons, and the stockpile goal was 42,674 tons.

On May 8 and May 16, separate bills were introduced by Senators Bradley (S. 2593) and Reid (S. 2637) in the U.S. Senate; both bills called for either a ban or reduction in the use of lead in certain products, including solder. A series of hearings were held at which industry representatives presented their views, and, as a result of these, the bills' particulars took a slightly different direction. Consideration of the bills continued through the end of the year. Certain features of the bills calling for drastic lowering of lead content could be of special importance for tin because tin is often a coalloy of lead.

Strategic Considerations

Tin's strategic importance is indicated by its major position in the NDS. Tin finds application in such defense-related fields as solder for printed circuit boards in aircraft and night-vision weaponry and brass or bronze fittings and gears for naval needs. Tin in the NDS is stored in warehouses around the country, often close to plants that would use the tin during wartime.

It is considered unlikely that domestic tin deposits will yield significant amounts of tin in the next 10 years, so strategic needs must be met by imports, the NDS, and recycling.

Issues

The United Nations Conference on Trade and Development (UNCTAD) expressed concern that only 5 of the original 37 tin producer and consumer countries that had agreed in early 1989 to the terms of reference for an International Tin Study Group had thus far provided formal acceptance. These five countries represented only 30% of the total world tin trade, whereas a 70% minimum target was agreed to at the UNCTAD meeting in April 1989.

Production

The Cache Creek Mine, located in the Tofty District near Manley Hot Springs, AK, was the only mine in the United States to produce significant amounts of tin concentrates. The tin was recovered as a byproduct of gold mining. The mine, owned by Shoreham Resources, Inc., Houston, TX, was in its first year of production. The total output from the mine amounted to only a small fraction of domestic tin requirements.

The United States was believed to be the world's largest producer of secondary tin. Tin metal recovered from new tinplate scrap and from used tin cans was the only type of secondary tin available in the marketplace as free tin; other secondary tin was available in scrap materials as an alloying ingredient. Secondary tin from recycled fabricated parts was used in many kinds of products and was a major source of material for the solder and the brass and bronze industries. The Steel Can Recycling Institute in Pittsburgh, PA, funded and operated by five domestic tinplate producers, sought to advance the collection, preparation, and transportation of can scrap. Also, they expanded a program of installing representatives in several regions of the United States to work with municipalities, scrap dealers, and detinners to promote the recycling of tin cans.

Until 1989, generally all domestic detinning operations treated only new (factorygenerated) tinplate scrap. This usually came from steel plant tin mills or can plants. Little or no old scrap, such as that from used (post-consumer) tin cans, was detinned. This was partly due to relatively inexpensive and nearby landfills, which in earlier years could readily accept municipal trash, but mostly it was due to technical difficulty in processing the cans. These

used cans typically have enamel coatings, outside paper wrappers, remnants of food particles, and are often crushed, making it difficult to treat them effectively with chemical detinning solutions on a highvolume basis. However, in recent years, new scrap preparation procedures were developed, especially a new shredding method, that permitted detinning of used tin cans. Also, municipalities, by the late 1980's, faced increased costs for disposing of trash in landfills and dwindling landfill sites. These developments began to set the stage in 1990 for large-scale detinning of used tin cans. The domestic detinning industry responded with the construction of several new plants.

Proler International Corp. started up the world's largest detinning facility in Houston, TX. The new plant was capable of recycling 163,000 tons of tinplated steel cans and clippings per year, the equivalent of 2.5 billion tin cans per year. The operation involved the shredding of feedstock followed by continuous detinning in a series of rotating cylinders. The separated products were sold to various foundries and steelmakers. Plans were announced for the establishment of a new \$260 million steel minimill, a joint venture of Proler International Corp., Birmingham Steel Corp., and Danielli & C. Officine Meccaniche S.p.A. (Italy). An important feature of the new operation was to be the assured supply of detinned can scrap generated by Proler's new Houston detinning plant. The new minimill was to be constructed on the site of the shuttered former USX Corp.'s Baytown, TX, steelworks. Plans were delayed when Birmingham Steel withdrew from the deal, although the two remaining partners sought a replacement.

AMG Resources Corp. started its new tin can recycling plant at St. Paul, MN. The facility had an electrolytic detinning system with a capacity to process up to 40,000 tons of tin cans annually.

Consumption and Uses

Primary tin consumption remained about the same as in the prior year. The only significant increases were in the categories of solder and tinning, and the only significant decline occurred in the category of brass and bronze. Tinplate remained the largest use item for primary tin, followed by solder and tin chemicals. The use of secondary tin declined perhaps owing to continuing low prices for primary tin.

Tinplated steel and tin-free steel accounted for 29% of the 126 billion cans shipped domestically and aluminum accounted for 71%; these were the same market shares as in 1989. Aluminum held an overwhelming advantage in the beverage can market, while steel predominated in the food can and the general-line markets. Steel cans notably increased their market penetration of the soft drink can market, accounting for 8% of 53 billion cans, compared with 6% of 49 billion cans in 1989.³

Statistics released by the Steel Can Recycling Institute illustrated some aspects of the current domestic status of tinplate. Canned food accounted for 12% of grocery sales in the United States, encompassing 1,500 different foods and items. Tinplate held about 92% of this canned food market, about 99% of the general-line can market, and about 8% of the growing soft drink market. Ball Corp. made a \$1 billion takeover bid for Con-

tinental Can Europe Ltd., a subsidiary of Peter Kiewit Sons Inc., but later withdrew it owing to financing problems. Reportedly, Kiewit still hoped to sell its packaging industry operations.

In a major merger in the container industry, Crown Cork & Seal Co. Inc. purchased the food and beverage metal can divisions of Continental Can Co. Inc. Crown paid \$336 million and assumed certain liabilities. Continental operated more than 30 plants domestically and employed about 4,000 persons. Crown operated 104 plants worldwide and had 15,000 employees, with revenues of \$1.9 billion. The purchase made Crown the

largest U.S.-owned maker of metal cans and the second largest maker of metal cans in the United States after Pechiney (France). Both Crown and Continental were major users of tinplate. The purchase followed other consolidation moves in the past 2 years among major can makers in the world.

¹Tin recovered from new and old copper-base scrap, brass mills, and foundries.

²Brass-mill stocks include home scrap, and purchased-scrap consumption is assumed equal to receipts; therefore, line does not balance.

³Includes tinplate and other scrap recovered at detinning plants; Bureau of Mines not at liberty to publish separately.

⁴Data may not add to totals shown because of independent rounding and data concealed in "W."

Includes tin in transit in the United States.

Stocks

The LME announced approval of Baltimore, Chicago/Toledo, and Bridgeport/New Haven as locations for the siting of LME warehouses. The LME started to take applications from warehouses in these areas. The decision to expand the LME warehouse network, which already covered Europe, Japan, and Singapore, was a natural consequence of the LME's role as a facilitator of global pricing and hedging for major metals. The U.S. warehouses could accept aluminum, nickel, tin, and zinc.

Markets and Prices

Marketing of tin metal in the United States was performed mostly through trading firms, which imported the tin from a variety of countries and warehoused it in this country until they sold it to consumers. Some tin was also marketed directly in the United States by large foreign producers who maintained sales offices here and sold their tin metal, usually on a 1-year contract basis, only to the largest users. Among these direct-sale operations were Indo-Metal Corp. and Renison Consolidated Goldfields Corp.

Most traders and direct-sale operations were based in the New York, NY, area.

Among the ranks of trading firms, the year saw a significant shakeout. Burdened by competition from too many tin trading firms and by continuing low tin prices, an estimated 10 firms closed their operations.

The price of tin metal, as published in Metals Week, remained in a narrow band all year. The LME remained the primary trading focus for tin, trading having been reintroduced there in 1989 following its early 1986 suspension related to the 1985 tin market "collapse." The Kuala Lumpur Commodities Exchange in Malaysia continued as an active tin trading forum.

TABLE 6

Foreign Trade

Imports of tin concentrates declined to zero, as expected in view of the conversion of the TexTin Corp. smelter in Texas City, TX, away from tin processing. Bolivia replaced Brazil as the major source of tin metal imports. Brazil ranked second, followed by China, Indonesia, Malaysia, and Mexico.

Imports of tin in all forms (ore and concentrate, metal, and waste and scrap) remained free of U.S. duty.

World Review

Capacity.—The data in table 13 represent rated annual production capacity for mines and smelters on December 31, 1990. Rated capacity was defined as the maximum quantity of product that can be produced in a specific period on a normally sustainable, long-term operating rate, based on the physical equipment of the plant and routine operating maintenance. Capacity includes both operat-

ing plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Estimates of the rated capacities of mines and smelters were based on discussions with officials from private industry, on past and present production rates, and on published capacity data.

Australia.—The Renison Bell Mine in Tasmania, owned by Renison Consoli-

dated Goldfields Ltd., remained the largest tin mine, accounting for more than 90% of total mine output. Renison Bell was the world's largest hard-rock underground tin mine and a relatively low-cost producer with substantial high-grade reserves. Late in the year, Renison announced it would reduce its tin output from about 7,000 to 5,500 tons annually of tin-in-concentrate; the firm declared it was forced to do so because its costs were increasing while tin prices were falling.

¹Includes tin in transit in the United States.

²Data represent scrap only, tin content.

Renison's entire output of tin concentrate was believed to have been toll-smelted in Malaysia. Renison continued direct sales of refined tin to large American consumers from an affiliate office in Green Cove Springs, FL.

Greenbushes Ltd. continued to mine tin and tantalum near Perth. This operation produced about 200 to 300 tons of tin-in-concentrate annually in recent years. A major project to develop underground access to the tin-tantalite ore body at the Greenbushes tin-tantalite operation in Western Australia was approaching completion by yearend. Improvements included the construction of a 300,000ton-per-year integrated mining and processing operation. It was expected that when completed, tin output would be

increased to about 1,200 tons annually, with one-half of that coming from the underground mine.

Bolivia.—The tin industry continued to recover from the low production levels of 1986-87, when suddenly depressed tin prices lead to a massive restructuring of the mine and smelter sectors.

Historically, the Huanuni tin mine, located in the Department of Oruro, has been the richest underground tin mine in Bolivia. The mine was closed in 1986, but reopened in mid-1988 following modernization. The capacity of the mine was 3,600 tons of tin-in-concentrate annually, with the output being delivered to the Vinto metallurgical complex of Corpo-

ración Minera de Bolivia (COMIBOL). Huanuni had reported reserves of 42,800 tons

Other important mines included the Bolivar tin-zinc-silver mine in the Department of Oruro; development work was proceeding here in an attempt to increase the reserves, which were reported as 10,900 tons of tin. Also important were the Catavi-Siglo tin mine in the Department of Potosí, leased by COMIBOL to 4 cooperatives employing 4,500 miners, and the Caracoles tin mine in the Department of Potosí, with reported reserves of 3,900 tons.

COMIBOL, the Government-owned mining company, announced the invitation of private bids for the leases of sev-

eral of its key operations. Among the mines offered were Huanuni, Caracoles, and the tailings at Catavi-Siglo. COMI-BOL would retain ownership of the mines. The decision to privatize these mines was taken in light of the low prices for tin and coproduct metals and low productivity. The approved companies would be required to provide job guarantees to workers as part of the contracts. The condition of job guarantees was an attempt by COMIBOL to curb resistance from the militant Bolivian miners union.

COMIBOL closed its Viloco tin mine in the Quimsa Cruz region near La Paz. The mine was operated by COMIBOL's subsidiary Empresa Minera Subsidiaria La Paz. The Government-owned smelting organization, ENAF, announced that its smelter was running at only one-third of its capacity of 32,000 tons of tin metal annually. ENAF also postponed plans to refurbish part of the smelter to increase production from about 10,000 tons now to 15,000 tons annually.

Pan-Andean Ltd., an Irish exploration firm, signed a joint agreement with COM-IBOL calling for Pan-Andean to spend \$175,000 testing the viability of recovering gold, silver, and tin from three tailing dumps in the Telemayu region.

At yearend, the Congress in Bolivia was preparing to pass a bill that would change the country's mining code, with special emphasis on attracting overseas firms for joint-venture exploration. The bill, which reportedly had support from varied interests, would give the executive branch the final authority to set fiscal parameters for these joint ventures. Currently, this power was in the legislative branch. Bolivia's present code permits only national mining interests to explore in a 50-kilometer-wide zone along the country's borders, unless otherwise authorized by Congress. The new code would allow foreign investment in these zones. One feature of the new code would prohibit neighboring countries from participating in exploration consortiums for any project within 50 kilometers of any Bolivian border. Observers indicated this feature was intended to blunt the alleged intrusion of Brazilian mining firms into Bolivia.

During the year, reports continued of an active market in smuggling tin concentrates from Brazil into Bolivia. As a result, some tin mined in Brazil shows up on statistical tables as being of Bolivian origin.

Bolivia emerged in 1990, for the first time in many years, as the major exporter of tin to the United States.

Brazil.—Brazil was the world's leading tin producer from both mine and smelter (when one considers the smuggling

aspect) for the third consecutive year. Tin mines and smelters were mostly privately owned. Tin was mined from both alluvial and lode deposits. Brazilian mines were generally considered the lowest cost to operate in the world. Brazil was not a member of the ATPC, but generally

agreed to cooperate with the spirit of its guidelines and restrict its tin exports.

The Paranapanema Group was the largest private tin producer in the world, owning and operating five tin mines. The mines were Capipore in the State of Amapa, Massangana (also known as C-75, Ariquemes, and Serrinha) in the State of Rondônia, São Francisco in the State of Mato Grosso, São Raimundo in the State of Pará, and Iarape Preto and Pitinga, both in the State of Amazonas.

Pitinga, the country's largest tin mine, used four Elliot bucket wheel dredges and mined to a depth of 6 to 8 meters. The mine site employed nine floating wash plants and seven gravel-pump plants. The dredging capacity was about 13 million cubic meters annually. Management was in the process of developing mining of a soft weathered tin ore, separate from the alluvium, and reportedly was considering constructing a tin smelter. Total investment at Pitinga was about \$115 million.

Tin mining activity by "garimpeiros" or independent miners increased. Estimated to number 10,000, "garimpeiros" worked an area of about 6 by 12 kilometers in the State of Rondônia, with no specific limits to each person's mining area and with only limited control by the local government.

A new firm, Industria e Comercio Minerios e Metais Mineoeste Ltda., commenced operations at a new tin smelter at Guaíra in Paraná State. The smelter initially produced 10 tons daily of 99.91% pure tin metal, with output planned to expand to 25 tons daily within a year. Mineoeste had four rotary furnaces and planned to add four more later. Cassiterite concentrate for the new smelter was trucked 2,500 kilometers from the Bom Futuro. Tin Mine near Ariquemes. The smelter's output was initially aimed at the domestic market.

Rhodia S.A., the Brazilian subsidiary of Rhône-Poulenc Co. (France), announced it had sold three tin mines in Brazil to two São Paulo industrialists. The three tin mines in northeastern Pará State were operated by Mineraçao Canopus and Mineraçao São Francisco; and ownership passed to two officials of Silex, a São Paulo-based holding company. The new owners announced plans to make new investments in the three mines, which they estimated would soon be producing 2,400 tons of tin-in-concentrate. They planned to have the tin concentrate smelted in São Paulo.

Brumadinho closed all its tin mines, including the São Lourenço-Macisa Mine, the Cachoerinha Mine, and the Monte Negro Mine. The closures were attributed to low tin prices.

Although Cesbra closed no tin mines, it reportedly was considering closing its tin mine complex at Jacunda if low tin prices persisted.

Government officials reported that large quantities, perhaps 6,000 tons, of tin-in-concentrate were smuggled out of the country from the Bom Futuro site. Much of the illicit concentrate was believed to be trucked to the Madeira and Marmore Rivers, then barged across these rivers to neighboring Bolivia. This contraband tin is believed to have helped

sustain the world tin oversupply and thus contributed to continuing low prices.

At the September meeting of the ATPC in Cochabamba, Bolivia, it had been expected that Brazil would announce its willingness to join. However, Brazil decided not to join the ATPC. The country's tin producers favored joining the ATPC only if the Government could

Contained tin basis. Data derived in part from the Monthly Statistical Bulletin of the International Tin Council, London. Table includes data available through June 28, 1991.

²Reported figure.

regulate the unchecked output from the Bom Futuro Mine; otherwise, they reasoned, Brazil could not adhere to an ATPC-set production quota.

Burma.—Mining Corp. Two, based in Rangoon, was responsible for the country's entire production of tin, as well as tungsten, antimony, and other metals. The organization totaled about 1,000 persons who operated various underground, opencast, gravel-pump, and dredge tin operations, as well as a tin concentrator at Tavoy. The country's tin ore was smelted at the Syriam smelter, with a capacity of 1,000 tons annually.

Following the electoral defeat of the military government early in the year, the investment climate in Burma reportedly improved. The tin deposits in the southern coastal region were of special interest. Thailand's Offshore and Exploration and Mining Co. and Burma's Mining Corp. Two signed three contracts for the exploration and production of tin offshore.

Canada.—The East Kemptville Tin Corp. Ltd., owned by Rio Algom Ltd., continued tin-mining operations at its open pit mine at East Kemptville, Nova Scotia. The mine contained 41 million tons of high-grade tin ore and 15 million tons of low-grade tin ore. The tin ore at the site

was complex, and concentration by gravity and magnetic methods reportedly was difficult. In recent years, Rio improved the recovery rate by improving the grinding, dewatering, and gravity equipment and installation of a new flotation circuit. Reportedly, the mine increased its recovery rate to more than 70%, and its tin concentrates graded 50% tin.

Stelco Ltd., a major tinplate producer, suffered a 3-month strike at its Hilton Works in Hamilton, Ontario. Then, the United Steel Workers Union approved a new 3-year labor contract with the firm.

Cominco Ltd. produced a small quantity of tin-lead alloy at its Trail, British Columbia, smelter as a byproduct of the production of indium.

NovaGold Resources Ltd. signed a letter of intent with current owners Billiton Metals Canada Ltd. and Lac Minerals Ltd. to purchase the Mount Pleasant tinmolybdenum-tungsten property in New Brunswick. The letter of intent specified that Billiton and Lac would sell their interest in Mount Pleasant and fixed assets for \$10 million, payable via a 15% net profit royalty from any production from the property. NovaGold would indemnify the two sellers against any future environmental liability. The mine had operated in the early 1980's as a molybdenum and tungsten producer and had

closed in 1985. Babcock Contractors was undertaking a feasibility study on the property to evaluate prospects for starting production as a tin-base mine. Minable underground reserves at Mount Pleasant totaled 5.1 million tons grading 0.70% tin and 9 tons grading 0.40% tungsten and 0.20% molybdenum. In addition, drill-inferred near-surface reserves totaled 5 to 10 million tons grading 0.25% to 0.30% tin, 3% zinc, and smaller quantities of indium and bismuth.

China.—Yunnan Tin Corp., Gejiu City, Yunnan Province, was the largest tin producer. It operated 5 underground mines, 7 open pit mines, 10 mineral dressing plants, and 1 smelter, giving it an annual mine production capacity of 7.5 million tons of tin ore, while the smelter capacity was 20,000 tons of refined tin yearly. Both surface alluvial deposits and underground lode deposits were worked. After 100 years of exploitation, the highgrade alluvial deposits were virtually depleted. In 1990, low-grade alluvial tin ores of fine particle size, tailings, and underground lodes were the main sources.

Yunnan used reverberatory smelting of tin concentrate, pyrometallurgical refining of tin metal, electrolytic separation of tin-lead alloy, and tin slag fuming. It used a continuous electrothermal crystallizer

Data derived in apart from the Monthly Statistical Bulletin of the International Tin Council, London and, since 1988, UNCTAD. Wherever possible, total smelter output has been separated into primary (from ores and concentrates) and secondary (tin metal recovered from old scrap). This table reflects metal production at the first measurable stage of metal output.

Reported figure.

for removal of lead and bismuth, using the different melting and specific gravities of tin and lead-tin alloy; direct recovery of tin was increased by 6% over former methods, and staffing levels reduced by 50%. Several other tin smelters around the world utilized Yunnan crystallizer technology.

The Da Chang Tin Mining Bureau Mine in the southwest region of Guangxi continued its expansion program that was expected to eventually make it China's largest tin mine.

France.—Pechiney, the large aluminum and can producer, announced it was starting construction of a \$50 million tinplate beverage can plant at Dunkirk. The plant was designed to consume 24,000 tons of tinplate annually and to produce 1,200 million cans annually. Startup was set for 1991. It was believed that Sollac, the flat-rolled products division of Government-owned Usinor, would be the main tinplate supplier.

Hong Kong.—Mainland Metals and Minerals Ltd. announced the startup of a new 7,200-ton-per-year tin smelter. The smelter was intended primarily to treat low-grade tin concentrates from China. It had two furnaces and an output of about 5,000 tons of tin metal annually.

India.—The State Mining Corp. of India and the Bhabha Research Centre at Hyderabad announced they were constructing a new tin smelter in Madhya Pradesh State.

The Asian Can Co. Ltd. announced plans to expand can production in northern India. Four major firms accounted for 70% of India's total canmaking capacity and supply 200,000 tons of cans annually to the domestic market. About 80% of the cans made in India are general line, with most of the productive capacity being around Bombay. Asian Can had three factories near New Delhi that solely produced general-line cans. Its planned expansion would make the firm the largest canmaker in India. The firm also planned to install a line for making threepiece beverage cans in 1991, making it the first firm to produce beverage cans in India.

Indonesia.—Tin mining was performed mostly offshore, usually by means of large-scale dredging. P.T. Tambang Timah (P.T. Timah), the Government-

owned mining firm, ranked as one of the world's largest tin-mining organizations, accounted for about 80% of Indonesia's tin output. P.T. Timah's three primary tin production complexes were on the islands of Bangka, Belitung, and Singkep. The facility on Bangka Island accounted for 70% of the firm's tin production.

P.T. Timah announced plans to sell some of its onshore mining operations on Belitung and Singkep Islands to private firms. The move was expected to lower Timah's tin output by several thousand tons annually. The move was part of Timah's plan to overhaul facilities and reduce production costs. Reportedly, Timah was seeking \$500 million in loans from the World Bank for the restructuring program. Priority was expected to be given to the modernization of old mining and smelting equipment. Timah also announced plans to transfer its headquarters from Jakarta to Bangka Island, the site of most of its tin operations. Timah employed about 1,000 persons at its headquarters.

Malaysia.—Malaysia Mining Corp. (MMC) remained the largest tin producer in the country, but continued low tin prices depressed its operations. MMC reduced the number of dredges in operation from 21 to 16; among those idled were two dredges at Berjuntai Tin Dredging, two dredges at Bidor Malaysia, and one dredge at Southern Kinta. During the year at least 30 gravel-pump mines closed down partly owing to high fuel prices.

Japan reportedly suspended imports of ilmenite from Malaysia because of its high radioactivity level. Ilmenite is a byproduct at many tin-mining operations in Malaysia, and its exports have been helping miners to offset the effects of currently depressed tin prices.

MMC, predominantly dependent on its tin operations until recent years, announced expansion of its exploration program to cover other base metals and gold in several countries, including Brazil, Burma, China, Laos, and Vietnam. Tin contributed only 26% to the firm's 1990 pretax profits.

Construction began on a second tinplating line at the tin mill operated by Perstima. The new line was expected to double the plant's capacity to 180,000 tons annually and was expected to be completed by 1991. Perstima was partially owned by Kawasaki Steel Co. of Japan, and the technology for the tinplating line was being supplied by Kawasaki. Perstima announced that the new line would be designed to permit later installations that could produce tin-free steel as well as tinplate. Tinplate demand in Malaysia was about 130,000 tons annually.

The Government announced it would eliminate export duties on tin metal as of January 1, 1991. The duty had been 10% to 12%. The action was taken to stimulate exports.

Mexico.—Tin mining occurred in the north-central region in the three adjoining States of Durango, Zacatecas, and San Luis Potosí. The country's major tin mine, the El Perro Mine, was owned by Cía. Minera Pizzuto.

Estaño Electro S.A. de C.V. operated a tin smelter at Tlalnepantla, near Mexico City. Fundidora de Estaño S.A. operated a tin smelter at San Luis Potosí. Metales Potosí S.A. had a smelter in San Luis Potosí as did Minera de Rio S.A. Most of the tin concentrates processed by the four smelters were imported primarily from Canada and China.

Namibia.—During the first part of the year, the Uis Mine, owned by Industrial Minerals Mining Corp. Pty. Ltd., a wholly owned subsidiary of South African Iron and Steel Industrial Corp. Ltd. (Iscor) continued as the largest producer. Tin concentrates from Uis were shipped directly to the Vanderbijlpark steelworks in the Republic of South Africa, where they provided a large part of Iscor's tin for use in producing electrolytic tinplate. However, near yearend, Iscor closed the Uis Mine owing to continued depressed tin prices.

Nigeria.—Tin was mined from alluvial deposits by two major companies: Consolidated Tin Mines Ltd. and Nigerian Tin and Allied Minerals Products Ltd. Cassiterite was mined in association with columbite, tantalite, and tungsten minerals. All tin concentrates were shipped to the sole tin smelter, the Governmentowned Makeri Smelting Co., in Jos, Plateau State. Makeri continued to operate well below capacity.

Substantial amounts of tin concentrates were reportedly smuggled out of the country. The Government officially permitted only refined tin to be exported, on which a 15% royalty per ton was charged. These exports were then marketed by London-based Decacia International Ltd.

One domestic solder plant used about 40 tons of tin annually, and the remainder of Nigerian tin production was exported.

Peru.—The only tin mine was the San Rafael Mine, near Juliaca, owned by Minsur S.A. The mine was located within the northern extension of the Bolivian tin belt. Tin grades averaged 1.8%.

Minsur announced that its plans to build a tin smelter had been postponed indefinitely. Most of Minsur's tin concentrates were shipped to Capper Pass (United Kingdom), Billiton (The Netherlands), or Metales Potosí (Mexico) for smelting.

Portugal.—The new Neves Corvo Mine, in its third year as a copper producer, began tin production in 1990. This mine was developed by Sociedad Minera de Neves Corvo (SOMINCOR), owned 51% by the Government-controlled Empresa de Desenvolvimento Mineiro E.P. and 49% by RTZ Corp. PLC. RTZ states that the tin reserves at this southern Portugal mine were about 2.8 million tons of tin ore with an average grade of 2.6%. The company planned to gradually increase the output to 5,500 tons in 1993. Because tin was a byproduct of copper, tin production costs could be among the lowest in the world. In 1990, mining was restricted to the Upper Corvo and Graca deposits.

Neves Corvo's tin ore was treated in two circuits. The first, treating a shalehosted ore of 4% tin content, with a design capacity of 100,000 tons annually, suffered from equipment failures, but was expected to be at full capacity by mid-1991. The second circuit treated sulfide ore with high-copper grades and locally enriched tin (1.3% average) at a design throughput of 200,000 tons annually; it performed above design capacity. SOM-INCOR sold concentrates ranging from 25% to more than 50% tin. SOMINCOR had a 3-year agreement with the Billiton tin smelter in the Netherlands to purchase about 30% of its 20% to 25% and about 20% of its 50% to 55% tin concentrates. Neves Corvo was expected to become the major tin producer in Europe once it achieved full capacity.

Industria de Estaños de Mangualda Ltd. announced the restart of its Neostano tin smelter, which was closed in 1986 because of financial problems. Plans called for eventual tin metal production of 2,000 to 2,400 tons annually.

Spain.—Estaños de Zamora announced a planned 70% increase by yearend in its tin smelter output. This was to be achieved by a modernization of its furnaces and construction of a new electrolysis line. Currently, most of its tin concentrates came from Burma, China, Nigeria, the United Kingdom, and Zaire. After the expansion, the firm expected to receive tin concentrates from SOMINCOR'S new Neves Corvo mine in Portugal. Most of the smelter's output of tin metal was sold to Ensidesa and Altos Hornos de Vizcaya in Spain's steel industry for making tinplate.

Taiwan.—Tong Yi Industrial Corp. began commercial production from its second 90,000-ton-per-year tinplate line. The firm imports from Japan about 100,000 tons of steel annually for its tinplate production; Kawasaki Steel Corp., which has an equity stake in Tong Yi, supplies about 50%, while Nippon Steel Corp. and NKK Corp. supply the balance.

Thailand.—Tin remained the principal mineral product and export, but in 1990, tin fell in relative importance as other industries gained. In Phuket, where 48 onshore mines were in operation in 1985, only one mine was still working. In neighboring Phangnga, less than 100 of a prior 550 mines still were worked.

Offshore mining declined also. The Jootee Offshore Mining Co., Ltd., in Phuket, shut down its modern bucket line dredge. Tonkah Harbor Ltd. lost its dredges in high seas. Aokan Thai Ltd. continued operating its two dredges with heavy losses. Dredger production at the Government-owned Offshore Mining Organization declined by one-half since 1989. Small illegal dredges numbered about 4,000 in 1978, but numbered only about 100 in 1990. Consolidated into a single fleet under the title Stin Andaman Co., the small dredgers worked a large offshore concession (Block 117) but the deposits proved to be negligible.

South Thailand accounted for 90% of the country's tin production. Onshore facilities, including gravel-pump and dry strip mines, produced 60% of Thai tin, and offshore bucket dredges and cutter section boats produced the remainder. Onshore gravel-pump mines, with their high operating costs, were particularly vulnerable to tin's price slump. Besides low tin prices and depleted tin ore beds, onshore miners were also squeezed by the sharp rise in diesel fuel and lubricant prices and by the need to file costly environmental impact statements. Thai tin mine operators virtually abandoned further tin exploration, preferring to invest instead in tourism, rubber, parawood, palm oil, and prawn cultivation.

Established in Phuket in the mid-1960's, Thaisarco, a subsidiary of Royal Dutch Shell Co. Ltd., smelted most of the domestically mined tin concentrates. The smelter had two electrical and four reverberatory furnaces, with a total plant capacity of 40,000 tons. This year, Thaisarco utilized only one electrical and one reverberatory furnace, as it operated well below capacity. Most of the smelter's revenue came from the sale of tin slag for the extraction of tantalum, but the price of tantalum declined by 50% in 1990. Thaisarco shipped 70% of its tin slag to Bayer Starck AG in Germany and the balance to Fansteel Corp. in the United States. In 1992, it was expected that the Thailand Tantalum Industry Co. would open its long-delayed tantalum processing plant in Mab Ta Put, Rayong Province, and then Thaisarco would be legally obligated to sell all of its tin slag to them.

In an effort to keep the smelter profitable, Thaisarco began experimenting with smelting tin ore from Africa, Burma, China, Laos, and South America. Should the project prove feasible, Thaisarco's furnaces would have to be adjusted to work the lower quality foreign concentrates, which typically assay at less than 60% tin compared to 74% tin for domestic material.

The Sea Exploration and Mining Co. Ltd. signed a production-sharing contract for exploration and production of tin in Burma's offshore mining block No. 4 in the Bokpyin area of the southern Tenasserim division.

The Thai Tinplate Co. (TTP) commissioned a new electrolytic tinplating line at its Samutprakharn plant, effectively adding another 150,000 tons annually to its capacity. Before the addition, the plant had a dual tin-free-steel-tinplate line with a capacity of 120,000 tons yearly and an older electrolytic tinplate line with a capacity of 90,000 tons yearly. The firm's output was 198,000 tons, of which 28% was tin-free steel (TFS). Kawasaki Steel Corp. of Japan had an equity stake in TTP and supplied the bulk of its blackplate.

U.S.S.R.—Tin mining was conducted mostly in the far eastern regions of the country. The Khingansk tin mine in eastern Siberia announced plans to expand its tin concentrate output to 3,000 tons annually by 1995 from 1,200 tons currently. Newly discovered deep-lying tin ore bodies extended the mine's life. Two 1,000-meter-deep shafts were sunk to access the new ore bodies with ore grades reportedly about 0.65% tin.

Government officials announced plans to rapidly expand tin mine operations, which would eliminate the need to import the metal and even allow the U.S.S.R. to begin exporting by 1995. Just north of the border with China, the Hingansk tin mine would be the source of most of the increased production. The Soviets had been ready to close the Hingansk Mine in 1971 after 26 years of extraction, but, in 1990, they discovered several deep deposits that reportedly hold high-quality tin ores. It was planned to begin extracting those ores by 1992, reaching maximum production rates by 1995. Hingansk produced 1,200 tons of tin-in-concentrate annually, in recent years.

United Kingdom.—Tin mining was concentrated in the Cornwall district, where mining costs were reportedly among the highest in the world.

Carnon Consolidated Ltd. operated the Wheal Jane and the South Crofty tin mines in Cornwall, but Carnon began diversifying away from a total dependence on tin mining. Most Carnon tin concentrates were shipped to the Billiton tin smelter at Arnhem, the Netherlands. At midyear, Carnon closed operations at Wheal Jane, citing the continuing low price of tin and the high cost of mining at Wheal Jane. The closure, following the recent shuttering of Geevor's tin mine at Pendeen, left South Crofty as the United Kingdom's only operating tin mine at yearend.

The Royal Cornish Consols United Tin Mines Cost Book Co. Ltd., with a reported 1.5 million shareholders, planned to start a new tin mine near St. Austell in Cornwall, where it owned 30 acres and leased an extra 1,500 acres of tin-bearing land nearby for eventual mining. The firm planned to exploit an ancient law to avoid taxes, including the newly proposed poll tax. Under the charter of the Pardon Treaty Agreement of 1508 between England and Cornwall, no laws passed by the English Government were valid in Cornwall without ratification by the Cornish

Stannary Parliament. The Stannary Parliament, defunct for more than two centuries, was revived in 1990. Indications were that the British Government would try to thwart this attempt.

The Capper Pass tin smelter, owned by RTZ Corp., continued operating, having returned to profitability by its recent downsizing and restructing. Most of the feed for Capper Pass was imported low-grade and complex primary and secondary materials. In addition to producing normal purities of tin metal, the plant was also a refiner of tin to very high purities for specialized applications and produced a variety of byproduct metals such as bismuth and indium.

British Steel Corp., a major tinplate producer, announced that it would invest \$5 million in a new Packaging Steel Development Centre (PACS) located near its steel plant at Port Talbot, Wales. The aim of the PACS would be to reproduce under full production conditions all the manufacturing and processes used by canmakers and to link this with the laboratory and testing facilities of the firm's tin mill.

British Steel Corp. acquired the Save-A-Can collection organization, which had 217 collection points for cans. The firm planned to expand this to 1,000 locations by 1994.

Current Research

In Japan, Otsuka Chemical Co., in Osaka, announced development of a new material for antistatic paints, a joint development by itself and the Research Institute for Production Development in Kyoto under a commission from the Government's Research and Development Corp. The electrically conductive composite material was fiberform potassium titanate, as fine as 10 to 20 microns, coated with tin oxide, and in powder form. The highstrength white-colored potassium titanate reinforced the transparent tin oxide. The powdered composite material could be mixed with pigments to make electrically conductive paint or used in sheet form in electronic and other advanced materials areas. Otsuka predicted that the new material would find applications not only in antistatic paint, but in electronic equipment and antistatic flooring material.

In Brunswick in the Federal Republic of Germany, Schmalback Lubeca AG announced the development of a new tin-

plate can for packaging nuts. Basically, it was an adaptation of a tinplate beverage can that kept the nuts fresh and unbroken. Lubeca developed a special process to replace atmospheric oxygen in the cans with inert gas, thereby overcoming the problem of rancidity caused by exposure to oxygen. Excess pressure in the can contributed to the rigidity and strength of the thin-walled tinplate container. A wide-opening pull tab enabled the nuts to be poured easily and hygienically into the hand, and the can was reclosable with a plastic slip lid. The 200-gram can was the same size as the most common beverage can and therefore suitable for distribution through beverage can vending machines.

The Wilkens Anderson Co., Chicago, IL, announced the successful introduction of a new "Sumetal Stannomatic" computerized instrument that provided instant measurement of the thickness of the tin coating on tinplate. A tin-chromium model was also available, which could determine the thickness of metallic chromium as well. Both models could be used to make in-process inspection checks.

The Davies Can Co. announced the development of a unique paint can, the "Trim-Rim." The principal novel feature of the design was the ringless top, which eliminated problems of paint accumulation. Other advantages claimed were easier filling and pouring, easier brush access to the contents, and less splatter and mess. A gasket in the lid provided an air-tight seal to prevent paint skinning, and the can had a welded side seam. Davis commenced construction of two new plants to make the new style cans in Covington, GA, and York, PA.

The Seymour Specialty Wire Co., Seymour, CT, announced development of a copper-nickel-tin wire alloy. This was a 15% Ni-8% Sn-77% Cu alloy, a spinodal material that could be age-hardened after forming. Seymour stated this alloy combined high-tensile strength with resistance to oxidation, stress relaxation, fatigue, and stress-corrosion cracking. In round wire form, these alloys were expected to challenge phosphor bronzes for applications as electronic leads, contact pins, and sockets. In flat wire form, they could compete with beryllium copper for eveglass frames, circuit boards, and electronic-contact clips. The alloy could also be used for rivets, self-threading screws, and a variety of cold-headed parts.

OUTLOOK

Supply

The supply of tin for the United States is expected to continue to originate primarily in Asia and South America and to enter the country in the form of refined tin metal. While some promising tin deposits exist in the United States, primarily in Alaska, these are not expected to become major production sites during the next 10 years, especially if tin prices remain low. The NDS is expected to continue to be a modest source of tin supply because the stockpile goal is substantially lower than the current inventory. Increased scrap recovery, both through alloy recycling and detinning, is a possibility, and that could help ameliorate the Nation's dependence on imported tin.

Worldwide, the oversupply of tin that has existed since the early 1980's appears likely to persist for at least a few more years. The advent of several new tin mines in countries like Bolivia, Brazil, China, Portugal, and the U.S.S.R. appears likely.

Demand

The demand for primary tin in the United States is forecast to be static in the

next few years. There appears to be some chance that tinplate may regain a small portion of the beverage can market in the next few years, especially if tin can recycling increases and if tinplate can maintain or widen its cost advantage over aluminum.

Among the major metals, tin has had a relatively good record as regards toxicity and the environment, and this aspect may help tin gain market share at the expense of more troublesome metals. In particular, if regulations continue to negatively impact the use of lead in applications such as solder, the demand for tin as the complimentary alloy component may increase.

Worldwide, new tinplating lines are being built in developing countries, and tinplate traditionally is a stronger competitor than aluminum in canmaking markets outside of the United States. Therefore, the outlook for overall tin demand is for modest growth of about 1% annually in the next few years.

Numerous research efforts in recent years have resulted in new applications for tin that could result in small-scale increases in tin consumption in future years, but there have been no major new applications. ²Pearce, S. TITANIUM

By Deborah A. Kramer

Ms. Kramer, a physical scientist with 7 years U.S. Bureau of Mines experience, has been the acting titanium specialist since April. Domestic survey data were prepared by Regina R. Coleman, mineral data supervisor, and Giovanni C. Jacarepaqua, mineral data assistant; international data tables were prepared by Virginia Woodson, international data coordinator.

he year 1990 represented the 200th anniversary of the discovery of titanium, although more than 100 years passed until its commercial use. Today, titanium dioxide (TiO₂) is used widely as a white pigment in paints, paper, and plastics, and titanium metal is an important component of commercial and military aircraft.

Because of a slowing economy, U.S. production and consumption of both TiO₂ pigments and titanium metal dropped slightly during 1990. The

decline in consumption also had an effect on prices for pigments and metal, both of which also fell by yearend. Consumption of concentrates also fell, in line with the decreased demand for TiO₂ and titanium metal. U.S. TiO₂ producers increased their capacity during 1990 and planned to bring an additional 245,000 metric tons of annual capacity on-stream by the end of 1991. Capacity expansions for titanium metal production also were planned in the United States within the next few years.

World demand for TiO₂ was estimated to be nearly 3 million tons, with a total production capacity of about 3.3 million tons. The slight increase in world TiO₂ production capacity coupled with reduced demand helped to ease the tight supply-demand situation that had occurred during the past few years. Because of a tightening of waste disposal regulations, particularly in Europe, sulfate-process TiO₂ plants were either being replaced by chloride-process plants or additional waste-treatment facilities were being added.

DOMESTIC DATA COVERAGE

Consumption data for titanium raw materials are developed by the U.S. Bureau of Mines from one voluntary survey of domestic operations. Of the 32 operations canvassed, 97% responded, representing 99.9% of the data in tables 6 and 11. Data for the one nonrespondent was estimated based on prior-year consumption levels.

BACKGROUND

Definitions, Grades, and Specifications

Ilmenite is the most abundant titanium mineral, with the chemical formula $FeTiO_3$ and theoretical composition of 52.7% TiO_2 and 47.3% FeO. However, the term "ilmenite" is also used to include material that has been oxidized and leached during weathering, containing up to 70% TiO_2 , about 25% to 30% iron oxides, and about 5% of oxides of other elements. When the alteration is extreme, the residual material is essentially amorphous to finely crystalline TiO_2 and is called leucoxene.

Rutile is essentially crystalline TiO₂, and commercial concentrates usually contain about 95% TiO₂. Synthetic rutile or rutile substitutes are derived from ilmenite by processes involving oxidation and reduction treatments followed by leaching of iron. Synthetic rutile concentrates approach rutile in chemical composition but, being residual leached grains, are porous and composed of very fine crystallites, while natural rutile grains are usually single crystals.

Anatase also is crystalline TiO₂, but has a different crystal structure than rutile. Anatase is not yet available commercially, but large deposits of anatase-bearing ore in Brazil are being developed.

Commercially available titaniferous slags made by electric furnace smelting of ilmenite with carbon contain 70% to 85% TiO₂. Slags being produced at the end of 1990 were 80% TiO₂ slag from Sorel, Quebec; 85% TiO₂ slag from Richards Bay, Republic of South Africa; and 75% TiO₂ slag from Tyssedahl, Norway.

Titanium tetrachloride (TiCl₄), the intermediate compound from which titanium metal and chloride-process TiO₂ are manufactured, is a colorless to pale yellow liquid at room temperature, with a boiling point of 136° C.

Titanium sponge metal is the primary

metal form obtained by vapor phase reduction of TiCl₄ with magnesium or sodium metal. It is called sponge because of its appearance and high porosity. Titanium ingot for forging into billet and mill products is obtained by melting sponge in a vacuum-arc furnace, with or without scrap titanium or alloying additions. Specifications for titanium sponge for the National Defense Stockpile (NDS) are given in table 1.

Titanium dioxide pigment is characterized by its purity, refractive index, particle size, and surface properties. The particle size is critical and must be closely controlled within the range of about 0.2 to 0.4 micrometer to develop optimum pigment properties. The superiority of TiO₂ as a white pigment is due mainly to its high refractive index and resulting light-scattering ability, which impart excellent hiding power and brightness. Titanium dioxide pigments are produced as two major types: rutile and anatase. Rutile-type pigment, less reactive with paint vehicles in sunlight than is the anatase type, is preferred for use in outdoor paints. Anatase pigment has a bluer tone than the rutile type, is somewhat softer, and is used mainly in indoor paints and in paper manufacturing.

Specifications for natural rutile for the NDS are shown in table 2. There are no

rigid specifications for raw materials to be used as feed for making TiCl₄ for metals or pigment manufacture, or for ilmenite or slag to be used in the sulfate pigment process. Certain impurities such as chromium, columbium, manganese, phosphorus, and vanadium, however, can seriously impair pigment properties, so these impurities are an important consideration in the selection of concentrates for pigment production. Concentrates to be used for making TiCl₄ should be low in calcium and magnesium, which form high-boilingpoint chlorides that cause trouble in fluidbed chlorinators. Chemical compositions of typical commercial titanium concentrates are shown in table 3.

Industry Structure

The titanium industry is moderately integrated from raw materials to semifinished products. The world's largest TiO, producer, E. I. du Pont de Nemours & Co. Inc., obtains ilmenite, rutile, and leucoxene from its own mines in Florida and from various suppliers in other countries, mainly Australia. NL Industries Inc. for many years has supplied ilmenite to its European pigment plants from its mine at Tellnes, Norway. Since 1987, a smelting plant at Tyssedahl, Norway, has been processing part of the Tellnes ilmenite to produce titanium slag for the same market. The Tioxide Group PLC, United Kingdom, owns a 40% share of Westralian Sands Ltd. in Australia. In 1989, Hanson Industries PLC, United Kingdom, owner of SCM Chemicals Inc., acquired a 49% interest in Renison Goldfields Consolidated Ltd. (RGC), the major producer of titanium minerals in Australia. Also in 1989, a joint venture between Minproc Holdings Ltd. and Kerr-McGee Chemical Corp. was established to develop integrated operations in Western Australia involving the mining and concentrating of ilmenite, processing of the ilmenite to make synthetic rutile, and manufacture of TiO₂ from the synthetic rutile. Nearly all of the remaining TiO₂ pigment manufacturers buy their raw materials from independent producers of titanium concentrates.

None of the sponge metal producers outside China or the U.S.S.R. owns its own titanium mine. Titanium Metals Corp. of America (TIMET) purchases Australian rutile and manufactures TiCl₄, the intermediate compound universally used for commercial production of titanium metal. The other two U.S. titanium metal producers purchase TiCl₄ from a TiO₂ pigment manufacturer. Titanium mineral raw materials are purchased also for use in welding rod coatings, chemicals, and fiberglass.

The United States accounts for about 26% of the world's sponge production capacity. Overseas sponge producers and their share in total world capacity of about 117,000 tons in 1990 were the U.S.S.R., 44%; Japan, 23%; the United Kingdom, 4%; and China, 3%.

Titanium dioxide pigment output in 27 countries in 1990 came from about 60 separate facilities ranging in annual capacity from a few thousand tons to almost 300,000 tons. The United States accounted for 33% of the world's TiO₂ pigment capacity, followed by Japan, 10%; the Federal Republic of Germany, 10%; the United Kingdom, 9%; and France, 7%.

The world's four largest TiO₂ pigment producers are Du Pont with four plants in the United States and one in Mexico and

a total annual capacity of about 700,000 tons; Tioxide with two domestic plants and facilities in Australia, Canada, France, Italy, Spain, and the Republic of South Africa and total capacity of 437,000 tons; SCM, with plants in Australia, the United Kingdom, and the United States and annual capacity of 412,000 tons; and Kronos Inc., with producing plants in Belgium, Canada, the Federal Republic of Germany, and Norway, with a total annual capacity of 313,000 tons.

U.S. companies, mainly Du Pont, SCM, Kronos, and Kerr-McGee, own or control about one-half of the world productive capacity for TiO₂ pigments. Tioxide controls about 13%. An estimated 6% is owned by governments of countries with centrally planned economies. The remaining 33% is owned principally by large chemical firms or groups such as Bayer AG of the Federal Republic of Germany, Ishihara Sangyo Kaisha Ltd. (ISK) of Japan, and Kemira Oy of Finland.

Technology

Exploration.—Hard-rock ilmenite deposits, because of their inherent magnetic properties, are readily amenable to the application of aero- and ground-magnetic geophysical surveys. These deposits generally respond to such surveys by reflecting abnormally positive magnetic intensities, although in some cases negative magnetic anomalies may result. Once such anomalies are mapped, further exploration may take place in the form of detailed geological observations and ultimately drilling to test the anomalies and delineate the associated ilmenite deposit.

If initial diamond drilling indicates an economic deposit, development drilling proceeds on a set grid pattern of about 200 or 300 feet. Intermediate holes are drilled to fill in major gaps in information on geologic structure or ore continuations. Drill cores are visually logged and split for chemical assay to determine TiO₂ and iron content.

Sand deposits of titanium minerals are mostly near continental margins where erosion of regional granitic and metamorphic rocks containing ilmenite and rutile has led to accumulation of these minerals in coastal plain sediments. Working and reworking of these sediments by ocean waves on beaches and in streams resulted in various degrees of sand sorting and concentration by particle size, density, and resistance to abrasion. Well-sorted sands are much more likely hosts for ilmenite, rutile, and other heavy minerals than are unsorted sands.

Titanium minerals are dark in color, and their concentration in predominantly quartz sands is often readily visible. Initial discovery has, therefore, often been made through surface observation. In exploration, hand panning of samples has been a very useful exploration tool.

Some titanium mineral ore bodies are detectable by ground or airborne magnetometer surveys or, if monazite or zircon is present, by low-level radiometric surveys.

Drilling to determine the extent of sand deposits in the first phase of development should be done to a depth of at least 50 feet and preferably 100 feet. The type of drill needed will depend on the nature of the ground, including the presence of clay, hard-pan, roots, stumps, and other organic material, as well as the depth of the water table.

Approximate minimum requirements for an economic sand deposit of titanium minerals include reserves of 300,000 to 1 million tons of TiO₂ content in rutile or ilmenite and heavy mineral content in the ore of 1% to 5%, depending on the mix of ilmenite, rutile, and other valuable minerals.

Mining and Concentration.—For mining sand deposits of titanium minerals, a dredge is usually used. This may be bucket-ladder type but is more likely to be suction type. The dredge floats in its own pond, digging forward and stacking tailings aft.

Rough concentration, the separation of

heavy minerals from the lighter quartzfeldspar-mica fraction, is usually accomplished by wet-gravity methods. The Humphreys spiral has been standard for this separation since its introduction in about 1940, but pinched-sluice separators of various designs have also been used.

In Australia, the Reichert cone concentrator, which operates on the pinched-sluice principle, has been successful for large-tonnage operations. Flotation has also been used to some degree. For separating the minerals from stream-type deposits, jigs are usually chosen because they are the concentrating device least sensitive to extreme grain size variation.

The final wet-mill concentrate is dried, usually in a rotary kiln, prior to further treatment. The subsequent flowsheet depends on the mineral assemblage to be treated. Ilmenite and rutile are usually removed together by electrostatic separation. The ilmenite-rutile conductor fraction of dried wet-mill concentrate is then subjected to high-intensity magnetic separation, yielding a final ilmenite product. The rutile fraction is further cleaned by screening and additional electrostatic separation. Zircon and monazite products are recovered from the nonconductor fraction of the wet-mill concentrate by a combination of gravity, electrostatic, and high-intensity magnetic separation.

Ilmenite is mined from two hard-rock deposits, one in Canada and one in Norway. The ore bodies are massive, and open pit mining is practiced.

At Tellnes, Norway, the ore is crushed, ground, and subjected to wet-magnetic separation to recover magnetite. An ilmenite concentrate containing about 44.5% TiO₂ is recovered by flotation of the nonmagnetic portion, as was formerly done at the MacIntyre Development, Tahawus, NY, where ilmenite-mining ceased in 1982.

At Allard Lake, Quebec, ore at 32% to 36% TiO₂ is shipped from the mine to the beneficiation plant at Sorel, Quebec; some of the ore is shipped to steel companies as a substitute for fluorspar flux. For upgrading to slag, the ore is crushed and ground, concentrated by gravity methods, roasted to remove sulfur, mixed with a reducing agent, and smelted in an electric arc furnace. A high-purity pig iron is produced. The titanium is concentrated in the slag, known as Sorelslag, which contains 80% TiO₂. Because the iron content of the slag is low, its use reduces the quantity of iron sulfate in the

liquid effluent of sulfate-process pigment plants. Because of its relatively high content of magnesium and calcium, which causes operating problems during chlorination, Sorelslag is not used to make TiCl₄.

At Richards Bay, Republic of South Africa, both rutile and ilmenite are produced from heavy-mineral sand deposits. The ilmenite, containing about 50% TiO₂, is relatively low in magnesium and calcium and is smelted with carbon in an electric furnace to produce an 85% TiO₂ slag. Because of its low content of the aforementioned impurities, the Richards Bay (RB) slag is acceptable for manufacturing TiCl₄ and is also a feed material for the sulfate pigment process.

Materials made from ilmenite that have a TiO₂ content approaching that of natural rutile are known as synthetic rutile or beneficiated ilmenite. Processes to produce rutile substitutes from ilmenite fall into three general classes: those in which the iron is completely reduced to metal and separated from the reaction mass either physically or chemically, those in which iron is reduced to the ferrous state and chemically leached away from the titanium, and those in which the ilmenite is selectively chlorinated to remove iron and other impurities. The RB slag described in the previous section may also be regarded as a rutile substitute because of its high grade (85% TiO2) and suitability for the manufacture of TiCl₄.

Pigment Production.—Titanium dioxide pigment is produced commercially by two methods that require different raw materials. In the sulfate process, ilmenite or titanium slag is reacted with sulfuric acid; a portion of the iron sulfate formed may be crystallized and removed; and titanium hydroxide is precipitated by hydrolysis, filtered, and calcined. In the chloride process, rutile is converted to TiCl₄ by chlorination at 850° to 950° C in the presence of petroleum coke. All U.S. commercial chloride-process plants use fluid-bed chlorinators, although static-bed systems can be used for this purpose.

Titanium tetrachloride so prepared may be used either in making pigment, or with additional purification, for reduction to metal. In making pigment, the TiCl₄ is oxidized with air or oxygen at about 1,000° C, and the resulting fine-size TiO₂ is calcined at 500° to 600° C to remove residual chlorine and any hydrochloric acid that may have formed in the reac-

tion. Aluminum chloride is added to the TiCl₄ to ensure that virtually all of the titanium is oxidized in the rutile crystalline form.

Recoveries of ${\rm TiO_2}$ in pigment are approximately 90% and 80% to 85% for chloride process and sulfate process plants, respectively.

Metal Production.—Feed materials needed for metal production are the same as those for chloride-process pigment because formation of $TiCl_4$ is required in both cases. Rutile and rutile substitutes are the only titanium raw material used for metal production in the market economy countries.

Titanium sponge is produced by reducing TiCl₄ with sodium or magnesium under an inert atmosphere at temperatures up to 1,040° C. Residual chlorides are removed by vacuum distillation, inert gas sweep, or after cooling and crushing by leaching in very dilute acid. The sponge is compacted, usually with some scrap

and alloying additions, and made into ingot by two or more successive vacuum-arc melting operations.

Recycling.—Scrap titanium generally accounts for 40% to 50% of ingot production. Scrap is generated by producers of ingot and mill products and by consumers of mill products in fabricating finished products or components. It is estimated that up to 75% of titanium ingot metal becomes scrap during processing to finished parts. However, the proportion of scrap is gradually being lowered because of increased use of castings and other near-net-shape technologies.

Clean and well-segregated scrap, processed to remove impurities, is blended with sponge metal and alloying constituents and remelted to ingot. Remelting is mainly by vacuum-arc consumable-electrode processing. Electron-beam and plasma-arc cold-hearth melting is also used, especially for chips and turnings. Cold-hearth melting is very effective in ensuring removal of high-density inclusions, such as tungsten carbide tool particles, that settle out in the hearth area during melting. A substantial quantity of titanium scrap, particularly unprocessed turnings, is consumed directly or in making ferrotitanium for use in steel and other alloys.

Economic Factors

Prices.—The price of rutile pigment and titanium sponge in constant dollars decreased 20% and 14%, respectively, from 1969 through 1972, as shown in table 4. Reflecting a sharp increase in pigment demand, the constant dollar price rose 32% in 1974. The pigment price did not surpass that level until 1989, following 6 consecutive years of record-high demand. As the tight supply-demand situation eased in 1990, the constant dollar price dropped slightly. The titanium sponge price reached a record high in 1980 because of unprecedented demand for commercial aircraft, then dropped sharply in 1982 and 1983 following a severe downturn in the commercial aircraft market. Although sponge consumption was near record-high levels in 1989, the constant dollar price was several percent below the moderate levels of 1975-77. The decline in sponge consumption in 1990 was mirrored by a decrease in price. Published prices of titanium concentrates and products in 1989-90 are listed in table 15.

Costs.—Construction cost of a 110,000-ton-per-year synthetic rutile plant completed in 1977 at Mobile, AL, was reportedly \$53 million, or about \$480 per annual ton of product.

The cost of constructing a new 82,000ton-per-year chloride-process pigment plant in 1989 was about \$2,500 per ton of annual capacity. Sulfate-process plants, including neutralization facilities, were said to cost considerably more. The operating costs for chloride plants, which may be operated continuously and are more easily automated, reportedly were as much as 30% lower than those for sulfate plants. The cost of finishing titanium pigment for marketing is about the same for both processes and composes a significant portion of the total costs. Mineral raw material costs in the sulfate process are appreciably lower than those in chloride-process plants that use rutile as feed material.

Plant costs for producing titanium sponge are very high. The estimated cost per annual ton of capacity in 1989 was about \$12,000 to \$15,000. Raw material costs for producing titanium sponge are about the same, whether reduction is with sodium or magnesium, and the selection of one reductant over the other depends upon local market economics.

Tariffs.—The duties shown in table 5 reflect results of the Tokyo Round of Multilateral Trade Negotiations completed in 1979 under which tariffs on many items were reduced in several stages during the period January 1, 1980, to January 1, 1987.

Depletion Provisions.—The depletion allowance for ilmenite and rutile is 22% when mined from domestic deposits and 14% from foreign deposits.

Operating Factors

Environmental Requirements.—Heavy-mineral sands mining presents few serious environmental hazards. The land is restored by returning the bulk of the sand after removal of the ore minerals and may even be improved in low, flat areas. Dune areas can be left in nearly their original form, and the sand can be stabilized by seeding and replanting.

The major environmental problem in

the titanium industry is the disposal of wastes from pigment-producing processes that use ilmenite, generating up to 3.5 tons of waste per ton of product. Solutions to this problem required the development of methods to neutralize and control the effluent now produced by the sulfate pigment process, mainly a solution of waste sulfuric acid and ferrous sulfate heptahydrate. Deep well disposal has been used for waste ferric chloride produced when ilmenite is used to make TiCl₄. In processes for making synthetic rutile, the effluent solutions are treated to regenerate the original leaching agent, such as hydrochloric acid, which is recycled, and to form useful byproducts such as sodium sulfate, ammonium sulfate, and iron oxide. In sulfate-process technology, there is a strong trend away from disposal of waste materials in streams or in the oceans. Both U.S. sulfate-process producers now are using waste treatment plants that neutralize acid effluent with limestone and lime and produce gypsum and iron oxide byproducts. Such neutralization processes add about \$100 per ton to the cost of the TiO₂ pigment product. The sale of all byproducts would recover only a small fraction of this cost.

On September 1, 1989, the Environmental Protection Agency (EPA) published a newly revised interpretation of the Bevill exclusion, which exempts mineral processing wastes from regulation under subtitle C of the Resource Conservation and Recovery Act (RCRA). EPA's revised interpretation addressed the definition of mineral processing and established high-volume and low-hazard

criteria for waste streams to be retained within the Bevill exclusion.1 Subsequent proposed rulemaking later in 1989, published in January 1990, applied this revised interpretation to 20 waste streams that were conditionally retained in the Bevill exclusion.² In the TiO₂-TiCl₄ sector, chloride processing waste solids were retained, passing both the high-volume and low-hazard criteria. However, other waste streams in this sector were not retained: sulfate process waste acids, having failed to pass the low-hazard criterion; and sulfate process waste solids, chloride process waste acids, and titanium leach liquor, which all failed the high-volume criterion. EPA estimated compliance costs for the sulfate process portion of the titanium dioxide sector to average 0.8% of the value of shipments for the affected facilities.

Toxicity.—Titanium is a nontoxic material, as demonstrated by the use of TiO₂ in cosmetics and the use of titanium for making pacemakers and other implant devices for humans. However, some titanium compounds can be hazardous; for example, TiCl₄, which reacts violently with water or moisture in the air, forming TiO₂ and hydrochloric acid.

Energy Requirements.—According to a 1975 study for the U.S. Bureau of Mines, energy requirements for alluvial mine production are about 5.1 million British thermal units (Btu's) per ton of TiO₂ in concentrate. Production of pigment requires about 75 to 112 million Btu's per ton of TiO₂, depending on the process and feed material used. Titanium

sponge production uses from 408 to 466 million Btu's per ton of metal, of which about 248 to 270 million Btu's is required to regenerate the reductant and chlorine. The conversion of sponge metal to titanium ingot requires an additional 46 million to 57 million Btu's per ton of titanium ingot.³

ANNUAL REVIEW

Legislation and Government Programs

In October, the International Trade Administration of the U.S. Department of Commerce announced final results of its antidumping administrative review of titanium sponge imports from Japan for the periods November 1, 1986, to October 31, 1987, and November 1, 1987, to October 31, 1988. Antidumping margins for the 1986-87 period were as follows: Showa Titanium Co. Ltd., 2.07%; Toho Titanium Co. Ltd., 2.07%: and Osaka Titanium Co. Ltd., 0%. For the 1987-88 period, antidumping margins were as follows: Showa, 9.26%; Toho, 18.39%; and Osaka, 0%. A cash deposit of the estimated antidumping duties will be required on sponge from Showa and Toho based on the above margins.4

On September 28, 1990, Commerce announced its determination not to revoke the antidumping finding on titanium sponge from the U.S.S.R. In August, Commerce intended to revoke an antidumping finding on titanium sponge from the U.S.S.R. because of an apparent lack of concern by interested parties. Late in August, two U.S. sponge producers objected to the proposed revocation; Commerce no longer intended to revoke the finding. Titanium sponge from the U.S.S.R. will continue to be subject to antidumping duty deposits of 83.96% of declared value.

A draft report to Congress, prepared by EPA in August, presented recommendations on regulating the 20 waste streams that had been conditionally retained in the Bevill exclusion to RCRA. After evaluating three scenarios, which were based on some flexibility built into certain sections of RCRA, EPA recommended that chloride-process waste solids from TiCl₄ production be regulated under subtitle C- or subtitle D. After evaluating and responding to

public comments, EPA would issue final regulations by January 31, 1991.⁵

Following an information meeting with representatives of major titanium sponge producers in the United States and Japan, the Defense Logistics Agency (DLA) announced that it would not proceed with its planned acquisition of titanium sponge for the NDS. DLA said the action was taken after the Department of Defense reevaluated its needs, and it was determined that current Government requirements could be met with existing inventories and present and future industrial capacities in the United States. DLA's February 9, 1990, proposal for acquisition of 2.177 tons of Type A sponge (magnesium reduced, vacuum distilled) was strongly opposed by the U.S. titanium industry and Congress because Type A sponge is currently produced only in Japan.

Strategic Considerations

Security of Supply.—Although imports supply a very large proportion of domestic consumption of titanium concentrates, these imports come predominantly from Australia and Canada, which have historically been reliable and politically stable suppliers.

Import reliance, defined as imports less exports plus adjustments for inventory changes, may be used as a measure of dependence on foreign sources of supply. Expressed as a percentage of consumption, import reliance for ilmenite, including high TiO2 slag made from ilmenite, was 35% in 1980 but increased to about 80% in the 1982-84 period because of cessation of production at two U.S. ilmenite mines. Ilmenite import reliance through 1990 generally has been in the 70% to 80% range, although it dropped to about 60% in 1990. Import reliance for rutile declined from about 90% in 1980 to about 60% in 1983, and in later years it has remained in the 60% to 70% range because of increased production of synthetic rutile. However, this decline was at the expense of increased import reliance for ilmenite because the domestic synthetic rutile was made from Australian ilmenite.

Dependence on foreign rutile sources could be eased or eliminated in an emergency in two ways, using current commercial processing methods. Synthetic rutile could be made from domestic ilmenite now being mined in Florida or from ilmenite that could be mined from other deposits, such as the Tennessee ilmenite sand deposits. Titanium tetrachloride for metal production could be made directly from ilmenite, as is done by Du Pont for TiO₂ pigment manufacture.

Another possible solution to this problem is the development of new processes that utilize domestic ilmenite and perovskite that contain too much calcium

¹Production plus imports minus exports plus stock decrease or minus stock increase.

²Excludes U.S. production data to avoid disclosing company proprietary data.

and magnesium to be used directly for making TiCl₄. Availability of such processes would encourage production of domestic ilmenite, which fell from about 450,000 tons of contained TiO₂ in 1975 to about 165,000 tons of TiO₂ in 1982. In 1990, ilmenite mine production capacity was about 200,000 tons per year of contained TiO₂.

Import reliance for titanium sponge as a percentage of consumption has ranged from 0% to 16% between 1980 and 1989, and the United States was a net exporter in 1990. Titanium concentrates currently used to make TiCl₄ for metal production are mostly imported rutile and synthetic rutile, but domestic concentrates could be used for this purpose in an emergency, possibly at higher cost.

Stockpile.—Rutile and titanium sponge metal are included in the list of strategic and critical materials for stockpiling purposes. Titanium sponge has been acquired periodically for the NDS from domestic producers and from producers in Japan and the United Kingdom. Rutile for the NDS was acquired mainly in the early sixties from Australia.

The Government's NDS goal for titanium sponge metal remained at 176,901 tons. The NDS inventory in December contained 23,555 tons of specification metal and 9,857 tons of nonspecification material. The NDS goal for rutile was unchanged at 96,162 tons. The total rutile stockpile inventory at yearend was 35,549 tons, including 51 tons of nonspecification material.

Issues

U.S. Ore Supply.—Although the United States has large reserves of titanium in the form of ilmenite, nearly all of U.S. titanium sponge production has been derived from imported rutile and synthetic rutile. This heavy reliance on foreign concentrates has developed because most producers of TiCl₄, the intermediate compound used to make titanium and a large part of the world's TiO₂ pigment, prefer rutile or synthetic rutile over ilmenite as plant feed material. Possible ways of better utilizing U.S. ilmenite resources and reducing U.S. dependence on foreign sources of titanium concentrates were discussed previously.

Fluctuations in Metal Demand.—A

major problem affecting the titanium industry is the wide fluctuations in demand caused by changes in requirements for both military and commercial aircraft programs. Titanium sponge producers have repeatedly increased capacity in response to anticipated demand and have then been left with excess capacity when those programs were canceled or cut back. The most recent example of such a fluctuation was the historic peak in demand and price reached in 1980-81 and the subsequent collapse in 1982-84. The sharp rise and fall of demand and prices were believed to have been aggravated by overestimation of aircraft orders that did not materialize or were later canceled as the aircraft market deteriorated. Following the market collapse, some producers and consumers were left with high inventories to be worked off during a period of lower demand.

It has been suggested that the aerospace industry could help stabilize demand and match supply to demand by better long-range planning and forecasting of their requirements and greater use of multiyear contracts. In the event that additional capacity is needed quickly in a national emergency, incentives such as loan guarantees and a guaranteed floor price for purchases from new capacity could be used, as authorized under the Defense Production Act. Further diversification of titanium into nonaerospace industrial applications would also help stabilize titanium demand.

Production

Concentrates.—U.S. producers of ilmenite in 1990 were Associated Minerals (USA) Ltd. Inc. (AMU) at Green Cove Springs, FL; Du Pont at Starke and Highland, FL, both from mineral sands deposits; P. W. Gillibrand Co., Simi Valley, CA, as a coproduct of its rock, sand, and gravel operations; and Nord Ilmenite Corp., Jackson, NJ, from a previously mined mineral sands deposit.

AMU was the only U.S. producer of natural rutile. Kerr-McGee, Mobile, AL, was the sole domestic producer of synthetic rutile.

Interest continued in exploration and potential development of mineral sands in Virginia and North Carolina. AMU and RGC (USA) Minerals Inc., both members of the RGC group of companies (Australia), continued development of the Old Hickory mineral sands deposit in

Dinwiddie and Sussex Counties in southern Virginia. These companies also were acquiring mineral rights to two deposits in North Carolina, near Aurelian Springs and Bailey. Minerals of value in these deposits were primarily ilmenite and zircon. If detailed drilling and feasibility test results are favorable, mining at one or more of these deposits could begin by 1993

South East TiSand, a joint venture between Becker Minerals Inc. of England and Consolidated Rutile Ltd. of Australia, also was investigating heavymineral sands deposits in southern Virginia and North Carolina. TiSand was operating a pilot plant at Brink in Greensville County, VA, as an aid in determining processing plant design and the quality of concentrates that could be produced.

Piedmont Mining Co. Inc. announced a preliminary agreement with Corona Corp. for a joint venture to explore for and develop heavy-mineral sands deposits in the Carolinas. Piedmont has been investigating occurrences of such sands, containing titanium-bearing minerals and zircon, in eastern North Carolina since 1989.

Ferrotitanium.—Ferrotitanium was produced by Galt Alloys Inc., Canton, OH; HTP Co., Sharon, PA; and Shieldalloy Metallurgical Corp., Newfield, NJ. Two grades were produced—a 40%- and a 70%-titanium grade.

Metal.—In March, Baroid Corp., Houston, TX, became the sole owner of TIMET by purchasing Allegheny International's 30% interest in TIMET for \$50 million. In November, Baroid completed the spinoff of its titanium and mining business, creating Tremont Corp., based in Denver, CO. Tremont included Baroid's bentonite mining operations in addition to TIMET.

TIMET purchased an equity interest in a metal distributor, Tisto GmbH, in the Federal Republic of Germany, which specializes in titanium and zirconium. This purchase complemented TIMET's 100%-owned subsidiaries in France and the United Kingdom. TIMET also completed a \$3.5 million expansion of its technical laboratory in Henderson, NV, to provide additional services in titanium product and process development. Additionally, the company started operations at its Morristown, TN, bar, sheet,

¹Based on 7-day-per-week full production. Includes 61,700 tons vacuum arc double/triple melt, of which triple melt generally ranged from 10% to 30%. The remaining 7,100 tons was single-melt (electron-beam and plasma-arc) capacity for remelt electrodes and commercially pure ingot and slab.

²Single melt only.

plate, and tube finishing facility in July. This facility was expected to be fully operational in early 1991.

In April, TIMET announced the signing of a \$70 million debenture purchase agreement with a Japanese consortium, Union Titanium Sponge Corp. (USTC), to finance the construction of a new 10,000ton-per-year titanium sponge plant. The new plant will be built in Henderson, NV. the site of TIMET's current sponge and ingot production facilities. USTC will provide state-of-the-art vacuum distillation technology, which was developed in Japan by Toho Titanium Co. Ltd., and will participate in construction of the new plant. Once the plant is operational, USTC will have the option of converting its debentures into 25% of the common stock of TIMET. The plant was scheduled for completion in 1993.

Oregon Metallurgical Corp. (Oremet) completed installation of two new reduction furnace systems, bringing its total annual sponge production capacity to 6,800 tons. Installation of two more reduction furnace systems, with an additional capacity of 1,400 tons per year, was deferred until the third quarter of 1991; this capacity was originally planned for yearend 1990 or early 1991.

Oremet reportedly signed a long-term agreement with SCM in November for SCM to continue to supply Oremet with

TiCl₄ for its titanium sponge production. Under the terms of the agreement, SCM would be Oremet's sole supplier of TiCl₄. In December, RMI Titanium Co. also signed an agreement with SCM for SCM to remain the TiCl₄ supplier for its Ashtabula, OH, sponge plant. The multiyear agreement, effective January 1, 1992, includes provisions to permit RMI to construct its own TiCl₄ production plant in the future. In November, RMI had postponed previously announced plans to build a TiCl₄ facility because of uncertain economic conditions.

In April, RMI became a public company as a result of an initial public offering of the 7.5 million shares of the company's common stock held by Quantum Chemical Corp. Prior to the offering, RMI was operated as a 50-50 partnership between Quantum and USX Corp. USX retained its 7.5 million shares of RMI common stock.

Teledyne Allvac began operation of its new plasma-arc cold-hearth melting furnace for titanium, increasing its melting capacity by 60%. The company said that because of equipment scheduling problems, its new continuous bar mill will come on-stream by the second quarter of 1991 rather than in late 1990 as originally planned.

Dynamet Inc. expanded its facilities for production of shaped wire at its Washington, PA, headquarters at a cost of

about \$2 million. Dynamet, a manufacturer of titanium- and nickel-base alloy bar, wire, and precision forgings, has been producing shaped titanium wire for about 3 years, primarily for medical applications. Dynamet's shaped-wire process was described as being on the cutting edge of technology, so that increased production could open up new markets. One of these new markets was aerospace gas turbine manufacturing, where shaped wire could displace rounds and other finished machine parts. Production from Dynamet's expanded facilities began in November.

Titanium Dioxide Pigments.—U.S. production of TiO₂ pigments decreased about 3% in 1990. Producing plants operated at 90% of their nearly 1.1-million-ton-per-year capacity.

New U.S. TiO₂ pigment production capacity scheduled to be in operation in 1991 includes Du Pont's 110,000-ton-per-year expansion at DeLisle, MS; the new Kronos 82,000-ton-per-year plant at Lake Charles, LA; and SCM's 53,000-ton-per-year expansion at Ashtabula, OH. These additions will increase total U.S. TiO₂ capacity to about 1.33 million tons per year. Kerr McGee rescheduled completion of its planned 54,000-ton-per-year TiO₂ plant, at a still undisclosed location, to 1994.

³Includes 2,100 tons of single-melt capacity.

Revised. NA Not available.

Consumption and Uses

Concentrates.—Total U.S. consumption of TiO₂ in concentrates decreased about 2% from the 1989 level. This decline mainly was attributed to a slowing economy. Both ilmenite and rutile consumption increased slightly, while slag consumption dropped by about 6%. Distribution of total consumption by end

use was pigments, 93%; metal, 4%; and other uses, 3%.

Ferrotitanium.—Consumption of titanium in the form of ferrotitanium and scrap in steel and other alloys rose about 10% in 1990.

Metal.—Net shipments of mill products fell by about 4%, and sponge pro-

duction also decreased by about 2%. Consumption of scrap for remelting continued to drop and supplied a calculated 40.7% of ingot feedstock compared with 42.5% in 1989. Castings shipments were about the same.

Mill product shipments by product type were forging and extrusion billet, 45%; sheet, strip, plate, extrusions, and other, 40%; and rod and bar, 15%.

Because of the implementation of the Harmonized Tariff System in Jan. 1989, import and export categories for 1989 and 1990 are not necessarily comparable with those in previous years.

²Data may not add to totals shown because of independent rounding.

³Data for sheet and strip, plate, extrusions (other than tubing), pipe and tubing, and other have been combined to avoid disclosing company proprietary data.

TABLE 9

CAPACITIES OF U.S. TITANIUM DIOXIDE PIGMENT PLANTS
ON DECEMBER 31, 1990¹

	Pigment capacity (metric tons per year			
Company and plant location	Sulfate process	Chloride process		
E.I. du Pont de Nemours & Co. Inc.:				
Antioch, CA	_	36,000		
De Lisle, MS		160,000

SCM Chemicals Inc., Hanson Industries U.S.A.:				
Ashtabula, OH	_	111,000		
Baltimore, MD	63,000	49,000		
Total	117,000	969,000		

¹The table does not include Hitox Corp.'s Corpus Christi, TX, production capacity of about 18,000 tons per year of buff TiO₂, which is made by refining and fine-grinding of synthetic rutile.

Estimated U.S. mill product usage by application was as follows: commercial aircraft, 41%; military aerospace, 37%; chemical industry, including pulp and paper, 10%; powerplant condensers, 4%; naval and other marine uses, 3%; medical implants, 1%; and other uses, mainly oil drilling, flue gas desulfurization, and automotive, 4%.

Current use of titanium in large commercial aircraft represents about 6% of aircraft empty weight. Titanium is utilized where high-strength toughness, heat resistance, and high structural efficiency are required. Typical aircraft uses are for structural forgings, such as the landing

gear beam in the Boeing 757; wing skins for the F-14 and F-15 fighter aircraft; rotor parts for helicopter systems; B-1B fracture-critical forgings and wing support sections; and rotor discs and compressor blades on various engines. Major nonaerospace industrial uses are mainly those requiring superior resistance to corrosion.

Prospective use of titanium was enhanced by United Airlines' order for 68 Boeing 777 airplanes in October. A Boeing spokesperson said that the company was expected to build a 9%-titanium aircraft in the 1990's, surpassing the 6% titanium in the Boeing 757.

Construction of the first 777 was set to begin in 1992. In the meantime, Boeing expected to build 38 aircraft per month, starting in the second half of 1991, compared with 34 per month in 1990.

Pigment.—Apparent domestic consumption of TiO_2 pigments was about 925,000 tons, about 2% less than in 1989, despite full-capacity operation of U.S. TiO_2 pigment plants.

Stocks

The TiO₂ content of inventories of ilmenite and rutile increased by 43% and 11%, respectively, while titanium slag stocks decreased by 14%. Overall TiO₂ content of concentrate stocks rose by 18%. Stocks of TiO₂ pigment decreased slightly to about 62,000 tons, a 20-day supply.

Markets and Prices

Prices of ilmenite and titanium slag rose slightly during the year; rutile prices, however, increased by about 50% in 1990. Titanium dioxide prices decreased about 3 cents per pound in the fourth quarter in response to the easing of the tight supply and demand situation.

Titanium sponge prices averaged about \$5.25 per pound in the first half of the year, \$5.00 per pound in the third quarter, and \$4.75 per pound in the fourth quarter according to industry sources. The decrease in sponge prices was attributed to increased production capacity and

somewhat lower requirements for ingot production. Prices of mill products rose about 5% early in the year in response to high demand and increased costs. Scrap metal prices remained low throughout the year, probably because of the relative abundance of sponge and increased availability of scrap in Europe from the U.S.S.R.

Foreign Trade

Imports of titanium raw materials decreased by 28% from those in 1989, with sharp declines in ilmenite and slag imports. On the basis of TiO₂ content, principal import sources for raw materials were Australia, 45%; the Republic of South Africa, 35%; Canada, 11%, and Sierra Leone, 8%.

World Review

Capacity.—The data in table 20 are rated capacities for mines and benefication plants, sponge metal facilities, and TiO₂ pigment plants as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time at a normal-

ly sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and temporarily closed facilities that, in the opinion of the author, can be brought into production within a short period of time

and with minimum capital expenditure.

Mine and mill capacity for the production of titanium concentrates, metal production plant capacity, and TiO₂ pigment plant capacity are generally based on close to a 365-day-per-year operation, 3 shifts per day. Capacity figures are based on information obtained from the producing companies, from news items, and

from U.S. Bureau of Mines estimates.

Reserves.—U.S. and world reserves and reserve base data for titanium are shown in tables 21 and 22. U.S. reserves of 7.8 million tons of TiO₂ in ilmenite and 300,000 tons of TiO2 in rutile occur mainly in ancient beach sand deposits in Florida. Ilmenite concentrates from the U.S. sand deposits contain about 60% to 65% TiO₂, while those from rock deposits contain 45% to 50% TiO2. The U.S. reserve base of 34.7 million tons of TiO₂ occurs as 23.5 million tons in ilmenite, 9.8 million tons in perovskite (CaTiO₃), and 1.4 million tons in rutile.

Other U.S. resources include additional rock deposits of ilmenite in California, Minnesota, New York, Wyoming, and sand deposits of ilmenite and/or rutile in Georgia, Idaho, New Jersey, North Carolina, Oregon, and South Carolina, as well as large quantities of accessory rutile in porphyry copper ores and mill tailings.

The U.S. Bureau of Mines is compiling a computerized file of worldwide mineral deposit data called the Minerals Availability System (MAS). When fully developed, MAS will provide a means of analyzing supply positions relative to available reserves, mineral-related land use issues, environmental issues, and a variety of problems associated with the mining, processing, and transporting of titanium and other commodities. Most of the resource data in tables 21 and 22 were derived from MAS reports.

Major titanium reserves in the United States are owned by Du Pont and AMU in Florida. Reserves in Australia are held mainly by Associated Minerals Consolidated Ltd. (AMC), a subsidiary of RGC, Consolidated Rutile Ltd.; Westralian Sands Ltd.; and Cable Sands Ltd. Reserves at Allard Lake, Quebec, Canada, are held by QIT-Fer et Titane Inc. (QIT), now a subsidiary of RTZ Corp. PLC. QIT also has a 50% interest in Richards Bay mineral sands deposits in the Republic of South Africa. Major deposits in Brazil, India, and Sri Lanka are held by the respective Governments.

Yearend.

¹Because of the implementation of the Harmonized Tariff System in Jan. 1989, import categories for 1989 and 1990 are not necessarily comparable with those in prior years.

Source: Bureau of the Census. Data adjusted by the U.S. Bureau of Mines.

NL Industries controls Titania A/S, owner of the large hard-rock deposit at Tellnes, Norway.

U.S. reported consumption of titanium dioxide in concentrates in 1990 was 1,107,000 tons. At this annual consumption rate, U.S. reserves of 8,100,000 tons would be sufficient for only about 7 years, without imports. However, with

the current level of import reliance, 62% of reported consumption, these reserves would provide almost a 20-year supply of titanium. The U.S. reserve base of 35 million tons TiO₂ content is equivalent to almost 32 times the 1990 domestic consumption level.

World production of TiO₂ in concentrates decreased in 1990, in line with the

slight decrease in world demand. Production capacity for TiO₂ in concentrates increased by about 1%, and TiO₂ pigment production capacity increased by about 2% in 1990. These capacity increases along with the slight decrease in demand helped alleviate the tight supply-demand relationship that has affected TiO₂ pigments in the past few years. Because of increased environmental regulations, particularly in Europe, regarding disposal of waste acid from sulfate-process TiO₂ plants, several producers have invested in additional acid recycling equipment to reduce or eliminate acid disposal.

Australia.—In May, the Cooljarloo, Western Australia, joint venture between Kerr McGee and Minproc Holdings was named TiWest, and production of ilmenite and rutile began in mid-1990. The second stage of the project, production of synthetic rutile, was expected to begin in early 1991, providing concentrate for sale as well as feed material for TiWest's TiO₂ pigment plant, to be completed by mid-1991. Total annual production capacities at the various facilities when completed were expected to be ilmenite, 400,000 tons; rutile, 35,000 tons; leucoxene, 9,000 tons; synthetic rutile, 68,000 tons; and TiO₂ pigment, 54.000 tons.

Although commissioned in 1989, startup of Australmin Holdings Ltd.'s mineral sands operations at Newrybar, New South Wales, was delayed until the first quarter of 1990 by an appeal to the Land and Environment Court of New South Wales. Conditional approvals for mining and processing were suspended until the appeal was dismissed in November 1989. The proposed plan was to recover about 12,000 tons of rutile and 10,000 tons of zircon annually from mineral sands mined at Newrybar and a processing plant at Woodburn.

Wimmera Industrial Minerals Pty. Ltd. (WIM), a subsidiary of CRA Ltd., announced an upgrading of reserves for its main mineral sands deposit near Horsham, Victoria. The company revised its grade of heavy minerals from 3.2% to 4.0% by excluding some of the low-grade material overlaying the main ore body. WIM also detailed four additional mineral sands resources in the same area, grading from 3.5% to 7.2% heavy minerals. Because of the fine grain size of the minerals, WIM was operating a pilot plant to develop techniques to separate

²Country of transshipment rather than country of origin.

³Data may not add to totals shown because of independent rounding.

⁴Less than 1/2 unit.

⁵Includes materials consumed for purposes other than production of titanium commodities, principally heavy aggregate and steel-furnace flux.

and concentrate the various minerals.

Nissho Iwai, a Japanese trading group, purchased the Australian mineral sands operations from Pioneer International Ltd. for \$193 million in January. The two operations included in the sale were RZ Mines Pty. Ltd., which has operations in New South Wales and holdings in Queensland, and Cable Sands, with operations in Western Australia.

Brazil.—In February, Compania Vale do Rio Doce began operation of a 50-ton-per-year pilot plant to produce titanium sponge in Minas Gerais. The company planned to spend 2 years testing the sponge for quality and another 3 years gearing up to produce sponge on an industrial scale of 5,000 to 10,000 tons per year.⁶

A \$400 million consortium of Brazilian and Japanese companies was formed to develop the ilmenite and zircon reserves along the coast of the State of Bahia. The companies in the consortium were the Bahia State Prospecting Co., Multiquartz Mining Co., both of Brazil, and Sumitomo Corp. and Kawatetsu Co. of Japan. Bahia State Prospecting conducted exploration and located the deposit, estimated to contain 3 million tons of ore, Sumitomo planned to provide titanium technology, and Kawatetsu planned to provide the zircon technology. Total cost of the project, up to the point of bringing the mine onstream, was estimated to be \$16 million. The concentration plant was expected to upgrade the crude ore from 4% to 55% ilmenite, with an estimated production rate of 200,000 tons per year. Initial production was scheduled for 1996.

China.—Marubeni Corp. of Japan announced that it had set up a joint venture with Malaysia Mining Corp. to mine ilmenite on Hainan Island in the South China Sea. The companies expected to recover 50,000 tons per year of ilmenite by late 1992. Sixty percent of the ilmenite was destined for export to Japan, and the remaining 40% would be used to produce 10,000 tons per year of TiO₂ on Hainan Island.

Finland.—Kemira planned to invest \$25 million in acid waste recycling equipment at its sulfate-process TiO₂ plant in Pori. By the beginning of 1992, Kemira expected to increase the concentration of the waste acid from 70% to 80% so that the company could use all the recycled

acid in its TiO₂ production process. Kemira also was investigating pilot-plant-scale purification technology for dilute waste acid streams, for which recycling was not economical. The long-term goal for Kemira was to eliminate all discharges to the sea.

Germany, Federal Republic of.—Sachtleben Chemie GmbH announced the startup of a waste acid recycling plant early in 1990 near the company's operations in Duisberg. The new plant will serve Sachtleben Chemie's plant and Kronos Titan GmbH's plant in Leverkusan. The new acid plant will concentrate waste acid to form reusable sulfuric acid and was expected to end the dumping of acid into the North Sea.⁷

India.—The Indian Government reportedly approved the construction of a 1,000-ton-per-year titanium sponge plant to meet the country's domestic needs. Feed for the plant was expected to come from domestic ilmenite and rutile reserves in the State of Kerala. No timetable for construction was established.

Italy.—Tioxide announced that it would construct an ultrafine TiO₂ production plant at its Tioxide Italia SpA operation in Scarlino. Using the company's patented technology, Tioxide planned to have the plant on-stream in 1991, with an initial production capacity of 400 tons per year and potential for expansion at a later date. Ultrafine TiO₂ is less than 0.2 micrometer in size and was expected to be used as a barrier against ultraviolet radiation in products such as plastics and food packaging.

Japan.—Estimated production of tita-

nium sponge in Japan was 26,000 tons, a 22% increase from the 1989 level of 21,341 tons. Annual sponge production capacity by the three Japanese producers was as follow: Osaka, 13,200 tons; Toho, 10,000 tons; and Showa, 3,000 tons. Osaka began a \$19 million expansion program to increase its annual sponge capacity to 15,000 tons by April 1991.

The Japanese sponge producers reportedly began a 5-year plan to develop a new sponge production process that would allow continuous output at lower costs. The producers planned to conduct laboratory tests in 1990 and build a 1,000-ton-per-year pilot plant by 1992. The new process involved mixing gaseous TiCl₄ with magnesium vapor at a high temperature and suitable pressure to produce titanium metal.

Korea, Republic of.—After a 4-year delay because of environmental concerns, the Republic of Korea approved a proposed \$97 million, 60,000-ton-per-year TiO₂ plant. The plant will be 80% controlled by Du Pont, which invested \$77.6 million, and the remaining 20% was invested by a local firm, Hanyang Chemical Corp. Plant completion was scheduled for late 1993 or early 1994.

SCM and Lucky Metals Corp. announced that they would construct a 40,000-ton-per-year TiO₂ pigment plant near Ulsan by the end of 1991. The plant would use SCM's chloride-process technology, and SCM would supply the raw materials to the Ulsan plant. Lucky Metals would then process the TiO₂ into various grades for the coatings, plastics, and other industries.

Malaysia.—U.S.-based Hitox Corp. completed construction of a 50,000-ton-

per-year synthetic rutile plant. The synthetic rutile will provide a captive source of feed material for Hitox's buff TiO₂ plant in Corpus Christi, TX.

Because of its allegedly high radioactivity level, Japan reportedly suspended imports of Malaysian ilmenite. The ilmenite, a byproduct of tin mining in Malaysia, supplied about one-half of Japan's ilmenite requirements.8

Mozambique.—Kenmare Resources PLC of Ireland suffered a setback in its plans to develop the Congolone mineral sands deposit near Angoche. In November, Johannesburg Consolidated Investment Corp. (JCIC) withdrew from negotiations to joint venture the project. JCIC was expected to take a 51% option on the project, but failed to gain the support of the Credit Insurance Guarantee Corp. of the Republic of South Africa.

Netherlands.—In June, TDF Tiofine BV began operation of a new 45,000-ton-per-year chloride-process TiO₂ plant at Rosenberg that replaced its sulfate-process plant at the same location.

Saudi Arabia.—Crystal Pigment Co. expected to complete a 50,000-ton-per-year chloride-process TiO₂ plant at Yanbu by mid-1991. Crystal Pigment is owned 25% by Kerr McGee, 25% by Shairco of Saudi Arabia, and the remainder by other investors.

Spain.—Tioxide planned to invest \$31 million in an acid recycling plant at its subsidiary Tioxide Espana SA plant at Huelva. The new recycling facility will be based on a pilot plant that used technology developed jointly by Lurgi and Tioxide Espana.

Because of the implementation of the Harmonized Tariff System in Jan. 1989, import categories for 1989 and 1990 are not necessarily comparable with those in prior years.

¹Sulfate process.

Sources: Technical publications, especially Industrial Minerals; industry contacts; and U.S. Bureau of Mines estimates.

South Africa, Republic of.—Completion of a new dry mill by Richards Bay Minerals substantially increased rutile production capacity to about 100,000 tons per year. The new mill also will provide ilmenite for increased production of RB slag beginning in 1991.

Installation of a fourth ilmenite smelting furnace in the second half of 1991 will increase production capacity of RB slag to 1 million tons per year.

Taiwan.—ISK Taiwan, a subsidiary of Japan's ISK, began operating an 18,000-

ton-per-year rutile finishing plant in Kaohsing in July. Raw materials for the plant will be supplied from ISK's Yokkaichi, Japan, plant, and the wastes from the Taiwanese plant also will be treated there.

Du Pont received Government approval for

its new 60,000-ton-per-year TiO₂ plant in Taiwan, but still is awaiting a construction permit from local authorities. Completion of this plant was scheduled for 1992.

United Kingdom.—In December, IMI PLC acquired TiLine Inc., an Albany, OR, manufacturer of titanium investment castings, for about \$6 million. IMI said that the acquisition would complement the line of castings made by TiTech International Inc., Pomona, CA, which IMI acquired in June 1989.

SCM Chemicals Ltd. announced that it would invest in technology to reduce wastes from its chloride-process TiO₂ plant at Stallingborough. A new plant would convert the acid wastes into hydrochloric acid and metal oxides, reduce solids, and dilute acid discharge. If the plant proves successful, SCM will evaluate the feasibility of using the technology at its other chloride-process plant locations.

Current Research

Scientists at the National Aeronautics and Space Administration (NASA) and Boeing Co. developed a new aircraft wing design that could cut jet fuel consumption by an estimated 10%. In the new design, a titanium surface that contains about 19 million tiny laser-drilled holes was added to the leading surface of the wing. These holes suck in air to reduce turbulence across the wing surface. Boeing successfully flew a 757 jet with a 22-foot wing section retrofitted with the new design.⁹

Research continued on titanium alu-

minide (Ti₃Al) primarily for aircraft components. Texas Instruments Inc. reportedly was supplying Ti₃Al foil to several military aerospace contractors for use in iet engine parts and advanced aircraft structures, such as fuselage and wing panels. By using clad-metal rolling and bonding technology, Texas Instruments developed cold-rolling and annealing processes that make alpha-2 Ti₂Al commercially feasible. According to the company, the greatest demand for these Ti₃Al foils was in metal-matrix composite applications, but the alpha-2 material also can be used for actively cooled structures.10

Investigators at Southwest Research Institute demonstrated that additions of columbium to Ti₃Al act as phase stabilizers and enhance the fracture toughness of the alloys. Unalloyed, Ti₃Al is brittle, but at ambient temperature, additions of columbium increase the fracture toughness by a factor of four. Columbium also increases the resistance of Ti₃Al to crack extension, consequently propagation of cracks in the material is reduced, even at higher temperatures.

Shape-memory alloys are materials that when deformed can return to their original shape when heated. One of the commercially feasible shape-memory alloys is nickel-titanium. Joint development between Raychem Corp. and Mercedes-Benz AG led to the installation of nickel-titanium shape-memory alloy springs in engines in some Mercedes-Benz automobiles. When the engine temperature is low, the shape-memory valve spring is soft, which allows a steel

spring to move a piston. At high temperatures, the shape-memory spring becomes stronger than the steel spring, pushing the piston in the opposite direction. These piston movements help to optimize shifting pressure.¹¹

At the University of Tokyo, a professor developed a method to produce titanium by deoxidation. In the process, TiO, is melted in an argon atmosphere by highfrequency heating; it is then combined with aluminum and a small quantity of calcium fluoride. Aluminum reacts with the oxygen in the TiO₂ to produce alumina. The alumina is then absorbed by the calcium fluoride. After remelting, a titanium ingot containing less than 0.6% oxygen was produced. According to the researcher, the new process is estimated to consume less than 2,500 kilowatthours of electricity per ton of titanium ingot, compared with 16,000 kilowatthours for the present process.12

OUTLOOK

U.S. demand for titanium mill products in 1990 declined about 2%, despite the continued high level of orders for commercial aircraft. Industry sources indicated that some inventory buildup by customers had occurred, and the shipments in the next few years would therefore be somewhat lower than those in 1990. Defense needs, however, tend to offset effects of previous inventory building and economic slowdown. It was expected that recently completed and future planned expansions of U.S. titanium sponge capacity will provide an adequate supply of titanium for the next several years.

World TiO₂ pigment production capacity in 1990 was estimated at about 3.3 million tons per year and demand at a little less than 3 million tons. An industry forecast of annual growth in demand was lowered from 3% in 1989 to 2%, or about 60,000 tons per year, because of the effect of inventory reduction and the potential effect of higher oil prices on the world economy. Planned net annual capacity increases were about 240,000 tons in 1991 and 230,000 tons between 1992 and 1995. With these increases, it is likely that a moderate capacity surplus will exist, at least through 1995, even if some of the planned expansions are postponed or cut back.

If plans for all of the announced pro-

²Ilmenite except for the 9.8 million tons in Colorado perovskite.

³Rutile except for the 200,000 tons in Arkansas anatase.

jects for development of titanium raw materials are implemented, an additional 1.4 million tons per year or more of TiO₂ in concentrates could be produced by 1995. At the projected 60,000-ton-peryear growth rate for TiO₂ pigment demand and little if any projected growth in titanium metal demand in the next few years, the world supply of TiO2 in concentrates should be more than adequate through 1995.

¹Table excludes production of unbeneficiated anatase ore in Brazil, in metric tons, as follows: 1986—2,772,082; 1987—3,344,318; 1988—3,400,000; 1989—3,500,000 (estimated); and 1990—3,500,000 (estimated). This material reportedly contains 20% TiO₂. Table contains data available through June 14, 1991.

²Ilmenite is also produced in Canada and in the Republic of South Africa, but this output is not included here because an estimated 90% of it is duplicative of output reported under "Titaniferous slag," and the rest is used for purposes other than production of titanium commodities, principally as steel furnace flux and heavy aggregate.

³Reported figure.

⁴Revised to zero. ⁵Contains 80% TiO₂.

⁶Contains 85% TiO₂.

TUNGSTEN

By Gerald R. Smith

Mr. Smith, a physical scientist with 27 years of research and commodity experience with the U.S. Bureau of Mines, has been the commodity specialist for tungsten since 1986. Domestic survey data were prepared by Cheryl Jackson, mineral data assistant; the world production table was prepared by Virginia Woodson, international data coordinator; and the outlook data were prepared by Barry Klein, Economist.

he high melting point, high density, good corrosion resistance, and good thermal and electrical conductivity properties of tungsten and its alloys and the excellent cutting and wear-resistant properties of its carbide are used advantageously in the production of numerous end-use items for domestic and military applications.

Total domestic consumption of tungsten in primary end-use categories increased about 6% in 1990 compared with that of 1989. Demand for products other than carbides, such as steels, superalloys, and mill products, was moderately strong and accounted for approximately 4% of the increase.

Most U.S. tungsten mines remained closed because of the persistently low prices for tungsten concentrate. Average prices for wolframite and scheelite concentrate decreased by 18% and 4%, respectively, in 1990, according to quotations published in Metal Bulletin (London).

Based on a revised assessment of military requirements, the goal for the tungsten family group in the National Defense Stockpile was raised to a level essentially equal to the present inventory in the stockpile.

A summary of the important U.S. and international statistics for 1990 and the previous 4 years are shown in table 1.

DOMESTIC DATA COVERAGE

Domestic production data for tungsten are developed by the U.S. Bureau of Mines by means of three separate, voluntary surveys. These surveys are "Tungsten TABLE 1

Ore and Concentrate," "Tungsten Concentrate and Tungsten Products," and "Tungsten Concentrate." Of the 51 known mining and processing operations to which survey requests were sent, 94% responded and are represented in the production totals shown in table 1.

BACKGROUND

Definitions

Tungsten, a silvery gray metal, has an atomic number of 74 and an atomic

weight of 183.92. Its most outstanding physical property is its high melting point of 3,410° C, the highest of all metals. Tungsten is one of the heaviest of elements, with a density of 19.3 grams per cubic centimeter at 20° C. It has good corrosion resistance, good thermal and electrical conductivity, and a low coefficient of expansion. At temperatures above 1,650° C, tungsten has the highest tensile strength of all metals.

Tungsten concentrate is sold in units of tungsten trioxide (WO₃). In the United States, sales are based on the short ton unit of WO₃. This is equivalent to 1% of a short ton, or 20 pounds of WO₃, and contains 7.19 kilograms (15.86 pounds) of tungsten. In most other countries, tungsten is sold in the metric ton unit (mtu) and contains 7.93 kilograms (17.48 pounds) of tungsten.

Natural or synthetic scheelite concentrate, in nodular form, is ideal for direct addition to steel melts because the calcium is removed as slag. Fine material in either synthetic or natural scheelite is not desirable because of high dust losses. Wolframite concentrate is not satisfactory for steelmaking because of the manganese and tin content.

Tungsten ores and concentrates are converted into the following intermediate products: ammonium paratungstate (APT), tungstic acid, sodium tungstate, tungsten metal powder, and tungsten carbide powder. Most of the APT is reduced to tungsten metal powder, which then is processed into tungsten carbide powder.

Tungsten alloys and tungsten mill products such as rod, wire, and sheet are produced from hydrogen-reduced tungsten metal powder. The tungsten carbide produced from powder is cemented, usually with cobalt, to form various cutting and wear-resistant tools and parts.

Tungsten chemicals (APT, tungstic acid, and sodium tungstate) are produced as coproducts at some tungsten processing plants and as primary products at others. When not processed further into metal powder, they generally are used in the chemical industry.

Products for Trade and Industry

Tungsten materials can be divided into four major classes, depending on use: (1) a carbide in cutting and wear-resistant materials and welding and hard-facing rods; (2) mill products made from essentially pure metal; (3) an alloy constituent in high-speed and tool and die steels,

superalloys, and nonferrous alloys; and (4) various chemicals and compounds for nonmetallurgical applications.

The extreme hardness of tungsten carbide at temperatures exceeding 1,000°C makes it a preferred metalworking material for cutting edges of machine tools subject to intense wear or abrasion and for metal surfaces in forming and shaping dies. The mining and petroleum industries use tungsten carbide in drill bits, in the cutting edges of earth-moving equipment, and in crushing machinery. Tungsten carbide is used widely in wear parts of transportation and electrical equipment.

In most applications, tungsten carbide generally is cemented with a powdered cobalt metal binder by compaction and sintering. The cobalt content can range from about 3 to 25 weight percent, with the higher content providing greater shock resistance at a sacrifice in hardness. Tantalum and/or titanium carbides are used in conjunction with tungsten carbide in certain cutting and chipping tools. Also, coatings such as titanium carbide, titanium nitride, and aluminum oxide on tungsten carbide are used extensively to increase the life of inserts for machining applications.

Mill products made from pure or substantially pure tungsten metal powder are used in significant quantities by the electrical and electronic industries. Tungsten wire is used as the filament in electric lamps and as cathodes for electronic tubes. Disks produced from tungsten rods or sheet are used in automotive distributor points, although this end use is declining as the number of automobiles with electronic ignition systems increases. They are also used as contact points in numerous manufactured products. Tungsten metal is employed as heat and radiation shielding, as electrodes for inert-gas welding, as components of X-ray and cathode-ray tubes, and as heating elements in high-temperature resistance furnaces. Tungsten metal is used by the aerospace industry because it retains its strength at elevated temperature in reducing or inert atmospheres. The use of tungsten as a heavy metal for counterweights and balances, especially by the aircraft industry, has been replaced, to a significant extent, by depleted uranium, which approaches the density of tungsten.

Cast tungsten carbide is used principally as a hard-facing material. In this application, carbide particles are applied by

a welding process to provide an abrasionresisting surface layer on the surface to be coated. The carbide may be initially in the form of rod or loose grains in a tube.

As an alloy constituent, tungsten is used primarily in the production of high-speed steels and tool and die steels. Hardness and oxidation resistance at elevated temperatures are the most important properties possessed by these steels, which are used for machinery and equipment in the metalworking, construction, and mining industries. Certain grades of stainless and other alloy steels contain tungsten to improve wear and abrasion resistance, shock resistance, corrosion resistance, and/or strength at high temperatures.

Tungsten is an important constituent in a wide variety of superalloys and nonferrous alloys. Tungsten-containing superalloys are being utilized increasingly in high-temperature applications for their high-temperature strength and oxidation resistance. Tungsten alloyed with copper or silver is used for electrical contacts to provide wear resistance with adequate electrical conductivity.

Nonmetallurgical applications of tungsten include chemicals used in textile dyes, paints, enamels, toners, and coloring glass. Certain tungsten compounds are luminescent and used as phosphors in pigments, X-ray screens, television picture tubes, and fluorescent lighting. Sodium tungstate is employed as a corrosion inhibitor and a fireproofing agent in textiles. APT is used in making catalysts for the refining of petroleum. Among other chemical applications, tungsten compounds are used in chemical-vapor deposition, as catalysts in other chemical processing, and as laboratory reagents.

The chief nonindustrial use of tungsten is in armor-piercing ordnance, but this has been replaced, in part, by depleted uranium.

ANNUAL REVIEW

Legislation and Government Programs

The National Defense Authorization Act for Fiscal Years 1990 and 1991 included no authority for disposal of tungsten from the National Defense Stockpile during 1990. This was the first time since 1961 that no tungsten was shipped from the defense stockpile.

Goals for the tungsten family group in the National Defense Stockpile were increased based on a revised assessment of military requirements. On June 26, 1990, requirements were raised by 9,178 metric tons (20,234,000 pounds) of tungsten content and established at 32,160 metric tons (70,900,000 pounds) of tungsten content. As a result, the new goal essentially equaled the existing inventory level for the tungsten family group as shown in table 2. The preceding action was taken under authority vested in the Assistant Secretary of Defense and in compliance with the National Defense Authorization Act for Fiscal Years 1990 and 1991.

On August 3, 1990, the Environmental Protection Agency (EPA) published the final regulations under the Clean Water Act affecting nonferrous manufacturing (55 FR 31692). The regulations limited effluent discharges to waters of the United States and the introduction of pollutants into publicly owned treatment works by existing and new sources that conduct metal manufacturing operations in the metallurgical acid plants subcategory. Issued for the purposes of judicial review on August 17, 1990, the regulations became effective on September 17, 1990, and covered the secondary tungsten and cobalt subcategory along with five other subcategories. Amendments included in these final regulations were in response to settlement agreements with six petitioners, published October 30, 1989, (54 FR 45299), regarding regulations in 40 CFR 421 promulgated September 20, 1985, (50 FR 38276). The regulations for the secondary tungsten and cobalt subcategory (40 CFR 421.310-40 CFR 421.317) affected only cobalt effluents, but were directed toward processing methods integrally involved with the secondary recovery of cemented tungsten carbide components.

Regulations regarding "best available technology" and "pretreatment standards for existing sources" were to be complied with on EPA's effective date. The compliance date for "new source performance standards" and "pretreatment standards for new sources" will be the date the new source begins operation.

A bill introduced in the House of Representatives to extend the temporary suspension of duties on tungsten ore concentrates to December 31, 1993, did not proceed beyond the Committee on Ways and Means. As a result, the duty of 37.5 cents per kilogram (17 cents per pound)

TABLE 2

Revised.

of tungsten content on imports from countries with most-favored-nation status was reinstated on January 1, 1991. The suspension had been in effect since October 1, 1988.

Strategic Considerations

Tungsten is an important strategic material necessary for defense purposes. Currently, the heavy-metal alloys of tungsten, containing 3% to 10% nickel and small quantities of iron or copper, are used in several of the smaller diameter projectiles for penetrating armorplate. Cemented tungsten carbide parts, which exhibit excellent cutting and wear-resistant properties, are vital to the U.S. metalworking, machining, construction, transportation, mining, and oil and gas drilling industries. Tungsten mill products and powders are essential to the lamp and lighting industry as filaments and electrodes: to the electrical and electronic industries as wearresistant, electrically conductive contact surfaces; and to the superalloy and steel industries as alloying components. The

U.S. Department of Defense relies heavily on the maintenance of a broad domestic production base to cover mobilization contingencies. The entire tungsten industry, from mined ore to manufactured products, thus represents an important component of the U.S. defense policy. The Department of Defense continually assesses the U.S. ability to produce tungsten to ensure that this and other sources of supply are sufficient to meet current and projected levels of demand necessary to preserve the national defense. To that end, the quantity of tungsten in the National Defense Stockpile was increased to a level approximating that of the existing inventory in the stockpile.

Issues

During 1990, China continued to be the dominant supplier of tungsten products to the world market. Concentrate, APT, and ferrotungsten prices generally remained low, while market opportunities were limited by a supply-demand imbalance. Many Western World producers

¹Defense Production Act (DPA) of 1950.

²Apply the multiplication factor 0.851 to obtain the tungsten metal equivalent used in calculating the total recoverable metal in the tungsten family group.

believed that much of the problem rested with China's failure to place adequate controls on its production, distribution, and pricing policies. As a result of the depressed market, most tungsten mines in the United States and other Western nations remained closed or were operated at reduced capacity during the year. Also, two other mines, one in Australia and one in Brazil, were added to the list of closed mines during the year. Market conditions generally offered little or no economic incentive for producers to explore or develop other tungsten resources. One U.S. company, however, began an effort during the final quarter of the year to request U.S. Government action that would adjust the apparent inequities in the concentrate market. U.S. Tungsten Corp., a subsidiary of Strategic Metals Corp., Danbury, CT, and the operator of the Pine Creek tungsten mine and mill, Bishop, CA, initiated plans to file an antidumping suit against imports of Chinese tungsten ore concentrate.

Some indication of changes in China's tungsten production policies were reported near the end of 1990. Senior officials from China National Minerals and Metals Import and Export Corp. directed that all Government subsidies be removed from tungsten production operations effective January 1, 1991. Essentially, only economically sound operations would be able to continue under this new policy. A few industry officials viewed the Chinese action as an encouraging step toward achieving a more balanced supply-demand condition.

Production

Tungsten mining activity in 1990 was limited because prices for concentrate remained low. Recent statistics on domestic mining as well as a list of major concentrate producers and those processing the various stages of intermediate tungsten materials are shown in tables 3 and 4, respectively. Net production statistics for tungsten metal powders, carbides, and chemicals are shown in table 5.

Curtis Tungsten Inc., Upland, CA, announced a shipment of 24 metric tons of scheelite concentrate in February 1990. This was the first concentrate delivered from Curtis's Andrew tungsten mine, in the San Gabriel Mountains north of Los Angeles, since being operated intermittently during a 10-year period prior to 1985. The company reportedly was recovering its material from relatively rich

¹Excludes "withheld" data.

veins containing in excess of 1% WO₃. Efforts to produce additional concentrate were hampered by a severe drought that struck southern California for most of the year. Curtis reported in mid-June that it would attempt to increase its assets by entering into an agreement with Gartung Industries Inc., owner of the Strawberry tungsten mine, mill, and 90-man camp in Madera County, CA. These facilities, formerly owned by Teledyne Tungsten, a subsidiary of Teledyne Inc., were operated from July 1978 through December 1986.

U.S. Tungsten Corp., Bishop, CA, continued as the only other company producing tungsten concentrate. The Pine Creek Mine and mill again was operated on an intermittent basis at levels below capacity to provide supplemental feedstock to the company's APT conversion facility. Imported concentrate was the primary source of raw material.

Canada Tungsten Mining Corp. Ltd. suspended operations at its Fort Madison, IA, APT conversion facility at the end of March and did not produce additional APT the remainder of the year. The closure was described as an inventory control measure. The company continued

during the year to supply its customers with APT and other upgraded products from its inventories.

Consumption and Uses

Total domestic consumption of tungsten in primary end-use categories (table 6) increased by about 6% in 1990 compared with that of 1989. Demand for cemented carbides in the combined cutting tool, mining tool, oil drilling equipment, and wear-resistant component industries remained strong during the year, ending with an increase of about 2% compared with that of 1989. Demand for other tungsten products, including specialty steels, superalloys, chemicals, and mill products made from metal powder, was moderately strong during the year, accounting for the remaining 4% increase in demand for tungsten products.

Strength in the cemented carbide enduse sector was due, in part, to an increase in oil drilling activity in the final months of the year. As a result of the Iraqi invasion of Kuwait and the subsequent increase in the price of crude oil, the number of operating oil rigs in the United States rose notably. Figures reported by the International Association of Drilling Contractors and Baker Hughes Inc. showed a drill rig count of 1,179 by mid-December 1990 compared with a count of 966 on August 6, immediately after the invasion.

Markets and Prices

Average prices for wolframite and scheelite concentrate decreased by 18% and 4%, respectively, in 1990, according to quotations published in Metal Bulletin (table 7). Wolframite prices generally declined as the year progressed, showing only minor recovery in the second quarter of the year. Scheelite prices were considerably more stable, but also exhibited a declining trend throughout the year.

Domestic APT prices decreased about 4% during the year from a range of \$66.69 to \$67.79 per mtu in January 1990 to a range of \$63.93 to \$65.59 per mtu by the end of December. Prices for tungsten metal powder and tungsten carbide powder remained virtually unchanged during the year, quoted at \$22.00 and \$21.65 per kilogram, respectively.

Wolframite and scheelite prices published by Metal Bulletin are a standard

The average equivalent price per short ton unit of WO₃ was \$42.11 for 1990.

³Low and high prices are reported with the average equivalent price per short ton unit of WO₃ was \$42.11 for 1990.

³Low and high prices are reported weekly. Monthly averages are arithmetic averages of weekly low and high prices. The average price per short ton unit of WO₃, which is an average of all weekly low and high prices, excluding duty, was \$37.98 for 1990. The average equivalent price per metric ton unit of WO₃ was \$41.87 for 1990.

Weighted average price per metric ton unit of WO₃ was \$54.27 for 1990. The equivalent weighted average price per short ton unit of WO₃ was \$49.23 for 1990.

for the industry. Discussions regarding the magazine's tungsten pricing methods were held at the International Tungsten Industry Association's (ITIA) Fifth International Tungsten Symposium in Budapest, Hungary, December 1990. Responses to a questionnaire on pricing, sent to many tungsten industry representatives by Metal Bulletin, served as the basis for most of the discussion. In general, most respondents felt that the published prices were a fair reflection of the market, especially over an extended period of time and given the parameters within which they were formulated. There were some broad criticisms that the prices were influenced to a large degree by merchants, in spite of the fact that only confirmed purchases by consumers are taken into account when formulating the published quotation. Confirmation of consumer transactions is carried out to the best extent possible by contacting the seller in the transaction and/or requesting copies of the sales contract. An

additional broad criticism centered on the fact the published quotations did not include also the quantity of transacted material. Although this is true, Metal Bulletin does provide an indication of the quantity transacted by publishing, twice monthly, the tonnages represented in the International Tungsten Indicator price statistics. Furthermore, in situations where there is significant movement in price, there is usually an accompanying article in Metal Bulletin explaining such change that includes some information on the sales quantities involved.

On the matter of the adequacy of the concentrate specifications used to formulate the wolframite price, most respondents were satisfied with the minimum 65% WO₃ limit, but suggested that tin, arsenic, and phosphorus limits be lowered and calcium and antimony limits be added. With respect to the effectiveness with which the quotations reflect the wide range of wolframite grades transacted, most respondents were opposed to

splitting the quotation into separate grades or separate origins. This would only serve to reduce further the reportable quantities used in formulating the quotations.

Little change was recommended in the manner in which the present scheelite concentrate prices were quoted. There were, however, some suggestions that the maximum molybdenum content be specified and that artificial scheelite be excluded since it is not, strictly speaking, a concentrate, but rather a chemical product.

Foreign Trade

Comprehensive lists of U.S. export and import trade statistics by material quantity and value and by country of destination and origin are shown in tables 8 through 16. Import tariff rates for the various materials are shown in table 17.

Total U.S. imports of tungsten materials decreased about 13% in 1990 compared with that of 1989. China continued

to be the dominant supplier, providing about 50% of all imported tungsten materials, although its share of the import market declined by 11 percentage points from that of 1989. Restrictions on the

imports of APT and tungstic acid from China continued through 1990 in accordance with the 1987 Orderly Marketing Agreement (OMA). Of the aggregate APT and tungstic acid import quota of 757.8 metric tons (1,670,687 pounds) tungsten content designated for 1990, approximately 413 metric tons (910,508 pounds) was actually imported. Concentrates, oxides, ferrotungsten, and sodium tungstate continued to represent a significantly greater post-OMA share of tungsten materials imported from China. In 1990, these four types of materials constituted about 90% of all Chinese imports, whereas in 1987 they made up only about 50% of the Chinese imports.

In view of the fact that the present OMA will expire on September 30, 1991, U.S. processors of tungsten began discussions to consider future options to this trade agreement. Among the options reportedly mentioned were an extension of the present OMA for an additional 3 years, an increase in the OMA's scope to include other upgraded tungsten products, and an initiation of other trade actions, such as dumping or countervailing suits.

World Review

Capacity.—The data in table 18 are rated capacity for mines and mills as of December 31, 1989. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable longterm operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Mine capacity for tungsten is based on published reports, maximum production statistics, and estimates. The latter is utilized particularly for certain countries where capacity information is either incomplete or unavailable.

United Nations Conference on Trade and Development (UNCTAD).—The UNCTAD Committee on Tungsten convened its 22d session in Geneva, Switzerland, in December 1990. A Secretariat paper and national statements presented to the Sessional Working Group provided a review of current market conditions. The Secretariat presented a pessimistic outlook for the industry. The present trend of declining prices for tungsten concentrates was expected to continue into

1991, given the persistent oversupply of material and the weakening demand due to the slowdown in the world economy. The chairman of the session indicated that longer term prospects for the tungsten economy will be influenced by developments in Eastern Europe and Asia

as well as by disarmament decisions and environmental considerations. The invasion of Kuwait by Iraq in August 1990 contributed to some uncertainty in the future defense-related demand for tungsten.

Comments from delegates at the meeting indicated that the low prices and large

overhang of stocks had led not only to extensive mine closures but also to price-cutting competition among suppliers, especially for concentrates and intermediate materials. In addition, it had led to increased protectionism as evidenced by the recent trade actions against China. Moreover, low price levels had led to the termination of certain bilateral trading arrangements between major consumers and the major producer, but the effects of such changes on the tungsten market remained unclear.

The delegation from China noted that the main cause for the deterioration in the tungsten market since August 1989 was not the increase in world production, but rather the stagnation or steady decline in the domestic demand of the major consumers. They indicated that world tungsten output had not increased substantially, as had been alleged, and that the report of a rise in China's output, specifically, also was incorrect. They explained that the declining activity in the automobile, steel, machine building, and construction industries of the major consuming countries; new technological developments; increased recovery of scrap tungsten; and the growth of substitutes had all contributed to a steady decrease in demand. After stating that they had made efforts to improve the health of the tungsten market, the Chinese proposed that the appropriate form of action by the Committee on Tungsten was one directed toward reaching an agreement among the producers and consumers on measures to stabilize the tungsten market.

The Committee on Tungsten agreed to seek designation as an International Commodity Body (ICB) for the purpose of obtaining access to the account for developmental activities within the Common Fund for Commodities under UNCTAD. A separate item was added to the provisional agenda of the 1991 meeting for the purpose of considering project proposals by Governments and industry that could then be submitted for possible financing under this account. The decision to seek designation as an ICB was based on a proposal made by the delegation from Brazil at the 1989 meeting.

European Community (EC).—Subsequent to its investigation into complaints that China was dumping tungsten materials into the EC, the EC Commission's Council of Ministers reached a final

decision on September 24, 1990, on the question of permanent imposition of tariffs on certain tungsten imports from China. In that decision, imports of concentrate, tungstic acid and oxide, and tungsten carbide powder and fused tungsten carbide were made subject to duties of 42.4%, 35%, and 33%, respectively. The duties applied to all exporters to the

EC with the exception of China National Nonferrous Metals Import and Export Corp. and China National Minerals and Metals Import and Export Corp. Rather than being subject to the imposed duties, the latter exporters were required to comply with certain undisclosed minimum price standards for their products. According to the Official Journal of the

EC, the price standards will have the effect of "increasing the prices of the products concerned, to remove the injury caused to the EC industry. The definitive duties, while substantially lower than the dumping margin, correspond to the minimum price required to ensure that the EC producers receive an adequate return on sales in the case of the concentrates and,

tungsten end-use items, and environmental issues associated with tungsten processing methods.

Australia.—The Dolphin scheelite mine on King Island, Tasmania, Australia, was offered for sale in August by North Broken Hill Ltd. Company officials stated that continuing depressed tungsten prices and a declining market for the company's gravity-separation grade concentrate were primary reasons for the offer to sell. Although interest in purchasing the mine was shown by at least four investors, the company was unable to attract an immediate buyer. As a result, the mine was closed at the end of November 1990. The King Island closing left the Kara Mine, Tasmania, Australia, as the only operating tungsten mine in Australia. Annual production of tungsten

concentrate in Australia was expected to be reduced by about 80%.

Brazil.—Tungsten concentrate production was reduced by about 40% in 1990 compared with that of 1989 as a result of the closure of the Boca de Lage Mine, Currais Novos, Rio Grande do Norte Province. Tungstenio de Brasil Mineirios e Metais Ltd., the operator of the mine, stopped production after its parent company, Anglo American Corp., failed to renew its contract with the present owner. This closure will drop the country's concentrate production level significantly below its estimated consumption level of 670 metric tons of tungsten content per year. Annual concentrate production and consumption statistics for the world are shown in tables 19 and 20, respectively.

A tungsten concentrate upgrading plant was constructed in conjunction with tungsten mining operations near Currais Novos, Rio Grande do Norte. Operation began in late 1990 and was expected to produce 240 and 120 metric tons per year of ferrotungsten and tungsten carbide, respectively. Mineracao Tomas Salustino S.A., owner and operator of the nearby Brejui tungsten mine, holds a partial ownership in this facility.

China.—In addition to the administrative actions to halt Government subsidies to tungsten operations, certain other moves reportedly were initiated near the end of 1990 to gain more control over tungsten sales, exports, and price structure. The moves included terminating the pricing procedure that fixed sales transactions, in many instances, more than 3

¹Temporarily suspended through Dec. 31, 1990.

months in advance to one that offered the material on a short-term, spot market basis, generally of 1 to 3 months. Steps were also taken to reduce tungsten concentrate production by 30% to decrease global stocks and strengthen market prices.

India.—Sterling Tungsten, a subsidiary of Sterling Computers, began construction of India's first tungsten metal powder production plant in early 1990. The company is collaborating with Lucky Goldstar International, Republic of South Korea, on the technical aspects of construction and operation. India's Stateowned Tamil Nadu Industrial Development Corp. holds a 26% interest, and Sterling, 25%. The remainder will be publicly owned. Production is projected to begin by mid-1991 at this Madras, India, facility.

Japan.—Tokyo Tungsten Co. Ltd. reportedly began a significant expansion project at its Toyana tungsten powder production facility near Tokyo. The project is expected to increase the metal powder output of the plant from the present 840 metric tons per year to 1,200 metric tons per year.

Mongolia.—According to published reports, the trial operations that began at the Tsagaan Davaa tungsten mine in September 1988 were discontinued in early 1990. The mining facility, a joint venture between Mongolia and several Hungarian interests, apparently was unable to be operated economically. At full capacity, the operation was expected to treat 36,000 metric tons of ore annually.

Peru.—Production of tungsten concentrate by Minera Regina at its scheelite and ferberite mine southeast of Lima was increased appreciably in 1990 in spite of the generally depressed tungsten prices. According to a company representative, in addition to the increased production, the company had achieved greater processing efficiency and had improved the quality of its product, although only minimal profit had been achieved at the low 1990 price levels. Total Peruvian production in 1990, of which Minera Regina accounted for 70%, was about 1,200 metric tons tungsten content. Minera Regina's production was increased by approximately 30% compared with that of 1989.

Portugal.—In mid-October 1990, Charter Consolidated Ltd., London, completed the sale of its 75% interest in Portugal's Beralt Tin and Wolfram Ltd., which, through its Portuguese subsidiary, owns 80.55% of the Panasqueira Tungsten Mine near Fundao, Portugal. The purchaser, Minorco SA, an affiliate of Charter Consolidated, has other significant mining interests and additional Portuguese investments. Minorco's plans for the mine were not revealed.

Current Research

Several advancements in tungsten carbide (WC) technology were reported during 1990. Tungsten carbide spray coatings of improved quality were produced with a Super-D-Gun, developed by Union Carbide Coatings Service Corp., which produces higher supersonic speeds than the original D-Gun. A mixture of oxygen and acetylene explodes in the presence of the coating powder in a detonation chamber. The expanding gases reach a temperature of about 4,000° C and accelerate the coating powders to supersonic speeds, thereby improving the bond strength, density, and

surface quality of the coating. This wear-resistant coating exhibits compressive residual stress that also improves the fatigue resistance of the coating on substrates such as 4130 steel, 7075 Al, and Ti-6Al-4V.

Either chemical compounds or amorphous mixtures containing tungsten and cobalt were reacted in a gas mixture of controlled carbon concentration to produce a nanophase (ultrafine) WC-cobalt (Co) composite powder.² Nanophase

WC-23Co powder, after consolidation and formation of a wear-resistant coating by low-pressure plasma (ionized gas) spraying, exhibited good wear resistance and a lower coefficient of friction than conventional WC-Co coatings.

Alloys of WC-6.3Co and WC-6.15Ni implanted with chromium, molybdenum, and titanium ions exhibited lower overall corrosion rates and improved resistance to excessive localized corrosion in accelerated electrochemical corrosion

Table includes data available through May 8, 1991.

tests using dilute sulfuric acid and dilute sodium chloride-sodium sulfate solutions.³ The most promising results were obtained with implanted molybdenum ions.

Composites of Fe-5WC and Fe-20WC exhibiting excellent wear resistance were prepared using hot isostatic pressing (HIP) methods.⁴ Dense, pore-free composites were obtained by minimizing the reaction between the iron matrix and the

WC particles at pressures from 50 to 200 mega Pascals and a temperature of 800°C. Wear resistance of the composite increased as the HIP pressure was increased.

The wear resistance of plasma-sprayed WC-Co coatings was improved by infiltration with copper alloys. One such alloy consisting of copper, nickel, and phosphorus served as an excellent infiltrant. Hardness of the infiltrated coatings compared

favorably with that of conventional cemented WC-Co material.

OUTLOOK

Total apparent consumption of tungsten was correlated with three economic indicators to provide a basis for a statistical projection of tungsten demand through 1995.

Correlation was poor between the consumption data and the Federal Reserve Board (FRB) indexes of Industrial Production-Total and Industrial Production-Metalworking Machinery. Correlation was fair between the consumption data and the FRB index of Industrial Production-Construction and Allied Equipment. On the basis of this indicator, total apparent consumption of tungsten in 1995 was estimated to be about 12,150 metric tons. This corresponds to an average increase of about 2.5% per year over the 1989 level of 10.475 metric tons. Reports by industry spokesmen and studies revealed by independent market analysts apparently share the view that a 3% to 4% average annual increase in total tungsten demand is realistic for the short term. There is expected to be somewhat higher demand for metal powder in the short term due to the anticipated growth in the powder metallurgy market. Demand for tungsten carbide powder, on the other hand, is not expected to increase as rapidly. Growth in the demand for this material will continue to be tempered, particularly in the cemented carbide tool industry, by further competition from substitute materials, including ceramics, ceramic composites, polycrystalline diamond, and cubic boron nitride. Further slowing the rate of demand for these cemented carbide products will be the increased use of ceramic coatings to extend the life of the carbide. In addition, increases in the production of near-net-shape products by techniques such as precision casting, rolling and forging, and powder metallurgy will lessen machining requirements.

Information reported by manufacturers of machine tool equipment indicated that demand for these items could be down as much as 8% in 1991 compared with that of 1990. Such a decline in business activity would likely have a temporary effect on the demand for the cemented carbide tools and cutting inserts

associated with the operation of this machining equipment. A rebound in the demand for machine tool equipment will be expected in 1992. Machine tool requirements in the automotive and aerospace sectors are expected to increase as the economy begins to strengthen in many industrialized countries. Furthermore, solid growth potential reportedly exists in reindustrialized Eastern Europe as well as the United States, where energy exploration and conservation approaches will require new tooling equipment.

Supplies of tungsten concentrate and intermediate materials for U.S. consumption are expected to be sufficient in spite of the continued lack of production at domestic mines in recent years. Actions initiated by the Chinese Government in late 1990 to gain further control over

tungsten production, distribution, and pricing will very likely alter the sources of new tungsten supply if implemented for an extended period of time.

VANADIUM

By Henry E. Hilliard

Mr. Hilliard, a physical scientist with more than 20 years U.S. Bureau of Mines experience, has been the commodity specialist for vanadium since 1986. Domestic survey data were prepared by Lisa Harley, mineral data assistant; international data tables were prepared by William L. Zajac, Chief, International Data Section.

he principal use of vanadium is as an alloving element in steel. The addition of small amounts of vanadium, often less than 1%, to an ordinary carbon steel can significantly increase its strength and improve both its toughness and ductility. Such high-strength low-alloy (HSLA) steels are attractive in the construction of highrise buildings, bridges, pipelines, and automobiles because of the weight savings obtained. Vanadium-aluminum alloys of titanium are widely used in the aerospace industry. Oxides and chlorides of vanadium play important roles as catalysts in the production of sulfuric acid and other key organic chemicals.

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on vanadium that are consistent with international usage, will henceforth report data in kilograms (kg) and metric tons unless otherwise stated.

The year 1990 was a good but not great year for the U.S. vanadium industry, as the data tabulated on the following pages of this report demonstrate. Demand and production were relatively strong when the year began. However, the industry experienced a sharp decrease in production

at yearend as demand for vanadium products in many of the major markets weakened appreciably.

Overall, shipments of vanadium products in 1990 were essentially unchanged from 1989 shipments. Production was down by about 20% as some producers shipped from stocks. For the big-volume ferrovanadium (FeV), which is the core of the industry, shipments were down by about 12%. Consumption of FeV in the production of HSLA steel was down by more than 8%, and consumption for full alloy steel decreased by about 9%. Vanadium chemicals reported an increase in shipments for the year.

³Includes vanadium recovered from fly ash, and spent catalysts.

⁴May include ores and concentrates.

⁵Excludes U.S. production.

DOMESTIC DATA COVERAGE

Domestic consumption data for vanadium are developed by the U.S. Bureau of Mines from a voluntary survey of all known domestic consumers. In 1990, there were 83 responses to the consumption survey, representing 81% of the total canvassed. These 83 respondents are estimated to have consumed 95% of total domestic consumption, or about 3,893 metric tons. The estimated consumption of nonrespondents, derived using their past consumption relationships, trends, and data from nonsurvey sources, was about 205 tons. The consumption quantity of 4,098 tons shown in table 1 is the U.S. Bureau of Mines' estimate of total U.S. vanadium consumption.

BACKGROUND

Definitions, Grades, and Specifications

The term "ferrovanadium" as used by the U.S. Bureau of Mines includes vanadium-carbon-iron-nitrogen proprietary alloys as well as the conventional forms of ferrovanadium. Some of the more common commercial products are listed in table 2. A standard specification for ferrovanadium has been developed by the American Society for Testing Materials (ASTM).¹

Aluminum-vanadium master alloys contain fixed ratios of vanadium to aluminum and are used in the manufacture of titanium alloys. Amounts of vanadium up to 1 weight-percent improve the strength of titanium-base alloys and promote their thermal stability in the presence of moderate amounts of aluminum. When amounts greater than 4 weight-percent are added, the titanium-base alloy can be significantly strengthened by heat treatment. The three most important commercial titanium alloys containing vanadium are Ti-6Al-4V, Ti-6Al-4V-2Sn, and Ti-8Al-1Mo-1V. The Ti-6Al-4V alloy presently accounts for more than one-half of the titanium-base alloy market.

Products for Trade and Industry

Vanadium has been used as an alloying element in steel since 1902 when it was first added to tool steels used for high-

speed machining operations. It was found that vanadium prevented grain growth in tungsten-bearing steels and enabled the steels to maintain their hardness at the high temperatures generated in tool steels during high-speed machining. Vanadium is also widely used in high-temperature steels used in steam powerplants. Chromium-vanadium steels are used for steel pipes and headers, and molybdenum-vanadium steels are used for rotors because of the high creep resistance produced by vanadium carbides.

About 85% of all vanadium consumed is accounted for by use in the steel industry as an alloying agent. Another 10% is used in aerospace titanium alloys, with the remainder for chemical and catalyst preparations. Vanadium is an essential but not totally indispensable alloying metal. Often the addition of small amounts can provide considerable improvement in performance without further processing or a significant increase in cost over standard grades. The small amounts of vanadium combine with carbon or nitrogen or both and precipitate, causing an increase in strength and toughness. In addition, vanadium provides such added benefits as better weldability and heat resistance.

An increasing amount of vanadium has been used in the production of HSLA steels to provide yield points between 36 and 47 kilograms per square millimeter. The addition of small amounts of vanadium, often less than 0.1 weight-percent, to an ordinary carbon steel can significantly increase its strength and improve both its toughness and ductility. HSLA steels with high yield points are attractive for structures such as automobiles, bridges, highrise buildings, and pipelines where advantage can be taken of the savings in weight produced by the high yield points. Vanadium is also used extensively to provide elevated temperature strength to certain aerospace titanium alloys, the most common of which is an alloy containing 6 weight-percent aluminum and 4 weightpercent vanadium. This alloy is widely used for aircraft engine casings and fans and accounts for about 10% of U.S. vanadium use. Oxides and chlorides of vanadium play important roles as catalysts in the production of sulfuric acid, maleic anhydride, synthetic rubber, and other key intermediate organic chemicals.

Vanadium is usually traded on the international market in the form of technical grade V_2O_5 and 50% to 80% FeV. Most world exports of vanadium raw material

are in the form of vanadium-bearing iron slag from China and the Republic of South Africa, while U.S. and Western European converters are the major importers of these materials. U.S. and Western European converters are the major exporters of vanadium oxides to the many small consuming countries. These converters also compete for the major markets for pentoxide exported to Japan and the Republic of Korea. Trade in ferrovanadium is dominated by the major European exporters. A large part of this trade is within Europe, but exports are also made to many other consuming countries, particularly by the Federal Republic of Germany.

Industry Structure

The vanadium industry has a five-tiered structure with facilities on six continents. As expected, mines and oilfields form the base of the structure (figure 1). Since 1979, an estimated 83% of world production has come from vanadiferous magnetite (Fe₃O₀). The principal sources of the magnetite ore were China, the Republic of South Africa, and the U.S.S.R. World vanadium production for 1986-90 is shown in table 17. The other 17% of the vanadium was recovered from pertroliferous materials and spent catalysts.

The second tier is a set of economically unrelated facilities that include (1) pig iron plants with slag recovery units, (2) elemental phosphorus smelters, and (3) generators of petroleum residues, fly ash, and spent catalysts that contain vanadium either as the active material or as a contaminant.

The third tier consists of (1) acid leaching plants with solvent extraction circuits and (2) salt roasting operations. Technical-grade V_2O_5 and NH_4VO_3 are the principal products at this level.

In order to have an easily marketable product, it is customary at this point to either convert the oxides into an alloy or upgrade their purity to greater than 98.5 weight-percent. The two traditional alloy products have been the 80 weight-percent ferrovanadium and 35 weight-percent aluminum-vanadium master alloy. Variations of five different reduction processes are currently in use throughout the world, with aluminum, carbon, or silicon serving as the reductant. These conversion and upgrading plants, which form the fourth tier of the structure, may be located a considerable distance from the mills and

slag plants and frequently blend feed materials to improve recovery.

Of the more than 30 privately owned vanadium companies, only one, the Republic of South Africa's Highveld, operates facilities at all four lower levels and can be considered totally integrated. Highveld has plants that process vanadiferous magnetite ores from the Bushveld Igneous Complex. Two other producers, Shieldalloy Metallurgical Corp. and Stratcor, have extensive operations on the second, third, and fourth tiers. Shieldalloy traditionally used Highveld slag as its starting material for low vanadium grades of ferrovanadium.

The fifth tier is composed of producers of vanadium specialty alloys, high-purity vanadium metal, primary vanadium chemicals, and vanadium catalysts. Reading Alloys Inc., Akzo Chemical, and Teledyne Wah Chang Albany illustrate the diversity of operations at this level.

The Republic of South Africa is the world's largest producer of ore and vanadium-bearing slag. Its annual production of more than 17,000 tons is approached only by production in the U.S.S.R. The bulk of Soviet production is consumed internally or by other Eastern European countries. Other major producers include China and the United States. Canada, Japan, and Western Europe are heavily dependent on imports of vanadium slag and pentoxide from the Republic of South Africa. Any disruption of South African supplies could seriously upset the balance between vanadium supply and demand.

Geology-Resources

Vanadium is found in many parts of the world, usually in association with other minerals. There are few ores from which

vanadium can be economically extracted as a single product. It is, therefore, often extracted as a byproduct or coproduct in the production of other elements, such as iron, phosphorus, or uranium. Increasing amounts are being recovered from petroleum residues and spent catalysts. The world also has extensive subeconomic resources of vanadium contained in oil sands, carbonaceous shale, and bauxite.

The crustal abundance of vanadium is estimated to be 100 to 150 parts per million (ppm), about twice that of copper, 10 times that of lead, and almost 100 times that of molybdenum.² As a result, trace vanadium mineralization occurs in a wide range of geologic provinces and environments. At the same time, ore deposits of vanadium are rare because much of the vanadium in igneous rocks occurs dispersed in the relatively insoluble trivalent state and is substituting for ferric iron in ferromagnesian silicates, magnetite, ilmenite, and chromite. Because of the substitutional phenomenon at the atomic level, vanadium is more abundant in mafic (those high in magnesium and iron) than silicic rocks. Gabbros and norites typically contain 200 to 300 ppm vanadium compared with 5 to 80 ppm for granites. When mafic rocks weather in a humid climate, the vanadium remains in the trivalent state or is weakly oxidized to the relatively insoluble tetravalent state. In either case, the vanadium is captured along with aluminum in the residual clays. Subsequent leaching of the clays can produce bauxite and lateritic iron ores that contain 400 to 500 ppm vanadium. When mafic rocks are intensely oxidized in an arid climate. some of the vanadium is converted to the pentavalent state. The pentavalent cation is considerably more soluble than the trivalent cation, is readily dissolved by

ground water, and can be transported over long distances. This transport phenomenon can be observed in arid parts of Western Australia where carnotite precipitates from ground water in calcreted drainage systems.³ At Yeelirrie, for example, thin films of carnotite were formed in the voids and cavities of river fill when ground water percolated through a tertiary river channel.

Organic materials frequently play a key role in the depositional process by helping to create a reducing environment. At many locations on the Colorado Plateau, carnotite, tyuyamunite, and other secondary uranium-vanadium minerals replace fossil logs and other carbonized plant debris. Some of the best examples of this phenomenon can be seen in the Monument Valley and White Canyon districts where uranium-vanadium ores have been deposited in paleochannels of the Shinarump Member of the Upper Triassic Chinle Formation. Fossils in the Shinarump indicate that the stream channels were cut into the underlying Moenkopi mudstones and then filled with sands, pebbles, and plant debris before the end of the Triasssic Period 195 million years ago. Although the uranium-vanadium ores are associated with plant remains, the two elements were precipitated from aqueous solutions percolating through the stream channels long after the host sandstones and conglomerates had formed. The genesis and age of the mineralization remain controversial.

The role of vanadium during the formation of fossil fuels is obscure. There appears to be a relationship between the relatively high concentration of vanadium in coal and petroleum and the burial and subsequent degradation processes that apparently formed the fuels from organisms. The structures of the vanadyl por-

phyrins found in crude oil are approximately identical to the structures of chlorophylls (magnesium-centered porphyrins present in green plants) and hemoglobin (iron-centered porphyrins present in the red corpuscles of blood). The ratio of vanadium to nickel in crude oil is a function of the oxidation-reduction potential (Eh), the hydrogen ion activity (pH), and sulfide activity of the environment in which the oil source rocks were deposited. The two metals both form stable metalloorganic complexes in the high molecular weight fractions of crude oil.4 Cleavage of these vanadium and nickel bonds will not occur unless the crude oil is subjected to a temperature greater than 300°C. As a result, the vanadium-to-nickel ratio remains constant for a specific reservoir even when the lower molecular weight components migrate away. The ratio is therefore useful in identifying unmetamorphosed crude oil from different depositional facies of the same source rock.

Technology

Mining.—In the United States, vanadium is recovered as a principal mine product, as a coproduct from carnotite ores, and from ferrophosphorus slag as a byproduct in the production of elemental phosphorus. Increasingly, it is also being recovered from petroleum refinery residues, fly ash, and spent catalysts. In China and the Republic of South Africa, vanadium is recovered as a byproduct of pig iron production from titaniferous magnetite.

Processing.—The steel industry accounts for 80% to 85% of the world's consumption of vanadium as an additive to steel. It is added to the steelmaking process as a ferrovanadium alloy, which is produced commercially by the reduction of vanadium pentoxide or vanadium-bearing slag with aluminum, carbon, or ferrosilicon.

The first stage in the processing of vanadium-bearing ore is the production of an oxide concentrate. The ore is crushed, ground, screened, and mixed with a sodium salt. This mixture is roasted at about 850°C to convert the oxides to water soluble sodium metavanadate. The vanadium is extracted by leaching with water and precipitated at pH 3 as sodium hexavanadate (red cake) by the addition of sulfuric acid. The red cake is fused at 700°C to yield a dense black product that is sold as technical-grade vanadium pen-

toxide. Technical-grade vanadium pentoxide contains a minimum of 86 weight-percent pentoxide and a maximum 8 weight-percent sodium oxide. The red cake may be further purified by dissolving it in an aqueous solution of sodium carbonate. Aluminum, iron, and silicate impurities precipitate from solution upon pH adjustment. Ammonium metavanadate is then precipitated by the addition of ammonium chloride. The precipitate is calcined to give a vanadium pentoxide product of greater than 99.8% purity.

Vanadium is extracted as a coproduct with uranium from carnotite by direct leaching of the ore with sulfuric acid. An alternative method is roasting the ore followed by countercurrent leaching with dilute sulfuric acid. In some cases, the first leach may be with a sodium carbonate solution. The uranium and vanadium are then separated from the pregnant liquor by liquid-liquid extraction techniques.

In China and the Republic of South Africa, vanadium is concentrated in slag resulting from the production of pig iron from magnetite ore. The ore, containing 1.5% to 2.5% vanadium pentoxide, is partially reduced with coal in rotary kilns. The ore is then melted in an enclosed furnace that produces a slag containing most of the titanium and pig iron containing most of the vanadium. After the titanium-bearing slag is removed, the molten pig iron is blown with oxygen to form a slag containing 12 to 24 weight-percent vanadium pentoxide. The slag is separated from the molten metal and may then be used as a high-grade vanadium raw material in the usual roast-leach process.

In the aluminothermic process for preparing ferrovanadium, a mixture of technical-grade pentoxide, aluminum, iron scrap, and a flux are charged into an electric furnace, and the reaction between aluminum and pentoxide is initiated. The reaction is highly exothermic, producing very high temperatures. The temperature can be controlled by adjusting the particle size of the reactants and the feed rate of the charge and by using partially reduced pentoxide or by replacing some of the aluminum by a milder reductant. Ferrovanadium containing up to 80 weightpercent vanadium can be produced by this method.

Ferrovanadium can also be prepared by the thermit reaction, in which vanadium and iron oxides are coreduced by aluminum granules in a magnesia-lined steel vessel or in a water-cooled crucible. The reaction is initiated by a barium peroxide-aluminum ignition charge. This method is also used to prepare vanadiumaluminum master alloys for the titanium industry.

The production of ferrovanadium by the reduction of vanadium concentrates with silicon involves a two-stage process in which technical-grade vanadium pentoxide, ferrosilicon, lime, and flurospar are heated in an electric furnace. An iron alloy containing about 30% vanadium but undesirable amounts of silicon is produced. The silicon content of the alloy can be reduced by adding more pentoxide and lime to effect the extraction of most of the silicon into the slag phase. An alternative process involves the formation of a vanadium-silicon alloy by the reaction of vanadium pentoxide, silica, and coke in the presence of a flux in an arc furnace. The molten metal reacts with vanadium pentoxide yielding ferrovanadium. The silicon reduction method has not been used extensively.

A process developed by Foot Mineral Co., Cambridge, OH (now Shieldalloy Metallurgical Corp.), has been used to produce tonnage quantities of ferrovanadium. This process involves the reaction of vanadium-bearing iron slag with silica, flux, and a carbon reductant followed by refinement by vanadium pentoxide. The reaction takes place in a submerged electric arc furnace yielding a ferrovanadium alloy containing about 40 weight-percent vanadium, 3.5 weight-percent silicon, 3.8 weight-percent manganese, 0.1 weight-percent carbon, and the remainder iron.

Substitutes

Various metals, such as columbium. manganese, molybdenum, titanium, and tungsten, are, to some degree, interchangeable with vanadium. So far there are no substitutes for vanadium in the all-important aerospace titanium alloys, which were used in jet engine mountings and wing structures. High-purity vanadium compounds were used as catalysts in the production of sulfuric acid, maleic anhydride, and in pollution control technology where it was required to remove hydrogen sulfide gas from flu gases (Stretford Process). In only a few chemical applications could platinum and nickel replace vanadium catalyst.

Reported consumers' and producers' stocks of vanadium oxides, metal, alloys, and chemicals at yearend totaled 2,198

tons of contained vanadium; at yearend 1989, the number was 1,736 tons.

Economic Factors

Prices.—Highveld Steel & Vanadium Corp. of the Republic of South Africa produced more than 60% of market economy countries' vanadium in 1990. Even though the bulk of Highveld's production was in the form of vanadium-bearing iron slag, its pentoxide price was seen as the benchmark worldwide, with other suppliers indexing some of their contracts on the price. South African producers, who set their prices quarterly, were charging \$5.00 per pound for V₂O₅ in first quarter 1990. By the fourth quarter, the price had fallen to \$2.95 per pound; spot, or free market, prices were even lower at about \$2.40 per pound. On December 11, 1990, Highveld announced that it would maintain the \$2.95 price tag through first quarter 1991. These prices were down from \$7.50 per pound in second quarter 1989. The poor performance of vanadium prices over this period reflected an oversupplied market and low demand as major consumers reduced their usage of vanadium. This was to be expected after the extraordinary perfor

mance of 1989. Given the current state of the world steel industry, markets for vanadium products will remain stable in terms of quantity, but prices will remain low.

Tariffs.—U.S. import duties on selected vanadium items as of January 1, 1990, are listed in table 3. The tariff listing includes rates for both most-favored-nation (MFN) and non-MFN status.

Operating Factors

Environmental Requirements.—Because some segments of the geochemical cycle of uranium and thorium coincide with the vanadium cycle, the environmental considerations of vanadium mining are frequently linked to the management of radioactive mine wastes. In addition to careful placement and containment of tailings ponds, special attention must be given to preventing or limiting radioactive contamination of ground water aquifers and to the impoundment and long-term storage of mill tailings and mine waste to control radon daughter exhalation.

In 1982, the Environmental Protection Agency (EPA) published a regulation dealing specifically with the mining of both vanadium ores and uranium-radium-vanadium ores.⁵ Under these rules, the concentration of uranium in mine drainage must be less than 4 milligrams per liter per day for 30 consecutive days. In addition, the U.S. Nuclear Regulatory Commission has issued two regulatory guides dealing with personnel monitoring at uranium mills and processing facilities. The two guides delineate techniques for performing bioassays on workers routinely exposed to airborne yellowcake (U₃O₈) or airborne uranium ore dust.⁶

In October 1983, EPA published rules dealing with the stabilization and longterm control of mill tailings at inactive uranium-vanadium processing sites.⁷ These rules, which took effect on December 6, 1983, required uranium-vanadium mill operators to install plastic liners or other protective barriers under their tailings piles to prevent uranium, its radioactive daughter products, and nonradioactive toxic substances such as selenium from contaminating ground waters. Each tailings pond was required to have an earthen cover to minimize emissions and prevent erosion of the sand-like surface by wind and rain. The rules also limited radon release from the surface of

Toxicity.—Vanadium compounds are irritants chiefly to the conjunctive and respiratory tract. Prolonged exposure may lead to respiratory irritations with mucus discharge and lower respiratory tract irritation with bronchitis and chest pains.8 Other noted effects of vanadium and its compounds have included contact dermatitis, conjunctivitis, and discoloration of the tongue. Vanadium in high concentrations may alter metabolic processes in animals and humans. The reported toxic effects of exposure to vanadium compounds have been acute, never chronic. Toxic effects vary with the compound involved, e.g., vanadium oxytrichloride (VOCl₃) liberates hydrogen chloride gas, and the oral lethal dose (LD₅₀) for V₂O₅ dust in rats is 23 milligrams per kilograms of body weight.9 The lethal dose value is used to express the toxicity of many compounds and is determined by experiment. As used here, it is milligrams of V_2O_5 per kilogram of body weight (taken by mouth) that is lethal to 50% of the experimental animals.

Vanadium metal and its alloys pose no particular health or safety hazard, but they do react violently with certain materials, including bromine trifluoride (BrF₃), chlorine, and some strong acids. The toxicity of vanadium alloys depends upon other components in the alloy.

The adopted threshold limit values for time-weighted averages for airborne vanadium, including oxide and metal dusts of vanadium, is 0.5 milligrams per cubic meter; the value for fumes of vanadium compounds is 0.05 milligrams per cubic

meter. These limits are for normal 8-hour workday and 40-hour workweek exposures. The short-term exposure limit is 1.5 milligrams per cubic meter for dust. ¹⁰ The ammonium salts of vanadic acid and vanadium pentoxide have been listed as toxic constituents in solid wastes under the Resource Conservation and Recovery Act. ¹¹

ANNUAL REVIEW

Legislation and Government Programs

The annual report to Congress by the Secretary of Defense on U.S. stockpile needs for fiscal year 1991 was postponed. Also, Congress was asked to support a moratorium on the National Defense Stockpile (NDS) acquisition of metals and other materials beginning October 1, 1990. According to a Department of Defense spokesman, more time was needed to reassess out-of-date threat assessments and warning times and to develop new war scenarios. A new report was expected to be completed in June or July of 1991.

The Department of Defense was first required to report to Congress on NDS requirements in 1989. In its first report, some changes were recommended, including deletions, increases, reductions, and upgrades for certain items. Vanadium pentoxide (V₂O₅) was one of the materials recommended for upgrading. Solicitations were first issued in August 1989, but were immediately withdrawn after potential bidders raised questions about the composition of the materials to be upgraded. The solicitation was reissued in July 1990 with August 21 as the closing date for

receiving bids on upgrading 1.93 million pounds of V_2O_5 contained in 2.12 million pounds of bulk material that was produced in the 1950's.

The Government of Argentina petitioned for duty-free treatment for ferrovanadium (HTS subheading 7202.92.00) under the General Systems of Preferences (GSP). In its request, Argentina stated that (1) this product has not been exported to the United States; (2) duty-free treatment of this product was accorded to certain other countries under the Caribbean Basin Economic Recovery Act and the United States-Israel Free-Trade Agreement; (3) the U.S. steel industry would benefit from a lower priced product; and (4) duty-free treatment would more than double the current Argentinean production level, thereby increasing (Argentinean) employment. The list of materials accorded GSP status is revised annually.

Affiliated Metals and Minerals Inc., Shieldalloy Metallurgical Corp., and the U.S. Vanadium Corp. requested that duty-free treatment of ferrovanadium (FeV) be denied. In its request, Affiliated stated that (1) duty-free treatment would likely drive one of the few domestic producers out of the market by adding another competitor to a small-size market, and (2) duty-free imports of FeV would increase the level of unused industry capacity and cause unemployment in this labor-intensive industry. Shieldalloy and U.S. Vanadium opposed the petition, noting that FeV has been treated by the U.S. Government as a "strategic and critical" mineral in the NDS. Extending duty-free treatment would only serve to further decrease domestic FeV production and increase U.S. dependency on foreign sources.

The International Trade Commission (ITC) accepted comments through January 10, 1991, on the economic effects of the proposed revisions. A GSP subcommittee was to meet in January and February to evaluate ITC's advice and hearing-related testimony. The President and the U.S. Trade Representative were expected to announce GSP selections in early April 1991, with GSP treatment going into effect soon thereafter. 12

Strategic Considerations

Vanadium is classified as a strategic and critical material because of the significant import dependence of the United States for its vanadium supply and because of the essential use of vanadium in equip-

TABLE 4

STOCKPILE STATUS, DECEMBER 31, 1990

Ferrovanadium	907	

ment for defense, energy, and transportation. The industrialized countries of the Western World are highly dependent on imports of vanadium pentoxide and vanadium-bearing slag from the Republic of South Africa. The Republic of South Africa was the world's largest producer of vanadium in 1990 and was the source of about 60% of the vanadium consumed by market economy countries. Between 1985 and 1990, more than 30% of U.S. vanadium imports came directly from the Republic of South Africa. Additional material was processed in Western Europe and then imported to the United States as FeV, V_2O_5 , and other vanadium products. The European Community and Japan are more heavily dependent on South African imports than the United States. Any extended cutback in supplies from the Republic of South Africa would seriously upset the balance between supply and demand in the market economy countries. Sizable, near-term deficits could only be offset by material from China or the U.S.S.R.

The 1990 goal for the NDS was 6,985 tons of vanadium contained in V₂O₅ and 1,000 tons in FeV. Actual yearend stockpile inventories were only 654 tons of vanadium as V₂O₅. At this point, no FeV had been added to the NDS. The 1989 fiscal year Defense Authorization Act required the Department of Defense to outline plans for at least \$20 million in upgrading projects. The Department responded by submitting to Congress an ambitious \$30 million plan to upgrade vanadium pentoxide and other materials in the NDS. To justify the planned upgrading program, the Department stated that while the need for some traditional stockpile materials remains substantial, current and projected military strategies and high-technology weapons systems would require more of the advanced and upgraded forms of industrial materials and less of the conventional materials and unprocessed mineral ores. On September 29, 1990, U.S. Vana-

NOTE. — If the weight percent of U_3O_8 is less than 0.71 and the radioactivity is essentially evenly distributed, it is not considered radioactive in terms of Department of Transportation requirements. If the weight percent of U^{238} in the U_3O_8 is in excess of 0.05 weight percent, then it is considered a radioactive material according to the Nuclear Regulatory Commission and CFR 10, Parts 20, 40, and 70 apply.

dium Corp., Hot Springs, AR, was awarded a \$3.76 million Defense Logistics Agency contract to upgrade 1.93 million pounds of V₂O₅ from the NDS into Grade B fused flake. U.S. Vanadium, a subsidiary of Strategic Minerals Corp., Danbury, CT, won the contract with a bid of about \$1.95 per pound. Terms of the contract required U.S. Vanadium to complete the upgrade within 2 years after the contract was awarded. Chemical requirements for the material are listed in table 5.

Issues

Prior to about 1984-85, more than onehalf of the vanadium mined in the United States was recovered as a coproduct with uranium from sandstone mined on the Colorado Plateau. Companies recovering vanadium from uranium ores were hurt by the downturn in nuclear powerplant construction in the aftermath of the Three Mile Island nuclear reactor accident and the subsequent reduced demand for enriched uranium. Worldwide recession, high interest rates, and the cancellation of powerplant construction in the United States caused the Nuclear Exchange Corp. (Nuexco) exchange value of uranium oxide (U_3O_8) to decline from \$40.75 per pound in early 1980 to less than \$10.00 per pound in 1990. The exchange value is Nuexco's judgment of the price at which transactions for significant quantities of uranium concentrates could be concluded on a specified date. Value is based on bids to buy and offers to sell, as well as recently completed and pending transactions.

A direct result of the price decrease was mill closing and decommissioning, personnel cutbacks, and canceled development and expansion plans. This unstable situation had the potential for creating a much higher degree of dependence by the United States on South African and Chinese imports. However, some of the slack was taken up by increased recovery of vanadium from petroleum residues, including spent petroleum catalysts. Recovery of vanadium from this source began during the 1973 and 1978 Arab oil embargoes. After being cut off from light crude from the Middle East, refiners were forced to process crude oils with high-sulfur and high-metal content. The trend toward heavier, sour crude and a tightening of sulfur restrictions on fuel products led to the development of the "Flexicoking" process, which concentrated 99% of the metals in the feed in a 2% solid purge from the system. This material has become an important source of vanadium, and in some instances, molvbdenum and nickel. At the same time, the combustion of increasingly metalliferous fuel oils at powerplants created a second source of feed materials in the form of fly ash and boiler scale. The author has performed chemical analyses on some boiler scales that contained as much as 35 weight-percent V₂O₅. More than 30% of the V₂O₅ produced in the United States is now being recovered from refinery residues, fly ash, boiler scale, and spent catalysts. In 1990, the United States recovered 2,308 tons of vanadium oxides from these petroliferous materials, most of which were imported. This source of vanadium may also dry up as clean air standards lead to a tightening of sulfur restrictions on fuel oil products leading to less production of vanadium-containing residues. Gradual depletion of Colorado Plateau vanadiferous uranium ores that have been the principal source of domestic vanadium and the expected reduction of available petroleum residues will require the development of alternative sources to maintain domestic self-sufficiency in this strategic mineral.

Production

Vanadium is often considered to be an uncommon element, but actually its abundance in the Earth's crust is comparable to or greater than that of copper. nickel, and zinc. Although there is a plentiful supply of vanadium, it is one of the most expensive elements to recover. In most cases, whether vanadium occurs as a primary ore, a coproduct, or in petroleum, the vanadium content of the material usually runs 1.5% V₂O₅ or less. V₂O₅ is the principal starting material for the production of all vanadium compounds. Therefore, when one speaks of vanadium production or the supply side of the industry, only those involved in the production of V_2O_5 should be included.

At yearend, there were five companies producing V_2O_5 in the United States. Of these, one was a totally integrated company that produced V_2O_5 , vanadium

chemicals, FeV, and other vanadium alloys. The others produced mainly V_2O_5 from a variety of raw materials.

Consumption and Uses

Reported consumption of vanadium was a little more than 4,000 tons of contained vanadium or about 12% less than that in 1989. Part of this reduction was attributed to reduced demand by the steel industry, in which production was down by about 10%. The decrease might have been greater if some consumers had not returned to using vanadium. In 1989, these consumers substituted other materials or treatments for vanadium when the price of V_2O_5 was abnormally high.

Foreign Trade

Overall U.S. export of vanadium products was down by more than 50% in 1990. Canada, Brazil, the Republic of Korea, and Mexico were the leading importers of U.S. materials. Most countries imported almost exclusively V₂O₅. Austria, Canada, and the Republic of Korea also imported substantial quantities of FeV. Exports of V₂O₅ totaled 2,608 tons gross weight, less than one-half of 1989 exports. The average declared value of the pentoxide was \$4.99 per pound of contained vanadium; the price averaged \$7.62 in 1989. Exports of FeV totaled 334 tons gross weight, down from 493 tons in 1989. The average declared value of the FeV was about \$13.00 per kilogram of contained vanadium.

Imports for consumption of vanadium raw materials and downstream vanadium compounds decreased in 1990. FeV imports totaled 323 tons gross weight, down from 650 tons in 1989 and 383 tons in 1987. The imported FeV averaged 81% vanadium with a mean custom value of \$7.60 per kilogram of contained vanadium. Canada was the largest source of FeV with shipments of 101 tons, followed by Austria, 95 tons, and Belgium, 28 tons. Vanadium pentoxide imports totaled 83 tons of contained vanadium, down from 133 tons in 1989; the average declared value was \$5.15 per pound of contained vanadium. Imports for consumption of vanadium-bearing slag and residues totaled more than 4,600 tons of contained vanadium. About 34% of these imports was from the Republic of South Africa in the form of vanadium-bearing iron slag. Another 18% was vanadium-bearing steel-

making slag from Chile. The remaining 48% consisted of an assortment of petroleum residues, spent catalyst, and fly ash.

World Review

Industry Structure.—Vanadium was traded on the world market in vanadiumbearing slag, petroleum residues, technical-grade V₂O₅, and FeV. The Republic of South Africa was the largest producer with more than 60% of the Western World's market. Most of the Republic of South Africa's exports of vanadium were in vanadium-bearing iron slag. Japan and Western Europe were the chief importers of this material. The United States imported slag from the Republic of South Africa and slag, fly ash, petroleum residues, and spent catalyst from many other sources. The large importers of vanadium raw materials, e.g., slag, were the chief exporters of V₂O₅, FeV, and other downstream vanadium products. This trade was dominated by a few large West European converters who competed not only within Europe, but also exported to many small and large consumers outside of Europe. Reliable statistics from the U.S.S.R. were not available, but it is believed to be second only to the Republic of South Africa in vanadium production. All Soviet trade was thought to be with other East European countries.

Capacity.—The data in table 15 are rated capacity for mills producing vanadium oxides as of December 31, 1990. Included in this data is capacity to produce vanadium-bearing iron slag and petroleum coke. Rated capacity is defined as the maximum quantity of product that can be produced on a normally sustainable longterm operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that can be brought back into production within a short period with minimum capital expenditure.

Australia.—Western Australia has large deposits of magnetite ores containing vanadium and titanium. The deposits consist of a large magnetite-rich intrusive rock. A chemical analysis of the material, undertaken more than 20 years ago, found only about 0.32% V₂O₅. This deposit was

ignored for many years because of the low price of vanadium. As the price of vanadium climbed from 1987 through 1989, Precious Metals Australia (PMA) reevaluated the deposit at its wholly owned Wagoo Hills Project in the Murchison District of Western Australia. Surprisingly, the titanium and vanadium

mineralization was found to grade up to $0.93\%~V_2O_5$ and 12% titanium dioxide (TiO₂). The deposit lies within a distinct and reasonably well-defined geologic structure known as Shepard's Discordant Zone (SDZ), which extends along a 10-mile strike within PMA's property. The latest sampling was carried out

across the SDZ in areas of abundant titano-magnetite surface rock with samples collected at 2- and 6-yard intervals. Analysis of the samples indicated that the region was likely to contain up to 40 million tons of high-iron magnetite ore containing an average of $0.75\% \ V_2O_5$ and as much as 12% titanium.

Preliminary metallurgical work suggested that a magnetite concentrate could be produced from grinding and magnetic separation. A \$70 million mine development and processing plant was planned to produce about 2,100 tons of V_2O_5 per year. PMA was determined to continue with the development of this project despite low vanadium prices in 1990 and pessimistic predictions for 1991. PMA officials believed Australian mining and materials

handling technoloy to be more efficient than methods used in the Republic of South Africa. They also believed that the Australian ore would be easier to process. PMA has the disadvantage of higher energy costs.

Canada.—Agra Industries Ltd. of Saskatoon, Saskatchewan, teamed with Renzy Mines Ltd. and Fairfax Financial Holdings Ltd. of Toronto, Ontario, to construct a vanadium pentoxide facility at Fort McMurray, Alberta. The plant, which cost about \$14 million, was designed to extract about 2.5 million pounds per year of V_2O_5 from waste fly ash produced by the Suncor Inc. oil sands plant. ¹⁴ The Athabasca oil sands in northern Alberta was well known for its wealth of oil, and a number of projects have been launched to extract it. A number of other elements besides vanadium are found in the oil

¹Includes V₂O₅ in vanadiferous iron slags and petroleum refinery residues.

sands. The Athabasca oil sands may prove to be the largest reserves of vanadium in North America.

Vanadium and other minerals appear in the oil sands only in trace concentrations making economic recovery impossible. However, when the material was treated to recover heavy oil, vanadium was concentrated in a stream of waste petroleum coke. Subsequent burning of this coke in the plant's power steam boiler produced a fly ash consisting mainly of carbon and V₂O₅ concentrations ranging from 2% to 5%. The Alberta Suncor and Syncrude refineries produced about 43,000 tons of fly ash per year. To secure access to the vanadium-rich fly ash, Carbovan Inc. obtained an exclusive longterm agreement to purchase the waste fly ash produced by Suncor. Carbovan also gained access to fly ash that had been stockpiled by Suncor over the years. In addition to these supplies of raw materials, Carbovan obtained agreements to purchase vanadium-rich spent catalyst discharged by various petroleum processors in Canada.

Initial concepts of Carbovan's recovery process were developed by Renzy Mines in 1972. Between 1972 and 1985, Renzy spent about \$500,000 to further develop and improve the process. In mid-1985, Renzy and Agra entered into an agreement to conduct further research and development of the Renzy process. Under terms of the agreement, Agra provided

financial, management, and engineering support to the research. After expenditures of \$1.5 million and 3 years of research and development, an economical process was developed. The process utilized a hydrometallurgical flotation technique to remove carbon from the fly ash. The carbon-free ash fraction was next treated with a high-temperature alkaline leach and pulse column solvent extraction circuits to extract vanadium.

Carbovan began production of vanadic acid (HVO₃) in September 1990 and shipped the material to consumers in Canada and the United States. The second stage of the process, which was not yet underway at the end of 1990, involved calcining the HVO₃ to produce flake V₂O₅.

China.—Based on its production of pig iron, China's production of vanadiumbearing iron slag was estimated at about 85,000 tons in 1990 or about the same as 1989 production. Approximately 80% of the output was from the Panzhihua Steel Works in Sichuan Province. Slag from this plant averaged 14% V₂O₅, which placed China's vanadium production at about 7,400 tons of contained vanadium; only the Republic of South Africa and the U.S.S.R. produced more.

Exports of V₂O₅ and vanadium-bearing slag were lower than in previous years mostly because of increased internal demand.

South Africa, Republic of.—South Africa, the world's largest producer of vanadium, increased its capacity by 28% in 1990, but is estimated to have produced about the same quantity of vanadium as in 1989. In 1988, production of vanadium marked an alltime high of 63 million pounds of V_2O_5 , more than 10% above 1987 production. Production in 1989 was even higher at more than 66 million pounds. Sales in 1989 of vanadium totaled 30,400 tons V_2O_5 with a value of R23.6 million. Eight hundred and thirty-one tons was used internally and the remainder exported. 16

Most of the increase in capacity was from a new facility, which obtained its feedstock from reserves of titaniferous magnetite in Bophuthatswana. The project, designed to produce 9,900 tons of V_2O_5 annually, was a co-operative venture between Union Steel Corp. (Usco) and Rhombus Exploration (RhoEx) to exploit a high-grade deposit stretching over a distance of 10.5 miles. Ore reserves were es-

timated to be sufficient to support production for about 100 years.

Usco extracted V_2O_5 by the roast-leach process. The company estimated that the cost of production of V_2O_5 flake would be in the range of R11,500 to R12,000 per ton. Mechanical commissioning of the beneficiation plant at Rhovan's mine, which provided the magnetite concentrate, was completed, and wet commissioning started in March 1990.¹⁷ Brandeis Goldschmidt Ltd., headquartered in London, acted as sole agent for V_2O_5 produced by Usco.

Vansa Vanadium Corp. began production of V₂O₅ in October 1988. Its operations were supplied by the Kennedy's Vale high-grade ore deposit. The plant, in Eastern Transvaal, had a design capacity of 3,000 tons per year of V₂O₅. During the second half of 1990, the company reported that, as a result of postcommissioning problems, the plant had been unable to achieve its full design capacity. For most of the fiscal year ending September 30, 1989, the plant operated at just over 60% of capacity. The company, expecting to achieve full production in 1990, continued to be plagued with technical problems and was never able to reach full production capacity. Finally, Vansa announced in November 1990 that it would stop production of V₂O₅. Vansa's decision was influenced by the entrance of Usco and Carbovan into an already oversupplied market. Meanwhile, Highveld was estimating that the shutdown of Vansa and other curtailments of production would lead a 3,000-ton supply shortfall in 1991.

Other established producers in the Republic of South Africa apart from High-veld and Vansa are Vametco in Bophuthatswana and Transvaal Alloys, which produced V₂O₅ and other vanadium chemicals. The Republic of South Africa's domestic consumption of vanadium was believed to be about 1% of total production.

OUTLOOK

Vanadium consumption in the United States is expected to decline by 10% to about 4,000 tons in 1991 as the recession and consumer uncertainty continues to affect orders for appliances, automobiles, and construction materials. Shipments of vanadium products will decline as demand for steel in most industrial nations falls by 4%. Steel is the largest market for vanadium.

²Includes capacity of operating plants as well as plants on standby basis.

^eEstimated. ^PPreliminary. W Withheld to avoid disclosing company proprietary data; not included in "Total."

World demand is forecast to increase by about 2% per year, with total world demand reaching 45,000 tons by the year 2000. World production in 1990, including production from petroliferous materials and spent catalysts, was estimated to have been more than 34,000 tons, of which about 2,300 tons was produced in the United States from petroleum residues and spent catalysts. U.S. production from domestic ores and concentrares was not reported.

Prolonged unrest in the Persian Gulf would have consequences that reach far beyond the region and the oil industry, and that would include the vanadium industry. A protracted war in the region would not only have a huge effect on oil prices, but it would also threaten vanadium pentoxide producers who depend on spent catalyst from this area as a source of feed material. Higher oil prices would slow or halt economic growth around the world, cutting into demand for industrial and consumer products that are markets for vanadium.

The likely drawdown of inventories by vanadium consumers through the first and second quarters of 1991 should also have

an adverse effect on domestic demand. Consumers were expected to draw down their inventories because they would no longer be concerned about difficulties in obtaining vanadium in a timely manner and at a reasonable price. Prices of most products were projected to stabilize in the third or fourth quarter of 1991 and could begin to rise as the country draws itself out of the economic downturn.

Long-term prospects for this highly cyclical industry depend on a number of factors. Producers will certainly be adversely affected by any future economic downturn. Because of restructuring and downsizing that has occurred in the industry since the last recession, the industry will be better able to cope with a recession than it was in the early 1980's. Traditional forces, such as the demand for motor vehicles and machinery, the level of economic activity, and the use of substitute materials, will continue to be of central importance. The strength of the U.S. dollar and its trade effects will also influence the industry's long-term future.

About 85% of the demand for vanadium is driven by the iron and steel industry. This dependence of the vanadium industry

on the demand for steel products is not likely to change in the near future. The remaining 15% of demand is driven by aerospace titanium alloys (13%) and chemicals (2%). The reader is referred to the outlook section of the Iron and Steel Annual Report for more information on the long-term outlook for the steel industry.

In addition to the countries listed, vanadium in also recovered from petroleum residues in the Federal Republic of Germany, the U.S.S.R., and several other European countries, but available information is insufficient to make reliable estimates. Table includes data available through June 28, 1991.

²Production in this section is credited to the country that was the origin of the vanadiferous raw material.

³Includes production for Bophuthatswana.

⁴Data on vanadium content of vanadium slag are estimated on the basis of a reported tonnage of vanadium-bearing slag (gross weight) multiplied by an assumed grade of 14.1% vanadium.

⁵Excludes U.S. production.

⁶Production in this section credited to the country where the vanadiferous product is extracted; available information is inadequate to permit crediting this output back to the country of origin of the vanadiferous raw material.

VERMICULITE

By Michael J. Potter

Mr. Potter, a physical scientist with 24 years of industry and U.S. Bureau of Mines experience, has been the acting commodity specialist for vermiculite since 1989. Domestic survey data were prepared by Pam Shorter, minerals data assistant.

that rapidly expands upon heating to produce a low-density material. The expanded (exfoliated) product is used as lightweight aggregate and thermal insulation in construction applications; as a fertilizer carrier and soil conditioner in agriculture; and as a filler and texturizer for plastics and rubber, among many other uses.

U.S. vermiculite concentrate sold and used was 230,000 short tons, a decrease from that of the previous year, according to the Bureau of Mines, U.S. Department of the Interior. The tonnage of exfoliated vermiculite sold and used was 157,000 tons, also a decrease from that of 1989. Markets have been affected by competition from other building product materials and by reduced construction activity.

Domestic production data for vermiculite were developed by the U.S. Bureau of Mines from two separate, voluntary surveys, one for domestic mine operations and the other for exfoliation plant operations. Of the six mining operations to which a survey request was sent, data or estimated data were received from five operations. The one nonrespondent's data were estimated by the U.S. Bureau of Mines. Of the 33 active exfoliating plants to which a survey request was sent, data were obtained from 27. This represented 63% of the total exfoliated vermiculite sold and used shown in table 1. The six nonrespondents' data were estimated by the U.S. Bureau of Mines using previous years' production levels.

The leading domestic producer of vermiculite concentrate continued to be W.R. Grace & Co. with sales of material from its Libby, MT, location (from stockpiles) and from its operation at Enoree, SC. Other producers during the year were Virginia Vermiculite Ltd., Louisa County, VA; Carolina Vermiculite Div. of Virginia Vermiculite Ltd. mine near Woodruff, SC; Patterson Vermiculite Co., Enoree, SC; and Enoree Minerals Corp., Spartanburg County, SC. South Carolina, with four pro-

ducers, was the leading producing State for the fourth consecutive year. W.R. Grace closed its Libby, MT, mine in late 1990, although shipments of concentrate were to continue through 1992. The company also closed five exfoliating plants in 1990.

Domestic sales of exfoliated vermiculite by 13 producers came from 33 plants in 20 States. Of these plants, 20 in 16 States were operated by W.R. Grace. In descending order of output sold and used, the principal exfoliated vermiculite-producing States were estimated to be Ohio, South Carolina, California, New Jersey, Illinois, Florida, and Texas.

The average value of vermiculite concentrate sold and used by U.S. producers was \$83 per ton, f.o.b. plant, or a decrease from that of 1989. The average value of exfoliated vermiculite, f.o.b. plant, was approximately \$251 per ton, although some of the data used to arrive at this figure were estimated.

Imports of vermiculite concentrate were approximately 50,000 tons and were mainly from the Republic of South Africa. U.S.

imports in 1989 were approximately 55,000 tons. U.S. exports to Canada were estimated to be 20,000 tons, about 9% of total U.S. sales of vermiculite concentrate.

The data in table 4 are rated annual capacity for vermiculite plants as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced on a normally sustainable longterm operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Plant capacity for vermiculite is based on engineering capacity provided by the companies or estimated by considering recent peak production during the past 5 years to be equal to rated capacity.

Vermiculite has been facing competition from other materials, especially in the building products market. Another adverse

Estimated. PPreliminary. Revised.

¹Includes capacity at operating plants as well as at plants on standby basis.

²Excludes countries for which data were not available.

³Data do not add to total shown because of independent rounding.

¹Excludes production by countries for which data are not available and for which general information is inadequate for formulation of reliable estimates. Table includes data available through July 19, 1991.

²In addition to the countries listed, Tanzania may produce vermiculite, but available information is inadequate to make reliable estimates of output levels, if any.

³Reported figure.

WOLLASTONITE AND ZEOLITES

By Michael J. Potter and Robert L. Virta

Mr. Potter, a physical scientist with 24 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for wollastonite since 1976. Domestic survey data were prepared by Pam Shorter, mineral data assistant.

Mr. Virta, a physical scientist with 15 years of U.S. Bureau of Mines experience, has been the commodity specialist for natural zeolites since 1986. Domestic survey data were prepared by Maureen Riley, mineral data assistant.

WOLLASTONITE

Wollastonite is natural calcium silicate and has a theoretical composition of CaO·SiO₂. It has developed a significant role as a high-performance mineral filler in paint, plastics, and thermal board. It is used in asbestos replacement and in ceramics such as wall tile, where it promotes low shrinkage, good strength, low warpage, and fast firing.

After preliminary drilling of an extensive wollastonite deposit on the Gilbert properties near Tonopah, NV, Sikaman Gold Resources Ltd. was considering a proposed followup drilling program to prove a minimum of 2 million tons grading more than 50% wollastonite. If successful, this would be followed by a further expenditure for detailed reserve definition, extensive sample testing, and market evaluation. In late 1990, ownership of the Gilbert properties remained uncertain. During early 1990, Vancouverlisted White Plains Resources Corp. purchased a 25% stake in the properties from Sikaman. In mid-1990, White Plains raised its option to 100% by intending to purchase Sikaman's remaining 75% interest in the properties.1

Domestic sold and used data for wollastonite were developed by the U.S. Bureau of Mines by means of a voluntary survey. Both active operations responded, representing 100% of the total canvassed. Specific data were withheld to avoid disclosing company proprietary data.

The two U.S. producers were NYCO, a division of NYCO Minerals Inc., Essex County, NY, and R. T. Vanderbilt Co. Inc., Lewis County, NY. The tonnage of

wollastonite sold or used in 1990 decreased compared with that of the previous year.

Wollastonite is used as a filler in ceramic tile, paint, and plastics. It serves as an asbestos replacement in some applications such as a reinforcement filler for boards and panels in various heat containment applications, including ovens, dryers, thermal ducting, and many other thermal applications. Wollastonite also replaces asbestos in certain cement formulations, in ceilings and floor tile, and in friction applications such as brake linings.

Prices from Industrial Minerals, December 1990, for wollastonite, exworks, converted to dollars per metric ton, were approximately \$278 to \$292 for acicular, minus 200 mesh; \$193 to \$204 for minus 325 mesh; and \$209 to \$215 for minus 400 mesh. Prices per metric ton for wollastonite, f.o.b. plant, bulk, were \$125 to \$177 for 200 mesh and \$235 for 325 mesh.

In Canada, a joint venture between Cominco Ltd. and Platinova Resources Ltd. continued to assess the Deloro wollastonite property near Marmora, Ontario, halfway between Toronto and Ottawa. Four zones had been outlined, with the grade of wollastonite ranging from 28% to 60%. The mineralization consisted of calcite-wollastonite-diopside marbles. Wollastonite concentrates were obtained by cofloating wollastonite and diopside from calcite and then magnetically separating diopside from the wollastonite. Both companies were reassessing calcite and wollastonite markets and conducting further tests to optimize products.

Another wollastonite project involved Ram Petroleums Ltd.'s evaluation of a deposit at Mount Grove in eastern Ontario. Drilling in late 1990 had proved 2.8 million tons of ore grading an average of 35% wollastonite with calcite and minor diopside. Laboratory work was being carried out.

In British Columbia, Performance Minerals of Canada Ltd. agreed to acquire a 50% working interest in Tri-Sil Minerals Inc.'s Wormy Lake wollastonite property about 45 kilometers northwest of Vancouver. Potential reserves were estimated to be more than 50 million tons. During the next 5 years, Performance Minerals was to prove up the reserves. Material tested down to minus 100 mesh showed high aspect ratios of 20:1 on average. A crushing plant was sizing low-grade wollastonite and selling it to Tilbury Cement of Richmond, British Columbia.

In the Yukon Territory, Archer, Cathro, & Associates discovered a deposit about 450 kilometers from the port town of Haines, AK. Surface grab samples indicated some material containing 60% and 80% to 85% wollastonite; but drilling of core samples had yet to be carried out.²

In China, wollastonite production in Jilin and Hubei Provinces was estimated to be at least 70,000 tons per year. In Yunnan Province, a deposit was reportedly discovered in early 1989 containing an estimated 50 million to 100 million tons of reserves. If proven, this would represent the world's largest wollastonite deposit.

Domestic consumption probably accounted for the bulk of the wollastonite

produced in China. Wall tile was the major end use, but increasing quantities were being used in other applications such as pigments, paper and plastic fillers, ceramics and porcelains, electrode coatings, and other uses. The most rapid increase in consumption was in steel-making, where wollastonite is used as a protective slag for continuous casting carbon steel and for casting silicon steel sheet.

Exact figures for total annual wollastonite exports from China were not available. However, exports in 1985 from the Jilin branch of the China Metallurgical Imports and Export Corp. were an estimated 36,000 tons.³

In Greece, Metallic & Industrial Minerals Mevior SA of Thessaloniki was developing a wollastonite deposit in Kimmeria. The deposit contained 300,000 tons of 60% to 70% wollastonite and 10% calcite. Construction of a 500-ton-per-year pilot plant was to begin in late 1990.

In Mexico, Cia Minera Constelacion S.A. de C.V., an affiliate of Cominco Resources International Ltd., continued to develop the San Martin wollastonite deposits about 50 kilometers northwest of Hermosillo in the State of Sonora. Drilling was being carried out in the South Body, which contains 0.7 million tons grading 70% wollastonite. Mineralization consisted of wollastonite-calcitequartz-diopside marble. Some hand-sorted material was ground into test quantities of powder and acicular grades suitable for the ceramics, plastics, and coatings markets. Marketing studies were underway, and a small-scale production test was being planned.

In the Republic of South Africa, the country's first commercial wollastonite operation appeared ready to come onstream in early 1991. Pella Refractory Ores' mine at Modderfontein, 18 kilometers northeast of Garies in Namaqualand, contained in excess of 2 million tons. The ore, containing 50% to 60% wollastonite, requires a complex threestage beneficiation process, including electrostatic and high-intensity magnetic separation and flotation, to give a product containing more than 90% wollastonite. An output of 13,600 tons per year of wollastonite was anticipated from treating 72,000 tons per year of ore.

Initial production was slated to be about 500 tons per month, increasing to

1,000 tons per month as markets develop. Two grades would be produced for the ceramics and asbestos replacement markets. Much of the output would be exported.⁴

Research on the synthesis of Bwollastonite (synthetic wollastonite) was performed. Highly reactive silica such as diatomite was used, important deposits of which occur in Spain. Other silica materials were also used for comparison, such as quartz and silica gel. In the whiteware industry, modern fast-firing technology has almost fully replaced traditional double firing, resulting in high energy savings. B-wollastonite is one of the raw materials suitable for compositions to be fast fired because of the good characteristics it gives to ceramic bodies, such as low drying and low firing shrinkage, high bending strength, etc.5

A paper described the surface modification of silica and silicate minerals by silanes, on which Quartzwerke GmbH has done development work and has commercialized since the early 1970's. A variety of silanes are used to coat silica flour, cristobolite, wollastonite, alumina trihydrate, and calcined clay.

The company's TREMIN-wollastonite (silane-treated wollastonite) is used in the improvement of polyamide, polypropylene, and polyurethane engineering resins as well as fluorosilicone elastomers. TREMIN-wollastonite used in polyamide compounds in the automotive industry adds toughness and impact strength to the polymer. It may be used partially to replace glass fiber reinforcement without loss of strength and stiffness of the composite. TREMIN-wollastonite can also be employed in fluoroelastomers instead of carbon black.⁶

The outlook appears to be favorable for wollastonite, especially in fine particle size, high aspect ratio, and chemically modified grades.

The plastics market is one area of further potential growth. Chemically treated grades of wollastonite are increasing by being required to satisfy customer and product requirements. In the United States, plastics consumption has been affected by reduced activity in two major markets, construction and automobiles. However, plastic consumption in Europe in 1990 was at a high level.

Wall tile has been a major end use of wollastonite. U.S. consumption of tile increased during the past 10 years, including U.S. output and imports from Europe. In 1990, the U.S. remodeling market was strong, although the construction industry was experiencing a slowdown. European tile producers generally rely on cheaper lime, silica, and feldspar raw materials rather than on wollastonite for their wall tile bodies.

Asbestos replacement is a possible growth area because of a proposed ban in the United States on almost all asbestos-containing materials in stages during the next 7 years. Outside the United States, asbestos is being replaced to some extent by wollastonite in brake linings, gaskets, and products where short-fiber asbestos was previously used. If legislation should be taken up by authorities in Europe and Asia, prospects of a growing market for high aspect ratio wollastonite are good.⁷

ZEOLITES

Zeolites are hydrated aluminosilicates of the alkaline and alkaline-earth metals. Approximately 40 natural zeolites have been identified during the past 200 years, the most common of which are analcime, chabazite, clinoptilolite, erionite, ferrierite, heulandite, laumontite, mordenite, and phillipsite. Zeolites are commercially valuable because of their unique ion-exchange, molecular sieving, and catalytic properties.

Commercial zeolite deposits in the United States are associated with the alteration of volcanic tuffs in saline, alkaline lake deposits, and open hydrologic systems. The deposits are in Arizona, California, Idaho, Oregon, Nevada, New Mexico, Texas, and Utah. The major components of these deposits are chabazite, clinoptilolite, mordenite, and phillipsite. Erionite, orthoclase and plagioclase feldspar, montmorillonite, opal, quartz, and volcanic glass may be present in some deposits as minor components. The composition of these deposits was determined primarily by the temperature and pressure of formation and the chemistry of the altering fluids. When the alteration process went to completion, the zeolite content of portions of some deposits approached 100%.

Conventional mining techniques were used in the mining of natural zeolites. The overburden was removed to permit

access to the ore, and the ore was stripped for processing using front-end loaders or tractors equipped with ripper blades. The fractured ore was dried and then crushed using either jaw crushers or roller mills. The crushed ore was packaged directly for shipping or was screened to remove fine material when a granular product was required.

Nine companies mined or sold natural zeolites in the United States in 1990. Clinoptilolite was mined in California, New Mexico, Nevada, Oregon, Texas, and Wyoming. Chabazite was mined in Arizona. Total domestic production and sales were 15,569 metric tons (17,162 short tons) in 1990, an increase of 28% from those of 1989.

Natural zeolites were used for pet litter, odor control, animal feed supplement, desiccant, chemical carrier, aquaculture, wastewater cleanup, aquarium filters, gas adsorbent, water purification, and oil and/or grease adsorbent, in decreasing order of consumption. The properties that made natural zeolites commercially valuable included ammonium adsorption (aquaculture, aquarium filters, odor control applications, pet litter, and water purification), moisture adsorption (desiccants, odor control, and pet litter), and ion-exchange capabilities (wastewater cleanup).

Specialty Minerals, and the Advanced Minerals and Hazardous Waste Processing Center for Excellence at Montana Tech investigated the use of clinoptilolite for removing heavy and toxic metals from mine water in a former copper mine in Montana. The mine water contained arsenic, copper, and zinc that potentially could contaminate the local ground water. Preliminary tests indicated that the heavy-metals content of the water could be reduced with the application of lime, but that the water did not meet drinking water standards. The partnership will perform tests to determine if the levels of heavy metals can be reduced further through an ion-exchange process using clinoptiliolite as the exchange media.8

The Montana Bureau of Mines and Geology received a grant for a 2-year study of the potential use of natural zeolites to remove metals from polluted waters and soils. The zinc content of one polluted water was reduced from 175 parts per liter to 0.02 parts per liter in a preliminary ion-exchange test.9

Mordenite, a natural zeolite, performed poorly as a shape-selective catalyst. It was rapidly deactivated during the reaction process. Researchers at Dow Chemical Co. modified the mordenite structure through an acid washing, calcining, and activation process to improve its performance as a shape-selective catalyst. The treatment increased the ratio of silicon to aluminum from 5:1 for the natural zeolite to 15:1 for the modified form of mordenite and increased the pore volume of the zeolite. The modified mordenite was suitable for use as a shape-selective catalyst for industrial applications such as the alkylation of biphenyl with propylene.10

Zeolites were fed to roosters and breeder hens in an effort to increase the strength of shells of eggs for market. The zeolite additive strengthened the shell strength by increasing the absorption of calcium. Researchers at Ethyl Corp. began feeding pigs, cows, and sheep zeolite as a feed additive to see if it improves bone strength and increases growth rates of the animals.11

Researchers at the University of California, Santa Barbara, studied molecular interactions on the surface of a zeolite by using an atomic force microscope. The study examined how positively charged t-butyl ammonium ions and neutral

t-butanol molecules were bound to the surface of a zeolite that is used to remove ammonium and phosphate ions during wastewater treatment. Positively charged t-butyl ammonium ions occurred as clumps on the surface of the zeolite, while the neutral t-butanol molecules spread over the surface as a sheet. A better understanding of the molecular interactions that affect catalytic reactions was gained through the use of the atomic force microscope. 12

Demand for synthetic zeolites for detergents continued to grow in Europe and the United States. Annual consumption in Europe was estimated to be 325,000 tons. Present U.S. demand was estimated to be 100,000 tons per year. 13 Manufacturers substituted synthetic zeolites for phosphates because phosphates promoted plant growth that degraded the quality of the water into which the phosphate-rich wastewater was released. Zeolites exchanged sodium for calcium and magnesium in the washwater much the same as the phosphate additives but at a slower rate. Fine grinding was used to enhance ion exchange and avoid visible zeolite deposition on clothes. Zeolite additives were nontoxic to marine and freshwater life.14

ZINC

By James H. Jolly

Mr. Jolly is a physical scientist (geologist) with more than 30 years of mining experience, including positions with Hecla Mining Co., Roan Selection Trust, and the U.S. Geological Survey. He has been a mineral commodity specialist for the U.S. Bureau of Mines for 18 years and the zinc specialist for the past 9 years. Domestic survey data were prepared by Tony E. Morris, statistical assistant. International production tables were prepared by Virginia A. Woodson and Harold D. Willis, international data coordinators. Historical figures were prepared by James W. Smith, Branch of Metals.

inc is an essential element for health and for development and maintenance of modern society. It has been used by humankind in compounds, alloys, and metal for more than 2,000 years and has been surpassed only by iron, aluminum, and copper in historical quantity used. Zinc uses range from medicines and rubber to metal products. Its main use has been to provide corrosion protection for iron and steel.

The state of the domestic zinc industry was variable in 1990. Zinc mine output was the highest in 24 years, and smelters operated at high-capacity utilization rates. Industrial consumption of zinc, however, declined to its lowest level since 1985. The value of unmanufactured zinc exports, about \$370 million, was up significantly owing largely to a threefold increase in the value of exported zinc concentrates. The value of unmanufactured zinc imports, \$1,133 million, was down more than \$200 million from that of the previous year.

World mine production was a record high, whereas world smelter output was third highest. In 1990, U.S. mines produced 7.4% of the world zinc output and U.S. smelters produced 5% of the world refined metal output. World zinc consumption exceeded 7 million tons for the fourth straight year but was estimated to have been only the third highest, after 1988 and 1989. The United States continued to be the world's largest consumer of zinc metal, consuming about 14% of the world total.

Major changes in the U.S. zinc pricing structure were underway as virtually all producers had switched to a London Metals Exchange (LME) pricing basis before yearend. Zinc prices held at high levels through midyear, but rapidly declined in the last quarter of the year with the onset of a decline in U.S. economic activity.

DOMESTIC DATA COVERAGE

Domestic data for zinc were developed by the U.S. Bureau of Mines from five separate, voluntary surveys of U.S. operations. Typical of these was the "Slab Zinc" consumption survey sent out monthly or annually, depending on consumption quantities; small consumers are canvassed annually. Of the 299 operations to which the survey was sent, 281 responded, representing an estimated 94% of the total slab zinc consumption shown for 1990 in tables 1, 15, 16, 17, and 18. Consumption for the nonrespondents was estimated using prioryear levels adjusted for general industry trends.

BACKGROUND

Zinc is the fourth most widely used metal, yet through most of its history, it was not known as a distinct metal. Zinc has been found in bronze artifacts made 5,000 years ago and has been used as a component of brass in Europe and Asia for more than 2,500 years. Although a few artifacts composed mainly of zinc metal have been dated back to 500 B.C., the extreme scarcity of such items before A.D. 500 suggest the metal was made by accident or the technology was short lived and forgotten. The Chinese are known to have produced articles from zinc metal in the 6th century A.D. and are generally credited with being the first to develop the technology to make zinc metal. Zinc was smelted in the Zawar area of India as early as A.D. 1000 and was produced there on a large scale beginning in the 13th century. Europeans apparently were unfamiliar with zinc metal until the 16th century, even though they had used

earthy forms of zinc compounds for many years to make brass.

Uses before zinc metalmaking involved the naturally occurring zinc minerals and oxidic zinc materials resulting from smelting lead and copper ores. Zinc's presence in bronze was most likely accidental and dependent on the ores used, whereas zinc compounds were recognized and were deliberately mixed with copper to produce brass by the cementation process. Some cosmetics and medicines of ancient Egypt contained appreciable amounts of zinc carbonate and/or zinc oxide.

The technology of smelting zinc is thought to have been brought to Europe from China around 1730, and in the early 1740's, the first European zinc smelter was erected in England. By the end of the 18th century, large-scale commercial smelting had begun in Europe, mainly using the Silesian method, an improved distillation process utilizing horizontal muffles of large capacity. Zinc distillation by the Belgian method, which employed numerous small horizontal retorts in a single furnace, followed within a few years. The Belgian method gained widespread acceptance and became the preferred production method for the next 100 years.

In the United States, the first zinc metal was produced in 1835 at the Arsenal in Washington, DC. The Government brought in workers from Belgium to build and operate a small spelter furnace to produce zinc from zincite ore from New Jersey. The primary purpose for the zinc produced was to provide alloying metal to make brass for the manufacture of U.S. standard units of weight and measure.

The U.S. zinc mining industry began about 1850 with production of oxides and compounds from zinc ores in New Jersey and Pennsylvania. The first commercial zinc metal production began in 1859 in

Pennsylvania. In 1860, smelters were built in Illinois and New Jersey to treat nearby ores. By the turn of the century, U.S. zinc mining and smelting activity had grown rapidly, mainly developing in Illinois, Kansas, Missouri, and Pennsylvania because of closeness to zinc ores and adequate coal for smelting fuel. The discovery of low-cost natural gas in Kansas in the mid-1890's led to increased smelting in that State and made Kansas the leading zinc-producing State by 1899. The development of mineral flotation processes early in the 20th century made it possible to recover zinc from complex ores and produce high-grade concentrates. This led to

zinc production in many areas of the United States.

World zinc metal production was centered in Europe in the 18th and 19th centuries; however, toward the end of the latter century, U.S. zinc production had risen substantially, resulting in a second major world production center. By 1901, the United States had become the leading world zinc metal producer, a position held for most of the next 70 years. After World War I, a number of countries, including Australia, Canada, Japan, and the U.S.S.R., developed substantial zinc smelting industries. Despite increased zinc production elsewhere, Europe, except

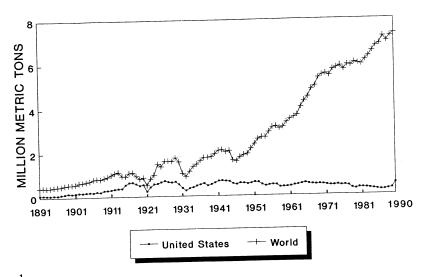

during the two World War periods, and the United States continued to be the main zinc smelting centers, in part because they also were the high zinc consumption areas. From the late 1960's, U.S. zinc metal production declined because numerous smelters closed for environmental and technical reasons, resulting in the reduction of U.S. zinc smelter capacity to onethird of its former level.

Trends in U.S. zinc mine and smelter production compared with world production from 1981 are shown in figure 1 and figure 2, respectively. For the most part, the trends are similar. U.S. mine and smelter output of zinc was dominant until

²Domestic production plus net imports plus or minus stock changes.

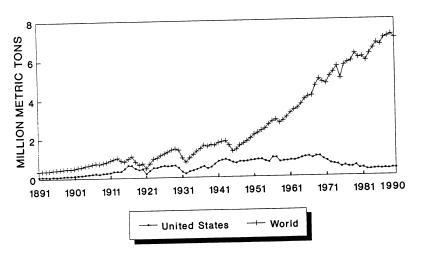

³Based on apparent consumption of slab zinc plus zinc content of ores and concentrates and secondary materials.

FIGURE 1
U.S. AND WORLD ZINC MINE PRODUCTION

Recoverable content.

FIGURE 2
SLAB ZINC PRODUCTION,
UNITED STATES AND WORLD

after World War II, but declined in relative importance thereafter owing to new production in many foreign countries. Despite production decreases in recent decades, the United States, cumulatively, has accounted for more of the world's zinc mine and

smelter output than any other country. Cumulative U.S. recoverable mine production through 1990 has totaled about 41 million metric tons, or about 15% of the world total output (about 270 million tons). U.S. primary and secondary slab zinc

production cumulatively has totaled about 51 million tons, about 20% of the world total (about 250 million tons).

Historical salient zinc statistics and graphical illustrations of various aspects of U.S. production and consumption of zinc are given in table 42 and in figures 3 through 7. In the above-mentioned table and figures, some data, especially those prior to 1907, were estimated. Data for the U.S. zinc industry, for the most part, have been well documented in annual volumes of Mineral Resources of the United States and subsequent volumes of the Minerals Yearbook. These were the principal sources for the statistical data used.

Zinc has been mined in 30 States. New Jersey has been the largest producing State, followed by Oklahoma, Tennessee, Missouri, and Idaho. Figure 3 shows, graphically, historical zinc mine production by State through 1990.

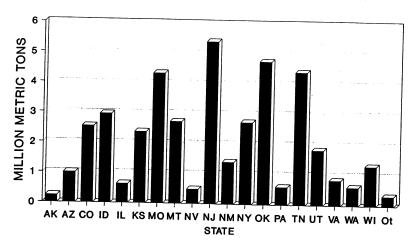

Since 1859, domestic smelters in 16 States have processed an estimated 61 million tons of zinc contained in ores and concentrates, yielding about 47 million tons of slab zinc and about 8 million tons of zinc contained in compounds, mainly American-process zinc oxide. Pennsylvania has been the largest metal-producing State. Other principal metal producers, in decreasing order of output, are Illinois, Oklahoma, Montana, and Texas. Historical cumulative smelter output of metal by State is graphically given in figure 4. A breakdown of ore-sourced zinc compound production by State is not available, but Pennsylvania, followed by Illinois, Kansas, and Ohio, have been the leading producing States of American-process oxide.

An additional 4 million tons of refined zinc metal was produced in the 1859-1990 period from secondary materials at primary and secondary smelters in the United States. Secondary slab zinc production has accounted for less than 8% of the total historical U.S. refined metal output, but percentagewise it has increased in the past few decades, owing mainly to decreased primary production and, in 1990, accounted for about one-fourth of U.S. production. The trends and sources of U.S. slab zinc production over the past 100 years are shown in figure 5.

The United States has been the world's largest zinc-consuming country since the early 1900's. U.S. zinc consumption was about 14% of the world total in 1990, but, cumulatively, since 1850, the United States has accounted for an estimated one-fourth of the total world consumption. Figure 6

shows the 100-year trend in U.S. zinc consumption and the component sources of consumption. The consumption shown is an approximation only because figures on net trade with foreign countries in zinc compounds and alloys generally were not available and are not included. Net trades in ores and slab zinc, by far the largest

components of U.S. zinc trade, however, are considered in the data.

In figure 6, the "consumed as ore" category mainly reflects ore-sourced zinc oxide production. This category has declined sharply in the past few decades owing to plant closings; only a few thousand tons of zinc fell into this category in

1990. The "slab zinc" component includes net metal trade with foreign countries, stock changes, and U.S. production, including that from secondary sources. The secondary zinc component includes compound and alloy production from wastes and scrap but not from secondary slab zinc. About one-half of this component is brass scrap, most of which is remelted to make additional brass rather than being separated into its component elements.

A breakdown of the basic use areas of U.S. slab zinc consumption for the past 90 years is given in figure 7. Galvanizing has been the largest consumer of slab zinc, and, overall, has accounted for about one-half of domestic slab zinc consumption. The most significant change in slab zinc consumption was the rapid rise in the use of zinc-base alloy following development of satisfactory alloys for diecasting purposes in the mid-1920's. Spurred on mainly by use in the automobile industry, zinc diecasting use expanded manyfold, reaching its highest level in the 1960's and early 1970's. In the mid-1970's, the energy crisis led to downsizing and weight reduction programs in the automotive industry and substantial reductions in zinc-base alloy use. Rolled zinc use increased 20,000 to 30,000 tons per year from 1982 when "zinc penny" production started. To protect proprietory data, rolled zinc in figure 7 was included in "Other" from the mid-1980's.

ANNUAL REVIEW

Legislation and Government Programs

The Environmental Protection Agency (EPA) conditionally exempted 15 of 20 mineral processing wastes from hazardous waste regulations as provided by the Resource Conservation and Recovery Act (RCRA). Slag from primary zinc processing was one of the wastes exempted. A final rule on how these wastes were to be regulated was expected in early 1991.

The EPA promulgated wastewater treatment standards for zinc, cadmium, chromium, and nickel in steelmaking electric arc furnace (EAF) dust and treatment standards for zinc phosphide before disposal.² Effective dates for both standards were August 8, 1990. In this final rule, EPA extended the existing interim treatment standard for EAF solid waste for 1 more year to August 1991.

EPA published its Toxics Release Inventory of 1988 data.³ Zinc compounds and

FIGURE 5

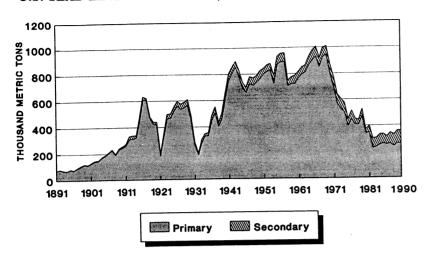

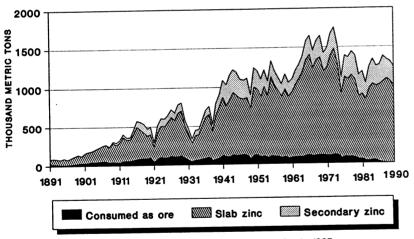

FIGURE 6
U.S. ZINC CONSUMPTION, ALL CLASSES

Note: Data on secondary consumed unavailable prior to 1907.

zinc fume were 2 of the top 25 chemicals with the largest releases and transfers in 1988.

U.S. zinc-producing companies continued to be granted a depletion allowance of 22% on domestic production of zinc and 14% on foreign production in 1990. The Superfund taxes on production of zinc

chloride and zinc sulfate also were unchanged, remaining at \$2.22 and \$1.90 per ton, respectively.

Strategic Considerations

Supply.—U.S. zinc mine and smelter production and available capacity are

inadequate to supply U.S. zinc requirements. Ore reserves are sufficient at operating mines to permit increased output on a short-term basis, and some mines now on a care-and-maintenance basis could be reactivated in 3 to 12 months.

The domestic ore reserve base is large (see table 41) but could not be tapped adequately until after the first year or so of an emergency condition. Domestic smelter capacity is woefully lacking and would be the limiting factor for increased U.S. refined zinc output. Inadequate zinc smelter capacity also severely limits the Nation's ability to produce a number of strategic and critical zinc byproduct materials, such as cadmium, germanium, and indium.

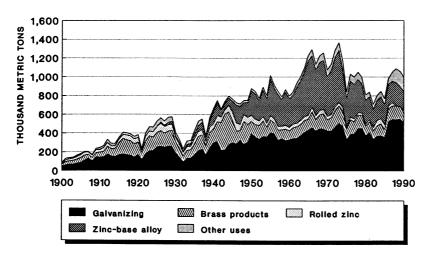

Although the Red Dog Mine in northwest Alaska nearly doubled U.S. zinc mine output in 1990, this new output was not expected to improve U.S. self-sufficiency because all of the zinc concentrates were scheduled for export. Even if Red Dog concentrates were redirected for U.S. consumption only, little or no smelter capacity is available to process the material. In 1990, for example, domestic zinc mine production substantially exceeded U.S. smelter feed requirements, resulting in net exports of about 174,000 tons of zinc in concentrate.

Although imports constitute a large proportion of U.S. zinc supply, about 60% of the zinc metal, concentrate, and compound imports comes from Canada and Mexico, and, therefore, the risk of supply disruption is low. Other traditional sources of zinc supply depend on sea transport, and the risk of supply disruption is considerably higher.

Stockpile.—A stockpile of zinc for national defense purposes has been maintained by the Government for more than 50 years. Materials in the National Defense Stockpile (NDS), managed by the Department of Defense since July 1988, can be released by the President if deemed necessary for defense or essential civilian purposes.

During World War II, the Government regulated the zinc industry and accumulated zinc stocks to ensure adequate supplies for the war effort. Concerns related to national defense after the war resulted in various stockpiling programs that evolved into the current NDS. The stockpiles contained a record-high inventory of 1.44 million tons of zinc in 1959, but sales of zinc considered excess of goals reduced this inventory to 340,194 tons by the end of 1975. The stockpile goal for zinc,

FIGURE 7 U.S. SLAB ZINC CONSUMPTION

Source: Bureau of Mines IC 7450, 1900-45 and Minerals Yearbook 1946-90.

1.293 million tons, was established in April 1980, but no zinc had been purchased through 1990 to meet this goal. At the end of 1990, the zinc stockpile totaled 343,202 tons, including 2,625 tons of zinc contained in brass. Sharply lower goals for zinc have been proposed in the past few years, but none have been approved.

Production

Mine Production.—U.S. zinc mine output was the highest since 1966 and almost double that of 1989. The newly opened Red Dog Mine in Alaska accounted for most of the additional production. Contributing to production was the opening of a new mine in Nevada and the reopening of a zinc-lead mine in Idaho. The Idaho mine, however, closed after operating for only 7 months.

The 20 leading U.S. zinc-producing mines accounted for more than 98% of production, with the 5 leading mines accounting for 60%. Alaska supplanted Tennessee as the principal zinc-producing State; those two States were followed by New York, Missouri, Colorado, and Montana. The leading domestic zinc mine producers were ASARCO Incorporated, Cominco Alaska Inc., Union Zinc Co., and Zinc Corporation of America (ZCA).

Two mines, Red Dog and Greens Creek, accounted for all of Alaska's zinc production and an estimated 40% of total U.S.

output. Cominco Alaska, a subsidiary of Cominco Ltd., officially opened its Red Dog Mine in northwestern Alaska in August. The mine was operated all year, although in the early part of the year startup problems hindered production. In 1990, the company milled 904,000 tons of ore averaging 26.5% zinc, 8.5% lead, and 3.6 ounces of silver per ton and produced 306,100 tons of zinc concentrate averaging 56.9% zinc, 51,400 tons of lead concentrate averaging 55.1% lead, and 45,000 tons of bulk concentrate averaging 31.7% zinc and 22.9% lead. Ore reserves at yearend were 61 million tons averaging 18.5% zinc, 5.4% lead, and 2.7 ounces of silver per ton. An additional 14.5 million tons of lower grade ore was classed as inferred reserves.

The Greens Creek Joint Venture, a consortium 53% owned by RTZ Ltd. through its Kennecott subsidiary, Greens Creek Mining Co., and 47% owned by minority partners-Hecla Mining Co., Exalas Resources Corp., and CSX Alaska Mining Inc.—reached normal production and operated its mine on Admiralty Island at design capacity in 1990. Greens Creek Mining, the mine operator, milled 348,000 tons of ore grading 9.7% zinc, 4.4% lead, 22 ounces of silver per ton, and 0.11 ounce of gold per ton and produced 33,660 tons of zinc, 15,200 tons of lead, 7.6 million ounces of silver, and 38,200 ounces of gold in concentrates. Three types of concentrateszinc, lead, and bulk zinc-lead—were produced; all were exported to foreign smelters. Exploration during 1990 more than doubled the ore reserves. At yearend, ore reserves were about 5.8 million tons averaging 12.4% zinc, 4.2% lead, 16.6 ounces of silver per ton, and 0.14 ounce of gold per ton.

In Tennessee, zinc was produced at six underground mines by Asarco and two divisions of Union Zinc, Jersey Miniere Zinc Co. (JMZ), and Jefferson City Zinc Div. Asarco's production at four mines was 63,050 tons of zinc in concentrate, down slightly from that of 1989. At yearend, ore reserves at the four mines were 5.7 million tons averaging about 3.3% zinc, about the same ore tonnage and grade reported at the end of 1989.

Production at Union Zinc's two mines was about the same as that of last year. JMZ's Elmwood-Gordonsville Mine was developing the nearby Stonewall ore body and planned to integrate Stonewall production into present operations.

In Missouri, zinc was produced as a coproduct of lead at nine underground lead mines along the Viburnum Trend by three companies, Asarco, Doe Run Co., and Cominco American Inc., a subsidiary of Cominco Ltd. According to Asarco's annual report, zinc output in concentrate at the West Fork Mine was 14,250 tons, up about 1,200 tons from that of 1989, and at the Sweetwater Mine, production was 3,175 tons, down about 1,200 tons. At yearend, ore reserves at the West Fork Mine were 7.8 million tons averaging 1.38% zinc and 5.8% lead with some copper and silver, and at the Sweetwater Mine, 21.1 million tons of ore averaging 4.9% lead and 0.58% zinc. Zinc output at the Magmont Mine, a joint venture of Cominco American and Dresser Industries Inc., increased over that of 1989 owing to an increase in ore output. According to the Cominco annual report, the Magmont mill processed about 0.98 million tons of ore grading 1% zinc, yielding 8.030 tons of zinc in 13,800 tons of concentrate in 1990. Ore reserves continued to decline and were expected to be exhausted in about 3 years. At yearend, ore reserves totaled 3.2 million tons and averaged 8.2% lead, 1.3% zinc, and 0.3% copper.

Fluor Corp. became the sole owner of Doe Run in May when it bought out for \$125 million the 42.5% interest held in the company by Homestake Lead Co. of Missouri. According to Fluor, Doe Run produced about 25,000 tons of zinc in 44,500 tons of zinc concentrate at its six

¹Data may not add to totals shown because of independent rounding.

lead mines and four mills in the fiscal year ended October 31. Fiscal 1989 zinc production was about 3,000 tons higher. At yearend, Doe Run's ore reserves were estimated to be about 70 million tons grading 4.8% lead, 0.9% zinc, and 0.3% copper.

In Montana, the Montana Tunnels Mining Co., a subsidiary of Pegasus Gold Inc., mined and milled 3.8 million tons of ore at its Montana Tunnels Mine in 1990; concentrates containing 15,500 tons of zinc, 6,030 tons of lead, 1.2 million ounces of silver, and 59,100 ounces of gold were produced. The discovery of low-grade zones in the ore body and harder than expected ore in 1989 resulted in redesigning the pit, cutting the stripping ratio in half, adding additional flotation cells, and installing a clast reject gravity circuit in the mill. Net losses in ore reserves owing to pit changes were minor. At yearend, ore reserves were down only slightly more than the mining rate and totaled 31.1 million tons averaging 0.6% zinc, 0.24% lead, 0.34 ounce of silver per ton, and 0.021 ounce of gold per ton. At expected mining rates, a mine life of 8 years was anticipated.

New Butte Mining Co., a subsidiary of Butte Mining PLC, continued to reactivate mine stopes closed several decades ago at Butte, MT. A mining rate of 450 tons per day was attained in March; this rate was sharply reduced at midyear owing to a strike at the smelter processing New Butte's concentrate. The ore was custom milled at

W Withheld to avoid disclosing company proprietary data; included in "Total."

the Contact Mill in Phillipsburg. Ore grades milled at midyear averaged 4.75% zinc, 2.12% lead, 0.13 ounce of gold per ton, and 13 ounces of silver per ton.⁴ Zinc recovery was 95%. According to Butte Mining, exploration in 1990 resulted in the defining of an additional 4.1 million tons of inferred ore reserves between the 400 and 1,000 levels in the Rainbow Block. At yearend, ore reserves totaled about 1 million tons averaging 5% zinc, 2% lead, 10 ounces of silver, and 0.06 ounce of gold per ton.

In Colorado, zinc was produced as a coproduct of gold-silver operations at the Leadville Unit (managed by Asarco, but jointly owned with the Resurrection Mining Co.) and the Sunnyside Mine (owned by San Juan County Mining Venture, a company composed of Alta Bay Venture, 67%, and Washington Mining Co., 33%). Asarco produced almost 12,900 tons of zinc in concentrates, down about 100 tons from that of 1989. At yearend, ore reserves were up about 92,000 tons from those of 1989 and totaled 801,000 tons averaging 7.77% zinc, 3.56% lead, 1.7 ounces of silver per ton, and 0.07 ounce of gold per ton.

In Idaho, Hecla Mining Co. fully implemented its Lucky Friday Underhand Longwall (LFUL) mining method at the Lucky Friday Mine. The LFUL method, which utilizes rubber-tired vehicles, more mechanized equipment, a ramp system, and cemented sandfill, was developed to enhance safety and improve efficiency. In

1990, ore milled increased about 9,000 tons to 134,000 tons, resulting in an output of 3,000 tons of zinc in concentrates, up slightly from that of 1989. Zinc recovery from ore was about 76%. Ore reserves were up by about 60,000 tons, and at yearend, totaled 479,000 tons and averaged 2.7% zinc, 13.4% lead, and 16 ounces of silver per ton.

Star Phoenix Mining Co. rehabilitated its leased Star-Morning Mine in Idaho and began ore production in mid-April. Although production levels increased as the year progressed, financial difficulties led to the closure of the mine in mid-November. Star-Phoenix had estimated ore reserves at 2 million tons grading 10% to 12% combined lead and zinc with good silver values when the mine reopened.

Cyprus Minerals Co. increased zinc production at its Pinos Altos Mine in New Mexico to 3,600 tons in concentrate compared with only 900 tons in 1989. Zinc ore reserves at yearend totaled 3.4 million tons grading 8.46% zinc; the ore reserve tonnage was up almost fourfold from that of 1989.

Cyprus and Mitsui Mining and Smelting Co. Ltd. formed Western Zinc Inc., a joint-venture company set up to explore for and develop zinc deposits in western North America. Included in the agreement was the possibility of building a zinc smelter to process zinc concentrates produced by the venture.

^rRevised. W Withheld to avoid disclosing company proprietary data.

In Nevada, the Ward Mine, owned by Alta Gold Co., and the leased Taylor mill officially opened in May, processing ore at a 900-ton-per-day rate. More than 100,000 tons of ore had been stockpiled prior to the opening of the mill. Plans called for an annual production of about 10,500 tons of

zinc, 600 tons of copper, 700 tons of lead, and 300,000 ounces of silver in concentrates. At yearend, ore reserves were about 1.4 million tons averaging 6.1% zinc, 1.1% copper, 1.1% lead, and 2.4 ounces of silver per ton. The Ward Mine last operated in 1880.

Two long-closed zinc mines in Washington were being evaluated and could open in 1991. Equinox Resources Ltd. completed a feasibility study on the Van Stone Mine near Coville, WA, and planned to reopen the mine in the first half of 1991. The mine last produced in 1970. Ore was to be produced by open pit methods for the first 3 years with underground mining thereafter. At capacity, annual production was projected to be 15,000 tons zinc and 2,000 tons lead in concentrates. Ore reserves were estimated to be 2.5 million tons averaging 5.7% zinc and 1.1% lead.

Resource Finance Co. (RFC) continued to evaluate the Pend Oreille lead-zinc mine near Metaline Falls, WA, for possible reopening in late 1991. The Pend Oreille Mine last operated in 1977. RFC estimated ore reserves to be 3.4 million tons averaging 8.8% zinc and 1.6% lead. Reserves were adequate for a 9-year mine life at anticipated production rates.

Smelter and Refinery Production.— Refined metal production was up slightly from that of 1989 and was the highest since

1981. Three companies, ZCA, JMZ, and Big River Zinc Co., operated four primary zinc refineries in 1990. Secondary zinc metal was produced at 12 secondary plants from waste and scrap materials; however, the largest producer of secondary zinc metal was ZCA at its primary electrothermic smelter at Monaca, PA. A substantial part of the plant's secondary feed was crude zinc calcine recovered from EAF dust by a sister company, Horsehead Resource

Development Co. (HRD). The largest producers of zinc metal at secondary plants were Huron Valley Steel Corp., Interamerican Zinc Co., and Gulf Metals Corp.

ZCA's zinc production capacity at Monaca continued to increase and was expected to attain 146,000 tons per year in early 1991. Most of the new capacity, 45,000 tons since 1988, was expected to be dedicated to the processing of EAF zinc calcine. The processing of EAF dusts gained new urgency in 1990 as the total landfill ban on disposal of these dusts was to be implemented in August 1991. Thermal processing was expected to be required on all dusts containing more than 15% zinc. The number of plants processing these materials increased in 1990. A list of operating and proposed domestic plants and their EAF dust capacities is given in table 10.

Zinc Oxide.—Domestic American- and French-process zinc oxide was produced entirely from zinc metal and scrap by eight companies in 1990. All but one company, Eagle Zinc Co. of Hillsboro, IL, produced French-process zinc oxide. Some impure oxide produced at secondary plants was sold directly for use in animal feed and for other agricultural purposes. The principal zinc oxide producers in 1990 were Asarco, Pasco Zinc Corp., and ZCA. Hitox Corp. of America permanently closed its zinc oxide plant in Spokane, WA, in March.

In 1990, Asarco produced 12,000 tons of zinc oxide, down about 3,600 tons from last year, at its 17,300-ton-per-year Hillsboro, IL, plant. In July, North American Oxide Inc., an affiliate of the Rogers Group Inc., began production at its new 18,000-ton-peryear French-process zinc oxide plant at Clarksville, TN.

Byproduct Sulfur.—Production of sulfur in byproduct sulfuric acid at primary zinc plants was 134,700 tons, about the same as that produced in 1989. Acid production at zinc plants in 1990 was valued at \$17.4 million.

Consumption and Uses

Zinc is found in all sectors of the economy, but its role is not obvious to the public because zinc tends to lose its identity in the end products. Zinc-containing products were used extensively in 1990 by the military, industry, and general public for construction, transportation, electrical, machinery, and chemical purposes. Zinccoated steel sheet, structural shapes, fencing, storage tanks, fasteners, nails, and wire rope were widely used in all types of construction, including transmission and radar towers, industrial plants, culverts, roads, bridges, and airfields. Zinc sacrificial anodes were used to protect ship hulls, offshore drilling rigs, and submerged and buried steelworks, tanks, and pipes. Brass was used as shell casings in ammunition and tubes, valves, motors, refrigeration equipment, heat exchangers, communication units, and electronic devices. Zinc diecast parts, such as handles, grilles, bezels, brackets, locks, hinges, gauges, pumps, mounts, and housings, were used extensively in vehicles, machinery, business machines, appliances, scientific equipment, and electronic equipment. Zinc dust was used in primers and paints; in alkaline dry cell batteries; in the sherardizing

¹Inactive.

process to protectively coat nuts, bolts, and small parts; for the precipitation of noble metals from solution; and in the zinc industry for the removal of impurities, such as copper, cadmium, and lead, before electrolysis. Zinc oxide was a necessary ingredient in the vulcanization of rubber and as pigment in paints. The metal casings of zinc-carbon dry cell batteries were zinc. In 1990, about 30,000 tons of Special High Grade (SHG) rolled zinc was used by the U.S. Mint to produce 12.5 billion pennies.

Zinc compounds were used in corrosioninhibiting paint primers, chemical catalysts, welding and soldering fluxes, fungicides and pharmaceuticals, phosphors for cathode tubes and radar scopes, chemical smoke, and additives to lubricating oils and greases. Zinc ferrites were used in electrical devices in transformers, coils, amplifiers, motors, and tuners, and in electronic devices in radio, television, and computers.

Domestic consumption of slab zinc fell about 70,000 tons to slightly less than 1 million tons in 1990. Galvanizing and electrogalvanizing, mainly for sheet and strip, continued to be the principal use of zinc metal, consuming an estimated 52%, followed by zinc-base die-cast alloys, 20%; brass alloys, 13%; and other uses, 15%. SHG accounted for about 53% of the reported slab zinc consumed, followed by Prime Western (PW), 23%; High-Grade (HG), 14%; and other grades, 10%.

Overall, the construction sector of the economy was the largest consumer of zinc, accounting for an estimated 46%, followed by transportation, 20%; machinery, 11%; Revised. W Withheld to avoid disclosing company proprietary data

manufacture, and decreased construction activity.

According to the Bureau of the Census, zinc-base alloy die and foundry casting shipments totaled about 188,000 tons, down from 200,000 tons reported in 1989. The decline was attributable to a weaker economy in 1990. Zinc die-cast shipments by weight were estimated to have been equally distributed between automotive, hardware, and other uses.

Zinc consumption in the production of copper-base alloy by brass mills, ingot makers, and foundries was down slightly from that of 1989 according to the Copper Development Association Inc. (CDA). The brass and bronze industries were estimated to have consumed about 280,000 tons of zinc, the source of which was about equally divided between refined zinc metal and brass and bronze scrap metal. According to CDA data, brass mills accounted for 85% of the total zinc consumed as metal and scrap in making copper-base alloys.

The zinc content in typical U.S. manufactured automobiles was estimated to average about 40 pounds in 1990, about the same as that in 1989. Diecastings accounted

for about 20 pounds; corrosion protection via galvanizing and coatings, 17 pounds; and other, including rubber, brass, and zinc solder, 3 pounds.

The apparent domestic consumption of zinc oxide was about 165,000 tons, down from 176,000 tons in 1989. Domestic production declined; exports and imports also declined. Because the U.S. Bureau of Mines information on zinc oxide consumption by industry sector reflects only shipments as reported by the domestic producers, the consumption data listed in table 22 only account for about three-fourths of the apparent market. Of the reported amounts, the rubber and chemical industries continued to be the principal consumers.

Stocks

Metal stocks held by domestic producers, consumers, and merchants declined slightly in 1990 and were near the record-low stock levels of 1988. In recent years, stock levels have tended to range in the 4- to 6-week consumption range, reflecting the general trend by consumers and merchants for low inventories and just-in-time delivery. In 1990, yearend stock levels were strongly influenced by anticipation of further declines in the zinc price in 1991. Metal stocks in the market economy countries (MEC), according to the International Lead and Zinc Study Group (ILZSG), were 545,000 tons at the end of 1990, down 47,000 tons from those at the end of 1989. The LME terminated its HG zinc contract in March 1990 in favor of the SHG zinc contract introduced in September 1988. As a result, SHG stock levels on the LME had built up to 74,800 tons by the end of 1989. However, in early 1990, stock levels fell to the mid-40,000 tons and remained at that level through November. At yearend, stocks totaled 55,000 tons.

Inventories of zinc in concentrate at domestic primary smelters totaled 34,800 tons at yearend compared with 35,500 tons at the end of 1989, according to the American Bureau of Metal Statistics Inc. Concentrate stocks were at their lowest level at midyear.

Markets and Prices

Zinc metal prices continued a 10-month downtrend through January 1990 before improving toward the end of February. Prices moved upward in the summer months in response to strong world

demand; production problems at smelters in Australia, Canada, and Peru; and fears of concentrate shortages owing to mine strikes and startup problems at the Red Dog Mine. Weaker demand, especially in North America, and stock buildup on the LME led to declining prices in the last quarter of 1990.

By yearend, virtually all North American slab zinc producers had switched to an LME price-basis for zinc metal. This resulted in the demise at yearend of the Metals Week (MW) North America producers' average used in the Minerals Yearbook since 1971. A new MW price quote for North America based on the LME cash price plus a premium was expected to be instituted in January 1991. The LME planned to establish a number of warehouse facilities in the United States; the first to be approved was expected to be located in Baltimore, MD, in early 1991.

Foreign Trade

U.S. exports of zinc concentrates were the highest ever and were almost three times higher than those of 1989. Exports of waste and scrap were also at record levels; Taiwan imported about two-thirds of the total.

General imports of zinc concentrate relative to imports for consumption continued to be high. The large disparity was due to shipments of Canadian concentrate through Skagway, AK, to world markets. Imports of slab zinc and zinc oxide both fell, reflecting the general decline in domestic zinc consumption.

According to CDA, 347,600 tons of brass mill products was imported and 158,000

¹Excludes leaded zinc oxide and lithopone.

²Includes zinc content of zinc ammonium chloride

¹In addition, zinc oxide was imported as follows, in metric tons: 1986-43,924; 1987-57,276; 1988-73,042; 1989-59,557; and 1990-49,454; distribution cannot be distinguished by industry.

TABLE 26
ESTIMATED STOCKS OF SLAB ZINC IN THE UNITED STATES,
DECEMBER 31

(Metric tons)

	1986	1987	1988	1989	1990
Primary producers	16,722	13,448	6,005	7,200	6,000
Secondary producers	3,203	3,162	695	1,031	633
Consumers	54,079	57,410	64,864	60,297	61,027
Merchants	26,559	22,352	14,290	22,183	20,444
Total	100,563	96,372	85,854	90,711	88,104

tons exported in 1990, compared with 397,500 tons imported and 133,200 tons exported in 1989.

World Review

World zinc mine production was a record high 7.3 million tons in 1990. Metal output exceeded 7 million tons for the fourth straight year and was the third highest ever recorded. Zinc consumption was slightly less than the record level of 1988 but was the second highest in history.

According to ILZSG, the MEC consumed 5.24 million tons of zinc metal compared with 5.20 million tons in 1989 and 5.27 million tons in 1988. The MEC accounted for three-fourths of consumption and the Eastern European and Socialist (EES) countries slightly less than onefourth, or about 1.75 million tons. The world's leading consuming nations, in order of estimated consumption, were the United States, the U.S.S.R., Japan, and Federal Republic of Germany. The United States, Japan, and Western Europe accounted for one-half of world consumption and about 70% of the MEC total. According to ILZSG,5 the principal uses of zinc metal in 1989 in the major western countries were as follows: galvanizing. 47%; brass and bronze, 20%; zinc-base alloys, 14%; chemicals, 8%; zinc semimanufactures, 7%; and other, 4%. In 1990, galvanizing was estimated to have increased slightly to about 48%.

Although many countries produced less in 1990, world zinc mine output rose sharply owing mainly to new production in the United States, Australia, and Bolivia. Canada, because of strikes and closure of the Sullivan Mine; Denmark, because of the August closing of the Black Angel Mine in Greenland; and the U.S.S.R., because of labor and supply problems, recorded the largest drops in production.

On a geographic basis, the Americas accounted for about 40% of world mine output. Europe, including Greenland and the U.S.S.R., Asia, and Australia with 27%, 16%, and 13%, respectively, were the other principal producing areas. Despite 3 straight years of declining output, Canada remained the world's largest producer. Canada, together with Australia, Peru, the U.S.S.R., and the United States, accounted for 54% of the world's zinc mine production.

World exports of zinc in concentrates totaled about 2.3 million tons, of which more than 90% was from the MEC.

²New plant opened in 1990.

³Pigment & Chemical Inc. acquired plant from Pacific Smelting in May 1989.

¹London Metal Exchange.

Source: Metals Week.

Australia, Canada, Peru, and the United States accounted for 78% of MEC concentrate exports. Canada, Japan, the Republic of Korea, and the Western European countries, were the largest importers.

World refined metal production was about 160,000 tons less than that in 1989. The largest decrease in production occurred in the U.S.S.R. The MEC and EES countries accounted for 73% and 27%, respectively, of world output. The largest producers were Canada, China, Japan, and the U.S.S.R.; these countries accounted for about 38% of world zinc metal output in 1990.

World zinc mine capacity was about 8.35 million tons, up about 150,000 tons from that of 1989. Twelve mines opened, 5 expanded, and 11 closed, including 3 that had opened or expanded capacity in 1990. The Golden Grove Mine in Australia, rated at 95,000 tons capacity, was the largest new mine to open. The Black Angel, Caribou, and Daniels Harbor Mines in Canada and the Morro Agudo Mine in Brazil, with combined capacities of 196,000 tons, were the largest to close.

World smelter capacity totaled about 8.24 million tons at yearend, increasing about 73,000 tons through expansions at existing smelters. According to ILZSG,6 an additional 540,000 tons of smelter capacity

was scheduled to come on-stream by 1995. Greenfield smelters were under construction in China, India, and Iran, and major expansions were underway in Belgium, the Federal Republic of Germany, and Spain.

OUTLOOK

U.S. demand for zinc was forecast to rise slowly, increasing from slightly less than 1.0 million tons in 1990 to about 1.2 million tons by the year 2000. No major shifts in domestic zinc use were foreseen, although some present uses may yield further to substitution.

Although the United States has an adequate zinc resource base, imports were expected to continue to account for more than one-half of U.S. zinc supply in the next decade. Mine output was anticipated to reach record-high levels in the 1990's, but smelter capacity was expected to rise only modestly. No new primary zinc smelters will likely be built in the United States during the 1990's owing to permitting delays and economic indecision caused by the uncertainty of environmental regulations and the long-term liability threat posed by Superfund legislation. Ironically, the

United States was expected to be a major world exporter of zinc concentrates, and, at the same time, to remain the world's largest importer of refined zinc metal.

Secondary zinc recovery from waste and scrap was anticipated to be a strong growth sector for the zinc industry. Domestic secondary zinc production could increase by more than 50% above the present level in the next decade and constitute the source of 40% of total U.S. zinc metal and compound consumed annually by the year 2000. Increased secondary recovery was expected to be driven by public policies related to waste and scrap recycle, environment, and public health.

World zinc metal consumption was expected to continue upward, rising to about 8.5 million tons by the year 2000 from the 7.0 million tons consumed in 1990. No new major uses of zinc were on the horizon. Traditional zinc uses in meeting the needs of a rapidly growing and more affluent world population were expected to be the driving force for increased zinc use in the next decade. World per capita consumption of zinc metal was about 1.32 kilograms per person in 1990, down from 1.40 kilograms per person in 1988 and 1.35 kilograms in 1989. Global per capita use of zinc, despite being significantly affected by periodic economic downturns, has tended to climb steadily since 1800, as shown in table 43. Assuming the 1980's decade per capita average rate of about 1.35 kilograms is unchanged in the 1990's decade, the above forecast zinc consumption in the year 2000 would be attained.

World zinc resources and ore reserves were adequate to supply the increased demands of the 1990's. Cumulative zinc mine output for the 1991-2000 period, about 80 million tons, however, would result in the extraction of more than one-half of the 145 million tons of estimated 1990 world zinc ore reserves (see table 41).

Since 1800, quarter-century cumulative world zinc metal production and consumption has been, at least, double that of the previous quarter century, except for the 1926-50 quarter when it was only 1.9 times the previous 25-year period. The cumulative production and consumption forecast for the last quarter of this century is expected to total about 175 million tons, again only 1.9 times that previous quarter; but, interestingly, more zinc metal will have been produced and consumed in the 1976-2000 period than the world had produced and consumed throughout history up to 1975.

²Based on High-Grade zinc delivered.

³As of May 1989, LME cash price changed to Special High Grade from High-Grade.

Wherever possible, detailed information on raw material source of output (primary-directly from ores, and secondary-from scrap) has been provided. In cases where raw material source is unreported and insufficient data are available to estimate the distribution of the total, that total has been left undifferentiated (primary and secondary). To the extent possible, this table reflects metal production at the first measurable stage of metal output. Table includes data available through July 2, 1991. ²Excludes zinc dust.

³Reported figure.

ZIRCONIUM AND HAFNIUM

By David A. Templeton

Mr. Templeton is a physical scientist with the Branch of Industrial Minerals. He has covered zirconium and hafnium for about 3 years. Domestic survey data were prepared by Imogene P. Bynum, Chief, Section of Nonferrous Metals Data, and Jean K. Moore, Mineral Data Controller. World production data were prepared by Harold D. Willis.

irconium and hafnium are sister metals of Group IVB on the Periodic Table of Elements and have atomic numbers 40 and 72, respectively. Their predominant commercial ore mineral is zircon, a zirconium silicate usually containing 65% to 66% zirconium and hafnium oxides combined. Hafnium is always present in zircon minerals, usually accounting for about 2% of the mineral composition. An ancillary source is baddeleyite, the naturally occurring oxide of zirconium, and as such is quite valuable. It contains better than 95% zirconium oxide. Other possible ore minerals for which economic deposits have been discovered include eudialyte and gittinsite, though the mineral beneficiation techniques for these have yet to be commercialized. The zirconium oxide content of these ores is quite low (roughly 1% to 4%) compared to zircon and baddelevite, but are considered economic because of the high value of coproduct yttrium (less than 1% yttrium oxide).

Zircon is mined as a byproduct of heavymineral sand deposits, which almost always contain titanium and rare-earth minerals as well. The highly abundant titanium minerals, sought for their use in pigment and metal markets, are the primary product. The deposits are mined using dredges or typical earth-moving equipment. Once ore is extracted, the suite of heavy minerals, normally composing about 10% or less of the deposit, is separated from the gangue (nonresource ore) by nature of its higher specific gravity, or weight. The heavy minerals are concentrated in a wet treatment plant using equipment such as jigs, cones, or spirals. Dredged ore is pumped to the plant and processed as a watery slurry. Ore that is not dredged, but rather is mined with heavy equipment, is trucked to the plant and mixed with water. The plant equipment is designed to selectively remove the heavy minerals from the water stream, and unwanted material, about 90% of what was mined, is pumped back to the dredge pond or to a tailings pile. After the heavy minerals are concentrated, they are dried and sorted from one another using magnetic and electrostatic principles.

Zircon sand is the primary ore for the production of zirconium and hafnium metal, but this use accounts for very little of total zircon consumption. Zircon is also the main raw material source for the production of zirconia (zirconium oxide, or ZrO₂) and zirconium chemicals. Milled zircon, or flour, is used as a foundry mold wash to protect the mold facings, to provide a cleaner finish on the casting surface, and to make it easier to separate the casting from the mold. Zircon grains and flour can be mixed in a slurry and applied over wax patterns in multiple layers to make molds for high-quality investment castings. After the wax is removed, molten metal is poured into the mold, allowed to solidify, and removed by breaking the mold. This is a rapidly growing industry owing to the quality products so manufactured. Zircon bricks and special shapes are important refractories in the steel and glass industries, though the former has many comparable substitutes available to it, particularly highmagnesia spinel. The glass industry is relatively dependent on zircon refractories due to the lack of suitable substitutes.

Zirconium and hafnium found unique roles in the nuclear industry in the 1950's, and this continues to be their mainstay to this day. While they both retain excellent metallurgical properties and corrosion resistance in the extreme environment of a reactor core, they are used because each has exactly the opposite effect on the thermal neutrons that drive the fission process of nuclear energy: Zirconium is relatively transparent, and hafnium is an excellent sink, or absorber. Hence, the former is used to clad fuel rods, and the latter is used in control rods to regulate the rate of fission within the reactor. Zirconium has also found wide usage in the chemical process industries because of its corrosion resistance to harsh chemicals, and hafnium is used as a additive in several superalloys to improve their high-temperature properties.

Hafnium is refined from zircon sand just as zirconium is, by chlorination, and then separated using solvent extraction. This is done primarily because of the need to produce hafnium-free zirconium for nuclear fuel cladding. There is also a persistent need for hafnium as a control rod medium and as an alloy addition in superalloys. Hafnium metal can be produced by the Kroll process (magnesium reduction of the tetrachloride), as can zirconium, to produce sponge metal. Sponge metal, called so because of the spongelike pores produced by the process, is then vacuum distilled to remove the reacted magnesium chloride salts, crushed, and compacted to form a first ingot. This ingot is then remelted more than once with small additions of other alloying elements by electric arc and electron beam furnaces to further refine it. Both metals can also be produced as crystal bars, a process first described in 1925 by its developer, deBoervan Arkel. The only difference is that more hafnium crystal bar is produced because of the high-purity requirements of superalloys and hafnium's greater use therein. To do so, hafnium metal is placed in a 200° C to 300° C iodine atmosphere alongside a superheated hafnium filament at 1,300° C. Gaseous metal halides (hafnium tetraiodide) gradually sublime from the feed by the attack of the hot gas. When these come in contact with the wire, the hafnium is deposited in crystal form, freeing the iodine to repeat the process until the feed has been completely transferred to the crystal bar.

For the most part, hafnium metal has only been used as control rods in nuclear reactors and as a constituent in superalloys. The former arises from the fact that hafnium is an excellent absorber of thermal neutrons and retains its metallurgical properties while doing so. The latter is done to strengthen grain boundaries between the metal crystals in the alloy; this refinement improves the alloys properties of creep resistance, tensile strength, and high-temperature ductility. As regards neutron absorption, it is a striking coincidence that

ZIRCONIUM AND HAFNIUM—1990 1275

zirconium and hafnium have exactly opposite effects here, yet they are sister elements. Zirconium, as mentioned above, is used to clad nuclear fuel rods because of its transparency to thermal neutrons. This allows reactors to run at optimum efficiency. Any hafnium not removed from the zirconium during refining would slow down neutron activity within the reactor's core. Aside from nuclear and chemical process industry uses mentioned earlier, zirconium metal also has minor uses in photographic flash bulbs, fireworks, military ordnance, lesser use than hafnium in superalloys, and as a getter in vacuum tubes. Because of the two metals' similar properties, they can be used interchangeably or combined in most applications except nuclear; but, commercially pure zirconium, which contains hafnium, has wider usage because of its lower cost.

Nonmetallic uses of hafnium have been quite limited so there is much opportunity for growth in this area. While hafnium-carbide is used to coat tungsten-carbide cutting tools, perhaps the most promising nonmetallic use is in hafnium oxide refractories. It has a higher melting temperature than zirconia, second only to thorium oxide. Thoria melts at about 3,300° C and hafnia at 2,900° C, while zirconia's is 100° lower than magnesia, or 2,700° C.

Zirconium oxide, or zirconia, is used largely in refractories, ceramics, abrasives (when alloyed with alumina), and electronics. It is produced from zircon by removing silicon dioxide. (Silica, SiO2, and zirconia, ZrO₂, combined make zircon, ZrSiO₄). Several methods are commercially employed to accomplish this. These include both electric arc and plasma arc dissociation and chemical methods such as caustic fusion and chlorination. The process used depends on the quality of zirconia necessary for the desired end product. Although baddeleyite does not require the removal of silica, some beneficiation is needed to remove trace quantities of impurities. This mineral is used in special applications for refractories, abrasives, ceramic colors, and chemicals.

ANNUAL REVIEW

It was indeed an active year for zircon and its related forms. Areas of activity concerned domestic and foreign mine closings and expansions, exploration in North Carolina and Virginia, lifting of the trade embargo on parastatal baddeleyite from the

Republic of South Africa, two company acquisitions, and a significant reduction in the price of zircon.

Legislation and Government Programs

On January 17, 1990, zircon, baddeleyite, and zirconium-bearing materials were added to the list of materials deemed essential for the economy or defense of the United States. (Public Notice 1150 was issued in the Federal Register on January 18th.) This certification exempted certain items grown, produced, marketed, or otherwise exported from parastatal organizations in the Republic of South Africa. Baddelevite produced by Foskor Ltd., one of only two free world producers, was henceforth permitted U.S. importation. Foskor and the Palabora Mining Co. both mine the same deposit in the Transvaal and together produce about 20,000 metric tons of baddeleyite per year.

Production

In Florida, E.I. du Pont de Nemours & Co. Inc. announced plans to expand its operations onto a 7,200-acre property acquired in 1985. The Maxville extension is just north of the Trail Ridge deposit, which Dupont has mined for the past 30 years. Beginning in 1992, a portion of the current operations,

which include both the Trail Ridge and Highland deposits, will be closed as the Maxville site is commissioned. A 50% increase in production is expected. The Ellicott Machine Corp., Baltimore, MD, was to supply a 2,100-ton-per-hour dredge to complement the two already operated by Dupont. It will outproduce both of the existing dredges combined. Dupont expected the new property to produce until the year 2010.

Associated Minerals (USA) Ltd. doubled the capacity and improved the efficiency of the wet-treatment plant at its mine in Green Cove Springs, FL. (Wet plants are concentrators and dry plants are separators of mineral sands.) The \$20 million upgrade, performed while the facility remained online, was made so that lower ore grades could be processed with utmost efficiency.

Heritage Minerals Inc. completed its processing of stockpiled tailings at an old ilmenite mine in Lakehurst, NJ. The original ore deposit still contained reserves of zircon, but the company had made no definite plans to dredge those resources, an activity that could extend its presence there another 6 years. Market stability was awaited before a decision would be made. Nord Ilmenite Corp. completed its first full year of similar reprocessing in Jackson, NJ, after commencing operations last December.

There was much activity in southern Virginia generated by a handful of compa-

nies in the exploration and development stages of heavy-mineral deposits, and it seemed almost certain that one, if not more, of the deposits would come on-line by the middle of the decade, depending on positive feasibility studies and permit approvals.

South East TiSand Joint Venture, composed of Becker Minerals Inc. (Cheraw, SC) and Consolidated Rutile Ltd. of Australia, began close-spaced drilling to prove up ore bodies, acquired mineral leases for its Ringwood and Roanoke Rapids, NC, deposits, and produced pilot plant concentrates for laboratory analysis. The deposit in Brink, VA, for which mineral leases were signed in November 1989, was the site of the pilot plant runs, which were performed on ore samples from other deposits as well. Soil reclamation studies were also furthered with the assistance of the Virginia Polytechnic Institute and State University. Preparations to secure the necessary permits were also made.

RGC (USA) Minerals Inc. continued exploration and development work on three separate deposits. Furthest along was the Old Hickory deposit, 90 kilometers (km) southwest of Richmond, VA, near Stony Creek, with an estimated 210 million tons of zircon and titanium mineral-bearing sands grading 6.5% on average. Zones with grades as high as 20% were said not to be uncommon, and a few contained as much as 60% to 70%. Ore body assessment, completed in July, and lease acquisitions had advanced such that the permitting process was begun toward year's end. At the same time, drilling of 2,400 new, close-

spaced holes was begun, the analysis of which would be used to better mine the deposit. Studies continued at the Virginia Polytechnic Institute and State University to ensure that soil reclamation would sustain the type of crops currently grown on the farmlands. Property acquisition (leases) and drilling also continued at two projects in North Carolina near Aurelian Springs and Bailey. Pilot plant trials took place on-site at the former toward yearend.

On May 3d, Piedmont Mining Co. announced a tentative agreement with the Corona Corp. to explore for heavy-mineral deposits in North Carolina along the same ancient shoreline the deposits mentioned above are located on. The company began investigations in the region last August.

Magnesium Elektron, Inc. completed the expansion of its Flemington, NJ, zirconium chemical facility in May. The increase in capacity was necessary to meet current and future demand for this growing market. Zirconium chemicals are used in a wide variety of applications such as antiperspirants, kidney dialysis, oil well fracturing fluids, ink and paint dryers, food container coatings, leather tanning agents, and many others.

Coors Ceramics Co., Golden, CO, broke ground at yearend for production and office facilities to house its year-old consumer product division, Coors Ceramicon Design, Ltd. The 117,000-square-foot complex, composing only a portion of the Coors Technology Center, was scheduled for July 1991 commissioning. Ceramicon produces specialty zirconia ceramics such as golf putters, labware, and knife sharpeners.

The Norton Co. agreed to accept a \$90-per-share tender offer from the French glass producer Compagnie de Saint Gobain after successfully defending repeated hostile takeover attempts by the British conglomerate BTR PLC. The announcement was made on April 25th and became effective on April 30th. Headquartered in Worcester, MA, Norton operates 113 plants in the United States and 25 worldwide. The plant at Huntsville, AL, which produces zirconiatoughened alumina for abrasives and zirconia for refractories and advanced ceramics, is one of the world's largest zirconia production facilities.

M & T Chemicals, Inc. of Andrews, SC, a leading domestic producer of milled and micronized zircon, was merged with two other chemical companies by its parent company, Europe's Elf Aquitaine and its subsidiary, Atochem S.A. The new company, Atochem North America, also ab-

sorbed the Pennwalt Corp. and Atochem Inc.

Stocks

Stockpiles of zirconium and hafnium held by U.S. Department of Energy totaled 949 tons and 34.5 tons, respectively. The stocks were held in various forms, but mostly as ingots and wrought shapes. The National Defense Stockpile continued to hold 14,507 tons of baddeleyite. Although there was no goal for raw ore materials, there also was no current legislative authority for its disposal.

Markets and Prices

Record prices and insufficient supply, conditions that plagued raw material consumers in the past few years, abruptly reversed in 1990. Lower demand, reduced by lagging economies, and an increase in supply, brought to market by new and expanded operations, coupled to deflate prices significantly. Producers, especially in Australia, the world's largest producer, sought to mitigate the price collapse and curtailed production at some mines by extending yearend, holiday-season closures, thus bringing the supply-demand balance more in line. (It was thought by some industry observers that similar moves in the mid-eighties had been purposefully implemented to undersupply then-current demand, thereby instigating price increases.) Other factors were attributed to the record-high prices seen at the end of the decade too: the sinking of the Singa Sea off the coast of Australia in July 1988 (13,400 tons of zircon onboard), the general media/ industry hype about a shortage, and consumer attempts to build inventories during the purported shortage. Yearend prices of zircon are given in table 3.

One manifestation of short supply, whether real or not, was the emergence of a spot market and its highly inflated prices. Prices as high as \$1,000 per ton for nonbulk standard grades were reported. This represented about a 30% to 40% premium over contractual prices for similar material. Another result of the tight supply was shortened contract periods, down from semiannually or yearly to quarterly or semiannually. All in all, had the world's primary consumers maintained and utilized substantial inventories of zircon, the effect of this past boom-bust cycle would have been much less severe, or at best would not even have occurred.

Dense and pressed zircon brick and shapes.

²Fused cast and bonded alumina-zirconia-silica-base refractories.

³Alumina-zirconia-base abrasives.

⁴Excludes alloys more than 90% zirconium.

⁵Includes chemicals, zirconium metal, welding rods, sandblasting, and other miscellaneous uses.

TABLE 3
PUBLISHED YEAREND PRICES OF ZIRCONIUM AND HAFNIUM MATERIALS

Specification of material	1	989	10	990
Zircon:			1:	
Domestic, standard-grade, f.o.b. Starke, FL, bulk, per short ton ¹		\$320.00		\$368.00
Domestic, 75% minimum quantity zircon and aluminum silicates, Starke, FL, bulk, per short ton		1204.00		204.00

World Review

Exploration and development of ore deposits continued despite reduced demand and faltering prices. Even so, some expansions were completed and others were planned, and a few new projects were commissioned.

The situation in which supply exceeded demand, as was expected by some because of additional capacity coming on-line, was exacerbated by the industrial nations' recessionary economies. So, both supply and demand were moving in opposite directions, and consequently, prices suffered from the imbalance. Reaction to this condition was seen at yearend when a few producers temporarily ceased operations, perhaps to add some price-stabilizing support to the market.

Australia.—Australian producers implemented yearend mine closures to bolster prices and bring supply in line with demand. Temporary closings included Westralian Sands Ltd.'s North Capel and Yoganup Extended Mines (planned to restart in 1991 and 1992, respectively), and Cable Sand's dry plant operations at Bunbury were halted during the holiday season. AMC Mineral Sands ceased operations at Capel and Eneabba also during Christmas and later announced that Eneabba North would stay off-line for 12 months duration, a sizable reduction in supply because this mine produces roughly 100,000 tons of zircon per year. There were no changes planned for the 1991 commissioning of the lower cost Eneabba West deposit, which contained an estimated

920,000 tons of zircon. Similar closings were expected to be exercised by other producers in 1991.

In September, RZ Mines (Newcastle) Pty. Ltd. commissioned a new bucketwheel suction dredge that increased the throughput of its five operations in New South Wales by about 200 tons per hour. The 800-ton-per-hour dredge supplied feed to an existing wet-treatment plant at Tomago that was upgraded from its original 600-ton-per-hour constant feed rate. New total capacity of the five operations was 1,630 tons per hour.

CRA Ltd.'s subsidiary Wimmera Industrial Minerals Pty. Ltd. made significant new finds in the Murray basin in the Wimmera Region of Victoria. The WIM projects now total five and have the follow-

⁵American Metal Market. V. 97, No. 252, Dec. 30, 1989, p. 6; and v. 98, No. 251, Dec. 28, 1990, p. 6.

ing designations, grades, heavy-mineral tonnages (in millions), and reserve types, respectively: WIM 050, 3.5%, 25, inferred; WIM 100, 5.9%, 50, inferred; WIM 150, 4.0%, 30, measured; WIM 200, 7.2%, 31, indicated; and, WIM 250, 5.3%, 67, indicated. The flagship project, the WIM 150, has been estimated to contain 5 million tons of zircon. The ore minerals of these resources, composed almost entirely of fines, required innovative processing methods to make the projects viable. The company has developed novel techniques to overcome the obstacles of separating the fine sand grains from the gangue minerals and of processing the titanium minerals for use in the manufacture of pigment-grade titanium dioxide. The initiation of environmental studies was, as is usual, interpreted as a positive indication of the company's intent to proceed with the project.

Centenary International Mining, Perth, Western Australia, discovered heavy-mineral deposits rivaling those in the Perth basin, which supply an estimated 40% of the world's heavy-mineral sands. Focusing its efforts near South Balladonia in the Eucla basin, consistent zircon grades of 25% to 30% have been found in mineral suites ranging from 3.6% to 4.5% total heavy minerals. Beach and dune sands of Doubtful Island Bay yielded heavy-mineral grades as high as 38% and 3%, respectively. The former suite was indicated to contain 100,000 tons of heavy minerals, composed of 70% ilmenite and 20% zircon.

A mine with a zircon capacity of 10,000 tons per year came on-stream in April at Newrybar, New South Wales. Established by Australmin Holdings Ltd., the mine was assumed by Newmont Australia Ltd. early in the year. Mine output was separated in a 45,000-ton-per-year dry separation plant at Woodburn.

Heavy-mineral exploration licenses were issued to Broken Hill Pty. Co. Ltd. (BHP) for an area on the western boundary of a 1950's era atomic test site in the South Australian desert near Maralinga. The issue of the licenses was contingent on BHP reaching an agreement with the Maralinga Tjarutja, the aborigines to which the State returned the land (outside the test site) in 1984. The agreement permits BHP to survey sacred grounds under the inspection of the Aboriginal people.

Brazil.—The mineral sands industry in Brazil has recently expanded, and more growth is expected in the coming years. Zircon production between 1986 and 1989

doubled from 15,116 to 32,970 tons, and more growth is expected in the next few years as new projects come on-line.

Two Japanese companies entered a consortium with the State of Bahia and Multiquartz Mineraçao, based in Rio de Janeiro, to mine heavy-mineral sands near the coastal towns Valença and Itacaré. Kawatetsu Co. and Sumitomo Corp., along with the Brazilian company and the State concern, were to lease the properties for 25 years in exchange for a 3% royalty and a complete evaluation of the reserves. The deposit has been estimated to contain 3 million tons of ore, but further exploration hoped to increase this to 10 million tons.

Paranapanema subsidiary Mineraçao Taboca SA has been mining the tin mineral cassiterite at its Ptinga deposit in Amazonas since 1982, and in April of last year, began processing the zircon-bearing stockpile that had accumulated. The mining activity performed until about the middle of this year was conducted to remove the resourcebearing overburden covering the primary hardrock ore body, which also contains zircon (4 million tons estimated) as well as tin and rare-earth mineralization. Minable reserves of zircon also were in placer deposits washed away from the ore body. In processing the stockpile, the company expected to produce about 170,000 tons of concentrate in 3 or 4 years from a plant with a 3,500-ton-per-month capacity. The company also planned to begin production of zirconia at its Minebra facility in 1991, using output from the mine, at a rate of 1,300 tons per year, later increasing to 4,000 tons by 1994.

Pending approval, zircon production of 5,000 tons per year is expected to commence in 1991 on the Sapucaí river near São Gonçala in southern Minas Gerais. SA Mineração da Trindade (Samitri), an established iron ore producer, estimated that reserves in the channel and adjacent banks contained 115,000 tons of zircon as well as other heavy-mineral sands (ilmenite, 630,000 tons, and monazite, 50,000 tons). The company also was active in the exploration of seven sites on the country's northeastern and eastern coasts. Established reserves in a northeastern dune project comprised 145 million tons grading 4% heavy minerals. These included 1.7 million tons of ilmenite, 398,000 tons of zircon, 48,000 tons of monazite, and 59,000 tons of rutile.

Canada.—The Iron Ore Co. of Canada entered an agreement with Acadia Mineral

Ventures Ltd. to continue development of its unique deposit on the Quebec-Labrador border 250 km northeast of Schefferville, Quebec. High grades of zirconium oxide contained in the mineral gittinsite range between 2.99% and 3.25%. Reserves containing the former grade were put at 55 million tons and 1.5 million tons for the latter. The calcium-zirconium-silicate mineral was said to be digestible in weak sulfuric acid at low temperature (80° C) and standard pressure; zirconia of 99.5% purity could then be obtained via solvent extraction. The deposit also contained reserves of rare earths. ¹

Denmark.—Norstral Minerals A/S (incorrectly stated as Morstral by the reference cited in the 1989 chapter) continued exploration of heavy-mineral deposits, 10 to date with one-half showing some promise. The company, granted mining rights in exchange for exploring potential mineral deposits, expected to conclude exploration within 2 years and hoped to commence production within 5. Geophysical surveys were conducted using a special radar capable of penetrating to depths approaching 50 meters. The georadar was successful in detecting heavy minerals in gravel deposits, some with grades as high as 10% to 15%. One particular deposit that was drilled was found to contain lowgrade ilmenite, rutile, poor-quality zircon, and garnet. The deposit also was said to be "juvenile," meaning that it has not been reworked by the forces of nature to create a clean ore body (few organics) with clearly defined horizons of heavy minerals.2

Greenland.—The unique zirconium and yttrium mineralization (eudialyte) of the Illmaussaq Igneous Complex has been under investigation in recent years as world demand for zirconia and the rare earth has increased. (A deposit in New Mexico, U.S.A., also has been studied.) The 3million-ton ore deposit at Gardar (near Narssaq) contains four delineated ore bodies grading 2% to 3.5% zirconia on average, a grade reportedly second only to a deposit in the U.S.S.R. Pilot-plant trials were to have begun in March at Lakefield, Ontario, using 60 tons of the sulfuric acid-soluble ore. Zirconium and yttrium could then be won using liquid-liquid solvent extraction. However, past attempts to beneficiate eudialyte, predominantly a silicate mineral, have proven difficult because of the formation of a silica gel. The deposit's development, economic assessment, and pilot-plant trials were the affairs of a triventure composed of Platinova Resources Ltd., Highwood Resources Ltd., and A/S Carl Nielsen. Initial plans called for an on-site plant capable of producing 2,000 tons of zirconia per year, expanding to 4,000 tons within 5 years. Ore grinding and magnetic separation would increase the ore grade from 4% to 8% ZrO₂. Sixty tons annual production of yttrium concentrate also is expected.³

Madagascar.—The capital financing required to place and upgrade the infrastructure necessary to transport and export, respectively, the heavy minerals from QIT-Fer et Titane Inc.'s (QIT) deposit continued to hold up the advancement of this project. QIT had already agreed to pay for the construction of electrical power generating facilities, but a 100-km tarmac road from the mine to the port is needed because of the wet season, and an estimated \$100 million port upgrade is required as well. QIT reportedly was considering building the road if it were granted special concessions by the National Military Office for Strategic Industries (OMNIS). However, the port financing would have to be raised by OMNIS from an outside source, because the cost would be exorbitant for the company to bear. Annual zircon production of 24,000 tons is expected if the deposit, located near Toalagnaro, is ever developed and commissioned.

Malaysia.—The oversupply of tin on world markets nearly halved the price of this commodity and led many companies to idle their dredges, whilst others operated at a loss. This is important regarding the country's zircon production because it is a byproduct of mining cassiterite for tin. In 1990, zircon production was drastically reduced to 4,279 tons, a 77% decline from 1989's level of 18,704 tons. However, the decline in tin production was only 11%, from 32,034 tons in 1989 to 28,468 in 1990. Still, there could have been other factors that would have led to such low zircon production: lower ore grades, tin tailings stockpiled in favor of processing because of low demand and/or prices, or the fact that gravel pumping of ores showed large declines (treatment plants are predominantly associated with this method of mining as opposed to dredging).

Mozambique.—Dublin, Ireland-based Kenmare Resources PLC received word in November, 1 year after announcing the positive completion of its feasibility study,

that its expected 51% joint-venture partner for the Congolone deposit, Johannesburg Consolidated Investments (JCI) PLC, was denied the backing of the Credit Guarantee Insurance Corp. (CGIC) of the Republic of South Africa. Because CGIC already has other investments in the country and JCI's valuation of the project supported Kenmare's, the refusal was thought not to be politically related, but rather for reasons of financial diversity.4 JCI was chosen from a field of a few interested companies which now may be reconsidered. In unrelated events, Kenmare's interest in the project was increased from 71.25% to 95%, and Yugoslavia's geological survey (Gelolski Zavod), the discoverer, from 3.75% to 5%. The Mozambican Government previously held a free-carried 25% stake in the project.

Netherlands.—RZM Europe was founded by its Australian parent company to manufacture and market micronized zircon. Micronized zircon typically ranges in size from 1 to 10 microns and is about 5 to 50 times smaller than zircon flour (325 mesh or 45 microns). This form of milled zircon is used for the opacification of tile, sanitaryware, and tableware. Because of the very fine particle size, a small quantity of material covers a large area. A 7,000-ton-per-year mill was installed on the grounds of the Eggerding & Co. in Amsterdam.

South Africa, Republic of.—Richards Bay Minerals new dry mill was commissioned in October, nearly doubling zircon capacity to 300,000 tons per year. Also being added was a new facility to produce 60,000 tons of "prime-grade" zircon. Lower iron impurities will be attained by acid leaching, and titania and alumina will be reduced through additional separation techniques.

In August, the Palabora Mining Co., which produces byproduct baddeleyite (naturally occurring zirconium oxide) from its open pit copper mine in the Transvaal, began in August sinking a shaft for the purpose of conducting underground exploration. A drilling program and tunneling from the shaft are also planned. Reserves at the mine, currently about 400 meters deep, are expected to be exhausted by the year 2002 at a depth of 800 meters. The tentative date for sinking a production shaft, pending exploration findings, is 1995. Foskor Ltd. also produces baddeleyite from the Phalaborwa Complex as a byproduct of phosphate mining. Still, this deposit is the world's only current source of this invaluable mineral. A pilot plant in Brazil is planned, but production would probably remain captive even if a tentatively planned expansion to 1,000 tons per year is executed. A Russian deposit at an iron ore mine on the Kola Peninsula could possibly produce about 3,000 tons per year, harsh climate permitting, but potential domestic customers reported that although the mineral is of exceptional quality, a 30% premium over the price for South African product was not justifiable.

Foskor Ltd. completed construction of a world-class (third largest) fused zirconia plant that was designed on technology acquired from Fukushima Steel in Japan. The 3,000-ton-capacity plant, using feed from Phalaborwa (baddeleyite) or Richards Bay (zircon), is capable of producing monoclinic, stabilized, or electrofused hollow zirconia.

United Kingdom.—It was reported last year that Butte Mining PLC had purchased a zircon milling concern, Gramcol Zircon Ltd., with a mill capacity of 1,500 tons per year. The public limited corporation has now formed Zirceram Ltd. as a result of that purchase and soon is to commission a new wet mill capable of producing 2,250 tons per year of micronized zircon using a recently developed zirconia grinding media. The mill's product was reported to be capable of covering 34 square meters with just 1 gram of material.

Vietnam.—In July, the State Committee of Sciences and the Ministry of Heavy Industry approved Hong Kong-based Crusader Investments Ltd.'s proposal to conduct heavy-mineral exploration along 1,300 km of southern coastline.

Even more promising news regarding exploitation of the country's resources came to light when the Australian company W.T. Exporters Pty. Ltd. was granted a license to develop a \$16 million ilmenite and zircon sand processing and upgrading facility in the Nghe Tinh Province with a combined yearly production of about 27,000 tons. The company expected to place other such projects as it had concluded negotiations with other Provinces too.

Sixteen deposits totaling more than 1/2 million tons of zircon have now been measured, indicated, or inferred, and concentrations with ilmenite to zircon ratios as close as 3:1 have been found (ilmenite fraction typically much higher). To date, Vietnam's captive consumption has been limited to use as an opacifier in ceramic glazes.⁵

Current Research

In recent years, rare-earth-doped fluorozirconate fibers have made great inroads in optical communications as attenuation losses have been greatly reduced and fiber laser amplifiers have extended the distances between necessary repeaters. Now inroads are being laid in nontelecommunication applications, and British Telecom Research Laboratories in Martlesham Heath, United Kingdom, has issued an exclusive license to Galileo Electro-Optics in Sturbridge, MA, for such use. British Telecom has also developed a new method to mass produce cast preforms. The fibers so developed recorded losses of 0.65± 0.25 decibels per kilometer in a 110-km length, which was said to be a record. The license to Galileo involves using fluoride fibers (mole ratio hafnium-zirconium fluoride: 40% to 60%; balance: barium, lanthanum, sodium, and lead fluorides) to monitor specific manufacturing processes. This would include gasoline refining and the curing of printed circuit boards or other plastics and resinfiber composites. The molecular vibrations in these processes release energy in the form of infrared radiation, which is precisely where these fibers are the most transparent (2.59 microns). Then, by monitoring the molecular activity, manufacturers can maintain better control and awareness of the production process and its various stages.

Scientists at the Argonne National Laboratory in Illinois developed a new process that can produce ceramic fibers from any type of sinterable ceramic compound. The "universal ceramic fiber process" is similar to the continuous casting of metals and includes the following basic steps: micron-size metal oxides are mixed with a plastic binder, injected into an airstream, and then fired at the temperature necessary to sinter the compound. Fibers thus produced typically range from 1 to 10 microns in diameter. Success was reported in manufacturing what is believed to be the first magnesium oxide fibers ever. This is significant because not only does this material have a higher melting temperature than zirconia (2,800° C compared with 2,700° C), but the process is claimed to be less costly than current batch methods for producing zirconia fibers (e.g., spin melting or using natural and/or synthetic fibers as substrates which, after being impregnated or coated with zirconia, are burned away). Metal carbides, nitrides, and such could also be produced by this process if the firing were to occur in a controlled atmosphere; otherwise, carbon and nitrogen monoxides and dioxides would form. The developers have formed a new company, Sky Fibertech, Plainfield, IL, to manufacture and market ceramic fibers.

In other ceramic-related developments, Ceramatec, Inc., Salt Lake City, UT, won the "R & D 100" award for its new NZP (sodium-zirconium-phosphate) advanced ceramic, LE-1500. One of its extraordinary abilities is that it can be heated to 1,250° C and then emersed in ice water without experiencing any loss of strength, elastic modulus, or thermal expansion qualities. The thermal shock resistance and tolerance to low mechanical stresses at temperatures above 1,400° C, combined with the nearzero isotropic thermal expansion, make this material suitable in numerous applications. NZP can be manufactured or applied using a variety of standard methods.

A solution to the problems of strength and toughness degradation, which arises in ceramic monoliths and fibers when microstructural grains grow in size at elevated temperatures, may have been found. Air Force-sponsored research at Lehigh University, Bethlehem, PA, led to the development of a ceramic material, AZ50 (50% alumina and 50% cubic zirconia), that showed no change in grain size or loss of strength after 100 hours at 1,650° C. Mechanical testing showed that many of the material's property attributes were enhanced. Creep, the plastic deformation under loading at elevated temperatures, did not occur on samples tested at 1,150°C. AZ50's resistance to creep was said to be comparable, if not superior, to that of commercial alumina. Hardness tests carried out at 1,250° C indicated fourfold and 25% increases over cubic zirconia and alumina. respectively, and very little structural damage was observed around diamond indentations. The mechanism by which AZ50 is able to maintain its fine microstructure at high temperatures is described as "interpenetrating phase mixtures."6

Conversely, specially prepared zirconia of another type may one day be exploited for its high-temperature ductility. Two types of superplasticity occur in metals and ceramics: crystal phase transformation and structural. The former was demonstrated more than 20 years ago by the monoclinic-tetragonal, temperature-induced phase change in zirconia. (Transformation-toughened zirconia, TTZ, is a unique structural ceramic that volumetrically expands in dimension upon strong impact by transforming from the tetragonal to the mono-

clinic phase. This expansion arrests the propagation of fractures that would otherwise destroy the ceramic body.) Structural superplasticity, expressed by tensile elongation, was documented in Japan in 1985. Extensive and ongoing research to determine the mechanism enabling some samples to stretch up to three and one-half times their original length has found some commonality in the materials and processes at work. First, an extremely small grain size, 1 micron or less, is prerequisite. Second, although other compositions will exhibit superplastic flow, yttria-stabilized, tetragonal zirconia polycrystal (Y-TZP) has received the most attention because of its superior performance. Yttria stabilization

of 3 mole percent (3Y-TZP), with or without various other metallic oxide dopants, has been the benchmark specimen for research. Finally, it appears that structural superplasticity involves an "intergranular glassy phase that gradually transforms through a thin liquid phase." Although work to date has covered small ranges of both temperature and strain, continued investigation may expand both of these parameters and thus allow widespread use of this unique material. One application was developed where a Y-TZP bar was fabricated around a silicon carbide disk at 1,450° C to form a piston ring.⁷

The magnetic properties of cobalt-zirconium-boron alloys and their structural resemblance to rapidly solidified alloys have recently received attention. Some qualitative property analyses have found Curie temperatures of 500°C, anisotropy fields of 34 thousand Oersteds, and coercivities of 6.7 thousand Oersteds, properties that equal and, in some cases, better those of the rareearth magnets. Hafnium can substitute for zirconium and additions of silicon yield further gains in some properties. It is unfortunate that cobalt is the magnetic atom in these alloys because of its import dependence, a factor that hinders availibility and cost. Iron would be preferred. However, they further extend the list of magnetic alloys in which rare-earth atoms are unnecessary in order to yield outstanding properties. Others include cobalt-platinum, iron-platinum, and manganese-aluminum.8

Specialty Metals Processing Consortium Inc. was formed to address problems in melting and processing "high-technology" metals (viz. superalloys). Composed of metal and superalloy producers, including zirconium producer Teledyne Wah Chang Albany, and aerospace engine builders, the consortium will work with the U.S. Department of Energy and Sandia National Laboratories. Specific areas of research to be conducted at Sandia's Process Metallurgy facility included vacuum arc and electroslag remelting, plasma arc and electron beam melting, precision investment casting, and fluid flow computer modeling. The goal of the 5-year project, funded through company contributions and government subsidies, is to secure a domestic competitive advantage in hightemperature metallurgy.

Zircon has recently been used as a geologic indicator mineral in two specific instances. After conventional techniques failed to determine the age of Canadian rocks collected near the Great Slave Lake, United States geologist Dr. Samuel Bowring and his Canadian colleagues used a one-of-a-kind device developed at the Australian National University in Canberra. The Sensitive High-Mass-Resolution Ion Microprobe (SHRIMP) determined the infinitesimal amount of lead that had formed in the zircon minerals within the rocks through the radioactive decay of uranium, an element usually found in zircon only in trace quantities. The instrument, which was designed and constructed over a 7-year period, analyzed each layer of the minerals' growth (each a few thousandths of a millimeter thick) to determine the ratios of uranium and its decay product, lead. It was these ratios that indicated, by knowing

uranium's half-life, the age of the rocks at about 4 billion years.

Another exploitation of zircon came to light in a research project on diamond exploration that was sponsored by the Geologic Survey of Canada and resulted in a five-volume Open File report (No. 2124, released January 23, 1990). The international study was conducted by C. F. Mineral Research, Kelowna, British Columbia. Volume 5 of the report listed new diamondindicator minerals to complement those currently known and which may be destroyed, thus rendered useless, in certain potassium-rich lamproites, an intrusive igneous rock conducive to diamond formation. Among the new minerals that may be used to indicate a host rock favorable to the formation of diamonds was pink- to purple-colored zircon of Archean age.

Silica Products Group, Somerville, NJ, developed a new pigment, or pigment additive, which essentially is a coprecipitate of silicon and zirconium oxides, 80% and 20%, respectively. The zirconium silica hydrogel is durable against abrasion, corrosion, and weathering. These qualities were attributed to an impermeable film that resulted from chemical reactions with the organic polymers used to formulate paint. Because the gel is a recovery product of another process, it is relatively inexpensive to produce.⁹

Another pigment, produced by SCM Chemicals, Inc., Baltimore, MD, also derives some benefits with zirconia. The tita-

nium dioxide that composes no less than 92.5% of the pigment is coated with zirconia and other compounds through a proprietary precipitation process licensed from a European patent. The zirconia aids in preventing ultraviolet light from breaking the bonds of the polymers used to formulate paints. The zirconia also replaces soluble silicate coatings that have been commonly used to impart a high resistance to chalking, or weathering. And zirconia, because of its exceptional stability under ultraviolet light, has pushed titania aside in some special military uses.

Specifically, the Valspar Corp., High Point, NC, has obtained a license, also from overseas, to produce a special camouflage coating that is especially useful in arctic environments where infrared (IR) signatures are very pronounced and ultraviolet radiation is quite harsh. Ultrapure zirconia is complemented with other metal oxides to produce this IR-absorbing pigment. The white coating presently is applied only to netting.

Beginning in 1989, certain television cathode-ray tube faceplates manufactured in the United States began incorporating small quantities of zircon sand. When added to the batch glass melt, zirconium replaces lead as an electronic browning inhibitor in the faceplate and rids the processor of the environmental and health concerns regarding lead.

A new zirconia-base ceramic was introduced specifically for application to low-

temperature metals. Developed by the Kaman Sciences Corp., Colorado Springs, CO, MAC-1000 (multiattribute ceramic) is applied in slurry form and subsequently fired at about 270° C. Metal parts so treated inherit many of the qualities of zirconia ceramics: wear, corrosion, and thermal shock resistance, low thermal conductivity, and increased hardness. Also, the coating resists caustics and most acids (not hydrofluoric or boiling sulfuric) and is not wetted by molten glass.

Oxygen sensors made primarily of zirconia have long been used to monitor oxygen levels in boilers, furnaces, and combustion chambers. They are now incorporated into virtually every car manufactured in the world today in order to control fuel efficiency and emissions. The devices produce voltage proportional to the current of ionic oxygen flowing through a zirconia electrolyte sandwiched between two platinum electrodes. Now it appears that commercial devices exploiting the reversal of the same process are set for market introduction. By applying a voltage to the same apparatus, oxygen can be extracted from atmospheric molecules and conducted through the electrolyte, recovered, and stored for medical, welding, or other uses. One such unit was said to have operated continuously for 26 months and was expected to be commercialized in 1991.

A refractory-free metal-melting system was introduced by Inductotherm, Inc., Rancocas, NJ. Developed jointly with the University of Alabama in Tuscaloosa, the process, magnetic suspension melting as it is called, works on the established technology of electric induction. The improved method does not require refractory containers (e.g., crucibles) to hold the melt; the induction also provides magnetic suspension currently capable of handling 30 pounds. And because there is no contact, there is no chance for refractory contamination of the melt. Superalloy producers demand the highest quality zircon and zirconia to mitigate the effects of iron, aluminum, and titanium on their products. They typically melt superalloys in a zirconia crucible and pour the liquid metal into an investment casting made up of alternating layers of zircon grains and flour. While the new process may one day eliminate the need for zirconia crucibles, it will not obviate investment casting, or zircon products use in, as an indispensable foundry method for producing near-net-shape components.

A method developed in the eighties for casting aluminum engine blocks has pro-

vided a new foundry demand for zircon sand. The process, developed by Cosworth Castings Ltd. of Worcester, England, is a low-pressure die-casting method that uses zircon because of its low thermal conductivity and dimensional stability at high temperatures. These properties provide good crystallization and accurate castings. Moreover, no mold wash (zircon flour) is needed, and the sand is completely recyclable. Furthermore, the flour produced by the recycling process is a salable commodity. The Ford Motor Co. planned to implement this process in 1994 at a plant under construction in Windsor, Ontario.

Research begun in 1983 to investigate the effects of zirconia on dolomite (calciummagnesium oxides) refractories has, in recent years, led to increased use of bricks containing both materials. The J.E. Baker Co., York, PA, found that by adding small amounts of zirconia (less than 5%) to its dolomite bricks, which are primarily used in cement kilns, the resistance to thermal shock was significantly increased. The gains were attributed to the formation of "microcracks" in the brick's structure, not the phase transformation of zirconia. Upon formulation of the brick, a volume expansion caused by the formation of calcium zirconate creates some fractures, and then upon firing, differing degrees of thermal expansion between the constituents causes more fracturing.

Global efforts to prevent counterfeiting have extended the use of zirconia to paper currency in Canada. An optical variable device, similar to the holograms used on credit cards, in the upper lefthand corner changes color from green to gold depending on the angle of incident light. The reflective panel is composed of five alternating layers of silica and zirconia welded together by an electron beam. The \$50 and \$100 bills were introduced in December of 1989 and 1990, respectively, and a new \$20 bill is expected to be in circulation by 1993.

OUTLOOK

The demand for zircon appears to be quite steady, and even with the drastic price fluctuations of late, the market seems to be well established in all sectors. The only niches where somewhat equal performance can be realized with substitutes are in steel refractories and certain foundry uses. It is widely accepted that those who would choose to substitute have already done so, given two cycles of rising prices in the 1980's. Aside from raw-form utilization

remains the fact that zircon is the primary feed for the production of zirconium metal, chemicals, and zirconia. The latter two, because of expanding markets and new uses, should experience moderate to marked growth. And regarding stagnant demand for nuclear metal and steel refractory substitutions, growth in investment casting and new foundry uses should more than offset the weakened demand in these sectors.

Supplies of zircon have markedly risen in the past few years, and with a great deal of new mine capacity in place or planned, they can be expected to remain at or near present levels. The temporary mine closings seen in 1990 and expected in 1991 are merely short-term moves to stabilize zircon prices by matching demand more closely. Long-term market stability seems virtually unattainable, but not impossible, given all its variables and nuances (e.g., titanium mineral byproduct, and hence subject to those demands; producer competition; and, continuously shifting demand within consuming markets).
