As a work of the United States government, this material is in the public domain.

For information on re-use see: http://digital.library.wisc.edu/1711.dl/Copyright

The libraries provide public access to a wide range of material, including online exhibits, digitized collections, archival finding aids, our catalog, online articles, and a growing range of materials in many media.

When possible, we provide rights information in catalog records, finding aids, and other metadata that accompanies collections or items. However, it is always the user's obligation to evaluate copyright and rights issues in light of their own use.

Minerals Yearbook

U.S.
DEPARTMENT
OF THE
INTERIOR

BUREAU OF MINES

1990

UNITED STATES DEPARTMENT OF THE INTERIOR • Manuel Lujan, Jr., Secretary BUREAU OF MINES • T S Ary, Director

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

U.S. GOVERNMENT PRINTING OFFICE

WASHINGTON: 1993

Foreword

This edition of the Minerals Yearbook discusses the performance of the worldwide minerals industry during 1990 and provides background information to assist in interpreting that performance. Content of the individual Yearbook volumes follows:

Volume I, Metals and Minerals, contains chapters on virtually all metallic and industrial mineral commodities important to the U.S. economy. A chapter on organic materials also has been added to the Minerals Yearbook series beginning with the 1990 volume. In addition, a chapter on survey methods used in data collection with a statistical summary of nonfuel minerals and a chapter on trends in mining and quarrying in the metals and industrial mineral industries are included.

Volume II, Area Reports: Domestic, contains chapters on the minerals industry of each of the 50 States, Puerto Rico, Northern Marianas, Island Possessions, and Trust Territory. This volume also has a chapter on survey methods used in data collection including a statistical summary of domestic nonfuel minerals.

Volume III, Area Reports: International, contains the latest available mineral data on more than 150 foreign countries and discusses the importance of minerals to the economies of these nations. Beginning with the 1989 review, Volume III is presented as six reports: Mineral Industries of the Middle East, Mineral Industries of Africa, Mineral Industries of Asia and the Pacific, Mineral Industries of Latin America and Canada, Mineral Industries of Europe and the U.S.S.R., and Minerals in the World Economy. This year's reports incorporate location maps, industry structure tables, and an outlook section previously incorporated in our Minerals Perspectives Series quinquennial regional books, which are being discontinued.

The U.S. Bureau of Mines continually strives to improve the value of its publications to users. Therefore, constructive comments and suggestions by readers of the Yearbook will be welcomed.

T S Ary, Director

Acknowledgments

Volume I, Metals and Minerals, of the Minerals Yearbook, presents data on about 90 mineral commodities that were obtained as a result of the mineral information gathering activities of the U.S. Bureau of Mines.

The collection, compilation, and analysis of domestic minerals industries data were performed by the staffs of the Division of Mineral Commodities and the Division of Statistics and Information Services. Statistical data were compiled from information supplied by mineral producers and consumers in response to canvasses, and their voluntary response is gratefully appreciated. Information obtained from individual firms by means of the U.S. Bureau of Mines canvasses has been grouped to provide statistical aggregates. Data on individual firms are presented only if available from published or other nonproprietary sources or when permission of the respondent has been granted.

The chapter "Survey Methods and Statistical Summary of Nonfuel Minerals" discusses in somewhat greater detail procedures for canvassing the minerals industry and the processing and evaluation of these data.

Other material appearing in the volume was obtained from the trade and technical press, industry contacts, and other sources; this cooperation is gratefully acknowledged.

Statistics on world production were compiled in the Branch of Geographic Data, Division of International Minerals, from numerous sources including reports from the U.S. Department of State. U.S. foreign trade data were obtained from reports of the Bureau of the Census, U.S. Department of Commerce. Data on production costs for several commodities were supplied by the Bureau of Mines, Minerals Availability System.

The U.S. Bureau of Mines has been assisted in collecting mine production data and other supporting information by numerous cooperating State agencies. These organizations are listed in the acknowledgments of Volume II.

Donald G. Rogich, Chief, Division of Mineral Commodities

SURVEY METHODS AND STATISTICAL SUMMARY OF NONFUEL MINERALS

By Jacqueline A. McClaskey and Stephen D. Smith

Ms. McClaskey, an Operations Research Analyst with 5 years of Government experience, has been with the U.S. Bureau of Mines Branch of Statistics and Methods Development since 1990.

Mr. Smith, Mineral Data Assistant in the Branch of Data Collection and Coordination, was assisted in the preparation of the Statistical Summary by Sarah P. Guerrino, Chief, Section of Ferrous Metals Data; Imogene P. Bynum, Chief, Section of Nonferrous Metals Data; Barbara E. Gunn, Chief, Section of Industrial Minerals Data; and William L. Zajac, Chief, Section of International Data.

SURVEY METHODS

The U.S. Bureau of Mines Information and Analysis Directorate collects world-wide data on virtually every commercially important nonfuel mineral commodity. These data form the base for tracking and assessing the health of the minerals sector of the U.S. economy.

The Bureau's data collection activity was instituted by the 47th Congress in an appropriations act of August 7, 1882 (22 Stat. 329), which placed the collection of mineral statistics on an annual basis. The most recent authority for the U.S. Bureau of Mines survey activity is the National Materials and Minerals Policy, Research and Development Act of 1980 (Public Law 96-479, 96th Congress). This act strengthens protection for proprietary data provided to the U.S. Department of the Interior by persons or firms engaged in any phase of mineral or mineral-material production or consumption.

Data Collection Surveys

The Bureau begins the collection of domestic nonfuel minerals and materials statistics by appraising the information requirements of Government and private organizations of the United States. Information needs that can be satisfied by data from the minerals industries are expressed as questions on U.S. Bureau of Mines survey forms. Figure 1 shows a typical survey form.

Specific questions about the production, consumption, shipments, etc., of mineral commodities are structured in the survey

forms to provide meaningful aggregated data. Thus, the entire mineral economic cycle from production through consumption is covered by 169 monthly, quarterly, semiannual, annual, and biennial surveys. After the survey form has been designed, a list of the appropriate establishments to be canvassed is developed. Many sources are used to determine which companies, mines, plants, and other operations should be included on the survey mailing list. U.S. Bureau of Mines State Mineral Officers, State geologists, Federal organizations (e.g., Mine Safety and Health Administration), trade associations, industry representatives, and trade publications and directories are some of the sources that are used to develop and update survey listings. With few exceptions, a complete canvass of the list of establishments is employed rather than a sample survey. The iron and steel scrap industry is one of the exceptions where a sample survey is conducted.

The Paperwork Reduction Act requires that any Government agency wishing to collect information from 10 or more people first obtain approval from the Office of Management and Budget (OMB). OMB approves the need to collect the data and protects industry from unwarranted Government paperwork.

Survey Processing

Approximately 26,000 establishments yield more than 50,000 responses to 169 surveys annually. Each completed survey form returned to the Bureau undergoes extensive scrutiny to ensure the highest possible accuracy of the mineral data. The

statistical staff monitors all surveys to ensure that errors are not created by reporting in physical units different from the units requested on the form. Relationships between related measures, such as produced crude ore and marketable crude ore, are analyzed for consistency. Engineering relationships, such as recovery factors from ores and concentrates, are also employed. The totals for each form are verified, and currently reported data are checked against prior reports to detect possible errors or omissions.

For the majority of the surveys, which are automated, the forms are reviewed to ensure that data are complete and correct before entering into the computer. The computer is programmed to conduct a series of automated checks to verify mathematical consistency and to identify discrepancies between the data reported and logically acceptable responses.

The U.S. Bureau of Mines is modernizing and automating all of its survey processing and data dissemination functions. Automated commodity data system functions include computerized preparation of statistical tables; the use of desktop publishing to integrate text and tables; and the implementation of a microcomputer bulletin board, known as MINES-DATA, for electronic dissemination of minerals data.

Survey Responses.—To enable the reader to better understand the basis on which the statistics are calculated, each commodity annual report includes a section entitled "Domestic Data Coverage." This section briefly describes the data sources, the number of establishments surveyed, the response

percentage, and the method of estimating the production or consumption for nonrespondents.

To produce reliable aggregated data, the Bureau employs efficient procedures for handling instances of nonresponse. Failure to return the initial survey form results in a second mailing of the form. If the second form is not returned, telephone calls are made to the nonrespondents. The followup calls provide the necessary data to complete the survey forms and/or verify questionable data entries. Periodic visits to important minerals establishments are also made by Bureau commodity specialists or State Mineral Officers to gather missing data and to explain the importance of the establishment's reporting. By describing the use of the published statistics and showing the impact of nonresponse, the Bureau hopes to encourage respondents to give a complete and accurate reply.

The OMB "Guidelines for Reducing Reporting Burden" stipulates that the minimum acceptable response rate shall be 75% of the panel surveyed. In addition, the Bureau strives for a minimum reporting level of 75% of the quantity produced or consumed (depending on the survey) for certain key statistics. Response rates are periodically reviewed. For those surveys not meeting the minimum reporting level, procedures are developed and implemented to improve response rates.

Estimation for Nonresponse.—When efforts to obtain a response to a survey fail. it becomes necessary to employ estimation or imputation techniques to account for missing data. These techniques are most effective when the response rate is relatively high. Some of the estimation methods depend on knowledge of prior establishment reporting, while other techniques rely on external information to estimate the missing data. When survey forms are received after the current publication has been completed, the forms are edited, necessary imputations are made for missing data, and the survey data base is updated. The revised data are reported in later publications.

Protection of Proprietary Data.—The U.S. Bureau of Mines relies on the cooperation of the U.S. minerals industry to provide the mineral data that are presented in this and other Bureau publications. Without a strong response to survey requests, the Bureau would not be able to present reliable statistics. The Bureau in turn respects the proprietary nature of the data

received from the individual companies and establishments. To ensure that proprietary rights will not be violated, the Bureau analyzes each of the aggregated statistics to determine if the data reported by an individual establishment can be deduced from the aggregated statistics. If, for example, there are only two significant producers of a commodity in a given State, the Bureau will not publish that total because either producer could readily estimate the production of the other. It is this obligation to protect proprietary information that results in the "Withheld" or "W" entries in the published tables. However, if a company gives permission in writing, the Bureau will publish the data as long as the data from other producers are protected from disclo-

International Data

International data are collected by country specialists in the U.S. Bureau of Mines Division of International Minerals with assistance from the Section of International Data. The data are gathered from various sources, including published reports of foreign Government mineral and statistical agencies, international organizations, the U.S. Department of State, the United Nations, the Organization of Petroleum Exporting Countries, and personal contact by specialists traveling abroad. Each February an annual "Minerals Questionnaire" is sent through the Department of State to more than 130 U.S. Embassies asking them to provide estimates of mineral production for the host country for the preceding year. Missing data are estimated by Bureau country specialists based on historical trends and specialists' knowledge of current production capabilities in each country.

Publications

The U.S. Bureau of Mines disseminates current and historical minerals information through a broad range of printed publications.

The Minerals Yearbook summarizes annually, on a calendar-year basis, the significant economic and technical developments in the mineral industries. Three separate volumes are issued each year: Volume I, Metals and Minerals; Volume II, Area Reports, Domestic; and Volume III, International Review. Chapters in these volumes are issued separately as annual reports before the bound volumes are available. (Volume III country reports appear in bound volume only.)

Volume I of the Minerals Yearbook presents, by mineral commodity, salient statistics on production, trade, consumption, reserves, and other measures of economic activity.

Volume II of the Minerals Yearbook reviews the U.S. minerals industry by State and island possessions.

Volume III of the Minerals Yearbook presents the latest available mineral statistics for more than 160 countries with a summary review of the role of minerals in the world economy.

Mineral Industry Surveys contain timely statistical and economic data on minerals. The surveys are designed to keep Government agencies and the public, particularly the mineral industry and the business community, informed of trends in the production, distribution, inventories, and consumption of minerals. Frequency of issue depends on the demand for current data. Mineral Industry Surveys are released monthly, quarterly, semiannually, or annually.

Mineral Commodity Summaries, up-todate summaries of about 90 nonfuel mineral commodities, is the earliest Government publication to furnish estimates covering the previous year's nonfuel mineral industry data. It contains information on the domestic industry structure, Government programs, tariffs, 5-year salient statistics, and a summary of international mining news.

State Mineral Summaries provides estimated data and summaries of mineral activities at the State level for the previous year. These summaries have been prepared in cooperation with State geological surveys or related agencies.

Minerals Today, published bimonthly, provides readers with the latest information about developments, trends, and issues concerning the mining, processing, and use of minerals and materials.

Metal Industry Indicators, which began monthly publishing on a trial basis in 1991, contains an index that measures the current and future short-term performance of four U.S. minerals industries. For each of the four industries, a composite coincident index and a composite leading index have been developed based on procedures and data similar to those used to construct the U.S. Department of Commerce's coincident and leading cyclical indicators for the national economy.

Information Circulars are primarily concerned with Bureau economic reviews and interpretative analyses. The series also includes surveys of mining and operating activities, guides to marketing of mineral commodities, and compilations of historical information and statistical and economic data on minerals.

To purchase Volumes I, II, and III of the Minerals Yearbook and Minerals Today, contact the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402. For free copies of individual annual reports of the Minerals Yearbook, the Mineral Industry Surveys. the Mineral Commodity Summaries, the State Mineral Summaries, and Information Circulars, contact Publications Distribution, U.S. Bureau of Mines, Cochrans Mill Road, P.O. Box 18070, Pittsburgh, PA 15236. To receive a copy of the Metal Industry Indicators, contact the Branch of Statistics and Methods Development, U.S. Bureau of Mines, MS 9701, 810 7th Street, NW, Washington, DC 20241.

Electronic Data Dissemination

In addition to the Bureau's printed publications, current Mineral Industry Surveys for several commodities and selected annual reports from the Minerals Yearbook are now available through the Bureau's

MINES-DATA computer bulletin board. Using this system, the public may obtain information up to 4 weeks before published copies of the reports would arrive in the mail. The MINES-DATA system may be accessed by calling (202) 501-9825 using a modem set to 1200 or 2400 baud, 8 data bits, no parity, and 1 stop bit. Further information on how to use the MINES-DATA system may be obtained from the system operator by calling (202) 501-9554.

STATISTICAL SUMMARY

This annual report summarizes data on crude nonfuel mineral production for the United States, its island possessions, and the Commonwealth of Puerto Rico. Also included are tables that show the principal nonfuel mineral commodities exported from and imported into the United States and that compare world and U.S. mineral production. The detailed data from which these tables were derived are contained in the individual annual reports of Volume I and in the State reports of Volume II of this edition of the Minerals Yearbook.

Although crude mineral production may be measured at any of several stages of extraction and processing, the stage of measurement used in this annual report is what is termed "mine output." It usually refers to minerals or ores in the form in which they are first extracted from the ground, but customarily includes the output from auxiliary processing at or near the mines.

Because of inadequacies in the statistics available, some series deviate from the foregoing definition. For copper, gold, lead, silver, tin, and zinc, the quantities are recorded on a mine basis (as the recoverable content of ore sold or treated). However, the values assigned to these quantities are based on the average selling price of refined metal, not the mine value. Mercury is measured as recovered metal and valued at the average New York price for the metal.

The weight or volume units shown are those customarily used in the particular industries producing the commodities. Values shown are in current dollars, with no adjustments made to compensate for changes in the purchasing power of the dollar.

TABLE 2

NONFUEL MINERALS PRODUCED IN THE UNITED STATES AND PRINCIPAL PRODUCING STATES IN 1990

Mineral	Principal producing States, in order of quantity	Other producing States
Abrasives ¹	AR, WI, OH	
Antimony (content of ores, etc.)	ID	
Aplite	VA	
Asbestos	CA and VT	
Barite	GA, NV, MO, CA	IL and MT.
Bauxite	AR and AL	
Beryllium concentrate	UT	
Boron minerals	CA	
Bromine ^e	AR	
Brucite	NV	
Calcium chloride (natural)	MI and CA	
Cement:		
Masonry	IN, FL, MI, PA	All other States except AK, CT, DE, LA, MA, MN, NV, NH, NJ, NC, ND, RI, VT, WI.
Portland	CA, TX, PA, MI	All other States except CT, DE, LA, MA, MN, NH, NJ, NC, ND, RI, VT, WI.
Clays	GA, CA, WY, SC	All other States except AK, DE, HI, RI, VT, WI.
Copper (content of ores, etc.)	AZ, NM, UT, MT	CA, CO, ID, IL, MI, MO, NV, TN.
Diatomite	CA, NV, WA, OR	AZ.
Emery	OR	
Feldspar	NC, CA, CT, GA	ID, OK, SD.
Fluorspar	IL, UT, NV	
Garnet (abrasive)	ID and NY	
Gold (content of ores, etc.)	NV, CA, UT, SD	AK, AZ, CO, ID, MT, NM, OR, SC, WA.
Graphite (natural)	MT	

¹Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

²Recoverable content of ores, etc.

³Content of ore and concentrate.

⁴Revised due to the separation of palladium metal from platinum metal.

⁵Data may not add to totals shown because of independent rounding.

⁶Grindstones, pulpstones, and sharpening stones; excludes mill liners and grinding pebbles.

 $^{^{7}}$ Beginning with 1989 data reported in $\mathrm{B_2O_3}$, 1988 data converted.

⁸Excludes abrasive stone and bituminous limestone and sandstone; all included elsewhere in table.

TABLE 2—Continued

NONFUEL MINERALS PRODUCED IN THE UNITED STATES AND PRINCIPAL PRODUCING STATES IN 1990

Mineral	Principal producing States, in order of quantity	Other producing States
Gypsum (crude)	IA, MI, OK, NV	AR, AZ, CA, CO, IN, KS, LA, NM, NY, OH, SD,TX, UT, VA, WA, WY.
Helium	KS, WY, TX, NM	CO.
Iodine	OK	
Iron ore (includes byproduct)	MN, MI, MO, UT	CA, MT, NM, SD, TX.
Iron oxide pigments (crude)	GO, MO, VA, MI	AZ.
Kyanite	VA	
Lead (content of ores, etc.)	MO, AK, ID, CO	IL, KY, MT, NM, NV, NY, TN.
Lime	MO, OH, PA, KY	All other States except AK, CT, DE, FL, GA, HI, KS, ME, MD, MS, NH, NJ, NM, NY, NC, RI, SC, VT.
Lithium minerals	NC and NV	
Magnesite	NV.	
Magnesium compounds	MI, CA, FL, DE	UT and TX.
Magnesium metal	TX, UT, WA	
Manganiferous ore	SC	
Marl (greensand)	NJ	
Mercury	NV, UT, CA	
Mica (scrap)	NC, GA, NM, SC	CT, PA, SD.
Molybdenum	CO, AZ, ID, MT	CA, NM, NV, UT.
Nickel	OR	
Olivine	NC and WA	
Palladium metal	MT	
Peat	MI, FL, MN, IL	CO, GA, IA, IN, MA, MD, ME, MT, NC, ND, NJ, NY, OH, PA, SC, WA, WI, WV.
Perlite	NM, AZ, CA, ID	CO and NV.
Phosphate rock	FL, NC, ID, TN	MT and UT.
Platinum metal	MT	
Potash	NM, UT, CA, MI	
Pumice	CA, OR, AZ, NM	HI, ID, KS.
Pyrites (ore and concentrate)	AZ	
Rare-earth metal concentrates	CA and FL	
Salt	NY, OH, LA, MI	AL, AZ, CA, KS, NM, NV, OK, TX, UT, WV.
Sand and gravel:		
Construction	CA, OH, TX, MI	All other States.
Industrial	IL, CA, TX, NJ	All other States except AK, DE, HI, IA, ME, NH, NM, ND, OR, SD, VT, WY.
Silver (content of ores, etc.)	NV, ID, AK, MT	AZ, CA, CO, IL, KY, MI, MO, NM, NY, OR, SC, SD, TN, UT, WA.
Sodium compounds:		
Soda ash	WY and CA	
Sodium sulfate (natural)	CA, TX, UT	
Staurolite	FL	
Stone:		
Crushed	PA, VA, FL, GA	All other States except DE.
Dimension	IN, VT, MN, SD	All other States except AL, AR, AZ, CA, CO, CT, GA, IA, ID, IL, IN, KS, MA, MD, ME, MI, MO, MT, NC, NH, NM, NY, OH, OK, PA, SC, TN, TX, VA, WA, WI.
Sulfur (Frasch)	TX and LA	
Talc and pyrophyllite	MT, TX, NC, VT	AL, AR, CA, GA, NY, OR, VA.
Tin	AK	
Titanium concentrates	FL and CA	

See footnotes at end of table.

TABLE 2—Continued

NONFUEL MINERALS PRODUCED IN THE UNITED STATES AND PRINCIPAL PRODUCING STATES IN 1990

Mineral Principal producing States, in order of quantity		Other producing States
Tripoli	IL, AR, OK, PA	
Tungsten (content of ores, etc.)	CA	
Vanadium (content of ores, etc.)	CO, ID, AR, UT	
Vermiculite (crude)	SC, MT, VA	
Wollastonite	NY	
Zinc (content of ores, etc.)	AK, TN, NY, MO	CO, ID, IL, KY, MT, NM, NV.
Zircon concentrates	FL and NJ	

^eEstimated.

TABLE 3

VALUE OF NONFUEL MINERAL PRODUCTION IN THE UNITED STATES AND PRINCIPAL NONFUEL MINERALS PRODUCED IN 1990

State	Value (thousands)	Rank	Percent of U.S. total	Principal minerals, in order of value
Alabama	\$560,639	21	1.68	Stone (crushed and broken), cement (portland), lime, sand and gravel.
Arkansas	302,640	33	.91	Bromine, stone (crushed and broken), sand and gravel (industrial), cement (portland).
California	2,779,799	2	8.34	Sand and gravel (construction), cement (portland), boron, gold.
Colorado	386,192	27	1.16	Molybdenum, sand and gravel (construction), cement (portland), stone (crushed and broken).
Connecticut	117,893	41	.35	Stone (crushed and broken), sand and gravel (construction), feldspar, sand and gravel (industrial).
Delaware ¹	6,968	50	.02	Sand and gravel (construction), and gem stones.
Florida	1,564,204	4	4.69	Phosphate rock, stone (crushed and broken), cement (portland), sand and gravel (construction).
Georgia	1,495,124	5	4.49	Clays, stone (crushed and broken), cement (portland), sand and gravel (construction).
Hawaii ¹	106,095	43	32	Stone (crushed and broken), cement (portland), sand and gravel (construction), cement (masonry).
Idaho	399,761	26	1.20	Phosphate rock, silver, molybdenum, zinc.
Illinois	665,134	16	2.00	Stone (crushed and broken), cement (portland), sand and gravel (construction), sand and gravel (industrial).
Indiana	431,766	25	1.30	Stone (crushed and broken), cement (portland), sand and gravel (construction), stone (dimension).
Iowa	316,370	32	.95	Cement (portland), stone (crushed and broken), sand and gravel (construction), gypsum (crude).
Kansas	346,119	31	1.04	Salt, stone (crushed and broken), cement (portland), helium (Grade-A).
Kentucky	358,864	30	1.08	Stone (crushed and broken), lime, cement (portland), sand and gravel (construction).
Louisiana	367,918	29	1.10	Sulfur (Frasch), salt, sand and gravel (construction), stone (crushed and broken).
Maine	62,544	46	19	Sand and gravel (construction), cement (portland), stone (crushed and broken), stone (dimension).
Maryland	368,614	28	1.11	Stone (crushed and broken), sand and gravel (construction), cement (portland), cement (masonry).
Massachusetts	127,498	40	.38	Stone (crushed and broken), sand and gravel (construction), stone (dimension), lime.
Michigan	1,438,123	8	4.32	Iron ore (usable), cement (portland), sand and gravel (construction), stone (crushed and broken).

 $^{^{\}rm I}\textsc{Grindstones}$, pulpstones, and sharpening stones; excludes mill liners and grinding pebbles.

TABLE 3—Continued

VALUE OF NONFUEL MINERAL PRODUCTION IN THE UNITED STATES AND PRINCIPAL NONFUEL **MINERALS PRODUCED IN 1990**

State	Value (thousands)	Rank	Percent of U.S. total	Principal minerals, in order of value
Minnesota	\$1,469,922	6	4.41	Iron ore (usable), sand and gravel (construction), stone (crushed and broken), stone (dimension).
Mississippi	112,313	42	.34	Sand and gravel (construction), clays, cement (portland), stone (crushed and broken).
Missouri	1,093,618	11	3.28	Lead, stone (crushed and broken), cement (portland), lime.
Montana	567,684	19	1.70	Gold, copper, molybdenum, silver.
Nebraska	90,329	44	.27	Cement (portland), sand and gravel (construction), stone (crushed and broken), clays.
Nevada	2,610,876	3	7.84	Gold, silver, sand and gravel (construction), cement (portland
New Hampshire	35,166	47	.11	Sand and gravel (construction), stone (dimension), stone (crushed and broken), gem stones.
New Jersey	229,470	37	.69	Stone (crushed and broken), sand and gravel (construction), sand and gravel (industrial), zircon concentrates.
New Mexico	1,097,550	10	3.29	Copper, potash, sand and gravel (construction), molybdenum.
New York	772,839	14	2.32	Stone (crushed and broken), salt, cement (portland), sand and gravel (construction).
North Carolina	564,591	20	1.69	Stone (crushed and broken), phosphate rock, lithium minerals, sand and gravel (construction).
North Dakota	26,568	48	.08	Sand and gravel (construction), lime, stone (crushed and broken), clays.
Ohio	728,840	15	2.19	Stone (crushed and broken), sand and gravel (construction), salt, lime.
Oklahoma	260,177	35	.78	Stone (crushed and broken), cement (portland), iodine (crude), sand and gravel (construction).
Oregon	237,406	36	.71	Stone (crushed and broken), sand and gravel (construction), cement (portland), nickel.
Pennsylvania	1,030,042	12	3.09	Stone (crushed and broken), cement (portland), sand and gravel (construction), lime.
Rhode Island ¹	17,844	49	.05	Sand and gravel (construction), stone (crushed and broken), gem stones.
South Carolina	449,853	24	1.35	Stone (crushed and broken), cement (portland), gold, clays.
South Dakota	298,452	34	.90	Gold, cement (portland), sand and gravel (construction), stone (crushed and broken).
Tennessee	662,560	17	1.99	Stone (crushed and broken), zinc, cement (portland), gem stones.
Texas	1,457,225	7	4.37	Cement (portland), stone (crushed and broken), magnesium metal, sulfur (Frasch).
Jtah	1,334,010	9	4.00	Copper, gold, magnesium metal, cement (portland).
Vermont	81,954	45	.25	Stone (crushed and broken), stone (dimension), sand and gravel (construction), talc and pyrophyllite.
Virginia	507,275	22	1.52	Stone (crushed and broken), sand and gravel (construction), cement (portland), lime.
Vashington	473,229	23	1.42	Sand and gravel (construction), gold, magnesium metal, cement (portland).
Vest Virginia	136,338	39	.41	Stone (crushed and broken), cement (portland), sand and gravel (construction), salt.
Visconsin	212,047	38	.64	Stone (crushed and broken), sand and gravel (construction), lime, sand and grave (industrial).
Vyoming	910,848	13	2.73	Soda ash, clays, helium (Grade-A), sand and gravel (construction).

Total ²		XX	167,057	XX	163,677	XX	126,335	

Estimated. NA Not available. W Withheld to avoid disclosing company proprietary data; not included in "Total." XX Not applicable.

¹Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

²Excludes certain clays; kind and value included with "Combined value" figure.

³Excludes certain stones; kind and value included with "Combined value" figure.

⁴Recoverable content of ores, etc.

⁵Grindstones, pulpstones, and sharpening stones; excludes mill liners and grinding pebbles.

⁶Beginning with 1989 data reported in B₂O₃, 1988 data converted.

⁷Less than 1/2 unit.

Partial total, excludes values that must be concealed to avoid disclosing company proprietary data. Values excluded from partial total included with "Undistributed States."

⁹Value excluded to avoid disclosing company proprietary data.

¹⁰Excludes salt in brines; value included with "Combined value" figure.

¹¹Palladium metal separated from platinum-group metals in 1990. 1988-89 data revised.

¹²Platinum metal separated from platinum-group metals in 1990. 1988-89 data revised.

¹³Excludes traprock.

¹Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

¹Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

²Total does not include value of item withheld.

TABLE 8
U.S. EXPORTS OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS

Minaral		1989 ^r	1990		
Mineral	Quantity	Value (thousands)	Quantity	Value (thousand	
METALS				(urousand.	
Aluminum:					
Aluminum sulfate metric tons	941	\$1,208	6,807	#1.20	
Castings and forgings do.	20,482	128,974	•	\$1,29	
Metals and alloys, crude do.	593,103	1,260,475	7,003	67,98

Mineral	Quantity	Value (thousands)	Quantity	Value (thousands
INDUSTRIAL MINERALS—Continued				
Helium (Grade-A) million cubic feet	796	\$33,830	892	\$33,450
Iron oxide pigments:				
Pigment grade metric tons	9,966	15,700	9,510	18,533
Other grade do.	34,631	54,567	198,631	110,73
Lime short tons	32,241	3,893	44,287	4,75
Lithium compounds:				
Lithium carbonate kilograms	9,045,732	28,214	9,312,903	30,16
Lithium hydroxide do.	4,691,991	17,914	3,147,248	12,95
Lithium metal do.	141,225	NA	111,737	N/
Magnesium compounds:				
Calcined dolomite metric tons	39,639	10,683	10,379	2,213
Caustic-calcined magnesia do.	4,375	2,263	2,313	1,400
Compounds, includes magnesium hydroxide, magnesium				
peroxide, magnesium chloride, and magnesium	14054	C 100	1	
sulfate metric tons	14,851	6,100	14,162	14,165
Dead-burned and fused magnesia do.	22,525	10,685	58,610	19,709
Magnesite, natural do.	10,380	8,299	8,009	8,060
Other magnesia do.	15,843	9,213	37,747	16,108
Mica:	4.00			
Crude and rifted do.	1,082	476	572	427
Powder do.	1,230	1,634	4,319	2,050
Waste do.	202	235	156	491
Worked do.	415	7,227	612	7,567
Nitrogen compounds (major):				
Fertilizer materials thousand short tons	13,569	NA	13,032	NA
Industrial chemicals do.	192	150,813	89	126,658
Phosphate rock (ground and unground) thousand metric tons	8,323	288,990	6,959	254,104
Phosphatic fertilizers:	0,323	200,770	0,939	254,10-
Diammonium and monoammonium phosphates				
thousand metric tons	9,102	1,608,264	8,493	1,414,219
Elemental phosphorus metric tons	19,934	28,294	17,916	29,620
Phosphoric acid thousand metric tons	703	124,074	555	95,881
Superphosphates do.	534	151,861	747	100,630
Potash:		,		,,,,,,
Potassium chloride metric tons	496,575	NA	445,810	NA
Potassium sulfate, all grades do.	448,880	NA	561,914	NA
Quartz crystal:	,		,	
Cultured thousand kilograms	57	2,600	39	1,745
Natural do.	NA NA	NA	NA	NA
Salt, crude and refined thousand short tons	1,567	20,211	2,498	32,944
Sand and gravel:	1,507	20,211	2,470	32,7 (
Construction:				
Gravel do.	852	7,703	NA	NA
Sand do.	273	5,888	468	11,880
Industrial sand and gravel do.	2,060	78,308	1,155	83,826
Sodium compounds:	0.640	265 460	2.202	246 600
Soda ash thousand metric tons	2,648	365,469	2,392	346,693

U.S. IMPORTS FOR CONSUMPTION OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS

	1	989 ^r	199	90
Mineral	Quantity	Value (thousands)	Quantity	Value (thousands
METALS				
Aluminum:				
Aluminum oxide (alumina) thousand metric tons	4,311	\$1,228,123	4,070	\$1,268,973
Metals and alloys, crude metric tons	923,030	1,898,132	959,615	1,596,886
Plates, sheets, bars, etc. do.	340,382	950,902	340,334	340,334
Scrap do.	206,610	309,122	214,196	259,674
Antimony:				
Antimony metal do.	10,621	21,143	13,940	23,380
Antimony oxides do.	12,041	19,770	14,472	19,574
Ore and concentrate (antimony content) do.	4,550	8,462	3,454	4,835
Arsenic:				
Acid do.	 48	67	21	31
Arsenic trioxide do.	28,348	13,526	26,256	12,570
Metallic do.	928	2,150	796	4,091
Sulfides do.		19		_
Bauxite:	_			
Calcined thousand metric tons	531	34,677	558	35,564
Crude and dried do.	10,893	NA	12,142	NA
Beryllium ore metric tons	601	655	342	418
Bismuth, metals and alloys (gross weight) kilograms	1,880,321	21,586	1,611,862	11,747
Cadmium metal metric tons	2,787	30,161	1,741	11,904
Chromium (gross weight):	_			
Chemicals do.	12,895	23,677	10,130	24,136
Chromite ore and concentrate do.	525,044	43,949	305,507	22,150
Metals and alloys:				
Chromium ferroalloys do.	343,732	330,427	415,893	246,439
Chromium metal do.	4,202	27,590	6,664	43,161
Pigments and preparation based chromiuum do.	- 5,963	13,355	5,652	13,708

Either quantity or value data are incorrect. The U.S. Bureau of Mines and Bureau of the Census were unable to verify the correct data at time of publication.

²Artificial graphite includes a large amounts of materials made from petroleum coke.

³Data may not add to totals shown because of independent rounding.

^eEstimated. ^pPreliminary. NA Not available. W Withheld to avoid disclosing company proprietary data; not included in world total.

For those commodities for which U.S. data are withheld to avoid disclosing company proprietary data, the world total excludes U.S. output and the U.S. percent of world production cannot be reported.

²Content of ore and concentrate.

³World total does not include an estimate for China.

⁴U.S. figures represent dried bauxite equivalent of crude ore; to the extent possible, individual country figures that are included in the world total are also on the dried bauxite equivalent basis, but for some countries available data are insufficient to permit this adjustment.

⁵Shipments.

⁶Less than 1/2 unit.

⁷Primary and secondary blister and anode copper, including electrowon refined copper that is not included as blister or anode.

⁸Includes bullion

⁹Refined nickel plus nickel content of ferronickel, nickel oxide, and other nickel salts.

¹⁰World total does not include estimates for output in the U.S.S.R. or China.

¹¹Includes tin content of alloys made directly from ore.

¹²Quantity sold or used by producers.

¹³Includes Puerto Rico.

MINING AND QUARRYING TRENDS IN THE METALS AND INDUSTRIAL MINERALS INDUSTRIES

By R. Lindsay Mundell and Steven J. Schatzel

Mr. Mundell is a mining engineer who has been with the U.S. Bureau of Mines, Denver Research Center, for 9 years, and Mr. Schatzel is a geologist who has been with the U.S. Bureau of Mines, Pittsburgh Research Center, for 13 years. Domestic survey data were prepared by Stephen D. Smith, statistical assistant.

MINING HIGHLIGHTS

In the first half of 1990, lessening of cold war tensions was welcome. But Iraq's invasion of Kuwait in August led to the Persian Gulf War in January and February 1991. The subsequent oil shock contributed to a dampening of the U.S. economy, and the U.S. gross national product rose only 0.9% to \$5,463 billion (U.S. billion = 10°).

The buildup of military forces in the Persian Gulf area focused greater attention not only on petroleum but also on other strategic materials. The U.S. Department of Defense continued to review stockpile goals and upgrade several mineral materials. In addition, the U.S. Bureau of Mines continued to maintain the standby Emergency Minerals Administration. After the Defense Production Act, which authorizes priorities, allocations, and supply expansion, lapsed on October 20, 1990, the Selective Service Act of 1967 became the authority to ensure that orders of the Armed Forces and defense atomic energy programs were given priority treatment.

Imports of crude and refined petroleum, costing \$61 billion, increased 2% to 3 billion barrels (bbl). Domestic petroleum production fell 2% to 3.6 billion bbl. In February 1991, a National Energy Strategy was announced to encourage domestic production of fossil fuels and nuclear and renewable energy and to stimulate efficiencies in use. Petroleum supplied about 40% of U.S. energy, and natural gas and coal each supplied about 22%.

Although most nongold metal mining and beneficiation production finished below that of 1988-89, almost all production was at levels well ahead of a few years ago. This fact, together with the reduced lure of gold, might be expected to increase the funds available for exploration and

development in the ferrous and base metals sectors.

By January 1991, a general consensus was reached among traders and analysts that base metals prices will weaken through 1991 because of economic recession. In January, the price of copper, so often a general indicator, was at a 29-month low and silver was at a 15-year low.²

Experts speculate that over the next few years the international mining industry will be dominated by three issues: increasingly widespread environmental concerns; a change in the balance of activity between precious-metals and base-metals operations; and the impact of newly generated base metal demand from Eastern Europe.

Production Overview

Total processed nonfuel mineral materials produced in the United States during 1990 were valued at approximately \$310 billion, essentially unchanged from that of 1989. However, metals from U.S. ores rose 3% over those of 1989 to \$12.5 billion, and industrial minerals rose 5% over those of 1989 to \$20.9 billion. Recycled scrap, largely steel and aluminum, rose a tremendous 50% over that of 1989 to \$15 billion.

Steel production—a major consumer of many minerals—fell 2% to 96 million short tons (st). Iron ore mining fell 8% to 60 million st, 97% of which was pelletized. Net iron ore imports fell 14% to 13 million st. There was no domestic mining of chromium, cobalt, manganese, or nickel.

Primary aluminum smelters operated at capacity, producing 4.4 million st. Some bauxite was mined, but most came from net imports of 14.0 million st. This was supplemented by net imports of 3.1 million st of alumina.

Imports of nonfuel, mineral-based materials were valued at \$44 billion and

exports at \$38 billion. Canada, with which the United States has a free-trade agreement and which is a partner in the North American Defense Industrial Base, was a major supplier of many minerals.

Discussions were under way with Mexico, looking toward a possible free-trade agreement that, in turn, might be a prelude to a Western Hemisphere agreement. Concerns about apartheid in the Republic of South Africa continued despite reform efforts. Imports from that country were limited to 10 minerals essential for defense or the economy.

Magnesium and titanium production totaled 165,000 st and 28,000 st, respectively. Copper mine production rose 4% over that of 1989 to 1.7 million st, and refinery production was 2.1 million st. Lead mining rose 18% over that of 1989 to 546,000 st. Primary refined lead production of 435,000 st was supplemented by 865,000 st refined from scrap. Primary slab zinc tonnage of 292,000 st was supplemented by 116,000 st of secondary production and net imports of 496,000 st.

Cement production rose 3% to 80 million st. About 3,400 quarries produced 1.2 billion st of crushed stone, and 5,700 sand and gravel pits produced 920 million st. Nearly 1,100 clay pits produced 49 million st, and 65 gypsum mines produced 18 million st.

Magnesium compounds totaling 700,000 st were produced from brines and seawater. Titanium dioxide pigments totaling 1.1 million st were produced from domestic and imported minerals. Sulfur production totaled 12.4 million st, 32% by the Frasch process. Production of other major nonmetallics included 39 million st of salt, 17 million st of lime, 10 million st of soda ash, and 625,000 st of B₂O₃.

Phosphate rock mining fell 8% to 51 million st, and ammonia rose 3% to 14

million st. Potash mining rose 3% to 1.8 million st of K₂O. Significant quantities of ammonia and potash were imported, but fertilizer exports totaled \$4.1 billion.

Gold production edged up to 65 million ounces (oz) worldwide during 1990. This 2% gain over that of 1989 was low in comparison to 6% gains prevailing in recent years. The rankings of the million-oz-peryear producing countries remained unchanged. U.S. mines yielded 9.6 million oz of gold and 64 million oz of silver. About $10\overline{\%}$ of the gold and 75% of the silver was a byproduct of base metal mining. Approximately 50% of the U.S. gold production was from surface leaching operations. The 1990 average price of \$387 per oz was little changed above that of 1989. However, the 1990 price was more volatile than during the previous year. Gold mine openings and expansions were on the decline in 1990.

The gold industry entered a period of economic hardship during 1990. As a result, North American exploration and new mine developments were greatly curtailed. In addition, increasing regulatory burden and pending legislation regarding mineral tenure could drive small miners offshore or out of business. Small miners, ultimately, are responsible for most U.S. mineral discoveries.

Australian output is forecast to drop by 20% per year following imposition of an income tax on gold mining that was effective on January 1, 1991. Output of silver mined in the world, at 469 million oz, was up only 1% over that of 1989. An estimated 60% of newly mined silver is recovered as a byproduct of gold and polymetallic base metal deposits. In 1990, the price briefly slipped below \$4 per oz.³

Incentive Systems on the Rise

More mining companies used incentive bonus plans as part of their wage systems in 1990. A survey by Mining Cost Service of Spokane, WA, found that of the 156 mines responding to inquiries, a remarkable 42% reported using some sort of incentive bonus plan in 1990. This represents the continuation of a steady growth pattern in the use of incentive systems by the mining industry. In 1987, only 20% reported having a bonus system in place compared with 23% in 1988 and 35% in 1989. According to the survey, metal mines were the largest users of incentive bonus plans this year. About 33% of the responding coal mines and 25% of the responding industrial mineral mines

also had bonus systems in place. In the metal mines, production was the most commonly mentioned incentive factor. Development advance, safety, ore grade, cost saving, profits, commodity prices, housekeeping, and length of service were also mentioned. Attendance, production, safety, and profits were all mentioned by industrial mineral mines. Of the 24 industrial mineral mines responding, 21 reported wage increases ranging from 1% to 13%. The remaining three reported no change. Forty of the 66 metal mines reported wage increases ranging from 1% to 18%. No metal or industrial mineral mines reported wage decreases in 1990.4

Reclamation Bonds

New Federal reclamation bonding requirements were not expected to have a significant impact on large mining concerns, but might put smaller companies and prospectors out of business. The new policy was drafted to ensure that reclamation bonds are posted, but in a manner that companies would not pay both Federal and State bonds. Several mining company officials said the new policy will burden small miners who may not be able to afford bonds. Many States currently do not require bonds for small prospectors.⁵

Soviets Open Mineral Deposits to Joint Ventures

Because the U.S.S.R. does not have sufficient funds to develop many of its natural resources, the Soviets were forced to pare mining activities. In an effort to raise much-needed hard currency, the U.S.S.R. prepared a list of 100 mineral deposits made available to foreign companies for joint ventures. This marked the first large-scale effort by the Soviets to encourage joint ventures in mining.

The U.S.S.R.'s joint-venture master plan included proven deposits of aluminum, chromium, gold, iron, lead, manganese, nickel, silver, tungsten, and zinc. The Soviet Ministry of Geology explored the deposits and determined that they are minable.⁶

The Soviet North East Gold Mining Association and Bering Straits Trading Co. awarded a contract for a joint venture between Cominco Engineering Services Ltd. of Vancouver, British Columbia, Canada, and Watts, Griffis and McOuat, geologists and engineers, of Toronto for a planned silver recovery system with a capacity of 1 million st of ore annually.

Plans call for construction of a plant in Dukat, northeast of Magadan in the extreme northeast U.S.S.R.⁷

LEGISLATION AND GOVERNMENT ACTIONS

Pending Legislation

Efforts were put forth in 1990 to amend the General Mining Law of 1872. House bill S. 1126 was introduced in June 1989. Hearings were held in June 1989 and again in September 1990. As introduced, the bill would withdraw certain types of lands presently open to mineral entry. Jurisdiction over Forest Service lands would move to the Department of Agriculture. It would eliminate exploration or development by joint ventures, partnerships, and multiple mineral development within the same operating area unless under a single operator and would eliminate different types of mining operations in the same area. It would also eliminate lode and placer distinction as well as larger sized claims currently allowed for placers.

All prospectors would be required to notify the land management agency before initiating mineral exploration. The claim recordation fee would be raised to \$100 per claim. Mining claims would be for exploration purposes only and would be limited to 20 acres. Jurisdiction would be divided among the Departments of Agriculture and Interior, who would have total discretion to deny the application without appeal. The exploration claim would be void after 10 years unless the locator applied for a mineral patent.

Prior to any mineral development or production, the locator of an exploration claim would be required to have an approved exploration plan and reclamation plan and would have to submit an application for mineral patent. A hard-rock mineral deposit capable of commercial development would have to exist on the property, and a mining and reclamation plan would have to be approved before a mineral patent could be issued. Such a patent would not, however, convey possessory title to the minerals. The patent would be void if mineral production did not begin within 15 years.

Exploration claims would require annual diligence, or in lieu of payments, of \$50 per acre until production began. Patents would require annual diligence from \$100 per acre for the first 5 years to \$300 per

acre during years 10 through 15. Once production commences, an 8% overriding royalty on production would be assessed. The bill also provides for payment of an annual \$100 "holding fee" for each exploration claim or mineral patent and a \$5 per acre surface-use fee.

All mined areas would have to be reclaimed and restored to a condition supporting the original use prior to mining. This work would have to be done with concurrent reclamation when feasible. Bonding sufficient to ensure complete and timely reclamation would be required for exploration claims and mineral patents. Further, the bill requires that landmanaging agencies address mining and exploration activities in their land use plans and provide conditions and restrictions on these activities.

The bill also addresses the conversion of existing claims. It would eliminate the right to patent claims located under the 1872 Mining Law and would take away valid existing rights. Further, it would require that within 3 years existing claimholders either relocate their claims under the terms of the new law, with some exceptions, or maintain them by performing assessment work fixed at \$5,000 per mining claim per year.

House of Representatives bill 3866 was introduced in January 1990. A hearing was held in September 1990. As introduced, the bill established procedures to locate and record mining claims. It eliminated distinctions between lode and placer claims and claims for "uncommon varieties." It would move jurisdiction over minerals on Forest Service lands to the Department of Agriculture. Mill sites and tunnel sites would be eliminated.

Claims would be 40 acres and would have to conform to the public land survey, where possible. Extralateral rights would be eliminated. The legal description in the notice of location would supersede the physical boundaries on the ground. A claimholder who relinquishes a claim or fails to maintain all requirements would not be permitted to file a new claim on the same ground for 6 months.

All mining activities on mining claims would have to prevent unnecessary degradation and minimize adverse environmental impacts on surface resources. A plan of operation would be required for prospecting and exploration. Adequate financial or other guarantees would be required to ensure reclamation, and the Secretaries of Agriculture and Interior would establish reclamation standards.

Land use plans would be required to include numerous specific requirements to ensure protection of nonmineral values. The bill also authorizes quarterly compliance inspections by the Office of Surface Mining and Regulation Enforcement.

A mining claim would be valid when the rental fee requirements and the diligence expenditures or the in-lieu-of-payment were met. The annual rental fee would be \$1.50 per acre prior to approval of a mining plan and \$5.00 per year after approval. Diligence would be required on a 5-year incremental scale ranging from \$20 per acre in the first 5 years to \$160 per acre after the 15th diligence year following recordation of the claim. Payments in lieu of diligence could not be made until the 6th year; these payments would also be graduated, ranging from \$20 per acre in the 6th through 10th years to \$80 after the 15th year. The bill further directs the appropriate Secretary to establish user fees to reimburse the United States for expenses incurred under the legislation. Failure to submit payments or file a diligence affidavit would void the claim.

Patenting of existing mining claims would be eliminated. Unpatented mining claims located under the Mining Law of 1872 would have to be converted to the new system within 3 years. Unconverted claims would be null and void.

The bill also directs that all monies received from rental fees collected be put into a fund for the reclamation and restoration of land and water resources adversely affected by past mineral mining.

The Resource Conservation and Recovery Act

In April 1991, the comprehensive Resource Conservation and Recovery Act (RCRA) bill (S. 976) was introduced. Although mine and mineral-processing wastes were not directly addressed in the bill, several provisions of the bill may still have an impact on the management of mines or mineral-processing facilities, such as requirements affecting recycling, secondary materials, and pollution-prevention activities.

EPA Activities—Mining- and Mineral-Processing Wastes

In May 1988, the U.S. Environmental Protection Agency (EPA) released a document that outlined an approach to manage noncoal mining wastes and materials, referred to as "Strawman I," for public

comment. In May 1990, EPA issued "Strawman II," incorporating comments and responding to raised issues. After court action, EPA was ordered to define largevolume, low-hazard wastes, and a final ruling was published January 23, 1991. EPA established that the temporary exemption from subtitle C requirements, established by the exclusion for mineral-processing wastes, was limited to 20 mineral-processing wastes, including (1) slag from elemental phosphorus production, and (2) phosphogypsum and phosphoric acid process wastewater. If the exclusion is retained, the wastes would be subject to regulation under the Resource Conservation and Recovery Act subtitle D and as solid wastes.

The mine waste regulatory program, as currently viewed by EPA, will be one in which the States have the lead role and will be responsible to develop, oversee, and enforce a mining waste and materials management plan. Consequently, the States will be expected to identify a lead agency; incorporate a multimedia approach that addresses air, surface water, ground water, and soil contamination; and incorporate any necessary permits under the National Pollution Discharge Elimination System (NPDES), the Clean Air Act, and the Underground Injection Control program. To be approved by EPA, the mining waste and materials management plan would need to provide for a State program adequate to meet established technical design criteria and performance standards.

Mineral-processing wastes are being addressed separately by EPA. The number of processing wastes afforded protection by the Bevill amendment from hazardous waste regulation under RCRA subtitle C was reduced. In EPA's July 1990 Report to Congress, the Agency concluded that no more than 4 of the 20 conditionally exempted wastes under Bevill needed to be regulated as a hazardous waste. The findings of the report will be the basis of a final regulatory determination. All other mineral-processing wastes are now potentially subject to regulation as hazardous wastes under subtitle C of RCRA.

Basel Convention

In March 1990, the United States signed the Basel Convention, an international agreement dealing with the international transboundary movement of hazardous waste. The Basel Convention is intended to put an end to the shipment of hazardous wastes for disposal in other nations,

particularly developing nations. However, the convention could affect the way metal waste and scrap, as well as other recyclable materials, are imported or exported because all of these materials are considered to be hazardous wastes in some countries, particularly in the European Community (EC). Materials that are likely to be affected include metal waste and scrap, scrap batteries, precious-metal wastes and residues, and materials recovered from municipal waste.

Under the Basel Convention, requirements will include advance notification of shipments of hazardous wastes through the Governments of the exporting and importing nations and acceptance of the material by the importing nation. Both the exporting and importing nations are obliged to assure that the handling and disposal of the waste is environmentally sound. Trade in hazardous waste between a nation that is a party to the convention and one that is not will be prohibited, unless the nations enter into a separate agreement that is at least as protective of the environment as is the Basel Convention.

The Basel Convention was submitted to the U.S. Senate for ratification, and legislation was introduced to provide the authority to implement its provisions in the United States. It could take effect as early as 1992.

Ocean Mining Leases Offered

For the first time since the sale of phosporite leases on California's 40-mile (mi) bank in 1963, the U.S. Department of the Interior issued a proposed leasing notice for minerals other than oil, gas, or sulfur on the Continental Shelf. The notice was published by the Minerals Management Service on June 11, 1990, in accordance with new regulations for leasing (30 CFR Part 281) under the authority of the OCS Lands Act of 1953, as amended.

About 150,000 acres is being proposed for leasing to include the right to explore for and recover gold and any other mineral, such as mineral sands, using similar technology. The proposed lease areas are along the boundary of Alaskan State waters 3 mi offshore and adjacent to the city of Nome and the town of Solomon, about 20 mi to the east. Both areas offered are of similar dimension.⁸

Lead-Acid Battery Recycling

Lead-acid battery recycling has been revived in recent years. The primary reason

has been relatively high prices for lead scrap and spent batteries. With RCRA and the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), commonly known as Superfund, looming over the secondary lead industry, they have been quite effective in getting the batteries into the recycling chain. An important factor in this respect has probably been State and local interest in collecting lead batteries by providing incentives; some States are offering \$2.00 bounties on spent lead-acid batteries. A further objective is to reduce the number of spent batteries going to landfills and municipal incinerators.

Federal legislation related to the recycling of lead-acid batteries that was introduced in the 101st Congress was not acted upon, but some bills were reintroduced into the 102d Congress. Bill H.R. 870, introduced in February 1991, in particular is essentially written to affect lead-acid battery recycling. The bill would require manufacturers and importers of lead-acid batteries to recycle an equivalent amount of batteries sold. In the case of importers, they would be required to purchase credits from others who recycle batteries. Another bill, S. 391, also introduced in February 1991, is designed to address all issues related to lead in general, with specific provisions for prohibiting disposal in landfills and incinerators.

Another important activity in lead-acid battery recycling is the regulatory negotiation in progress sponsored by the EPA. The regulatory negotiation was established under the Federal Advisory Committee Act (FACA). The committee's purpose is to negotiate issues leading to regulating the recycling of lead-acid batteries under section 6 of the Toxic Substances Control Act (TSCA).

Clean Air Act Amendments

The Clean Air Act Amendments of 1990, signed in November, will likely substantially affect the economics and viability of the minerals industry. For example, coke ovens are specifically mentioned as subject to stringent toxic emission limitations. Most other minerals processing facilities will also be required to limit their emissions of 189 listed air toxics, including such substances as cadmium, chromium, cobalt, lead, manganese, mercury, and nickel compounds. Also, the acid rain provisions of the act will bring about increased electric rates to many mineral producers, in

particular to about one-half of the energyintensive aluminum smelting and ferroalloy-producing industries.

Public Land Use

In 1989-90, Congress considered two bills to set aside areas of the California desert as new national park or wilderness areas. These were S. 11/H.R. 780 (California Desert Protection Act) and H.R. 3460. Both actions would have precluded or limited mineral access in large areas, including the East Mojave National Scenic Area (EMNSA). Neither bill was released from committee by the end of the Congress. At the outset of the 102d Congress in 1990, the California Desert Protection Act was reintroduced.

Potential impacts of the proposed legislation relating to the EMNSA were estimated in a study done by the U.S. Bureau of Mines, entitled "Minerals in the East Mojave National Scenic Area, California" (MLA 6-90, available from the U.S. Bureau of Mines). The study included economic analysis because the proposals raised questions about the profitability of mining in the affected area, as well as the regional economic benefits derived from mining. The study found that 24 deposits in the EMNSA would be profitable to develop under current economic conditions. If all 24 were to be developed, economic benefits would include \$3 billion in cumulative production revenues. That development could generate about 2,400 jobs for mines and supporting industries in San Bernardino County, plus jobs in transporting the minerals. The study also included estimates of the impact of proposed withdrawals on employment, personal income, and tax revenues.

Trade Issues

The United States and Mexico continued negotiations begun in late 1989 to eliminate barriers to trade (of goods and services) and investments between both countries. Mexico's foreign investments restrictions prohibit foreign majority ownership of Mexican mines. The United States has no such restrictions against foreign mineral investment. Many issues, including those related to Mexican foreign investment barriers and environmental standards, have to be resolved before both countries can conclude a formal United States-Mexico Free-Trade Agreement.

During 1990, as part of the continuing Uruguay Round of General Agreement on

Tariffs and Trade (GATT) tariff negotiations, the United States sought reductions in Japanese tariffs on processed minerals and metals. U.S. exporters of aluminum products and refined copper faced Japanese tariffs ranging from 5.8% to 12.8% for aluminum products and 7% for refined copper. At the same time, the United States and Japan continued to discuss nontariff trade barriers in both countries during the Structural Impediment Initiative (SII) talks that began in March 1989. The goal of the SII is to eliminate structural trade barriers (i.e., barriers to market access) and thus reduce the imbalance of payments in both countries. U.S. soda ash producers maintain that in 1990, Japanese imports of soda ash were unfairly limited by collusion among Japan's domestic producers. Two U.S. steel producers seeking to bid on nine Japanese Government contracts waited 2 years to be qualified before submitting any bids. In 1990, the Japan Fair Trade Commission drafted new guidelines to open the Japanese market. Japan also announced that in 5 years it would reduce its patent processing time to 2 years, similar to that of the United States.

Two mineral-related trade disputes involving the United States were resolved satisfactorily in 1990. In January 1990, the United States Trade Representative (USTR) negotiated an agreement with the EC. EC member countries agreed not to renew export restrictions on copper scrap that had expired in December 1989. The Copper and Brass Fabricators Council had filed a petition with the USTR charging that the EC had unfairly maintained export controls on copper scrap. After discussions between the United States and the EC failed, both asked GATT to resolve the dispute. The United States argued that there was no shortage of supply or national emergency to justify the EC's export controls on copper scrap. Before the GATT could reach a decision, the USTR and the EC reached an agreement.

In September 1990, the United States and Japan agreed that Japan would create opportunities for U.S.-produced amorphous metals to be marketed in Japan for a 2-year period. Allied-Signal Corp., a U.S. producer of amorphous metal, filed a petition with the USTR requesting an investigation of Japan's business practices. The company felt that with the consent and cooperation of the Japanese government, Japanese steel companies were refusing to enter into licensing agreements on terms with Allied-Signal. In addition, Japanese electric

utility companies were refusing to purchase electric power transformers made by Allied-Signal, and Allied-Signal felt that the composition and process patents applied for by Allied-Signal were unfairly delayed (11 and 12 years, respectively). Allied-Signal concluded that the Japanese government had targeted amorphous metals technology for its own use. It was simply using the time until 1993, when the Allied composition patent expired, to develop Japan's own amorphous metals technology while denying U.S.-made amorphous metals access to the Japanese market. Although an agreement was reached, Japan will not grant an extension of Allied-Signal's composition patent when it expires in 1993.

National Defense Stockpile

According to section 3301 of the National Defense Authorization Act for fiscal years 1990 and 1991 (Public Law 101-189, November 29, 1989), the Assistant Secretary of Defense determined that, effective in June, the National Defense Stockpile (NDS) goal for antimony was increased from 36,000 st to 88,500 st.

The Defense Logistics Agency (DLA) announced the awarding of the first in a planned series of contracts to upgrade metal-grade bauxite ore in the NDS to aluminum metal. The contract, awarded to a company headquartered in Pittsburgh, PA, called for the conversion of 243,852 st of bauxite ore to 55,157 st of aluminum ingots. Work on this contract was expected to be completed by September 1992. The Agency also awarded a contract to a domestic company to upgrade some of the beryl ore in the NDS to vacuum-hotpressed beryllium billets over a 2-year period, beginning in early 1991. The contract also had an option for the Government to purchase an additional 43,000 pounds (lb) of beryllium in 1993 for about \$13 million.

The DLA also initiated a number of other actions in June 1990. The Agency approved a reduction in the goal for bismuth in the NDS from 990 st to 480 st. The DLA began sales of excess bismuth from the NDS in August. Requirements for the columbium (niobium) group in the NDS were almost tripled from 4.85 million lb of contained columbium to 12.52 million lb of contained columbium. The Agency revised the goals for both acid-grade and metallurgical-grade fluorspar. The goal for acid grade went from 1.4 million st to

900,000 st. The goal for metallurgical grade went from 1.7 million st to 310,000 st. The Agency also lowered the goal for the battery-grade group from 87,000 to 50,000 st. Accordingly, within that group, the goal for the battery ore subsequently was decreased from 62,000 to 25,000 st, while that for synthetic dioxide remained unchanged. Goals for palladium and iridium were lowered to 147,430 and 5,897 lb, respectively. New goals for rhodium and ruthenium were established at 2,057 and 4.9 lb, respectively. In addition, the Agency accepted sale offers from two of six bidding firms for the DLA to purchase a total of 200,000 lb of tantalum pentoxide contained in tantalum natural minerals and concentrates for the NDS at an average purchase price of \$36.81 per lb of contained tantalum pentoxide.

Commodities

Presidential Proclamation 6123, in April 1990, made acid-grade fluorspar from Mexico eligible for preferential tariff treatment under the Generalized System of Preferences, pursuant to title V of the Trade Act of 1974, as amended. Effective July 1, 1990, this material was exempted from duty upon entering the United States. The preferential tariff treatment applies as long as Mexico's share of the import market does not exceed 50% or \$89.9 million. In August 1990, the 13.5% ad valorem tariff on imports of metallurgical-grade fluorspar was suspended through December 31, 1992. Imports of both acid-grade and metallurgical-grade fluorspar were down from those of 1989. The largest decrease was for acid grade, which was down more than 23% compared with that of 1989. This was a result of decreased production of chlorofluorocarbons (CFC's) owing to production restraints imposed by the Montreal Protocol and the new excise tax on CFC's.

In June 1990, at a congressional hearing, the Executive Director and two members of the Institute of Scrap Recycling Industries Inc. testified before a subcommittee on the fate of more than 100 mothballed ships that belong to the National Defense Reserve Fleet. Carnegie Mellon's Center for Materials Production conducted a case study of cryogenic scrap preparation to determine if the process is worth looking at again. The world's first dezincing line began commercial operation in Canada. The EPA listed electric furnace dust as hazardous waste and issued regulations requiring dust containing 15% or more zinc

to be processed with the best demonstrated available technology after August 8, 1991.

Changes in Eastern Europe probably would have little impact on the world's metal and scrap industries in the short term. However, for the long term, these changes most likely would have considerable influence. Reportedly, there has been a gradual decline in iron and steel content and growth in the use of other materials in U.S.-built cars. The U.S.S.R.'s Minister of Metallurgy called for a cut in ferrous scrap exports to avoid domestic shortages. The Brazilian Government shut down 20 pig iron producers in May for not reforesting areas cut down to make charcoal.

The principal issue that continued to confront the U.S. slag industry was the proposed Federal regulation that would classify iron and steel slags as solid wastes. In July 1990, the EPA published its required report to the Congress on the 20 mineral-processing waste streams proposed for retention under the Mining Waste exclusion, or the Bevill exclusion, of the RCRA. Blast furnace slag and those steel slags generated from open-hearth and basic oxygen furnaces were among the 20 waste streams proposed.

At midyear, the EPA's "third-third" rule became effective for landfilled process wastes. This rule required pretreatment for most secondary smelter slags at significant cost. However, the industry won a 2-year temporary reprieve to a less strict interim standard on appeal. In October, EPA proposed the "final" lead in drinking water standard, which eventually could result in a required 80% reduction of lead in process effluents and discharges at considerable cost to producers and battery plants. After 2 years of intense study, EPA completed a long-range, multimedia pollution prevention strategy for lead that will result in significantly stricter regulations imposed on both the producing and consuming sectors of the industry over the next several years.

The first stage of EPA's three-stage phaseout of asbestos went into effect in August. The first stage bans the manufacture, import, and processing of asbestos-containing flooring and roofing felt, pipeline wrap, asbestos-cement, corrugated and flat sheet, vinyl asbestos floor tile, and asbestos clothing after August 27, 1990. The sale of these products is banned after August 25, 1992. Stages two and three of the phaseout go into effect on August 25, 1993, and August 26, 1996, respectively.

In August 1990, the EPA, in cooperation with the domestic paint industry, banned the use of mercury in indoor latex paint, citing a risk of poisoning, especially to children, when the paint is used in poorly ventilated areas. The decision also required outdoor latex paint containing mercury to carry a warning label.

In addition, in August 1990, U.S. producers filed a petition with the U.S. International Trade Commission and the U.S. Department of Commerce (DOC) requesting the imposition of antidumping duties on imports of silicon metal from Argentina, Brazil, and China and the imposition of countervailing duties on imports from Brazil. Preliminary investigations determined that the petition warranted a full investigation of the allegations.

The Clean Air Act of 1990 was passed by the Congress and signed by the President in November 1990. Provisions of the new law require a 35% reduction in hydrocarbons and a 60% cut in nitrogen oxides beginning in 1994. In addition, catalytic converters must be guaranteed by manufacturers to last double the current 50,000 mi. As a result of these changes, increased amounts of platinum-group metals (PGM) are expected to be used in each catalytic converter.

EXPLORATION

International Overview

After the days of increased base metal prices and frantic gold exploration of the late 1980's, mineral exploration in 1990 continued at a reduced level. The lower gold price forced a reassessment of the viability of smaller and more remote discoveries. Many junior exploration companies were forced to make radical writeoffs of exploration expenditure on these prospects.9

Exploration for nonfuel minerals continued to decline after 1988 as recessionary pressures slowed growth in the industrialized economies. However, 1990 expenditures were still significantly greater than the low levels experienced in the mid-1980's. The Persian Gulf crisis introduced increased instability in energy prices and more uncertainty to the global economic picture.

Exploration funding levels are generally determined by cash-flows. Therefore, commodity price and production levels affect funds available for exploration. Average

gold prices for 1990 were slightly below the 1989 levels and significantly below 1987 levels. However, gold remained the major focus of mineral exploration in 1990. In addition to the lower gold prices, three factors had a large impact on worldwide exploration: the ending of flow-through funding in Canada, the introduction of the Australian gold tax, and the squeezing of margins on the deep South African gold mines. Estimates by the Prospectors and Developers Association of Canada suggest that spending will be about Can\$610 million for 1990, with a projected 30% cut in 1991.

Base metal exploration was not encouraged by the recession in North America and Europe and the uncertainty surrounding events in the Gulf at yearend. Exploration of platinum-group elements continued at a reduced rate compared to that of 1989.

Although many Western economies were in various stages of recession, copper, steel, and zinc prices remained steady or declined only slightly. Prices were nowhere near the low levels experienced in the early 1980's, and production in domestic and world markets was above 1989 levels.

One note of hope was the opening of Eastern Europe and, less certainly, the U.S.S.R., to commercial exploration. Although a considerable amount of discussion occurred on the formation of joint ventures with state companies, few contracts were signed.¹²

Domestic Overview

The U.S. Bureau of Land Management's (BLM) claimstaking data reflect a subtle shift to base metals in the United States. Arizona was the only State with a significant increase in new claims on Federal land. New claims in nearly all other States declined precipitously. The number of new claims follows the gold price very closely. Data for 1990 show claimstaking at about one-half of 1988 levels.

Data on domestic exploration expenditures by U.S. firms were collected in the Society of Economic Geologists (SEG) annual survey. It showed that a substantial decline in exploration occurred in 1989. For 1989, the inventory of claims serviced by BLM did not change significantly. However, in fiscal year 1990, there were about 50,000 more claims released than new claims accepted by BLM. The SEG survey also shows that about 30 cents of every exploration dollar spent by U.S. firms went outside the United States. ¹³

Antarctic Exploration.—Antarctica is the last continent unspoiled by man, and environmental proponents want to keep it that way. However, mineral industry executives and some governmental officials believe that Antarctica is too potentially rich in minerals to be completely conserved. Although an exploration prohibition is not in place, no Antarctic exploration has been conducted owing to the uncertain legal status of owning and developing a deposit, which is expected to be costly, considering accessibility, environmental concerns, and weather conditions.

An agreement regulating exploration, the Convention on the Regulation of Antarctic Mineral Resource Activities (CRAMRA), was adopted in 1987, but it still needs three votes to come into force. The United States is among the nations that have not signed the pact. The 101st Congress passed two bills that opposed ratification. The Administration has not yet decided whether it will sign the bills, but is thought to be leaning away from any measure that would impose a "permanent" ban on exploration. Some members of Congress believe a "permanent" ban would restrict any exploration for at least 100 years. Administration officials, including the head of the U.S. delegation, are thought to be in favor of a 30-year moratorium. Administration and industry representatives believe it will take at least this long for the Antarctic mining technology to be developed and made cost-efficient.14

The American Mining Congress (AMC) told a House subcommittee that a legal regime for mineral exploration in Antarctica should be in place before companies can be expected to invest in the region. The AMC criticized the CRAMRA because "explorers for hard minerals would face too much uncertainty and too much red tape under its terms." A spokesman stated the national agreement would provide "absolutely no incentive" for mining concerns that may be interested in mineral exploration in the future.

Because of constraints on mineral development in Antarctica, minerals with the best prospects of recovery would have to be low-volume, high-value minerals such as gold. Even if a major oil deposit were found in the near future, oil recovery in the region is unlikely before the year 2020, according to the study. It is also unlikely that anything smaller than a giant (500 million to 5 billion bbl) or supergiant (more than 5 billion bbl) field would ever be economical to develop. ¹⁶

Alaska.—Exploration expenditures rose 19%, from \$47.8 million in 1989 to \$56.7 million in 1990. Almost one-half of that, \$24.9 million, was spent on the three gold properties in advanced exploration near Juneau—the Kensington (Echo Bay-Coeur d'Alene Mines), the AJ-Treadwell (Echo Bay), and the Jualin (Placer Dome-Granges). Another \$11 million was invested in the Fairbanks area. This was predominantly spent on drilling the Ester Dome by Citigold and American Copper and Nickel Co., and on the Fort Knox property by Fairbanks Gold Inc. There was also significant exploration activity on the Seward Peninsula at Rock Creek, Anvil Creek, and Mount Distin by a complex joint venture that included Tenneco Minerals, Aspen Exploration, and the Sitnasuak and Bering Straits Native Corps. Moneta Porcupine Mines drilled three holes in the Lik deposit in 1990 and agreed to buy GCO Minerals' 50% stake in the project. The other 50% is owned by Echo Bay Mines. Stated reserves at Lik, which is only 12 mi from Cominco's Red Dog Mine, are 18 million st grading 10% zinc, 3% lead, and 1.5 oz per st silver. Initial plans consider milling 12 million st/yr, but an additional 10,000 to 15,000 feet (ft) of drilling will probably be necessary to refine the reserve picture. 17

Drilling Technology. — Arctic Gold Placer Drilling.—Exploration drilling and the mining of marine placer gold deposits was initiated in the Arctic off Alaska. Prospecting and ore reserve drilling was done both in the winter on the pack ice and in summer from a modified Landing Craft Tank (LCT). Weather was a major controlling factor, and both drilling seasons lasted approximately 4 months each, on the ice from December to April and at sea from July to October.

Western Gold Exploration and Mining adapted a Becker¹⁸ diesel top hammer drill to operate on a special broad-based skid in winter. This spreads the 41-st rig load over an 883-square foot (ft²) area; the rig can safely work on ice only 2.5 ft thick. This modified rig can be lifted by crane onto the drill ship in about 4 hours. The drill pipe used is dual-walled, 5.5 inches (in) outside diameter (OD) and 3.3 in inside diameter (ID) and, in sea depths up to 115 ft deep, can penetrate to 164 ft below the seabed. With a high-pressure booster compression, holes down to 230 ft have been achieved.

After bit-design trials, the most satisfactory is an eight-track bit with a crowd-out

profile. This pushes excess sediment away from the central bore and reduces the frequency of blocking. Bits with a crowd-in profile are satisfactory in the more granular sediments, but tend to push too much sediment into the inner barrel and cause frequent blockages.

The drill ship uses a four anchor system laid out at 45°, providing possible coverage of 62 acres. In theory, 16 holes can be drilled from one anchorage when drilling on 330-ft centers. Moving the anchors is accomplished by controlled winching and takes less than 10 minutes (min) to move from one hole to the next. During 4 seasonal programs over the past 2 years, an average of 10 holes per day were drilled. The Becker drill can also operate in a purely rotary mode to produce cores for detailed geological evaluation.

Reverse circulation (RC) drilling in conjunction with down-the-hole hammers (DTH) combines the advantage of DTH penetration speed with rotary chip-sample efficiency. Several companies are marketing RC-DTH hammers and dual-wall rods. ¹⁹

Reverse-Circulation Drills.—In the Entec Sampler system, high-pressure air is split so that one flow operates the 2,000 blows/min hollow piston as the second airflow bypasses the piston and is jetted upward behind the bit face. This causes a powerful suction that collects all the cuttings from the bit face and passes them directly up through the hollow piston and into the dual-wall drill pipe. Some other RC systems pass the cuttings up the outside of the hammer before they are guided via a special crossover sub into the inner drill tube. This can result in significant mineral losses due to smearing against the borehole walls.

Entec Industries reports that, in tests on a gold mining operation in the Western United States, their Samplex hammer gave more than 98% by volume cutting recovery and that just more than 15% of the sample was 0.5 in or larger. This enables the geologist to make a more detailed description of the rock types and helps produce more accurate borehole logs.

Bul Roc (United Kingdom) developed a similar type of RC-DTH hammer and reports that penetration rates of more than 39.4 feet per hour (ft/h) were fast enough to overcome ground water entry and produced dry bulk samples in a hard limestone in northeast England. The use of a 300-pounds-per-square-inch (psi) compression

in holes to 262 ft or less contributed to the restriction in water flow. Water flowed into the hole during rod changes, but if this water was blown clear before rock penetration was resumed, then dry bulk samples were obtained.

Halifax Tool Co. (Halco) introduced its new RC-DTH hammer, which has a stainless steel central sample tube to reduce corrosion problems. This tube can be replaced without dismantling the entire hammer, which is often a major problem on the drill site. Halco gives great importance to the ease of maintaining and servicing its hammer on-site. The Halco dualwall drill pipe is unique in that it is in integral lengths, has no separate central couplings, and uses no "O" rings. Halco claims that both inner and outer tubes transmit torque.

Core Drill (United Kingdom) Ltd. of Warwick has produced a double-tube swivel core-barrel and bit that cuts a 11.8-in-diameter core by 14.4 in (OD). During field testing, the strata were sufficiently soft to use a special TC core bit, and the double core springs effectively retained the marl and siltstone cores. One of the few problems was in handling the full 3.3- to 16.4-ft core-barrel and in safely transporting cores that weigh 122 pounds per foot (lb/ft).²⁰

Drill Systems Premiers EXPLORER 1000 Drill.—The EXPLORER 1000 is designed to operate in environmentally sensitive areas. The drill is mounted on a proven carrier manufactured by Canadian Foremost of Calgary, Alberta. The carrier is four-wheel drive and operates on terra tires, giving the unit a ground pressure of 10.2 psi. This all-terrain vehicle is also equipped with articulating and oscillating frame features that permit drilling in severe off-road conditions with minimal ground surface disturbance. The drill is specially designed for dual-wall reverse circulation drilling for the mineral exploration industry and is equipped with a deck raise that allows the deck of the drill to be leveled on mountain and/or hill sides with the carrier's wheels on the ground surface. Other standard features include a bulldozer blade, sliding angle mast and deck slide, 750 cubic feet per minute (ft3/min) at 350 psi air compressor, 485 horse power (hp) diesel deck engine, and a top-head rotary head that pivots to horizontal position providing an efficient pipe-handling system. The unit is completely self-sufficient and is capable of carrying a large supply of drill pipe.

Under suitable conditions, the drill has a rated depth capacity of 1,000 ft using Drill Systems' 3 3/4-in dual-wall drill pipe.²¹

Rotary Drill Rig.—Ingersoll-Rand (IR) Co.'s rotary-drill division introduced a hydraulic tophead-drive drill rig designed primarily for mineral exploration. This drill uses either a rotary or downhole hammer with conventional or dual-wall drilling methods. The truck-mounted, deckengine-powered TH75E features a "dumpangle derrick" system designed for angled exploration drilling. This system can position the derrick at any angle between vertical and 45°, then automatically move the derrick structure downward until the base rests firmly on the ground. Once the desired angle is set, an automatic pinning feature secures the deck in place. To make operations easier and more efficient at all angles and to ensure that the operator is always near the hole, the TH75E's control panel is positioned on the derrick and adjusts to a comfortable angle for the operator. The drill-pipe handling systems allow rapid, safe pipe changes in the vertical or angle positions. The TH75E is capable of handling 4 1/2-in by 20-ft dualwall pipe and can be supplied with a complete dual-wall package. The TH75E also has some unique features that include a two-speed rotary head design (that can be shifted "on the fly"), a remote control clutch between the engine and air compressor, and a remotely retracting hydraulic-powered top-head drive.22

All-Hydraulic Core Drill. — The Diamec-232, from Diamond Boart Craelius Inc., is an all-hydraulic core drill with mechanized rod handling. All-hydraulic means one person can perform all drilling and handling operations from the control panel. No tools are required with its mechanized rod handling feature. The machine is especially suitable for coring and drilling grout holes in narrow drifts or galleries. With its light weight and compact size, the Diamec-232 is easy to set up for drilling. This drill offers an advantage of fast moves between sites, without disturbing normal production routines.²³

Landing Indicator.—Manufactured by Longyear Canada Inc., the landing indicator is a device designed to improve productivity in diamond core-drilling operations. It is a fluid-pressure-activated device that tells the drill operator the inner tube assembly has landed in the core barrel

and drilling may be resumed. This avoids unnecessary delays estimating the time required for this operation. The landing indicator also reduces the chance of drilling in a mislatched condition. It is available for several core barrel types, including BQ, NQ, HQ, CHD 76, and CHD 101. The indicator is built into the inner tube assembly of the wireline system of core barrels. The landing indication occurs as an instantaneous fluctuation on the fluid pump gauge. This fluctuation is a result of increased pressure required to push a steel ball through a nylon bushing in the latch body. When the inner tube assembly contacts the landing ring, the waterflow is diverted through the latch body, applying pressure to the ball. Momentary pressure increase of approximately 300 psi forces the ball through the nylon bushing.24

Marlow Man-Portable Drill. — The Marlow Mole DD2 man-portable multipurpose drill equipped with a remote portable hydraulic power pack was field-proven from the Arctic to the tropics without modification. Conceived as a state-of-theart drill suitable for diamond core drilling, auger, DTH hammer, and slim hole RC drilling, a conservative depth rating of 165 ft was claimed by the manufacturer. However, it has now been shown that a 330-ft depth can be achieved using a thin kerf, double tube 1.8-in-diam core barrel taking a 10-ft core on each run and drilling at an angle of 60°. As the Mole DD2 has an integral dual-purpose gearbox (0 to 150 revolutions per minute (r/min) and 0 to 1,250 r/min), it is possible to auger rapidly through overburden and case or to simultaneously drill and case through to bedrock, then withdraw the interior drill string, leaving the casing in bedrock prior to continuing the hole by diamond drilling.25

Ground Surveying.—GPS Receiver.—
The GPS Nav 1000 Pro is one of the least expensive handheld global positioning system of satellites (GPS) receivers currently available. Cost savings are experienced through the Nav 1000 Pro's ability to replace a surveying team in determining preliminary calculations and positions. The uses of the Nav 1000 Pro include establishing survey control in remote, unmarked areas in the field, plotting coordinates, and storing coordinates. The Nav 1000 Pro is capable of storing up to 200 position fixes in its data buffer. These fixes may then be downloaded through its RS232

port into a data logger or laptop computer. The unit weighs only 30 oz and is shock resistant and waterproof.

Portable X-Ray Analyzer.—The metal Analyzer Probe (MAP) III Portable X-Ray Fluorescence Analyzer, from Scitec, allows the prospector-explorationist to have onsite, real-time analysis performed for assessment work. No sample preparation is required, and each analysis takes an average of 1 minute. MAP III is a handheld, multielement probe that performs quantitative analysis for silver, base metals, and trace elements, including those elements associated with gold. The in situ analysis can be performed in drill holes up to 250 ft deep.²⁶

Laser Mapping.—A new method to map planar geologic features in underground mines—where metal interferes with compass readings—is being patented by the U.S. Bureau of Mines. Based upon extensive testing, time savings of 50% in mapping—using the "geolaser"—are estimated. The geolaser operates on the principle that any beam of light laid horizontally along a planar feature will define its strike. Thus, the laser can project where a planar feature should occur along the back or opposite rib in an underground drift.

Geophysical Surveying.—The development of new geophysical and geochemical techniques and equipment continued during 1990 at a somewhat decreased pace from former years, in part reflecting generally reduced levels of mineral exploration in most parts of the world. There were, however, some notable highlights. Several new sensitive magnetometers for aeromagnetic survey work are in an advanced stage of development in North America. The first triaxial aeromagnetic gradiometer system was built in the Republic of South Africa. In Australia, considerable funding is going into the development of airborne electromagnetic survey systems. The Global Positioning System (GPS) is now being employed by most airborne survey operations and making feasible preliminary field compilation of survey results.27

Remote Sensing.—Development of Landsat 6, the next-generation U.S. land remote sensing satellite, is on schedule for launch in late 1991, according to the Earth Observation Satellite Co. (EOSAT).

Landsat 6 will orbit the Earth at the same altitude, inclination, and with the same equatorial crossing time as Landsats 4 and 5, both of which are still operational. The Landsat 6 enhanced thematic mapper will provide improved spatial resolution capable of discerning objects smaller than a tennis court. The satellite will have the same multispectral imaging capabilities of Landsats 4 and 5—technology still unrivaled by any other commercial remote sensing platform.²⁸

Projects.—Agnico-Eagle Mines Ltd., Asamera Minerals Inc., Comaplex Minerals Corp., Hecla Mining Co., and Lucky Eagle Mines Ltd. jointly announced the results from drilling for gold mineralization on the Meadowbank Project, about 60 mi northwest of Baker Lake in the Northwest Territories, Canada. In 1989, the third year of exploration drilling the Third Portage property, 12 diamond drill holes defined mineralization to a 300-ft depth over a 1,300-ft strike length. A followup program to test the continuity and size of the deposit is budgeted at Can\$1.15 million and was scheduled to begin by mid-1990.

In Mexico, Campbell Resources Inc. has gold properties covering 400,000 acres in the State of Sonora. Most notable is the reserve at La Colorado with a reverse-circulation drill program planned for 1990 and a feasibility study for 1991. Also in Mexico, more than 5 million st of gold ore in massive sulfide mineralization has been outlined on the Cerro de Oro property, including a zone containing 0.07 oz/st gold and 1.9 oz/st silver.

Anglo Swiss Mining Corp., formerly Carolin Mines Ltd., recently announced plans for a \$1 million exploration of its 1,500-short-ton-per-day (st/d) Ladner Creek gold mine near Hope, British Columbia, Canada. The exploration will be followed by a feasibility study conducted by Wright Engineers Ltd. An independent consultant estimated potential geological reserves of 5 to 6 million st in addition to the 990,000 st of defined gold mineralization, with expected grade on the McMaster zone.²⁹

Stroud Resources Ltd. reported that diamond drilling increased reserves of the Creek zone on its Hislop property, near Timmins, Ontario, Canada, to 1.016 million st grading 0.186 oz/st gold. The Main zone, about 1,600 ft southeast along the strike, contains an estimated 102,000 st grading

High Frontier Resources Ltd. acquired

the Washington Dome Project in Washington County, UT. The property consists of approximately 2,880 acres of unpatented placer and lode claims, as well as a royalty interest in an additional 480 acres of unpatented placer and lode claims (about 133 claims). The property is on the axis of the Virgin anticline in Permian and Triassic rock.

Placer Dome (U.S.), Inc., recently completed the second phase of its exploration at Mexican Hat, AZ, spending \$1.39 million to date to earn a 60% interest in the property. About 137 holes have been completed, including 54,103 ft of reverse circulation and 8,017 ft of core drilling on the relatively shallow volcanic-hosted target. Fire assays were made on drill holes that were completed in 1990.

Coral Gold Corp., with Amax Gold Inc. as the operator, reported the first drill results from a four-phase, \$11.5 million exploration and development program for the Robertson gold property on the Battle Mountain gold trend of northern Nevada. The first deep hole produced gold values from near surface to a depth of about 1,900 ft.³¹

Windarra Minerals Ltd.'s subsidiary, Westward Explorations Ltd., together with its partner and operator, Cameco, and Uranerz Exploration and Mining Ltd. claimed a major new discovery after drilling over the lake section of the Bakos zone of the Preview Lake property in the La Ronge area of Saskatchewan, Canada. Previously reported reserves in the BK1 and BK2 zones are 1.2 million st probable at 0.29 oz/st gold plus 230,000 st possible at 0.31 oz/st gold.³²

In British Columbia, Canada, attention was directed to the Golden Triangle that connects three new producing preciousmetal mines (Golden Bear, Premier, and Skyline) and two advanced exploration areas encompassing about 175,000 square miles (mi²) near its eastern corner. The three producers struggled to keep their portals open for the same reason five new gold mines opened and closed elsewhere in 1988-89. Golden Bear, Premier, and Skyline all have well-established reserves. However, production costs have far exceeded estimates due to the inaccessibility of the mines and infrastructure problems. 33

Ghanaian-Australian Goldfields, Ltd. (GAG) finalized a second drilling program within its Iduapriem gold mining lease near Tarkwa in Ghana. The company drilled 48,000 ft of diamond drilling in 178 holes. A resource of almost 17.6 million st containing an average of 0.06 oz/st gold was

delineated, contained within 3.1 mi of sedimentary rocks having a total strike length of 5.6 mi in the mining lease area. The resource includes 2.3 million st of ore averaging 0.08 oz/st gold. The company also located low-grade mineralization in other areas of the property. The sedimentary host rocks were also found in GAG's adjoining prospecting license areas.

Boulder Gold's U.S. subsidiary, Chrome Corp. of America (CCA), reached an agreement with Phelps Dodge Mining Co. on its Stillwater Complex. The property includes two previously operated chromite mines, one of which, the Mountain View Mine, would be reopened for the project.

Ontario's Ministry of Northern Development and Mines announced funding a 4-year Can\$2.2 million Geological Reassessment Program for the Elliot Lake region. The project will concentrate on the potential for deposits of base metals, PGM's, and aggregate resources and industrial minerals. Separately, the Ministry will provide Can\$50,000 to support the evaluation of prospecting technology developed in the U.S.S.R. A group of researchers led by the Ontario-based geophysical firm Scintrex Ltd. will test a geoelectro-chemical method for prospecting that was developed in the U.S.S.R. over the past 30 years. The method can reportedly detect the presence of ore formation elements at considerable depth, making it potentially valuable for exploration in areas covered with deep overburden. The work will be carried out by Soviet scientists in collaboration with industry, university, and government.34

Recent geologic studies in northern Minnesota indicate a greater potential for deposits of gold and silver in the area than had previously been thought, a U.S. Geological Survey scientist told a meeting of mining engineers and geologists in Salt Lake City, UT. "Geologists' mapping and geochemical surveys in northern Minnesota have revealed mineralized shear-zones and bedrock fractures similar to those in known gold- and silver-producing districts, including nearby areas in Canada." 35

Pegasus Gold Corp. announced two joint ventures: one with Lac Minerals Ltd. in New Mexico and another with Quartz Mountain Gold Corp. in southern Oregon. Spokane, WA-based Pegasus and Toronto-based Lac Minerals will explore and develop the Ortiz gold project in a mining district 25 mi northeast of Albuquerque, NM. Pegasus will be the operator. Several deposits are on the property, but the joint

venture will address the Lukas Canyon deposit, which could be in production in less than 2 years. The total geologic resources are estimated to contain 1.4 million (troy) oz of gold.³⁶

Homestake Mining Co. announced a 5-year, \$23 million underground exploration program to follow up encouraging gold discoveries approximately 3 mi north of its Homestake gold mine near Lead, SD. Deep drilling from the surface intersected the gold mineralization more than 1 mi below the surface. The exploration program will include a drift from existing Homestake underground operations to reach the mineralization.³⁷

Inco Ltd., Vior Inc., and Cambior Inc. announced a new gold discovery on the Douay j.v. property 8 mi northeast of Joutel, Quebec, Canada. The j.v. property, which covers approximately 18 mi², is owned by Inco Ltd., the operator; Vior; and Cambior. An ongoing diamond drill program intersected 60 ft containing 0.23 oz/st gold and included 16 ft grading 0.35 oz/st and 10 ft grading 0.39 oz/st gold.

Canyon Resources Corp. announced that more than 600,000 oz of gold was discovered at the Briggs deposit in the Panamint Range, CA. In its recent purchase of Addwest Gold, Inc., Canyon acquired 100% ownership of the Briggs property, which includes approximately 24,000 acres of mining leases and claims in the southern Panamint Range.³⁸

DEVELOPMENT

A small decline occurred in the total number and value of new mining- and mineral-processing projects worldwide: 318 at a projected capital cost of \$59,700 million in 1989 versus 296 at a projected capital cost of \$55,700 million in 1990. The data may indicate a trend toward greater stability, with robust markets returning for certain base metals. Projected investment in North American copper production at \$1,260 million almost doubled the figure of the previous year. In Asia, projected investments soared to \$1,680 million, nearly triple the total of the previous year. Worldwide productive capacity for copper was predicted to increase by as much as 775,000 st between 1990 and 1992.39

Alaskan Mines

According to the Department of Natural Resources, lower development spending

but a higher level of mineral revenues is attributed to the changing status of two big mineral projects, Greens Creek and Red Dog, from development to production. The final development cost of \$144 million for Greens Creek is substantially higher than the \$80 million estimated 3 years ago. An environmental benefit at Greens Creek is the relatively small area that will be required for tailings disposal. Approximately 50% of the tailings will be used as backfill underground, and the employment of a mill process that yields dry tailings has reduced the size of the surface tailings disposal area to 34.6 acres—less than one-third that which would be required for a wet-tailings area for a mine of an equivalent size.

Regulatory officials accused Red Dog of fouling the fish-rich Wulik River with zinc and cadmium downstream from the mine. The company must pump contaminated water back upstream into the company's tailings pond, build culverts to divert uncontaminated water into the streams, and submit plans to prevent future ground water seepages. When in full production, the Red Dog open pit is expected to produce 560,000 st/yr of zinc concentrates, 120,000 st/yr of lead concentrate, and 50,000 st/yr of bulk concentrate from 2.1 million st/yr of mined ore.⁴⁰

The National Park Service (NPS) completed an environmental impact study on mining activity in three national parks in Alaska: Denali, Wrangell-St. Elias, and Yukon-Charley Rivers. The study was done in response to a lawsuit brought by several environmental groups. The review evaluated the effects of mining, including cumulative effects, within the three parks. The study recommends that NPS reacquire all lands held under both mining patent and claims in the three parks. NPS will make a final decision after a procedural review of the study and determination by the EPA.⁴¹

Mining Manganese From the Ocean Floor

In November 1990, the U.S. Department of the Interior and the University of Hawaii's Look Laboratory released the long-awaited final Environmental Impact Statement (EIS) on mining manganese nodules from the ocean floor near Hawaii. The study is the culmination of a 6-year effort by a State-Federal task force. The two-volume report points to the possibility of a new source of cobalt, manganese, and platinum ore for American industry, as

well as new economic opportunities for the State of Hawaii. Ocean floor mining would do little harm to marine life because there is little life under 8,000 ft of water, according to the report. However, bigger environmental problems would occur on land where the nodules would be processed, including air pollution, ground water contamination, noise, landfilling, and the need for large areas of land. The nearest leasable tract is about 200 mi from the main Hawaiian Islands.

Hawaii's Look Laboratory scientists said it is unlikely such a plant would be built in Hawaii because of strict Federal environmental controls. It is estimated that it could take another 10 years to develop the technology to mine the ore. The EIS addresses 10 potential seamount mining sites, estimated to contain 2.9 million st of cobalt, 1.8 million st of nickel, and 89 million st of manganese. Commercial amounts of platinum might be present, but that has yet to be confirmed.

New Nickel Projects

Strong nickel prices during 1988 and the first half of 1989 brought several previously shutdown mines back to life in 1990 and have prompted a spate of investment in new mines. Three underground mines are in the preproduction stage in the Sudbury basin and at least three more, in Botswana, Western Australia, and Indonesia, are at comparable stages of development. Another eight nickel projects are under consideration for development.

The largest of the projects at the feasibility stage is BRGM's proposed \$1.03 billion Tiebaghi development in New Caledonia. The project, in the north of the islands, would include a refinery that would incorporate BRGM's hydrometallurgical process.

In Western Australia, the Mount Keith deposit is under consideration for development by a joint venture of Australian Consolidated Minerals (50%) and Outokumpu Mining Oy (50%). Preliminary estimates for development cost are on the order of \$330 million. Reserves, which would be mined from an open pit, total 270 million st, grading 0.6% nickel.⁴²

Cyprus Reopens Iron Ore Property as Northshore Mining

The taconite mine and plant at Babbitt and Silver Bay, MN, formerly called Reserve Mining Co., was brought back into operation. Cyprus Minerals Co. breathed

new life in the property, which was in bankruptcy since 1986. Cyprus planned to produce more than 2.0 million long-ton (lt) pellets in 1990. By 1993, it plans to be producing 4.0 million lt/yr. Cyprus bought the bankrupt mine for \$52 million in June 1989 and began a \$29.9 million refurbishing program that will continue into 1991. The facility is undergoing renovations aimed primarily at meeting the requirements of its acid-pellet customers by increasing quality control and lowering costs. Northshore had only scheduled production of 1.7 million lt pellets in 1990, but interest from other customers raised that target to about 2.2 million lt in its first year of production.43

UNDERGROUND MINING

The Kiruna iron mine in Sweden is using innovative mining technology to increase production. Kiruna installed remotely controlled driverless trains for ore transport on the 775 level in the 1970's. This was a technically sophisticated system that still maintains a high efficiency. With its experience of the driverless trains, Kiruna is now developing a remote control system for LHD's, the so-called SALT Project (System for Automatic Loading and Transport). Filling of the loader bucket is remotely controlled by means of a television monitor and radio control. The rest of the LHD's working cycle is automatic, with the LHD following a cable in the floor of the drift. Using this system, for which production tests started in February 1990, one operator can control up to three LHD machines from a remote control room.44 This parallels work being done by the U.S. Bureau of Mines on remote control LHD's for narrow underground veins. To more fully use the application of the remote control and automatic system, Kiruna is instituting a large-scale mining method by increasing substantially the distances between sublevels in its caving operations and arranging these sublevel stopes in blocks of nine. The block will be three stopes wide and three stopes deep, and the stopes are mined in sequence. Blast holes are drilled up 79 ft and down 427 ft from the sublevels. This is reportedly twice the distance that any other operation is drilling. The size of the stopes and concentration of operations should not only be more productive, but adaptable to automation.

Computerized 35-st trolley locomotives operating at Molycorp's New Mexico mine increased underground block caving production from 1,250 to 1,900 st/d. Computerized communications, command, control, and monitoring equipment are reportedly producing savings on the order of \$500,000 per day.

The use of electric trolley trucks for underground applications continues with the purchase of a Kiruna-type truck and trolley system for haulage at Mount Isa Mines in Queensland, Australia. Wagner also introduced a new four-wheeled electric drive trolley truck for the industry.

A prototype compact underground boring machine for rapid excavation of underground exploration headings was developed by a joint venture and was tested in Canada. It is reported to bore 8-ft-diameter tunnels through hard rock at twice the rate of conventional drill-and-blast methods, with the inherent safety and improved working conditions of boring machines.

Hydrotransformers that drive closed-circuit, water-emulsion systems to operate equipment in the deep mines are now commercially available. The units were first shown to be economically feasible by the Kloop gold mine in the Republic of South Africa. The system operates rock drills, cleaning rods, watering-down and waterjetting guns, prop-setting intensifiers, and scraper winches for rock handling. Currently, one stope at the mine is operated completely by hydropower. Plans are to operate 40% of the mine with hydraulic systems.

An accurate nondestructive evaluation system to locate cracks in mine winder shafts and power-generating turbines is now being used in the South African mining industry. Originally developed to test turbines in nuclear power stations, the new hydropower system, containing 18 ultrasonic transducers mounted in 6 arrays, covers critical areas far more efficiently. Previous techniques used a single transducer placed at one end of a shaft. There are about 900 mine winder shafts in the Republic of South Africa.

Other innovations are the use of a grouting system and timber cribs for underground supports. The system consists of a pump, bag, and a high-yield grout with rapid setting and curing properties. The grout is chemically engineered to have the same comprehensive strength as the timber. It replaces blocking and wedging, a time-and labor-intensive process, and provides a more effective support.

To minimize wear and maintenance on vehicles used in trackless mines, one company developed a system of concrete paving slabs that interlock with a degree of flexibility to counter the less-thanperfect base found in underground mine haulageways. It can be installed with minimal disruption to the mining operation and is reported to result in cost savings for vehicle maintenance and repair. 45

Drill-Split

Drill-split primary fragmentation, an innovative mechanical excavation method, was developed to supplement or supplant drill-blast methods. The hydraulically powered, radial-axial splitter used by the system breaks rock in a unique action that gives the appearance of pulling a plug of rock from the mass. This fragmentation activity causes the rock to fail in tension, resulting in highly efficient excavation. Because the radial-axial splitter reacts to the forces it generates internally, it is a small device that can be adaptively mounted on lightweight carriers to meet different excavation needs.

After extensive laboratory testing of smaller tools, the U.S. Bureau of Mines developed and built a field-scale drill-split machine that has the ability to excavate one-half st of hard rock per operation. Both the drill and splitter are mounted on an indexing mechanism that provides the handling and feed operations for both tools from a single highly maneuverable boom. The boom is carried on an air-track crawler chassis for complete mobility. Excavation by this system is carried out through repetitions of the basic drill-split process.

Field tests of the mobile drill-split fragmentation system were conducted in an underground limestone mine. During this test, the drill-split fragmentation system produced more than 100 st of ore and produced an average 1 1/4 st per break. The underground field testing demonstrated several desirable characteristics of drillsplit fragmentation: (1) compatibility with concurrent operations, as the testing was conducted during the mine's normal day shift with no disruptions, (2) environmentally attractive operations that produce virtually no dust and no dangerous byproducts, and (3) inherently safe operations because of the static, nonviolent excavation action. Drill-split is a low-cost primary excavation method with the flexibility to meet the needs of diverse operations.

Decoupling

Decoupling methods once used primarily at surface mines are finding increased underground applications. A good example is the Bureau's tests conducted in the Homestake Mine's Vertical Crater Retreat (VCR) stopes. Hanging wall blastholes were loaded with less than one-half the normal explosive and decoupled. In comparison to control panels using conventional blast designs, ore dilutions as great as 35% were reduced to 3% to 9%.

Concave Bit

The U.S. Bureau of Mines developed a new bit that promises greater productivity and longer life than conventional point-attack bits while using less force and energy. This new bit is called the concave bit because of its concave front surface. Normally the efficiency is better when the concavity is greater. It has a round shank that allows use with standard bit holders and continuous rotation making the entire periphery of the front surface the effect cutting edge. This bit is designed to replace drag bits and can be used on all mechanical excavators such as roadheaders, continuous miners, shearers, and plows.

Camera System on Roadheader

Closed-circuit television equipment specially designed for use in mine development work by Rees Instruments Ltd., United Kingdom, is reported to have successfully completed trials at British Coal's Sherwood Colliery in Nottinghamshire. The system, incorporating an R331.01.000 intrinsically safe camera and R305.00.000 flameproof monitor with integral IS powersupply unit was developed by Rees in order to improve roadheader performance and enhance the operator's safety.

In roadway drivage underground, once the roadheader's boom-mounted cutting head has made sufficient progress, the machine is withdrawn to allow insertion of steel support arches, before advancing again. When it does, the machine must cut out past the last arch set on the blind (left) side. This is normally a two-person job, with one acting as a "spotter" to pass information to the operator.

The camera-television system dispenses with the spotter. The camera is mounted in a stainless steel tube inside an adjustable steel box on the handrail at the left side of the roadheader and transmits black-and-white pictures to a 12-in screen within its

flameproof enclosure. The driver can thus accurately position the machine prior to resuming cutting.

Rees engineers found that, in practice, certain on-site modifications were necessary because of the tough mine operating environment, but excellent pictures are now being achieved consistently, and the system is used by all drivers. Modifications have included mounting a diffused headlight on top of the camera enclosure to improve lighting levels. Once actual cutting has started, the television picture is obscured by the reflection of the main lights on the machine on the dust but, by this time, the camera has fulfilled its purpose and accurately positioned the cutting head.⁴⁶

SURFACE MINING

The advent of the microprocessor and its adaptation to the rugged conditions of mobile-equipment operations in the mining industry has caused a radical, but often underestimated, revolution in surface mining. The range of this new technology is all-embracing. It includes geological and survey instrumentation, geotechnical measuring devices, manufacturing design of all types of mobile equipment, and applications in control, operation, and maintenance of all types of surface plants. The variety of microprocessor uses include drilling performance monitoring parameters, providing fault system diagnostics for electric face shovels, measuring ore weights in loaders and trucks, and eliminating torque spikes in large mechanical-drive trucks. The pace of change has been and is rapid. New fields continue to open, and it is not unlikely that the next decade will see such items as the guided automatic haul truck or the automated rock drill.47

The number of surface mine closures in 1990 due to depressed markets was small and largely offset by the number of mines opened. Gold remained the most sought-after commodity. Copper continued to stage a remarkable recovery. High commodity prices continued to fuel the strong comeback. Asarco announced plans to spend an additional \$80 million at its Ray Mine and Silver Bell unit in Arizona. This will further expand the company's total domestic copper production from 220,000 st to 360,000 st/yr.

Santa Fe Pacific Gold began production at its \$77 million Rabbit Creek Mine near

Winnemucca, NV. The 1,600-st/d carbonin-leach (CIL) plant is expected to produce 100,000 oz/yr in 1993. The company also announced plans to expand the production capacity at the mine and mill to 200,000 oz/yr by 1992 at a cost of \$60 million. The direct cost of production for the expanded plan is expected to be \$190 per oz. Proven and probable gold reserves at Rabbit Creek is 3.6 million oz. American Barrick is in the midst of a major, \$365 million expansion program at its Goldstrike Mine near Elko, NV. When completed, the mine will increase its production from 352,880 oz in 1990 to 900,000 oz by 1993. Pegasus Gold began building the \$11.8 million Black Pine open-pit, heap-leach gold mine in Idaho. The mine is expected to produce 40,000 to 80,000 oz/yr.

Atlas plans to spend \$80 million to develop the Grassy Mountain Mine in Oregon to produce 100,000 oz/yr of gold and 100,000 oz/yr of silver for 8 years.

The Denton-Rawhide is a joint venture among Kennecott, Kiewit Mining Group, and Plexus. The open-pit, heap-leach operation began operation in 1990. The mine is expected to produce 80,000 oz/yr of gold and 399,000 oz/yr silver for the next 5 years.

Battle Mountain was given the go-ahead to develop its San Luis Project in southern Colorado. Total cost of the carbon-in-pulp (CIP) facility is estimated at \$20 million. At full capacity, the San Luis plant will produce 61,000 oz/yr. Cominco brought the Red Dog zinc-lead mine into production at a cost of \$415 million. Current reserves at Red Dog are 85 million st at 17% zinc, 5% lead, and 2.4 oz/st silver.

The Escondido Mine came on-stream in northern Chile. This \$900 million mine and concentrator is expected to produce 352,000 st/yr copper in concentrates. Geologic reserves amount to 2 million st grading 1.6% copper. Production began at the Bogosu gold project, a joint venture between Billiton BV (62%), Sikaman Gold Resources (14%), IFC (13.5%), and the Government of Ghana (10%). The \$86 million open-pit mining operation has reserves of 21 million st grading 0.1 oz/st. Gold production at the (1.2 million st/yr) mine is expected to total 137,000 oz/yr.

The Porgera Mine Project consists of Placer Dome (30%), Highlands Gold (30%), Renison Goldfields (30%), and Papua New Guinea (10%). The \$1 billion project is expected to produce 900,000 oz/yr of gold at an average cost of \$150/oz. Ore reserves are 56 million st grading

0.22 oz/st gold. The Granny Smith mine (Placer Pacific 60% and Delta Gold NB 40%) began gold production at a rate of 150,000 oz/yr in Western Australia. The \$77 million project contains ore reserves of 25 million st, with an average grade of 0.05 oz/st. 48

Alcoa closed the last operating bauxite mines in the United States at the end of May 1990, after 91 years of operation because ore reserves were exhausted. The mines are in Saline County, AK, adjacent to Alcoa's Arkansas operations. The operations include a bauxite refinery and alumina chemical facilities. The refining operations, which produced 275,000 st/yr of alumina, will also be closed. Chemical production will continue at the site using alumina feedstocks from other Alcoa locations. For most of the history of the plant, alumina was produced to be made into aluminum, but more recently the alumina was used to produce 135 different products from 6 alumina-based chemicals. These chemical products were used in highperformance refractories and cements, ceramics, fire retardants, and in paper and pharmaceuticals. About 200 people either retired or were laid off, reducing staff at the plant to about 700 49

Equipment

Perhaps the two most obvious trends in the past few years have occurred in haul trucks. The 240-st-capacity haul trucks appear to be here to stay, as well as the mechanical-drive, 170-st trucks from Caterpillar. One major trend common to both mechanical-drive and electric-drive systems trucks is the rapidly improving electronic control systems. A memory logger can be placed on-board to record the readings of a wide assortment of gauges. When problems occur, they can be played back in the shop, revealing under what conditions the problem appeared, much like a flight recorder. If a failure occurs, the onboard electronics can not only determine which component has failed, but how serious the failure is, whether it requires immediate attention, or whether service can wait until the end of the shift or later in the week.

Haulpak (Komatsu-Dresser) is one of several manufacturers offering its own onboard weighing system. In the Haulpak system, sensors are mounted in strategic places in the frame of the truck and connected to a microprocessor in the payload meter mounted in the driver's cab. While the driver watches the weight, the shovel

operator watches the light assembly mounted outside on the deck. The lights flash green, amber, and red, depending on whether the truck is underloaded, loaded between 90% and 105% of rated capacity, or overloaded. Because the system has a microprocessor, it is capable of recording the final weight just before the truck begins its haul. The payload meter has the capacity to store data for 200 haul cycles. A printer is available that typically lists the driver, total number of loads, the weight of each load, the time each haul cycle began, the date, and the total weight moved for that shift.

High quality is another trend. All manufacturers are gaining a solid reputation for reliable machines. Problems inherent with the larger haul trucks have largely been overcome. Haulpak has a multimillion dollar test center where entire truck frames, pulled off the assembly line at random, are tested with bending and twisting loads, simulating years of normal stress in just a few day's time. Any potential problems show up in the laboratory where they are corrected before they have a chance to cause downtime. The result is that their frames have benefited from increased reliability.

Many remarkable trends are found in front-end loaders (FEL's). In addition to their increasing size, they are also benefiting from the electronics revolution. Loaders are also beginning to compete with shovels in some applications. Not only are loaders more mobile than shovels, they can clean up more efficiently.

Many mines have introduced in-pit crushing with mobile crushers, and many more are considering it. Conveyors can move material inexpensively, but need an in-pit crusher to ensure the proper size material. For mobile crushers with mobile connecting belts, FEL's are required to move the material the short distance from the face to the crusher head.

Big loaders in easily diggable material offer shovels more competition. The FEL is more maneuverable than a shovel and requires a lower initial investment. It can be easily moved to get out of the way of blasts. The FEL can also do limited load-and-carry work.

This trend toward using FEL's as short-haul units is causing a change in their design. FEL's are required to haul material further as distances increase between the face and the crusher hopper. Suspensions of FEL's are notorious for having very little shock absorption, causing them to

bounce wildly at increased speeds. Now, Caterpillar has introduced a Ride Control System to allow FEL's to move material longer distances at higher speeds.

Caterpillar has come up with a clever way for a FEL to weigh the material in the bucket-not just while the machine is at rest, but while it is in motion. Knowing how much is in each bucket can greatly aid loading a truck to its proper capacity, not underloading or overloading. By taking the system dynamics and geometry of the loader and knowing where the various loads will be, the FEL's can precisely report the load in the bucket. The scales have an accuracy of 3% when the loader is moving and 1% when stationary. The hardware is the same as for Caterpillar's haul-truck payload monitors, but the software is different, taking into account the fact that the FEL will be moving while the load is being measured. It was under field tests in 1990 and was scheduled to be commercially available in 1991.

According to Caterpillar researchers, the next generation of electronic systems will monitor performance over the life of the machine, allowing performance trends to be easily spotted. This should happen soon because electronic memory is steadily becoming less expensive. Variabilities in performance can be traced to shifts, operators, or other variables. Also, a telemetry system would send operational data to a central point with more detailed software capable of spotting trends common to all trucks. Ultimately, these systems will provide a warning before a major failure, not just on an individual-truck basis, but on a fleetwide basis.

There is also a trend toward modular components. For example, in order to decrease downtime, many large units, especially haul trucks, have engines that can be changed out easily and their waiting replacements slipped back into place. The machine is immediately operational, with the shop free to repair or overhaul the engine without the intense pressure of getting the truck back out on the line again immediately.⁵⁰

World's Largest Mechanical-Drive-Wheel Bulldozer.—A machine originally devised early in the past decade for use in the major opencast iron ore mines of Western Australia was further developed and refined for use in ore and coal mining and power station applications. The Tiger 690B, built by Tiger Engineering Proprietary of Perth, West Australia, is

reportedly the world's largest mechanical-drive-wheel dozer with an operating weight of almost 90 st. It can be equipped with dozer blades up to 54 cubic yards (yd³) capacity. Studies in Australia and North America reportedly show that the 690B can doze coal at 750 st/h over a one-way dozing distance of 600 ft. This increases to 1,000 st/h over 300 ft and 2,100 st/h at 100 ft.

A particular benefit of the machine design in bulk coal handling work is the high compaction effect of its large radial tires; this significantly reduces the risk of spontaneous combustion in coal stockpiles. Other tasks for which the machine is well suited are cleaning work around large mining shovels, push-loading scrapers, and selective dozing work in the large open pits.⁵¹

Largest Mineral-Sand Dredge.-The world's largest mineral-sand dredge, and the largest dredge of any kind in Australia, began work at Cooljarloo in Western Australia in December 1989. Eighty-seven mi north of Perth, Cooljarloo is the world's first integrated project to turn titanium minerals into paint pigment. Partners in the venture, which will generate annual exports worth Aus\$200 million, are Minproc Chemicals Pty. Ltd., a subsidiary of Kerr-McGee. The "Cooljarloo I" bucketwheel dredge is the first electric line-shaft-driven dual-wheel excavator. The 900-hp dualwheel excavator head is 160 inches in diameter and weighs approximately 110 st.52

Backhoe-Mounted Dredging Excavator. - Ellicott Machine Corp., Baltimore, MD, developed a hoe-mounted dredging excavator (HMDE) known as the "Hoe Dragon," which makes possible the continuous excavation and pumping of underwater minerals when used in conjunction with a standard model track-mounted backhoe. The combination of backhoe and dredging excavator is said to maximize the capability of the backhoe and provide continuous excavation and material transport from point of loading to disposal without interruption for swinging with boom and bucket manipulation typical of normal backhoe operation. It is in effect a new tool for underwater excavation of both loose and consolidated materials and can extract mineral in both a forward and aft digging mode.

The backhoe can also be walked onto a barge and operated as a swinging ladder-

type dredge while discharging to a shore point, into another vessel, or attendant mineral processing system. This type of equipment is well-suited to recovery of small alluvial gold and diamond deposits inaccessible to floating equipment.

The Hoe Dragon offers the combined advantages of a dual-wheel excavator and a wide-bodied pump that transports virtually all excavated material. A flotation option is available in which special devices are fitted to reduce the submerged weight of the module. This feature allows its use in backhoes not normally able to handle the Hoe Dragon because of its weight. Flotation in this manner also allows for extended reach, without impairing the hydraulic or stability limits of the backhoe. Specially designed extendable stick mechanisms are offered for deep digging applications. 53

Hydraulically Powered Machines Getting Bigger.—At surface mines hydraulic excavators are getting bigger—and are challenging rope shovels in more and more applications. Excavator weights have been climbing, and some of the newer hydraulic shovels on the market have working weights of 400,000 lb and more. One Supersize hydraulic excavator is Demag's H485, which has a gross operating weight of 1.2 million lb. The first units were placed in coal and tar-sand mines. A unit was put into operation in 1990 at Boliden Mineral's Aitik copper mine in northern Sweden. A 920,000-lb, 530- to 1,060-cubic feet (ft3)capacity prototype, the SMEC 4500, built by Japan's Kobelco, underwent long-term mine trials at BHP-Utah's Blackwater coal mine in Queensland, Australia.

Despite all this, the rope shovel remains the dominant digging machine in the shovel family. Some of the advantages in design that have been recently incorporated into some of the electrically powered rope shovels include the following: advanced direct current static power conversion, dual planetary propel drives for improving maneuverability and travel speed; electronic programmable logic controllers that replace all the mechanical logic relays previously used for sequencing the electrical system; and solid-state electrical control systems that eliminate moving parts between the high voltage alternating current power coming in and the direct current power for the motion motors.54

Controlled Blasting

Surface mines are using controlled blasting techniques to reduce rockfall

hazards and improve blast casting by maintaining a uniform and predictable burden. Since the bulk of the material is cast by the front row of blastholes, this burden dimension is critical to the success of the entire cast. Many mines are adapting presplit techniques to reduce rockfall hazards. The economic aspect of transitory highwalls encourage methods such as the popular air deck prosplit, low-density explosives, and decoupling techniques. The U.S. Bureau of Mines demonstrated several techniques that deal with a broad range of conditions where air decks and decoupling may be used.

REMOTE MINING

Borehole Mining

The frozen placers in Alaska contain vast deposits of columbium, gold, platinum, and tin. In the past, dredging has most often been the choice for mining these deposits. Now that most of the shallow, dredge-type deposits have been mined out, the use of conventional surface and underground methods to mine the remaining deposits would not be economical.

The U.S. Bureau of Mines-developed borehole mining system has been successfully tested in coal, oil sands, phosphate, and uranium ore. This system can remotely extract a mineral deposit through a borehole. A tool consisting of a water-jet nozzle and slurry eductor is lowered into the deposit, and the water jet erodes a cavity in the mineralized ore, which it slurrifies and pumps to the surface. The values are extracted from the slurry through settling ponds or other means, and the waste material is then returned underground by operating a similar tool in reverse.

In addition, borehole mining research is continuing in the U.S.S.R. To date, gold ore, iron, and titanium have been mined successfully using the borehole mining system.

In Situ Leach Mining

The U.S. Bureau of Mines is conducting research to develop in situ leach mining technology for oxidized copper deposits and oxidized manganese deposits. In situ leach mining offers the potential to significantly reduce production costs that would allow the economic recovery of minerals from small-, deep-, and/or low-grade mineralized deposits. In addition, the method requires significantly less surface

disturbance when compared to conventional mining methods.

Preparations for an in situ copper leach mining field test are underway at the Santa Cruz site near Casa Grande, AZ. A five-spot well pattern was constructed, and a salt tracer test was conducted to obtain hydrologic leaching tests. Geologic characterization studies of the ore were also conducted. These data were used to prepare the field test design plan, and the environmental permit applications required before the in situ mining test with dilute sulfuric acid can begin.

Two manganese deposits in the Cuyuna Range of north-central Minnesota are being evaluated for in situ leach mining in the future. One core hole was drilled into each deposit to provide additional information on site geology and to provide samples for geologic characterization studies and laboratory leaching. Laboratory leaching tests with a sulfur dioxide leach manganese from the metal-bearing solution are being developed. These data will provide a basis to evaluate the technical, economic, and environmental feasibility for in situ mining these deposits.

Hot Spots Show Coal-Rock Interface

Development began on a new coal interface detection (CID) system by the U.S. Bureau of Mines. The system employs a highly sensitive, passive infrared (IR) capable of measuring the temperature changes that occur when mining machines contact different types of geological materials, such as coal, sandstone, and limestone. In a passive IR system, naturally generated, thermal IR radiation can be detected—no active IR illumination source is required. With the recent advances in sensor technology and computerprocessing capabilities, researchers have been seeking an instrument to sense precisely the interface between coal and the other strata. Such an instrument would become indispensable in longwall and continuous mining, boosting productivity, reducing amounts of rock and minerals that must be removed from coal, and providing additional technology for underground automation.55

Automated Hoisting

One area of many underground mines that has already become automated is the shaft. Because of a hoisting accident 2 years ago, Placer Dome was forced to replace the skips, chairs, and dump in its No. 8 shaft in the Timmins Mine. Placer Dome also decided to enhance the automated ore-hoisting process.

Programmable "logic controllers" (PLC's), installed on the mine's underground water pumps in 1985, worked so well that they were also used to automate the loading pocket operation. During a 3-year, fault-free operating period, the number of 14-st skips hoisted during an 8-hour shift jumped to 152 from 127. After shaft rehabilitation during 1988, the mine now hoists 160 16-st skips per shift.56

Automated Train Haulage

An automated ore-handling system exists at the Golden Giant Mine in Hemlo, Ontario, Canada. Ore from the mine's ore pass system is fed through chutes into 22-stcapacity, bottom-dump ore cars on the 4335 level. The (unstaffed) PLC-equipped locomotive is controlled remotely during the loading cycle by an operator in the surface control room using video monitors. The locomotive is then placed on automatic control and hauls cars to a coarse ore bin that feeds into the underground crusher on the 4295 level and returns for another load. PLC's also monitor the ore feeder, crusher, discharge conveyor, and levels in the fine ore bin. The 4235-level loading pocket below the crusher is fully automated as is the production hoist. Having achieved a hoisting record of 6,600 st in a 24-h period, the company is now looking seriously at increasing the speed at which the 17.6-st skips are hoisted along the 3,756-ft distance to the surface.57

BENEFICIATION

Effect of Grinding

Effect of grinding and electrochemical interactions on the flotation of minerals was studied extensively in 1990. For example, it was found that the grinding media and environment can affect the surface properties of sulfide minerals, thus causing either improvement or deterioration in their floatability. 58

Flotation

Froth flotation continued to be the most widely used separation process in mineral processing. In the past year, research continued to focus on the hydrodynamics within the flotation cells and the description of the bubbles in the pulp and froth

phases. Kinetic models of bubble and particle collisions were refined to more accurately portray real-world results.⁵⁹

Rapid Flotation

The U.S. Bureau of Mines is developing a rapid flotation system. The speed of flotation is governed by the rate of bubbleparticle attachment and bubble-pulp separation. In most conventional flotation cells, attaching the bubble to the fine particles is the slowest step in the flotation process, often requiring 5 to 15 minutes for completion. Intense mixing of the air bubbles and ore pulp speeds up this process, but the higher levels of agitation also disturb the relatively quiescent surface of the cell where the froth concentrates the hydrophobic minerals. The disturbance usually lowers recovery by detaching particles from the bubbles and lowers grade by allowing suspended gangue to overflow into the concentrate. In a conventional flotation cell, interaction between the agitation for rapid bubble-particle attachment and the pulp quiescence required for selective recovery of the froth make it virtually impossible to optimize one of the processes without sacrificing the effectiveness of the other. In 1990, the Bureau devised a revolutionary flotation system using discrete unit operations for bubble-particle attachment and bubble-pulp separation. The conditioned ore is pumped to the bubble-particle attachment unit where intense agitation with another stream of externally generated bubbles quickly attaches the hydrophobic particles to the bubbles. After passing through the bubble-particle attachment unit, the mixture enters a shallow tank where the mixture spreads horizontally near the top of the tank. The bubbles quickly rise to the top and overflow at the outer edge of the tank. The relatively quiet flow in the tank cleanly recovers the bubbles from the pulp, and the shallow depth of the tank allows the bubbles to separate quickly from the pulp. Using a phosphate-bearing sample, the rapid flotation system recovered 76% of the phosphate at a speed 20 times faster than a conventional flotation system using the same sample. In addition, the conventional flotation system process only recovered 65% of the phosphate. Similar test work on coal and porphyry copper ore samples demonstrated rapid flotation with acceptable product grades and recoveries. The rapid flotation circuits will be many times smaller than the current conventional flotation circuits and

should cost less to construct. In addition, present facilities with limited space will be able to expand their capabilities with the rapid flotation system without enlarging their buildings.

New Phosphate Resource Produced From Waste Ponds

New reclamation techniques have yielded large quantities of dried mining waste containing high amounts of phosphate from impoundment ponds in Florida. But these wastes also contain significant amounts of undesirable contaminants such as aluminum, iron, and small amounts of radium.

The U.S. Bureau of Mines developed a way to remove most of these contaminants so that this "new" phosphate resource can be used. The Bureau's technology involves leaching phosphate values from the clay wastes using sulfuric acid as the leaching agent and methane as the solvent. Research showed that about 85% of the phosphate can be recovered in the form of a phosphoric acid suitable for fertilizer manufacture. A new flotation technique, also developed by the Bureau, enables the leach tailings to be separated efficiently from the methane-phosphoric acid product.⁶⁰

Procedure Demonstrated to Take Valuable Metals From Sulfide Ores

The U.S. Bureau of Mines developed a procedure, based on oxidation under pressure, to recover valuable metals from sulfide ores. Cobalt, copper, nickel, and zinc, commonly found in the United States in massive sulfide ores, cannot be effectively upgraded by physical separation. They must be processed by chemical methods. These ores also contain gold and silver; however, these precious metals cannot be extracted by standard cyanide processes.

The Bureau successfully demonstrated a laboratory process to recover cobalt, copper, gold, silver, and zinc from an Oregon massive-sulfide ore. The ore is pulverized and placed in a medium-pressure vessel. With the addition of water and oxygen, the ore is heated to 392° F. The cobalt, copper, and zinc are dissolved and recovered from the solution, and the ore residue is altered so that the gold and silver can be easily extracted by cyanide solution. The use of pressure oxidation is being used by a few operations to recover gold.⁶¹

New Bio-Oxidation Technology

U.S. Gold Corp. produced its first gold-utilizing bacterial oxidation. The company has been a pioneer in commercializing this new technology over the past 2 years. The bio-oxidation process developed at the Tonkin Springs Mine in Nevada uses naturally occurring bacterium *Thiobacillus ferrooxidans* and pretreats refractory gold ore. The process breaks down the iron and sulfur compounds within the ore releasing the gold, which is then recovered using conventional milling methods.

Because bio-oxidation allows for development of this important class of gold deposits, it could be the technology of the nineties for the gold industry. The process should provide a lower cost in processing sulfide refractory ore and has important environmental benefits. For example, byproducts of bio-oxidation can neutralize residual cyanide in mill tailings, rendering the cyanide harmless.

The newly constructed \$31 million Tonkin Springs mill has a design capacity of 1,500 st/d with a designed 90% recovery rate that should produce 50,000 oz of gold annually. This initial gold pour represents a major milestone for the company demonstrating the technical feasibility of bio-oxidation. However, the mill must still demonstrate commercial and economic viability, which is dependent on operations reaching full-scale production. 62

Wet Milling

Minimizing a worker's exposure to asbestos fiber remains a top priority in 1990 for operators of mills that treat asbestos ore. Current Canadian regulations permit two fibers of asbestos per milliliter (ml) of air, while other countries have lowered the limit to 0.5 fibers per ml. Baie Verte Mines, a 100%-held subsidiary of Cliff Resources Corp., which operates an asbestos mine in north-central Newfoundland, Canada, thinks it has found a solution to airborne fiber-a solution that could keep the operation going for another 18 years. To recover more fiber from its ore, the company spent \$18 million to construct a wet mill that in March began recovering more asbestos from the tailings stream of the existing dry mill. When that dry mill is decommissioned 3 years from now, the new mill will continue to treat asbestos tailings that have been stockpiled for the past 36 years. At a rate of 55,100 st per year, that would suffice for about 15 years of operation.

Experience in a prototype mill constructed at the Woods Reef Mine in New South Wales, Australia, in 1981 showed that occupational exposure to asbestos fiber could be maintained at less than 0.08 fibers per ml. The process was developed in a research project that began in 1977.63

Carbon-in-Leach With Oxygen (CILO) Cost Study

Minproc Engineers (United States) prepared a cost study to compare carbon-in-leach with oxygen (CILO) and conventional CIL circuits designed for equivalent extraction of gold. The key assumption is that CILO can reduce the retention time by a factor of four compared to CIL—something that can reportedly be demonstrated in laboratory tests for a specific ore.

The study provides capital and operating cost comparisons for the leach-absorption section of CILO and CIL circuits of 1,100, 3,310, and 5,510 st/d throughput. Costs for an open design in moderate climate conditions and for an enclosed design for more inclement weather are included for each case. Capital savings range from about \$900,000 for the 1,100-st open plant to about \$3.2 million for the enclosed design. The savings become increasingly significant as the capacity increases and may suggest some new options for large-tonnage, low-grade projects that are currently being considered only for heap leaching.

Operational savings are based on reduced power requirements and reduced cyanide consumption, with an allowance for oxygen costs. Projects savings are said to range from about \$70,000 per year for the 1,100 st circuit to about \$315,000 per year for the 5,510 st circuit.

Kamyr Inc., from whom the patented CILO process can be licensed for commercial production, suggests that the capital and operating cost savings are also compelling reasons to consider CILO for any new project. The company can provide a variety of services to process users ranging from technical assistance in process application to a complete mill.⁶⁴

Real-Time Ore Analysis

The new model 200, offered by Outokumpu Electronics of Finland and widely used in the minerals extraction industries, was introduced to the range of Beltcon on-line analyzers. The novel feature of the model 200 is its measurement principle: the Beltcon uses X-ray fluorescence (XRF) to measure simultaneously the concentrations of any two elements from potassium to uranium.

The analyzer is able to operate on both fine and course bulk materials directly from the moving conveyor belt and is thus well suited to mineral processing and metallurgical applications. A typical use is in analysis of calcium and iron in limestone. The noncontact system is easy to install on operating conveyors without the conveyor being modified. The analyzer is above the belt; there is no contact with the moving ore stream, and no physical sampling is required.

Analysis is reportedly very rapid at 300 measurements per minute and, as each assay is based on several thousand measurements, the results obtained are described as highly reliable and accurate. A personal computer can be interfaced to the analyzer for versatile data processing. The results are available on a serial output to either a terminal and/or printer for standalone operation or to a personal computer for more versatile data processing. The data are also available as 4 to 20 milliamperes current outputs for recorders, controllers, etc. The control and alarm outputs allow the system to be used for direct-process control. Benefits are said to include lower production costs through improved selective loading, as well as increased efficiency and higher product quality through process stabilization.

The personal computer calculates and displays measured average analyses over the measurement period; it stores the 6,000 latest measurements, 200 shift levels, and 350 latest daily levels. These measurements are also available for statistical processing. The display shows continuously the results of the latest assays as well as cumulative shift and daily averages, indicating any trends.

The Beltcon 200 requires little maintenance as there are no moving parts, and, under normal operating conditions, no user intervention is necessary.65

Magnetic Separators

In 1990, Boxmag-Rapid Ltd., the Birmington, United Kingdom-based magnetic mineral separation specialist, launched a new range of high-intensity magnetic separators utilizing powerful rare-earth permanent magnets.

Designated the Magnaroll, the new separator was designed to remove weakly paramagnetic minerals or fine iron scale

from nonmagnetic feed material. The feed passes over a head pulley, and nonmagnetics are thrown from the roll by centrifugal force while the magnetic particles adhere to the belt and are discharged into a separate chute. Separation flexibility is introduced by providing an adjustable splitter plate to separate the nonmagneticmagnetic fractions and by varying the rotational speed of the Magnaroll. The head pulley is manufactured from powerful neodymium-boron-iron rare-earth magnets. The choice of two different roll diameters, 3 in for fine particle and 4 in for course materials, allows an optimum magnetic circuit to be designed for each individual mineral.

The magnetic field strength produced by the Magnaroll on the feed belt surface is usually between 9,000 and 10,000 gauss, and the exceptionally high field gradients achieved by the magnetic circuit design gives excellent separation performance, reportedly comparable to traditional induced roll magnetic separators.

Typical applications for the Magnaroll include purification of silica sand and feldspar, andalusite upgrading, and removal of iron scale from spray-dried ceramic granules. Capacities for the MRI.1000 Magnaroll, which has a feed belt width of 39 in, range from 2.2 to 11 st/h, depending on the mineral application and particle size of feed.

The Magnaroll can effectively process a wide size range of feed materials, from 1.5 in down to 1.77 x 10⁻³ in. This compares very favorably with the feed range to an induced roll (less than 0.1 in down to 1.77 x 10⁻³ in). The extra flexibility is said to have opened up new uses for high-intensity, dry magnetic separation; for example, coarse magnesite-serpentine separation. 66

New Rare-Earth Metal Refining Method

A new method to refine rare-earth metals by means of laser purification and selective ionization was developed by researchers at the National Research Institute for Metals of the Science and Technology Agency and Nippon Steel Corp.

The process, while not new in concept, is reported as the world's first demonstration and proof of the purification concept. The new technology involves vaporizing a rare-earth metal with a beam of electrons and then directing a laser into the metal vapor to separate impure elements. The technology could enable purification of any

type of rare-earth metal simply by altering the wavelength of the laser.

In the experiment, however, efforts were directed at the metal neodymium and praseodymium was removed, considered to be the most difficult element to separate from neodymium. The experiment succeeded in reducing the amount of praseodymium in neodymium metal from 1.5% to 0.09%. Previously, a purity of 99.9% was considered the limit of refining for rare-earth metals, but the new process should permit even purer final products.⁶⁷

HEALTH AND SAFETY

Safety Data

Preliminary injury and employment statistics compiled by the Mine Safety and Health Administration (MSHA) for 1990 showed that there were 56 mine fatalities in the Nation's metal and industrial mineral mines, eight more than in 1989. The same data showed that the average number of employees increased by only 0.5%, much less than the 4.0% average increase in 1989 and the 5.6% increase in 1988. From the MSHA data, employee-hours were shown to decrease by an early estimate of 6.6%, in contrast to 1989's increase of 2.7%. Total reported injuries decreased following an increase for 4 consecutive years, dropping to about 7.2 per 200,000 employee-hours, down from a 8.0 rate for 1989 and 7.9 in 1988. The rate of nonfatal injuries requiring lost work time was essentially the same as those in 1989 and 1988. Approximately 4.3 of such injuries occurred per 200,000 employee-hours in 1990, 4.4 in 1989 and 4.3 in 1988. All figures include independent contractors.

Legislation

The Occupational Safety and Health Administration (OSHA) revised its 1986 asbestos standard by banning smoking by workers in all areas where there is occupational exposure to asbestos; requiring employers to provide workers with literature on smoking cessation programs; issuing new requirements for respirator use; and modifying its hazard-communication program on training, labeling, and posting of warning signs. The agency also proposed reducing the permissible 8-hour time-weighted average limit to 0.1 fiber per cubic centimeter (f/cm³); introducing work practice standards for

certain occupations; requiring notification of OSHA prior to asbestos removal, demolition, or renovation; modifying hazard communication standards and project monitoring requirements; and dealing with requirements for negative-pressure enclosures.

OSHA extended a partial stay on the ruling that established exposure limits for the nonasbestiform varieties of actinolite, anthophyllite, and tremolite through November 30, 1990, while it continued to evaluate the economic impact on the mining and construction industries and whether to regulate nonasbestiform amphiboles under the standard for asbestos.

MSHA continued a review of its proposed revision to its existing asbestos standard. The proposed permissible 8-hour time-weighted average exposure limit will be reduced from 2.0 f/cm³ to 0.2 f/cm³ if the proposed standard is enacted.

In February 1990, OSHA proposed to reduce the Permissible Exposure Limit (PEL) for airborne cadmium to either 1 or 5 micrograms cadmium per cubic meter of air $(\mu g/m^3)$. The current PEL is $100~\mu g/m^3$ PEL for cadmium fumes and $200~\mu g/m^3$ for cadmium dust.

OSHA held two public hearings, one in Washington, DC, in June, the other in Denver, CO, in July. These hearings were held to obtain further information on the feasibility of meeting a 1 or $5 \mu g/m^3$ PEL for cadmium using engineering controls and/or administrative controls. The Agency was expected to reach a final decision by the second quarter of 1991.

MSHA continued to review a proposed revision to its existing talc exposure standard and proposed introducing an exposure standard for soapstone. The proposed permissible 8-hour time-weighted average exposure limit is 2.5 milligrams per cubic meter (mg/m³) for talc (containing no asbestos), 3 mg/m³ for respirable soapstone dust, and 6 mg/m³ for total soapstone dust.

Human Factors

The use of extended workdays, shift lengths longer than 8 hours, received increasing attention in 1990 by the mining industry in the United States and Canada.

Despite the attractive features of these alternative work schedules, questions remain about possible safety and health risk factors associated with extended workdays in mining.

Increased fatigue, decrements in behavioral performance, increased errors, and longer exposure to airborne contaminants and environmental hazards are factors that must be considered in a 10- to 12-hour day. To address these, the Bureau initiated a human factors field research study of extended workdays in underground mining. Cooperators are an underground metal mine in western Canada and the British Columbia provincial government. The first phase of the study was completed in May 1990, while mine workers participating in the study still were on a rotating 8-hour shift schedule. The second phase of the study is scheduled for May 1991, 10 months after the workers in question changed to 12-hour shifts. The same measures will be repeated on the same subjects.68

Research

Ground Control, Roof Support.—The U.S. Bureau of Mines is developing improved waveform processing and tomographic image capabilities to assist in the interpretation of subsurface geologic and hydrologic features. The crosshole systems are used with advanced tomographic imaging. They permit visually opaque earth structures to be viewed by acoustic (sound-seismic) waves in a manner similar to the way computer-assisted tomography (CAT) scans view parts of the body.

The first known application of fiberglass dowels, or forepoles, in a room-and-pillar continuous mining development section was completed at the South Field Mine in Utah by the Bureau. The forepoles were installed ahead of the working face into the mine roof for distances of up to 20 ft and were held in place by a resin-type grout. Air was injected into the face and overlying strata to evaluate the tightness of the fractured rock strata before and after forepole installation. This demonstration of the use of forepoles provided access to previously inaccessible coal reserves. It also verified theoretical models that indicated that forepoling maintained the integrity of roof strata after mining.

An automated, minewide monitoring system was successfully deployed by the Bureau at the Foidel Creek Mine, Cyprus Yampa Valley Coal Corp. This system is obtaining ground and shield pressure data from 100 instruments and continuously transmitting the information to a central site. Three-dimensional computer programs

were developed to graphically display the data and permit detailed examination of stress buildup and load transfer trends as mining progresses. The system has predicted ground pressures ahead of the face for distances of up to several hundred feet. It will form the foundation for developing an effective tool for mining engineers and management to evaluate and control the ground conditions in real time.

Bureau field testing of a short-pulse radar system in a West Virginia coal mine successfully located cased and uncased boreholes 50 ft inside a block of coal. Radar penetrations of 200 ft were achieved with minimal attenuation. Experience showed that the best radar configuration from operational and analysis viewpoints involved transmitting from one side of the panel (headgate) to the other side of the panel (tailgate).

The analysis of longwall pillar stability (ALPS) method was used to size pillars in operating mines that are essential to protect critical gate entries that provide access to the face. In using the Bureau-developed ALPS method, the candidate mines have improved the safety of miners by reducing the possibility of rock falls in the gate entries. The ALPS method was formatted for personal computers and is now being distributed throughout the coal industry.

Acid Mine Drainage.—Research studies continued to evaluate the performance of constructed wetlands to accomplish passive treatment of acid mine drainage (AMD). Generally, data collected by regulatory agencies and mining companies about the performance of constructed wetlands consist of influent and effluent water chemistry. In the absence of valid flow rate measurements, it is difficult to separate the effect of the wetland from that of the dilution by fresh water. As some wetlands received inflows of surface water during storm events, dilution may be an important component of wetland performance at these sites, possibly complicating the analysis of water chemistry data.

The Bureau developed a method that allows adjustment of water chemistry data so that dilution is no longer an analytical concern. It is based on the following observations:

- Concentrations of calcium, magnesium, and sodium are commonly quite high for AMD versus fresh water; and
- These cations are not affected by wetland processes.

By calculating a dilution factor from changes in the ions, iron and magnesium concentration can be adjusted, resulting in a better evaluation of wetland performance.69

Rock Reinforcing Cables.—Researchers at the U.S. Bureau of Mines found that steel cables grouted into drill holes offer a safe and effective method to support the roof prior to cut-and-fill (overhand) mining. Steel cable supports recently gained popularity in conventional mining practices as a means to reinforce rock before mining it.

As each slice of ore is blasted and removed, the rock above it remains in place because it is supported by the cables. Bureau engineers found that presupporting the rock increases miners' safety and improves ore production primarily by allowing mining to take place in rock that may be difficult to support after blasting. The steel cables offer unique advantages as a support system. They are strong, able to carry about 58,000 lb of load, and since they are flexible, they are useful in even confined areas.⁷⁰

Smart Roof-Bolt Drill.—Researchers at the Bureau developed a system that provides data needed by miners to evaluate roof conditions in a mine. Even though about 25% of the production budget of a typical coal mine is used for ground control, roof falls still occur because of the difficulty involved in detecting hazardous geological conditions.

The Bureau's system is mounted on a roof-bolt drill. This smart drill system provides the operator with real-time displays of the specific energy of drilling and drill bit position. Through the use of a microcomputer, critical drilling parameters can be instantaneously interpreted and analyzed. The operator can be informed of hazardous roof conditions about which he or she may be unaware, such as voids, inclusions, or changes in strata. Mine workers can use this information to help them decide when to install longer bolts, change spacing between bolts, or use a different bolt system.

The Bureau plans to improve the capability of the existing system by incorporating a means to automatically control drilling efficiency. As a result, equipment maintenance and downtime will be reduced, and the useful life of drilling components will be extended. Other plans include the development of computer

software that can be used to achieve better drill control and that will provide additional data on rock structure. Through judicious use of sensor technology, an expert system could determine imminent failure of roof strata.⁷¹

Dust Control.—Airborne dust in mineral processing facilities poses health risks for plant workers. The U.S. Bureau of Mines successfully lowered the dust exposure of workers by approximately 70% during the bag-stacking process at processing plants by developing a dust-control system specifically for pallet loading. The system not only lowers dust levels, it makes bag stacking much easier for workers, thereby reducing back fatigue and injuries in this job function. The system employs a hydraulic lift table to ensure the pallet height remains constant throughout the entire bag-stacking cycle. A number of operations are presently pursuing implementing this technique at their facilities.

The system uses a push-pull ventilation technique to capture dust generated during bag stacking. A low-volume, high-velocity blower system blows a stream of air over the top layer of bags on a pallet and traps the dust. The exhaust air can then be dumped into a baghouse ventilation system or filtered before being discharged outside the mill. The system has been tested successfully at two mineral processing plants.

Reducing Worker Exposure to Silica Dust.—The health effects of exposure to respirable silica dust continued to be a major concern to the U.S. mining industry in 1990.

The Bureau investigated optimizing total mill ventilation systems. By properly designing ventilation flow patterns to sweep major contaminants, dust levels inside these facilities can be substantially lowered in a cost-effective manner. A Bureau-designed total mill ventilation system was installed at a clay operation in New York and lowered respirable dust concentrations throughout the facility by approximately 40%. This system provided 10 air changes per hour, and the total cost to purchase and install this system was less than \$10,000. A second total mill ventilation system was evaluated at a silica sand operation in central Texas where the system provided approximately 30 air changes per hour. Reduction in respirable dust levels up to 80% was measured in a number of locations throughout the facility.

Diesel Breakthrough.—A breakthrough in diesel particulate control was achieved by the U.S. Bureau of Mines through the development of disposable filters used after water scrubbers. Two evaluations in operating mine sections showed a 98% reduction in diesel particulate loading in the return airway.

Also in the diesel area, field validation of the dichotomous nature of diesel particulate in mineral dust in underground coal mines progressed. Analysis of the data collected to date confirmed that the aerosol is less than 0.8 micrometer (μ m) in diameter, while the diameters of mineral dust tend to be greater than 1 μ m (\approx 1/25,000 in).

During these studies, the research version of the Bureau's personal diesel aerosol sampler (PDAS) performed effectively. It accurately separated the two particulates to determine the respective mass fractions. The success of the work is attracting attention in the United States and abroad, specifically in Australia, Canada, and the United Kingdom. Because of excessive manufacturing costs of the PDAS research version, the Bureau designed and tested prototypes of a less expensive version that could be commercially manufactured for about \$10.72

Catalytic Diesel Purifier.—A new highperformance catalytic purifier—the Englehard PTX-Ultra exhaust purifierclaims to reduce poisonous and noxious emissions from diesel-powered mining and tunneling equipment. In addition to converting hydrocarbons and carbon monoxide (CO) to water and carbon dioxide (CO₂), it is said to achieve significant reductions in sulfate and sooty fume emissions (which include soluble organic fractions or SOF's) commonly associated with diesel engines. The purifier can also be rapidly retrofitted on-site to diesel-powered equipment, such as personnel carriers, dump trucks, and front-end loaders, with engine capacities up to 1,281 in³.

Soot and heavy hydrocarbons produced by the incomplete combustion of diesel fuel and lubricating oils, besides being a severe respiratory irritant, can also cause headaches, nausea, and dizziness which, in turn, can lead to accidents. The PTX-Ultra reportedly reduces SOF's by about 60% compared to conventional purifiers and also retards formation of sulfates, which existing systems can accelerate by as much as 10%, as well as converting gaseous hydrocarbons and CO. The purifier unit was specially designed to achieve maximum emission

reduction without loss in engine efficiency and to withstand any rough handling in the tough mining and/or tunneling environment.⁷³

Reducing Exposure to Diesel Exhaust Emissions.—To reduce worker exposure to diesel exhaust emissions, the U.S. Bureau of Mines successfully developed and tested several new control technologies. These developments enable the mining industry to comply with increasingly stringent health and safety standards.

Diesel engines emit both gaseous and particulate pollutants into the atmosphere, and control of these emissions is necessary to ensure a healthful work environment. Diesel particulate matter is the greatest concern because it is almost entirely respirable in size.

The Bureau, with industrial cooperators, successfully developed a disposable diesel exhaust particulate filter system. Tests in an underground coal mine showed diesel soot reductions of 95%. The filter element is similar to intake air filters used on large diesel engines. The filter material can be made of various types of treated natural or synthetic materials.

The DDEF system consists of adapters, a water trap, the filter, and canister. These components are downstream of the water scrubbers used on part 36 permissible coal mining equipment. Installation at this location takes advantage of the cool exhaust exiting the water scrubber.

A week-long study determined the effects of the disposable filter on air quality in an underground coal mine. Analysis of measurements taken in the mine indicate that diesel-generated soot was reduced by 95%. The filters have a useful service life of about 10 to 12 hours and cost about \$40 each.

Sheathed Explosive.—Setting off unconfined explosive charges in gassy or dusty underground mines is prohibited by law because their detonation could cause catastrophic mine explosions or fires. However, there are advantages in using unconfined charges underground. These explosive charges can be used effectively to break up large boulders, rocks, and slabs when cleaning up roof falls. They can also be used to dislodge dangerous overhangs.

The U.S. Bureau of Mines developed a nonincendive explosive charge that will not ignite gassy or dusty atmospheres, even methane-laden air. The explosive charge effectively breaks rock in underground coal mines and can be safely fired without the

use of blastholes and stemming. Firing the charge can be performed safely because the explosive is encased in a sheath of salt that disperses into a fine cloud upon firing. As the salt scatters, it acts as a flame retardant. The shock from the explosive detonation breaks the rock.

The Department of Labor's MSHA approved the device as "permissible" or legal for use in underground coal mines. An explosives manufacturer, Austin Powder Co., began marketing the commercial version of the charge in spring 1990 under the name "Sheathed Rockbuster."

Shock-Resistant Emulsion Explosive.

-The U.S. Bureau of Mines, in 1990, designed a safer emulsion explosive. Emulsions are preferred in many applications because they are more powerful than traditional explosives, offer a reduced risk of being accidentally detonated, and are easy to handle. Emulsions do have some undesirable characteristics, however. When used in a delay blasting pattern in underground mines, shock waves from neighboring explosive-loaded boreholes can damage emulsion explosives to the point that they will, at best, not detonate properly, or at worst, not detonate at all. Reports from the field suggest similar events may be occurring during blasting at surface mining operations. The Bureau's new safer emulsion explosive solves this problem. The safer emulsion is resistant to shock waves and detonates properly because it contains an improved, pressureresistant emulsion composition. In addition, the safer emulsion retains the favorable characteristics of conventional emulsion-type explosives.

The Bureau applied for a patent on this novel shock-resistant explosive and is seeking a commercial manufacturer.⁷⁴

Rock Movement Forecasting.—A computer technique developed by the aircraft industry is being used by U.S. Bureau of Mines mining engineers and geologists to evaluate and optimize shaft designs for deep mines. The technique, called "finiteelement modeling" (FEM), was adapted by Bureau scientists specifically for the mining industry. Using the FEM technique, Bureau researchers can forecast how rock in a deep mine shaft will behave. To evaluate the stability of a shaft pillar, for example, a finite-element model would be developed by entering information about three critical factors: mining geometry, premining stress state, and material properties of the rock mass. Using this information, different shaft designs can be analyzed for safety and stability. The Bureau successfully used the FEM program to forecast the stability of a mine shaft at the Homestead Mine in Lead, SD.

Computers and Blasting.—The use of computers for scheduling, inventory control, and mine planning in 1990 expanded rapidly. Computers also saw increasing use in machine-mounted instrumentation to monitor various operating parameters onboard blasthole drills and rock-loading equipment. Related work involves using expert systems to interpret data and advise on machine maintenance timing and troubleshooting procedures.

The application of explosive casting technology to surface mining continued to grow. Two companies reported that, even in geologically disturbed overburden, modified drilling patterns and presplitting resulted in reduced operating costs with dramatic improvements in highway stability and safety.⁷⁵

Computer-Aided Fire Detection.—Based on a Bureau-developed, patent-pending process algorithm, a unique computer program was prepared during 1990 to quickly determine the location of a fire in a complex network of mine workings. The computer program utilizes real-time data from a network of in-mine fire detection devices, along with the output from a mine ventilation simulator, to calculate the probable location of a fire. In-mine tests of the complete system are planned to validate the process.

Mine Fire Modeling.—A Bureaudeveloped computer simulation program called "MFIRE," originally released in 1988, underwent various upgrades to improve performance and ease of use in 1990. The program is an enhanced ventilation network simulator that enables quantitative evaluation of complex interactions between mine fires and mine ventilation systems. The program is unique among ventilation simulators in that it calculates natural ventilation forces, due both to natural strata heat and fires; identifies reversals and recirculation paths; tracks the production and time-dependent spread of combustion products; and permits analysis of multiple, overlapping transient events involving the ventilation system and mine fires. Upgrades completed during 1990 include increasing the range of conditions that the program

can simulate and increasing the accuracy of the predictions of the program.

New Communication System Enhances Mine Safety.—The system developed and patterned on novel Bureau-developed technology is hailed as a breakthrough in underground mine communications in that it can transmit messages through the Earth, from surface to locations underground without cables and without radio aerial networks. Known as PED (Personal Emergency Device), in its most basic form this innovative system consists of four elements: a personal computer, a transmitter, a single-surface aerial, and a portable receiving unit.

To send messages, they are typed into the personal computer—each message can be up to 32 characters long. Once created, the message is sent by transmitter in the form of low-frequency electromagnetic waves. By linking additional personal computers into the system, messages can be sent from numerous mine locations—both above and below ground. Messages can be directed to an individual, to a group (e.g., blasting crew or longwall face crew), or simultaneously to all personnel.

The PED receiving unit is integrated with the miner's battery pack—already carried for his or her cap lamp. When a message is received, the cap lamp flashes over 10 seconds; the miner can then read the message from a liquid crystal display on top of the battery pack.

PED is reportedly suitable for both coal (it is intrinsically safe) and hard-rock mines and is very durable, having been designed for long-term use in physically arduous environments.*

Safety at Surface Mining Dump Points.—A specialized computer simulation program that models surface mine dump points was completed and released during 1990. The software, "INSLOPE3," is unique in that it accounts for the dynamic loads imparted by haulage trucks operating near the dump point slope under the surcharge loading of the truck. Distribution of the program is pending completion of a user manual, which is scheduled for release in 1991.

Human Factors Research to Prevent Groundfall Accidents.—In most years, roof falls are the leading cause of fatal accidents in the underground coal mining industry. During the 5-year period 1985-89, 92 coal miners were killed by falls and more than 4,000 miners were injured.

According to MSHA's accident investigation reports, 47% of the 92 victims of fatal roof fall accidents were in an area of unsupported roof at the time they were killed. One cause of these accidents relates to the problem of properly positioning roof bolting machines prior to installing new rows of bolts. An employee at a mine in eastern Ohio suggested welding flexible wire antennas onto one of the support pads of the bolter's temporary roof support system. These antennas serve as a convenient gauge to determine if the next row of bolts will be spaced the appropriate distance from the rib and from the last row of bolts bordering the area of unsupported roof.

Portable Alarm.—A new handheld, three-gas portable alarm designed for combustible gas, oxygen, and toxic gas monitoring was made available from Mine Safety Appliances Co. (MSA). The MiniGard III Portable Alarm is battery-operated, can be handheld or worn on a belt, and is designed to detect combustible gas, oxygen, and either hydrogen sulfide or carbon monoxide. It uses a microcomputer and state-ofthe-art electronics to provide full-function capabilities, according to MSA. Its compact size (7 by 3.5 by 1.7 in) makes it suitable for confined space applications. The alarm features three diffusion-type sensors with concentrations of gases and vapors shown individually on an easy-to-read liquid crystal display. The display can scroll through the three channels or be locked on one, but all three gases are monitored simultaneously regardless of display setting. An earphone or optional remote alarm module is available for use in high-noise environments. A common audible and visual alarm alerts the user of dangerous gas and oxygen concentrations. When in the alarm mode, a descriptor activates in the display to indicate the type of alarm. Combustible gas calibrations are either generalpurpose 0 to 100% Lower Explosive Limit pentane-in-air, or 0 to 5% methane (CH₄) in a methane-air mixture for mining applications. For toxic gas, the alarm can be selected with either a 0 to 50 parts per million (ppm) hydrogen sulfide sensor or with a 0 to 500 ppm carbon monoxide sensor. All alarms indicate 0% to 25% oxygen."

Contractor Training

Dependence on using contractor personnel to perform a variety of production, extraction, and support services throughout the mining industry is increasing.

Analysis of accident and/or injury statistics for the past 8 years indicated several trends among independent contractors in the mining industry. The most alarming one is the fatality incident rate (calculated from fatality figures and normalized on the basis of 200,000 hours worked). This rate is significantly higher for contractors than for operators in both coal and metal-nonmetal mining. The fatality incident rate for contractors at coal mines averages almost twice that for operators, and the rate for contractors at metal-nonmetal mines is almost five times as great. Further analysis shows that four major accident types account for 70% of these fatalities. They include powered haulage, machinery, slips and/or falls, and electrical.

The fatal injury trend has compelled regulatory and company personnel to look at existing standards to deal with health and safety training. Policymakers and safety practitioners agree that current 30 CFR training regulations designed for mining company employees are not appropriate for the myriad of contractors and agents hired by operators to perform various services on-site.

MSHA Crackdown on Mine Fatalities

MSHA developed a program to identify high-hazard metal mines so necessary safety corrections can be made. As a part of its spotlight on safety, MSHA worked at improving accountability and strengthening the investigations unit.

A decision was made to expand the upgrading of MSHA's enforcement capability to the metal and nonmetal sector after evaluating an internal review of the Agency's performance preceding a coal mine explosion in 1989 that killed 10 Kentucky miners. The review listed several "shortcomings" of MSHA personnel, including weak enforcement at the mine where the explosion occurred.

Hoping to prevent similar disasters, MSHA called for closer monitoring of mines in the United States. "It's our intention to have a parallel program for metal and nonmetal mines," MSHA confirmed. Based on MSHA statistics, there is room for safety improvements in the metal industry.78 Both the number of coal and noncoal mining facilities and the rate of fatalities per total hours worked increased in the first half of 1990 compared to the same period last year.

Twenty-eight metal and nonmetal (noncoal) miners died in accidents in the first 6 months of 1990 compared with 25 for the same period in 1989. The rate of fatal injuries in metal and nonmetal mining through June 1990 was 0.03 per 200,000 employeehours compared with 0.02 for 1989.

rRevised.

¹Data may not add to totals shown because of independent rounding.

²Includes industrial sand and gravel. Construction sand and gravel data were not available for 1985, 1987, and 1989 because of biennial canvassing.

³Crushed and broken and dimension stone data were not available for 1986 and 1988 because of biennial canvassing.

⁴Less than 1/2 unit.

This table is a compilation of previous Minerals Yearbook tables 2 and 3. Data have been compiled and reorganized.

²Excludes materials from wells, ponds, or pumping operations.

³Data may not add to totals shown because of independent rounding.

Includes beryllium, magnesium, mercury, molybdenum, platinum-group metals, tin, tungsten, uranium, zinc, zirconium, and metal items indicated by symbol W.

⁶Excludes volcanic cinder and scoria.

Includes aplite, asbestos, boron minerals, fluorspar, graphite (natural), kyanite, magnesite, marl (greensand), olivine, soda ash, and industrial minerals indicated by symbol W. 8Includes Delaware, North Dakota, and States items indicated by symbol W.

*Some quantities of this use are included with "Ammonium nitrate: Fuel oil blasting agents and unprocessed" to avoid disclosing company proprietary data.

*Training agents are quantities from "Other high availables "and "Water gels and slurgies". ⁶Includes some quantities from "Other high explosives," and "Water gels and slurries."

ABRASIVE MATERIALS

By Gordon T. Austin

Mr. Austin, a physical scientist with more than 30 years industry and Government experience, has been the commodity specialist for abrasive materials since 1986. Mr. William Field, mineral data assistant, prepared the domestic data tables.

he combined value of production of natural abrasives, which include tripoli, special silica stone, garnet, staurolite, and emery, increased about 4% in 1990. The increase in the value of tripoli production was the result of an increase in the unit value. Emery increased owing to an increase in the volume of the material produced and an increase in the unit value. Special silica stone experienced a decrease in unit value and an increase in the quantity produced. Garnet showed a 10% increase in quantity and a 73% increase in unit value. Staurolite decreased about 8% in the quantity produced, and the value of production decreased about 10%.

The fused aluminum oxide industry

showed a 5% decline in the quantity produced and in the value of production. The silicon carbide industry saw a 10% decrease in the quantity produced and a 9% decrease in the value of production. Production for both industries decreased 7% in quantity and value compared with those of 1989.

The quantity of metallic abrasives sold and shipped was essentially the same as for 1989, and the value increased slightly. This was the second stable year after 4 consecutive years of increases in both quantity and value. The industry includes the primary producers of steel, chilled and annealed iron, cut wire shot and grit, and shot and grit reclaimed by primary producers. Shipments in 1990 were about

13% below the industry's high of 239,619 metric tons¹ in 1979.

The United States continued as the largest single manufacturer, exporter, importer, and consumer of synthetic industrial diamond in the world. The estimated apparent U.S. consumption of industrial diamond stones continued its rebound from the 48-year low in 1987 with an increase of 52% to 9.3 million carats in 1990

¹Includes grindstones, oilstones, whetstones, and deburring media. Excludes grinding pebbles and tube-mill liners

²Primary garnet; denotes first marketable product. Includes crude concentrates.

Includes Canadian production of crude silicon carbide and fused aluminum oxide and shipments of metallic abrasives by producers.

Excludes United States and Canadian production and value of aluminum-zirconium oxide.

⁵Bureau of the Census.

materials were from seven separate voluntary U.S. Bureau of Mines surveys. Of the 61 operations producing natural and manufactured abrasives canvassed, all responded, representing 100% of the total production shown in tables 1, 5, 6, 8, 14, 15, and 16.

FOREIGN TRADE

The total value of abrasive materials, exports plus reexports, was \$295.5 million, a very slight increase compared with the 1989 value.

The total value of abrasive materials imported was \$469.8 million, an increase of 12% compared with the 1989 value. The average total value for the past 10 years was \$382.3 million per year, with the high in 1988 of \$501.7 million and the low of \$245.0 million in 1982. Abrasive material imports had, until the 1989 decrease, increased at a compounded rate of slightly less than 13% per year for the past 6 years. The 1990 increase put the level of imports back on trend.

The United States has shown a trade deficit in abrasive materials for every year

of the past 10 years. In 1990, the deficit increased 40% compared with 1989's 38% decrease from 1988's record high of \$200.8 million.

TRIPOLI

The category of tripoli includes not only tripoli, but other fine-grained, porous silica materials that have similar properties and end uses. It does not include fine-grained or porous silica materials included in other Mineral Annual Report chapters, such as pumice.

Production

In 1990, the quantity of crude tripoli produced decreased 10% after 1989's increase, which followed 5 consecutive years of decline. The value of 1990's production increased 27% compared with that of 1989. The average production for the past 10 years was 103,229 tons per year, with a high of 112,928 tons in 1984 and a low of 94,389 tons in 1990. Six firms produced tripoli in four States. Malvern Minerals Co., Garland County, AR, produced crude and finished material.

American Tripoli Co. produced crude material in Ottawa County, OK, and finished material in Newton County, MO. Illinois Minerals Co. and Tammsco Inc., both in Alexander County, IL, produced crude and finished amorphous (microcrystalline) silica. Keystone Filler and Manufacturing Co. in Northumberland County, PA, processed rottenstone, a decomposed fine-grained siliceous shale, produced by B. J. Ulrich & Sons, also in Northumberland County, PA.

Consumption and Uses

Processed tripoli, sold or used, decreased 6% in quantity, but increased 17% in value; the increase in value was the result of an increase of 25% in the average value per ton. Because tripoli grains lack distinct edges and corners, it has unique abrasive uses. It is the mild abrasive in toothpaste and tooth polishing compounds, industrial soaps, and metal and jewelry polishing compounds. The automobile industry uses it in buffing and polishing compounds in lacquer finishing. The largest use of the mineral was as a filler and extender in paint, plastic, rubber, and enamel. The use of tripoli as an abrasive decreased about 8% in

W Withheld to avoid disclosing company proprietary data. ¹Includes amorphous silica and Pennsylvania rottenstone.

1990 to a 10-year low of 24,089 tons; 1990 was the sixth consecutive year of decline. During the 6-year period, consumption declined about 35%. The average annual consumption of abrasive tripoli for the past 10 years was 30,810 tons, with a high of 37,024 tons in 1984 and a low of 24,089 tons in 1990. The 1990 consumption was the lowest since 1953, when only 22,680 tons was sold or used.

After 5 consecutive years of growth, from 1982 to 1987, the amount of tripoli used as a filler declined for the third consecutive year. The 10% decline in 1990 followed an 8% decrease in 1989 and an additional 4% decrease in 1988. The average consumption of filler-grade tripoli for the past 10 years was 60,953 tons per year, with a high of 71,160 tons in 1987 and a low of 50,180 tons in 1982. U.S. Bureau of Mines data show that tripoli use in the United States is greater as a filler than as an abrasive.

Prices

The average reported value of abrasive tripoli, sold or used, in the United States was \$173.10 per ton. The average annual value reported for abrasive tripoli for the past 10 years was \$103.44 per ton, with the high value in 1990 of \$127.98 and the low in 1981 of \$70.50. The value of abrasive tripoli has increased over the past 10 years at an annual compounded rate of 10% per year. The increase has been continuous; the annual rate of increase from 1985 to the present was significantly lower than the annual rate of increase from 1981 through 1984.

The average reported value of filler tripoli, sold or used, in the United States

was \$195.53 per ton. The average annual value for the past 10 years was \$125.06 per ton, with a high of \$195.53 per ton in 1990 and a low of \$85.06 per ton in 1981. The value increased at an annual compounded rate of 9% for the past 10 years.

SPECIAL SILICA STONE PRODUCTS

Special silica stone products include hones, whetstones, oilstones, stone files, grindstones, grinding pebbles, tube-mill liners, deburring media, and certain specialty products. Manufacture of these products was from novaculite, quartzite, or other microcrystalline quartz rock.

Production

Plants manufactured oilstones, hones, whetstones, and files in Arkansas, New Hampshire, and Indiana and cuticle stones and coaster stones in Indiana. Additional production includes grindstones in Ohio, deburring media in Arkansas and Wisconsin, and grinding pebbles and mill liners in Minnesota. Production of the crude materials was in the same State as the products manufactured, except the oilstones in New Hampshire. Production of novaculite for New Hampshire oilstones was from Arkansas.

The process for estimating production of crude material changed in 1981 and again in 1987. Because of two changes in estimating production, 10-year averages and other production trends would be of no practical use.

The production of oilstones, hones. whetstones, files, and grindstones increased about 19% in quantity from the 10-year low of 1989 to 450 tons and 13% in value to \$6.2 million. The average annual production of the products for the past 10 years was 509 tons, with a high of 647 tons in 1982 and a low of 378 tons in 1989. The average value of annual production for the past 9 years was \$5.8 million, with a high of \$7.4 million in 1987 and a low of \$3.8 million in 1983. In the past 10 years, two distinct and different trends in the value of production appeared. One was from 1980 through 1984. when the average value of production was \$4.1 million per year. The other was 1985 through 1990, when the value of production was 68% greater at an average value of \$6.9 million per year. During 1985-90, the average annual quantity of production was less than the 10-year average, 467 tons versus 509 tons. During the same period, the average annual value of production was 19% greater than the 10-year average. The change in average annual value was the result of a significant increase in the value per ton of manufactured products, starting in 1985.

The industry manufactured four main grades of whetstone. They ranged in grade from the high-quality Black Hard Arkansas Stone down to the Washita Stone. The Black Hard has a porosity of 0.07% and a waxy luster, while Washita Stone has a porosity of 16% and resembles unglazed porcelain. The four main types are shown in table 8.

Arkansas accounted for 99% of the value and 97% of the total quantity of special silica stone products reported as sold or used by U.S. producers.

TABLE 6

SPECIAL SILICA STONE FINISHED PRODUCTS SOLD OR USED BY PRODUCERS IN THE UNITED STATES¹

TABLE 8
TYPES OF ARKANSAS STONES

Trade name	Use				
Black Hard Arkansas Stone	Polishing the most perfect edge possible.				
Hard Arkansas Stone	Polishing blade to a very fine edge.				
Soft Arkansas Stone	General purpose.				
Washita Stone	Rapid sharpening.				

Consumption and Uses

The domestic consumption of special silica stone products resulted from a mixture of residential, industrial, leisure, and craft uses. The major residential uses were the sharpening of knives and other cutlery such as scissors, shears, and lawn

and garden tools. Major industrial uses were the sharpening and honing of cutting surfaces, polishing of metal surfaces, and the deburring of metal and plastic castings. The manufacture, repair, and modification of guns also make use of stone files. The recreational uses were the sharpening of sports knives, arrowheads, spear points, fish hooks, and other recreational items. Craft applications included uses in wood carving, gun engraving, jewelry making, and other engraving work. The estimated value of U.S. apparent consumption was \$1.3 million.

Prices

The value of crude novaculite suitable for cutting into finished products varied from a low of \$0.33 per kilogram to as much as \$2.75 per kilogram. The low

value was for Washita grade and the high for Black Hard Arkansas grade. The manufacture of deburring media or special-purpose crushed stone is from material not suited for making oilstones, hones, or whetstones. The value of these materials ranged from \$39 per ton to more than \$300 per ton. The average value in 1990 of oilstones, hones, whetstones, and grindstones, sold or used by U.S. producers, was \$13,861 per ton or about \$13.86 per kilogram. The average annual value of the same items for the past 9 years was \$11,367 per ton, with a high of \$14,443 per ton in 1989 and a low of \$6,411 per ton in 1984. In the past 9 years, the unit value of special silica stone products followed two distinct negative trends with a significant increase in 1989 and 1990 indicating what may be the start of another negative trend. The first trend, a gradual decrease, occurred during the period 1980-84. The value per ton averaged \$7,227, with a high of \$8,284 and a low of \$6,411. The lowest value occurred in 1984. A second trend began in 1985 when the value per ton more than doubled from \$6,411 to \$13,361. The average annual value per ton for the period 1985-88 was \$13,006, with a high of \$14,113 in 1986 and a low of \$12,229 in 1988. One possible explanation for the series of step-ramp trends is the introduction of new high-value products by a single manufacturer. The product then encounters significant price competition from other producers in subsequent years. Because the special silica stone products industry is not high technology, new products can be duplicated by competitors. This very quickly results in short-term price pressures.

Foreign Trade

The value of exported special silica stone products was \$6.2 million, an increase of 148% compared with that of 1988. The average annual value of exports for the past 10 years was \$2.7 million, with a 10-year high of \$6.2 million in 1989 and a low of \$2.0 million in 1987. The annual value of exports during the past 10 years did not appear to have established a trend. Instead, the value drifted between \$2.0 million and \$2.6 million with as many increases as decreases until the significant increase in 1989.

The value of imported products was \$1.8 million, an increase of 13% compared with that of 1988, but essentially the same compared with those of 1985

and 1986. The average annual value of imports for the past 10 years was \$1.2 million, with a high of \$1.8 million in 1985 and 1989 and a low of \$0.3 million in 1980. The trend for products imported to the United States was generally upward with some occasional decreases. The United States continues to be a net exporter of special silica stone products. A portion of the finished products imported was from crude novaculite produced within the United States and exported for processing.

In 1989, the trade surplus in special silica stone products was \$4.4 million, an increase of about 389%. During the past 10 years, the United States has enjoyed an average trade surplus of \$1.5 million per year, with a high of \$4.4 million in 1989 and a low of \$0.4 million in 1985. The trend for the past 10 years has been one of declining surpluses until the significant increase in 1989. The average annual surplus for the previous 4 years had been only \$0.6 million or about 40% of the 10-year average.

GARNET

High-quality U.S. industrial garnet is a mixture of almandite and pyrope that, when under pressure, breaks into sharp chisel-edged plates. Industry uses this garnet as an abrasive powder and to manufacture coated abrasives. Low-quality industrial garnet found uses primarily as airblasting or hydroblasting media and as filtration media.

Background

Definitions, Grades, and Specifications.—Garnet is a general name for a family of complex silicate minerals having similar physical properties and crystal form, the most common being the magnesium-aluminum silicate (pyrope) and the iron-aluminum silicate (almandite). Almandite is the most important type of industrial garnet. It ordinarily has a hardness of 7.5, an average specific gravity of 4, and a melting point of 1,315 °C. It has a color of various shades of red, a chemical composition of Fe₃Al₂(SiO₄)₃, and a cubic crystal structure.

Each domestic producer has distinctive products. The Barton Mines Corp. garnet is a mixture of almandite and pyrope and is at the top of the garnet hardness range. It occurs as large crystals and exhibits incipient lamellar parting planes

that break under pressure into sharp chisel-edged plates. It retains this chisel-edged shape even when crushed to a very fine size. The NYCO and International Garnet Abrasive garnet is a mixture of andradite and grossularite, and the crude garnet concentrate may contain diopsidehedenbergite (Ca[MgFe]Si₂O₆). The Idaho garnet is an alluvial material with rounded small-to-medium grains.

Consumers purchase crushed, ground, and graded-to-size material depending on the intended end use. The sale of garnet for sandblasting and water filtration is by screen size. Some popular mesh sizes are minus 7 plus 12, minus 7 plus 20, minus 20 plus 40, minus 30 plus 50, minus 50 plus 94, and minus 120 plus 230.

Descriptions of testing methods for materials to be used in coated abrasives manufacture are in American National Standards Institute (ANSI) Specification B74.18-1977² and other sources.³ Data on other graded sizes are in ANSI Specification B74.12-1976.⁴

Industry Structure.—Currently, four firms produce garnet from five plants in three States. Barton Mines Corp., Warren County, NY, produced garnet for use in coated abrasives, glass grinding and polishing, and metal lapping. The NYCO Div. of Processed Minerals Inc., Essex County, NY, recovered garnet as a byproduct from its wollastonite operation. It sold both crude garnet concentrate for additional refining and refined garnet for use as blasting and filtration media. International Garnet Abrasives Inc., Clinton County, NY, produced garnet for use as blasting and filtration media. Emerald Creek Garnet Milling Co. continued to operate six mining operations, two jigging plants, and a single mill in Benewah County, ID. Blasting and filtration media were the primary uses of the garnet. International Garnet Abrasives also operated its garnet reclaiming plant in Jefferson Parish, LA. The petroleum industry used the garnet as blasting media. Abrasive garnet production in the United States began in 1878 at the Gore Mountain site of Barton Mines, near North Creek, Warren County, NY. During the first year, production was less than 100 tons. It was used in coated abrasives, both paper and cloth.⁵ Barton Mines Corp. mined and processed the abrasive-grade garnet on Gore Mountain until the company moved the mining operation and processing plant in 1982 to the adjoining Ruby Mountain. Barton Mines has been a family-owned operation since its

formation. Reported past domestic garnet production was from California, Connecticut, Florida, Maine, New Hampshire, North Carolina, and Pennsylvania.⁶

Nine manufacturers at 10 plants produced garnet-coated abrasive papers and cloths. The plants are in New York and Virginia, two in each, and Massachusetts, Michigan, Minnesota, Mississippi, Ohio, and Pennsylvania, one in each.

Geology-Resources.— Members of the garnet group are common accessory minerals in a large variety of rocks, including granites, gneisses, schists, marbles, serpentine, and peridotite. The geographical areas in which it may be found are enormous both in extent and in number. Commercially attractive industrial garnet occurrences are not common. Many garnets that occur in deposits of economic size degrade during processing because of internal stresses. These stresses developed in the garnet crystal during formation and cooling. Stress relieving is not economical; therefore, these deposits have no commercial value as a high-grade abrasive material source.

The best abrasive garnets are of the almandite variety, but andradite, grossularite, and pyrope also are used. All varieties of garnet have been mined for gem stones.

The garnet occurrence near Rangeley, ME, is very unusual. Some classify the host rock as metamorphic, but others, as igneous. The ore exhibits characteristics of both classifications. Because it has a very high garnet content, 50% to 80%, some geologists argue that the ore is a garnet granofel of metamorphic origin. Others contend that the ore is igneous in origin because of the lack of foliation and other textural considerations. In any case, the rock is similar to granite, an igneous rock, except that garnet crystals replace the quartz crystals, a major constituent of granite.

New York and Maine have the only known high-quality garnet reserves in the United States. A rough estimate suggests that more than 600,000 tons of high-quality garnet can be recovered from Barton Mines Corp. deposit on Ruby Mountain in New York. Other similar deposits occur in the area. The estimate of reserves in the igneous rock deposit near Rangeley, ME, are more than 1.8 million tons of garnet. The quantity of garnet-bearing gravels reported at Emerald Creek and Carpenter Creek in Idaho is large. A minimum of 450,000 tons of

garnet is available in the Emerald Creek Garnet Milling Co. deposits.

There can be little doubt that tremendous reserves of garnet similar to the lower priced materials can be located as needed.⁷ Also, the production of byproduct garnet from many current mining operations is possible if demand improved.

Reserves are significant in Australia, India, and the U.S.S.R., but accurate data are not available. Huge inferred and undiscovered resources are likely to exist throughout the world.⁸

Technology.—Mining.—At the Barton Mine in New York, garnet occurs in a metamorphosed igneous rock. The Ruby Mountain ore body covers approximately 4.1 hectares, which is nearly the entire mountain. The estimated total depth of the deposit is 50 to 60 meters. The ore benches in the mine are about 9 meters high. A drop ball breaks the large pieces, and power shovels load trucks to haul the ore to the crusher at the mill, about 0.4 kilometer away.

At Emerald Creek and Carpenter Creek, Benewah County, ID, stripping from 1 to 2 meters of overburden exposes the garnetiferous gravel. Mining is accomplished with a dragline dredge.

Wollastonite mining at Willsboro, NY, produces a byproduct concentrate containing garnet, diopside-hedenbergite, and minor amounts of wollastonite. The ore at the NYCO mine contains 60% wollastonite, 30% garnet, and 10% diopside. After blasting and loading, the ore is transported 22 kilometers to the plant for separation of the wollastonite from the garnet-diopside.

Beneficiation.—Today practically all grade-grain abrasive garnet is heat treated as a processing function, not to improve its inherent abrasiveness. Impurities picked up during processing stick to the garnet particle surfaces. These impurities destroy the cleanliness and capillarity needed in later processing to give adhesion for bonding. In the early 1960's, scientific investigations determined that heat treating only cleaned the particle surfaces and that too high a temperature could destroy the abrasive quality of garnet. In the mid-1960's, the coated abrasive industry accepted uniform color standards. These standards ensured the cleanliness of the grain surface and a color most closely approaching the natural red color of abrasive garnet. The heat treatment needed to do this is the RT treatment.9

At Barton Mines Corp., separation of garnet from other minerals is by combinations of crushing and grinding, screening, tabling, flotation, magnetic separation, water sedimentation, drying, heat treating, and air separation. Sometimes the same process will do both sizing and removal of gangue minerals, but usually it requires consecutive processes. Particle size control is difficult.

At Emerald Creek, sizing of the garnetiferous gravel is by trommeling and then treatment with jigs and concentrating tables. The garnet concentrate is dried, crushed, and screened. The maximum product grain size is 46 millimeters.

At NYCO, the processing and beneficiation of the wollastonite-garnet ore involves two stages. The first stage includes drying, crushing, screening, and recrushing the feed to minus 16 mesh. In the second stage, the minus 16-mesh raw material passes over a battery of screens to attain minus 16-, minus 20-, minus 40-, and minus 60-mesh splits. Then a battery of magnetic separators removes the garnet fraction from these splits. The final product includes four sizes bagged for shipment.

Annual Review

Production.—The United States continued to be the largest garnet producer and consumer, accounting for about 45% of the world's production. Four domestic producers operated five plants, three in New York and one each in Idaho and Louisiana.

In 1990, the quantity and value of crude garnet concentrates produced were 47,009 tons worth \$8.3 million, a 10% increase in quantity and a 89% increase in value. The average annual production for the past 10 years was 33,485 tons, with a high of 47,009 in 1990 and a low of 23,089 in 1981. During the past 10 years, production increased about 104%, or at an annual compounded rate of about 8.5% per year. The production trend for the past 10 years has been one of continued long-term growth with occasional downward adjustments.

Consumption and Uses.—In 1990, the quantity of garnet sold or used by producers was 45,934 tons, an increase of 11%, and the value increased about 19% to \$11.7 million. The average annual quantity of garnet sold or used for the past 10 years was 32,158 tons, with a record high of 45,934 tons in 1990 and

a low of 23,150 tons in 1981. The trend for the past 10 years was one of steady annual growth, except for 4% decreases in both 1981 and 1984. The growth rate averaged about 8% compounded annually.

Much of the growth in the use of garnet was the result of new regulations. These regulations established new limits on leachable minerals and free silica content in hydroblasting and airblasting media. These changes made garnet the preferred blasting media in some work environments.

The major industrial use for high-quality, high-value garnet since before 1880 has been as material for free-abrasive machining in such applications as optical lens grinding and plate-glass grinding. In recent years, its applications included the high-quality, scratch-free lapping of semiconductor materials and other metals. The finishing of wood, leather, hard rubber, felt, and plastics often requires the use of garnet-coated abrasive papers and cloths.

The aluminum aircraft and shipbuilding industries in California and the Pacific Northwest use lower quality, lower cost alluvial garnet, primarily from Idaho, for sandblasting. Similar uses in the Eastern United States are for the cleaning and conditioning of aluminum and other soft metals and for cleaning of metal by structural steel fabrication shops. Mixed-media water filtration, using a mixture of sand, anthracite, and garnet. has displaced older filtration methods because it is more reliable and gives a better quality of water. Demand for this use has greatly increased. The manufacturers of nonskid floor paint also use alluvial and other low-cost garnets.

Garnet has obtained an intermediate place in the coated-abrasive field between

TABLE 9
GARNET SOLD OR USED
BY PRODUCERS IN THE
UNITED STATES

Year	Quantity (metric tons)	Value (thousands)
1986	28,899	\$6,748
1987	35,812	7,744
1988	41,896	11,144
1989	41,320	9,768
1990	45,935	11,759

low-cost quartz sand and more costly synthetic abrasives (silicon carbide and fused alumina). Garnet is reportedly more efficient based on unit production costs than quartz sand. It also produces a more desirable finish on items made of wood, leather, hard rubber, felt, and plastic.

Garnet, especially the lower grades, cannot compete with synthetic abrasives for most metalworking applications requiring substantial metal removal because of its friable nature and lower hardness.

Prices.—The average value per ton of crude garnet concentrates was \$178, a 73% increase compared with the 1989 average. The average value for the past 10 years was \$105 per ton, with a high of \$178 in 1990 and a low of \$88 per ton in 1986. During the past 10 years, the trend for the value of crude concentrates was one of general increase with decreases in some years. The 1990 value was 100% of the 1981 value.

In 1990, the average value per ton of garnet sold or used was \$255, an increase of 8% from that of 1989. The average value for the past 10 years was \$232 per ton, with a high of \$266 in 1988 and a low of \$216 per ton in 1987. The price trend of garnet sold or used during the past 10 years has been one of stable prices with very minor changes, except the 23% increase from 1987 to 1988.

Foreign Trade.—Garnet exports, as reported to the U.S. Bureau of Mines, by producers were about 10,000 tons, essentially the same as those for 1989. Export data on garnet were not available from the Bureau of the Census (Department of Commerce). Producers have reported exports to the U.S. Bureau of Mines for the past 3 years. Before 1987, the U.S. Bureau of Mines estimated garnet exports. Trend analysis beyond the past 4 years would be of limited value because of the large number of estimates included with the data. According to reports by producers, exports increased significantly during the past 10 years.

Mineral brokers and other garnet importers reported to the U.S. Bureau of Mines about 5,000 tons of imported garnet, unchanged from that of 1989. Import data for garnet also were not available from the Bureau of the Census. U.S. Bureau of Mines data, which are available for only 4 years, showed a significant increase in garnet imports each year. The United States was a net exporter of garnet

in 1990; exports exceeded imports by 200%.

World Review.—The United States was the dominant world producer and consumer of garnet, accounting for approximately 47% of the estimated world output and nearly 40% of estimated world consumption. Target Mines Ltd. continued to produce at near capacity from its Australian garnet sand operation. During 1989, Target sold a 50% interest in the operation to Barton Mines, a U.S. garnet producer. The Chinese mines continued to increase production of garnet for the export market. Yet, to date the quality of the garnet routinely has not met requirements for the U.S. market. Two mineral-sand mining operations in India continued to produce garnet as a byproduct of mineral sands production. Samples of the garnet were tested for applications in the United States, but to date the major market for the Indian garnet has been Japan. Norway, Turkey, and the U.S.S.R. primarily produce for local markets.

Outlook

The U.S. production and consumption

TABLE 10

WORLD GARNET ANNUAL PRODUCTION CAPACITY, DECEMBER 31, 1990¹

(Metric tons)

Country	Capacity
North America:	
United States	63,503
Europe:	
Norway	7,257
Turkey	635
U.S.S.R.	907
Total	8,800
Asia:	
China	18,144
India	27,216

Total	45,450
Oceania:	
Australia	14,515
Others	907
World total	133,175

¹Includes capacity at operating plants as well as plants on standby basis.

of industrial garnet during the next 5 years will be a function of the installed capacity. Currently, the industry is operating at or near capacity. If capacity can be added, production and consumption will increase to approximately 60,000 tons per year by 1996. If garnet were not available, other abrasives could be used in its place, but in many cases with some sacrifices in work volume, quality of work, or cost.

Substitution of other natural and synthetic material is present to some extent for all major end uses of garnet. Fused alumina and staurolite compete with garnet as a sandblasting material in the transportation equipment industries. Ilmenite and plastics compete as filtration media. Diamond, corundum, and fused alumina compete for lens grinding and for many lapping operations. Finally, sand, silicon carbide, and fused alumina compete for grinding and finishing of plastics, wood furniture, and other products.

EMERY

Emery is an impure corundum containing magnesium-aluminum silicates. Its uses include use as an abrasive aggregate for nonskid, wear-resistant floors, pavements, and stair treads; as tumbling or deburring media; and in the manufacture of coated abrasives.

Production

A single firm, Oregon Emery, Albany, OR, produced emery in 1990. The U.S. production of emery increased about 100% in quantity and value compared with those of 1989. Production from the historical emery producer near Peekskill in Westchester County, NY, stopped in 1988. The emery mine was sold to a firm that converted the mine into a crushed stone quarry.

Consumption

The Bureau estimated that the United States consumed approximately 10,000 tons of emery in 1990. Imports from Greece and Turkey accounted for most of the material consumed. Four firms processed and distributed emery for domestic consumption: Washington Mills Abrasives Co., Emeri-Crete Inc., Oregon Emery, and General Abrasives Co.

Foreign Trade

The United States did not export emery in 1990, nor has it exported emery in the

past 10 years. During the past 10 years, the United States may have reexported a small amount of emery. The Bureau of the Census reports emery exports and reexports in mineral group categories; thus, exact data on emery are not available. The Bureau of the Census also reports emery imports in a mineral group category; therefore, data on emery imports are not available.

World Review

Turkey was the world's largest producer of emery. The second largest producer was Greece.

STAUROLITE

Staurolite is a naturally occurring, complex, hydrated aluminosilicate of iron having a variable composition. The mineral most commonly occurs as opaque, reddish-brown to black crystals. It has a specific gravity ranging from 3.74 to 3.83 and Mohs' hardness of between 7 and 8.

Production

Georgia, North Carolina, and Virginia produced mineral specimen staurolite crystals. The crystals were in the cruciform twinned form commonly called "fairy crosses." E.I. du Pont de Nemours & Co. Inc. produced industrial-grade staurolite in Florida. Publishing production data would disclose company proprietary data; but, production of industrial staurolite decreased 8% in quantity and 10% in value compared with those of 1989.

Industrial staurolite was a byproduct of heavy-mineral concentrates recovered from a beach sand deposit in Clay County, north-central Florida. Electrical and magnetic separators remove staurolite from the concentrates after scrubbing, washing with caustic, rinsing, and drying. The resulting material was about 77% clean, rounded, and uniformly sized grains of staurolite, with minor amounts of tourmaline, ilmenite and other titanium minerals, kyanite, zircon, and quartz. A nominal composition of this staurolite sand is 45% aluminum oxide (minimum), 18% ferric oxide (maximum), 5% silica (maximum), and 3% zirconium dioxide (maximum).

Consumption

During 1990, shipments of staurolite increased 16% in tonnage and 13% in value compared with those of 1989.

Staurolite, marketed under the trade name Biasill, was used as molding material in nonferrous foundries because of its low thermal expansion, high thermal conductivity, and high melting point. Its low softening temperature often restricts its use to nonferrous casting. The major use of staurolite was as an abrasive for impact finishing of metals and sandblasting of buildings. The blasting media trade names were Starblast (80 mesh) and Siasill (90 mesh). A coarse grade (55 mesh) also was used as an abrasive. Some portland cement formulations consumed a minor amount. As regulations limiting the amounts of free silica in airblasting media became more stringent, the demand for staurolite increased.

Foreign Trade

Neither the Bureau of the Census nor the staurolite industry reported any exports or imports of staurolite. Given the limited market and the low price per ton, no international market for staurolite should develop in the near term.

World Review

India continued to produce small amounts of staurolite for local consumption. Other countries sometimes produce small amounts of staurolite as a byproduct of mineral sands or gem stone production.

INDUSTRIAL DIAMOND

Industrial diamond is natural diamond that does not meet the standards of gem diamond because of its color, size, or other imperfection. Or it may be a synthetic diamond that is tailormade for industrial applications.

Background

Definitions, Grades, and Specifications.—Natural industrial diamond is diamond that, because of color, structure, size, or shape, is unsuitable for use as gem stones. Major categories are industrial stones (die stones, tool stones, and drilling stones), crushing bort, and grit and powder. The distinction between stone and grit is not well defined; generally, the dividing line is a range of sizes. Stones usually are particles larger than 16 to 20 mesh, grit from 16 to 20 mesh to 325 to 400 mesh, and powder as particles smaller than 325 to 400 mesh. These categories are subdivided further into more than 100 groups, 10

Bort is natural diamond that occurs in finely crystalline aggregates and usually is crushed into finer material. Originally, the term was the name for all crystalline diamonds not usable as gems. Later it designated those diamonds not usable as gems, tool stones, die stones, or drill stones. Currently, the term refers to low-grade industrial diamond suitable only for use in a fragmented form.

Most synthesized diamond marketed to date is 20 to 30 mesh and smaller. Recently, producers began to manufacture synthetic stones of 2 carats or larger. Marketing of these stones to date is of engineered pieces of the stones, not the entire stone. Polycrystalline synthetic diamond compacts and shapes can replace some larger stones. There are several types of synthetic diamond. They range from very friable material with a highly irregular shape to blocky, regular shapes with excellent crystal structure. The manufacture of industrial diamond stones is not commercially viable.

The metric carat, 0.2 gram, is the unit of measure for industrial diamond. One pound contains 2,268 carats, and 1 kilogram contains 5,000 carats. The carat is equal to 100 points. Diamond grit and powder sizes are identified by U.S. standard screen classifications, by ANSI Specification B74.16-1971, 11 ANSI Specification B74-20-1981, 12 and by a proposed standard developed by the Industrial Diamond Association 13 for subsieve micron-sized diamond or cubic boron nitride powders. The terms "sand," "grit," and "powder" also describe decreasing orders of fine diamond.

Machine-shop waste containing diamond is sludge if obtained from wet grinding and is called swarf if obtained from dry grinding.

Industry Structure.—The original discoveries of diamond in India, Borneo, and Brazil, and later in South Africa, were due to chance finds by local inhabitants. Certain desirable characteristics in diamond were noted first in India and led to active search by open pit workings and to concentration by hand methods.

Probably the first industrial use of diamond was as diamond powder for polishing gem diamonds and other precious stones. The art of diamond cutting and polishing was known in India, probably well before A.D. 1400.

Glasscutting was an early application of diamond in industry. It was the most important use of industrial diamond until the 1860's.

England issued a patent in 1819 for drawing wire through a diamond die. Diamond wiredrawing dies gave close dimensional accuracy to wire, even after long periods of use.

The use of diamond for metalcutting began in the 1860's, but the high price of diamond tools was a drawback to their acceptance. As the economic advantages of using diamond tools became known, demand increased rapidly.

The use of the first diamond drill was in 1864. The discovery of diamond in South Africa in 1867 provided ample supply for the new and growing demand for diamond drill bits.

With the introduction of cemented tungsten carbide cutting tools during World War I, industrial diamond use increased. The cause of the increase was that diamond was the most effective agent in grinding tungsten carbide. Requirements for industrial diamond expanded tremendously because of World War II, when demand increased for grinding wheels, die stones, tool stones, drill bits, dresser stones, and polishing dust. The apparent supply of industrial diamond decreased rapidly following World War II.

In 1955, General Electric Co. announced the development of a process for the manufacturer of diamond at its Schenectady, NY, laboratories. Commercial production started in 1957 at its plant in Detroit, MI. In 1969, production moved to Worthington, OH. In 1959, De Beers Consolidated Mines Ltd. announced the manufacture of industrial diamond at its laboratory in Johannesburg, Republic of South Africa. Since these two announcements, the production of synthetic diamond by General Electric, De Beers, and others continued to increase. Today it exceeds the production of natural diamond worldwide about five times.

Geology.—The major source of inplace diamond is kimberlite, an altered, dark-green basic rock of igneous origin. Throughout the world there are approximately 1,000 occurrences of kimberlite, but most do not contain diamonds or do not contain diamonds in economic quantities. The term "diamond pipe" refers to an occurrence of kimberlite large enough and sufficiently diamondiferous to be mined. The size and shape of these pipes depend on the manner in which molten kimberlite passed through the country rock. They may be columnar, tabular, or

irregular in shape. Where mining is deep enough, the diamond pipe always decreases in area and assume a dikelike habit. The diamond may contain inclusions of many minerals, and many of these minerals have inclusions of diamond. These accessory minerals include olivine, garnet, diopside, ilmenite, magnetite, rutile, and phlogopite. Every mine has some diamond that is typical of it, but most diamond is indistinguishable from that of other mines.

Currently, approximately 40% of diamond is from alluvial deposits. These may be alluvial placers, recent or elevated marine beach placers, or glacial deposits. Often the distance of transport has been great. In many areas, the diamond-bearing, alluvial placers were deposited in former drainage systems unrelated to any present system. ¹⁴

Technology.—Mining.—Currently, the United States has no commercial deposits of diamond. In other countries, mining methods range from very crude hand mining and panning to block caving of kimberlite pipes. Large-scale surface mining operations in Australia, Zaire, Angola, Namibia, and Sierra Leone¹⁵ use modern equipment, such as continuous bucketwheel excavators, power shovels, draglines, scraper-loaders, and motor trucks, to remove overburden and to mine and transport the diamond ore.

Processing.—The type of ore, size of operation, and other factors decide the types of processing equipment used. Crushing, where necessary, is done mostly with gyratory and roll crushers to avoid impact to diamond stones. Additional grinding is done with attrition and ball mills to further separate the gangue from diamond stones. Clayey ore may require the use of log washers. Diamond washing pans, jigs, heavy-medium separators, or hydrocyclones collect the primary or intermediate concentrates. Depending on the types, shapes, and sizes of diamond present, various final treatments are used. They include the use of grease tables and grease belts, electromagnetic separators, electrostatic separators, optical sorters, X-ray sorters, and other devices. In all processing plants, hand sorting is the final recovery process.16

Reclaiming industrial diamond stones from drill bits and grit from the wastes generated in grinding, sawing, and other operations is common. This is because of

the high unit value of diamonds. Reclamation processes include physical methods such as distillation to remove coolants and lubricants, followed by electrostatic, magnetic, or flotation separation. Reclamation also uses chemical methods, including combustion, acid treatment, and fusion with alkalies. The treatment used depends primarily on the contaminants present.

Commercial production of synthetic diamond grit is by two basic methods. Currently, the primary method used involves the application of ultrahigh pressure and high temperature to carbon-metal catalyst mixtures by powerful hydraulic presses. This method uses pyrophyllite and other materials for the reaction vessel. Pyrophyllite for this purpose is from the Republic of South Africa, where the local name for it is wonderstone. The major user of the method now uses synthetic reaction-vessel materials, alleviating the dependency on foreign sources for pyrophyllite. The material used for these replacement reaction vessels is proprietary. The other method employs explosive shock to the carbon-metal catalyst mixtures.

Industrial diamond particles of good quality up to 20 mesh and perhaps larger are produced. The shape and other characteristics can be controlled by proper manipulation of the variables, pressure, temperature, time, and catalyst type. Only micrometer-size particles are presently available from the explosive process. Other methods of diamond synthesis exist, but none is in commercial use in the United States. Other countries produce diamond grit; all of these apparently use the ultrahigh-pressure, high-temperature method involving hydraulic presses.

Polycrystalline synthetic diamond compacts are a laminated structure of synthetic diamond powder bonded to a cemented carbide substrate. Their production is by a proprietary high-pressure, high-temperature process that gives the product excellent uniform physical properties. ¹⁸

The polycrystalline synthetic diamond shape is a dense, nonporous, fully intergrown product that is thermally stable to 1,200° C. Production uses a proprietary high-pressure, high-temperature process using a special binder phase that is retained as an integral part of the product and results in high resistance to shock loading.¹⁹

Annual Review

Government Programs.—The National Defense Stockpile (NDS) for industrial diamonds, as of December 31, 1990. had a goal of zero carats and an inventory of 19.0 million carats for crushing bort. The goal for industrial stones was 7.7 million carats, and the inventory was 7.78 million carats. There was 2.98 million carats of sales of crushed and crushing bort diamonds from the stockpile during 1990. There is currently legislative authority for disposal of 5,000,000 carats of bort and 2,400,000 carats of industrial stones, but there were no disposals of stones during the year. The inventory of small diamond dies was 25,473 pieces compared with a goal of 60,000 pieces; but, no purchase authorization was issued.

Production.—The United States was the largest producer of synthetic industrial diamond. This has made the United States independent of foreign sources for crushing bort or similar diamond except the grit sizes larger than about 20 mesh. Having no production of natural diamond, it was dependent on other countries for its natural diamond supply.

Three domestic firms produced synthetic industrial diamond in the United States: Du Pont Industrial Diamond Div., Gibbstown, NJ; General Electric Co., GE Superabrasives, Worthington, OH; and Megadiamond Industries Inc., a subsidiary of Smith International Inc., Provo, UT. A fourth company, U.S. Synthetics Corp., Orem, UT, manufactured polycrystalline diamond from purchased synthetic diamond grit. U.S. Synthetics had the capability to manufacture synthetic industrial diamond grit, but chose not to for economic reasons. Publishing production data would disclose company proprietary data. Domestic production did increase significantly. The United States continued to be the largest single producer of synthetic industrial diamond, a role it has enjoyed since 1957. During the past 10 years, production increased at an average rate of 9% compounded annually.

U.S. secondary production of industrial diamond was from six firms. They were Amples Corp., Bloomfield, CT; Diamondsharp Corp., Keene, NH; Industrial Diamond Laboratory Inc., Bronx, NY; Industrial Diamond Powders Co., Pittsburgh, PA; International Diamond Services Inc., Houston, TX; and National

Research Co., Fraser, MI. The firms reclaimed a total of about 6.4 million carats from used drill bits, diamond tools, and wet and dry diamond-containing waste, an increase of 78% compared with that of 1989.

Consumption and Uses.—The United States continued to be the largest single consumer of industrial diamond. The U.S. Bureau of Mines estimate of apparent consumption of industrial diamond was approximately 86 million carats, an increase of about 19% compared with 1987 consumption. Average annual consumption for the past 10 years was about 55.7 million carats. During this period, two different trends for consumption occurred. The average annual consumption for 1979-83 was about 37.5 million carats, whereas that for 1984-88 was 97% greater or about 73.9 million carats. The second trend was the result of the strong movement to industrial diamond in the U.S. manufacturing sectors. This was because of the economic advantages in removing material and finishing surfaces using industrial diamond and diamond tools and wheels. Additionally, the continued economic growth of the U.S. industrial sector affected demand.

Diamond is far harder than any other natural or artificial abrasive material. So it was essential for some uses and much more efficient than other abrasives for many others. The primary uses for industrial diamond stones were in drilling bits and reaming shells, single- or multiplepoint tools, saws, and wiredrawing dies. Miscellaneous uses for stones include engraving points, glasscutters, bearings, surgical instruments, hardness testers, radiation counters, and other instruments and special tools.

Mineral, oil, and gas exploration were the primary uses of drilling bits and shells. Foundation testing for dams, buildings, and other construction also used diamond bits and shells, as did masonry drilling in buildings for conduits and access and testing of concrete in various structures and other similar applications. The primary uses of diamond tools were for dressing and trueing grinding wheels and for cutting, machining, boring, and finishing. Beveling glass automobile windows also was a use. Cutting dimension stone, ceramics, and concrete in highway reconditioning were the major uses of diamond saws. The forming of refractory shapes for furnace linings also uses diamond saws. Diamond wire dies were essential

for high-speed drawing of fine wire, especially from hard, high-strength metals and alloys.

Diamond grit, powders, and fragmented bort go into diamond grinding wheels, saws, impregnated bits and tools, and loose abrasives compounds for lapping and polishing.

Three major types of grinding wheels were made—resinoid, metal, and vitrified bonds-in many shapes and sizes designed for specific applications. The sizes range up to 1 meter in diameter for very large industrial wheels. Sharpening and shaping of carbide machine tool tips, grinding of dies, edging of plate glass, and optical grinding were among the primary applications of diamond grinding wheels. The cutting of concrete, stone, ceramics, and composite materials were uses of saws made with diamond grit. Very fine saws sliced wafers from brittle metals and crystals for use in electronic and electric devices.

Finishing optical surfaces, jewel bearings, gem stones, wiredrawing dies, cutting tools, and metallographic specimens were the primary uses of polishing and lapping powder and compounds. Hundreds of other important items made from metals, ceramics, plastics, and glass also were finished with diamond compounds.

Changes in technology and conventional wisdom resulted in an increased use of synthetic industrial diamonds and polycrystalline diamond shapes (PDS) and compacts (PDC) for many of the uses listed above. In the past 3 years, the use of PDS, PDC, and matrix set synthetic diamond grit increased in drilling bits and reaming shells. The manufacture of single- and multiple-point tools use PDS and PDC. Many manufacturers of diamond wire-drawing dies use PDC. Diamond saws, diamond wheels, and diamond abrasive grit and powder still are made almost exclusively from synthetic diamond.

Prices.—The U.S. Bureau of Mines does not collect price data on industrial diamonds. The Bureau did track the average import value of various classifications of industrial diamonds. The average value of U.S. imports of natural grit and powder, synthetic grit and powder, and industrial stones was \$0.63 per carat, \$0.74 per carat, and \$6.94, respectively. The average annual value of imported natural grit and powder for the past 10 years was \$1.64 per carat. The high value was \$2.86 in 1980 and the low was \$0.82 in 1988.

The average value of natural grit and powder, in current dollars, declined every year since 1980. The 1980 average value was 425% greater than that of 1988.

The average annual value of imported synthetic grit and powder for the past 10 years was \$1.49 per carat. The high value was \$1.86 per carat in 1981 and the low was \$1.08 in 1988. The average value of imported synthetic grit and powder decreased every year since 1981. The 1988 value declined 72% compared with 1981, while the decline from 1987 to 1988 was only about 7%. During the past 10 years, a major change occurred in the relationship of the average value of natural grit and powder to the average value of synthetic grit and powder. In 1979, natural grit and powder average value was 49% greater than the average value for the synthetics. In 1988, the average value for the synthetics was 32% greater than that for natural material. Natural grit and powder declined in value at a much greater rate than did synthetic grit and powder. This made the synthetic material more valuable.

The average annual value of imported industrial diamond stones for the past 10 years was \$10.26 per carat, with a high value of \$13.93 in 1981 and a low of \$7.24 in 1986. The trend for the value of industrial stones was mixed for the past 10 years. There was a small, 7%, decrease in the average value. The period started with 3 years of increasing values, followed by 3 years of decreasing values. Values the final 4 years were alternating decreases and increases. The 1988 average value was 4% less than the 1987 value, 50% less than the 1981 high, and 12% less than the 1979 value.

Foreign Trade.—The United States was the largest exporter of industrial diamond grit and powder in the world. The United States exported and reexported a record 74.5 million carats of natural and synthetic grit and powder. The material was worth a record \$115.4 million. Additionally, the U.S. exported and reexported approximately 3.0 million carats of industrial stones, valued at \$29.3 million.

Six countries received approximately 76% of the total U.S. exports of synthetic grit and powder. The countries and the percentage of exports they received were as follows: Japan, 27%; Federal Republic of Germany, 21%; Ireland, 8%; Italy, 7%; Belgium, 7%; and Republic of Korea, 6%. Six countries received about

74% of the total U.S. exports of industrial stones. The countries and the percentage of exports they received were as follows: Belgium, 24%; Ireland, 21%; Canada, 10%; Japan, 9%; France, 8%; and Federal Republic of Germany, 6%.

The average annual exports plus reexports of natural and synthetic grit and powder for the past 10 years was 44.0 million carats, with an average value of \$81.3 million. The highest level of exports plus reexports during the past 10 years was 74.5 million carats valued at \$115.4 million in 1988. The lowest was 27.8 million carats valued at \$72.8 million in 1979. The trend of exports plus reexports for the past 10 years was one of continued growth. There was an increase of 168% during the period or an annual average compounded growth rate of 11.2%. The increase from 1987 to 1988 was about 31%, showing very strong growth at approximately three times the 10-year average.

The average annual exports plus reexports of industrial stones for the past 10 years were 2.9 million carats per year, and the average value was \$33.3 million. The high was 3.6 million carats in 1986, and the low was 1.9 million carats in 1982. There was not a distinct trend for the past 10 years. Exports plus reexports of about 3.0 million carats were 18% greater than in 1987, but only about 9% higher than those in 1979. The 1987 exports plus reexports were 28% less in quantity than the 10-year high in 1986.

The average annual imports of natural diamond grit and powder was 7.3 million carats per year for the past 10 years. The high was 13.0 million in 1988, and the low was 3.3 million in 1982. Imports as measured in carats were about 7% less than those in 1988 and 235% greater than those in 1980. The trend for the quantity of natural grit and powder imported during the past 10 years was one of significant increases. Yet, during this period, the quantity of natural grit and powder decreased from 23% to 20% of total grit and powder imports. During 1989, four countries supplied 85% of U.S. imports of natural grit and powder: Ireland, 37%; U.S.S.R., 25%; Japan, 15%; and the United Kingdom, 8%. Only the U.S.S.R. was a producer of natural diamonds.

The average annual imports of synthetic diamond grit and powder was 26.8 million carats per year for the past 10 years. The high was 50.7 million carats in 1988,

and the low was 10.9 million carats in 1981. Imports in 1989 were about 3% less than those in 1988 and 311% greater than those in 1980. The trend of synthetic grit and powder imports during the past 10 years was one of an early decline of about 8% over 2 years followed by continued strong growth until the slight decline in 1989. The average annual compounded growth rate for the 10 years was about 17%; but, the average annual compounded rate of growth from the low in 1981 through 1989 was about 21%. The level of imports in 1988 and 1989 indicated that the growth trend has begun to increase at even a greater rate. Three countries furnished 89% of the synthetic diamond grit and powder imported into the United States in 1988: Ireland, 74%; Japan, 11%; and Federal Republic of Germany, 4%.

The 10-year average for imports of industrial diamond stones was 6.9 million carats per year, with a high of 9.4 million in 1985 and a low of 3.9 million in 1987. Imports of industrial diamonds lacked a distinct trend during the period; the quantity imported in 1989 was about 42% greater than the quantity imported in 1980. The 1989 imports were about 27% greater than 1988 imports, but 1988 imports were less than the 10-year average. Four countries accounted for about 81% of the diamond stones imported into the United States during 1988: Zaire, 40%; United Kingdom, 22%; Belgium, 10%; and Ireland, 9%.

The United States was a net exporter of diamond grit and powder and a net importer of industrial diamond stones. The United States was a net exporter of

industrial diamond based on the total quantity and total gross value. The excess trade balance in industrial diamonds was about 6.4 million carats and \$14.4 million.

World Review.—Botswana and the Republic of South Africa were the largest producers of good-quality industrial diamond stones. Australia and Zaire were the world's largest producers of natural industrial diamond and were the primary sources of natural crushing bort as well as substantial producers of industrial stones. Estimates suggest that the U.S.S.R. was the third largest producer

of natural industrial diamond, but reliable data were lacking. ²⁰ The next largest, in order of volume, were Botswana and the Republic of South Africa. Other smaller but significant producers were Angola, Brazil, China, Ghana, and Venezuela. ²¹ Total world output of natural industrial diamond in 1989 was approximately 51.8 million carats, a slight increase over that of 1988.

Angola.—Endiama, the state diamond company, signed a two-part agreement with De Beers' Central Selling Organization that reestablished a trading relationship that was ended in 1985. The first

part of the agreement calls for De Beers to provide a \$50 million loan to Endiama to be used to increase the production from the Cuango area. De Beers will market all of the production from the Cuango area, which accounts for about 80% of Angola's production.

The second part of the agreement calls for De Beers to spend \$50 million over 5 years on the evaluation of the Camutue kimberlite in northeastern Angola and looking for additional kimberlite sources of diamonds. Any sources found will be jointly developed by De Beers and Endiama, according to the terms of the agreement.

World total	80,370,000	428,010,000				

¹Includes capacity at operating plants as well as plants on standby basis. Rated capacity based on 340-day-per-year effective operation.

Endiama also signed an agreement | with Steinmetz Evens Diamonds for the

Andrada and Lucapa areas. The alluvial deposits of these areas are nearly depleted sale of diamonds produced in the and are of little interest to De Beers.²²

Australia.—Diamond production in Australia decreased slightly because of a decrease in the production from Argyle. Argyle produced 33.8 million carats compared with a 1989 production of 34.4 million, a decrease of about 2%. Estimates of 1990 Bow River production are about 900,000 carats.

More than 90 companies are involved in diamond projects in Australia, with another 23 companies exploring for diamonds on offshore projects. The success of the Argyle mine and reassessment of the old information has led to the latest rush concentrated in New South Wales. with some companies in northern New South Wales claiming to have discovered pipes larger than that at Argyle.

Botswana.—Corona Corp. agreed to acquire control of Repadre Capital Corp., and the new firm will be named Corona Diamonds International Corp. Repadre had agreed to a joint venture with Ampal (Pty.) Ltd. to develop Ampal's diamond licenses in Botswana. Ampal holds multiple prospecting licenses covering about 20,700 square kilometers upon which a number of kimberlites have been identified. Exploration drilling is scheduled to start on 30 to 50 of these targets. Corona Diamonds could earn a 40% interest in the properties by spending about \$1.75 million before December 31, 1991.

Canada.—Uranerz Exploration and Mining of Canada reported finding two diamonds, one 2 millimeters and the other 4 millimeters, near Melfort in the area of Fort a la Corne. These diamonds are significantly larger than the microdiamonds found in the past. Microdiamonds have been found in the area by other companies, including Claud Resources and Monopros Ltd., a subsidiary of De Beers. None of the companies exploring in the area has vet to discover a commercial deposit of diamonds, but these larger stones increase the interest of the companies exploring the area. Uranerz plans to spend \$2 million on exploration in the area in the next 2 years.

China.—The Mineral Resources Bureau reports that geologists discovered 13 diamond deposits along the Tanlu Fault Zone, which stretches across several Provinces in the eastern part of the country. The Bureau claims to have found more than 100 kimberlites and 4 diamond placers in Shandong Province, and in Liaoning Province, it has found

3 large primary deposits and 3 smaller placer deposits.

Guinea.—Currently, at least four companies are either exploring for or mining diamonds in Guinea. Aredor, the company with the longest history in diamond operations in the country, is experiencing a decline in production and in profits. The decline in production is because of decreasing ore grades. The decreasing profit is because of a combination of lower diamond production and a lower sales price for diamonds. The 1990 average sales price for Aredor's diamonds was down 19% to \$245 per carat.

Star Diamonds has a prospection license 30 kilometers to the south and east of the Aredor lease. The alluvial deposits that are of the most interest are those on the flats near Bouro and those at the headwaters of the Bouloumba.

Sidam-Minorex is exploring in an area for diamonds near Forecariah, east of Conakry, and Hydro Mineral Exploration is exploring for diamonds near Bounoudou.

Brigade Aurifere de Guinee has a concession to mine gold in an area north of the Aredor lease in which diamonds may be also found.

Indonesia.—Development of the Danau Seran diamond project in southeast Kalimantan began in late 1990. Dry mining and a conventional diamond recovery plant will be used in place of a dredge. This approach is cheaper and easier to finance. The Danau Seran contains about 2.9 million cubic meters of diamondiferous gravel with a grade of greater than 0.1 carat per cubic meter. The deposit will be mined during the next 3 years at a production rate of 72,000 cubic meters per month. The group that put up the \$2 million in financing will control a 25% equity interest. The interests of Indonesian Diamond Corp. (formerly Acorn Securities) and Keymead have been reduced to 44.7% and 10.3%, respectively, with PT Aneka Tambang (Indonesian Government) holding the remaining interest.²³

Sierra Leone.—The Government of Sierra Leone granted a 20-year concession to Sunshine Mining Co. of the United States to mine and market diamonds from the Kono kimberlite deposit. Exploration and development work to date indicates the deposit contains about 2.4 million carats of recoverable gemquality diamonds. Sunshine estimated the project capital costs at about \$54 million.

The Government of Sierra Leone granted a lease to Intertrade Prospecting, a Swedish firm, to mine diamonds in an area north of Freetown. The firm announced plans to spend about \$3 million dollars on deposits that reported to be of marginal viability.

Wildcat Holdings PLC, a wholly owned subsidiary of Pioneer Resources, entered into an agreement with Xerxes Ltd. to explore for diamonds in the Baoma district. The area is believed to contain both alluvial and kimberlite diamond deposits.

South Africa, Republic of—The De Beers Mine, the smallest of the four mines De Beers Consolidated Mines Ltd. operates in Kimberley, is scheduled to close in October 1990. Treatment of surfaces stockpile ore at the mine will continue well into 1991. The mine was discovered in 1871 and operated as an open pit mine until 1885, at which time underground operations were started. The mine closed in 1908 and remained closed until opening once more in 1960 and operating until 1990.²⁴

Tanzania.—The Government of Tanzania and Tanex Ltd., a company associated with De Beers Centerary AG, concluded an agreement to explore for diamonds over a large area south of Lake Victoria and to the south and west of the Williamson Mine. Exploration in the past has discovered several kimberlites that contained diamonds, but none were economical to mine.

U.S.S.R.—Reportedly, the U.S.S.R. is considering a joint venture with unnamed Western concerns to open a new diamond mine and cutting factory. The mine would be on a deposit about 100 kilometers north of Archangel. Reports indicate that the deposit contains 50% gemquality diamonds.

Zimbabwe.—De Beers was unable to reach agreement with the Government of Zimbabwe on the development of the River Ranch kimberlite deposit near the southern border at Beitbridge. The deposit was originally discovered in 1975. The Government of Zimbabwe was unwilling to grant De Beers' Central Selling Organization an exclusive marketing agreement. The Government wanted to market the production through its Minerals Marketing Corp., which would also retain a portion of the production for domestic processing. The Government has initiated procedures for the forfeiture of the River Ranch claims held by De Beers.

Outlook

Diamond grit and powder should experience substantial increases in domestic demand for every end use during the next 5 years. The increases for synthetic grit and powder are expected to be greater than for natural. The constant-dollar prices of these materials, especially the synthetic diamond products, should continue to decrease or at least remain constant. This is because planned production increases will make them more costeffective. The contract construction industry is an area in which the greatest increases will occur. This is because large quantities of saw-grade diamond will be required for highway and bridge repair and replacement. Large increases also are expected in the dimension stone industry as a cutting and polishing media. The stone, clay, and glass industries will increase their uses in cutting, shaping, and polishing media. Additionally, polycrystalline synthetic diamond compacts and shapes will continue to displace natural diamond stone and tungsten carbide drill bits in the mineral services sector. The probable average annual growth rate in U.S. production is about 6%, based on estimates by the U.S. producers. U.S. production of synthetic material is sufficient to supply U.S. diamond grit and powder demand. The United States will continue to be a major exporter.

The major domestic end use for industrial stones in the next 5 years will continue to be in the oil, gas, and mineral industries. These stones are natural and cannot yet be manufactured commercially. Polycrystalline synthetic diamond compacts and shapes have had a major negative impact on the natural industrial diamond stone markets. This will limit the growth of U.S. demand for stone during the next 5 years. U.S. consumption should average between 6 and 7 million carats per year for the next 5 years. Approximately 50% of the potential natural stone applications will be replaced by the synthetic compacts and shapes by the year 2000.

MANUFACTURED ABRASIVES

Manufactured abrasives include fused aluminum oxide, silicon carbide, aluminazirconia oxide, and metallic shot and grit. Production data for fused aluminum oxide, silicon carbide, and alumina-zirconia

^eEstimated. ^rRevised. W Withheld to avoid disclosing company proprietary data.

¹Table includes data available through May 17, 1991. Total diamond output (gem plus industrial) for each country actually is reported except where indicated by a footnote to be estimated. In contrast, the detailed separate production data for gem diamond and industrial diamond are Bureau of Mines estimates in the case of every country except Australia (1986-87), Botswana (1987), Brazil (1987), Central African Republic (1986-89), Guinea (1986-89), and Liberia (1986), for which source publications give details on grade as well as totals. The estimated distribution of total output between gem and industrial diamond is conjectural, and for most countries, is based on the best available data at time of publication. Estimated distribution figures have been revised as necessary to correspond to reported total production figures.

Includes near-germ and cheap-germ qualities.

³Includes all synthetic diamond production.

⁴Reported figure.

⁵Figures are estimates based on reported exports and do not include smuggled diamonds.

⁶Figures do not include smuggled artisanal production.

⁷Other De Beers' Group output from the Republic of South Africa includes Kimberley Pool, Koffiefontein Mine, Namaqualand Mines, and Venetia Mine.

⁸Data may not add to totals shown because of independent rounding.

General Abrasives, a division of Abrasive Industries Inc.	Niagara Falls, NY	Fused aluminum oxide (regular and high-purity).
Do.	Niagara Falls, Ontario, Canada	Fused aluminum oxide (regular) and silicon carbide.
Norton Co	Huntsville, AL	Fused aluminum oxide (high-purity) and aluminum-zirconium oxide.
Do.	Worcester, MA	General abrasive processing.
Do.	Chippawa, Ontario, Canada	Fused aluminum oxide (regular and high-purity) and aluminum-zirconium oxide.
Do.	Shawinigan, Quebec, Canada	Silicon carbide.
Washington Mills Ltd.	Niagara Falls, Ontario, Canada	Fused aluminum oxide (regular).

oxide were for the United States and Canada. Data for metallic shot and grit were for the United States only.

The fused aluminum oxide and silicon carbide industries underwent consolidation and reorganization during the year. Many of the changes were related to the purchase of the Norton Co., the world's largest producer of abrasives, by Campaign de Saint Gobain of France. Additional changes in the silicon carbide industry resulted from a closing of a Canadian plant for economic and environmental reasons and the construction

of another unit of capacity at the single U.S. plant.

Fused Aluminum Oxide

Government Programs.—The NDS, as of December 31, 1990, contained 227,152 tons of crude fused aluminum oxide and 46,169 tons of abrasive-grain fused aluminum oxide. The NDS goal for abrasive-grain fused aluminum oxide is 340,000 tons. There is no NDS goal for crude fused aluminum oxide; it is held as an offset against the abrasive-grain goal.

Production.—At yearend, four firms were producing fused aluminum oxide at seven plants in the United States and Canada. Production of regular-grade fused aluminum oxide in 1990 was 164,226 tons, essentially unchanged from that of 1989. The average annual production for the past 10 years was 140,322 tons. The high was 172,157 tons in 1988, and the low was 105,893 tons in 1982. The production trend for the past 10 years was one of sharp decline, 27% in 3 years, followed by up and down years to full recovery. The 1990

¹Figures include material used for refractories and other nonabrasive purposes.

²Shipments for U.S. plants only.

³Excludes U.S. and Canadian production and value of aluminum-zirconium oxide.

production was 8% greater than that of 1981.

Production of high-purity fused aluminum oxide decreased 30% to 21,383 tons. The average annual production for the past 10 years was 21,155 tons. The high was 33,569 tons in 1981, and the low was 13,468 tons in 1982. The production trend for the past 10 years began with a very sharp decline, 60%, between 1981 and 1982. Then production swung between about 14,000 and 28,000 tons until the major increase of 82% in 1988, followed by 2 years of decline. The period ended with production 37% less than that of 1981. Total 1990 production of 185,479 tons was 5% less than 1989 production, 36% higher than the low of 119.361 tons in 1982, but essentially the same as that of 1981.

Consumption and Uses.—Fused aluminum oxide has a number of different end

TABLE 17

¹Includes capacities of operating plants as well as plants on standby basis.

uses in the form of graded grain. The total value of sales of fused aluminum oxide-graded grain for all uses increased slightly in 1990, but were still only 78% of the 10-year high recorded in 1988. Total value of sales by individual end use were a mixture of increases and decreases. Sales for use in bonded abrasives were down, coated abrasives were down 22%, refractories increased 13%, tumbling media were up 15%, wiresawing abrasive were up slightly, polishing cake and buffing compounds were up 22%, antislip abrasives were down 21%, polishing abrasives were up slightly, and all other uses were up about 11%.

Prices.—The Bureau did not collect data on the prices of various grades of fused aluminum oxide. It did collect data on the value of fused aluminum oxide production. The average value of regulargrade fused aluminum oxide, as reported by producers, was approximately \$394 per ton. The average annual value for the past 10 years was \$363 per ton, with a high of \$394 in 1990 and a low of \$324 in 1988. In 1990, the average value of high-purity fused aluminum was \$611, down 4% from the 1989 10-year high at \$635 per ton. The average annual value of the past 10 years was \$551 per ton, with a low of \$476 per ton in 1988. The average value of all grades of fused aluminum oxide in 1990 was \$419 per ton. essentially unchanged from the 10-year high in 1989. The average annual value for the past 10 years was \$387 a ton, with a low of \$348 in 1988. The trend for fused aluminum oxide values for the past 10 years was a general upward trend from 1981 to 1983, then a general downward trend from 1983 to 1988. The 1989 and 1990 average values increased about 21% compared with that of 1988 and 5% with that of 1981. Mineral price quotations in various December issues of trade magazines listed prices for regular-grade fused aluminum oxide of \$832 to \$925 per ton, while high-purity was quoted at \$1,110 to \$1,221 per ton.

Foreign Trade.—The quantity of exports plus reexports of fused aluminum oxide decreased 21% to 13,675 tons; the value of exports plus reexports decreased 8% to \$17.7 million. The average value of 1 ton of fused aluminum oxide, exported or reexported, increased 16% to \$1,294. During the past 10 years, exports plus reexports have averaged 14,360 tons per year, with an average annual value

of \$18.3 million and an average value per ton of \$1,361. The largest quantity of material exported in a single year in the past 10 years was 26,638 tons in 1982, and the smallest amount was 9,915 tons in 1986. During the past 10 years, no trend developed in the export and reexport of fused aluminum oxide. Quantities increased and decreased randomly, and the period ended in 1990 with exports about 7% below those of 1981.

Imports increased about 4% in 1990 to 102,342 tons, and the value of imports increased about 6% from \$62.8 million in 1989 to \$66.7 million in 1990. Average annual imports for the past 10 years were 128,704 tons, with a high of 170,589 tons in 1981 and a low of 98,000 tons in 1989. The trend of fused aluminum oxide imports for the past 10 years was one of general decline throughout 1986, then stabilizing for 3 years at about 81% of the 1981 level. This was followed by a significant 32% decline in 1989 and the 4% increase in 1990.

World Review.—An Australian company and a Japanese partner announced plans for a high-purity fused alumina plant in Western Australia. The 10,000-ton-per-year plant would upgrade alumina into high-quality abrasive and refractory material. The project was fostered by the Ministry of Economic Development.

Silicon Carbide

Government Programs.—The NDS, as of December 31, 1990, contained 43,634 tons of silicon carbide; the goal was 26,364 tons. During 1990, the Defense National Stockpile Center of the Defense Logistics Agency disposed of 9,253 tons of silicon carbide at an average price of about \$591 per ton for a total of \$5,470,760. Existing legislation authorizes disposal of 17,384 tons in the future.

Production.—During 1990, four firms produced silicon carbide at six plants in the United States and Canada. At yearend, three firms were operating only four plants, one having closed during the third quarter of the year and another at the end of the third quarter. Production of abrasive-grade material increased slightly to a 10-year high of 54,339 tons. Average annual production for the past 10 years of abrasive silicon carbide was 46,620 tons, with a low of 36,193 tons in 1983. Production of metallurgical-grade silicon carbide decreased about

20% to 49,890 tons. Average annual production of metallurgical-grade silicon carbide for the past 10 years was 55,716 tons, with a high of 64,998 tons in 1988 and a low of 38,374 tons in 1983. Production of refractory and other grades of silicon carbide increased 4% from the 10-year low of 980 tons in 1989 to 1,022 tons. It was only 4% of the 1981 production, the high for the past 10 years. The average annual production of refractory and other grades of silicon carbide for the past 10 years was 11,059 tons, with a high of 25,903 tons in 1981. Total production of silicon carbide decreased 19% in 1990 to 105,251 tons, compared with a 10-year average annual production of 113,401 tons. The high was 141,442 tons in 1981, and the low was 98,973 tons in 1983. The 10-year production trend for all grades of silicon carbide was one of sharp decline, 30% in 3 years, and then slow growth and recovery through 1989 to 82% of the 1981 production level, followed by the 1990 decline.

Consumption and Uses.—Silicon carbide has a number of different end uses in the form of graded grain. The total value of sales of silicon carbide-graded grain for all uses decreased about 8% in 1990 and was only 81% of the 10-year high recorded in 1988. The total value of sales by individual end use was a mixture of increases and decreases. Sales for use in bonded abrasives were down, coated abrasives were up slightly, refactories decreased 14%, tumbling media decreased, wiresawing abrasive were up slightly, polishing cake and buffing compounds were up 20%, antislip abrasives were down slightly, polishing abrasives were up slightly, and all other uses were down.

Prices.—The Bureau did not collect price data on the various grades of silicon carbide. Data were available on the value of production of the various grades. The average value per ton of abrasivegrade silicon carbide, as reported by producers, was \$514; metallurgical-grade averaged \$458; refractory- and othergrade material averaged \$571; and the average value of all grades was \$488. The average value per ton of abrasive-grade material for the past 10 years was \$507, with a high of \$626 in 1982 and a low of \$436 in 1985. Metallurgical-grade silicon carbide averaged \$432, with a high of \$466 in 1983 and a low of \$391 in 1988. Refractory grade was \$545, with a high of \$644 in 1988 and a low of \$442 in 1986. For all grades the average was \$468, with a high of \$535 in 1982 and a low of \$417 in 1985. The trend for the value of all grades of silicon carbide for the past 10 years was one of increase, 10% in 1 year, followed by a general decrease through 1985, then stabilization with 3 years essentially unchanged at 88% of the 1981 value. Then 1989 saw a significant increase of 13% compared with the average value of the past 3 years, and 1990 was only slightly higher than 1989. Mineral price quotations in various December issues of trade magazines listed prices for metallurgical grades of silicon carbide of \$1,110 to \$1,388 per ton, while abrasive grade was quoted at \$1,573 to \$1,758 per ton.

Foreign Trade.—Exports plus reexports of silicon carbide in 1990 were 8.179 tons, essentially the same as those of 1989. While the total value of silicon carbide exported plus reexported increased about 4% to \$10.3 million, the value per ton increased 7% to \$1,263 and was within 32% of the 10-year high of \$1,865 in 1986. The average annual exports plus reexports for the past 10 years were 6,199 tons, with a high of 10,442 tons in 1981 and a low of 3,859 tons in 1986. The average annual value per ton of exports plus reexports for the past 10 years was \$1,454, with a high of \$1,865 in 1986 and a low of \$1,068 in 1981. The value of exports plus reexports fluctuated greatly during the past 10 years; values were up as much as 75% of the value at the beginning of the period and closed the period 18% greater than at the beginning.

Imports of silicon carbide in 1990 decreased 23% in quantity to 75,640 tons, 19% in total value to \$52.5 million, and increased 5% in average value per ton to \$694. The average annual imports for the past 10 years were 76,966 tons, with a high of 101,600 tons in 1988 and a low of 56,250 tons in 1985. The average value per ton for the period was \$597, with a high of \$694 in 1990 and a low of \$539 in 1986. The trend of silicon carbide imports for the past 10 years was one that generally decreased to a low in 1985, followed by continuing increases until 1988, followed by continuing decreases until 1990 imports were only slightly greater than those of 1981.

Alumina-Zirconia Oxide

One firm produced fused aluminazirconia oxide in two plants, one each in TABLE 18

the United States and Canada. Abrasive applications accounted for all the production. Output increased in both tonnage and value compared with that of 1989. Publishing production data would disclose company proprietary data. Export and import data were not available.

Metallic Abrasives

Production.—Nine firms produced metallic abrasives in 11 plants at the end of 1990. During the year, one firm closed its plant and went out of business, and another firm closed one of its plants, but opened another. The quantity and value of steel shot and grit produced increased about 4%. The average value per ton was essentially the same as that for 1989, \$386 per ton. The average annual

¹Excludes secondary (salvage) producers

production for the past 10 years was 178,167 tons, with a high of 213,879 tons in 1990 and a low of 135,843 tons in 1982. The average value per ton during the period was \$359, with a high of \$402 in 1982 and a low at \$310 in 1987. The trend of steel shot and grit production for the past 10 years was one of decline to the low in 1982 and then general continued recovery. The 1990 production was equal to about 114% of the 1981 production level. Michigan, Ohio, Pennsylvania, Virginia, and Indiana, in

decreasing order of quantity, supplied the production of steel shot and grit.

During 1990, two companies, one each in Indiana and Ohio, produced chilled and annealed iron shot and grit; by yearend, the Indiana plant was closed. Additionally, two firms, one in Michigan and one in New York, reported production of cut wire shot. Production of chilled and annealed iron and cut wire shot and grit declined significantly in 1990, 41% in quantity to 10,260 tons and 37% in value to \$6.6 million. The

average value per ton increased about 7% to \$646. The average annual production of these types of shot and grit for the past 10 years was 16,373 tons, with a high of 19,848 tons in 1981 and a low of 13,352 tons in 1986. The average value per ton for the past 10 years was \$474, with a high of \$646 in 1990 and a low of \$344 in 1981.

Consumption.—The quantity of steel shot and grit sold or used increased slightly to 209,095 tons, the total value increased 6% to \$86.6 million, and the

^rRevised. W Withheld to avoid disclosing company proprietary data; included with "Other." XX Not applicable.

average value per ton increased slightly to \$414. The average annual quantity of steel shot and grit sold or used for the past 10 years was 178,542 tons. The high was 214,787 tons in 1988, and the low was 133,275 tons in 1982. The trend for sold or used steel shot and grit for the past 10 years was one of fluctuating decreases and increases. The 1990 sold-and-used value was 13% greater than the value in 1981.

The quantity of chilled and annealed iron and cut wire shot and grit sold or used decreased 38% to 10,484 tons. The value decreased about 32% to \$7.8 million. The average value per ton increased 9% to \$742. The average annual quantity of these shot and grit sold or used for the past 10 years was 15,546 tons, with a high of 18,192 tons in 1984 and a low of 9,152 tons in 1985. The trend for the sold-andused value for the past 10 years was one of large individual increases and decreases. Changes were as much as 50% in 1 year, with the low in 1985. Since then, continued growth resulted in the 1989 value equaling 178% of the 1981 level before the significant decrease in 1990.

The estimated apparent domestic consumption of all types of metallic shot

and grit decreased 6% in quantity to 201.368 tons, 4% in total value to \$86.4 million, and increased slightly in average value per ton to \$428. The formula to calculate U.S. estimated apparent consumption is U.S. sold or used plus imports minus exports. The average annual estimated apparent consumption of metallic shot and grit for the past 10 years was 188,090 tons, with a high of 224,216 tons in 1988 and a low of 144,986 in 1982. The average value per ton for the same period was \$403, with a high of \$432 in 1985 and a low of \$375 in 1987. The trend of apparent consumption for the past 10 years was one of rapid increases and declines until 1985. This was followed by general growth until 1988 consumption was 13% greater than that of 1981, but with the declines in 1989 and 1990 consumption, it was slightly less than that of 1981.

Foreign Trade.—U.S. exports of metallic shot and grit increased 53% to 25,559 tons. The total value of exports increased 98% to \$12.9 million, and the average value per ton decreased 29% to \$505. The average annual tonnage of metallic shot and grit exports for the past 10 years was 10,473 tons, with a high of 12,900

tons in 1990 and a low of 6,334 tons in 1986. The average value per ton for the past 10 years was \$739, with a high of \$948 in 1987 and a low of \$390 in 1989. The trend for metallic abrasive exports for the past 10 years was one of general decline from 1981 through 1983, followed by fluctuating increases and decreases. The 1990 exports were 77% greater than the level of 1981 exports.

U.S. imports of metallic abrasives increased 76% in quantity to 7,346 tons, increased about 46% in total value to \$5.0 million, and decreased 18% in value per ton to \$678. The average annual imports for the past 10 years were 4,566 tons, with a high of 8,509 tons in 1984 and a low of 2,699 tons in 1987. The average value per ton for the period was \$877, with a high of \$965 in 1988 and a low of \$280 in 1984. The trend for the quantity of imports for the past 10 years was one of up-and-down fluctuations resulting in a general decline through 1987, followed by an increase until 1990 imports were about 154% of those of 1981.

The United State was a net exporter of metallic abrasives in 1990, a position it has enjoyed by a significant ratio for the past 10 years.

¹Excludes secondary (recycle) producers.

²Total quantity of the various types of metallic abrasives that a plant could have produced during the year, working three 8-hour shifts per day, 7 days per week, allowing for usual interruptions, and assuming adequate fuel, labor, and transportation.

³Includes cut wire, aluminum, stainless steel shot, and items indicated by symbol W.

ADVANCED MATERIALS

By Rustu Kalyoncu

Dr. Kalyoncu, industrial specialist, Branch of Materials, has more than 22 years of experience and has been with the U.S. Bureau of Mines for the past 12 years.

dvanced materials are metals, metal alloys, ceramics, polymers, and composites developed during the past 20 years that have higher strength-to-density ratios, greater hardness and wear resistance, and one or more superior thermal, electrical, optical, or chemical properties compared with traditional materials. They offer savings in energy consumption, improved performance at reasonable cost, and less dependence on imports of strategic and critical mineral resources.

The decade of the 1980's witnessed the recognition of advanced materials as critical to future technologies by the industrialized nations, with the United States, Japan, and the European Community (EC) being major competitors. All three have identified communications and information technologies, as well as biotechnology and advanced materials synthesis and processing as the key to future industrial leadership. The closing decade of the 20th century is expected to be an era of rapid development and restructuring of the advanced materials industries. Significant challenges are posed to the position of the United States in the world economy. European Community 92 is seriously challenging the United States through its effort to develop uniform standards and remove trade barriers in Western Europe. The Japanese are challenging the United States in their attempts to commercialize advanced structural ceramics, alloys, composites, and superconductors. Developing countries and other industrialized nations, such as Australia, Canada, and the Republic of South Africa, have recognized the need to move from the status of commodity mineral and materials suppliers to full participants in advanced materials technologies.1

A growing awareness by the U.S. Government of the importance of advanced materials in the race for global technological leadership has led to the reorganization of the Office of Science and Technology Policy (OSTP) in the Executive Office of the President. The Director of the OSTP, who is also the Science Advisor to

the President, designated advanced materials as the essential element of technical and industrial competitiveness. The Federal Coordinating Council for Science, Engineering, and Technology (FCCSET), chaired by the Science Advisor, has Assistant Secretary level participation by all agencies having responsibilities in materials research and development. The newly formed President's Council of Advisors on Science and Technology (PCAST), also chaired by the Science Advisor, has industrial and academic members with knowledge of and interest in advanced materials. Both FCCSET and PCAST report directly to the President.

National Competitiveness Technology Transfer Act of 1989 (Public Law 101-189) was signed by the President in November 1989. The law is designed to link industry, universities, and national laboratories to accelerate commercialization of new technologies, including advanced materials. The law makes provisions allowing national laboratories to enter into cooperative research and development agreements; negotiate licensing agreements for inventions; exchange personnel, services, and equipment with industry and universities; waive rights to inventions and intellectual property; and streamline the processing of agreements. It also assigns a technology transfer mission to the nuclear weapons laboratories.

The Department of Commerce established a new Office of Technology Administration in 1989. The Undersecretary for Technology is to work closely with the President's Science Advisor to help coordinate strategies and programs in the Federal agencies. The focus will be to remove barriers to and provide incentives for rapid commercialization of technology in the United States. Advanced materials are essential components of all new technologies and are to receive increased attention.

Two bills addressing advanced technologies and materials were introduced in the Congress in 1989. No action was taken. One bill, the American Technology

Preeminence Act of 1990 (H. Res. 3042), was reintroduced in 1990. This bill provides appropriations to strengthen the role of the National Institute of Standards and Technology (NIST, formerly the National Bureau of Standards) in assisting private industry in commercialization and marketing of new technologies and processes needed to remain competitive in the global marketplace. The funds, provided to the Commerce Department Advanced Technology Program, are to be administered by NIST. Prospects for this bill appeared to be positive at the time of its introduction. Congressman Don Ritter (R-PA), the only materials scientist in Congress, said a comprehensive effort such as H. Res. 3042 is needed to pull together tax, trade, regulatory, and research and development policies to improve U.S. competitiveness.

In the fall of 1990, an individual group workshop was asked to diffuse major hurdles so that composites representatives from the aerospace, automotive, electronic, and construction industries could identify critical barriers in composite processing and serious performance issues. The most important problems stated were the inability to control resin flow and fiber orientation. Higher priority was given to process monitoring, measurement, and control of fiber-matrix adhesion, and joining techniques as technical barriers to full exploitation of emerging fabrication technologies.

The energy crises of the second half of the 1970's not only resulted in low economic growth and recession on a global basis, but also indicated the extent to which the industrial health and economic wellbeing of the EC, Japan, and the United States were dependent on suppliers of energy, minerals, and commodity materials around the world. The need for improved energy efficiency and less reliance on other nations for raw materials have fueled the motivation for development of structural materials with higher strength-to-weight ratios, greater resistance to high temperatures, better corrosion resistance, and enhanced durability and reliability. The candidates for new structural materials (advanced structural ceramics, superalloys, engineering polymers, and their composites) have become subjects of intense research and development and constitute one of the major areas of international competition.

Advanced structural ceramics possess a number of outstanding high-temperature mechanical and chemical properties that make their application ideal in thermally and chemically demanding environments. They can replace metals and plastics in many existing systems to provide better performance and durability and are enabling components in new technologies. Advanced structural ceramics have been slow to develop owing to technical and economic factors. It is fair to say that advanced structural ceramics are in their infancy, but are predicted to become increasingly important as problems are solved and new applications requiring superior properties from materials are developed.

Advanced or superalloys are materials formed by combining two or more metals. They exhibit properties far superior to those of the individual metals comprising the alloy. Advanced alloys containing nickel, iron, and cobalt are generally used at temperatures above 500° C. Develop-

ment of advanced alloys has played an important role in creating interest in advanced materials.

Composite materials are two component materials in which one material of differing morphology, usually in the form of a fiber or whisker, is scattered within a powder matrix of similar or different composition. Fiber composites combine desired properties of ductility and high-fracture toughness of the matrix with high-temperature strength and stiffness of fibers in order to offer superior performance. Composites have dominated materials use in aerospace and defense applications for many years.

Advanced polymer matrix composites (PMC), consisting of a wide variety of engineering plastics reinforced with continuous fibers, filaments, or tapes or with short, discontinuous fibers, whiskers, or particles, also hold great promise for a variety of structural applications. Their superior strengths, high strength-to-weight ratios, corrosion resistance, and potential for reduction of the numbers of parts to be assembled in a given system ensure that their application areas will widen. Use of PMC's as replacements for metals, glass, or ceramics requires, however, essentially different plants and equipment, neces-

sitating large capital expenditures and development of automated equipment. For these reasons, PMC's are finding rapidly increasing applications in defense, aerospace, and sporting goods where improved performance justifies the higher costs. They have been slow to find extensive applications in the automobile industry. However, new fuel consumption standards, rising fuel costs, more stringent exhaust emission standards, and demand for improved durability and performance are adequate incentives for automobile manufacturers to reevaluate their use.

A significant portion of research and development (R&D) in advanced materials is conducted or sponsored by the U.S. Government. Expenditures are not available for estimating the extent of R&D and pilot plant operations in industry. Estimates put these industrial efforts on a par with, or even twice as much as, the Federal spending. Table 1 summarizes total materials R&D expenditures for a number of Federal agencies in fiscal years 1990 through 1992. The total R&D support for materials for 1990 was almost \$1.5 billion, with a significant increase in fiscal year 1991, and the President's request to the Congress for fiscal year 1992 shows a slight increase over that of fiscal year 1991.

TABLE 1
TOTAL FEDERAL MATERIALS RESEARCH AND DEVELOPMENT FUNDING, BY AGENCY

Agency	Fiscal year (actual)		Fiscal year (anticipate		Fiscal year 1992 (President's budget)	
	Million dollars	Percent	Million dollars	Percent	Million dollars	Percent

The U.S. Department of Energy (DOE) funds almost 50% (\$729.6 million in FY 1991) of Federal materials R&D, 70% of which is for research conducted in the DOE National Laboratories, 25% of which is provided in grants to universities, and 5% of which is given to industry. DOE's interests cover the entire range of ceramic science: processing and synthesis; deformation, fracture, and cyclic fatigue; stress corrosion; electronic ceramic, microstructure, defects, and dislocations; surfaces, interfaces, and grain boundaries; radiation effects; toughening mechanisms; and superplasticity.

The Department of Defense funds a wide variety of materials R&D, with the major emphasis on development and rapid application to military systems. Total funding for fiscal year 1991 was \$470.0 million, 26% of the total. The research is accomplished partly in-house, in such laboratories as the Army Materials Technology Laboratory, the Naval Research Laboratory under the Office of Naval Research (ONR), the materials laboratories of the Wright Research and Development Command, and the Naval Surface Warfare Center. The remainder is conducted by universities and industry through funding by the Army Research Office-Durham, ONR, the Air Force Office of Scientific Research, and the Defense Advanced Research Projects Agency.

Table 2 summarizes fiscal year 1992 Federal Government R&D expenditures as requested by the President from the U.S. Congress, by type of material and Government agency. For ceramics R&D, \$68.6 million was requested by DOE alone. This represents more than 55% of the total ceramic R&D expenditures. Department of Defense is the second with \$21.4 million or more than 17% of the total. National Science Foundation is the third major agency, with \$17.1 million.

The significance of advanced materials to the economic future of the United States has been made explicit by a number of official reports to the Congress and interested Federal agencies.² The Office of Technology Assessment, at the request of the Congress, prepared a report outlining the role advanced structural ceramics, engineering polymers, and composites would play in determining the future leadership among individualized nations. Along the same lines, the National Research Council (NRC) released a report,3 emphasizing the inadequacy to synthesis and processing of new materials by Federal research establishments. The U.S. Bureau of Mines published volumes

1 and 2 of the New Materials Society series that give a summary of the science and technology, economic and policy issues, and the status of new materials markets.⁴ The Bureau reports give adequate coverage to recent and potential developments in advanced materials with emphasis on improved processing for better physical properties.

DOMESTIC DATA COVERAGE

The structure of the advanced materials industries of the United States is diverse in terms of the wide variety of products and the kinds of companies engaged in manufacturing.⁵ Unfortunately. systematic data collection on the structure of the advanced materials industry or production of materials has been done. Between the U.S. Bureau of Mines data on commodity minerals and metals and the Bureau of the Census data on commodities and finished products, the flow of processed materials through various value added steps between commodity and product is not covered. The U.S. Bureau of Mines is in the process of developing data acquisition methods to cover advanced materials production but presently must rely on data from existing sources. The limited accuracy

ADVANCED MATERIALS—1990 105

²Data may not add to totals shown because of independent rounding.

and inadequacy of these data, mostly in highly aggregated form, permit only broad generalizations about the current status of new materials and virtually allow the depiction of no historically valid trends.

The publishers of Ceramic Industry magazine, over the past 9 years, have conducted the only systematic survey of the industry, relying on voluntary reporting of sales figures and their own estimates of those of nonreporting companies. Most of the information on ceramics reported here is from the results of the Ceramic Industry surveys of 1986, 1987, 1988, 1989, and 1990. The data for 1990 were generously provided in advance of publication by Ms. Patricia Janeway, Editor in Chief and Associate Publisher. Similarly, data on production and costs of PMC's are from the open literature.

In 1990, the Suppliers of Advanced Composite Materials Association (SACMA) and the European Trade Association of Advanced Composite Materials Suppliers (ETAC) jointly reported more than 10,000 metric tons of advanced fibers and almost 13,000 metric tons of preimpregnated composites were shipped worldwide as shown in table 3. On a dollar value basis, shipments increased 14% for advanced fibers and 11% for preimpregnated composites over the comparable period in 1989. More than 90% of the total world production was by the 26 member companies of SACMA. Twelve companies in the United States accounted for the 60% of total production, 10 companies in Europe represented about 15% of the total, and 4 companies in Japan delivered most of the 26% share of Asian production. Epoxy resins continued to make up the bulk (more than 90%) of the matrix materials, with carbon fibers accounting for almost 60% of fiber production by weight, followed by Aramid fibers with 25% and glass fibers with 13%.

The aerospace sector continued to be the primary beneficiary, accounting for 50% to 55% of advanced polymer composite shipments, recreational use with about 30%, and the remaining for marine and other industrial applications. Total shipment of advanced composite materials was \$1.1 billion, with about \$700 million the U.S. share. Estimated production figures for 1991 are reported to be 11,550 metric tons of fibers and almost 14,000 metric tons for preimpregnated composites for a total of 25,500 metric tons with total dollar value of \$1.25 billion. Again, the expected share of the United States is 60%.

ADVANCED STRUCTURAL CERAMICS

Background

Definitions, Grades, and Specifications.—Advanced structural ceramics are a relatively new class of high-performance ceramics with significant potential for future economic impact. They differ from traditional ceramics by the nature of their specialized properties such as high-temperature strength and higher resistance to chemical corrosion. On the other hand, these materials also require more expensive, sophisticated fabrication techniques.

In recent years, great interest has been shown in advanced, high-technology ceramics by scientists, engineers, and policymakers. This interest has been especially fueled by the competition between the United States and other industrial nations in developing new commercial applications for advanced ceramics. Nowhere is the attention given to advanced ceramics more pronounced than in Japan. Interest in the "new ceramics," or "fine ceramics" as they are referred to in Japan, has reached a "fever" pitch. This interest is evident by the large number of nonceramic manufacturers entering into ceramic R&D and production.

Ceramics are defined by the National Academy of Sciences as "inorganic, nonmetallic materials processed or consolidated at high temperatures." Traditional ceramics are primarily based on aluminosilicate compositions, more commonly known as clay minerals, such as kaolin used in pottery, brick, and classical porcelain. On the other hand, advanced, high-technology ceramics include a wide variety of oxides, nitrides, carbides, borides, and others. Unique properties of these inorganic materials enable applications ranging from electronic components to heat- and wear-resistant parts to optical devices. These properties are hightemperature strength, controlled thermal and electrical conductivity, and resistance to high-temperature corrosion and erosion. Depending on the specific application, these materials can also exhibit singular electrical, electronic, magnetic, and optical properties.

The number of chemical compositions and processing variables in advanced structural ceramics is quite large. However, potentially important materials for large-scale applications are limited. These are alumina (Al₂O₃), boron carbide (B₄C), silicon carbide (SiC), silicon nitride (S₃N₄), sialons (solid solutions of silicon nitride and alumina), and various forms of zirconia (ZrO₂). Attention is focused on these, with brief mention of other materials and their uses.

Alumina (aluminum oxide), though one of the most abundant oxides in the crust of the Earth, is for practical purposes obtainable only from bauxite, a complex mixture of hydrated aluminum oxides. Bauxite must be refined to produce anhydrous oxide suitable for use as feedstock for reduction to aluminum, refractory grain, or other specialty products. Alumina is used for a wide variety of ceramic products,

including refractory brick, cements, and castable refractories. High-purity alumina compositions, those with 75% to 99% Al₂O₃, are high-value materials used because of their electrical resistivity for semiconductor and integrated circuit substrates, high-frequency insulators, holders and spacers for printed circuits, and spark plug insulators. The high strength and hardness of alumina make it suitable for seal surfaces for rotary pumps, nozzles for a variety of applications, cutting tools, nonlubricated roller bearings, grinding media, and a host of other applications requiring strength, hardness, and wear resistance. Alumina retains about 90% of its mechanical strength up to 1,100° C, though its high thermal expansion coefficient results in poor thermal shock resistance, which limits its use in applications involving rapid temperature changes. A promising new material is transformation-toughened alumina, with 8% to 15% by volume of ZrO₂ included in the composition. Cracks that normally develop during rapid cooling are prevented from growing and causing catastrophic failure by the transformation in ZrO₂, which is discussed later. A family of alumina fibers targeted for use as reinforcement in a variety of composites is now commercially available. These are spun from solutions or slurries of alumina-containing precursors, followed by heat treatment. They are available as woven preforms, papers, and mats.

Boron carbide (B₄C) is harder than all known materials, other than diamond and cubic boron nitride. It has found use, therefore, as an abrasive, abrasion-resistant component, and ceramic armor. Because of the high neutron cross section of boron, both boron and boron carbide have been used as reactor control elements, radiation shields, and moderators.

Silicon carbide (SiC) has been used for almost 100 years as an abrasive and as a component of electrical heating elements and, more recently, as a super refractory. High-purity silicon carbide, with less than 1.2% impurities, is a prime candidate for many structural applications requiring high strength at high temperatures and good wear resistance, such as in automotive engines. High-strength fibers of silicon carbide have been produced by chemical vapor deposition; platelets and whiskers have also found use as reinforcements for ceramic, metal, and polymer composites.

Silicon nitride (Si₃N₄) exhibits excellent corrosion and oxidation resistance over a

wide temperature range and retains its high strength up to 1,100° C. Because of such properties and high hardness, it has been under evaluation for use as components in gas turbine engines and heat engines and as high-temperature bearings, cutting tools, industrial wear parts, and ceramic armor. Sialons, oxynitrides of silicon and aluminum, are similar in structure and properties to silicon nitrides. They are being used as lubrication-free bearings, rocket nozzles, and gas shrouds for orbital welders.

Zirconia (ZrO₂), produced from the mineral zircon (ZrSiO₄) or less commonly from baddeleyite (ZrO₂), exists in three different crystalline forms, depending on temperature and amounts of other oxides (magnesia, MgO; lime, CaO; or Yttria, Y₂O₃) included in the crystal structure during synthesis. By incorporation of several percent of the stabilizing oxide, a mixture of cubic and tetragonal forms can be produced. Stress applied to the materials, by external mechanical force or resulting from rapid temperature change. causes transformation of the tetragonal form to the low-temperature monoclinic form. This results in an increase of 3% to 5% in the volume of the crystal, effectively blocking crack growth and total fracture of the ceramic body. This phenomenon is called transformation-toughening because the impact resistance is increased manyfold. Zirconias containing both cubic and tetragonal phases are called partially stabilized zirconia (PSZ). Those containing only tetragonal zirconia are called tetragonal zirconia polycrystal (TZP). Ceramics with added zirconia are called transformation-toughened ceramics (TTC); transformation-toughened alumina (TTA) has found application as a grinding and cutting material.

Other ceramics used or being evaluated for advanced applications include aluminum titanate, Al_2TiO_5 , stable to 1,865° C, for use as shock-resistant materials in catalytic converters and diesel engine components, and cordierite, $Mg_2Al_4Si_5O_{18}$, with a low thermal expansion coefficient, in similar applications.

Products for Trade and Industry.—Advanced ceramic products may be categorized in several ways. A pragmatic classification is illustrated in figure 1, taking into account functions, applications, and materials.⁷

As figure 1 illustrates, electrical, magnetic, optical, thermal, mechanical,

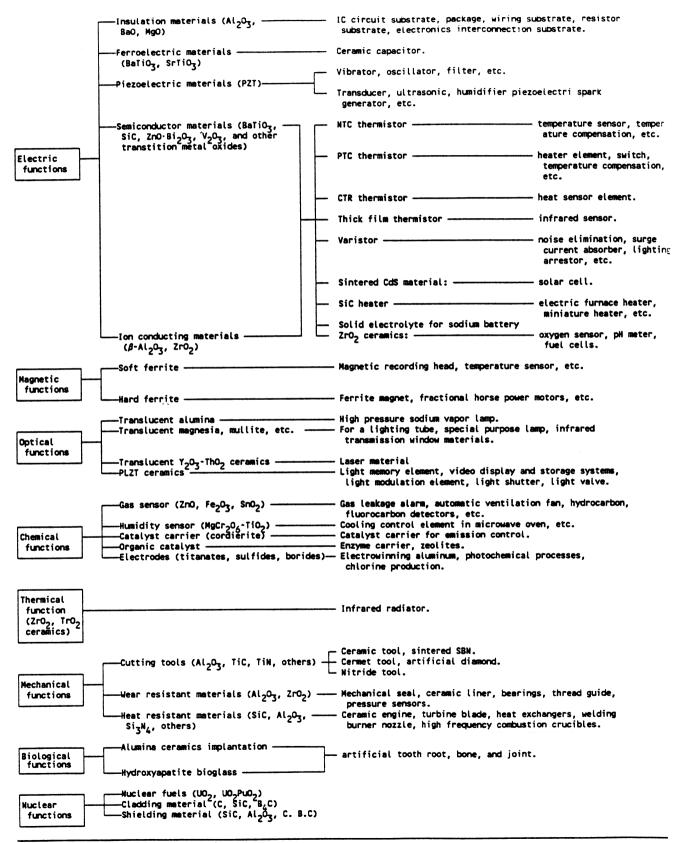

and nuclear properties of advanced structural ceramics dictate their suitability for a specific application. On the one hand, they can be employed as insulators, while on the other, they can be used as semiconductors or even superconductors. Ferrite compositions are used in many magnetic applications as soft and hard magnets. Fiber-optic technology owes its advances to translucent yttria-thoria ceramic compositions. Many well-known ceramic materials find applications as sensors (titania), catalyst supports (cordierite), and electrodes (borides, sulfides, etc.) because of their unique chemical characteristics. High-temperature stability of refractory compounds (alumina, magnesia, etc.) make metal and gas refining technologies possible. Refractories are also used as wearresistant (cutting tools) and heat-resistant (silicon carbide) structural materials because of their superior hardness and strength. Finally, advanced ceramics find utility in nuclear applications as shielding (carbon, silicon carbide, boron carbide, etc.), cladding (carbon, silicon carbide, etc.), and nuclear fuels (uranium oxide and plutonium oxide).

Industry Structure.—The structure of the ceramic industry of the United States is diverse in terms of the wide variety of products and the kinds of companies engaged in manufacturing. Table 4 is a synthesis of information available for calendar year 1990, derived from the Ceramic Industry survey and compared with data for 1986, 1987, 1988, and 1989.8

Two of the largest U.S. producers of advanced structural ceramics are Corning Inc., Corning, NY, a major manufacturer of glass, glass ceramics, and other commodity ceramics, whose major advanced products are ceramic honeycomb for automotive catalyst carriers and optical fibers, and Cooper Industries, Houston, TX, which recently acquired the Champion Spark Plug Co. Reported sales for Corning were \$895.3 million and for Cooper Industries were \$460 million for 1990. Within the \$200 to \$500 million range are AC Spark Plug Div. of General Motors Corp., which accounted for \$336 million in sales of spark plugs; GTE, Stanford, CT, reporting sales of \$398.3 million; and Allied Signal, Morristown, NJ, whose Autolite Div. posted spark plug sales of \$212 million. Table 5 shows the number of largest U.S. and worldwide advanced ceramics producers for 1990.

Among the top 10 advanced ceramics producers with sales of more than \$50 million dollars, all but 1 are primarily manufacturers of spark plugs, optical fiber, electronic components, and porcelain insulators.

The smaller companies with sales of less than \$50 million, as tabulated in table 5, are the major producers of advanced structural ceramics. As evident in table 5, many of these are privately held entrepreneurial companies. Ownership of these small companies over the past 5 years has been changing rapidly through mergers and acquisitions, many with and by foreign companies. Some large foreign companies such as Kyocera America Inc., which has plants in nine locations within in the United States, have been expanding rapidly in the United States and Europe.

In summary, 1990 was a relatively active year in terms of acquisitions and cooperative agreements. Acquisition by foreign companies interested in expanding capacity for production of advanced ceramics and developing new markets for these materials continued.

Table 6 summarizes sales of major categories of finished ceramic products. The importance of advanced ceramics to the economy can be noted in that sales constitute 23% of the total ceramic industry.

Technology.—Processing.—Conventional processing methods of the 1950's, consisting of dry pressing, slip casting, and firing into final shape, have proved to be inadequate to create superior properties within advanced structural ceramics. However, through intensive R&D efforts in the 1970's and 1980's, a number of novel powder processing and fabrication methods

³41.200

¹Sales are reported for only United States in 1986-89. In 1990, only a total U.S. value is available; however, a breakdown by category is given for the top 145 producers in total worldwide sales.

²The categories of ferrites and porcelain add up to \$513 million.

have been devised. These novel methods can be broadly classified according to whether solutions, vapor phases, or solid-state decomposition of salts are involved. Further division of these methods into subcategories can be made according to how the solvent is removed or by the presence and nature of the vapor phase reactions.

Solution preparation methods remove the solvent while maintaining as much of the homogeneity of the solution as possible. Such methods need to be easy to perform and still allow close control of desired compositions and purity. Sol-gel process is a well-known example of this type of solution preparation method. Sol, consisting of very small crystals dispersed in an aqueous solution, is introduced into a dehydrating solvent, such as alcohol, to form a gel. The gel is separated and dried further, leaving behind a fine powder residue with a high degree of chemical homogeneity and morphological (shape) uniformity. This method has been successful in preparing advanced structural ceramic powders, such as titanium and zirconium oxides.

Vapor phase preparation methods, both condensation and decomposition types, have been successfully used to synthesize ultrapure and ultrafine non-oxide ceramic powders, such as silicon nitride and silicon carbide. A straightforward way of producing a vapor of a desired composition is to evaporate or sublimate the ceramic material. Vapor decomposition and vaporvapor reactions are more commonly used for fine powder preparation. An excellent example of the latter reactions is the synthesis of silicon nitride from silicon tetrachloride and ammonia gas. Vapor decomposition of precursor salts is also an important step in the preparation of many fine powders. For example, fine powders of many carbonates and metallo-organic precursors are thermally decomposed into fine oxide and non-oxide powders.

The industry's ability to produce ultrapure, ultrafine ceramic powders created the need for new and improved fabrication methods beyond the more conventional ceramic processing techniques, such as extrusion and slipcasting. The dispersion of fine powders in liquids had to be improved in order to prepare stable suspensions. This improvement led to a better understanding of the physical chemistry of the solid-liquid interfaces, which in turn led to new colloidal forming techniques. Among such techniques, injection molding and isostatic pressing are the most prevalent.

Injection molding is a relatively inexpensive, high-volume method for making nearnet-shape, fine powder ceramic components. This method essentially consists of mixing fine ceramic powder with a thermoplastic or thermosetting polymer in a mold at a temperature that allows the mixture to have the proper fluidity under pressure. A plunger is then pressed against the heated mixture, forcing it into a tool cartridge of the desired shape. Injection molding, which was initially developed for the plastics industry, is finding increased use in the manufacture of advanced structural ceramic components.

Hot isostatic pressing involves heating an already fired ceramic piece at a very high constant pressure. The pressing is usually accomplished in an inert gas at a high temperature. This method has proven to be invaluable in the sintering of difficult to densify materials such as silicon carbide and silicon nitride.

Research efforts are in pursuit of better fabrication methods for advanced structural ceramics, especially fiber composites. One such method under development is called the Dimox method¹² developed by Lanxide Corp. This method makes a preform using a conventional ceramic forming process and a unique oxidation method discussed in greater detail under metal matrix composites.

Joining Methods.—Because of their size and complexity, some large components cannot be processed as a single unit. Moreover, different components have been made of different materials that usually require different processing methods. Such considerations make manufacturing of many structural parts as a single unit virtually impossible, requiring the joining of many advanced ceramics in structural applications. Among a number of new joining methods currently being considered are liquid phase brazing, active metal brazing, and solid-state and diffusion joining. ¹³

Thermal expansion mismatch between ceramics and metals poses the greatest difficulty in the ceramic-to-metal joints. Large thermal expansion difference results in high residual stresses at the joints, thus lowering joint strengths. Therefore, all the joining techniques concentrate on minimizing the residual stresses at the joint. Use of a ductile compliant metal layer helps minimize residual stress concentrations by distributing the stresses over the entire metal-to-ceramic interface. Choosing a compliant metal with an intermediate

thermal expansion value between the two materials to be joined helps to further reduce the residual stress.

Compression joining or shrink-fit brazing takes advantage of the thermal expansion mismatch between the ceramic and the metal by brazing the ceramic component into the metal at a temperature that allows the plastic deformation of the metal around the ceramic component. ¹⁴ Upon brazing, the metal with higher thermal expansion shrinks around the ceramic, providing a "good joint" and compressive stress on the ceramic.

A liquid phase brazing technique is a highly developed method for joining dissimilar materials. 15 Brazing of metals poses little or no difficulty, but brazing of ceramics is extremely difficult mostly due to high temperature requirements, difficulty of wetting of the ceramic surface by the metal, and differential thermal expansion between ceramics and metals. Most R&D efforts go into alleviating these problems in ceramic-metal joint systems. Wetting problems have mostly been overcome by inserting an intermediate layer between the metal and the ceramic. Eutectic compositions of Ni-Cr-Si, Nb-Mo, Ti-Al-Fe, and Ag-Al-Ti have been extensively studied as potential interlayers.

High-strength silicon nitride-metal joints have been made with a thin layer of aluminum metal sandwiched between two layers of aluminum-10% silicon alloy. Similarly, silicon carbide-steel joints have been successfully formed with copper-35% manganese and copper-carbon composite compliant layer.

The greatest disadvantage of active metal joints is their lack of high-temperature capability compared to the ceramic component. The use of very high temperatures during the brazing process—in order to form liquid for wetting of the ceramic surface—results in the formation of high residual stresses, which in turn cause high strain levels, leading to weakening of the joint.

Reduction of residual stresses at the joint has been the subject of numerous investigations. ¹⁶ Ceramics and metals with large thermal expansion differences have been shrink-fitted to form a compression joint. The essence of compression joint is to design a ceramic component with a hub or platform upon which the metal can be isothermally forged using a compliant interlayer. The metal component, momentarily heated to effect its plastic deformation under applied pressure, is placed around

the ceramic shaft and is shrink-fitted by gradual cooling. The shrink-fit joining is relatively simple and reproducible and gives joint strengths of 200 Mega Pascal or higher at 600° C.17 Moreover, this technique, which is the most expensive of joining methods, provides an intimate contact between the joined surfaces of complex shapes, uniformly distributes the residual stresses over the whole ceramic face so as to eliminate any stress concentrations, and avoids potentially harmful chemical reactions between the ceramic and metal. This method is especially appropriate for forming blades-to-disc, valveto-shaft, and rotor-to-shaft joints.18

Although surface morphology of the ceramic component in ceramic-metal joints appears to play an important role in the joint quality, very few studies have been concerned with surface morphology effects. Rough surface morphology leads to good mechanical bond when a ceramic-metal joint is formed using a metallic filler layer. However, excessive roughness can limit effective wetting of the ceramic by the liquid metal, thereby leaving voids in the joint that may act as fracture origin and stress concentration centers. When this happens the joint is significantly weakened.

Nitride glass compositions (in the system Y-Al-Si-O-N) have been shown to be excellent candidates for joining ceramics to ceramics, especially silicon nitride to silicon nitride, in the same manner the grain boundary phases join individual silicon nitride grains in monolithic polycrystalline ceramics on a microstructural level.19 Outstanding physical characteristics of nitride glasses, such as hardness, Young's modulus, and very high melting points help form strong hightemperature ceramic-ceramic joints. Such properties improve with nitrogen content. Close joints, formed by intimate glassceramic interaction, prevent the formation of voids, lead to excellent bond strengths, and exhibit excellent room temperature toughness.

Applications.—Current and potential areas for advanced structural ceramics range from heat engines to electronic devices and optical sensors. Theoretically, the development of an all-ceramic heat engine could increase efficiency threefold to fourfold. Currently, heat engines with cooling systems, such as automobile engines, operate at about 25% efficiency. Almost 65% of the energy is dissipated by internal cooling and through the exhaust

system. The remaining 10% is lost in the form of frictional heat.

Advanced ceramics also are used in capacitors, integrated optic devices, gas sensors, and cutting tools. Capacitors have electric components that store electric charges and are employed in conjunction with other active electric components to perform a variety of functions, such as reducing noise levels in an electric signal (static in radios). Ceramics used for nonconductive parts in capacitors serve as dielectric layers that insulate the conducting components from the electrical charge. Aluminum oxide, tantalum pentoxide, and natural mica are examples of ceramics used as dielectrics.

Integrated optic circuits are devices that perform a variety of functions on the light beams they guide. The largest end use for these devices will be in fiber-optic communication systems, especially for computer-to-computer data links. Other potential optical end uses may include sensing and signal processing. In the near term, these devices are expected to be manufactured using single-crystal ceramics, such as lithium niobate.

Sensors are devices that respond to a changing condition. As such, they are used to monitor a number of mechanical, chemical, electrical, magnetic, and thermal stimuli. For example, ceramic oxygen sensors are installed in automobiles to help monitor fuel combustion by responding to the amounts of oxygen levels in the fuel mixture. Other places that ceramic gas sensors are used in automobiles are self-regulating heaters and current limiters.

Metal cutting and machining tools have been used since ancient times to remove excess materials during the manufacturing process. A relatively new class of cutting tools made from advanced structural ceramics, such as alumina, silicon carbide, and silicon nitride, have enhanced power efficiency and cutting precision. In addition, a series of new ceramics, cubic boron nitride and alumina-titanium carbide, have allowed even higher cutting speeds, better precision, and longer tool life of cutting tools.

Testing.—Advanced structural ceramics are usually required to retain high strength, stiffness, and integrity in several thermal and chemical environments where stress, fatigue, corrosion, and impact are encountered. Development of such materials of diverse characteristics demands improved nondestructive evaluation (NDE) technology currently unavailable. Techniques²⁰

used in the characterization and testing of advanced ceramics include: X-ray diffraction (XRD), ultrasonics, acoustic emission measurement used to determine Young's modulus, and high-resolution optical and electron microscopy. During the past decade, special efforts have been devoted to developing high-sensitivity and highresolution NDE methods suitable for ceramics. High sensitivity denotes the ability of a technique to detect small differences in the property of a material. For example, an NDE method of high sensitivity designed to measure the elastic modulus of a solid will enable the tester to differentiate between two materials of elastic moduli very close to each other. The term resolution, usually, refers to a microscopic technique. A high-resolution light microscope, for instance, could independently observe two of the smallest grains on a polycrystalline surface. Conventional NDE methods designed to deal with metals and alloys have been modified to be helpful in studying surface and near surface regions in ceramics, but they are very limited in penetrating power to provide similar analysis for the bulk regions.21

A synergistic approach to ceramic component design, development, and fabrication needs to address the question of NDE as a part of each step. No one technique implemented at a single point in the process can provide sufficient information to produce a reliable ceramic component. Multiple NDE methods, carefully selected and implemented throughout the design and fabrication stages and correlated with one another, can help achieve this goal. NDE as a materials characterization method has been demonstrated, yet such techniques have not been applied systematically to advanced structural ceramic component fabrication. Better materials characterization through NDE will help improve the reliability and reduce the occurrence of nonconforming components in the production line. X-ray diffraction techniques (with relatively low X-ray intensities) are useful in phase identifications and in the study of the microstructure of surface and near surface regions.

Acoustic emission (AE) is sensitive to even very small cracks, thus showing promise in NDE of structural ceramics and ceramic-to-metal joints. In principle, the method involves application of a nominal load (stress) on the test specimen, reciprocal response of the test piece to the load, and recording of that response in the

form of acoustic waves. AE has been used to study the lifetime and integrity of plasma-sprayed thermal barrier coatings (TBC's). The integrity of the coating can be observed during thermal cycling.22 Acoustic microscopy techniques appear to qualify for certain specific application areas. Three such methods, scanning laser acoustic microscopy (SLAM), scanning acoustic microscopy (SAM), and C-SAM, find their own unique area of application in materials characterization. SLAM is a transmission technique in which the specimen is illuminated with an ultrasonic wave. It is suitable for inspection of complex geometries as well as thin, flat parts. Both qualitative and quantitative information may be obtained. SAM and C-SAM are reflection mode instruments that are suitable only for surface and near surface characterization. SAM, by virtue of the higher frequencies utilized, gives the highest resolution and, therefore, is the technique of choice. Neutron diffraction stress analysis, nuclear magnetic resonance (NMR) imaging, pulse video thermography, holographic interferometry, and microfocus X-ray diffraction analysis techniques are upcoming new methods currently being developed.23

Accurate mapping of spatial variations in residual stresses, especially in ceramicmetal joints at various stages of production, is extremely important. Such knowledge of stress distribution patterns can be used to optimize the manufacturing process and improve product quality and reliability. Neutron diffraction stress analysis, still in the development stage, can be applied to metals and ceramics alike. It is similar to X-ray diffraction stress analysis with one very important advantage over XRD in that neutrons can penetrate many orders of magnitude (106) greater distances into the material than X-rays. This feature enables the technique to characterize the bulk material rather than only surface region. The bulk accuracy of the method, however, needs to be improved.

Nuclear magnetic resonance (NMR) imaging techniques developed at Argonne National Laboratory (ANL) have been used to study whiskers and short fiber distribution and orientation in ceramic matrix composites to varying degrees of success.²⁴

Conventional radiographic techniques are not suitable for imaging volume (bulk) defects. For internal defects in complex ceramic components, microfocus X-ray diffraction provides high-resolution imaging beyond the surface regions. In this

technique, regular X-rays are concentrated by using a microfocusing tube equipped with an X-ray lens that can reduce focal spot sizes down to 1 micrometer. The method is capable of mapping both shortrange (<5 millimeters) and long-range (>5 millimeters) density gradients, detecting and sizing high- and low-density inclusions and, to a limited extent, microcracks, in both green and sintered ceramic components. It is capable of characterizing the bulk sample and appears to be suitable for complex shapes, such as turbocharger rotors and rotor shrouds.

Recycling.—The advanced ceramic industry, in spite of its rapid growth, is still in its infancy in comparison to established industries such as plastics, steel, and glass, and as such, the questions of waste management and recycling have received little attention from the industry or the Government.

The general understanding is that advanced materials are more difficult to recycle. Recycling many advanced ceramics may do little to alter the resource base for these materials, unlike many traditional materials that heavily rely on secondary recovery (e.g., steel, aluminum, and glass).

Advanced ceramic cutting tools offer the most promising and immediate potential for recycling, as they have a finite service life. Recovery of cemented carbide cutting and machining tools, including tungsten carbide (WC), using a number of chemical methods; e.g., cold stream, zinc, binder leaching, nitrate, and molten alloy fusion, has been studied.

Research on identification of recycling problems and opportunities is limited at present to several small-scale efforts to separate valuable components from used components. For example, the feasibility of separating Ti-Al-V alloy matrix components from SiC and B₄C-fiber reinforced metal matrix composites (MMC's) using eddy currents has been demonstrated. Similar techniques may be adapted for other MMC compositions to separate the reinforcements from the matrix. Recycling of the metallic component in MMC's should be relatively easy if the extent of chemical reactions between the metal matrix and the ceramic reinforcement is negligible at the melting temperature of metal. Separation can be accomplished by heating and simple filtration. However, if reinforcement significantly reacts with the molten metal, e.g., the case with B or SiC in contact with molten superalloy

composition, separation of the components by physical means may present serious practical problems. New separation techniques may be needed for such systems.

Annual Review

Production.—Production data for individual advanced ceramic powders are not available from a single consistent source. This is due in part to the proprietary nature of the information and also because the production levels are, in many cases, a small part of the individual company's total business.

The U.S. Bureau of Mines estimates total production of silicon carbide in the United States and Canada was 115,540 metric tons in 1989, most of it for abrasives and refractories. High-purity "green" silicon carbide production for advanced structural ceramics is primarily for R&D use and is produced in-house for those purposes or is imported from Japan and Western Europe.

Silicon nitride and sialons (silicon aluminum oxynitrides) find use strictly in advanced structural ceramics. Reliable figures for production are unavailable; it appears that the only U.S. production is by manufacturers for their own use, and there is no domestic supplier of high-purity powder. Powder can be purchased from sources in Canada, the Federal Republic of Germany, Japan, Sweden, and the United Kingdom. Worldwide production is estimated at about 400 metric tons. Production data for the various forms of zirconia for advanced structural applications are also unavailable. A rough estimate, based on conversations with major producers in the United States, is that 1,000 to 2,000 metric tons is currently produced. Though no reliable data are available, it can be reasonably assumed that production of advanced ceramic powders is a very small percentage of total ceramic production.

Consumption.—Sales of the advanced structural ceramic components (glass included) of the major categories of ceramics by U.S.-owned companies, derived from the Ceramic Industry surveys for 1986-90,²⁵ are listed in table 4. Worldwide sales are included for 1990. These data provide a perspective from which to view advanced ceramics (which include porcelain insulators, electronic, optical, and magnetic materials). In 1990, worldwide sales of advanced structural ceramics reached \$13.6 billion. While not inclusive, this figure represents the sales volume reported by

145 worldwide advanced structural ceramic producers in the Ceramic Industry's Annual Giants in Ceramics survey. Approximately 28% of these sales is from U.S.owned companies. Electronic applications dominated the field in 1990. Sales of capacitors, substrates, and packages captured 48% (\$6.5 billion) of the total: 12% (\$1.6 billion) went to low-voltage electrical porcelain; and the remaining 17% (\$2.3 billion) went to various electrical-electronic components (ferrites, piezoelectrics, and other sensors). Sales of engineering ceramics, ceramics used with optical fibers, and other ceramics captured 10% (\$1.4 billion), 9% (\$1.2 billion), and 4% (\$0.6 billion), respectively, of the total market.

Current Research.—TBC's have been gaining wide acceptance in heat engine applications.²⁶ Coatings typically consist of an insulating ceramic coating with an underlying oxidation-resistant metallic interface between the substrate and itself. The TBC's must endure repeated thermal cycling and severe chemical environment of operating engine. Coating of the combustion chamber with TBC's allows the operation of the engine at higher temperatures, leading to increased thermodynamic efficiency. In addition to insulating the metal against high temperatures, TBC's also protect the metal components against the corrosive environment of the combustion chamber.27

Currently, zirconia-base coatings are most commonly used as TBC's as they possess the properties of low thermal conductivity (good insulation), high thermal expansion (good match with metals), and high mechanical strength at elevated temperatures. Zirconia, however, undergoes polymorphic transformation (changes from one crystalline form to another), which causes volume changes, leading to excessive thermal strains and subsequent mechanical failure.28 This, however, can be controlled by additions of stabilizing compounds, which are magnesium and yttrium oxides. For heat engine applications, partial stabilization of ZrO₂ with magnesium oxide prevents this harmful transformation. Stabilized zirconia (Mg-PSZ) is one of the toughest ceramics developed that comes close to meeting the property requirements automotive applications pose for engine cylinder liners. valves, valve seats, and follower inserts and valve guides. For automotive engine applications, major property requirements of

ceramic TBC's are low thermal conductivity and low specific heat, high strength, high thermal shock resistance, matching thermal expansion to steel and/or iron, high fracture toughness, and high resistance to erosion and corrosion.

Outlook

Projections pertaining to advanced structural ceramic production are many with wide variations. Surveys and studies have been conducted and published. Among these more notable studies are those offered by R. N. Katz,²⁹ and Abraham.³⁰ Katz used a number of sources, including data from the U.S. Department of Commerce, the Long Term Credit Bank of Japan, and trade publications, as well as private discussions. The estimates, shown in table 7, do not include present or projected military applications, which could be significant.

TABLE 7

WORLDWIDE MARKET PROJECTIONS FOR HIGH-PERFORMANCE STRUCTURAL CERAMIC PARTS

(Million dollars)

Applications	1995	2005
Heat engine ceramics	1,000	4,000
Bearings	200	400
Cutting tools and metalworking	150	300
Industrial wear parts	450	900
Biomedical and dental, including crown	2,000	4,000
Total	3,800	9,600

Source: R. N. Katz.

Abraham's forecast of U.S. advanced ceramic markets is presented in table 8 for several different categories. Both Abraham's and Katz' predictions were made in the 1988-89 timeframe and reflect their opinion that advanced ceramics, which have held steady in sales during the latter part of the 1980's (see table 1), would experience rapid growth during this decade. Abraham estimates an almost doubling of the U.S. advanced market by 1995 and doubling again by the year 2000. Katz predicts similar doubling of sales between 1995 and 2005 for structural ceramics, as illustrated in table 7.

As of 1990, this rapid growth has not started; U.S. ceramic sales remained sluggish at a slightly lower level than that of 1986-89. The projections, however, are still reasonable expectations if continued progress is made in joining and testing technologies and cost efficiency for large-volume automotive applications as previously discussed.

TABLE 8 FORECAST U.S. ADVANCED CERAMICS MARKETS

(Millions of current dollars)

Applications	1990	1995	2000
Electronics	3,740	6,565	11,360

POLYMER MATRIX COMPOSITES

Background

Definitions, Grades, and Specifications.—A polymer matrix composite (PMC) is a combination of an organic resin (matrix) and a reinforcing material in the form of continuous fibers in a number of patterns and weaves or short fibers, whiskers, or particles. Polymer composites reinforced with continuous fibers are generally referred to as advanced polymer matrix composites (APC). APC's are lowvolume, high-value polymers that exhibit excellent strength-to-density ratios, high stiffness, and usually require specialized processing techniques. Matrix materials may consist of polyimides, polyacrylates, polyesters, or a number of other hightemperature resins. Fibers may be of high-strength glass, carbon, boron, various ceramics such as alumina and silicon carbide, or other high-strength organic polymers. In general, the important physical properties of APC's are determined by the properties of the fibers rather than the matrix, so a myriad of polymers, blends, and alloys may be used.

Polymers are classified as two basic types: thermoplastic and thermoset. Thermosets are those polymers that form by irreversible chemical reaction and consist of strongly cross linked chains. Thermosets cannot be remelted and reformed but, rather, decompose at elevated temperatures. Because of the cross-linking, thermosets are strong and heat resistant but tend to be brittle. Examples of thermosets are epoxies, phenolics, vinyl esters, polyesters, and urethanes. Thermoplastics are polymers, with less cross-linking, that can be remelted and reformed. They tend to be less brittle (tougher), more flexible, and stronger in the direction across the strongly linked chains than between. Consequently, if the chains are aligned, the polymer is much stronger in one direction than the others.

In the case of advanced polymer composites, the materials of interest are the engineering and high-performance thermoplastic polymers and epoxies. The epoxies presently are used in about 95% of composites, while performance polymers are still being evaluated for use as polymer matrices. Detailed definitions, grades, and specifications for the hundreds of polymer materials are beyond the scope of this work but are readily available in the Plastics Encyclopedia.31 Specifications for the composites themselves are not written as with commodity materials; the specifications are written for each individual application. About 95% of polymer matrix composites manufactured in 1989 were composed of an epoxy matrix reinforced with carbon fiber or high-strength glass fiber. This is a result of two factors. First, at the time, about 10 to 15 years ago, when property and performance specifications were written for current aerospace systems, epoxy was the only matrix material sufficiently developed and understood to be used successfully. Second, epoxy composites are relatively easy to fabricate because the resin-catalyst mixture has a low viscosity, suitable for a variety of prepregging and forming operations. Moreover, epoxies wet fibers effectively to produce a strong bond and possess the strength, stiffness, corrosion resistance, and high-temperature stability needed for many applications.

Epoxies have some disadvantages, however. Though strong, they do not have high fracture toughness; i.e., they are brittle and do not resist high impacts. Because epoxies are thermosets, they are difficult to recycle as they are formed by irreversible chemical reactions. They do not soften or melt but decompose.

Products for Trade and Industry.— Advanced polymer composites, because of cost, are afforded relatively few uses, most notably in defense, aerospace, and sporting goods where performance benefits outweigh cost considerations. In defense and aerospace they are used in helicopter rotors, blades, and tail assemblies and in weapons systems as rocket motor cases on missiles and space vehicles. They are finding increasing use in secondary aircraft structures such as control surfaces (flaps, rudders, and stabilizers) or fairings (streamlining covers for aerodynamics) and more recently as primary structures such as wing, tail, and fuselage sections. Composites used in McDonnell Douglas aircraft's military planes, for example, have increased from about 2% in the F-15 to 27% on the AV-8B Harrier currently in production.32 Boeing Co. has teamed with Bell Helicopter to manufacture the V-22 tilt-rotor aircraft and with Sikorsky Aircraft to make the new LH helicopters, both with airframes and skins largely constructed of epoxy-carbon composites.

For commercial aircraft, the major manufacturers are planning to increase use of polymer composites in new generation planes. Boeing, for example, plans to increase the composite content of its highly successful 757 line from the present 3% to 24.5% during the 1990-2000 timeframe.³³

In sporting goods, the desire for better performance regardless of cost has created a market for fiberglass and carbon reinforced polymers in tennis rackets, golf club shafts, skis, sleds, and toboggans; fishing poles; and bicycles.

In the industrial market, the primary use of polymer composites is in tooling, but many other applications are developing. Robot arms, for example, with less inertial mass than metals, contribute to greater speed and lower systems costs in automated manufacturing.

Technology.—Processing.—Most PMC materials processing technologies influence the properties of the finished product, perhaps far more than metals or ceramics. Various fabrication technologies applicable

to PMC's are listed and described briefly in table 9.34 The table also lists the predominant type of polymer processed, the form of the polymer prior to processing, and the typical shape of PMC made. The exact details of many of the techniques are proprietary. New processing techniques are often cited as reasons why a product has enhanced performance properties.

Properties can be controlled by conditions under which materials are processed. In particular, fibers and films are made by processes that include close control of polymer chain orientation by drawing under controlled temperatures. Orientation of polymers affects strength, stiffness, and elevated temperature properties. For example, PET bottles can now be made under controlled conditions to achieve a thermal stability to 190° F. This capability opened the hot-filled food packaging market to this resin for the first time. Another example showing the importance of this kind of processing technology is the optical disk. A new injection molding technology using a two-stage clamping cylinder and contractible mold (both patented) can lower disc stress through more even cooling. As a result, birefringence, the measure of the deflection of a laser beam designed to "read" the binary-coded disk, is reduced. Therefore, deflection is reduced from 40-60 to 10-20 nanometers, permitting faster cycle times (25% to 30%). The polycarbonate resin used by optical disk manufacturers has not changed for the new technology, but the final product is improved.

Mold design is a preliminary fabrication step. Molds must allow for surface appearance and be able to withstand corrosiveness of both the material and the process. It must also match the flow properties of the resin, the geometry of the part, and the mold materials. Most importantly, the mold should be tested as a prototype, just as the product itself should be tested. If the mold is changed, the product must again be prototyped. An example showing the importance of proper processing and mold design is reinforced thermosets. Because the long fibers in the thermosets are broken up and do not flow into the thinner sections, transfer or plunger molding will degrade strength compared to compression molding. In addition, fibers may flow off into thin, intricate sections of a resin product during compression molding. In such a case, equal properties may be available from a less expensive material that can be injection molded.

TABLE 9
POLYMER MATRIX COMPOSITES FABRICATION TECHNOLOGIES

Process	Predominate polymer processed	Materials type or form	Shape characteristics and common products	Process description
Open mold (contact molding)	Thermosetting (primarily RP forming process 40% of total)	Liquid resin (spray, hand applied) or thermoplastic sheet; reinforcing material	Large, complex	Reinforced shapes are formed by using open molds and room-temperature curing resin is brushed, poured, or sprayed onto reinforcing material layered in mold. Spray up method, resin and chopped fibers sprayed onto mold. Reinforced vacuum formed sheet method, mainly acrylic sheet is vacuum formed and reinforced resin applied to back surface. The process also includes encapsulating or potting.
Reaction injection molding (RIM)	Thermosetting (urethanes)	Liquid	Large, intricate, high-performance, solid, or cellular	Reactive components are generally mixed by impingement in a chamber and then injected into a closed mold.
Rotational molding	Thermoplastic	Powder, liquid, precatalyzed	Hollow bodies, complex	Premeasured material poured into mold. The mold is closed, heated, and rotated in the axis of two planes until contents have fused to inner walls of mold. The mold is opened and part removed.
Thermo- forming	do.	Film sheet	Simple, thin-wall	Film is continuously roll-fed or sheet is cut and either placed over male or female mold. Part is formed by vacuum forming, draping and heating, pressing or many other variations.
Bag molding	Reinformed thermosets	Prepregs (partly cured), epoxy or polyester soaked	Simple, contoured, large	A number of layers of reinforced material are placed (hand layup) between two inexpensive mold halves; the entire assemble is placed in plastic bag and low pressure applied (via vacuum, external air or auto-clave methods); the assemble is heated and cured.
Centrifugal casting	Thermosetting	Liquid resin, fiber reinforcement	Uniform wall thickness	Resin is applied to the inside of a rotating cylindrical mold and is uniformly forced against the reinforcing material. Heating flowing and curing.
Continuous laminating	Polyester	Resin, reinforcement	Thin, flat or curved profiles	Reinforcement is passed through a resin bath, faced with cellophane, passed through squeeze rolls, and heated.
Filament winding	Epoxy, polyester	Resin	Round, rigid	Continuous filaments (usually glass) in form of roving are saturated with resin and machine wound onto mandrels having shape of desired finished part. Once winding is completed, part and mandrel are placed in oven for curing. Mandrel is then removed through porthole at end of wound part.

With the advent of sophisticated computer technology has come the plethora of computer-assisted design-computer aided manufacturing (CAD-CAM) software and supporting hardware. ³⁵ These CAD-CAM programs save labor by using computers to perform jobs formerly requiring large amounts of materials and design engineers' time. Skilled people are freed from repetitive tasks. Moreover, these tools have enhanced the ability of engineers to design

products that can meet demanding physical, chemical, or other environments. From the moldmakers' viewpoint, the advantages are similar: elimination of costly prototyping, rapid optimization of mold cavity configurations, and computerization of mold component selection.

Joining Methods.—Though the number of component parts in a system is generally less with polymer composites than with

metal parts, particularly in aerospace systems, parts must still be assembled with fasteners or adhesives. Obviously, if the strength of the joint is less than that of the composite parts, much of the advantage of the composite is nullified. Joining methods are, therefore, receiving a great deal of attention. Improved metal and polymer materials for use as bolts and rivets are being sought, and high-strength adhesives and direct bonding methods are under

investigation. Perhaps more importantly, new computer-aided design methods have been developed to predict stress levels within the composite and at the joints of assemblies. This enables engineers and designers to develop structures in which stresses are minimized in critical areas.

Applications.—Polymers have been replacing glass, ceramics, metals, and paper in many applications. They are being used in applications from microwave food packaging to sporting goods and satellites. Their special properties have been exploited by design engineers in structural applications as engineering plastics. Polymers have much to offer. In general, they are corrosion resistant, less expensive to produce, higher in strength-to-density ratios, and readily adaptable to a single fabrication of a multifunctional component.

Recycling.—In 1990, the total U.S. resin production will reach about 54 billion pounds, and about 38 billion pounds will be discarded as waste.³⁶ In the case of APC's, the problem is how to separate the fiber from the resin and reuse them economically. Recycling APC scrap may be economically feasible because of the high cost of carbon fibers. Because the matrix materials currently used are predominantly epoxy resins, studies have been conducted for that type of material.37 In the uncured condition, epoxies are soluble in organic solvents such as acetone or methyl ethyl ketone. After the epoxy is dissolved, the recovered carbon fiber can be reused. After curing, however, epoxies are insoluble, so this procedure can only be used for prompt scrap and rejects.38 Epoxies can also be decomposed thermally below 400° C and the fiber may be recovered; the fiber surface, however, is affected so that lower fiber-matrix adhesion is observed in new products. Fiber breakage may be sufficient to render fibers useful only as discontinuous reinforcement. To date, the only satisfactory use for epoxy scrap is as finely ground filler for virgin resins.

Annual Review

Sales figures for 1989 and 1990 for a number of common polymeric products are summarized in table 10. Although polymers (especially thermoplastics) are put into three separate categories, namely commodity, engineering, and high-performance or advanced composites, no sharp, unambiguous distinction exits among them.

Polyvinyl chloride and copolymers are the common examples of commodity products, whereas polyimides and polycarbonates represent two of the well-known engineering polymers.

the Society of Plastics Industry (SPI), Congress is considering the reauthorization of the Resource Conservation and Recovery Act for solid waste regulations. This act could ultimately dictate national recycling goals. The 1990 version of the Clean Air Act and the new energy taxes are also symptomatic of the new upcoming issues. In light of these happenings, an SPI task force is reviewing the industry's stand on a workable energy policy.

Consumption and Uses.—During the 1980's, PMC's grew at an average annual rate of 5%. This time period saw the introduction and market success of such products as all-composite business aircraft, composite frames for sports equipment, fiberglass underground gasoline storage tanks, and composite-skinned vehicles. On the whole, the PMC industry has weathered the current recession well, with significant downturns only in the construction, marine, and consumer products markets. The 1989 drop in shipments reflects general economic conditions rather than a reduction in the likehood for continued growth in PMC usage. The GNP, industrial production, housing starts, and retail sales experienced a decline in 1989, the first year since 1982. The market rebounded in 1990 with a strong performance in consumer products and electrical, transportation, and corrosion-resistant products, despite a weak economy. For the immediate future, higher gasoline prices due to new taxes should increase the use of PMC's in cars and trucks in order to further improve fuel economy through weight reduction.

U.S. polymer matrix composite markets can be divided into nine categories: aircraft-aerospace-military, construction, consumer products, appliance-business equipment, corrosion-resistant equipment, electrical-electronic, marine, transportation, and other. Table 12 presents the shipments of these materials by market category for the years 1986-90 with 1991 estimated figures. Data for this table were compiled by the U.S. Bureau of Mines, The Society of the Plastics Industry Inc. and Composites Institute, and Kline & Co. Inc. ³⁹

The U.S. aircraft-aerospace-military market has remained somewhat stagnant during the past few years. The 1989 market was 41 million pounds. In 1990, the market reflects a similar figure. Sales for 1991 are expected to remain at 41 million pounds, through the replacement of existing aircraft parts containing PMC's.

The appliance-business equipment market used 152 million pounds of PMC's in 1989. Shipments in 1990 grew almost 2% to 155 million pounds, and 1991 figures are expected to remain about 155 million pounds.

The U.S. construction industry felt the recession with a 3.4% drop in PMC consumption in 1989 to 479 million pounds, down from 495 million pounds in 1988. No significant rebound was observed in 1990. The forecast for 1991 is a further decrease, down to about 450 million pounds.

The U.S. consumer products market stood at 162 million pounds in 1989. Shipments rose by 1.0% in 1990 to 164 million pounds. This market is not expected to change in 1991.

In 1989, the U.S. corrosion-resistant market stood at 349 million pounds. A modest rise was seen in 1990 to 354 million pounds. Shipments in 1991 are expected to be 358 million pounds. PMC's continue to replace other materials in places where corrosion resistance, high strength, and ease of assembly are required.

Shipments to the electrical market reached 231 million pounds in 1989. An increase of 2.2% was seen in 1990, with shipments to 236 million pounds. No increase in 1991 is expected. Penetration of PMC's into the electrical market is driven by the trend for smaller components. High strength, high electrical and corrosion resistance, and continually improved high-temperature performance should lead to increased use of PMC's.

The popularity of fiberglass boats over the past decade made the marine market the fastest growing user of PMC's. High interest rates, overproduction, and the economic slump left the retailers with excess inventories, resulting in a market

decline in 1989 sales. Continued high retail inventory caused the 1990 market to remain about the same. Purchases are expected to continue to decline in 1991, and shipments of PMC's should drop to 400 million pounds.

In 1989, U.S. PMC use in the transportation market stood at 685 million pounds. In 1990, use increased 2.6% to 703 million pounds. The 1991 market is expected to grow by 1.5% to 713 million pounds.

Other products using PMC's include medical equipment, orthopedic appliances, and dental materials. In 1989, consumption totaled 78 million pounds. This market increased to 80 million pounds in 1990. A modest increase to 81 million pounds is expected in 1991.

World Review.—There are 70 to 75 producers of AP resins worldwide, most of them in Japan, the United States, and Western Europe. The United States is the largest producer of advanced polymer resins, accounting for one-fourth of world production. It is a net exporter of the largest volume polymers.

The use of PMC's is highly concentrated in the aerospace sector. Of the 42 million pounds produced in 1990, 48% was con sumed by the aerospace industry. In terms of dollars, \$4 billion was generated in 1990, with almost 68% used in the aerospace industry. Owing to its large aerospace

industry, the United States is the leading producer and end user of PMC's. Within the aerospace market, military-defense applications contain nearly one-half the market share, 25% of the total world market. Western Europe has a rapidly developing commercial aerospace business, which will trigger PMC growth in this region.

The second largest market for PMC's in 1990 was the recreational market. Japan dominates the use of PMC's for recreational applications. The recreational sector accounted for 21% of the PMC's produced in 1990. In dollars, the recreational market was \$520 million or 13% of the world market.

Current Research.—The level of research effort in polymer technologies for structural, electronic, optical, magnetic, and medical uses is very high in the Federal, industrial, and academic sectors. General activities are summarized below.

New Matrix Materials.—Current research to develop new matrix materials is aimed at overcoming the disadvantages, such as low-fracture toughness, processing by irreversible reactions, and high viscosity. A number of epoxy blends with greater fracture toughness than epoxies and lower viscosity than thermoplastics are being formulated and evaluated. These materials will find uses in areas demanding improved

ADVANCED MATERIALS—1990 117

impact resistance, but will also be difficult to repair or recycle. A number of liquid crystal polymers and engineering polymers are also being evaluated as matrix materials to optimize strength, stiffness, fracture toughness, corrosion resistance, repairability, and recyclability.

New Fibers.—The effectiveness of fibers as reinforcements in advanced polymer composites depends on their intrinsic strengths, surface condition (failure is initiated at surface flaws), and the strength of the interfacial bond with the matrix. Research directed toward finding improved reinforcements for PMC is in high gear. A variety of silica, aluminosilicate, boron, silicon nitride, silicon carbide, and organic fibers is also being developed and evaluated for the formation of improved composite structural materials.

Nondestructive Evaluation (NDE).— Fiber breakage during fabrication, poor fiber-matrix adherence, and existence of voids and inclusions in polymer composites are potential causes of failure in service and are not readily detectable by visual inspection. Methods for inspection of each component prior to incorporation into a finished assembly are being tested as nondestructive evaluation methods. These include ultrasonic inspection, infrared thermography, thermographic stress analysis, X-ray tomography, eddy current measurement, acoustic emission measurement, fluorescence spectroscopy, magnetic resonance imaging (MRI), and pulsed nuclear magnetic resonance (a variation of MRI).

Any structural material under stress deteriorates with use because of formation of microcracks, weakening of the fibermatrix bond, and fiber breakage. Environmental conditions, such as exposure to chemical agents, ultraviolet radiation, heat, atomic oxygen (in space), and ionizing radiation, contribute to degradation of the properties of materials. Because of the lack of experience in longtime use of advanced polymer composites and the variability of properties and structures resulting from lack of uniformity in processing, much effort is being expended to evaluate new materials for deterioration in use. Nondestructive evaluation methods are being developed for periodic inspection of components in use, but the most promising methods being investigated at present are based on continual monitoring during service. Two methods presently under development involve incorporation of pressure sensitive detectors (piezoelectric or light emitters) coupled with wires or optical fibers to transmit data to a computer system or sound detectors to receive acoustic emissions from critical points in the component to be transmitted to an analyzing computer.

Outlook

The outlook for PMC's is steady growth. The aerospace industry is expected to continue to dominate the PMC marketplace, reaching about \$6 billion in sales by the year 2000. Industrial sales are expected to overtake recreational sales and become the second largest PMC market by the year 2000. In fact, current industrial sales, now at the \$400 million level, are expected to reach more than \$950 million, whereas the \$520 million recreational market is expected to reach about \$850, as forecasted by Kline & Co. Inc.

The current recession, which has affected the PMC shipments since 1988, may continue its negative effect in 1992 shipments, but a modest increase for 1992 shipments can be expected. In spite of the current recession in the construction and marine markets, which may continue through 1992, long-term prospects for the plastics industry look promising. The automotive and aerospace industries should more than offset the slowing market in the construction industry. Major U.S. auto manufactures are geared to producing cars and small trucks with more plastic components ranging from fenders (some 1993 Chrysler models) to all-body panels (General Motor's planned electric cars for 1994) in order to meet the demands for fuel efficiency, which is more readily achieved by weight reduction. With the anticipated price reductions, due mostly to improved processing methods, PMC's should continue penetrating the aerospace, corrosionresistant products and electrical markets.

ADVANCED ALLOYS AND METAL MATRIX COMPOSITES

Background

Definitions, Grades, and Specifications.—Metallic alloys are materials formed by combining two or more metals in order to develop a second material that has physical, mechanical, and thermal properties superior to any of the original metals. Brass, bronze, and stainless steel are the most commonly used alloys, but new compositions are constantly being developed. Advanced, or superalloys, which contain nickel, iron, or cobalt with significant amounts of chromium, frequently are used at temperatures above 500° C. Even though alloys originated a long time ago, there have recently been major advances in developing superalloys and processing technology. Their development has been a major contributor to the current interest in advanced materials. Compositions of selected superalloys that possess outstanding properties, including high-temperature strength and corrosion resistance, are shown in table 13.40

Although some metal matrix composites (MMC's) existed since the 1960's, they started gaining commercial significance in 1983 with the introduction of a composite diesel engine piston by Toyota Motor Corp. Virtually every piston manufacturer in the world is now developing composite pistons. MMC's are metals or metal alloys reinforced with ceramic fibers, whiskers, or particulates. Because of their superior mechanical strength and unique physical characteristics, such as low thermal expansion, MMC's find applications in structural and nonstructural components alike. They combine metallic properties (ductility and toughness) with ceramic properties (hightemperature strength and high modulus) to offer greater strength in shear and compression and higher service temperature capabilities. As a result of availability of relatively inexpensive reinforcements and the development of various processing routes, interest in MMC's for aerospace, automotive, and other structural and hightechnology applications has increased during the past 5 years.

Reinforcement materials for MMC's include carbides (SiC, B₄C), nitrides (Si₃N₄, AlN), oxides (Al_2O_3, SiO_2) , as well as elemental materials, such as carbon. SiC, for example, is utilized in aluminum and magnesium MMC's in all three forms (fiber, whisker, and particulate), and carbon is usually used as continuous fiber reinforcement. Discontinuously reinforced MMC's employ particulates, whiskers, or short fibers as reinforcing components. Table 14 provides a list of currently available fibers, whiskers, and particulates for reinforced aluminum in composites with aluminum. This class of MMC's has, recently, attracted considerable attention as

a result of availability of reinforcements at affordable prices (e.g., SiC particulates at \$2.20 per pound) and suitability to standard metalworking processes for manufacturing.⁴¹

Technology.—Processing.—Significant advances have been made in processing superalloys that have led to the development of compositions with much improved performance. Methods, such as directional solidification, single crystal growth, hot isostatic pressing, mechanical alloying, and

rapid solidification, have fabricated alloys with controlled and refined microstructure leading to tailormade properties. Metal refining methods, such as vacuum induction melting, vacuum and remelting, and electroslag remelting, have allowed metallurgists to produce very high-purity metals and alloys.

Fabrication of MMC's ranges in complexity, from simple pouring of molten metal into molds containing preformed fiber reinforcement skeletons, to intricate methods involving partially solidified metal, with

or without reinforcement that agitate vigorously and quickly force the molten metal under high pressure into a mold. Every method offers its own particular advantages in terms of cost, protection of reinforcement, and adaptability. A number of the processing methods discussed under advanced structural ceramics are applicable to MMCs. The hot-rolling, hot-pressing, and hot-isostatic-pressing methods can be used to consolidate MMC preforms made by chemical or physical vapor deposition (CVD or PVD), thermal spraying, and

electrodeposition. For example, carbon fibers are coated with aluminum vapors (PVD) to produce carbon-reinforced aluminum preforms that are subsequently consolidated using hot-pressing techniques. In addition to the methods already discussed, several novel MMC processing technologies in the advanced stage of development are ready for prototype production. One such method is the Dimox process. This method, which is even better suited to MMC, has also been discussed under advanced structural ceramics.

Another relatively novel method for preparing MMC's involves the introduction of reinforcement into a vigorously agitated, practically solidified melt or slurry, called "compocasting." The visocity of the melt or slurry is controlled to maintain uniformity in the reinforcement distribution. Sufficiently high viscosity prevents the settling of the reinforcement phase. Recently, an aluminum-copper alloy reinforced with alumina fibers has been prepared using this method.⁴²

Applications.—MMC's are currently used in several applications. Boron fiber reinforced aluminum tubes, for example, are used as cargo bay struts in the space shuttle and some sporting and recreational goods such as skis and bicycle frames. Aluminum-base MMC's are finding additional applications in airframes and in selective turbojet engine components. Titanium-base MMC's are being developed for turbojet compressors and superalloybase MMC's for the thrust turbine airfoils. Additional application areas include advanced automotive components, such as pistons, rocker arms, and cylinder heads.

Recycling.—In the alloy-melting industry, making use of alloy scrap is common practice. Scrap metal is usually less expensive than primary metal and sometimes more available. There is a problem, however, with contamination of some of the scrap superalloys. The recycling chain begins with scrap produced from alloy production with contributions of obsolete scrap from part manufacturers, fabricators, and users of superalloys, mainly from commercial airlines or Government military aircraft. A user is defined as an organization that uses a finished product until the product is retired from service owing to wear, corrosion, inefficiency, or obsolescence. The user generates "obsolete scrap" when equipment is overhauled and parts replaced, or when equipment is

²Range of values for Al alloys from ref. (99).

 $^{^2} SiC$ whiskers only.

dismantled at the end of its useful "life-cycle." The scrap is usually in the form of solids, such as turbine blades and vanes. 43

There are relatively few data available on the amounts of superalloy scrap being recycled, partly because of the proprietary nature of the data and partly because of the complexity of the recycling industry. Estimates, however, have been made by the U.S. Bureau of Mines for individual commodities based on reports received from producers. In a recent study conducted for the Air Force, based on superalloy scrap processor responses to the Bureau and extrapolated to account for the entire industry, about 55 million pounds of clean and contaminated superalloy scrap was processed in 1986. Of the scrap processed, about 92% was sold to domestic buyers and the remainder to foreign buyers. Most of the foreign material was refinery-destined grindings; the balance was vacuummelting-grade superalloy scrap. In addition, about 72% of the total scrap processed was recycled into the same alloy, 20% was downgraded to a nonsuperalloy, and 10% was sold to refineries. The average composition of superalloy scrap processed in 1986 contained about 44% nickel, 16% chromium, 5% cobalt, less than 1% manganese and tantalum, and nil for rhenium. The remaining 30% is primary iron, but also includes aluminum, hafnium, molybdenum, titanium, tungsten, and other minor constituents.

No significant research has been reported on methods to identify and recycle MMC's. Recent preliminary research⁴⁴ has shown that it is possible to separate conventional Ti-6Al-4V alloy from SiC or B₄C-fiber-reinforced Ti-6Al-4V using eddy current measurements. Similar techniques should be applicable for other MMC's, but since reinforcement may serve as a contaminant if mixed for recycling, segregation of MMC's from other alloys will be necessary.

For many MMC's recycling of the metallic fraction should be relatively straightforward. If the metal and reinforcement do not interact chemically at the melting point of the metal, purely physical separation, such as filtration, should present no problems. However, if significant reactions are likely to occur, techniques will be needed for separation. Currently, the amount of MMC's going into scrap is very low, but recycling should be expected to increase significantly as production of these materials increases.

Annual Review

The estimated worldwide market in 1990 for carbon-carbon composites is \$200 million (figure 2) for four different applications: aircraft brakes (\$50 million), rocket nozzles (\$70 million), nose tips-ablatives (\$64 million), and other (\$16 million). According to Kline & Co., the United States represents 75% of the worldwide carbon-carbon composite market, primarily due to its dominance in military and aerospace technology. Western Europe and Japan account for the remaining 25% of market share.

The estimated worldwide market in 1990 for metal matrix composites is \$60 million for four different applications (figure 3): automotive (\$15.6 million), aerospace (\$42.0 million), recreation (\$1.2 million). and other (\$1.2 million). Again, according to Kline & Co. the United States accounts for 60% of the worldwide market value due to the high cost of prototype materials used by the aerospace industry. The Japanese share is only 20% of this worldwide market. Note, however, that Japan is the leading consumer of MMC components, mainly because of its production of MMC engine pistons. A variety of aerospace applications appear to be large for MMC's. Military jet and rocket structures are specific target areas for MMC's.

A notable feature in figure 3 is the difference in the aerospace industry's share in terms of weight and dollar values; 15% by weight of the aerospace share accounts for 70% of the cost indicates that the average cost of MMC's for aerospace applications is an order of magnitude higher than those for automotive and other applications. These higher costs are attributed to involved labor-intensive fabrication and low-volume production. Potential commercial applications of MMC's are listed along with their desired properties in table 15.

World Review.—Currently, the United States is the leader in applications of all advanced fiber composites, including MMC's. Composites are being developed and used in spacecraft, land vehicles, fighter aircraft, tactical missiles, and virtually every weapon system. Although in 1990 the U.S. aerospace industry led manufacturing industries by posting almost \$30 billion positive trade balance, growing foreign activity is a definite threat to U.S. competitiveness in the composites field. U.S. dependence on foreign suppliers for raw materials adds another dimension

to the erosion of U.S. competitiveness. Japan and Western Europe are primary suppliers of high-grade fine ceramic powders and fibrous reinforcements, raw materials essential for ceramic matrix composites. The high cost of raw materials and manufacturing processes and shortage of skilled engineers cut further into the U.S. lead over its major competitors.

Major competitors and trading partners of the United States are spending significant sums to develop fiber composites. The Japanese focus their efforts on industrial applications, while in Western Europe and the United Kingdom, military and aerospace applications are emphasized. In the United States, NASA and Department of Defense are conducting programs for military and aerospace applications as well.

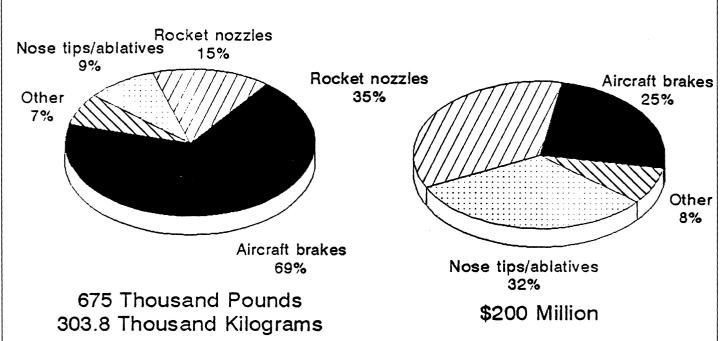

Current Research.—Matrix fiber adherence is an important factor in determining MMC properties. Optimum adherence of the matrix to the reinforcement may sometimes involve some degree of chemical reaction between the matrix and the reinforcement. However, if the reaction is extensive, matrix-reinforcement bonds may be weakened, and degradation of the reinforcement may limit the strength of the composite. For example, boron fiberreinforced aluminum has been observed to fail during fracture through debonding at the fiber-matrix interface. Upon heat treatment of the composite at 300° C, in an inert atmosphere, at room temperature, strength increased and fracture occurred within the fiber itself, rather than along the fiber-matrix interface. Additional research efforts will be necessary to improve the understanding of reactions at the fibermatrix interface in order to develop optimum adherence of the reinforcing phase to the matrix.

Outlook

Lockheed has taken delivery of the first lot of MMC's for use in the vertical tail fins on the Advanced Tactical Fighter, which is expected to result in a 25% weight reduction over current tail fins.

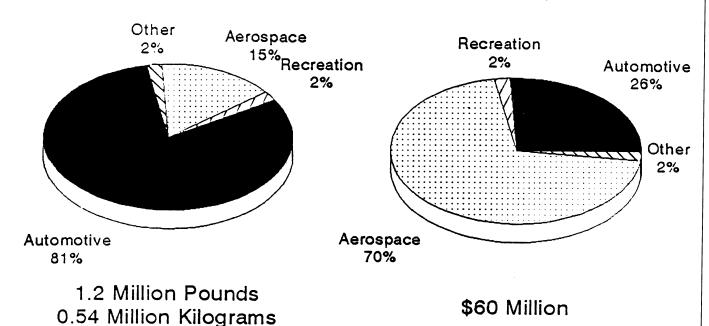

A wide range of metal companies are currently very active in fiber composites development, integrating their fiber operations to the point of composites production, especially particulate reinforced composites, in billet or ingot form. These companies, however, have not extended their business to production of specific components.

Pratt and Whitney Aircraft⁴⁵ is developing a fan blade for jet engines, utilizing an aluminum matrix composite with continuous boron fiber reinforcement wrapped around a titanium core. Arco Chemical Co. uses SiC aluminum composites in the manufacture of mirrors that maintain dimensional stability over an extensive temperature range.

For the airframe applications, Rockwell International and General Dynamics are leading the way with carbon-carbon and titanium-aluminum composites. In the development of jet engine components, ceramic matrix, and composites, along with superalloys, are the primary materials.

ALUMINUM, BAUXITE, AND ALUMINA

By Patricia A. Plunkert and Errol D. Sehnke

Ms. Plunkert, a physical scientist with 22 years U.S. Bureau of Mines experience, has been the commodity specialist for aluminum since 1987. Domestic survey data for aluminum were prepared by Shonta E. Osborne, statistical assistant; and international data tables were prepared by Audrey D. Wilkes, international data coordinator.

Mr. Sehnke is a physical scientist with 17 years of minerals industry and U.S. Bureau of Mines experience. Domestic survey data for bauxite and alumina were prepared by Shonta E. Osborne, statistical assistant; and international data tables were prepared by Harold D. Willis, international data coordinator and William L. Zajac, Chief, Section of International Data.

luminum is the second most abundant metal element in the Earth's crust after silicon, yet it is a comparatively new industrial metal that has been produced in commercial quantities for just over 100 years. It weighs about one-third as much as steel or copper; is malleable, ductile, and easily machined and cast; and has excellent corrosion resistance and durability. Measured either in quantity or value, aluminum's use exceeds that of any other metal except iron, and it is important in virtually all segments of the world economy.

Although the growth rate for world aluminum demand began to decrease toward the end of 1990, most primary aluminum smelters continued to operate at or near their rated capacity levels. The United States continued to be the world leader in primary metal production, producing more than 4 million metric tons of metal with an estimated value of \$6.6 billion.

World production of bauxite and alumina, feedstocks for the aluminum industry, rose in 1990 to new record levels in response to the sustained high rate of primary aluminum metal output. Mine production of bauxite was reported from 27 countries, and alumina was produced in 24 countries.

DOMESTIC DATA COVERAGE

Domestic production and consumption data for aluminum, bauxite, and alumina are developed by the U.S. Bu-

reau of Mines from five separate voluntary surveys of U. S. operations. Typical of these monthly, quarterly, and annual surveys is the "Consumption of Alumina" survey. Of the 18 operations canvassed by this form, all responded.

BACKGROUND

Definitions, Grades, and Specifications

Bauxite is a heterogeneous material composed chiefly of the aluminum oxide minerals gibbsite (Al₂O₃ • 3H₂O), the trihydrate, and boehmite and diaspore (Al₂O₃ • 3H₂O), the monohydrates.¹ Domestic bauxites and those imported from Brazil, Guyana, and Suriname are of the trihydrate gibbsitic type. Imports from the Sangaredi deposits of Guinea and the north coast of Jamaica are predominantly gibbsitic, but they also contain 4% to 10% of the monohydrate mineral boehmite. In most European and northern Asian bauxite deposits, boehmite is the principal alumina mineral. Recovery of the aluminum oxide in boehmite requires a higher temperature and higher caustic concentration than is needed in processing gibbsite. Major impurities in bauxite ores include iron oxides, silica, aluminum silicates, and titanium oxides.

Free moisture in crude bauxite, as mined, may range from 5% to 30%. Dried bauxite is produced by heating crude bauxite in rotary drying kilns at about 315° C, which removes most of the free moisture. Calcined bauxite is produced

by heating bauxite at 925° to 1,040° C to reduce total volatile matter, including chemically combined water, to less than 1%. About 2 tons of crude ore is required to produce 1 ton of calcined bauxite.

Aluminum metal has a relatively low density, high electrical and thermal conductivity, good resistance to corrosion, and good malleability. It is nonmagnetic, nonsparking, and highly reflective. It may be alloyed and treated to yield a high strength-to-weight ratio.

Ingot is a cast form of primary or secondary metal that is convenient to handle and store and is suitable for fabricating or remelting. Commercial-size ingots normally weigh about 30 pounds; however, some ingots weigh up to 9 tons. A significant portion of both primary and secondary metal is sold and transported in molten form.

Commercially pure aluminum usually contains about 99.7% aluminum. In the annealed condition, it has low strength and is relatively soft. However, it is available in strain-hardened conditions of higher strength and reduced ductility. Metal with more than 99.7% and up to 99.85% aluminum is available at higher cost than standard commercial metal. Superpurity aluminum contains a minimum of 99.99% aluminum.

Aluminum alloys have been developed that, after cold rolling, heat treating, annealing, or age hardening, have strengths approaching those of mild steels. More than 100 commercial alloys are available, and several new alloys are developed each year. The alloys offer a wide variety of combinations of mechanical strength,

ductility, electrical conductivity, and corrosion resistance.

Aluminum alloys are generally divided into two major groups: wrought and casting. The Aluminum Association uses a code to designate the purity and alloy content of wrought alloys and to register the composition of casting alloys and ingot. The range of compositions of wrought aluminum alloys and selected aluminum casting ingot alloys is given in table 3.

New aluminum-base scrap, generated in the production of intermediate and end products of aluminum metal, may be pure (unalloyed), segregated (one alloy type), or mixed (two or more alloys). It includes solids, such as new casting scrap; clippings or cuttings of new sheet, rod, wire, and cable; borings and turnings from the machining of aluminum parts; and residues, drosses, skimmings, spillings, and sweepings.

New scrap is further defined as either "runaround" (home) scrap or purchased scrap. Runaround or home scrap is new scrap that is recycled by the same company that generates it; such scrap by definition never leaves the company generating it and, therefore, is never marketed as scrap. New aluminum scrap that is purchased from manufacturers of end products may be referred to as consumer scrap. Purchased new scrap is sometimes referred to as prompt industrial scrap.

Old scrap, all of which is considered as purchased, comes from discarded, used, and wornout products. It includes aluminum pistons or other aluminum engine or body parts from junked cars, aluminum used beverage cans (UBC) and utensils, and old wire and cable. Sweated pig is scrap that has been melted (sweated) into a pig or ingot form for convenience and economy in shipping and storage. Obsolete scrap is new, unused, but technologically obsolete aluminum end products, outdated inventory materials, production overruns, and spare parts for machines and equipment no longer being used. In the United States, both sweated pig and obsolete scrap are considered old scrap.

Industry Structure

The aluminum industry is truly a worldwide industry. It is impossible to discuss the domestic industry without relating it to the total world aluminum industry. To more fully understand the global market in which the U.S. industry is competing, it

is necessary to discuss the U.S. position in each of the components of aluminum supply—bauxite, alumina, and aluminum metal. World production figures during the past 30 years for each of these commodities provide some idea of the changes that have taken place within the industry.

Bauxite resources (reserves plus subeconomic and undiscovered deposits) are currently estimated to be 55 to 75 billion tons. These resources occur mainly in South America (33%), Africa (27%), Asia (17%), and Oceania (13%). Mine production during the past 30 years has moved from North America and Europe to these bauxite-endowed regions of the world. U.S. mine production has decreased from about 2 million tons in 1960 to only 588,000 tons in 1988. Presently, there are only two companies conducting bauxite mining operations in the United States. Their mines are in Alabama and Georgia, and they do not produce bauxite for metal production. The bauxite produced by these operations traditionally has been utilized for refractory and other specialized applications.

The United States is entirely dependent on foreign sources for metallurgicalgrade bauxite. What aluminum resources the United States does have are low-grade bauxite substitute materials, which are not currently economic to exploit. To utilize these domestic alternative sources of alumina, an entirely new processing industry would have to be designed and developed. The United States currently receives most of its metallurgical-grade | Committee recommended specifications, May 1979.

bauxite from Australia, Guinea, and Jamaica.

Bauxite imports are shipped to five domestic alumina plants, which produce smelter-grade alumina for the primary metal industry. These refineries are in Louisiana, Texas, and the U.S. Virgin Islands. Even if these five refineries operated at full capacity levels and sold their product exclusively to the domestic metal smelters, the U.S. supply of alumina would be inadequate to meet the demand of the country's primary metal industry. Therefore, the United States must use imported alumina to supplement its domestic requirements, and Australia has become the major source of these imports.

2 Includes iron.

A continuing trend in world alumina production patterns has been the construction of alumina plants near areas of bauxite mining. More and more nations with bauxite reserves are realizing the economic advantages of processing the bauxite ore closer to the mine site and exporting the higher valued alumina product. In addition to providing a value added product for the raw material-producing country, this practice also reduces the bulk transportation requirements of the aluminum industry.

In 1960, the United States accounted for more than 50% of the world's production of alumina. In 1990, U.S. dominance in alumina production had been replaced by production from Australia. In addition to this change in the world alumina production picture, several countries, which either did not have an alumina industry or were very minor producers in 1960, have taken on a much stronger role. Some of these countries with a developing

alumina industry are Brazil, Greece, India, Ireland, Spain, Suriname, and Venezuela.

Although the United States continues to be the leading producer of primary aluminum metal in the world, its dominance in the industry has begun to wane. In 1960, the United States accounted for just over 40% of the world's production. In 1990, the U.S. share of world production had decreased to 23%. Most of the restructuring of the world aluminum industry began in the late 1970's and continues to this day. Australia and Canada have emerged as major metal producers. Japan, which had produced more than 1 million tons of aluminum as late as 1980, today produces only about 35,000 tons of primary metal. Other countries entering the world market today are Brazil, China, Norway, Venezuela, and several countries in the Persian Gulf region.

The driving force for most of these changes was the cost of energy. In the

early 1980's, the price of aluminum ingot decreased, an oversupply situation existed, and energy costs increased. These factors put pressure on aluminum companies to close their plants with high operating costs and low energy efficiencies. This was especially evident in the United States and Japan. Recent smelter expansions and new plant construction have been focused on areas of the world with access to low-cost energy and labor. Brazil, Canada, and Venezuela, for example, have access to hydroelectric power sources. Countries in the Persian Gulf are planning to use their abundant natural gas reserves to generate electricity for newly announced smelter construction.

Unlike past practice, when most of the cost for new aluminum plant construction was taken on by a single company, today's new plant construction costs are borne by a number of different aluminum companies in joint ventures. Even though the number of different companies pro-

ducing aluminum has been increasing, there are seven major companies that still control more than 40% of the total Western World primary aluminum production capacity. The leading company is the Aluminum Co. of America (Alcoa), followed by Alcan Aluminium Ltd., Reynolds Metals Co., Pechiney, Kaiser Aluminum & Chemical Corp., Alusuisse-Lonza Holding AG, and Alumax Inc. Most of these companies can be described as fully integrated, having interests in all

aspects of the aluminum industry from bauxite mining through semifabricated materials and, in some cases, even end product facilities.

Some of the most dramatic changes in the domestic aluminum industry occurred in the past 10 years. In 1980, there were 11 companies operating 33 smelters with a total annual domestic production capacity of 5 million tons of metal. By 1990, the number of operating companies had increased to 13, but the number of smelters

had decreased to 23 with a total annual capacity of about 4 million tons. Low aluminum prices and high operating costs forced domestic aluminum companies to close some of their higher cost operations. Even though 10 smelters were forced to close, the number could have been even greater were it not for some newly formed companies that purchased some of the marginal plants and negotiated new contracts with labor unions and electric utilities that helped to reduce their overall operating costs. Another new phenomenon that appeared in the domestic industry was the appearance of tolling operations, in which an aluminum plant charges an outside company a fee for converting alumina to metal.

In the mid-1980's, some power companies negotiated supply contracts that tied electricity rates to the price of aluminum ingot. The Bonneville Power Administration, which provides power to 10 smelters in the Pacific Northwest, operates under just such an arrangement. This pricing method provided domestic aluminum companies with a measure of relief by ensuring lower power costs during times of depressed prices. Major labor unions also provided concessions by negotiating lower hourly wage increases in exchange for a share in company profits.

Another factor that should be considered in analyzing the domestic aluminum industry is the growing importance of secondary aluminum to the domestic supply situation. Secondary aluminum is defined as aluminum recovered from both new and old purchased scrap. In 1960, 450,000 tons of aluminum was recovered from new and old scrap. In 1990, almost 2. 4 million tons of aluminum was recovered from scrap. More than 1 million tons of this secondary aluminum was recovered from post consumer, or old, scrap.

Growing concerns over waste disposal have placed increased emphasis on the recycling of materials. Both here and abroad, aluminum companies are promoting the fact that aluminum has a mature recycling industry. Not only does recycling of aluminum help to conserve landfill space, it also helps to save energy. It has been estimated that the recycling of aluminum consumes only about 5% of the energy required to produce aluminum metal from bauxite ore.

The United States remains the largest consumer of aluminum in the world. The container and packaging industry accounts for about 30% of domestic aluminum

consumption. This industry is followed by the transportation, construction, and electrical industries. The U.S. demand profile, however, does not reflect the demand pattern found in other parts of the world. World demand patterns, in general, show a much larger percentage of aluminum consumed by the construction and transportation industries and less by the packaging industry.

ANNUAL REVIEW— **ALUMINUM**

Once again, most primary aluminum

cases, above rated capacities during the year. Imports increased slightly after a 3-year downward trend as exports leveled off. A record 55 billion UBC's were recycled in 1990, equivalent to almost 64% of the aluminum can shipments for the year. Although aluminum metal prices trended upward during most of the vear, they began to slide downward toward the end of the year as the overall world economy slowed. World production of primary aluminum decreased slightly following several years of steady growth.

Legislation and Government Programs

The Defense Logistics Agency (DLA) smelters operated close to and, in some | announced that Alcoa was awarded a

\$100.4 million firm fixed-price contract for upgrading approximately 243,900 tons of bauxite to 55,157 tons of aluminum metal ingots for the National Defense Stockpile (NDS). Delivery of the metal was expected to be completed by September 1992. As of December 31, 1990, the NDS goal for aluminum metal remained at 635,030 tons, and the stockpile inventory held steady at 1,889 tons of aluminum metal.

The U.S. Bureau of Mines released a study that analyzed the application and impact of the Resource Conservation and Recovery Act's (RCRA) regulations on the mineral industry's efforts at resource recovery. Spent potliners were examined as a case study to demonstrate the impact of RCRA regulations.2

Production

Primary.—Domestic primary aluminum production increased slightly compared with 1989 production levels. Most smelters continued to operate near their rated capacity levels during most of 1990.

Southwire Co. of Georgia became the sole owner of the 172,000-ton-per-year primary aluminum smelter in Hawesville, KY. Southwire purchased the 54.5% interest held by its former partner in the smelter, National Aluminum Corp., a subsidiary of National Intergroup Inc.

Ormet Corp. temporarily closed a 41,000-ton-per-year potline at its primary smelter in Hannibal, OH. The potline was closed in March, but restarted in September.

In June, Alcoa announced the restart of a 42,000-ton-per-year potline at its Wenatchee, WA, smelter that had been idled since August 1989.

Ravenswood Aluminum Co. announced its decision to delay indefinitely the restart of the fourth potline at its West Virginia primary aluminum smelter that had originally been scheduled for February. In June, the company reported that it would also temporarily idle one of the three remaining potlines at the smelter, after the company and the United Steel Workers of America (USWA) officials failed to reach an agreement on work scheduling. The labor contract between Ravenswood and the USWA expired on October 31. The two parties failed to reach an agreement on a new contract by the end of the

In February, the USWA ratified a new 4-year contract, scheduled to expire on August 31, 1993, that covered workers at

Figures represent calcined alumina or the total of calcined alumina plus the calcined equivalent of hydrate, when available; exceptions, if known, are noted.

Noranda Aluminum Inc.'s New Madrid, MO, primary aluminum smelter. The contract reportedly included a 2% wage increase retroactive to January 1, 1990; a 2% increase effective July 1, 1990; and a 1% wage increase on September 1, 1992. A cost of living (COLA) increase of 29 cents per hour reportedly was included with an option for additional increases if the inflation rate rose above 3% per year. In addition to some enhancements in the worker benefit package, the contract also included changes in the company's profitsharing plan. Retroactive to September 1, 1989, profit sharing would go into effect only if the company earned more than a 3% return on assets, and the return on assets threshold would be increased to 4.1% on September 1, 1992.

On June 2, members of the USWA ratified a new 3-year labor agreement covering workers at Ormet's primary aluminum smelter in Hannibal, OH. The new labor contract, scheduled to expire on May 31, 1993, reportedly included a \$1,200 signing bonus, a \$500 bonus for each of the remaining 2 years of the contract, a 50-cent-per-hour increase in wages, and negotiated improvements in the company's pension plan.

In November, the USWA and Kaiser Aluminum announced the ratification of a new 4-year contract. The contract covered workers at the company's primary aluminum smelters in Tacoma and Mead, WA; the Trentwood, WA, rolling mill; the alumina refinery at Gramercy, LA; and two fabrication plants in Ohio. The new contract, scheduled to expire on October 31, 1994, reportedly included a 50-cent-per-hour increase in base pay for the first and fourth year, an increase in the pension multiplier of \$2 in the first year and \$1 in each of the next 3 years, a \$1,000 signing bonus, and bonuses of \$500 each in the second and third year. The agreement also reportedly continued the bonus plan tied to the price of aluminum and optional, plant-specific bonus plans based on performance.

Big Rivers Electric Corp. and the Kentucky Public Service Commission announced that an agreement on power rates had been reached with the owners of the two primary aluminum smelters in Kentucky. The agreement covered Southwire's 172,000-ton-per-year smelter at Hawesville and Alcan Aluminum Corp.'s 163,000-ton-per-year smelter at Sebree. The agreement reportedly established a balancing account to ensure an average

³Primary unalloyed metal plus primary alloyed metal, thus including weight of alloying material.

rate of 29 mills per kilowatt hour and maintained the variable rate structure through August 1997.

Alumax announced the signing of a new power contract with Santee Cooper, the supplier of electricity to the Mount Holly, SC, primary aluminum smelter. Alumax reportedly agreed to maintain the current power load at its smelter through 1993 and to maintain at least one-half of that load throughout the period April 1, 1995, to March 31, 2000. The contract reportedly provided a reduced power rate applicable to one of the smelter's two potlines effective January 1, 1994, and continuing until April 1, 2000.

Kaiser Aluminum announced the closure of its Permanente, CA, aluminum foil facility. The closure marked the company's complete exit from the aluminum foil business.

Kaiser Aluminum also announced a \$9 million expansion program at its Los Angeles extrusion facility, scheduled for completion in 1991. The project included a new 4,000-ton extrusion press and additional remelt and casting equipment for the production of 90 million pounds of high-quality aluminum billet and log annually.

Nichols-Homeshield announced plans to construct an aluminum minimill in Davenport, IA, with a potential 275 million pounds of capacity annually. The estimated \$60 million cost of the project reportedly included site acquisition, scrap processing and melting equipment, a Hazelett continuous caster, and equipment for hot and cold rolling, annealing, coil coating, and slitting.

Matsushita Electronic Corp. of America announced plans to build a \$10 million aluminum foil processing facility adjacent to the company's capacitor manufacturing operations in Knoxville, TN. The new plant was scheduled for completion by mid-1991.

Norsk Hydro A/S reported the purchase of Bohn Aluminum & Brass from Wickes Manufacturing Co. Bohn Aluminum operated two four-press operations in Adrian and Holland, MI. The automotive industry accounted for about 60% of the sales volume from these two plants. Norsk Hydro later announced that it merged Bohn Aluminum with its Floridabased subsidiary Hydro Aluminum Automotive. The new group would be known as Hydro Aluminum Bohn.

Secondary.—According to a survey conducted by the Aluminum Association Inc., the Institute of Scrap Recycling Industries, and the Can Manufacturers Institute, a record 54.98 billion aluminum UBC's were recycled in 1990, surpassing by more than 5.5 billion the number of UBC's recovered in 1989. The percentage of aluminum cans recycled in the United States increased from 60.8% of aluminum

cans shipped in 1989 to 63.6% of can shipments in 1990.

Îmco Recycling Inc. announced plans to expand its UBC recycling plant in Morgantown, KY. Upon completion, the plant's annual capacity reportedly would increase to almost 500 million pounds from its current level of 430 million pounds.

Alcan Recycling, a division of Alcan Aluminum, announced plans for a \$7 million upgrade at its Greensboro, GA, recycling plant. The expansion program, which was expected to increase UBC processing capacity by 25% to 5 billion cans per year, included the installation of two new electric induction furnaces and a large melting furnace.

Reynolds Metals announced a pilot program in five U.S. metropolitan areas to boost the recycling of aluminum foil, TV dinner trays, pie pans, and other lightweight aluminum items. The recycling centers were planned for the Baltimore/Washington area, Richmond, San Francisco, Seattle, and Tampa.

Alcan Aluminum announced the purchase of Summit Alloys Co., formerly known as Southern Alloys Co. Summit Alloys operated a 25,000-ton-per-year secondary smelter in Shelbyville, TN. The plant produced secondary aluminum ingot alloys for sale to diecasters and foundries in the area.

Plasma Technology Corp. announced

system and Europe. The new plant in West Virginia was scheduled to start production in 1991.

Consumption and Uses

The container and packaging industry remained the largest domestic consumer of aluminum products. The Can Manufacturers Institute reported that about 88 billion aluminum beverage cans were shipped in 1990, representing about 95% of the total metal beverage can shipments.

Reynolds Metals and Campbell Soup Co. announced the signing of a long-term supply agreement whereby Reynolds Metals would supply aluminum for Campbell's juice cans, which had been made of steel. Some of the products involved were Campbell's V-8 and Juice Bowl products in 5.5-ounce and 11.5-ounce can sizes.

Crown Cork & Seal Co. Inc. announced the purchase of Continental Can Co. Inc.'s steel and aluminum canmaking facilities. The combining of the two companies reportedly would make Crown the largest domestic producer of aluminum beverage cans.

Alcan Aluminum's building products division announced the purchase of Alumax's building specialties division, consisting of fabrication and distribution facilities at seven locations throughout the United States. These facilities produced aluminum and steel commercial and industrial siding and roofing, architectural panels, and exterior building products.

During the year, several companies announced either new or expanded uses of aluminum in automotive applications. Ford Motor Co. introduced a two-piece aluminum hood on its 1990 Lincoln Town Car. Ford announced plans to expand the use of these hoods by including them on the 1991 Mercury Marquis and Ford Crown Victoria models. General Motors Corp. announced plans to use aluminum driveshafts on some of its next-generation pickup trucks and sports utility wagons scheduled for the mid-1990's. Chrysler Corp. reported that it planned to put aluminum cylinder heads on its new 24valve, 3.5-liter V-6 engines scheduled for 1993. These were only a few of the many automotive applications for aluminum that were announced during the year.

In addition, several automakers and aluminum producers reported that they were joining forces to develop and pro-

¹Excludes recovery from other than aluminum-base scrap.

duce aluminum-intensive vehicles. For example, Alcoa entered a partnership with Audi to produce an aluminum-intensive vehicle, and Alcan Aluminium was working with Ford's Jaguar subsidiary on an aluminum structural model, the XJ220. In September, Honda introduced its NSX luxury sports car, which featured an all-aluminum structure and body.

Stocks

Inventories of aluminum ingot, mill products, and scrap at reduction and other processing plants, as reported by the U.S. Department of Commerce, increased slightly from 1.822 million tons at yearend 1989 to 1.825 million tons at yearend 1990.

Markets and Prices

The monthly average U.S. market price for primary aluminum trended upward during the first three quarters of the year before beginning a downward turn that brought yearend prices back to their January levels. The London Metal Exchange (LME) and New York Commodity Ex-

change (COMEX) prices for aluminum futures followed the same general trend as the U.S. market prices.

Purchase prices for aluminum scrap, as quoted by the American Metal Market (AMM), fluctuated during the year, but began and closed the year at approximately the same levels. The yearend price ranges for selected types of aluminum scrap were as follows: mixed low-coppercontent aluminum clips, 51 to 52 cents per pound; old sheet and cast aluminum, 42 to 44 cents per pound; and clean, dry aluminum turnings, 45 to 47 cents per pound.

Prices for UBC's fluctuated during the year, but closed 8 cents per pound lower than prices at the beginning of the year. Aluminum producers' buying prices for processed and delivered UBC's, which began the year at a range of 50 to 53 cents per pound, reached a high for the year of 56 to 60 cents per pound in September. The price range at the end of the year was 42 to 46 cents per pound.

Secondary aluminum ingot prices, as quoted by AMM, fluctuated during the year and closed slightly lower than prices at the end of 1989. The yearend 1990 price ranges for selected secondary aluminum

ingots were as follows: alloy 380 (1% zinc content), 73 to 74.5 cents per pound; alloy 360 (0.6% copper content) and alloy 413 (0.6% copper content), 76 to 77 cents per pound; and alloy 319, 74 to 75.5 cents per pound.

The LME announced the creation of a subcommittee to investigate the potential for an LME secondary aluminum ingot contract. The subcommittee was composed of members of the LME board and secretariat along with members of the international secondary aluminum industry. One major task of the subcommittee was to be the identification of a grade for

the secondary ingot that could be traded and used worldwide.

Foreign Trade

Exports of all forms of aluminum from the United States leveled off in 1990. Canada and Japan continued to be the major recipients of U.S. aluminum materials, accounting for just over two-thirds of total U.S. exports. Exports of UBC's, which were included in the scrap category, decreased dramatically in 1990 compared with those of the previous year.

UBC exports in 1990 totaled 2,854 tons compared with 17,354 tons in 1989. Japan continued to be the principal destination of UBC's exported, accounting for just over 40% of the total in 1990.

Imports for consumption of aluminum increased slightly compared with those of 1989. Canada remained the major shipping country to the United States, supplying three-fourths of the total imports in 1990. UBC imports in 1990 totaled 37,028 tons compared with 22,738 tons in 1989. Canada also continued to be the major source of UBC imports, accounting for almost two-thirds of the total in 1990.

²Includes other die-cast alloys and other miscellaneous.

³No allowance made for melt-loss of primary aluminum and alloying ingredients.

World Review

World aluminum demand, which remained strong during most of the year, began to slow toward the end of 1990. Inventories in market economy countries decreased during the first 9 months of the year before beginning an upward trend in the last quarter. Many of the world's producers of aluminum continued to operate their primary smelters at or near rated capacity levels.

In October, the LME announced the selection of Baltimore, MD, as the site for its first U.S. warehouse. The LME expected to accept delivery of aluminum at this location effective February 1, 1991.

Primary aluminum inventories held by members of the International Primary Aluminium Institute (IPAI), which represent the bulk of stocks held outside the centrally planned economy countries, decreased slightly from 1.576 million tons at yearend 1989 to 1.527 million tons at year-

¹Positive figure indicates a decrease in stocks; negative figure indicates an increase in stocks.

²Metallic recovery from purchased, tolled, or imported new and old aluminum scrap expanded for full industry coverage.

³Apparent aluminum supply available for domestic manufacturing less recovery from purchased new scrap (a measure of consumption in manufactured end products).

¹Data may not add to totals shown because of independent rounding.

end 1990. IPAI reported that total metal inventories, including secondary aluminum, decreased from a revised figure of 3.231 million tons at yearend 1989 to 3.138 million tons at yearend 1990.

Capacity.—The data in table 22 are rated annual capacity for plants producing primary aluminum as of December 31 for the years shown. Rated capacity is defined as the maximum quantity that

can be produced on a normally sustainable long-term operating rate, based on the physical equipment of the plant and given acceptable routine operating procedures for labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Australia.—Comalco Aluminium Ltd. announced that expansion plans at its Boyne Island primary aluminum smelter have been put aside. The decision followed the failure to reach an agreement with the government of Queensland for the purchase of the Gladstone power station, which supplies power to the smelter.

Southern Aluminium Pty. Ltd. commissioned an aluminum wheel casting plant in Tasmania. Comalco, the plant's largest shareholder, managed the operation. During the year, monthly production increased from 6,000 wheels January to more than 40,000 wheels in December. Most of the production from the plant, which has a nominal capacity of 600,000 wheels per year, was exported.

Austria.—Reynolds Metals announced plans to double the capacity at its can plant in Enzesfeld, Austria, to 900 million cans per year. Earlier in the year, Reynolds Metals became the sole owner of the plant when it purchased the 50% interest held by its former partner, Austria Metall AG.

Bahrain.—Aluminium Bahrain Ltd. (Alba) announced plans to construct a fourth potline at its primary aluminum smelter. The \$1.4 billion expansion included a 235,000-ton-per-year potline using Pechiney 300-amp technology, construction of a new powerplant, and an upgrade of existing facilities. Scheduled for completion by 1993, the expansion would increase the capacity of the smelter to 460,000 tons per year.

Brazil.—Increased energy costs and delays in the construction of new hydroelectric capacity were expected to slow the growth of primary aluminum production capacity in Brazil, which had expanded rapidly in recent years. A 32% increase in power rates raised electricity prices for most of the country's primary smelters to about 40 mills per kilowatt hour, one of the highest power rates in the world. The exceptions were the Consorcio de Alumí-

¹Net shipments derived by subtracting the sum of producers' domestic receipts of each mill shape from the domestic industry's gross shipments of that shape.

nio S.A. (Albras) and Alcoa Alumínio S.A. (Alumar) smelters, which had longterm power contracts that featured discounts and rate ceilings linked to aluminum metal prices. However, at the end of on Aluminerie Alouette Inc.'s 215,000-

the year, these contracts were also being reviewed.

Canada.—Construction work began

ton-per-year primary aluminum smelter at Sept îles in Quebec. However, the projected capital cost of the project reportedly increased to \$1.21 billion from the original estimate of \$1.08 billion, and the

Revised.

scheduled startup was delayed by 2 months to June 1992. Also, in an effort to reduce costs, the smelter would produce 50-pound, high-quality remelt ingot rather than the previously planned product range of sheet metal ingot, extrusion ingot, and wirebar.

Aluminerie de Bécancour Inc. (ABI) announced the startup of its new 120,000-ton-per-year potline in late October, about 4 months ahead of schedule. When this third potline becomes fully operational in early 1991, the capacity of the smelter will be 360,000 tons per year.

Alcan Aluminium announced that its 200,000-ton-per-year primary aluminum

smelter at Laterriere would be operating at full capacity early in 1991. As originally announced, Alcan Aluminium was scheduled to shut down three Soderberg-type potrooms at its Arvida smelter in Jonquière during the same period of time. Upon completion of the planned shutdowns at Arvida, the smelter there would operate four Soderberg and six prebake lines for a rated capacity of 230,000 tons per year.

Members of the Canadian Association of Smelter and Allied Workers ratified a new 3-year labor contract that covered approximately 1,500 unionized employees at Alcan Aluminium's primary aluminum smelter at Kitimat and the Kemano power station, both in British Columbia. The new contract, which expires on July 25, 1993, reportedly included a \$1,750 (Canadian dollars) signing bonus per worker, a 6% wage increase in the first and third year, a flat increase of \$1.24 (Canadian dollars) per hour in the second year, cost of living allowances triggered at 6% in the second and third year, and improvements in some fringe benefit items.

Reynolds Metals reported that construction began on an 80,000-ton-peryear aluminum redraw rod plant in Quebec. The plant was being constructed on a site adjacent to the ABI smelter, in

¹Includes plates, sheets, circles, and disks.

²Data may not add to totals shown because of independent rounding.

³Etched capacitor foil is excluded for 1990.

which Reynolds Metals has a 25% interest. Molten metal from the ABI smelter would be trucked to the rod plant, which was expected to be completed at the end of 1991.

Reynolds Metals also announced the signing of an agreement to purchase a 75% interest in an aluminum wheel plant in Collingwood, Ontario. Lemmerz Canada Inc., a subsidiary of Lemmerz-Werke K Ga A of Königswinter, Germany, would retain the remaining 25% interest in the 1-million-wheel-per-year plant. Reynolds Metals also announced plans to increase capacity at the plant to 1.5 million wheels per year by 1993.

Chile.—Proyectos de Aysten of Chile announced that they had contacted Kaiser Engineers International to conduct a feasibility study on the construction of a 200,000-ton-per-year primary aluminum smelter and a hydroelectric power station in southern Chile. The site chosen was on the Cuervo River.

Germany, Federal Republic of.—Alcan Norf GmbH (Alunorf), a joint venture of Alcan Deutschland GmbH and Vereinigte Aluminium-Werke AG (VAW), announced a \$535 million expansion plan at its rolling mill. The program, which would increase capacity by 700,000 tons per year, involved the construction of a second hot-rolling mill and a two-stand tandem cold-rolling mill. Upon completion in 1994, the Alunorf plant was expected to be the largest single aluminum rolling plant in the world with a total annual capacity of 1.4 million tons.

Iceland.—Atlantal, a joint venture of Alumax, Granges AB, and Hoogovens Aluminium BV, announced plans to study the feasibility of constructing a 200,000-ton-per-year greenfield primary aluminum smelter at Keilisnes.

Iran.—The Dubai-based International Development Corp. announced the signing of a joint-venture agreement with the Government of Iran for the construction of a 220,000-ton-per-year primary aluminum smelter at Bandar Abbas. The \$1.35 billion project also reportedly included a powerplant and desalination unit.

Japan.—Alcoa and Kobe Steel announced the formation of a joint venture to produce and market aluminum sheet for the beverage container market. The

Preliminary. Revised.

¹Detailed information on the individual aluminum reduction plants is available in a two-part report that can be purchased from Chief, Division of Finance, U.S. Bureau of Mines, Bldg. 20, Federal Center, Denver, CO 80225. Part 1 of "Primary Aluminum Plants, Worldwide" details location, ownership, and production capacity for 1988-95 and sources of energy for foreign and domestic primary aluminum plants, including those in centrally planned economies. Part 2 summarizes production capacities for 1988-95 by smelter and country.

first project in this new venture, named KSL Alcoa Aluminium, was reported to be the construction of a new 180,000-ton-per-year cold-rolling mill adjacent to Kobe Steel's Moka plant. The targeted startup date for the mill was mid-1993.

Korea, Republic of.—In mid-1990, Aluminium of Korea Ltd. (Koralu) announced the suspension of operations at its primary aluminum smelter in Ulsan.

Nigeria.—Aluscon, a partnership of the Government of Nigeria, Ferrostaal AG of Germany, and Reynolds Metals, announced plans to construct a 180,000ton-per-year primary aluminum smelter at Ikot Abasi in southeastern Nigeria. Financing of this project reportedly was incomplete.

Norway.—Norsk Hydro and Elkem Aluminium announced plans to expand capacity at their respective primary aluminum smelters. Elkem reportedly planned a total capacity expansion of 200,000 tons per year at its Mosjoen and Lista smelters. Norsk Hydro's plans reportedly included its smelters at Ardal and Sunndalsora with a total net increase in capacity of about 280,000 tons per year. A final decision on these plans reportedly was dependent on the companies' ability to secure long-term power supply contracts at internationally competitive prices.

Spain.—Instituto Nacional de Industria (INI), the state-owned industrial holding company, reported the purchase of Alcan Aluminium's 23.9% interest in the aluminum producer, Inespal. Following the purchase, INI became the sole owner of Inespal.

Norsk Hydro announced plans to purchase Riego Wright SA. Riego Wright reportedly was one of Spain's largest producers of extruded aluminum, serving primarily the construction market.

U.S.S.R.—Kaiser Aluminum reported the signing of an agreement to modernize 2 of the 23 potrooms at the Krasnoyarsk primary aluminum smelter. The modernization program reportedly involved the installation of Kaiser's computerized cell control technology, new emission control systems, and other anode and cell operations technology.

Current Research

The damping capabilities of a number of aluminum-matrix composites were measured over a wide range of frequencies at low strain amplitudes using a new laser vibrometer technique. The damping of composites of aluminum alloy 6061 reinforced with Al₂O₃ particulates, silicon carbide whiskers, continuous graphite (planar-random) fibers, and unidirectional graphite fibers was studied to determine which systems showed the most promise for improved damping in the 1- to 20-kilohertz range under ambient conditions.³

With their high stiffness and low weight, honeycomb materials reportedly are becoming an increasingly important element of advanced aerospace design concepts. Some of the factors that influenced the applicability of metallic-based honeycomb structural materials were examined.⁴

The Minerals, Metals, and Materials Society (TMS) published the proceedings of the Light Metals Committee technical sessions presented at the 119th TMS Annual Meeting held in Anaheim, CA, February 1990. More than 100 papers, in such topic areas as alumina and bauxite, reduction technology, carbon technology, and cast shop technology, were presented. The proceedings, entitled Light Metals 1990, were available from TMS, 420 Commonwealth Drive, Warrendale, PA 15086.

OUTLOOK—ALUMINUM

Demand for aluminum, both domestically and worldwide, continued to slow during the first half of 1991. This slow-down should continue through the end of the year before beginning a slow gradual rise in 1992. Thereafter, aluminum metal demand should show an average annual growth rate of about 2% per year over the next few years.

ANNUAL REVIEW— BAUXITE AND ALUMINA

World production of bauxite and alu-

mina advanced during 1990 to new record levels in response to the continued high pace of primary aluminum metal output. Mine production of bauxite was reported from 27 countries. Domestic consumption of bauxite once again continued its upward movement, but at a reduced rate from that of 1989, with the majority of the growth driven by metal market requirements for primary aluminum. Within the specialty products area, consumption of abrasive-grade bauxite was comparable with 1989 usage, but bauxite consumption by the chemical and refractory industries declined slightly in 1990. Demand for alumina remained strong throughout the entire year, mainly in response to high primary aluminum smelter operating levels. In spite of a national economic recession in the latter part of 1990, U.S. production and shipments of smelter-grade alumina continued the climb to new heights, as has been the pattern in recent years. U.S. alumina consumption, however, moderated slightly from the high levels of 1989, and a slight softening of the alumina market developed in 1990 as a buildup developed in alumina supply levels. Alumina reportedly was produced in 24 countries around the world.

Legislation and Government Programs

Effective as of February 14, 1990, the Environmental Protection Agency (EPA) removed nonfibrous alumina from its list of toxic substances covered under Emergency Planning and Community Right-to-Know legislation passed by the U.S. Congress in 1986.⁵ The action relieved U.S. alumina producers from a requirement to report releases of aluminum oxide that had occurred in 1989 and releases that could occur in the future because nonfibrous alumina was found not to cause adverse human health effects or environmental toxicity.

On July 31, 1990, as mandated by the U.S. District Court for the District of Columbia, the EPA released its Report to Congress concerning regulation of 20 special wastes from mineral processing operations that had been identified for temporary exemption from regulation as hazardous wastes under the Mining Waste Exclusion of RCRA.⁶ This was EPA's second Report to Congress (RTC II) on wastes from the mineral industry. The Agency, within the detailed conclusions of the report, determined that red and brown muds generated from the

bauxite refining process exhibit none of the characteristics of hazardous waste and, therefore, should not pose a threat to human health or the environment.

There were no additions or withdrawals of bauxite from the NDS in 1990. The NDS goals for bauxite remained unchanged at 21.3 million tons of Jamaicatype and 6.2 million tons of Surinametype metallurgical-grade bauxite. The goal for calcined refractory-grade bauxite was adjusted downward from 1.42 to 1.26 million tons, and the goal for calcined abrasive-grade bauxite was eliminated. The DLA, manager of the NDS, listed an inventory of 12.7 million tons of Jamaicatype and 5.4 million tons of Surinametype metallurgical-grade bauxite at yearend. The NDS calcined refractory-grade bauxite inventory was listed as 280,500 tons at the close of 1990.

In a plan to upgrade the NDS stocks, DLA announced on September 28, 1990, the awarding of the first in a planned series of contracts to convert metallurgical grade bauxite ore in the NDS to aluminum metal. The fixed price contract, awarded to Alcoa, called for the conversion of approximately 243,900 tons of bauxite to 55,157 tons of aluminum metal ingot. Work on this \$100.4 million contract was expected to be completed by September 1992.

Production

The total U.S. bauxite production during 1990 was markedly lower than that reported for 1989. The significant reduction in domestic mine production was partly attributed to the permanent closure of the last bauxite mining operation in Arkansas during mid-1990. The only currently active bauxite mines remaining in the United States are the surface operations in Alabama and Georgia that produce bauxitic materials, a natural mixture of bauxitic clay and bauxite with a very low iron oxide content, primarily used for the production of alumina calcines. Demand for these domestic ores remained relatively weak during 1990, and mine output was intermittent. Within this market sector, the Harbison-Walker Refractories Div. of Dresser Industries Inc. shipped bauxite from mines in Alabama to its local calcining plant and to Carbo Ceramic Co.'s proppant plant at Eufaula, AL. Throughout the year, C-E Minerals continued to operate and maintain its mines in Alabama and Georgia, with the

The U.S. Bureau of Mines defines primary aluminum as "The weight of liquid aluminum as tapped from pots, excluding the weight of any alloying materials as well as that of any metal produced from either returned scrap or remelted materials." International reporting practices vary from country to country, some nations conforming to the foregoing definition and others using different definitions. For those countries for which a different definition is given specifically in the source publication, that definition is provided in this table by footnote. Table includes data available through May 24, 1991.

2 Reported figure.

³Primary ingot.

Excludes high-purity aluminum containing 99.995% or more as follows, in metric tons: 1986—8,140; 1987—12,099; 1988—13,628; 1989—15,696; and 1990—16,292.

⁵Primary unalloyed ingot plus secondary unalloyed ingot.

⁶Primary unalloyed metal plus primary alloyed metal, thus including weight of alloying material.

raw ore shipped to its Andersonville, GA, facility for the production of refractory products.

Alcoa indicated that it had closed its Arkansas bauxite mining operation and 340,000-ton-per-year production capacity refining plant because of depleted ore reserves. The mining operation had supplied metallurgical-grade bauxite for aluminum metal production over tha major portion of the mine's history. The company's Arkansas mining facilities, opened in 1899, were the last mining operations in the United States capable of producing bauxite for smelter-grade alumina production. In recent years, however, mine output was primarily utilized as feed for the manufacture of proppants used in the petroleum industry and the production of a wide range of specialty alumina chemicals. It was reported that the production of alumina chemical products would be continued at the Bauxite, AR, location employing alumina feedstocks supplied from other Alcoa facilities.

Clarendon Ltd., an aluminum trading group based in Switzerland, reopened the 635,000-ton-per-year alumina plant on the Island of St. Croix within the U.S. Virgin Islands in early 1990 through its subsidiary Virgin Islands Alumina (VIALCO). The refinery had been idle since 1985 and was purchased from the previous owner, Martin Marietta Corp., in April 1989. Bauxite feedstock for the refinery reportedly was supplied from sources in Brazil and Guyana.

The net domestic capacity to produce alumina approached almost 5.62 million tons per year in 1990, with the reopening of the St. Croix, VI, plant and the closure

of the Bauxite, AR, plant. Apparent refinery capacity utilization in the United States for the year was approximately 93%.

In 1990, it was announced that the American Capital and Research Corp. subsidiary, ICF Kaiser Engineers, entered a 3-year contract with Kaiser Aluminum and Chemical Corp. involving engineering work on Kaiser's Gramercy alumina plant in Louisiana and affiliated Kaiser operations in Jamaica.

Consumption and Uses

A continued firm requirement for smelter-grade alumina moved the consumption of crude and dried metallurgical-grade bauxite to a level slightly above that of 1989. The majority of this increase was supplied from imports. Consumption of bauxite by the abrasive industries remained essentially unchanged throughout 1990, while consumption within the chemical and refractory industries decreased by modest amounts for the year. Approximately 90% of the bauxite consumed in the United States during 1990 was refined to alumina, and an estimated average of 2.21 tons of dried bauxite was required to produce 1 ton of calcined alumina. Twenty-two of the 23 active primary aluminum smelters reported to the U.S. Bureau of Mines a consumption of 7.6 million tons of calcined alumina in 1990, down slightly from the consumption level reported for 1989. This lower level of consumption, coupled with the high U.S. alumina production rates, resulted in the development of a modest oversupply of smelter-grade alumina on

the domestic alumina market. An estimated 92% of the alumina shipped by U.S. refineries went to domestic primary smelters for metal production. Consumption in various forms by the abrasives, chemicals, refractories, and specialties industries accounted for the balance of the alumina usage.

Markets and Prices

Contract terms for the purchase of metallurgical-grade bauxite and smeltergrade alumina in world markets are not normally made public, and, consequently, prices for these commodities are not published by trade journals. Price quotes are generally limited to certain specialty forms of bauxite and alumina for nonmetallurgical uses.

In 1990, the U.S. Bureau of Mines estimated the average value of domestic crude bauxite shipments, f.o.b. mine or plant, to be \$16 per ton. The average value of calcined domestic bauxite was estimated to be \$175 per ton. Base prices quoted by Industrial Minerals magazine and independent sources for imported calcined refractory-grade bauxite were as follows: Chinese, typical 85% alumina (Al₂O₃), f.o.b. barge, Burnside, LA, \$85 to \$125 per ton; and Guyanese, f.o.b. railcar, Baltimore, MD, or f.o.b. barge, gulf coast, \$175 ton. Abrasive-grade bauxite, minimum 86% Al₂O₃, c.i.f. main European ports, was priced at \$95 to \$108 per ton. Base prices were subject to adjustment for various grain-size specifications, size of order, and fuel cost factors.

A growing alumina surplus on world markets led to prices easing from the very

^eEstimated. ^rRevised.

high levels established during the previous 2 years. The average value of domestic calcined alumina shipments was estimated to be \$260 per ton. Trade data released by the Bureau of the Census indicated the average value of imported calcined alumina was \$305 per ton, f.a.s. port of shipment, and \$332 per ton, c.i.f. U.S. ports. Beyond these current prices, mediumterm projections support a reasonably buoyant market outlook for alumina toward the mid-1990's.

For 1990, the International Bauxite Association (IBA) recommended that its members set their minimum c.i.f. price for metallurgical-grade bauxite at between 2% and 2.5% of the composite reference price for primary aluminum ingot and, for metallurgical-grade alumina, between 13.5% and 15% of the composite reference price for primary aluminum ingot. The IBA members account for approximately 86% of the bauxite output from the market economy countries and about

56% of the alumina production.

Foreign Trade

Dried bauxite exports from the United States totaled 32,300 tons in 1990, a marked increase over the 1989 total of 18,900 tons. Canada received 30,400 tons and Mexico, 1,500 tons. U.S. exports of calcined refractory-grade bauxite totaled 13,700 tons for 1990. Mexico received 10,600 tons and Canada, 2,800 tons. Exports of all other grades of calcined bauxite (chiefly abrasive-grade) amounted to 7,000 tons for the year. Mexico received 4,500 tons and Venezuela, 1,200 tons. Specialty aluminum compounds exported included 6,800 tons of aluminum sulfate, 13,700 tons of aluminum oxide abrasives, and 13,900 tons of various fluoride-base compounds of aluminum, including synthetic cryolite and aluminum fluoride.

Imports for consumption of crude and dried bauxite increased from 1989 receipts, and the three primary suppliers were Jamaica, Guinea, and Brazil, in order of shipments. Brazil's shipments to the United States continued to increase during the year, and Brazil displaced Australia from the third place position on the list of countries that supplied bauxite to U.S. markets in 1990.

World Review

World production of bauxite and alumina remained on the upward trends that commenced following the aluminum industry slowdown of the mid-1980's. Twenty-seven countries reportedly mined bauxite in 1990, and the total world production of bauxite reached a record 109 million tons, an increase of 3% above 1989 production. Australia, Guinea, Jamaica, and Brazil, in order of volume, accounted for slightly more than 70% of the total bauxite mined during the year. The corresponding world output of alumina increased to 40 million tons, also a new production record, and was 3% higher than the 1989 production level. The traditional, principal producing countries, Australia, the U.S.S.R., and the United States, once again supplied almost 50% of the total world production.

Capacity.—A moderate increase in the annual rated capacity of plants producing alumina resulted in the development of a modest surplus of alumina stocks on

¹May exclude some bauxite mixed in clay products.

world markets in 1990. Apparent world-wide refinery capacity utilization for 1990 was estimated at approximately 92%. The 1990 world annual alumina plant capacity was rated at 2% above the previous record level that was posted in 1984. Any further increases in smelter-grade alumina production capacity are expected primarily to develop from incremental

expansions of existing plants and only in very special situations from new greenfield refineries, which normally demand a 4- to 5-year design, engineering, and construction period, plus very significant capital investment.

na production capacity are expected primarily to develop from incremental est bauxite- and alumina-producing

country achieved new production records for the eighth consecutive year.

Alcan Aluminium announced that its South Pacific Ltd. subsidiary would conduct a joint feasibility study with Comalco for the installation of a new alumina plant in northern Australia. The refinery was projected to have an initial capacity of approximately 1 million tons per year and would be built near bauxite reserves owned by both companies on the Cape York Peninsula of northern Queensland, where Alcan holds rights to the Wenlock River deposit and Comalco operates the Weipa bauxite mine. The initial cost estimates for the proposed refinery were indicated to be approximately \$1 billion.

Comalco reported that its 1990 production and shipments of bauxite from the Weipa mining operation were the highest in the mine's history, with beneficiated bauxite production at 11.0 million tons and metal-grade bauxite shipments at 10.5 million tons. The company attributed the increases to new markets in Eastern Europe, as well as higher demand from the Queensland Alumina Ltd. plant at Gladstone, which also enjoyed a record year, with alumina production more than 3 million tons. A continuing program for the upgrading of this plant was expected to result in the alumina production capacity of this facility being raised to the 3.3-million-ton-per-year level, a 400,000ton-per-year increase in refinery capacity.

The current expansion program of the Worsley Alumina Pty. Ltd. (50% Reynolds Metals, 37.5% Shell, and 12.5% Kobe/Nissho-Iwai) refinery in Western Australia was expected to be completed in early 1991 and would raise the capacity of this alumina plant to 1.5 million tons per year.

Alcoa of Australia reported that construction had begun on the previously announced \$250 million expansion of its Wagerup alumina plant in Western Australia. The expansion, expected to be completed in early 1993, would lift the refinery's capacity by 630,000 tons to 1.48 million tons per year. For 1990, Alcoa of Australia's three alumina plants (Kwinana, Pinjarra, and Wagerup) reportedly produced just under 5.5 million tons of alumina.

Nabalco Pty. Ltd. (70% Alusuisse-Lonza, 30% Gove Aluminium Ltd.) released plans to spend about \$109 million to upgrade its bauxite and alumina operations at Gove in the Northern Territory of

Australia. When completed in early 1992, the company would be producing an additional I million tons per year of bauxite, raising total mine output to approximately 6 million tons per year, and the related alumina production would be increased from the present 1.4 million tons per year to 1.6 million tons per year. Late in 1990, this Gove joint-venture company secured the right to export 40 million tons of bauxite during the next 20 years through an extension of an agreement with the government of Australia's Northern Territory that had been due to expire in 1991.

Alcoa of Australia was honored in June by the United Nations Environmental Program (UNEP) for rehabilitating and reforesting four bauxite mining areas in Western Australia during the past 20 years. This was the first mining operation ever to win environmental honors from the UNEP as part of the agency's Global 500 Roll of Honor. Alcoa of Australia reportedly spends \$9.24 million per year on rehabilitation planning, operations, and research for its mined-out areas.

Brazil.—Alto Brasil Mineração (ABM), a joint-venture company of Alcoa Alumínio and Billiton Metais, received an environmental license from the Brazilian Government to open a bauxite mine at Cruz Alta within the Trombetas River area of Brazil's Amazon region. It was estimated that the initial capacity of the mining operation would be 2.25 million tons per year; capacity may be expanded to 4.5 million tons per year at a later date. Investment in the first phase was projected to be \$150 million, and it was expected that construction would begin in 1991. ABM was reported to hold rights for bauxite ore reserves of 230 million tons within the Trombetas area.

Mineração Rio do Norte S.A. (MRN) reportedly produced 8.0 million tons of bauxite at its Trombetas mining operation in Pará State 31% above 1989 production levels. Its reported sales of 7.8 million tons were 22% above those of the previous year. The MNR bauxite exports totaled 5.6 million tons, and domestic sales amounted to 2.2 million tons. These new production and sales records were achieved in part because of the completion of a \$40 million mine expansion and modernization program. In addition, MRN announced that because of increased competition from other bauxite mines, it had initiated an ambitious cost

control program that had resulted in a reduction of almost 20% of its total work force by the end of 1990.

The long stalemated Alumina do Norte do Brasil S.A. (Alunorte) refinery project near Belém remained on hold in 1990 pending Cia. Vale do Rio Doce and Nippon Amazon Aluminium Co. arranging further financial support for the project.

China.—Chinese geologists reported the discovery of a large bauxite deposit in central Guizhou Province, China. It was thought to be one of the largest bauxite deposits to have been found in the country, and its total resources were estimated at 200 million tons. A 1.2-million-tonper-year mining operation was proposed to exploit the currently identified 70million-ton reserve base of the deposit.

Dominican Republic.—Government officials announced that Alcoa had entered a \$6.3 million agreement to purchase 350,000 tons of bauxite in 1990. Ideal Dominicana, S.A., a subsidiary of the U.S. firm Holnam Inc., continued to manage and operate the Cabo Rojo-Pedernales area bauxite mining operations for the Government. It was believed that approximately 300 new jobs would be created, directly and indirectly, as a result of the resumption of bauxite mining activities at this operation, previously owned by Alcoa. It was expected that the majority of the bauxite covered by this purchase agreement would be shipped to Alcoa's subsidiary in Suriname.

Egypt.—Billiton International Metals BV and Marc Rich & Co. AG (RICHCO) secured contracts to supply 350,000 tons per year of alumina to Egyptalum, the state-owned Egyptian aluminum smelter at Nag Hammadi. The supply agreements were reportedly such that Billiton would deliver 200,000 tons per year for the next 5 years, and RICHCO 150,000 tons per year. The first shipments were expected to commence in 1991.

Ghana.—It was announced that the Ghana Bauxite Co. (55% Government and 45% British Alcan Aluminium Co. Ltd.) had commenced a 5-year mine rehabilitation program that was expected to cost \$7 million and return bauxite output to within the range of production levels experienced in the 1970's. This modernization program at the Ichiniso Mine in the Awaso area of western Ghana would

Computed from quantity and value data reported to U.S. Customs Service and compiled by the Bureau of the Census, U.S. Department of Commerce. Not adjusted for moisture content of bauxite or differences in methods used by importers to determine value of individual shipments.

³Data may not add to totals shown because of independent rounding.

include major improvements in the mining operation's infrastructure and processing facilities.

Greece.—It was reported, despite various accounts of problems in arranging project financing, that the Hellenic Alumina Industry S.A. (ELVA) alumina plant under construction at Thisvi, in Boeotia,

was expected to be completed in late 1993 and start continuous alumina production at the 600,000-ton-per-year level within the second quarter of 1994.

Aluminium de Grèce S.A. reportedly lost approximately 8,000 tons of scheduled alumina production because of labor strikes in 1990. Supervisory staff handled plant operations during five 24-hour gen-

eral strikes called by Greece's trade union federation.

Guinea.—It was announced that Halco (Mining), Inc., a consortium of western aluminum companies that are partners with the Government of Guinea in the joint venture Compagnie des Bauxites de Guinée (CBG), had agreed on a formula by which CBG would expand its mining operations to the Bidikoum bauxite deposit, adjacent to the current Sangaredi mine. The Bidikoum ore body has a lower alumina content than that of the Sangaredi deposit, but placing it into production before the Sangaredi ore reserves are depleted would allow blending of the two ore types and thereby provide an extension of the overall mine life for the CBG mining operation.

Guyana.—Bauxite shipments commenced in late 1990 from the new mining operations developed in the Berbice region of Guyana by the Aroaima Mining Co., a 50-50 joint venture of Reynolds Metals and the Government of Guyana. The consortium, which was working a deposit with known reserves of 25 million tons, reportedly expected to ship 1.5 million tons of bauxite in its first year of operation and to phase production up to 2 million tons per year by 1994.

India.—It was announced that India's State-owned National Aluminium Co. Ltd. (NALCO) planned to commence a 4-year program to increase alumina production to 1.35 million tons and bauxite

production to 3.6 million tons within the context of an overall aluminum industry expansion program.

It was reported that the Bharat Aluminium Co. (BALCO), also State-owned, had been granted a 30-year lease for bauxite mining within the Khurkhuridadar area in the Mandla District of Madhya Pradesh. In a related effort, to secure bauxite resources for its Korba refinery, BALCO had also reportedly sought the right to open an additional bauxite mine within the Hazaridadar area of the Mandla region. Because the company's bauxite mines at Phutkapahar and Amarkantak in Madhya Pradesh are approaching depletion and because the Government of India has shelved the Gandhamardhan bauxite mining project in western Orissa on environmental grounds, BALCO has been compelled to rely on outside sources for its bauxite requirements. In this regard, under agreements currently in effect, NALCO would provide 250,000 tons of bauxite from its 2.4-million-ton-per-year Panchapatmali Mine in Orissa as feedstock to BALCO through the period 1991-92, with the possibility of increasing the amount supplied to 450,000 tons after 1992.

It was announced that NALCO had passed a major commercial milestone

during 1990, as its total cumulative alumina exports passed the 1-million-ton level. In August 1990, with shipments to Egypt and Indonesia, the company's aggregate export total reached 1.03 million tons.

Ireland.—The 3-year and \$50 million expansion plan that began in 1989 at the Aughinish Alumina Ltd. refinery, near Limerick, was expected to increase alumina production at the plant from its previously rated 800,000-ton-per-year capacity to 1 million tons per year by 1991.

With respect to setting records, a significant milestone was attained by the Aughinish refinery in August when it produced the five millionth ton of alumina generated since the plant startup in September 1983.

Italy.—It was reported that the Eurallumina SpA refinery at Portoscuso, Sardinia, achieved a record alumina production with an output of more than 750,000 tons. This increased level of alumina output was accomplished through a capacity expansion and upgrading program that was scheduled for final completion in 1992.

Jamaica.—According to provisional statistics released by the Jamaica Bauxite

Institute, Jamaica recorded its highest alumina shipments on record in 1990. Jamaican exports reached a total of 2.9 million tons of alumina during 1990, surpassing the previous high of 2.8 million tons set in 1974. The 1990 alumina shipments amounted to a 34.6% increase over the 2.1 million tons shipped from Jamaica in 1989 and were valued at approximately \$611.2 million. A major portion of this improvement in alumina export levels may be attributed to the 1989 reopening of the Alumina Partners of Jamaica (Alpart) alumina plant, which had been closed since the mid-1980's.

A Memorandum of Understanding, embodying the commercial relationships on bauxite and alumina, was developed between Jamaica and the U.S.S.R. during contract discussions held in October 1990. The accord covered the requirements for settlement of outstanding payments on bauxite shipments to the U.S.S.R. and arrangements to deal with shortfalls in bauxite shipments under the existing contract, through which Jamaica had supplied the Soviets with 1 million tons of bauxite per year, or about 250,000 tons per quarter, for the past 7 years. During these contract negotiations, Jamaican officials explored the feasibility of possible Soviet involvement in rehabilitating and

²Value at foreign port of shipment as reported to U.S. Customs Service.

⁴Data may not add to totals shown because of independent rounding.

reopening the bauxite mine at Lydford, St. Ann Parish, on the northern coast of Jamaica, that had been operated by Reynolds Metals and closed in 1984.

In 1990, Alpart, owned by Kaiser Aluminum (65%) and Hydro Aluminium (35%), indicated that it had a program underway to expand the annual rated capacity of its alumina plant at Nain, St. Elizabeth Parish, from 1.00 to 1.45 million tons per year. For 1990, it was reported that the refinery operated above its nominal capacity and produced approximately 1.2 million tons of alumina.

In late 1990, Alcan Aluminium provided the Jamaican Government with the results of a prefeasibility study for a 1-million-ton-per-year greenfield alumina plant. It was reported that a full feasibility study was contingent upon participation by other industrial investors and clarification of the Government's environmental policy.

Suriname.—Suriname Aluminium Co. (Suralco) announced that it intended to import 200,000 tons of bauxite from the Dominican Republic in mid-1990 to rebuild stocks at its Paranam refinery. The ore would replace bauxite stocks used during a 2-month mine shutdown caused by clashes between rebel insurgents and Government forces at Suralco's Moengo operations, in eastern Suriname.

In 1990, Billiton Maatschappij Suriname (BMS) announced that it had invested \$30 million in new mining equipment for its Suriname mining operations. This investment included a new bucket wheel excavator and auxiliary equipment that reportedly would be used to remove overburden at the new Accaribo bauxite mine near Paranam, a joint-venture operation between BMS (76%) and Suralco (24%). It was estimated that this new mine would come on-stream in early 1992 and would produce 1 million tons of bauxite per year when fully operational.

In further mining developments, Suralco reported that mine preparation was continuing at Coermotibo, a new site 10 to 15 kilometers east of Moengo. Suralco planned to commence bauxite production at the location in 1991, with this new mining area gradually taking over from its current Moengo operations, where ore reserves reportedly were nearing depletion.

Venezuela.—It was announced that Venezuela and Yugoslavia had signed a

letter of intent to construct and operate a 1-million-ton-per-year alumina plant in conjunction with an associated primary aluminum smelter within Bolívar State.

C.V.G.-Interamericana de Alúmina, C.A. (INTERALUMINA) was reportedly in the process of expanding the capacity of its alumina plant at Puerto Ordaz, Bolívar State. Present plans were to increase production capacity at the facility from the current 1.3 million tons per year to 2.0 million tons per year by the end of 1991.

Current Research

In 1990, the U.S. Bureau of Mines reported on research designed to remove or lower the organic matter levels in bauxite, plus the associated leach liquor of the Bayer process, without impairing the leachability of these aluminum-bearing materials. During Bayer processing, humates and lignins within bauxite undergo degradation to oxalate that builds up to equilibrium concentrations and remains in the recycled Bayer liquor of an alumina plant, causing undesired alumina precipitation as fine particles, reduced mud settling rate, foaming, loss of caustic, and a discolored alumina trihydrate product. To help overcome these problems, the Bureau investigated a method of reducing the amount of organic matter in these feedstock and processing materials by pretreatment of bauxite with oxygen or air at temperatures up to 440° C.7 The results of this work indicated that processing at temperatures above 160° C progressively diminished the bauxite's content of organic carbon. It was further determined that the bauxite's leachability was not impaired by high-temperature treatments, except at temperatures higher than 300° C.

In related research, involved with seeking improvements to the Bayer process, the Bureau demonstrated that treatment of bauxite with hydrogen under pressure at temperatures from 250° to 450° C partially reduced the ferric iron in Jamaican bauxite to magnetite, Fe₃O₄, as well as partially volatilized the contained organic carbon. This largely fulfilled the investigation's twin objectives of eliminating the organic carbon contaminants from the bauxite and making the leached residue, known as red or brown mud, susceptible to liquid-solid separation by magnetic fil-

tration methods. It was established, however, that tradeoffs were required in choosing the ultimate operating conditions because optimum carbon destruction and development of magnetic properties occurred at pretreatment temperatures of more than 340° C, while optimum aluminum extraction required leaching bauxite that had been pretreated at temperatures below 300° C.

Research conducted jointly by Alcan Aluminium, Carleton University, and Energy, Mines and Resources Canada successfully developed a laboratory procedure for the decomposition of sodium oxalate by microbial metabolism.9 Sodium oxalate, a byproduct of the Bayer process, is a hazardous toxic substance that, when removed from a Bayer circuit, must be disposed of in an environmentally safe manner. This experimental work determined that the disposal of Bayer sodium oxalate by a microbial method was a feasible economic option that resulted in complete degradation of oxalate into environmentally acceptable CO₂ gas and an innocuous biomass.

Alcoa of Australia Ltd. announced that it had developed a family of tracer substances that may be used to assist in detailed efficiency studies of Bayer-process operations.¹⁰ The flow behavior of solutions within continuous processes, such as the Bayer process, exert an enormous impact upon the efficiency of alumina plant operations. In the Bayer process, the use of tracers to study liquor flow patterns and residence-time distributions has been severely constrained due to the inherently aggressive chemical environment and the very high concentration of interfering substances. The Alcoa of Australia research work established that a number of halogenated organic acids could be successfully utilized as liquor tracers within alumina plant environments. These halogenated carboxylic acids are very similar to some naturally occurring Bayer-liquor organics and, therefore, they were found to be very stable within the harsh Bayer-process regime.

During 1990, the U.S. Geological Survey (USGS) published a compilation of reference information on the geology and worldwide distribution of nonbauxite aluminum resources (excluding alunite), plus the associated methods of extracting alumina from these alternative resources. ¹¹ This was the third, and last, of a series of recent research reports prepared by the USGS on the resources of aluminum.

In addition to the bauxite reported in the body of the table, the U.S.S.R. produces nepheline syenite concentrates and alunite ore as sources of aluminum. Nepheline syenite concentrate production was as follows, in thousand metric tons: 1986—1,638; 1987—1,660; 1988—1,639 (revised); 1989—1,697; and 1990—1,650 (estimated). Estimated alunite ore production was as as follows, in thousand metric tons: 1986—620; 1987—625; 1988—625; 1989—600; and 1990—550. Nepheline syenite concentrate grades 25% to 30% alumina, and alunite ore grades 16% to 18% alumina; these commodities may be converted to their bauxite equivalent by using factors of 1 ton of nepheline syenite concentrate equals 0.55 ton of bauxite and 1 ton of alunite equals 0.34 ton of bauxite.

OUTLOOK—BAUXITE AND ALUMINA

Known world bauxite reserves are sufficient to meet cumulative world demand well into the 21st century. Considering the high probability of discovering additional bauxite deposits and assuming reasonable energy costs, plus the added possibility of employing lower grade bauxite deposits and other alternative sources of alumina, world resources of aluminum remain adequate to satisfy demand for the foreseeable future.

The shift of alumina production facilities from the aluminum-producing industrial countries with high energy costs in North America and Europe to the bauxite-producing countries of the world

is expected to continue. If the costs of imported bauxite and alumina increase for U.S. companies, alternate domestic sources of alumina may appear to become economically more attractive. Alternatively, high fuel prices tend to make nonbauxitic materials less competitive because the processes for treating substitute materials require considerably more energy than Bayer-processed bauxite.

It, therefore, seems evident that nonbauxitic sources of aluminum would become viable only within the context of a prolonged national emergency or international embargo extending over a period of several years. Imports of primary alu-minum metal from countries with low electrical energy costs and secondary production from recycled aluminum appear likely to be used in ever-increasing proportions to meet the domestic demand for aluminum.

In addition, the political revolution that swept Eastern Europe in the last months of 1989 was followed by the current economic revolution that has changed, for the coming years, the style and structure of the aluminum industry within that part of Europe. The basic industries of these countries had been established primarily on the principle of national selfsufficiency and not on the basis of return on capital. The emphasis had been on production, rather than on costs or profit. Within the framework of a global economy, the Eastern European bauxite mines appear to be marginal operations. with the only economically sound mines in Yugoslavia. In the future, this economic restructuring would seem to provide substantially increased market opportunities for the firmly established

bauxite-producing countries of the world.

ANTIMONY

By Thomas O. Llewellyn

Mr. Llewellyn, a physical scientist with the Branch of Industrial Minerals, has been the commodity specialist for antimony since 1987. Domestic survey data were prepared by Elsie Isaac, mineral data assistant, Section of Nonferrous Metals Data; and international data were prepared by Virginia Woodson, international data coordinator, Section of International Data.

eported consumption of primary antimony declined about 5% in 1990 from that of 1989. Production of primary antimony, however, increased slightly compared with that of the previous year. Secondary smelter production totaled 20,380 tons. up from 19,501 tons produced in 1989. Total imports of antimony products increased considerably. The principal supplying country continued to be China, which accounted for about 61% of all antimony imported into the United States in 1990. Effective June 20, 1990, the National Defense Stockpile (NDS) goal for antimony was increased from 32,659 metric tons to 80,287 metric tons.

DOMESTIC DATA COVERAGE

Domestic production data for antimony are developed by the U.S. Bureau of Mines from two voluntary surveys of U.S. operations. Typical of these surveys is the "Primary Antimony" survey. Of the six operations to which a survey request was sent, all responded, representing 100% of the primary smelter production shown in table 1 and 100% of the total antimony content of primary antimony production by class shown in table 2.

BACKGROUND

Antimony, from the Greek anti plus monos, means "a metal seldom found alone." Although the name was intended to describe the metal's mineralogical association in ores, it also properly describes the use of antimony in modern industry because the metal is usually used as an alloy with other metals. The natural sulfide of antimony, stibnite, was known and

used in Biblical times as medicine and as a cosmetic for eyebrow painting. A vase found at Tello, Chaldea, reportedly cast in tallic antimony indicates that about 4000 B.C., the Chaldeans knew the art of reducing the sulfide to metal.

The known domestic deposits of antimony ore have generally been small and uneconomical when compared with foreign producers, resulting in a dependence on foreign sources of supply by the United States. Bolivia, China, Mexico, and the Republic of South Africa have historically been the principal sources of supply.

Definitions, Grades, and Specifications

Antimony is seldom found in nature as native metal because of its strong affinity for sulfur and the metallic elements such as copper, lead, and silver. Antimony in its elemental form is a silvery white,

brittle, crystalline solid that exhibits poor electrical and heat conductivity properties. The National Stockpile Purchase Specification P-2a-R4, June 10, 1980, covered two grades of refined antimony metal ingot form. Grade A has a minimum antimony content of 99.8% and the following impurity maximums: arsenic 0.05%, sulfur 0.10%, lead 0.15%, and other elements (copper, iron, nickel, silver, and tin), 0.05% each. Grade B material is composed of 99.5% antimony as a minimum with maximum impurity levels of 0.1% arsenic, 0.1% sulfur, 0.2% lead, and 0.1% each of other elements.

Chemical-grade ore is that which is sufficiently pure to be used directly in producing the trioxide, chloride, or other industrial chemical compound. For chemical-grade sulfide ore, total impurities, including arsenic and lead, must not exceed 0.25% and no single metallic impurity can exceed 0.1%.

Antimony trioxide, the most important of the antimony compounds, is used in flame-retarding formulations for many materials. Most commercial grades of antimony trioxide contain between 99.2% and 99.5% antimony trioxide, with varying amounts of impurities such as arsenic, iron, and lead. Commercial suppliers offer various grades of antimony trioxide based on the relative tinting strength of their product, which is related to average particle size. In general, the tinting strength increases as the particle size decreases.

Products for Trade and Industry

The commercial products are generally semicircular-shaped ingots, broken pieces, granules, and cast cake. Other forms are powder, ingot, shot, and single crystals.

Industry Structure

Antimony was produced from ores and as a byproduct of the smelting of base metals ores in about 23 countries. China, the world's leading producer, accounted for about 48% of the total world estimated mine production during 1990. China, together with the other four major producing countries, Bolivia, Mexico, the Republic of South Africa, and the U.S.S.R., accounted for about 89% of the total world antimony production. In 1990, antimony production from domestic source materials was largely derived from recycling of lead-antimony batteries. Recycling plus U.S. mine output supplied less than one-half of the estimated domestic demand. Primary antimony was recovered as a byproduct from the smelting of domestic lead and silver-copper ores.

Antimony metal and trioxide producers in the United States are essentially large, integrated companies with a variety of activities in marketing and manufacturing of base metals and chemical compounds. A few producers and processors of antimony have interests in foreign operations. Most of them purchase raw materials from mine and smelter operations either directly or through dealers.

Resources

Estimates of the abundance of antimony in the Earth's crust range from 0.2 to

0.5 parts per million. Antimony is chalcophile, occurring with sulfur and the heavy metals copper, lead, and silver. More than 100 minerals of antimony are found in nature. Stibnite (Sb₂S₃) is the predominant ore mineral of antimony.

Simple antimony deposits consist principally of stibnite, or rarely, native antimony in a siliceous gangue, commonly with some pyrite, and in places a little gold and small amounts of other metal sulfides, principally silver and mercury. Antimony ores commonly are associated with igneous activity and have common genetic association with such intrusives as granite, diorites, and monzonites. The mineralogy of the veins and their almost invariably shallow depth suggest a low temperature of formation at near-surface positions, possibly related to the configuration of the water table at the time of deposition. Most of these geologically simple stibnite deposits do not individually contain more than several thousand tons of ore. Deposits of this type are found in the world's most productive antimony districts, including those of Bolivia, China, Mexico, and the Republic of South Africa.

Complex antimony deposits consist of stibnite associated with pyrite, arsenopyrite, cinnabar, or scheelite, or of antimony sulfosalts with varying amounts of copper, lead, and silver, as well as common sulfides of these metals and zinc. Ores of the complex deposits generally are mined primarily for gold, lead, silver, tungsten, or zinc.

Most of the antimony produced in the United States is from complex deposits. The tetrahedrite ores found in the Coeur d'Alene district of Idaho are outstanding examples of complex deposits.¹

Principal identified world antimony resources, at about 5 million tons, are in Bolivia, China, Mexico, the Republic of South Africa, and the U.S.S.R. U.S. resources are mainly in Alaska, Idaho, Montana, and Nevada.

Technology

Antimony deposits are seldom explored in advance of actual mining because the deposits are generally small, irregular, and difficult to appraise.

Many of the typically small mines contain irregular and scattered ore bodies that cannot be readily exploited by large-scale mining methods. Mining methods used in mines that recover metalliferous ores, of which antimony is a minor

constituent, are designed for producing the principal metals such as lead, silver, or gold.

The antimony content of ores determines the method of recovery. In general, the lowest grades of sulfide ores, 5% to 25% antimony, are roasted; 25% to 40% antimony ores are smelted in a blast furnace; and 45% to 60% antimony ores are liquated. At some mines in Bolivia and the Republic of South Africa, the high-grade sulfide ore is concentrated by hand-cobbing and sold as lump sulfide ore, 60% antimony content. As higher grade deposits have become depleted, increasing emphasis has been placed on upgrading low-grade ores by flotation.

Roasting of the ore to yield a volatile trioxide or the stable nonvolatile tetroxide is the only pyrometallurgical procedure suitable for low-grade ores (5% to 25% antimony content). The sulfur is oxidized and removed from waste gases, and the volatilized antimony oxide is recovered in flues, condensing pipes, a baghouse, precipitators, or a combination of the above. The temperature and quantity of available oxygen determine the kind and quantity of the oxide produced. The oxide produced by this method is generally impure and can be reduced to metal. Careful control of volatilization conditions, however, produces a high-grade oxide that can be sold directly to consumers.

Water-jacketed blast furnaces are used in several plants to reduce ores containing 25% to 40% antimony. Oxides, sulfides, or mixed ores, residues, mattes, slags, and briquet fines or flue dusts can be used as blast furnace charges. A high smelting column and comparatively low air pressure are used, and the slag and metal are separated in the hearth.

Antimony sulfide can be separated from the gangue of sulfide ores by melting in a reverberatory furnace. A reducing atmosphere is kept to prevent oxidation. The solidified product is called liquated or needle antimony and may be used as sulfide or converted to antimony metal by iron precipitation.

Some complex ores can be treated by leaching and electrowinning to recover the antimony. A typical process uses an alkali hydroxide or sulfide as the solvent. The filtered leach solution containing sodium thioantimonate, Na₃SbS₄, is electrolyzed in a diaphragm cell using an iron or lead anode and an iron or mild-steel cathode. The cathode metal obtained is 93% to 99% pure antimony.²

Antimony metal is also produced as antimonial lead, which is an important product of the secondary lead smelter. A blast furnace charge containing used or discarded battery plates, type metal, and bearing metal is reduced to a lead bullion. The bullion is refined in reverberatory furnaces and melting pots to meet specifications.

Byproducts and Coproducts

Most of the domestic primary antimony production is a byproduct or coproduct of mining, smelting, and refining other metals and ores that contain relatively small quantities of antimony. In 1990, domestic production of antimony was mainly a byproduct of treatment of tetrahedrite, a complex silver-copperantimony sulfide ore. An undisclosed amount of antimony was also recovered as a byproduct of the processing of lead ores.

The antimony deposits of the Republic of South Africa contain gold. High-grade Bolivian antimony ores contain variable and minor values of gold and tungsten and objectionable amounts of arsenic, copper, and lead in some deposits. Chinese ores contain some tungsten.

Substitutes

Compounds of chromium, tin, titanium, zinc, and zirconium substitute for antimony chemicals in paint, pigments, frits, and enamels. A combination of cadmium, calcium, copper, selenium, strontium, sulfur, and tin can be used as substitutes for hardening lead. Selected organic compounds and hydrated aluminum oxide are widely accepted alternative materials in flame-retardant systems.

Economic Factors

Antimony and antimony trioxide are taxed under the new Superfund Amendments and Reauthorization Act of 1986, Public Law 99-499. The taxes, to be collected from producers and importers, were \$4.90 per ton of antimony metal and \$4.13 per ton of antimony trioxide. The taxes end on December 31, 1991.

Antimony producers are granted a depletion allowance of 22% on domestic production and 14% on foreign production.

Under the new Harmonized Tariff Schedule of the United States, which took

effect January 1, 1989, antimony ore and concentrates imports from both most favored nations (MFN) and non-MFN were duty free. Antimony and articles thereof, including waste and scrap and antimony oxide, were duty free for MFN. However, for non-MFN, a statutory duty of 4.4 cents per kilogram was imposed.

Operating Factors

Environmental and ecological problems associated with the treatment of antimony metal and ores are minimal because emissions and affluents are controlled at the processing plant.

The major conservation practice of the antimony industry is the recycling of the metal in used storage batteries, type metal, and babbitt. Antimony metal and antimonial lead from intermediate smelter products such as slags, drosses, flue dusts, and residues generated at copper and lead smelters are recovered at lead smelters.

Energy requirements for the production of antimony metal and antimony trioxide from stibnite ores are 163 million British thermal units (Btu's) per net ton of antimony metal and 186 million Btu's per net ton of antimony trioxide.³

An estimated 200 persons are employed in the domestic production of antimony ores and in conversion of antimony ores and raw materials to antimony metal and compounds.

ANNUAL REVIEW

Legislation and Government Programs

The Environmental Protection Agency (EPA) denied a petition submitted by Synthetics Products Co. (SPC) requesting removal of antimony tris (iso-octyl mercaptoacetate), ATOM, from the list of toxic chemicals under section 313 of the Emergency Planning and Community Right-to-Know Act of 1986. The petition was based on SPC's contention that ATOM does not meet the criteria for human health effects under the section 313 listing. EPA's decision to deny the petition was based on human health concerns for antimony and antimony compounds. ATOM degrades in the environment yielding antimony and antimony oxide.4

According to section 3301 of the

National Defense Authorization Act for Fiscal Years 1990 and 1991 (Public Law 101-189, November 29, 1989), the Assistant Secretary of Defense determined that, effective June 20, 1990, the NDS goal for antimony was increased from 32,659 metric tons to 80,287 metric tons, where it remained at yearend.⁵

Strategic Considerations

Antimony was included in the NDS because of its strategic uses in flame-retardant compounds, friction bearings, and batteries. No inventory acquisitions or sales were made during the year. As of December 31, 1990, the stockpile inventory was 32,658 metric tons of antimony metal.

Production

Mine Production.—Sunshine Mining Co. produced antimony as a byproduct of the treatment of tetrahedrite, a complex silver-copper-antimony sulfide ore, from the Coeur d'Alene district of Idaho.

Smelter Production.—Primary.—In March 1990, Laurel Industries and Empresa Metalurgica de Vinto (ENAF), the state-owned smelting and refining company of Bolivia, entered into an agreement to produce crude antimony oxide at the Vinto smelter. Under the terms of the agreement, Laurel will provide technical assistance to the antimony smelter to produce sulfur-free crude antimony trioxide. In return, the entire ENAF crude antimony trioxide production will be shipped to Laurel's refining plant in La Porte, TX. The first shipment of sulfur-free crude antimony trioxide from Bolivia was received at Laurel's refining plant in December.

The producers of primary antimony metal and oxide products were ASARCO Incorporated, Omaha, NE; Amspec Chemical Corp., Gloucester City, NJ; Anzon America, Laredo, TX; Laurel Industries Inc., La Porte, TX; Sunshine Mining Co., Kellogg, ID; and U.S. Antimony Corp., Thompson Falls, MT.

Secondary.—Old scrap, predominantly lead battery plates, was the source of most of the secondary antimony output. New scrap, mostly in the form of drosses and residues from various sources, supplied the remainder. The antimony content of scrap was usually recovered and consumed as antimonial lead.

Revised.

Consumption and Uses

Decreased reported domestic consumption of primary antimony, compared with that of 1989, reflected the continued national economic slowdown. Leadantimony alloys were used in startinglighting-ignition (SLI) batteries, ammunition, corrosion resistant pumps and pipes, tank linings, roofing sheets, solder, cable sheaths, and antifriction bearings. In 1990, the Battery Council International reported a 1.2% increase in the total shipments of replacement automotive SLI batteries in the United States compared with those of 1989. Antimony compounds were used in plastics, both as stabilizers and as flame retardant. Antimony trioxide in an organic solvent was used to make textiles, plastics, and other combustibles flame retardant. Antimony was used as a decolorizing and refining agent in some forms of glass, such as special optical glass. The estimated distribution of antimony uses were flame retardants, 70%; transportation, including batteries, 10%; chemicals, 10%; ceramics and glass, 4%; and other, 6%.

Markets and Prices

The New York dealer price range for antimony metal, published by Metals Week, started 1990 at \$0.81 to \$0.84 per pound. The price range showed minor fluctuations throughout the first 10 months, decreased to a range of \$0.78 to \$0.80 per pound by November 29, where it held steady until the end of December.

The price range for high-tint antimony trioxide was \$1.45 per pound at the beginning of the year, decreased to a range of \$1.10 to \$1.20 per pound by March 1, and remained constant for the rest of 1990.

The European price range quotation for clean antimony sulfide concentrate (60% antimony content), published by Metal Bulletin (London), which was \$15.50 to \$18.00 per metric ton unit at the beginning of 1990, decreased to a range of \$15.00 to \$17.00 per metric ton unit at the end of the first quarter and remained constant for the rest of the year. The European price range quotation for lump antimony sulfide ore (60% antimony content), which was listed at \$16.50 to \$18.00 per metric ton unit at the beginning of 1990, also decreased during the first quarter and closed the year at a range of \$15.50 to \$17.50 per metric ton unit.

Туре	Price per pound
Domestic metal ¹	\$1.25-\$1.40
Foreign metal ²	.7888
Antimony trioxide ³	1.10- 1.20

¹Based on antimony in alloy.

Foreign Trade

Exports of antimony oxide increased dramatically in 1990 and reached their highest level in 23 years.

Total imports of antimony products increased significantly compared with those of 1989. China, Mexico, and the Republic of South Africa, in descending order of shipments, accounted for approximately 82% of the total U.S. antimony imports in 1990.

World Review

Capacity.—The data in table 12 represent rated annual production capacity for mines and refineries on December 31, 1990. Rated capacity was defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable, long-term operating rate, based on the physical equipment of the plant and routine operating procedures for labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Mines and refineries rated capacity of antimony was estimated based on discussions with some officials from private industry, past and present production rate, and published capacity data.

Bolivia.—In May 1990, Bolivian officials withdrew their participation in the joint Bolivian-Chinese quarterly producer price for antimony concentrates, published by Metal Bulletin of London. Reportedly, the published producer price failed to achieve its objective of coordinating the policies on antimony production and trade between the two countries.

Duty-paid delivery, New York.

Includes antimony oxide plants.

³Includes estimates for China.

Japan.—Antimony trioxide production, mainly from imported materials, was 10,994 tons, an increase of about 6% compared with 1989 production. Antimony metal production also increased from 173 tons in 1989 to 216 tons in 1990.6

Current Research

The Roskill organization issued its 1990 antimony report. This comprehensive report discusses and analyzes world production of antimony by country and individual company. It also contains information on end-use markets, international trade patterns, and trends in prices.⁷

OUTLOOK

Mining, beneficiation, and metallurgical procedures for antimony have changed little in the past 30 years. No new technological developments that would affect productivity are foreseen for the near future.

The oversupply of antimony products from China that have saturated the market in the past 2 years will continue during 1991. Unless China's policy of offering discounts from the world market price for antimony products shows signs of changing, the prospects for Western antimony trioxide producers are not good.

²Data may not add to totals shown because of independent rounding.

ARSENIC

By J. Roger Loebenstein

Mr. Loebenstein, a physical scientist with 16 years industry and U.S. Bureau of Mines experience, has been the commodity specialist for arsenic since 1987. Domestic survey data were prepared by Evangeline Hemphill, mineral data assistant; and international data tables were prepared by Harold Willis, international data coordinator.

mall amounts of arsenic trioxide were shipped in 1990 from remaining stocks at ASARCO Incorporated's closed plant at Tacoma, WA.

The price of metallurgical-grade arsenic metal shot up from \$0.60 per pound in December 1989 to \$5.30 to \$6.00 per pound by February 1990 because of a disruption in the supply from China that began at yearend 1989 and did not completely end until October 1990. By October, the price had declined to about \$1.00 per pound.

ANNUAL REVIEW

Legislation and Government Programs

The Environmental Protection Agency (EPA) proposed to revoke tolerances for calcium arsenate and lead arsenate, which were used as insecticides on various agricultural commodities. EPA had canceled the registrations for the food uses of these arsenicals several years ago. EPA proposed to revoke the tolerances because no companies were manufacturing calcium and lead arsenate and because most of the stocks of these chemicals had been depleted. ¹

Issues

The problem of arsenic contamination of the environment is an unfortunate recurring theme near some nonferrous smelters. In the 1970's, Asarco sold slag from its copper smelter (now closed) in Tacoma, WA, to log yards and others. The log yards mixed the smelter slag with wood waste and used the material as pavement. Over time, rainwater weathered the pavement and leached arsenic, lead, zinc, and other toxins into Commencement Bay. The EPA is involved in the massive cleanup effort, but it appears

that it will be many years before the litigation between Asarco and the log yards will be settled.²

Consumption

All arsenic consumed in the United States was derived from imported sources. Apparent demand declined in 1990, as shown in table 1. The industrial chemical sector, specifically the wood preservative industry, accounted for about 70% of domestic demand. The wood preservative industry converted imported arsenic trioxide to arsenic acid, an intermediate used in the production of the wood preservative chromated copper arsenate (CCA).

In the wood industry, Hickson Corp. operated wood preservative plants in Conley, GA, Hickory Grove, SC, Valparaiso, IN, and Kalama, WA. LaPorte PLC, United Kingdom, produced arsenical wood preservatives through its U.S. subsidiary, CSI. CSI operated wood preservative plants at Valdosta, GA, Harrisburg, NC, Gilmer, TX, and Laramie, WY. Another company, Osmose Corp., produced wood preservatives at plants in Memphis, TN, Tangent, OR, and Rock Hill, SC. Hickson, CSI, and Osmose accounted for most of the arsenical wood preserving industry.

The major agricultural chemical use for arsenic was as the herbicides monosodium methanearsonate (MSMA) and disodium methanearsonate (DSMA). Arsenic acid was used as a cotton leaf desiccant. The major producer of DSMA and MSMA was Fermenta ASC Corp., Mentor, OH. Atochem Corp., Bryan, TX, was a major producer of arsenic acid for use by cotton growers and wood preservative companies.

The glass industry used arsenic acid as a fining agent. The wood preservative industry supplied some of the arsenic acid used by the glass industry.

A zinc producer in Illinois used arsenic

trioxide as a flotation reagent to separate zinc from cobalt, copper, and nickel. This was the only zinc producer known to use arsenic in its process.

Commercial-grade arsenic metal, 99% pure, was used in lead- and copper-base alloys as a minor additive (about 0.01% to 0.5%) to increase strength in the posts and grids of lead-acid storage batteries and to improve the corrosion resistance and tensile strength in copper alloys. China is the only country in the world that produces arsenic metal for use in nonferrous alloys.

Relatively small quantities of high-purity arsenic metal, 99.99% pure or greater, were used in electronics. Arsenic metal was used in gallium arsenide for a variety of electronic devices and in selenium-base xerography. Gallium arsenide crystals are grown in a highly controlled process that eventually results in gallium arsenide cylinders, generally from 2 inches to 4 inches in diameter. The cylinders are doped, sawed into wafers, and polished to create semiconductor devices used in optoelectronic devices.

Prices

Prices for arsenic trioxide and arsenic metal are shown in table 2. The average price for Mexican arsenic trioxide declined again in 1990. At \$0.23 per pound, arsenic trioxide was only worth about one-half of what it was in 1987.

Prices for arsenic trioxide are not readily available from published sources, although historical prices from 1955 to 1990 are published in the Chemical Economics Handbook published by SRI International, Menlo Park, CA. Normally, producers quote two prices, one for highgrade (minimum 99%) arsenic trioxide and one for low-grade (minimum 95%) arsenic trioxide. There is a spread of \$0.08 to \$0.12 per pound between the prices of the two grades.

Revised.

The price of Chinese arsenic metal rebounded from an extremely low level in 1989. In December 1989, Chinese producers stopped delivering arsenic metal to lead alloyers, causing the intermerchant price of arsenic (as quoted by Metal Bulletin) to rise from \$0.60 per pound to \$1.50 per pound in 1 week. By early February, the price had risen to \$5.30 to \$6.00 per pound, and several companies were involved in a legal battle over canceled contracts. However, by October, supply of metal from China had been replenished, and the intermerchant price had decreased to \$0.95 to \$1.10 per pound. The average price for the year was \$1.80 per pound.

World Review

Arsenic was recovered as arsenic trioxide from the smelting or roasting of nonferrous metal ores or concentrates in about 20 countries. Annual arsenic trioxide refinery production capacities for the three leading countries were as follows: Sweden, 11,000 metric tons; France, 10,000 metric tons; and the U.S.S.R., 10,000 metric tons. Arsenic metal, which accounts for only 3% of world demand for arsenic, was produced by the reduction

of arsenic trioxide. Commercial-grade arsenic metal, 99% pure, which accounted for the majority of arsenic metal production, was produced only in China. Highpurity arsenic, 99.99% pure or greater, for use in the semiconductor industry was produced by about 10 companies. Furukawa Electric Co. Ltd. in Japan and Preussag AG in the Federal Republic of Germany were believed to be the world's largest producers, with reported capacities of 30 and 15 metric tons per year, respectively. Other high-purity arsenic producers included Johnson Matthey Electronics in Canada, Mitsubishi Metal Corp. and Rasa Industries Ltd. in Japan, and Johnson Matthey Ltd. and MCP

Electronic Materials Ltd. in the United Kingdom.

Johnson Matthey Ltd. announced the relocation of its research and development facility for gallium arsenide from Trail, British Columbia, to Victoria, British Columbia. Johnson Matthey's subsidiary, Crystar Research, produced gallium arsenide. The closing of the Trail facility was part of a move to restructure Johnson Matthey's electronics business, which it had purchased from Cominco Ltd. in 1988. The decision to close the Trail facility was due in part to stiff price competition in the gallium arsenide industry from Japanese producers.

Current Research

The U.S. Bureau of Mines developed porous beads containing immobilized biological materials for removing metal contaminants from wastewaters. The beads, designated as BIO-FIX beads, are prepared by blending biomass, such as sphagnum peat moss or algae, into a polymer solution. Porous polysulfone beads containing nonliving biomass were successfully used to remove metal contaminants, such as arsenic, cadmium, copper, and lead, from acidic mine wastewaters. After treatment with BIO-FIX beads, effluents met the federally mandated National Drinking Water Standards.3

OUTLOOK

World production of arsenic trioxide is expected to decline by about 20% in 1991 because the Swedish producer, Boliden, decided to stop production in early 1991 (see table 4). Historically, Boliden has been a major producer of arsenic trioxide, as a byproduct of lead and copper. The absence of Boliden from the market could create some shortages for arsenic trioxide in 1991 and 1992, although supply was plentiful in 1990.

The major market for arsenic is its use in wood preservatives. The future for arsenic consumption is therefore tied to new housing starts, where wood decks containing arsenical preservatives have become almost standard items in recent years. People adding decks to existing houses also use treated wood. During the next 5 years, the growth of wood preservatives is expected to average 1% to 2%

per year because of the recession in the housing industry. No major environmental problems associated with the use of arsenicals in wood preservatives are anticipated because of the small amounts of

arsenic used and the fact that arsenic does not readily leach from treated wood.

The use of arsenic in agricultural chemicals has been under close scrutiny by EPA for many years. Many pesticide uses for arsenical chemicals have been banned by EPA. The use of the arsenicals DSMA, MSMA, arsenic acid, and cacodylic acid on cotton is not expected to grow and could even decline during the next 5 years.

Gallium arsenide components compete with silicon components in electronic applications. Gallium arsenide components are faster, but silicon components are cheaper. Advances in computer technology have led to the move from linear to parallel arrangement of processors, thus minimizing the relative slowness of silicon. For this reason, it is unlikely that gallium arsenide will replace silicon in most electronic applications, despite growth in gallium arsenide production capacity.

ASBESTOS

By Robert L. Virta

Mr. Virta, a physical scientist with 15 years of U.S. Bureau of Mines experience, has been the commodity specialist for asbestos since 1986. Domestic survey data were prepared by Joseph Daniels, mineral data assistant; and international data tables were prepared by Harold Willis, international data assistant.

he first stage of a regulation enacted by the Environmental Protection Agency (EPA) that phases out the use of asbestos went into effect on August 27, 1990. Health and liability issues continued to be a major factor in determining the economic stability of several former producers of asbestos products. The number of firms that produce asbestoscontaining products continued to decline in response to these issues. Domestic asbestos production increased slightly from that of 1989, but consumption decreased 25%, from 55,306 to 41,348 tons. Asbestos was consumed domestically for roofing products, 37%; friction products, 26%; asbestoscement pipe, 15%; packing and gaskets, 8%; and other, 14%.

DOMESTIC DATA COVERAGE

Domestic production data for asbestos are developed by the U.S. Bureau of Mines by means of a voluntary industry survey. Of the two canvassed operations to which a survey request was sent, both responded, representing 100% of the total production data shown in table 1.

ANNUAL REVIEW

Legislation and Government **Programs**

The first stage of the EPA rule banning the manufacture, importation, processing, and distribution of most

asbestos-containing products was implemented on August 27, 1990. The first stage banned the production of asbestos-containing flooring and roofing felt, pipeline wrap, asbestos-cement corrugated and flat sheet, vinyl asbestos floor tile, and asbestos clothing. Sales of these materials are banned after August 25, 1992.1 The validity of the regulation was contested in legal briefs filed on behalf of the Asbestos Information Association of North America, Asbestos-Cement Pipe Producers Association, the Asbestos Institute, and several other organizations and trade associations.²

The EPA issued revisions to the national emission standards for hazardous air pollutants under the Clean Air Act for asbestos. The revisions require daily monitoring of visible emissions

³ Does not include U.S. production.

for milling, manufacturing, and fabricating operations; weekly inspection of air cleaning devices; and recordkeeping. Notification requirements for demolitions and renovations are revised, and recordkeeping is required for asbestos waste disposal.³

The EPA published a summary of information submitted by manufacturers and processors of certain asbestos products in accordance with the Asbestos Information Act of 1988. The summary provided the names and addresses of the manufacturer, the type of materials produced, the years in which the materials were manufactured, and identifying characteristics of these materials.⁴

The Mine Safety and Health Administration (MSHA) issued a proposed rule to establish a hazard communication standard. The standard would require mine operators to assess the hazards of chemicals they produce or use and provide information to their employees concerning chemical hazards, including asbestos. Employers also would have to establish a hazard communication program, label containers, provide access to material safety data sheets, and provide employee training. Mixtures containing more than 0.1% of a carcinogen would be assumed to present a carcinogenic hazard.

The MSHA continued reviewing its proposed revisions to existing standards for air quality and chemical substances, including the lowering of permissible exposure levels to asbestos from 2.0 fibers per cubic centimeter to 0.2 fibers per cubic centimeters.⁶

The Occupational Safety and Health Administration (OSHA) conducted public hearings on the regulation governing exposure to the nonasbestiform varieties of actinolite, anthophyllite, and tremolite. An administrative stay was extended through August 31, 1991, on the regulation while it continued to review submissions to the docket. OSHA revised that section of the rule covering asbestos to reduce the short-term exposure limit to 1 fiber per cubic centimeter, to expand its ban on smoking in the workplace, and to increase worker risk awareness training. OSHA proposed to reduce the personal exposure limit from 0.2 fiber cubic centimeters to 0.1 fiber cubic centimeters, to require modified work practices to reduce exposures in certain occupations, to require additional warning of asbestos risks to owners and occupants of build-

ings prior to asbestos abatement operations, and to require oversight of all abatement work.

The National Institute for Occupational Safety and Health (NIOSH) issued a request for information on synthetic and natural mineral fibers, including asnonasbestiform amphiboles, glass fibers, mineral wool, and refractory and aluminosilicate ceramic fibers. The type of information that NIOSH requested covered the types of operations that mine, produce, or process these fibers; the number of workers in these occupations; and exposure data to these fibers. Other information requested included the results of medical and epidemiological studies of persons exposed to these fibers, the results of experimental animal studies in which these fibers were used, and criteria for defining fibers. 10

The EPA continued to review proposed changes in the national primary and secondary drinking water regulations. The proposal covers 30 organic chemicals and 8 inorganic chemicals, including asbestos. The proposed maximum contaminant level goal for asbestos is 7 million fibers (longer than 10 micrometers) per liter. 11

Strategic Considerations

A wide variety of asbestos-containing civilian products also have military applications. Examples include friction materials (brakes and clutches), electrical and thermal insulations, packings and gaskets, and asbestos-reinforced plastics for use on military vehicles, ships, rockets, missiles, and in military construction. During World War II and the Korean War, strict controls were placed on the export of asbestos because the United States was dependent on foreign sources for about 90% of its requirements of all grades of asbestos. The United States was totally dependent on foreign sources for low-iron, spinning-grade chrysotile. Since that time, equipment components have been redesigned, new products have been introduced, and substitutes for asbestos are being used more frequently. Many of the asbestos-containing civilian products that are used by the military will be eliminated because of the EPAmandated phaseout of asbestos. Because of the trend toward lower asbestos consumption, the Department of Defense has authorized the disposal of 6,155 tons of chrysotile, 33,844 tons of amosite,

and 33 tons of crocidolite from the National Defense Stockpile.

Issues

Environmental and liability issues continued to affect the asbestos industry. The first stage of the EPA regulation that phases out the use of asbestos went into effect in August 1990. The second and third phases become effective in 1993 and 1996, respectively. Most uses of asbestos will be banned after 1997. The EPA phaseout of asbestos is based on the assumption that there is no threshold level of exposure beyond which there is no reasonable risk. Industry representatives and many health scientists maintain that available data do not support this assumption and have challenged the legality of the regulation in court. A decision by the courts is expected in late 1991.

Production

Asbestos was produced in the United States by two companies, KCAC Inc., San Benito County, CA, and Vermont Asbestos Group Inc. (VAG), Orleans County, VT. Domestic production was limited to chrysotile, one of six commercial varieties of asbestos. KCAC operated a mine in a highly sheared serpentinite composed of matted short fiber chrysotile and unfractured serpentinite (also referred to as a mass fiber deposit). The ore was stripped, and wet processing was used to beneficiate the fiber. VAG operated an open pit mine in a serpentinite containing cross-fiber veins of chrysotile. Dry milling was used to process the fiber. While the California company produced only short fiber chrysotile, the Vermont company produced a wide range of chrysotile grades.

Domestic production increased slightly from that of 1989. While domestic markets for asbestos continued to weaken, foreign markets remained strong.

Consumption and Uses

Asbestos was used in a wide variety of products because of its high tensile strength, chemical and thermal stability, high flexibility, low electrical conductivity, and large surface area. Products made from asbestos were more heat resistant (and often incombustible), more resistant to chemical attack (particularly for alkalis), stronger (as-

bestos acted as a physical reinforcer), and less conductive (asbestos had a low dielectric constant). Products were also more viscose (asbestos stiffened compounds and coatings), faster setting (asbestos hastened water drainage in asbestos-cement pipe production), and more cost efficient than many nonasbestos products.

Asbestos cement is composed of 10% to 15% asbestos in a portland cement matrix. This mixture is widely used in the construction industry to produce corrugated and flat sheet. slates, and low- and high-pressure pipe. The main advantage of asbestoscement products is that they are inexpensive, incombustible, corrosion resistant, and can be produced locally. Markets in North America and Western Europe have declined owing to maturing markets and environmental concerns. However, markets grew in South America, Southeast Asia, the Middle East, and Eastern Europe because of the demands of infrastructure development.12

U.S. consumption of asbestos decreased 25% in 1990. Approximately 83% of the asbestos consumed domestically was chrysotile, 2% was crocidolite, and 15% was an unspecified fiber type, most likely chrysotile. Approximately 76% of the chrysotile consumed in the United States was grade 7, followed by grades 4, 6, 5, and 3.

The construction industry is the major consumer of asbestos fiber in the form of asbestos-cement pipe and asbestos-cement sheet, coatings, compounds, packings, and roofing products. These end uses accounted for 70% of the asbestos consumed in the United States.

Apparent consumption has declined dramatically from 800,962 tons in 1973 to 41,348 tons in 1990 in response to environmental and liability issues. There is a continuing interest among manufacturers of both organic and inorganic fibers in acquiring portions of the asbestos market. Product manufacturers gradually have been replacing asbestos with substitute materials, redesigning old products to eliminate the

need for asbestos, or designing new products that require neither asbestos nor asbestos substitutes. Economic, manufacturing, performance, and/or technical difficulties were considered before asbestos was replaced by a substitute material or product.

Examples of materials substituted for asbestos include aramid fiber, calcium silicate, carbon fiber, cellulose fiber, ceramic fiber, fibrous glass, graphite flake and fiber, several varieties of organic fiber, steel fibers, and wollastonite. Examples of alternative products include aluminum, vinyl, and wood siding; aluminum and fiberglass sheet; asphalt coatings; ductile iron pipe; polyvinyl-chloride pipe; prestressed and reinforced concrete pipe; and semimetallic brakes.

Markets and Prices

The average unit value of domestically produced asbestos increased slightly from that of 1989. Unit values for imported asbestos ranged from \$130 per ton to \$1,629 per ton and averaged \$261 per ton. Unit values for exported asbes-

⁵ Less than 1/10 unit.

tos ranged from \$128 per ton to \$2,158 per ton and averaged \$285 per ton. Customs unit values of imported crude chrysotile increased significantly because high-valued crude chrysotile from Canada and Zimbabwe was imported under this import category in 1990. The unit value of imported spinning chrysotile decreased 25% because lower valued chrysotile fiber was included under the "chrysotile, spinning" category. Approximate equivalents, in dollars per metric ton, of price ranges quoted in Industrial Minerals (London), December 31, 1990, for Canadian chrysotile, f.o.b. mine, were \$1,320 to \$2,125 for Group 3, \$918 to \$1,275 for Group 4, \$604 to \$714 for Group 5, \$442 for Group 6, and \$136 to \$264 for Group 7.

Foreign Trade

The total value of asbestos fibers and asbestos products exported and reexported from the United States was \$128,292,000. This is a 20% decrease from that of 1989. Exports and reexports of brake linings and disk pads accounted for 77% of the value of all manufactured asbestos products. Canada remained the largest importer of unmanufactured fibers and manufac-

tured products, followed by Japan, the United Kingdom, Mexico, and the Federal Republic of Germany.

Canada provided approximately 98% of the asbestos imported into the United States, and the Republic of South Africa provided 2%. Zimbabwe supplied the remaining amount. Approximately 98% of the asbestos fiber imports was chrysotile.

World Review

Canada continued to be the largest

market economy producer of asbestos, followed by Brazil, Zimbabwe, and the Republic of South Africa. The U.S.S.R. was the world's largest producer of asbestos. Canada and the U.S.S.R. accounted for 77% of the world production. Canada continued to be the largest exporter of asbestos.

Australia.—Woodsreef Mines continued to await governmental approval to rehabilitate its mine site. The site, consisting of an open pit mine and dry

processing facility, closed in 1983. Woodsreef Mine and ICI Australia constructed a prototype wet milling facility in 1982 to demonstrate its ability to improve fiber recovery. The prototype mill achieved a recovery of 90% compared to 67% recovery with dry processing. 13

Canada.—Baie Verte Mines completed construction and began operation of its wet-process plant in Newfoundland. The operation initially will process tailings from its dry mill plant. Later, it will be used to process stockpiled tailings. Fiber recovery is expected to approach 95%. The process permit-

ted the company to manufacture a pelletized open fiber product that was easier to handle, generated less dust during handling, and was of higher and more consistent quality.¹⁴

Italy.—Amiantifera di Balangero SpA closed its asbestos mine at San Vittore. The company produced asbestos for use in cement, gaskets, brakes, paint, and insulation products.¹⁵

Current Research

A new application under study is the use of preimpregnated asbestoscontaining products. An asbestos textile would be impregnated with a resin and heated sufficiently to partially polymerize the resin. At a later time, the impregnated fabric would be placed in a mold and heated to completely polymerize the resin and form the shaped part. Preimpregnation would reduce dust during handling by encapsulating the fiber. provide excellent resin-to-fiber bonding, provide a faster molding cycle, and permit a wide variation of performance characteristics by using different resins and resin-to-fiber ratios. Examples of potential applications include rocket blast pipe, electrical and thermal insulating panels, rocket fins, and clutch disks. 16

OUTLOOK

Domestic markets will decline as each stage of the EPA phaseout of asbestos becomes effective and consumer demand for asbestos substitutes continues. Foreign markets for asbestos fiber should remain strong for several years because of the high demand in developing countries for proven, low-cost construction materials. The prospects for the domestic asbestos manufacturing industry are poor because of the EPA-mandated phaseout of asbestos.

¹ Includes crudes, fibers, stucco, sand, refuse.

² Includes asbestos and cellulose fiber brakes and similar materials.

³Includes clutches and other friction materials, excluding brakes and brake pads.

⁴ Includes asbestos-cement and cellulose fiber cement products.

⁵Includes asbestos and cellulose fiber products.

¹ Marketable fiber production. Table includes data available through Apr. 15, 1991.

² In addition to the countries listed, Afghanistan, Czechoslovakia, North Korea, and Romania also produce asbestos, but output is not officially reported, and available general information is inadequate for the formulation of reliable estimates of output levels.

³ Excludes direct sales of run-of-mine material of 2,060 metric tons in 1986, zero in 1987-88, and estimated zero in 1989-90.

Estimated fiber production based on reported crude production, in metric tons, of: 1986—129,155; 1987—132,723; 1988—152,896; 1989—158,149; and 1990—160,000 (estimated).

⁵ Revised to zero.

⁶ Reported figure.

BARITE

By Joyce A. Ober

Mrs. Ober, a physical scientist with 13 years of industry and U.S. Bureau of Mines experience, is the acting commodity specialist for barite. Domestic survey data were prepared by Rosa L. McGee, supervisory mineral data assistant; and the international production table was prepared by Virginia A. Woodson, international data coordinator.

omestic production of barite increased more than 53% to 445,000 metric tons, while the value increased about 20% to \$15.9 million. Barite production has remained relatively stable for the past 4 years except for a marked decrease in production in 1989. Although imports remained greater than domestic production, domestic barite comprised a larger share of total U.S. consumption than had been the case for several years. Production from Nevada, the leading producing State, increased about 62%. Imports for consumption of crude barite remained about the same, and ground barite imports increased 22%. Imports of barite exceeded domestic production for the ninth consecutive year, but the import figure of 988,000 tons for 1990 was about 1.1 million tons below the record-high tonnage of 1982. Ground barite imports, except for the drilling boom years of the late 1970's and early 1980's, have been negligible. The principal use for barite, as a weighting agent in oil- and gas-welldrilling fluids (muds), accounted for more than 92% of U.S. consumption. Chemical, glass, and filler and/or extender uses accounted for the remainder.

The Iraqi invasion of Kuwait on August 2, 1990, caused oil prices to rise within days of the invasion. Concern over a stable oil supply prompted U.S. oil companies to increase drilling activity. Total world supplies were not significantly effected because of increased oil production in Saudi Arabia. Oil prices decreased after the initial spike with the stabilization of supply, but did not return to the lower preinvasion prices.

are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the 65 operations to which a survey request was sent, all responded, representing 100% of the total crushed and ground production sold or used shown in table 1.

BACKGROUND

Definitions and Specifications

The term "primary barite," as used in this report, refers to the first marketable product and includes crude barite, flotation concentrate, and other beneficiated material such as washer, jig, heavy media,

table, or magnetic separation concentrate. Most primary barite requires fine grinding before it is used for drilling muds. This grinding may or may not be done at the mine site.

Barite is the mineralogical name for barium sulfate and was derived from the Greek word "barus," meaning heavy. In commerce, the mineral is often referred to as "heavy spar" or "barytes."

Specifications for barite vary according to different uses. Material for weighting muds must be finely ground, dense, and chemically inert; consequently, barite for this purpose must have a specific gravity of 4.2 or higher, it must be free of soluble salts, and 90% to 95% of the material must pass through a 325-mesh screen.

Less than 1/2 unit.

²Sold or used plus imports minus exports.

³Includes imports.

Chemical Products Corp.	Cartersville, GA	ρυ.

A small percentage of iron oxide is not objectionable. In chemical manufacturing, purity is the principal concern, and a maximum of 1% each of ferric oxide (Fe₂O₃) and strontium sulfate (SrSO₄)

and a trace of fluorine usually are specified, with a minimum of 94% barium sulfate (BaSO₄). If the mineral is to be used in the production of lithopone, the SrSO₄ content may be somewhat higher. Mesh

size is important to chemical manufacturers; if the material is too fine, dust is lost, and if it is too coarse, mixing with carbonaceous material is poor. Most chemical manufacturers specify a size range of 4 to 20 mesh; some purchase lump barite and grind it to their own needs.

Glass manufacturers usually require a minimum of 95% BaSO₄ with a maximum of 2.5% silicon dioxide (SiO₂) and 0.15% Fe₂O₃. The particle size range generally preferred is minus 30 to plus 140 mesh. Fine-ground barite can be substituted when crushed material is not available.

Products for Trade and Industry

The principal use for barite, as a weighting material in well-drilling muds, accounted for more than 92% of total U.S. consumption in 1990. Drilling muds have five main functions: (1) to transport drill cuttings to the surface, (2) to control formation pressures, (3) to maintain borehole stability, (4) to protect producing zones, and (5) to cool and lubricate the bit and drill string. The principal function of the barite constituent is as a weighting agent to suppress high formation pressures and prevent blowouts. As the well is drilled, the bit passes through various formations, each with different characteristics. The deeper the hole, the more barite is needed as a percentage of the total mud mix.

The use of barite as a filler or extender and other uses accounted for about 7% of total U.S. consumption in 1990. Barite has a high specific gravity, low oil absorption, easy wettability by oils, and good sanding qualities. Unbleached barite may be substituted for bleached barite when brightness is not a factor. In painting automobiles, barite is used as a filler for the primer coats. The barite contributes to the gloss of the topcoat. When the primers are applied by the electrodeposition process, the body structure is dipped into a tank containing water and paint primer. The method eliminates one of the primary coats, thus reducing the quantity of barite used.

Barite is also used as a filler or extender in some plastic and rubber products. Processors of polyurethane foam use barite in manufacturing such products as floormats and carpet-backings to increase density and improve processing qualities. Barite is used in white sidewalls for tires; sidewalls consist mainly of rubber, zinc oxide, and a small quantity of barite.

Other industries use small quantities of barite fillers. In the paper industry, the white and dense barite coatings serve as a base for the sensitized layers in photographic prints. In the printing industry, barite is used in inks.

In glassmaking, barite is added to the glass melt to flux the heat-insulating froth that forms on the melt surface, thus saving fuel, and to act as an oxidizer and decolorizer, making the glass more workable and increasing its brilliance.

Minor uses include ballast for ships, heavy concrete aggregate for radiation shielding and pipe-weighting in low-lying areas, and applications in foundries.

Barite is also a raw material for barium chemical manufacturing. The major barium chemicals are the carbonate, chloride, oxide, hydroxide, nitrate, peroxide, and sulfate.

The most important barium chemical is precipitated barium carbonate, which is a raw material for production of many of the other compounds. It is also used in brick and tile manufacturing to control scum caused by gypsum or magnesium sulfate in the clay and to diminish porosity and prevent discoloration in brick. Other uses are in television picture tubes, optical glass, ceramic glazes, porcelain enamel, ferrites, and miscellaneous ceramic products.

Blanc fixe, chemically precipitated barium sulfate, is used as a white filler in paints, rubber, inks, and other materials where a degree of purity higher than natural barite is required. Lithopone (a white pigment composed of a mixture of barium sulfate, zinc sulfide, and zinc oxide), formerly manufactured in large tonnages for use as a white pigment in paints, has been largely replaced by titanium dioxide.

Barium chloride is used in casehardening and heat-treating baths, in leather and cloth, in making magnesium metal, in preventing scum on brick, in water treatment, and as a laboratory reagent. Fused barium chloride may be electrolyzed to produce barium metal.

Barium metal is also produced by reduction of barium oxide. The metal is used as a "getter" to remove traces of gas from vacuum tubes or in alloys for spark plugs and electronic emission elements in electronic tubes.

Barium nitrate is used in green signal flares, tracer bullets, primers and detonators, and enamels. Barium oxide is used in electric furnace ferrous metallurgy to increase the life of acid furnace linings, to give a quieter and steadier arc, to reduce the sulfur content of the iron, and to lower the slag viscosity.

Barium hydroxide prevents scumming in ceramics and is used in lubricating oils and to recover sugar from molasses by the barium saccharate process. Barium titanate finds use in miniature electronic and communication equipment.

Industry Structure

Domestic barite production began in 1845 in Fauquier County, VA. About 5 years later, production began in Missouri. In 1880, Tennessee became the third barite-producing State, and 1901 and 1903 saw Georgia and Kentucky, respectively, become producers. California began producing in 1914, Nevada in 1916, and Arkansas in 1941.

Barite was first used as a filler in white paints; however, in 1842, with the advent of the domestic lithopone industry, a second important market opened. In 1908, Chicago Copper Refining Co. (now Chicago Copper & Chemical Co.) began manufacturing barium chemicals at Blue Island, IL. The first washers and jigs used in the industry were installed in Georgia and Tennessee in 1914-16 and in Missouri in 1923-24. A fourth market for barite came into existence in 1916 when a patent was obtained on the use of barite as a weighting agent in rotary drilling muds; today this is the largest consumer of barite. In 1941, the deposit of barite at Malvern, AK, was opened when Magnet Cove Barium Corp. successfully separated barite from associated minerals by flotation. In 1977, IMCO Services Co. completed a multimillion dollar plant at Mountain Springs, NV, that produced barite concentrate using jigs, concentration tables, and flotation. This combination of beneficiating methods was unique in the barite industry.

Geology

Barite is the only commercial source of barium and barium compounds. Witherite (BaCO₃) has been produced from the Settlingstones Mine in England, and small quantities enter the United States every year.

Pure barite has a specific gravity of 4.5. Barite varies considerably in appearance depending on source and treatment. It is a moderately soft crystalline material with a Mohs' hardness between 3 and 3.5. In residual deposits, it ranges in size from

large boulders to fines. Shades of white to dark gray and black, depending on impurities and surficial coating, are common in commercial deposits.

Vein and cavity-filling deposits are those in which barite occurs along faults, joints, bedding planes, and other solution channels or sink structures. These deposits are found most often in limestone. Most of the vein deposits are believed to be of hydrothermal origin.

In central Missouri, barite occurs in circular deposits in karst or collapse and sink structures. These ores are rich, but the deposits are generally small in overall extent. These deposits are also important as the source of the residual ore upon weathering.

Residual barite deposits are formed by the weathering of preexisting deposits. The principal residual deposits are found in southeastern Missouri; the Appalachian region; Sweetwater, TN; Cartersville, GA; and in the Rio Grande area of Texas. A concentration of at least 100 to 300 pounds of barite per cubic yard is required in a commercial deposit. In Washington County, MO, the residuum is 10- to 15-feet thick, while in Cartersville, GA, the ore is 150-feet thick in some spots. This form of deposit has been of considerable economic significance.

The most important commercial deposits are of bedded barite. These are principally in Arkansas, California, and Nevada. The barite in these areas is generally dark gray to black and has a characteristic fetid odor when struck with a hammer. The beds, which vary in thickness from several inches to more than 50 feet, occur interbedded with dark chert and siliceous siltstone and shale. In most of the deposits, the barite is laminated. In some areas, barite nodules and rosettes make up a large part of the beds. Many of the beds contain 50% to 95% barite. Originally it was thought that these deposits were the result of the replacement of carbonate rocks; however, current thought is that the deposits are of sedimentary origin. The actual environment of deposition has not been established, but theories range from submarine volcanic emissions to hydrothermal solutions to recycling of barite from preexisting rocks.

Technology

Exploration.—In the past two decades, geological exploration has led to the discovery of bedded barite deposits in

Canada, India, Mexico, and the United States. Bedded deposits have not been sought in many parts of the world. As the search for barite expands in the coming years, it is likely that more bedded deposits will be discovered.

Mining.—Residual deposits of barite are generally mined by draglines in open pits after removal of overburden by conventional methods using elevating scrapers, trucks, dumpers, bulldozers, and front-end loaders. The ore is then beneficiated in washer plants equipped with rotary breakers, log washers, trommel screens, and jigs to separate barite from other material. Fine barite in the overflow from the log washers is recovered by tabling and flotation, while the jig concentrate is magnetically separated.

Bedded and vein deposits may be mined by open pit or underground methods depending on local conditions. The bedded deposits of Arkansas have been mined by both methods. The ore is crushed and ground for beneficiation by flotation. Bedded barite in Nevada is mined by open pit methods using a combination of bulldozers with ripping teeth and conventional blasting. The ore is picked up by front-end loaders and hauled in dump trucks to a processing plant. In some deposits, the ore is of sufficient grade to be either screened and direct shipped or washed, crushed, screened, and shipped to a grinding plant; however, much of the ore requires beneficiation by igging or flotation.

Quantities of barite have been recovered by underwater mining off Castle

Island near Petersburg in southeastern Alaska. The ore is blasted, recovered by a crane equipped with a special digging bucket, and loaded into barges.

Processing.—Barite grinding is usually accomplished by heated airswept Raymond mills, a type of roller mill; however, ball mills are used when iron contamination is not important, as in drilling muds. Barite is ground either wet or dry. For use in well drilling, barite is ground dry; if it requires upgrading by flotation, it is ground wet. Barite is ground wet when it is to be bleached for filler use; impurities are subsequently removed by treatment with sulfuric acid. The bleached barite pulp is then settled and separated, washed, dried, sized, and bagged.

Barite is converted into an intermediate soluble form before its use in the manufacture of lithopone. Crushed barite is roasted with coke in a kiln at about 1,200°C to reduce the barium sulfate to the more soluble compound, barium sulfide, commonly called black ash. The sulfide is leached from the clinker with hot water.² By adding zinc sulfate to the leach liquor, an intimate mixture of barium sulfate and zinc sulfide called lithopone is precipitated.

The leach liquor is also a precursor of a number of barium chemicals. Addition of sodium sulfate precipitates barium sulfate (called blanc fixe). Barium carbonate is precipitated by either carbonating or adding sodium carbonate to the leach liquor. Hydrochloric acid added to the leach liquor produces a solution of barium chloride. Barium carbonate and

barium chloride are the starting compounds for the manufacture of many other barium chemicals.

ANNUAL REVIEW

Production

Run-of-mine barite, the lowest cost primary barite sold or used by producers, representing 70% of total production, increased more than 140% in 1990. The remainder was flotation concentrate and other beneficiated material. The lower cost crude barite and jigged beneficiated materials were used chiefly in drilling muds; the higher valued floated and other beneficiated material was used mostly in chemical and glass manufacturing and in filler applications.

Reported primary production increased approximately 53% from 290,000 in 1989 to 445,000 tons. Nevada and Georgia remained the two leading barite-producing States. Other producing States, in descending order, were Missouri, California, Tennessee, Illinois, and Montana. Illinois production was as a coproduct of fluorspar mining and milling; in all other States, barite is the primary product.

The leading domestic barite producers were M-I Drilling Fluids Co. with mines in Nevada, a Dresser-Halliburton Co.; Milpark Drilling Fluids, a Baker Hughes Inc. company also with mines in Nevada; and Baroid Drilling Fluids Inc., a division of NL Petroleum Services Inc., with mines in Missouri and Nevada.

W Withheld to avoid disclosing company proprietary data; included with "Other."

Oil prices remained volatile throughout the year, but trends were to higher prices even before the Iraqi invasion of Kuwait. Drilling activity had risen somewhat before the invasion, and the higher prices experienced after the invasion prompted even more domestic drilling and an increase in demand for barite. Oil prices are expected to remain higher than they had been prior to the evasion after the problems in that part of the world are resolved. The invasion renewed concern over the U.S. energy dependence, leading to additional oil exploration and renewed interest in the development of alternative fuels.

Consumption and Uses

Consumption of crushed and ground barite increased about 11%, from 1.3 million tons in 1989 to 1.4 million tons in 1990. The oil- and gas-well-drilling industry completed more than 22,000 wells and drilled nearly 113 million feet of hole;³ these figures were 8% and 11% higher, respectively, than those in 1989. The relationship between barite production, consumption, and well drilling is illustrated in figure 1.

Total drilling footage exceeded 6 million feet in four States: Texas, 42.1 million feet; Oklahoma, 12.7 million; Louisiana, 9.1 million; and Kansas, 7.1 million. Generally, the deeper a hole is drilled, the more barite is used per foot of drilling. Among the four leading States, Louisiana had the highest average well depth, about 7,100 feet, and Kansas the shallowest, about 3,500 feet. Wyoming,

absent from the top States this year in well footage drilled and the perennial leader in the highest average well depth, recorded an average well depth of about 7,200 feet. The U.S. average increased slightly to about 5,000 feet. Barite consumption increased accordingly with the 8% increase in the number of wells drilled as well as the slight increase in average well depth. There was little change in the amount of barite used per foot of drilling, from 11.52 kilograms in 1989 to 11.76 kilograms in 1990.

Another barometer of drilling activity, the Baker Hughes rig count, showed the average number of operating domestic rigs in 1990 increased about 17% to 1,010.4

Prices

Price quotations in trade publications for barite remained unchanged. These prices may serve as a general guide, but do not reflect actual transactions.

The reported average value per ton of domestic barite, based on reported value of direct-ship, beneficiated, and floated material, decreased about 18%, f.o.b. plant, from \$43.53 per ton in 1989 to \$35.63. This decrease in value for domestic concentrate is attributed to a larger percentage of lower valued drilling-mud-grade material in the total. The average value of ground barite, sold or used by producers, was \$86.36 per ton, a 6% increase from the \$81.25 per ton reported in 1989. The average customs value of exported barite was \$181.53 per ton

Foreign Trade

Exports of natural barium sulfate or barite decreased about 5%, from about 9,700 tons to about 9,200 tons. Exports were still significantly lower than the record high of 109,000 tons in 1979. Export and import data provided by the Bureau of the Census did not indicate the grades of barite traded; however, based only on the value of individual shipments, from about \$75 to about \$5,000 per ton, drilling-, pharmaceutical-, chemical-, filler-, and glass-grade were all exported. Historically, barite exports were predominantly ground drilling-mud-grade material with less than 5% of the tonnage specialty ground barites. Canada and Mexico have been traditionally either first or second among export recipients of U.S. ground barite: these two major oil-producing countries accounted for about 75% of the total exports.

Imports for consumption of crude barite remained about the same as they were in 1989, at about 1 million tons. The 1990 barite import figure was approximately 50% below the record high of 2.32 million tons set in 1982. The c.i.f. value of this material averaged \$41.61 ton, slightly higher than that in 1989. The principal source countries, in descending order, were China, with an average value of \$41.33; India, \$34.94; and Peru, \$37.08. The higher priced material was chiefly crude filler and extender-quality barite. High-quality barite, generally material with a specific gravity greater than 4.2, is usually blended during grinding with lower

grade ore, foreign or domestic, to meet American Petroleum Institute specifications for 4.2 drilling-mud-grade barite. Most of the crude barite entered through customs districts along the gulf coast for delivery to grinding plants in the area. The import distribution by customs districts in 1989 (1988) was

New Orleans, LA, 73% (65%) and Houston, TX, 24% (31%). Small amounts were also received, in decreasing order, in Laredo, TX; Portland, ME; Pembina, ND; Detroit, MI; Savannah, GA; and Buffalo, NY.

Imports of ground barite increased to about 57,000 tons from about 47,000

tons in 1989; of this, Canada (16%), China (5%), Mexico (65%), and Morroco (13%) supplied almost all of the total. Prior to 1984, ground barite imports had been limited to premium-quality pharmaceutical grades, which were unavailable domestically. In recent years, this market has been dwindling because certain medical X-ray diagnostic procedures employing barium compounds have been largely replaced with computer-assisted tomography (CAT) scanners or imaging techniques. Sources of medical-grade barite were Canada, the Federal Republic of Germany, Japan, and the Netherlands. The average c.i.f. value of lower grade imports ranged from \$36 to \$309 per ton, suggesting that most of this ground barite is probably destined for the domestic filler and/or extender markets that usually are supplied by U.S. producers. The continued imports of ground filler- and extender-grade barite into this mature market will probably cause concern among domestic producers. Imports

for consumption of barium chemicals decreased slightly.

World Review

The data in table 13 are rated capacity for mines as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period with minimum capital expenditure.

Mine capacity for domestic barite production was aggregated from data voluntarily supplied by the producers. The rated capacity data for the foreign mines were estimated from the previous year's production in cooperation with the Division of International Minerals.

OUTLOOK

Prior to the Iraqi invasion of Kuwait, domestic demand for barite was expected to increase slowly at an annual rate of between 1% and 2% through 1995. Primary barite production was expected to approach 500,000 tons per year by 1995, and the apparent consumption of barite in this period was expected to be in the vicinity of 2.0 million tons. With the increased domestic drilling activity resulting from the situation in the

Persian Gulf area, demand may grow quicker than previously had been anticipated.

Although oil supplies have experienced no significant disruptions, attention has focused on the U.S. dependence on foreign oil. Exploration activities requiring additional barite supplies are expected in the short term. Long-term investigations may lead to development of alternative energy sources, ultimately resulting in a decreased demand for barite as oil and gas are replaced. It is anticipated that acceptance of alternate fuels, such as alcohol and nuclear power systems, will be challenged by a belatedly introduced newer and cleaner generation of petroleum products by the major oil companies. These two systems, if left to competitive market forces, will probably be resolved to the advantage of the new generation

BERYLLIUM

By Deborah A. Kramer

Ms. Kramer is a physical scientist with the Branch of Industrial Minerals. She has covered beryllium for 7 years. Domestic survey data were prepared by Shonta Osborne, mineral data assistant; and international data tables were prepared by William Zajac, Chief, International Data Section.

ince its first commercial production in the United States in the early 1920's, beryllium has become an important material in many industrial and defense applications. Properties such as its high strength, light weight, and high thermal conductivity allow beryllium to be used for components in aircraft, satellites, electronic circuits, oil drilling equipment, and consumer goods.

The United States is the only market economy country with an integrated beryllium industry. Bertrandite, mined and processed in Utah, is the primary mineral source for the end products—beryllium metal, beryllium alloys, and beryllium oxide—that are produced in Ohio and Pennsylvania. Imported beryl, mainly from Brazil, supplements domestic mineral supply.

In 1990, U.S. mine production declined slightly, continuing a 3-year trend. Persistent weak demand in the automotive, defense, and telecommunications markets led to a decline in usage of beryllium metal, alloys, and oxide. But the U.S. mine production supplied a greater percentage of the domestic demand, while beryl imports continued to decrease.

Brush Wellman Inc. was the sole U.S. beryllium mine producer with the capability to convert this ore and beryl into beryllium products. In an effort to upgrade the beryllium-containing materials in the National Defense Stockpile (NDS), the company was awarded a contract to recover beryllium metal from some beryl in the NDS.

DOMESTIC DATA COVERAGE

Beryllium data are collected from two voluntary surveys of U.S. operations. In Based on a beryllium metal equivalent of 4% in beryl.

1990, there were eight responses to the "Beryllium Mineral Concentrate and Beryllium Ore" survey, representing 80% of the total canvassed. These respondents are estimated to have produced 100% of total domestic mine shipments, shown in tables 1 and 9. A small number of unidentified producers may have shipped insignificant quantities of byproduct beryl, which have not been included.

BACKGROUND

Products for Trade and Industry

Beryllium principally is used in one of three forms—beryllium alloys, beryllium metal, and beryllium oxide. The most common products are beryllium-copper alloys, which contain about 2% beryllium and the balance copper. These average about 65% of U.S. beryllium demand and are produced in many shapes, including bar, plate, rod, strip, tube, and wire. Most beryllium-copper alloys are used as current-carrying parts in electronic, telecommunications, and computer equipment. They also are used in oil and gas drilling equipment, as molds

for plastic products, and in consumer goods, including golf clubs, stereo systems, and video cassette recorders.

Small quantities of beryllium-aluminum and beryllium-nickel alloys are used in applications such as automotive electronics. Adding small quantities of beryllium to some magnesium alloys inhibits oxidation.

Beryllium metal averages about 20% of annual domestic demand and is used mainly in aerospace and defense applications. Beryllium has been used in guidance systems and as structural components for satellites and deep space probes such as Galileo and Magellan. It also was used in firing control systems in advanced tactical aircraft. In medical applications, beryllium metal was used for radiation windows in diagnostic X-ray equipment.

The principal use for beryllium oxide is as a substrate for high-density electronic circuits for high-speed computers, automotive ignition systems, lasers, and radar electronic countermeasure systems. Its transparency to microwaves allows beryllium oxide to be used as windows in microwave communications systems.

Industry Structure

Although beryllium is a constituent of more than 90 minerals, only 2 are exploited commercially for their beryllium content. Bertrandite (4BeO•2SiO₂•H₂O) is the principal ore mined in the United States, and beryl (3BeO•Al₂O₃•6SiO₂) is the principal ore mined in the rest of the world.

Mechanized mining methods are used in the United States, but beryl mining operations in the rest of the world are limited to labor-intensive hand-cobbing of the host rock for beryl crystals. As a result, production from operations outside the United States is sporadic and largely is dependent on the economic and political situations within the individual country.

Little is known about beryl mining operations in China and the U.S.S.R., which are probably the two largest producers outside the United States. Beryl produced in China has been imported into the United States in the past, and China has supplied small quantities of beryllium-copper master alloy to the U.S. market. Little, if any, beryllium products from the U.S.S.R. have surfaced in the United States; it is assumed that the U.S.S.R. has an integrated beryllium industry, and its production is consumed within the country.

Geology

Beryl and bertrandite are the chief ores from which beryllium is commercially recovered. Commercial sources of beryl are heterogeneous granite pegmatites, where the mineral occurs in enriched zones, filled fractures, and replacement bodies. The principal beryl deposits occur in zones that usually contain only a few thousand tons of pegmatite rock; some deposits, however, contain 1 million metric tons or more of rock. When beryl occurs in zoned pegmatites, the largest crystals usually are near the core, and the fine-grained crystals are near the outer zone. Some forms of beryl are regarded as precious or semiprecious gems. Pegmatites normally are not mined solely for their beryl content. The beryl is recovered as a coproduct of mining other pegmatite minerals such as feldspar, mica, and lithium minerals. Bertrandite is found in both pegmatite and nonpegmatite deposits; the deposit currently mined in Utah occurs erratically in altered tuff

ANNUAL REVIEW

Legislation and Government **Programs**

Brush Wellman received a \$25.6 million contract from the Defense Logistics Agency (DLA) to upgrade some beryl in the NDS. The company will convert the beryl into 91,000 pounds of vacuum hot-pressed beryllium billets during a 2-year period. Deliveries of the beryllium billets were expected to begin in early 1991. Included in the contract is an option for DLA to buy an additional 43,000 pounds of beryllium in 1993 for about \$13 million. NDS inventories at yearend 1990 are shown in table 3.

The Environmental Protection Agency (EPA) issued final regulations to limit effluent discharge into public waters for several metal manufacturing operations, including beryllium, under the authority of the Clean Water Act. As part of these regulations, EPA set effluent limits for ammonia, beryllium, chromium, copper, cyanide, fluoride, total suspended solids, and pH for wastes from six processing steps that previously were not regulated. EPA also increased the maximum discharge levels for fluoride in the beryllium hydroxide supernatant wastewater and for mass pollutants in the beryllium hydroxide filtrate. These rules supersede the standards in effect since September 1985.¹

Beryllium metal	363	290

Issues

The health effects of airborne beryllium particles continue to be assessed by both the Federal Government and industry. The U.S. Department of Energy planned to implement a complete study of its workers with potential exposure to beryllium. The Agency also expected to review studies on beryllium exposure that were conducted at the National Jewish Center for Immunology and Respiratory Medicine, the University of Colorado Medical School, and the National Institute of Occupational Safety and Health.² Brush Wellman also assembled a study group to examine the health and safety concerns of beryllium users. In addition, the company sponsored publication of a book that details current techniques for safe handling of beryllium.3

Although both Federal and State environmental and health and safety regulations exist for beryllium, discharge of and exposure to the metal remain an issue. NGK Metals Corp. reportedly was fined \$300,000 by the State of Pennsylvania for illegal storage and disposal of chemical wastes. One of the company's employees also was charged with submitting monthly reports to the

State that underreported the number of instances that the company violated its discharge limitations for beryllium and copper. NGK pleaded no contest to one felony violation of the Solid Waste Management Act, two misdemeanor violations of the Act, one count of unsworn falsification, one count of pollution of water, and one violation of the Clean Streams Act.4

The Occupational Safety and Health Administration (OSHA) issued citations against Alloy Research Inc., a New Madrid, MO, casting foundry that produces beryllium-copper alloy billets and slabs, for alleged violations of Federal health and safety standards. Molten metal and steam explosions at the facility spurred OSHA to conduct inspections; the Agency found that some employees were exposed to airborne beryllium levels that were higher than the Permissible Exposure Limit. OSHA's citations included 16 willful violations, 31 serious, and 10 otherthan-serious and carry a total proposed penalty of \$170,480.

Production

Mine production declined slightly in 1990, and inventories were drawn down to meet part of the worldwide demand. Beryllium metal production increased by about 18%, but this increase was used mainly to fill the NDS requirements. Production of beryllium-copper master alloy increased slightly, and there was a significant drop in U.S. production of beryllium oxide. In addition, beryllium-nickel alloy production declined, and beryllium-aluminum alloy production increased sharply.

Brush Wellman was the only integrated producer of beryllium in the United States. The company mined bertrandite at its open pit near Delta, UT, and processed this ore, imported beryl, and small quantities of domestically produced byproduct beryl into beryllium hydroxide at its facility in Delta. Beryllium hydroxide was shipped to Brush Wellman's plant in Elmore, OH, where it was manufactured into beryllium metal, beryllium alloys, and beryllium oxide. NGK Metals also produced beryllium alloys at its plant in Reading, PA, from beryllium hydroxide supplied by Brush Wellman.

A joint venture between Beryllium International Corp. and Inspiration Gold, a subsidiary of Inspiration Re- | Sources: American Metal Market and Metals Week.

sources Inc., planned to develop a beryllium mining and milling operation in Utah. Inspiration Gold owns 51% of the joint venture, which it purchased from Cominco American Resources, a division of Cominco Ltd., in mid-1990. Cominco had completed a project feasibility study on this property and decided not to go ahead with beryllium production. The joint venture expected to mine beryllium from property next to Brush Wellman's and has set up a temporary office in Delta, UT, to handle early stages of project development. After obtaining Federal and State permits, the companies expect to begin plant construction in 1991.

Consumption and Uses

Reduced demand in the U.S. automotive, defense, and telecommunications markets led to a decrease in beryllium oxide ceramic usage. A decline in beryllium alloy demand in computerrelated applications partially was offset by an increase in automotive electronics and oil and gas drilling equipment.

Hughes Aircraft Co. ordered 110 beryllium blanks from Brush Wellman to be machined into mirrors for the firing systems of the South Korean K-1 Main Battle tank. This is the second order from the Government of the Republic of Korea, which took delivery of 170 tanks in 1989. The 2.2-pound mirrors originally were developed for the European Leopard II tank and were used to aim the tank's gun. Beryllium mirrors also have potential use in an upgraded version of the U.S. M-1 tank; if beryllium is chosen for this application, another 5,000 blanks may be required.

In January, Brush Wellman announced the purchase of Electrofusion Corp., a manufacturer of electronbeam welded, brazed, and diffusionbonded beryllium components, to give Brush Wellman more value added products. Electrofusion supplied the aerospace, defense, medical, and scientific markets.

During 1990, the Defense Reutilization and Marketing Service was a major source of beryllium scrap, primarily in worn aircraft brake disks and other components of aircraft brake assemblies. A total of 30,073 kilograms of beryllium-base scrap was offered for sale during the year, and Brush Wellman was the principal purchaser.

Markets and Prices

Yearend prices for beryllium ore, alloy, metal, and oxide are shown in table 4. Beryllium-copper strip, rod, bar, and wire prices increased about 4% from those at yearend 1989. Although the quoted price for beryllium powder appears to have increased significantly from that of yearend 1989 when it was quoted at \$196 per pound, revised prices for 1986-89 show that the price increase between 1989 and 1990 was about 3%. Revisions to the beryllium powder price since yearend 1986 are as follows, in dollars per pound: 1986— \$204; 1987—\$229; 1988—\$244; and 1989—\$261.

Foreign Trade

The Bureau of the Census does not separately identify imports and exports of beryllium-copper alloys; these data are combined with data for other cop-

per alloys. The Journal of Commerce Port Import/Export Reporting Service (PIERS) provides some data covering beryllium-copper alloy trade, but only on materials that are transported by ship, so the data may not represent U.S. totals. According to PIERS, the United States exported 430 tons (gross weight) of beryllium-copper alloys, with about 50% of the material shipped to Japan and 37% shipped to France. In addition, 21 tons (gross weight) of berylliumcopper master alloy was exported; 87% was shipped to France, and 13% was shipped to Brazil. Imports of berylliumcopper alloys were 154 tons (gross weight), of which 39 tons was scrap. Japan was the source of 50% of the beryllium-copper alloy imports.

Current Research

Nuclear Metals Inc. was awarded a contract by Oak Ridge National Laboratory to use the company's plasmarotating-electrode process to produce spherical, high-purity beryllium powder for optical applications. Beryllium powder produced by this process is expected to enhance properties needed for producing near-net-shape parts, particularly mirrors, by hot-isostatic pressing (HIP). The plasma-rotatingelectrode process essentially involves rapid longitudinal spinning of a highpurity beryllium bar and melting one end with a plasma torch. Liquid beryllium droplets are ejected from the end of the bar by centrifugal force and solidify into spheres. Because this is done in an inert atmosphere, the powder has little chance to oxidize and pick up other contaminants.

Brush Wellman also investigated new processing techniques to improve the properties of metallic beryllium parts and reduce their cost. In particular, its efforts were directed at improving nearnet-shape processing techniques. Using HIP, the company developed a new grade of beryllium, Grade O-50, for mirrors in reconnaissance satellites and tactical optical systems. HIP also was used to develop new families of beryllium products, including beryllide intermetallic compounds for rocket nozzles and high-temperature applications, metal-matrix components for hypersonic aircraft applications, and aluminum alloys containing as much as 40% beryllium. Brush Wellman also produced a prototype of a lower cost be-

ryllium foam, which is a potential substitute for honeycomb materials in a variety of applications. In addition, the company developed a laboratory-scale, inert-gas atomization method to produce spherical beryllium particles.

Research personnel at Los Alamos National Laboratories worked on developing methods to produce beryllium alloys by rapid solidification. The researchers modified an existing technique, but this was the first time this type of process was applied to beryllium. Test beryllium compounds were made with a centrifugal atomizer, in which molten metal is cooled at up to 1 million degrees per second. This rapid cooling produces spherical rather than

angular beryllium particles. The test compounds used unique alloying elements such as titanium, vanadium, yttrium, and zirconium. Beryllium alloys with a 2% yttrium content were shown to be thermodynamically stable, with a melting point of about 1,900° C. Alloys developed by these techniques were expected to be used on the U.S. Government's National Aerospace Plane.

OUTLOOK

In sales volume, the defense market is the largest consumer of beryllium, although the automotive electronics market is the fastest growing sector. Limited production of new defense systems because of declines in Federal funding would decrease the need for beryllium in this market. In addition, because of the perceived health hazards of beryllium, some defense components have been redesigned to use substitute materials. The combination of fewer beryllium components produced and the substitution of other materials for beryllium would lead to a decline in beryllium use in defense applications.

In 1991, U.S. automobile manufacturers plan to produce the fewest quantity of cars since the recession year of 1982. With a decrease in total automobile output, beryllium use in this application is not expected to increase in the near term, even though individually, each car may contain more beryllium components than those in previous years.

Normally, beryllium metal purchases by the NDS result in an increase in U.S. production to supply the additional requirements. But because the metal will be recovered from material that already is in the NDS, additional NDS

¹ Table includes data available through Apr. 26, 1991.

BISMUTH

By Stephen M. Jasinski

Mr. Jasinski is a physical scientist with the Branch of Metals. He has been the U.S. Bureau of Mines bismuth specialist for 3 years. Domestic survey data were prepared by Tony Morris, mineral data assistant; and international data tables were prepared by Harold Willis, international data coordinator.

omestic consumption of bismuth decreased for the third consecutive year, mainly because of a decline in usage by the chemical and pharmaceutical industries. Bismuth was produced in the United States as a byproduct of lead refining. One company accounted for all primary production. Consumer stocks and imports of bismuth both dropped from those of 1989. The U.S. dealer price, which declined steadily for the first three quarters of the year in response to weak demand, was unchanged in the last 3 months of the year.

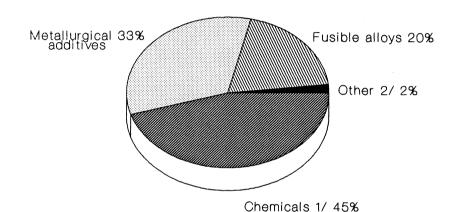

DOMESTIC DATA COVERAGE

Domestic consumption data are collected through a voluntary survey. Of the 69 firms that received the form, 88% responded. The respondents constituted 94% of the bismuth consumed in the United States. The amount used by the nonrespondents was estimated based upon data reported in the prior year or from other sources.

Legislation and Government Programs

The Defense Logistics Agency (DLA), which maintains the National Defense Stockpile (NDS), sold 58,967 kilograms of bismuth from the NDS in 1990. The DLA began monthly sales of bismuth in August; it awarded 29,484 kilograms in August and the same quantity again in October. The DLA had the authority to dispose of 57,924 kilograms in each of the fiscal years 1990 and 1991. The NDS inventory on December 31, 1990, was 885,119 kilograms, with a goal of 480,808 kilograms.

Production

ASARCO Incorporated was the only domestic producer of primary bismuth. Production of bismuth at the company's Omaha, NE, refinery increased slightly in 1990. Data are not published to avoid disclosing company proprietary data. Several firms recovered small quantities of bismuth from fusible alloys scrap.

Secondary production data are not available.

Consumption and Uses

Domestic consumption of bismuth in 1990 dropped 6% from that of 1989. The largest decrease occurred in chemical and pharmaceutical uses, which fell 12% from that of 1989, due to weak demand

for bismuth chemicals in the last half of the year. Increased production of free machining aluminum and steel caused the use of bismuth in metallurgical additives to rise 7% from that of 1989.

Markets and Prices

The domestic dealer price for bismuth decreased steadily from a high of \$4.40 to \$4.50 per pound in January to \$2.80 to \$2.90 per pound in September, where it remained until the end of the year. The drop was attributed to reduced demand and a plentiful supply of bismuth.

Foreign Trade

U.S. imports for consumption declined 14% from those of 1989 because of consumers using existing stocks to meet their orders and a decrease in bismuth chemical usage. U.S. imports from Belgium dropped 168 tons from those of 1989, but the country remained the largest supplier to the United States. Mexico and Peru were the second and third largest sources, respectively.

Bismuth articles, including waste and scrap (Harmonized Code 8106.00.0000) were imported free from most favored nations (MFN), but subject to a 7.5% ad valorem duty when imported from non-MFN.

World Review

Bismuth was recovered mainly as a byproduct of processing lead and copper ores. Only in Bolivia was bismuth produced as a primary product. Mexico and China were estimated to be the world leaders in mine production of refined bismuth for the fifth consecutive year.

Two Australian companies, Dragon Resources and Austmelt Pty., entered into a joint venture to recover bismuth, copper, and gold from stockpiled flue dust at the Mount Morgan smelter in Queensland, Australia. According to the companies, the 4,740-ton stockpile averages about 5% bismuth. The plant was expected to begin operation in March 1991 and process the entire amount in 7 months. The metals will be recovered using the Sirosmelt process, a method for treating high-value, small-tonnage resources invented by the Commonwealth Scientific and Industrial Research Organization of Australia and licensed to Austmelt. Pilot plant tests have recovered up to 99% of the contained bismuth from the copper flue dust.

²Includes other alloys and experimental uses.

Table includes data available through Apr. 2, 1991. Bismuth is produced primarily as a byproduct of other metals, mostly lead, and only in Bolivia is it mined for itself.

In addition to countries listed, Brazil, Bulgaria, Greece, and Namibia are believed to have mined and/or refined bismuth, but available information is inadequate for formulation of reliable estimates of output levels.

Figures listed under mine output are reported in Canadian sources as production of refined metal and bullion plus recoverable bismuth content of exported concentrate.

Mine output figures have been estimated based on reported metal output figures. Series revised to show data reported by Consejo de Recursos Minerales.

The Geological Society of Japan revised the bismuth reserve totals for Japan from 57,000 tons to 8,745 tons. ¹ The revision was based on an average bismuth content of 0.114% obtained from sampling ores at lead-zinc mines throughout the country. The highest percentages of bismuth were recorded in Kuruko and Skarn deposits, which have been the main source of lead and zinc production, from which bismuth is recovered as a byproduct. The new reserve figure confirms reports that the bismuth content of ores in Japan has been declining over the past decade.

Current Research

Glaxo Pharmaceuticals of the United

Kingdom patented a new drug, rantidine bismuth citrate, to treat ulcers.² The medication was expected to be used to heal duodenal ulcers linked to the Helicobater pylori bacterium. Unlike currently prescribed medications that only suppress the secretion of digestive acids, this new drug also will employ an antibiotic. The company plans to file for a license to manufacture the drug in 1993 or 1994, and the medication reportedly should be available in 1995.³

OUTLOOK

Although consumption of bismuth decreased, the outlook for the metal

remains optimistic. Bismuth has the advantage of being nontoxic and a potential substitute for lead or cadmium in some metallurgical and pigment uses. Medicinal uses for bismuth are increasing, especially for treating ulcers. World production is still well below capacity and, with bismuth being sold from the NDS, supplies should remain sufficient well into the next century.

BORON

By Phyllis A. Lyday

Mrs. Lyday has covered boron for 12 years. Domestic survey data were prepared by Rosa McGee, mineral data assistant; and international data were prepared by Harold Willis, international data coordinator.

S. production and sales of boron minerals and chemicals increased during the year. Domestically, glass fiber insulation was the largest use for borates, followed by sales to distributors, textilegrade glass fibers, and borosilicate glasses.

California was the only domestic source of boron minerals. The United States continued to provide essentially all of its own supply while maintaining a strong position as a source of sodium borate products and boric acid exported to foreign markets.

Supplementary U.S. imports of Turkish calcium borate and calcium-sodium borate ores, borax, and boric acid, primarily for various glass uses, continued.

DOMESTIC DATA COVERAGE

Domestic data for boron are developed by the U.S. Bureau of Mines from two separate, voluntary surveys of U.S. operations. Of the three operations to which a sold and used survey request was sent, all responded, representing 100% of the total boron sold or used shown in tables 1 and 9. A Bureau canvass of the three U.S. producers also collected data on domestic consumption of boron minerals and compounds shown in tables 4 and 5.

BACKGROUND

Definitions, Grades, and Specifications

Few of the many minerals that contain boron are commercially valuable. Only colemanite and ulexite minerals, primarily imported from Turkey, are marketed in the United States. The

boron oxide content of both minerals is usually marketed at about 40%.

Tincal and kernite ore and brines are the U.S. source of refined borate chemical compounds. The most common refined borates, borax pentahydrate and its derivative anhydrous borax, are marketed in technical and agricultural grades. Lesser quantities of borax decahydrate are produced in technical, United States Pharmacopeia, and special quality grades.

Boric acid is a white, odorless, crystalline solid sold in technical national formulary and special quality grades as granules or powder. Boron oxide is a

Ulexite (boronatrocalcite)	NaCaB ₅ O ₉ •8H ₂ O	43.0

¹ Parentheses include common names

hard, brittle, colorless solid resembling glass that is ground and marketed most often under the name anhydrous boric acid.

Elemental boron is a dark-brown powder in the amorphous form and a yellowish-brown, hard, brittle solid in the monoclinic crystalline form. Boron is marketed in grades from 90% to 99% purity.

Ferroboron is a name given to a variety of boron-iron alloys containing 0.2% to 24% boron used primarily to introduce small quantities of boron into specialty steels.

In the boron hydride series of compounds are diborane, a gas; pentaborane, a liquid; and decaborane, a solid. These compounds have been studied as fuels that range from 31,220 British thermal units (Btu) per pound for diborane to 27,850 Btu per pound for decaborane. Sodium borohydride is marketed in powder or pellet form and in sodium hydroxide solution.

Boron nitride, a soft, white, highly refractory solid resembling graphite, can withstand significant oxidation temperatures up to 650° C. Boron nitride produced in fibrous form equals glass fibers in strength and modules of elasticity, but is lighter in weight and more resistant to high temperature. When subjected to extremely high pressure and temperature, boron nitride forms cubic crystals that rival the hardness of diamond.

Boron carbide, produced by reacting carbon and boric acid at 22,600° C, is

a highly refractory material and one of the hardest substances known. Most commonly used for both abrasive and abrasion-resistant applications as well as nuclear shielding, boron carbide is marketed in technical and high-purity grades.

Byproducts and Coproducts

More than four-fifths of the U.S. production comes from mineral deposits mined only for their boron content. The remainder is produced from lake brines, which also supply sodium carbonate, sodium sulfate, potassium sulfate, and potassium chloride. Turkish colemanite, ulexite, and tincal ores are worked only for their boron content. Most Soviet borates are also mined only for their boron content, but the Gulf of Kara-Bagaz-Gol and the Sivash (lagoon) borates are extracted with coproduct chloromagnesium from brines. South American boron has been mined from ores and also has been produced as a coproduct of nitrate and iodine production.

Economic Factors

Costs.—Energy costs are especially high for producing anhydrous products. The anhydrous products were originally introduced to decrease freight costs per ton of contained boron oxide. Both domestic producers now use cogeneration facilities to reduce the cost of energy for processing and supplying excess electricity for sale.

Depletion Provisions.—The domestic and foreign depletion allowances for boron are 14% of gross income and may not exceed 50% of net income without the depletion deduction.

Operating Factors

Naturally occurring boron compounds have relatively low toxicity for man and other mammals. Sodium borates, boric acid, and boron oxide are not present to any significant degree in air and are placed in the same hazard category as general dust. Ingestion in quantities greater than 20 grams by an adult can cause nausea and skin rashes.

Small quantities of boron are essential for all plant life. Boron is added in trace levels to fertilizers; however, quantities well below concentrations affecting man and animals are so extremely toxic to vegetation that boron compounds are also used commercially as herbicides. Concentrated boric acid is used to control certain insects and in dilute solutions as a preservative to control the growth of bacteria.

ANNUAL REVIEW

Legislation and Government Programs

The Office of Foreign Availability (OFA), Department of Commerce, Bureau of Export Administration, requested comments in the October 23 issue of the Federal Register on the foreign availability of pyrolytic boron nitrite worldwide. On July 30, 1990, OFA accepted for filing a foreign availability submission relating to the decontrol of pyrolytic boron nitride crucibles, boats, furnace tubes, liner, and other specially designed shapes used in the manufacture of semiconductor devices and integrated circuits to controlled countries. The submission period for comments was to close November 23.

The desert tortoise was designated an endangered species by the Fish and Wildlife Service (FWS) of the U.S. Department of the Interior. About 500 plants and animals are now protected by the 1973 Act. By law, FWS looks only at scientific facts as to whether further pressure will lead to extinction.1 The FWS cited habitat deterioration and loss, disease, and varied human uses of the desert as some of the principal threats facing the tortoise. Energy and mineral development were listed as one of the land uses affecting the tortoise. The listing extends long-term protection to tortoises living north and west of the Colorado River, including eastern California, southern Nevada, northwestern Arizona, and southwestern Utah. The areas listed include boron areas being surface mined and a solution-mining project area. Any change in land use in these areas require consultation with the FWS beforehand.

Congress continued discussion and debate over whether there should be changes to the Mining Law of 1872, better known as the General Mining Law. Sodium borate minerals, which are excluded from the law, are included under the Mineral Leasing Act of 1920, as amended and supplemented.

The Bureau continued two ongoing studies dealing with Federal land availability in the California Desert Conservation Area (CDCA). The CDCA contains all commercial domestic deposits of boron minerals and most of the known reserves. One Bureau study is site specific and the other deals with

Federal land availability. The first study will examine in detail about 10 selected known deposits and active mines in the CDCA. In the second study, the Bureau will show how Federal land practices and withdrawals affect known mineral deposit areas in the CDCA.²

The U.S. Bureau of Mines, Division of Policy Analysis, completed an investigation of the East Mojave National Scenic Area, CA. The report was available as a Mineral Land Assessment open file in two volumes from the U.S. Bureau of Mines. Volume one is resource information, and volume two is related economics.

The Bureau of Land Management issued a new policy that mandates reclamation bonding on all mining and exploration plans of operation involving 5 acres or more of land. The policy applies for all new operations.³

A \$9 million plan to develop maglev systems was introduced into Congress as part of the U.S. Department of Transportation budget. Maglev transportation systems consist of a train-like vehicle riding several inches above a metal guideway on a magnetic field at speeds of up to 400 miles per hour. Currently, there are proposed systems connecting southern California with Las Vegas, NV, and a local system in Las Vegas that uses boron magnets.⁴

Production

The majority of the boron production continued to be from Kern County, with the balance from San Bernardino and Inyo Counties, CA.

American Borate Co., a wholly owned subsidiary of Owens-Corning Fiberglas Corp., continued sales of ulexite from storage at Dunn, CA.

Kerr-McGee Chemical Corp. operated the Trona and Westend plants at Searles Lake, in San Bernardino County, to produce refined sodium borate compounds and boric acid from the mineral-rich lake brines. At the Trona plant, a differential evaporative process produced borax with potash as a byproduct. Boric acid was produced by solvent extraction. The Westend plant continued production of sodium borates by a carbonation process. Brines used in the process were pumped to the Argus plant to produce sodium sulfate.

At yearend, three chemical processing facilities, of which two produce boron compounds, and the Trona Rail-

way were sold for \$210 million to an investment group led by D. George Harris & Associates. The organization will be known as North American Chemical Co. with a base of operations in Kansas City, MO. The investment group includes Oriental Chemical Industries of Korea and Chase Manhattan Investment Holdings Inc. Oriental Chemical will represent North American for certain product lines sold in the Far East.

United States Borax & Chemical Corp., a part of Borax Consolidated Ltd. of the RTZ Corp. PLC of London, United Kingdom, continued to be the primary world supplier of sodium borates.

U.S. Borax mined and processed crude and refined sodium borates, their anhydrous derivatives, and anhydrous boric acid at Boron, in Kern County, CA. A second plant at Boron used a proprietary process to produce technical-grade boric acid from extensive kernite ore reserves. The boric acid was produced to compete with imported colemanite used in glass manufacture. In addition, colemanite was mined at Shoshone, in Inyo County, CA.

The majority of material was shipped to Wilmington, CA. Products made at a plant in Wilmington included ammonium borates, potassium borates, sodium metaborates, and zinc borate. Corona Corp. continued ownership of the Fort Cady Minerals Corp., but construction of a boric acid plant was delayed by environmental assessment studies of mining and reclamation plans that were necessary to receive permits. The agreement between Corona and Avalon Corp. to acquire the Fort Cady Minerals Corp. was terminated. 5

Consumption and Uses

U.S. consumption of borates increased. Glass fiber insulation and glass fiber primarily used as reinforcement for plastics continued to be the largest consuming industries.

The use of borates in glass fiber thermal insulation, primarily used in new construction, was the largest area of demand for borates. Cellulosic insulation, the seventh largest area of demand, decreased.

The second major market for borates, manufacturing high-tensile strength glass fiber materials for use in a range of products, showed an increase in demand. The nonconductive and low dielectric properties of high-strength glass-reinforced materials make them transparent to radar and thus valuable for "stealth" applications. Carbon-fiberreinforced resins can be stronger than metals and, with higher modules, more dimensionally stable. Although composites can be 10 times more expensive than typical aerospace-grade aluminum, the flexibility they offer in design and consolidation of parts allows large, complex structures to be fabricated to exacting specifications. In addition, their light weight and ability to withstand high temperatures have made composites the material of choice for a variety of aerospace applications.

In advance composites, carbon, higher module glasses, and aramid fibers account for about 95% of the market; glass accounts for about 20% of the market. At \$200 to \$500 per pound, less than 1% of the market is specialty fibers, such as boron, silicon carbide, and quartz. In advanced composites, fibers generally make up 60% of the material by volume.⁶

The Bradley Fighting Vehicle is a new fiberglass composite weapon that faced combat for the first time in the Persian Gulf. Because of an invasion of Kuwait by Iraqi forces, troops and equipment, including the Bradley, were transported to Saudi Arabia. The Bradley is produced by FMC Corp. at San Jose, CA, for the U.S. Army. More than 5,249 Bradleys were delivered by yearend.⁷

Consumption of borates in borosilicate glasses remained the third major end use, and demand decreased. Boron added to glass reduced the viscosity of the melt, assisted with fiber formation during processing, and allowed for thermal expansion of the product.

Boron compounds in cleaning and bleaching were the fourth major end use. Oxygen systems, such as peroxygens, including perborates, may replace chlorine-base bleach systems because they are less harsh on fabric. Demand for monohydrate was reported to have doubled between 1987 and 1989. Sodium perborate is a solid peroxygen bleach used in powder detergents. Consumption of the monohydrate was reported to be in excess of 40,000 tons during 1990.8 E. I. du Pont de Nemours & Co. Inc. planned to become the first domestic producer of a solid peroxygen bleaching chemical. The plant,

in Memphis, TN, planned to be operational during 1991. Interox America announced the construction of a 45-million-pound monohydrate plant at Deer Park, TX. The planned startup date was to be early in 1992.

Boron compounds continued to find application in the manufacture of biological growth control chemicals for use in water treatment, algicide, fertilizers, herbicides, and insecticides. Boron can be applied as a spray or incorporated in herbicides, fertilizers, and irrigation water. Commercial Fertilizers magazine reported that total fertilizer consumed between June 30, 1989, and June 30, 1990, as boron compounds amounted to about 7,000 tons used in five regions. Only a small amount of boron is required on alfalfa, clover, and vegetables to promote optimum growth and yields.19

Boron compounds were also used in metallurgical processes as fluxes, shielding slag in the nonferrous metallurgical industry, and components in electroplating baths. Small amounts of boron and ferroboron were constituents of certain nonferrous alloys and specialty steels, respectively.

Boron carbide and boron nitride are two exclusively manufactured materials synthesized by the reaction of boron oxide with other materials. These products are consumed as abrasives, cutting tips, blasting nozzles, nuclear control rods, and various other uses. A market study by Mitchell Market Reports of Gwent, United Kingdom, contained approximately 300 companies in 20 countries that produce, use, or consume boron carbide and boron nitride.

SB Chemical Ltd., a refiner and manufacturer of elemental boron in Franklin Park, IL, changed names to SB Boron Corp. The company is the sole producer of elemental amorphous boron powder in 90% to 92% (pyrotechnic) and 95% to 97% (aerospace) grades. 12

Prices

Prices for anhydrous-, pentahydrate-, and decahydrate borax and technical boric acid remained essentially at 1989 levels. Other prices, including high-purity boric acid and colemanite, increased.

Foreign Trade

The majority of material from the U.S. Borax facility in Boron was shipped to storage, loading, and ship-

TABLE 4

U.S. CONSUMPTION OF BORON MINERALS AND COMPOUNDS, BY END USE¹

(Metric tons of boron oxide content)

Total	66,229	64,392

¹ Includes imports.

ping facilities at Wilmington, CA. A large part of output was exported to Western Europe from Wilmington to Botlek, Netherlands.

World Review

Capacity.—The data in table 9 are rated capacity for mines and refineries as of December 31, 1990. Mine capacity for boron was based on rated capacity as reported by the company, by another government agency, or another published source. Capacity outside of the United States was limited by the availability of loading and transportation equipment and market demand rather than limitations of ore grade.

Argentina. - Boroquimica S.A.M.I.-C.A.F., a subsidiary of RTZ, continued production of tincal and boric acid from a deposit at Tincalayu, Salta Province.

Belgium.—Degussa Corp. planned to add sodium perborate monohydrate capacity at its Antwerp, Belgium, facility while hydrogen peroxide capacity is expanded. Degussa now makes perborate tetrahydrate, which is used in solid detergents. The trend in Europe is toward liquid detergents using the monohydrate. 13

Bolivia.—Beginning in August 1987, the United Nations Development Program (UNDP) provided considerable assistance to Bolivia in the assessment of nonmetallic resources. A U.N. Revolving Fund of \$1.3 million drilling program began to investigate the economic potential of known and possible mineral resources in Bolivia. Lithium Corp. of America (Lithco) signed a preliminary contract November 17, 1989, for development of Salar de Uyuni, which is reported to contain the world's richest reserves of lithium salts and 3.2 million tons of boron minerals. On May 4, the \$46 million contact with Lithco was canceled, and the project was opened for international bidding. 14 During 1989, the Government reported that 10,000 metric tons of ulexite was exported.15

Chile.—At yearend, AMAX Exploration Inc. was seeking partners to purchase its 65.5% stake in the Sociedad Minera Salar de Atacama Ltda. (Minsal) project. The feasibility study included the development of a 22,000ton-per-year boric acid plant at the Salar de Atacama. The salar is one of about 74 arid salt basins in the Chile-Bolivia-Argentina border region. At capacity, the project will also produce

533,000 tons per year of potassium chloride, 276,000 tons of potassium sulfate, up to 35 million pounds of lithium carbonate, and 5 million pounds of lithium hydroxides. The availability of more than 1 million tons per year of sulfuric acid from the Chiquicamat copper smelter will enhance the economic viability of the project. 16

In 1988, production of ulexite and boric acid was estimated at 35,000 tons per year from salt deposits in the north. Quimica e Industrial del Borax Ltda. (Quiborax) is the main producer of boric acid and concentrated ulexite. Minera del Boro, Minera Ascotan, and Boroquimica are smaller local producers. Quiborax and Minera del Boro planned capacity increases. By 1994, Minsal planned to have completed a boric acid expansion of 18,000 tons per vear. 17

France.—Atochem Inc., a member of the Elf Aquitaine Group, planned a 13,000-ton-per-year sodium perborate monohydrate plant at Pierre Benite, near Lyon, to be operational in 1991.18 The company already operates a 48,000-ton-per-year plant at the same location for sodium perborate tetrahydrate, the starting material for the monohydrate form. Both hydrates are used as whitening additives in domestic detergents. 19 Atochem has also announced plans to build a monohydrate plant at Warrington, United Kingdom, and convert production from tetrahydrate to monohydrate at sites in Belgium, the Federal Republic of Germany, and Italy.²⁰

Cie. de St. Gobain signed an agreement to acquire Norton Co. of Worcester, MA, a producer of boron carbide. St. Gobain is a leading producer of glass products and owns CetainTeed Corp. 21

India.—The Ministry of Agriculture brought boron-enriched single superphosphate (SSP) under the Fertilizer Control Order to ensure greater benefits and better quality fertilizer in micronutrient-deficient areas. Dharamsi Morarji Chemicals has been asked to resume the production of boron-enriched SSP, a slow-release fertilizer. Maharastra and Gujarat Pradeshes are under intense cotton cultivation and suffer from boron deficiency.²²

³ American Borates Co.

Peru.—Throughout 1989, all companies in the mining sector, regardless of size, faced the problems brought on by high inflation and an unfavorable exchange rate. High interest rates and payroll increases led the rise in local costs, while the rise in revenues lagged behind costs because the depreciation of the currency failed to keep pace with inflation. The exchange rate applied to exporters, including miners, meant export receipts were exchanged at an average of only 74% of the free market exchange rate. Labor problems were less significant to production than in 1988, although terrorists increased their activities, causing loss of lives and important material damages.²³

Taiwan.—PPG Industries Inc. jointly owns a 20,000-ton-per-year fiberglass plant operated by PFG Fibre Glass Corp. in a joint venture with Nan Ya Plastics, a business of Formosa Plastics Group.²⁴

Turkey.—Turkey's boron operations are under the control of the Government corporation, Etibank, that mines boron from major deposits at Bigadic, Kirka, and Emet. Etibank operates refining facilities to produce refined sodium borates and boric acid from tincal concentrates at Bandirma. Boron minerals and compounds are shipped from the Port of Bandirma on the Sea of Marmara and Izmir on the Aegean Sea.

United Kingdom.—Pilkington Special Glass Ltd. closed a special glass plant producing nuclear shielding and electronics in St. Asaph, Clwyd, North Wales, with the loss of 140 jobs. The operation will continue to employ 190 people who manufacture high index ophthalmic and photochromic glass blanks using boron.²⁵

Venezuela.—PPG Industries Inc. (49%), Pittsburgh, PA, and the Sudamtex Group of Caracas began operation of a plant to produce continuous strand fiberglass at Barcelona operated by the Sudamtex subsidiary VFG-Sudamtex (51%). The company is the only fiberglass producer in the Andean Pact countries (Bolivia, Colombia, Ecuador, Peru, and Venezuela). 26

Current Research

Traditional ceramics are solids that are stable in temperatures as high as 1,000° C. Advanced ceramics such as boron carbide-aluminum are being developed that are stable at temperatures to 1,500° C or higher. Superconducting material in complex shapes is made by crystallizing material from a previously formed glass. Carefully controlled heating converts this glass to a crystalline ceramic. A combination of metal oxides useful in superconductors can be melted into a glass without adding

glass-forming compounds, such as silica or boric oxide, that would dilute the superconductivity of the crystalline ceramic. The boron carbide-aluminum ceramic-metal (cermet) composite combines the toughness of aluminum and the strength of boron carbide ceramic in a single material. Boron carbide powder is sintered at 2,000° C into solid boron carbide sponge and filled with molten aluminum at 1,100° C. The process produces a fully dense, boron carbide-aluminum cermet free of unfilled spaces where cracks could

originated.27

A plastic composite wheel for cars manufactured using fiberglass-reinforced compounds won the Society of Plastics Engineers' top automotive award. The wheel was developed by Motor Wheel and manufactured by the Goodyear Tire & Rubber Co. The new wheel is 2 to 3 pounds lighter than aluminum wheels and does not corrode.²⁸

PPG developed a new fiberglass product for reinforcement applications that creates a surface as smooth as preform molded parts, but at lower costs. The process was available for licensing.²⁹

A soccer ball shaped "buckyball" contains 60 carbon atom molecules of the fullerene motif, which are molecules that contain an even number of atoms arranged in closed, hollow cages. Fullerenes have exhibited superconductive properties that are high when compared to other organic superconducting systems. A laser was used to vaporize graphite impregnated with boron nitride and trap the products in macroscopic shapes known as "dopyballs." ³⁰

Boron 10, a stable isotope of boron, can be concentrated in tumor cells and bombarded with short-range radiation to destroy cancer cells. Developments in boron compounds show marked effectiveness in treating brain tumors. The

treatment of malignant melanoma, a pigmented form of skin cancer, is under study. Boron neutron capture therapy may be extended to cancers that respond poorly to current treatment.³¹

OUTLOOK

Production and consumption of boron minerals and compounds have decreased between 1981 and 1990. There are several factors that may lead to misleading outlooks in consumption. One is that production and imports reported in one year may be utilized during a period of years. In addition, environmental concerns may change the demand for boron significantly in a short period. The regulation of fire retardants in products have resulted in changes in boron usage as a fire retardant.

Agriculture

Boron usage in agriculture reached a low in 1982 and has continued to declined. The primary reason was attributed to the decline of the number of farms during the same time period. Farming exports are showing increased strength, and demand for boron usage in agriculture was expected to increase to 20,000 short tons of boron oxide content.

Ceramics and Glass

Boron usage increased during the 1980's, reaching a peak in 1984 that was a 36% increase over that of the prior year. This spike was probably a

demand to balance the sharp decline of 1982 of 41%. Ceramics and glass have both faced competition with polymers. In 1990, the U.S. fiberglass industry was reported to be feeling the effects of recessionary pressures. The sagging economy produced a decline in demand for fiberglass reinforcements that was expected to be long term. Fiberglass is closely related to construction and transportation, which continue to be depressed. The fiberglass reinforcements industry that represents 17% of the total composites market forecasts a 6% decline in its construction market for 1991.32

Coatings and Plating

Primarily used as a protective coating for steel products and as a glazing on ceramic tiles, usage has experienced a decline. This decline was a result of the demand for polymers that replace many of the coatings and plating uses. Demand was expected to remain at 1990 levels.

Fabricated Metal Products

Boron usage decreased in metal products during the past decade. Many traditional metal products that require soldering now are produced from polymers as one piece. Usage in specialized metal was expected to increase at the rate of 2% per year.

Soaps and Detergents

This usage declined primarily because chlorine bleaches and cold water washes replace boron soap powders.

Recent concern for environmental effects of chlorine may reverse the decline. Perborate bleaches have returned to name brand soap products. The usage of boron in soaps and bleaches was expected to increase by 4% per year during the next 5 years.

BROMINE

By Phyllis A. Lyday

Mrs. Lyday, a physical scientist with the U.S. Bureau of Mines, has been the commodity specialist for bromine for 12 years. Domestic survey data were prepared by Gail Mason, mineral data assistant; and international data tables were prepared by William Zajac, Chief, Section of International Data.

roduction of bromine worldwide in 1990 was as follows: the United States, 40%; Israel, 31%; the U.S.S.R., 14%; the United Kingdom, 6%; and other countries, 9%. The U.S. portion of world production has decreased steadily since 1973, when the United States produced 71% of the world supply. The decrease in world share has been a result of environmental constraints and the emergence of Israel as the world's second largest producer. The quantity of bromine sold or used in the United States was about 177 million kilograms valued at \$173 million based on the average actual price for 1990. Exports of elemental bromine and bromine contained in compounds amounted to 17 million kilograms. The price of elemental bromine in bulk was 95 to 101 cents per kilogram. Primary uses of bromine compounds were in flame retardants (28%), agriculture (20%), petroleum additives (14%), well drilling fluids (11%), and other (27%).

DOMESTIC DATA COVERAGE

Domestic production data for bromine was developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the six operations to which a survey request was sent, two responded, representing 41% of total elemental bromine sold or used. Production at the other four operations was estimated by using quantity of brine produced and estimated bromine concentration.

BACKGROUND

Definitions, Grades, and Specifications

In the elemental form, bromine is a

very dark, reddish-brown liquid. Bromine is the only nonmetallic element that is liquid at ordinary temperature and pressure. The natural form of bromine is a solution of sodium bromide in natural brines, saline deposits, salt lakes and seas, and oceans.

Elemental bromine is marketed in a "purified" grade. The specification for this grade is as follows: specific gravity not less than 3.1 at 10° to 20° C; bromine, not less than 99.7%; iodine, none; and chlorine, not more than 0.1%.

Specifications for the various grades of bromine compounds include technical bromine, 99.5% pure, with the chief impurities consisting of chlorine, traces of moisture, and organic matter. Specifications of the United States Pharmacopoeia and the American Chemical Society Committee on Analytical Reagents allow 0.3% chlorine, 0.05% iodine, 0.0002% sulfur (0.006% as sulfate), and no more organic matter in 1 milliliter than will saturate 50 milliliters of 5% sodium hydroxide solution. The term "chemically pure" signifies a minimum of impurities.

Geology-Resources

Bromine is widely distributed in the Earth's crust, but in small quantities. By far the largest potential source of bromine in the world exists in the oceans. At a concentration of only 65 parts per million (ppm), large amounts of water are processed to obtain the bromine.

Arkansas brines contain about 5,000 ppm at depths of 7,500 feet in limestone of the Smackover Formation of Jurassic age. In Michigan, brines containing about 2,600 ppm of bromine occur in the Sylvania Sandstone Formation of the Detroit River Group of Devonian age.

In Israel, bromine is produced from Dead Sea brines as a byproduct of salt, magnesium oxide, and potash production. The waste brines contain 14,000 ppm bromine.

Technology

The Arkansas Geological Commission report three east-west bromine-rich brine fields. Wells are drilled down to the brine level, and a submersible pump is lowered to pump the liquid to the surface. Brine is separated by gravity from any residual gas at the surface and pumped to one of six processing facilities.

At the processing facility, bromine is separated from the brine by a steamingout process. The brine is pumped into the top of a tower constructed of granite and filled with ceramic packing. As the brine falls through the packing material, it reacts with chlorine and steam that are injected at the bottom of the tower. One pound of chlorine yields 1 kilogram of bromine. About 95% of the bromine or about 0.7 to 0.8 kilograms of bromine per barrel of brine is recovered if the raw brine is first acidified to a pH of 3.5. The chlorine replaces the bromine in the brine, and the gaseous bromine rises with the steam out of the top of the tower; there bromine condenses to a reddishbrown liquid that separates from the condensed water vapor because of its heavier density. The bromine liquid can be further purified or reacted with other materials to form bromine compounds. Bromine vapor, a little chlorine, and water vapor are captured at the top of the tower. Hot bromine-free liquor emerges from the bottom of the tower. After neutralizing with lime, the waste liquor is pumped through a heat exchanger to a waste pond. Brine from the pond is reinjected into the same producing zone to maintain hydrostatic pressure.

Seawater contains about 60 to 70 ppm of bromine as sodium bromide or magnesium bromide. Production of bromine from seawater uses the blowing-out process. Raw seawater is acidified by adding sulfuric acid and then chlorine. Air was drawn into the base of the tower and rises as the brine descends. Air

³Bureau of the Census. Includes methyl bromine and ethylene dibromide.

containing bromine passes to the absorption tower. In the absorption tower, bromine reacts with sulfur dioxide and water to form hydrogen bromide and sulfuric acid. The bromine is separated by adding acid to the solution and is distilled by steam. The acid is recycled to acidify the incoming seawater. The gaseous bromine is condensed, separated, and purified. The air-blowing process can also be used to produce an alkali bromide by changing the absorption medium. For instance, using sodium carbonate produces sodium bromide and sodium bromate. The sodium bromate may be recrystallized from solution or reduced with iron to sodium bromide.

Substitutes

Brominated hydrocarbons are used in refrigerant units. Helium could replace a large segment of the chlorofluorocarbon (CFC) market in refrigeration with commercial development of the Stirling cycle engine. Development and testing on a helium refrigeration system is underway that uses less energy than current refrigeration systems.¹

Economic Factors

Costs.—Chlorine is the largest cost factor, representing about 30% of the manufacturing cost of bromine. Other cost factors include brine (22%), operating cost (15%), utilities (14%), overhead (12%), and other (7%).

Taxes.—During 1990, brines produced in Arkansas required the payment of \$2 per 1,000 barrels in severance taxes, and capital equipment was subject to the payment of property taxes. Bromine produced in the United States is subject to Superfund taxes of \$4.45 per ton. Bromine is manufactured using chlorine, which is also subject to a Superfund tax of \$2.70 per ton of chlorine.

Depletion Provisions.—Bromine producers (domestic and foreign) are granted a 5% depletion allowance under the Federal Income Tax Law on the value of bromine produced from brine wells. The depletion allowance can be calculated by the actual cost method.

Operating Factors

Environmental Requirements.—Some bromine-bearing brines contain hydrogen sulfide gas. This gas has a disagreeable odor, is highly toxic, and when burned, will oxidize to sulfur dioxide, an

acid-producing gas. Hydrogen sulfide gas is chemically removed from the incoming brine and converted into elemental sulfur or other nontoxic sulfur-containing compounds.

Toxicity.—Bromine is highly toxic and corrosive and must not be allowed to escape into the atmosphere. Many bromine compounds are also poisonous or irritating and must be packaged in leak proof containers to avoid personal injury. If bromine spills on paper, rags, wood shaving, etc., it will generate considerable heat, which may lead to spontaneous combustion. Bromine reacts with living tissue and must be removed immediately to avoid serious injury.

Bromine vapors are hazardous to the eyes and lungs. Any concentration above 1 ppm in the air for an 8-hour exposure is considered a health hazard. Bromine can be detected by its odor even at this level. Exposure to concentrations of 500

to 1,000 ppm for as little as one-half hour is lethal. The Occupational Safety and Health Administration regulates the working conditions of bromine plants.

When handling bromine, a person should use safety goggles, face shield, rubber gloves, rubber boots, and under some conditions, a self-contained breathing apparatus. Bromine spills are neutralized with a solution of sodium thiosulfate. Gaseous bromine is neutralized with controlled amounts of gaseous ammonia. Electrical switches and connections that may be exposed to bromine vapors should be made of corrosion resistant materials and/or completely sealed from contact with the room air.

Employment.—The U.S. bromine chemical industry employs directly an average of 20 personnel for each \$1 million of sales. These employees work in production, packaging, transportation, marketing, product and process development, quality control, and administration. More than two-thirds of these jobs are concentrated in Union and Columbia Counties of south Arkansas.

Energy Requirements.—Approximately 14% of the bromine manufacturing cost is energy related. The manufacturing cost of bromine is heavily dependent on chlorine and brine cost. Of the total brine cost, 46% is power related, 53% is maintenance cost, and 19% is other costs. Brine cost is dependent on well maintenance cost and energy cost associated with well pumping.

Transportation.—The Research and Special Programs Administration (RSPA), U.S. Department of Transportation, published final rules for hazardous substances (49 CFR Parts 171 and 172). The action complies with a 1986 amendment (Public Law 99-499) to section 306(a) of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) of 1980 (Public Law 96-510). The law mandates that RSPA regulate all Environmental Protection Agency (EPA) designated hazardous substances. The amendment requires shippers and carriers to identify CERCLA hazardous substances, to comply with the Hazardous Materials Regulations, and to make the required notifications if a discharge of a hazardous substance occurs. The effective date of the amendment was December 31, 1990.

ANNUAL REVIEW

Legislation and Government Programs

The EPA concluded that, on the basis of available information, hazards of using brominated flame retardants do not yet warrant regulatory action. Tests performed for the Brominated Fire Retardant Industry Panel and the EPA require extraordinary conditions to produce trace amounts of dibenzofuran, identified as a carcinogen.²

A final amendment to the final rule was published by the EPA in the Federal Register February 13, 1990, that amends 40 CFR part 82. The notice amends the Montreal Protocol on Substances that Deplete the Ozone Layer, a treaty to limit the production and consumption of CFC's and halons that included brominated CFC's.

A section 18 exemption was granted by the EPA to the U.S. Department of Agriculture (USDA) for the use of methyl bromide to control oak wilt on oak logs for export.3 The Governor of the Territory of Guam also received a section 18 quarantine exemption for methyl bromide to control various plant pests on cut flowers and greenery imported from Hawaii and the continental United States. The USDA received a methyl bromide exemption to control various plant pests on imported oranges.4 The EPA granted the Arkansas State Plant Board, the Mississippi Department of Agriculture and Commerce, and the Louisiana Agriculture Department a section 18 exemption for the use of bromoxynil to control certain weeds in rice growing within 1/4 mile of cotton or soybean fields.5

At yearend, 47 petitions and EPA proposals to exempt residues from tolerance requirements were pending, including three for bromoxynil and one for inorganic bromides.⁶

Ethyl Corp. filed with the U.S. Court of Appeals for the D.C. Circuit to stop a final rule issued by the EPA for methyl bromide. Ethyl contends that it does not generate waste because the material is not discarded but recycled, and that wastes from the production facility do not contain hazardous constituents.⁷

EPA assembled a list to use in completing the "Notification of Hazardous Waste Activity," Form 8700-12. Hydrobromic acid is included under EPA Hazardous Waste Number D002 published in the

Federal Register April 18, 1990. A complete description of corrosive wastes can be found in 40 CFR 261.22.

The Consumer Product Safety Commission listed in the Federal Register, December 18, 1990, requirements for child-resistant packaging for home cold wave permanent neutralizers containing sodium bromate or potassium bromate. Eight cases of accidental ingestion of bromate were reported since 1984. The Commission concluded that permanent wave products containing more than 50 milligrams of potassium bromate or 500 milligrams of sodium bromate should be subject to child-resistant packaging standards.

Production

Ethyl Corp. and Great Lakes Chemical Corp. produced and marketed bromine chemicals from plants in Arkansas. Small amounts of unpurified bromine were produced as a byproduct of magnesium production in Michigan and reprocessed for consumption in Arkansas. The Arkansas plants accounted for 97% of U.S. elemental bromine capacity at yearend 1990 and 100% of bromine sold or used. Plant capacity was dependent on brine supplies, concentration of the bromine in the brine, and individual plant extraction processes. In Arkansas, one supply and one disposal well were required for each 4.5 million kilograms per year of bromine produced.

Bromine concentrations in the brine decrease as waste brine depleted of bromine is returned to its source. New wells

must be drilled to provide adequate reserves to ensure future demands of elemental bromine. Each supply well requires an investment in excess of \$1 million and has an average life of about 10 to 15 years.

Consumption and Uses

Fire retardants were primarily tetrabromobisphenol-A and decabromodiphenyl oxide. The U.S. International Trade Commission's (ITC) publication "Synthetic Organic Chemicals, 1990" listed Ethyl Corp. as the only producer of hexabromocyclododecane. Sales of flame retardants account for one-half the worldwide plastic additives market and are growing. Brominated hydrocarbons are the major materials used to make flame retardants.

Suppliers of flame-retardant polymers continue to develop alternatives for brominated compounds. FMC Corp. planned a high-efficiency brominated phosphate-ester flame retardant for engineering plastics and alloys. The combination of phosphorus and bromine produce a product characterized by high molecular weight and low volatility.⁸

A bromine salt derived from pyridine has several advantages over the corresponding pyridine reagent because of ease in preparation of high yields, stability and ease of handling, utilization on a commercial scale, and ease of separation from the product stream for recycling. Fibers and cords prepared using organic bromides exhibit a high resistance to thermal degradation.⁹

1000				

Actual production capacity is limited by brine availability.

²Bromine produced at this plant is reprocessed in Arkansas.

³Data do not add to total shown because of independent rounding.

Agricultural usage is primarily as methyl bromide used in soil fumigation. During 1990, alternative agriculture became topical. Farmers practicing alternative agriculture aim at improving profits. limiting dependence on agricultural chemicals, and increasing use of environmentally friendly procedures. Several factors occurring during the 1980's have induced alternative agriculture. Farmers became interested in alternatives because of the rising costs of purchased pesticides and fertilizers and growing concerns about the contamination of water. In 1988, the EPA detected 46 pesticides, including Bromacil, dibromochloropropane, and ethylene dibromide (EDB), that were attributed to normal agricultural use in the ground water of 26 States. 10

Demand for EDB is in gasoline additives as a scavenger for lead antiknock. The ITC's publication "Synthetic Organic Chemicals, 1990," listed Great Lakes and Ethyl as the only producers of EDB used in gasoline additives during 1990.

Bromine was used in clear brine drilling fluids used in work-over and completion fluids. Clear fluids ensure protection, stability, and control. Densities between 8.35 and 19.2 pounds per gallon are possible. Clear fluids can produce drilling rates double or triple that of a mud systems if used without solids. Clear fluids keep clay damage to a minimum; small amounts of solids can reduce a well's production potential from 10% to 85%.

The ITC's publication, "Synthetic Organic Chemicals, 1990," reported that the Dyes & Pigments Div. of Mobay Chemical Corp. produced Pigment Red 168, dibromoanthranthrone orange. Red 168 was used in automotive metallic applications because of its transparency.

Bromoethane is used in pesticide and pharmaceutical manufacture and was imported by one company. ¹¹ The New York City Parks Department reported using bromadiolone, an anticoagulant containing 15% bromine, to decrease the rat population. The rat community was unusually large because poisoning was replaced last summer by "an ecological pure" plan that did not work. ¹²

Bromine was also used in water treatment as a slime and biocidal control product. Bromine rivals chlorine in hot water applications, such as hot tubs and spas, where the higher priced bromine-base sanitizers are more competitive because of their longevity due to heat resistance. Bromine is used in cold water,

mostly in the south and west where pools stay filled year-round and receive intense sunshine. 13

Prices

Bromine was sold under contracts negotiated between buyer and seller. Price quotations do not necessarily represent prices at which transactions actually occurred, nor do they represent bid and asked prices. They were quoted here to serve only as a guide to yearend price levels.

Foreign Trade

The ITC held hearings during 1989 concerning the withdrawal of the generalized system of preference (GSP) for imports of sodium bromide from Israel. Israel received duty-free treatment on its bromine products in all major world markets except the United States, where duties are paid on three significant bromine products. The GSP was withdrawn for sodium bromide, but the duty will drop to zero in 1995.

World Review

Capacity.—The data in table 4 are

rated capacity for mines and refineries as of December 31, 1990.

Israel.—Israeli Chemicals Ltd. (ICL), the parent company of Dead Sea Bromine, was for sale during the year. At the beginning of the year, a maximum of a 25% share was available for public ownership. In May, the Finance ministry officials stated that up to 49% of ICL was available for sale. Israel declined an offer for purchase of 51% of the ICL and continued plans to offer public shares on the stock exchange.

U.S.S.R.—The Soviet Institute of Geochemistry and Analytical Chemistry was seeking foreign investment for a process to manufacture bromine from seawater. The process uses a two-chamber device with an electrode in each side of the chamber that produces magnesium hydroxide and elementary bromine. Magnesium bromide is formed by reversing the electrical flow. The process was demonstrated on brines from the Black and Okhotst Seas. Extraction efficiency was 75%. 14

number 8838 to Sandia Laboratories from funds supplied by the U.S. Department of Energy (DOE), concluded studies on zinc-bromine batteries. The 5-year study (NTIS report number DE90014751/ABS) evaluates the potential of the batteries for bulk energy storage applications, such as utility load leveling. The low cost of the battery reactants and the potential for long life make the system attractive for energy storage.

An evaluation of the harmful results of exposure to dioxin, including brominated flame retardants, indicates that a certain minimum exposure level of any biological or toxic substance must be achieved before any adverse effect occurs. There is a dose level below which no biologically significant effects can occur. No human toxicity, with the exception of chloracne (a skin condition), can be reliably attributed to dioxin exposure. 15

Chemicals called halons pose a greater threat to the ozone layer than CFC's. Halons, by definition, are hydrocarbon fire extinguishers, and those in general use fluorocarbons that contain bromine. Halon 1301, a gas, and halon 1211, a liquid, are highly volatile, leave no residue on evaporation, and do not conduct electricity. Halons are used to protect aircraft, computer rooms, museums, art galleries, libraries, telephone exchanges, and other areas requiring a clean, non-damaging agent.

Halons suppress fires by several mechanisms. Like carbon dioxide and water, they cool and smother the fire and dilute the burning fuel and oxygen. They also act by combining chemically to remove fuel from the fire. Because of this additional chemical action, halon levels in air of less than 5% are sufficient to suppress almost all flames. Carbon dioxide, the other commercially used fire extinguisher, requires a concentration of greater than 30%, which is above toxic levels, or can leave a residue. 16

Great Lakes Chemical Corp., the only domestic producer of both halon 1211 and 1301, reported developing FM-100, an effective halon alternative. FM-100, bromodifluoromethane (halon 1201), has an ozone depletion potential (ODP) of one-twentieth of existing halons. E. I. du Pont de Nemours & Co. Inc. reported to have developed HCFC-125, a not fully halogenated CFC, as a replacement for halon 1301 and HCFC-123 as a replacement for halon 1211.¹⁷

¹Table includes data available through Apr. 19, 1991.

²In addition to the countries listed, several other nations produce bromine, but output data are not reported, and available general information is inadequate for formulation of reliable estimates of output levels.

OUTLOOK

Sales of bromine, primarily in compounds, has increased about 23% since 1969. This represents an annual rate of increase of about 1.1% per year. These increases have been attributed to increased use of bromine in fire retardants. sanitizers, and well drilling fluids. Bromine is expected to increase in demand at the same 1.1% rate through the next 5 years. Demand as a fire retardant will offset any decreases in petroleum. Bromine usage in well drilling fluids was expected to remain depressed because well drilling remains at 1990 levels and the

Clean Air Act amendments encourage alterate forms of energy.

Petroleum

Demand for bromine as a gasoline additive has declined each year since the EPA issued regulations in the 1970's to reduce the lead in gasoline. Bromine in the form of ethylene dibromide is used as a "scavenger" for the lead to keep the lead from depositing in the engine. In 1979, the amount of bromine sold reached a peak of 225 million kilograms. The rapid decline to 141 million kilograms in 1986 was a direct result of the limits on lead in leaded gasoline. The European Community

continued discussions to reduce lead levels in gasoline.

Sanitary Preparations

Bromine has found usage in swimming pools, hot tubs, and whirlpools. The sanitary preparation field is an area where bromine has been found to be safer than its substitutes. The use of bromine will continue to grow in this area, closely following the gross national product in real growth.

Fire Retardants

Federal regulations covering flammability of private and public building materials and furnishings have required greater amounts of fire retardant chemicals to be used in these materials and furnishings. The costs and/or benefits of fire retardants versus environmental hazards in the United States is expected to grow as organic materials replace metals in transportation, infrastructure, and packaging. Several State governments continue to support strong consumer laws that protect State residents from hazardous products produced in other States.

Other Uses

Usage of calcium bromide and zinc bromide in well drilling fluids decreased during the 1980's when the domestic petroleum industry suffered a severe recession. Federal laws enacted to encourage alternative forms of power in automotive engines are likely to have a depressive effect on increases in petroleum demand. The Clean Air Act Amendments of 1990 (Public Law 101-549) have

an amendment that will require mobile sources, such as cars and trucks, to use the most effective technology possible to control emissions.

CADMIUM

By Thomas O. Llewellyn

Mr. Llewellyn is a physical scientist with the Branch of Industrial Minerals. He has covered cadmium for 4 years. Domestic survey data were prepared by Giovanni Jacarepaqua, mineral data assistant; and international data were prepared by William L. Zajac, Chief, Section of International Data.

omestic production of cadmium metal in 1990 increased about 8%. Four companies operating four plants produced all of the domestic cadmium. Canada continued as a major source of imported zinc concentrates from which cadmium was extracted as a byproduct. The New York dealer price range of cadmium metal, at \$5.25 to \$5.35 per pound at the beginning of 1990, declined to \$3.00 to \$3.20 per pound by yearend.

DOMESTIC DATA COVERAGE

Domestic production data for cadmium metal and compounds are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the four metal-producing plants to which a survey request was sent, all responded, representing 100% of the total cadmium metal production shown in tables 1 and 3. Of the 10 operations that produced cadmium compounds to which a survey request was sent, all responded, representing 100% of the cadmium content of production of cadmium compounds shown in table 2.

ANNUAL REVIEW

Legislation and Government Programs

On February 6, 1990, the Occupational Safety and Health Administration (OSHA) published a proposed rule to reduce the existing limit for occupational exposure to airborne cadmium. The rule, as proposed, would lower the existing permissible 8-hour exposure limit (PEL) of 100 micrograms per cubic meter for cadmium fumes and 200 micrograms

per cubic meter for cadmium dust to an 8-hour time-weighted exposure limit of either 5 or 1 micrograms per cubic meter as alternatives for all forms of cadmium.

The proposed rule also covers supplementary provisions for employee protection, including exposure monitoring, medical surveillance, record keeping, and proper selection and maintenance of personal protective equipment. OSHA held two public hearings, one in Washington, DC, in June, and the other in Denver, CO, in July. These hearings were held to obtain further information on the feasibility of meeting a 1 or 5 micrograms per cubic meter PEL for cadmium using engineering controls and/or administrative controls. The agency was expected to reach a final decision by the fourth quarter of 1991.1

Strategic Considerations

Cadmium is included in the National Defense Stockpile (NDS) because of its importance in specialized military applications such as plating where substitutes may be in short supply or unsatisfactory. In addition, the United States depends on imports to meet part of its requirements.

Purchase of cadmium under the Strategic and Critical Minerals Stockpiling Act began in 1948, and the initial stockpile requirements were completed in 1955. Cadmium was also acquired for the supplemental stockpile from 1956 through 1963 under provisions of the Agricultural Trade Development and Assistance Act of 1954, which enabled the U.S Department of Agriculture Commodity Credit Corp. to barter surplus perishable goods for foreign-produced cadmium metal. Government shipments from stockpile excesses for 1964-76 totaled 3,918 tons. In April 1980, the stockpile goal for cadmium was set at 5,307 tons. At the end of 1990, the NDS cadmium inventory was 2,871 tons.

Production

Primary cadmium was produced by ASARCO Incorporated, Denver, CO; Big River Zinc Corp., Sauget, IL; Jersey Miniere Zinc Co., Clarksville, TN; and Zinc Corp. of America, Bartlesville, OK. The companies in Illinois, Oklahoma, and Tennessee recovered cadmium as a byproduct of smelting domestic and imported zinc concentrates. The company in Colorado recovered cadmium from other sources such as lead smelter baghouse dust.

Consumption and Uses

Based on production, trade, and stock data, the apparent domestic consumption of cadmium in 1990 was lower than that of 1989.

An estimated apparent consumption pattern for 1990 was as follows: batteries, 40%; coating and plating, 25%; pigments, 13%; plastic and synthetic products, 12%; and alloys and other, 10%.

Stocks

Inventories of cadmium metal held by metal producers at the end of 1990 were 221 tons, 8% under those held at the close of 1989. Compound manufacturers' stocks of cadmium metal rose 39% above those held at yearend 1989. Inventories of metal held by distributors were essentially unchanged from those reported the previous year.

Market and Prices

The New York dealer price range for cadmium metal, published by Metals Week, at the beginning of 1990 was \$5.25 to \$5.35 per pound, a sharp decline from the price range of \$8.45 to \$8.65 quoted at the beginning of 1989. The prices for cadmium metal followed a steady downward trend throughout the first 11 months of 1990 and, by the end of November, ranged from \$1.20 to \$1.50 per pound. The steady price decline was due to lower growth in demand for nickel-cadmium batteries and a decline in the market for other end uses of cadmium such as coating and plating, pigments, and plastics and synthetic products. However, the domestic cadmium market recuperated during December and closed the year at a range of \$3.00 to \$3.20 per pound.

Foreign Trade

The Bureau of the Census reported that the United States imported about 137 million nickel-cadmium batteries in 1990. Hong Kong, Japan, Mexico, and

²Total supply minus exports and yearend stocks.

Year	Quantity (metric tons)	Value (thou- sands)	
1988	613	\$3,697	
1989	369	857	
1990	385	1,174	

Source: Bureau of the Census.

Singapore supplied approximately 96% of the total battery imports.

Under the Harmonized Tariff Schedule of the United States, which has been in effect since January 1, 1989, cadmium sulfide and pigments and preparations based on cadmium compounds from most favored nations (MFN) are subject to a 3.1% ad valorem duty; for non-MFN, a 25% ad valorem duty was retained. Imports of unwrought cadmium, waste and scrap, and powders, are duty free for MFN, whereas a statutory duty of 33 cents per kilogram was imposed on these materials for non-MFN.

Cadmium producers are granted a depletion allowance of 22% on domestic production and 14% on foreign production.

Cadmium is taxed under the Superfund Amendments and Reauthorization

Act of 1986, Public Law 99-499. The tax, to be collected from producers and importers, was \$4.45 per short ton of cadmium metal. The tax ends on December 31, 1991.

World Review

Industry Structure.—World refinery production of cadmium was estimated at 20,097 metric tons in 1990. This represented a decrease of 4.6% below production levels achieved during 1989. The U.S.S.R. was the largest producer of refined cadmium in 1990, followed by Japan, Belgium, the United States, Canada, the Federal Republic of Germany, and Mexico. These seven countries accounted for approximately 60% of the world's refined cadmium production in

¹Because of the implementation of the Harmonized Tariff System in Jan. 1989, import categories for 1989 are not necessarily comparable with those in 1988.

²General imports and imports for consumption were the same in 1988, 1989, and 1990.

³Includes waste and scrap (gross weight).

Less than 1/2 unit.

⁵Data do not add to total shown because of independent rounding.

1990. Because cadmium is recovered mainly as a byproduct of zinc ore processing, many producers of zinc and zinc compounds produce primary cadmium as an integral part of their operation. In some cases, residues and flue dusts from zinc producers are used directly by cadmium producers. Some cadmium may also be recovered from flue dust generated at various lead and copper, smelters; however, the amount of this production is not known.

Capacity.—The data in table 7 represent rated annual production capacity for mines and refineries on December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable, long-term operating rate, based on the physical equipment of the plant and routine operating procedures for labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Estimated. Preliminary. Revised.

¹This table gives unwrought production from ores, concentrates, flue dusts, and other materials of both domestic and imported origin. Sources generally do not indicate if secondary metal (recovered from scrap) is included or not; where known, this has been indicated by a footnote. Data derived in part from World Metal Statistics (published by World Bureau of Metal Statistics, Ware, United Kingdom) and from Metal Statistics (published by Metallgesellschaft Aktiengesellschaft, Frankfurt am Main, Federal Republic of Germany). Cadmium is found in ores, concentrates, and/or flue dusts in several other countries, but these materials are exported for treatment elsewhere to recover cadmium metal; therefore, such output is not reported in this table to avoid double counting. This table includes data available through Apr. 2, 1991.
²Reported figure.

³Includes secondary.

Reserves.—Cadmium reserves were obtained by applying an average recovery factor of 0.36% to zinc reserve data. On this basis, the domestic reserves of cadmium were estimated at 72,000 tons. Total world reserves were estimated to be

about 535,000 tons. The world's largest reserves of cadmium were in the United States and Canada.

Cadmium minerals are not found in commercially viable deposits, and its abundance in the Earth's crust is about

0.2 parts per million. Greenockite (CdS) is the only cadmium mineral of importance. It is not found in any isolated deposit, but is nearly always associated with zinc sulfide. Cadmium is usually produced as a byproduct in the recovery of primary zinc from zinc ores and also from some lead ores or complex copperlead-zinc ores. However, it is generally agreed that the cadmium in lead and copper ores is associated with the zinc sulfide present rather than with the other minerals.

Current Research

Developments in cadmium technology during the year were abstracted in Cadscam, a quarterly publication available through the Cadmium Association, 42 Weymouth Street, London, WIN 3LQ, England.

The Cadmium Association, England; the Cadmium Council Inc., Greenwich, CT; and the International Lead Zinc Research Organization Inc., Research Triangle Park, NC, published the Proceedings of the Sixth International Cadmium Conference held in Paris, France, April 19–21, 1989. The edited proceedings contain the text of the

33 papers presented in Paris, which included topics of great interest such as Regulating Cadmium and New Technology and Markets for Cadmium.²

The Roskill organization issued its 1990 cadmium report. This comprehensive report discusses and analyzes world production of cadmium by country and individual company. It also contains information on end-use markets, international trade patterns, and trends in prices.³

OUTLOOK

The short-term demand for cadmium in the United States was expected to fall below the level of 1990. This decline was expected to be the result of continuing lower demand for cadmium in coating and plating, pigments, and plastics and synthetic products during the next 4 years. There was a strong indication that the world demand for primary cadmium will follow the same trend, for the reasons mentioned above, which are a consequence of stricter environmental and health controls now under consideration in North America and Europe.

CALCIUM AND CALCIUM COMPOUNDS

By M. Michael Miller

Mr. Miller, a physical scientist with 13 years of minerals experience with the Department of the Interior, has been the commodity specialist for calcium and calcium compounds since 1989. Domestic survey data were prepared by Joseph C. Daniels, mineral data assistant.

alcium, the fifth most abundant element in the Earth's crust, is chemically very active and is found in a host of minerals that occur in nearly every geologic environment. The U.S. Bureau of Mines publishes reports for a variety of calcium-containing minerals and compounds because of their commercial significance and contribution to the quality of human life. Calcium fluoride is sold as fluorspar; calcium sulfate as gypsum or anhydrite; calcium oxide and hydroxide as lime; calcium phosphate as phosphate rock; and natural calcium carbonate as either limestone, marble, calcareous marl, or shell. Information on these commodities can be obtained in the U.S. Bureau of Mines annual reports entitled "Fluorspar," "Gypsum," "Lime," "Phosphate Rock," "Crushed Stone," and "Dimension Stone." Other calcium compounds are discussed in the report concerning the element with which calcium is combined; for example, calcium bromide is covered in the "Bromine Annual Report." "Calcium and Calcium Compounds Annual Report" includes calcium metal, calcium chloride, precipitated calcium carbonate, and various other calcium compounds not covered elsewhere.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines develops domestic production data for calcium chloride from a voluntary survey of U.S. operations entitled "Calcium Chloride and Calcium-Magnesium Chloride." Of the nine operations polled, seven responded, representing less than 25% of the total production shown in table 2. Production for the two nonrespondents was estimated using data from previous | Source: Quigley Company Inc., a subsidiary of Pfizer Inc.

years, published plant capacity, and contacts within the industry.

BACKGROUND

Grades and Specifications

Calcium metal is usually sold in the form of crowns, broken crown pieces or nodules, or billets, which are produced by melting crowns in an argon atmosphere. The metal purity in these forms is at least 98%. Higher purity metal is obtained by redistillation. Calcium metal is usually shipped in polyethylene bags under argon in airtight steel drums. Table 1 shows typical specifications for commercial grade, melted grade, and redistilled grade.

The American Society for Testing and Materials (ASTM) issues a standard specification for calcium chloride designated D 98. It covers technical-grade calcium chloride to be used for road conditioning purposes, ice removal, concrete curing, acceleration of the set of concrete, and as a desiccant. D 98 covers two types of calcium chloride, solid (Type S) and liquid (Type L). Solid occurs in flake, pellet, granular, and pow-

der form in concentrations of 77%, 90%, and 94% minimum. Liquid occurs as water solutions of calcium chloride in concentrations varying from 30% to 45%. Calcium chloride is divided into three grades: Grade 1-77% minimum, Grade 2-90% minimum, and Grade 3-94% minimum. Within each grade there are sieve-size requirements for flake, pellet, granular, and powder forms.1

Technology

Calcium Metal.²—In 1808, Davy produced elemental calcium as a mercury amalgam by the electrolysis of calcium chloride in the presence of a mercury cathode. He and others were only marginally successful in attempts to isolate the pure metal by distilling the mercury. In 1855, Bunsen and Matthiessen attempted to produce calcium metal by the electrolysis of a mixture of calcium. strontium, and ammonium chlorides to lower the electrolyte melting point, but produced only finely divided calcium alloys. This process was slowly improved, and by 1904, Rathenau obtained calcium by the electrolysis of molten calcium chloride held at a temperature above the

TABLE 1 CALCIUM METAL—TYPICAL SPECIFICATIONS

(Parts per million)

melting point of the salt but below the melting point of calcium metal. An iron cathode just touched the surface of the bath and was raised slowly as the relatively chloride-free calcium deposited on its end. This process accounted for virtually all calcium metal production from 1904 to 1940.

Prior to 1939, calcium was manufactured exclusively in France and Germany. With the outbreak of World War II. an electrolytic calcium plant was constructed at Sault Ste. Marie, MI, by the Electro Metallurgical Corp. Large quantities of calcium were required as the reducing agent for uranium production. In addition, the U.S. Army Signal Corps used calcium to produce calcium hydride, which could easily be transported to remote areas and used as a source of hydrogen for meteorological balloons. To satisfy these needs, an aluminothermic reduction process was developed. Developed earlier on a laboratory scale in 1922, the process was improved and commercialized by the New England Lime Co. in Canaan, CT, which later became a division of Pfizer Inc.

The aluminothermic process, or Pidgeon process as it is sometimes called, begins with quarried high-calcium limestone calcined to form calcium oxide. The calcium oxide is ground to a small particle size and dry-blended with finely divided aluminum. The mixture is compacted into briquets to ensure good contact of reactants. The briquets are placed in horizontal metal tubes, called retorts, made of heat-resistant steel and heated in a furnace to 1,100° to 1,200° C under high vacuum, and the calcium oxide is reduced to calcium metal. The calcium metal vapor is collected in the water-cooled condenser section of the retort at about 700° C. After the reaction has proceeded for about 24 hours, the vacuum is broken with argon, and the condensed blocks of 98%-pure calcium metal, called "crowns," and the calcium aluminate reaction product are removed.

For certain applications greater than 98% purity is required, which is achieved by redistillation. Crude calcium is placed in the bottom of a large vertical retort equipped with a water-cooled condenser at the top. The retort is sealed and evacuated to a pressure of less than 6.6 pascal (0.05 millimeters of mercury), while the bottom is heated to

900° to 925° C. The calcium quickly distills into the condensing section, leaving behind the bulk of the less volatile impurities. Subsequent processing must take place under exclusion of moisture to avoid oxidation. Redistillation does not greatly reduce the impurity level of volatile materials such as magnesium.

Calcium Chloride.³—Domestic calcium chloride is produced from natural brines and by reacting hydrochloric acid with limestone. Most U.S. production is natural from brine wells in Michigan, with a small amount from dry lake beds in California.

Initial efforts to stimulate the development of Michigan salt and brine deposits took place in 1859. The State legislature passed a bill authorizing payment for Michigan salt. By 1870, saw mill operators were augmenting their income by using waste lumber as fuel to evaporate brines. In 1882, solution mining of rock salt began, and Michigan soon became the leading salt-producing State.

By 1914, an integrated process was developed using three vacuum evaporators to extract various brine components. Bromine was extracted first in an electrolytic cell, and the debrominated brine was then processed through a heated vacuum evaporator. This process precipitated sodium chloride, which was used to produce chlorine, hydrogen, and sodium hydroxide. The brine was then sent to a second evaporator where magnesium chloride was precipitated out. The brine from the second evaporator went to a third evaporator, which produced precipitated hydrates of calcium chloride and a 38% calcium chloride product.

Today the process has been expanded and improved to extract, in sequence, iodine, bromine, magnesium chloride, and calcium chloride. The calcium chloride is derived from the brine left over after processing the magnesium chloride into magnesium hydroxide. This brine is about 25% calcium chloride, and it is processed through double or triple effect vacuum evaporators to make a 32% to 45% solution. Unwanted alkali chlorides are precipitated here and can be removed by settlers and centrifuges. The brine undergoes further evaporation to attain an anhydrous product of 78% to 94% calcium chloride concentration.

Precipitated Calcium Carbonate. 4—Calcium carbonate occurs in two crystalline forms—aragonite and calcite. These forms possess different physical properties. There are three basic processes for the manufacture of calcium carbonate as a precipitate. The processes include the lime-soda process, the lime-ammonium chloride process, and the carbonation process. All three start with a dilute lime hydrate in aqueous suspension, descriptively called milk-of-lime.

In the lime-soda process, milk-oflime is reacted with sodium carbonate to produce calcium carbonate and sodium hydroxide. The commercial alkali manufacturers used this process, which produced as a byproduct a coarse calcium carbonate precipitate. Production of a uniform, fine-particle-size precipitate could only be achieved at the expense of the primary goal, caustic soda recovery.

In the lime-ammonium chloride process, milk-of-lime is reacted with ammonium chloride to produce calcium chloride. The calcium chloride is purified and then reacted with soda ash to form calcium carbonate. The process can be fine tuned by modifying the addition times, method and rate of agitation, pH, concentrations, and reaction temperatures. This process requires a lowcost source of sodium carbonate and calcium chloride, and production, historically, has been as a satellite to Solvay process synthetic soda ash plants. The last domestic synthetic soda ash plant closed in 1986.

The most common production process used in the United States is the carbonation process. Carbon dioxide is bubbled through milk-of-lime to form a precipitate of calcium carbonate and water. The reaction conditions determine the particle size and shape of the resulting aragonite or calcite. To modify the dimensions and performance characteristics of the precipitate, it is necessary to adjust a range of variables that include concentration, starting temperature, pH, degree and type of mixing, solution rates, and the addition of additives. Calcite, aragonite, or a mixture of both can be produced, although commercial forms are usually exclusively one form or the other. The carbonation process is the most complex of the three processes. Because of the low cost availability of raw materials, it has become the process of choice and forms the foundation of the expanding network of satellite precipitated calcium carbonate plants adjacent to pulp and paper mills.

ANNUAL REVIEW

Strategic Considerations

Redistilled-grade calcium metal was used to reduce uranium dioxide, a fuel in some types of fission reactors. The nuclear applications of calcium metal gave it strategic significance; the U.S. Department of State would not permit sales to countries not signatory to the United Nations Nuclear Nonproliferation Treaty.

Production

Pfizer Inc. produced calcium metal at Canaan, CT, by the Pidgeon process, in which high-purity calcium oxide (produced by calcining limestone) and aluminum powder are compacted into briquets and heated in vacuum retorts. The vaporized calcium metal product collects as a "crown" in a water-cooled condenser. Production was down about 10% compared with that of 1989.

Pfizer produced commercial-grade 98.5% calcium in eight shapes and high-purity redistilled 99.2% metal in three shapes, with other shapes available on request. They produced an 80%-20% calcium-magnesium alloy, a pure calcium wire used in the steel industry to modify inclusions, and a 73%-27% calcium-aluminum alloy or unalloyed calcium-aluminum briquet. Elkem Metals Co., a Norwegian-owned company with head-quarters in Pittsburgh, PA, produced a calcium-silicon-barium-aluminum alloy at its plant in Niagara Falls, NY, and imported several other calcium alloys.

Michigan was the leading State in natural calcium chloride production; California was a distant second. The Dow Chemical Co. and Wilkinson Chemical Corp. recovered calcium chloride from brines in Mason and Lapeer Counties, MI. Dow's Ludington plant produced calcium chloride pellets, flake, and liquid; Wilkinson marketed calcium chloride solutions only. In addition, Martin Marietta Magnesia Specialties marketed some byproduct calcium chloride from its brine operations in Michigan. National Chloride Co. of America.

Cargill's Leslie Salt Co., and Hill Brothers Chemical Co. produced calcium chloride from dry-lake brine wells in San Bernadino County, CA. Hill Brothers Chemical also produced from a second operation near Cadiz Lake, CA. Magnesium Corp. of America marketed some byproduct calcium chloride from its magnesium production operations in Rowley, UT.

Allied Signal Inc. recovered synthetic calcium chloride as a byproduct at its Baton Rouge, LA, plant using hydrochloric acid and limestone. Tetra Chemicals produced calcium chloride from a plant near Lake Charles, LA, and from its liquids plant at Norco, LA. Occidental Chemical Corp. manufactured calcium chloride at Tacoma, WA, using limestone and hydrochloric acid. Additional synthetic calcium chloride production came from Standard Chlorine at Delaware City, DE.

At the end of 1990, there were 24 precipitated calcium carbonate (PCC) plants operating in the United States. Pfizer Inc. had 15 satellite PCC plants in operation in the United States plus an additional 2 in Canada and 1 in Japan. GK Carbonate operated two satellite plants in the United States and one in Canada. There are reportedly four additional companies operating satellite PCC plants. There are three companies that produce PCC for the open market: Pfizer Inc. at Adams, MA; Mississippi Lime Co. at Ste. Genevieve, MO; and Continental Lime Inc. at Takoma, WA. The 24 U.S. plants have an estimated capacity of 950,000 metric tons.

Calcium hypochlorite was produced by Olin Corp. at Charleston, TN, and PPG Industries Inc. at Natrium, WV. Sales were relatively unchanged from those of 1990. Total domestic calcium hypochlorite capacity was 96,600 metric tons.

Consumption and Uses

Calcium metal was used in the manufacture of maintenance-free and sealed lead-acid batteries, as an aid in removing bismuth in lead refining, and as a desulfurizer and deoxidizer in steel refining. It was used to reduce oxides of the rare earth neodymium and boron for alloying with metallic iron for use in neodymium-iron-boron permanent magnets. It was used as a reducing agent to recover many of the less-common metals such as hafnium, plutonium, thorium, tungsten, uranium, and vanadium and the rare earths from their oxides or fluorides. Some minor uses were in the preparation of vitamin B and chelated calcium supplements and as a cathode coating in some types of photoelectric tubes. Domestic consumption of calcium metal decreased in 1990. This was evidenced by lower production rates by Pfizer Inc. and decreased imports reported by the Bureau of the Census, U.S. Department of Commerce.

Calcium chloride was used to deice pavements, to control dust, to stabilize road bases, to thaw coal and other bulk materials, in oil and gas drilling, for concrete-set acceleration, as tire ballasting, and in miscellaneous other uses. The principal use of calcium chloride was to melt snow and ice from roads. Calcium chloride is more effective at lower temperatures than rock salt and was used mainly in the Northern and Eastern States. Because of its considerably higher price, it was used in conjunction with rock salt for maximum effectiveness and economy.

Precipitated calcium carbonate was

used as a pigment for brightness and opaqueness in premium-quality coated papers and as a filler in uncoated papers. In coated paper, PCC was used in the coating to improve paper brightness and print clarity. In uncoated papers, it was used as a filler and extender in the paper to improve the optical, physical, and price-performance characteristics of the paper. The plastics industry used a fine and ultrafine grade of PCC to lower raw material costs, increase impact resistance, improve surface smoothness, and enhance color stability. Its major use was in polyvinyl chloride (PVC), but it was also used in such polymers as polystyrene, polypropylene, and polyethylene. The paint industry used it as a replacement for expensive TiO2 pigment and to control flow properties, provide body, and maintain dispersion.5

Calcium hypochlorite was used to disinfect swimming pools, which accounted for more than 85% of domestic demand, and in other municipal and industrial bleaching and sanitation processes. It was used as an algicide, bactericide, deodorant, water purifier, disinfectant, fungicide, and bleaching agent.

Calcium nitrate was used as a concrete additive to inhibit corrosion of steel reinforcement bars, accelerate setting time, and enhance strength.

Calcium carbide and calcium-silicon alloy were used to remove sulfur from molten pig iron as it was carried in transfer ladles from the blast furnace to the steelmaking furnace.

Prices

The published price of calcium metal last changed April 19, 1990, according to the Metal Bulletin. The yearend published price range for calcium metal, minimum 98%, was \$2.25 to \$2.75 per pound, U.S. free market.⁶ This was equivalent to \$4.96 to \$6.06 per kilogram. This represented a dramatic drop in the published price of more than 20% compared with that of 1989. Calcium metal is sold on a contract basis, and the contract price may vary greatly from the published price. The published price range only serves as a guide to the prices obtained by dealers and producers.

Solid calcium chloride prices were quoted by Chemical Marketing Reporter for Grade 1 (minimum 77%) and Grade 3 (minimum 94%), generally in flake or pellet form. Liquid

prices were quoted for a range of 30% to 42% concentration and for 45% concentration. Although actual prices are negotiated and usually discounted, yearend 1990 published prices and specifications are shown in table 3.

Foreign Trade

U.S. exports of calcium chloride increased by about 15% in 1990, with a substantial portion of the increase going to Canada and the United Arab Emirates. The United States exported 28,959 metric tons of calcium hypochlorite to many countries for an export value of about \$30,200,000. More than 5,326 metric tons of calcium carbide was exported to 20 countries for an export value of more than \$2,861,000. Exports of 534 metric tons of calcium cyanamide went to Canada and Mexico.

Imports of calcium metal decreased

by more than 4% compared with those of 1989; this broke a 5-year string of annual increases. The majority of shipments came directly from China, France, Canada, and the U.S.S.R., in descending order. According to Bureau of the Census import data, the average c.i.f. unit value of imported calcium metal was \$5.81 per kilogram (\$2.63 per pound). Although the average is within the published price range, there was a tremendous disparity between the value of material from the U.S.S.R. and China and the value of material from Canada and France.

During 1990, the U.S. International Trade Administration/Import Administration, Department of Commerce, completed several antidumping duty administrative reviews on calcium hypochlorite from Japan. The reviews covered April 1, 1986, through March

31, 1990, and involved Tohoku Tosoh Chemical Co. Ltd., Nankai Chemical Industry Co. Ltd., (previously Nissin Denka Co. Ltd.), and Nippon Soda Co. Ltd. The final results were the determination to assess dumping duties equal to the calculated differences between the U.S. price and the foreign market value and to revoke the antidumping duty order with respect to Nippon Soda Co. Ltd. The current antidumping duty was assessed at 10.56%.⁷

Current Research

The U.S. Bureau of Mines, through its basic research program, has investigated an alternative electrochemical process for the production of calcium metal. The process involved electrowinning of a calcium-tin alloy followed by electrorefining to produce calcium metal. The calcium metal analyzed 99.2%, which is purer than most commercial grades (see table 1). This twostep electrochemical process is a simple and efficient method for the production of calcium metal. Although the electrowinning cell should be easily scaled up, the electrorefining cell needs further development to determine what current efficiency can be expected and what recovery problems will be encountered in handling molten calcium metal, in scale up, and in longer term cell operation.8

In Israel, Tel Aviv University's Authority for Applied Research and Industrial Development Ltd. (RAMOT) reported the development of a patented, C-size, calcium-thionyl chloride prototype cell and announced that it is now ready for demonstration and evaluation. At low amperage rates of 0.2 milliamps to 25 milliamps, the cell delivers 5.5 ampere-hours, and at 0.8

amperes, it delivers 4.4 ampere-hours. It has an open-circuit voltage of 3.15 volts with a volumetric energy density 50% to 80% higher than a standard lithium-sulfur dioxide cell. Having undergone limited safety testing, it is considered safer than existing lithium-sulfur dioxide batteries.⁹

OUTLOOK

The major end uses of calcium metal are in the lead industry, primarily in maintenance-free and sealed lead-acid batteries; in the steel industry; and as a reducing agent of rare-earth oxides for permanent magnet manufacture. These three areas each account for roughly one-third of domestic calcium metal consumption.

The majority of the maintenancefree and sealed lead-acid batteries go into the U.S. starter battery market. Owing to the economic slowdown in 1990, it is estimated that calcium metal consumption in this market segment shrank by nearly 3%. Based on projections made for the battery industry, and assuming no growth in overall lead consumption and the continuation of sluggish economic conditions, it is estimated that consumption will be flat in

1991. Beyond 1991, calcium metal consumption in this market segment is expected to grow by 2% to 3% annually through 1994. 10

Raw steel production was essentially unchanged in 1990 compared with that of 1989. However, owing to the condition of the economy, raw steel production is expected to decrease by 5% to 10% in 1991. The number of steel companies using calcium metal is expected to increase in 1991, but because of the anticipated decrease in raw steel production, consumption of calcium metal in this market is expected to be flat in 1991. Industry estimates call for 5% to 10% annual growth when the economy and the steel industry rebound. This growth is fueled by the increased efficiences achieved by using calcium.

The most disappointing market for calcium metal in 1990 appears to have been its use as a reducing agent of rare-earth oxides for permanent magnet manufacture. Estimates of annual growth failed to materialize in 1990, partially owing to the economy and possibly owing to a shift in rare-earth production to Pacific Rim countries. Consumption in this area is expected to be flat in 1991 and then grow at a rate of 5% to 10% per year.

Calcium chloride consumption during the next 3 to 5 years is projected to

be static or decreasing for its major use in deicing and dust control. The mild winter hurt consumption in 1990 for deicing uses. Annual consumption for deicing is projected to be static or decrease. Dust control is expected to remain steady. Growth is expected in the area of drilling fluids for the oil and gas industry. Calcium chloride is added to specially designed oil muds to deal with plastic flowing shale encountered offshore Louisiana, in Wyoming, and in other locations.

The outlook for precipitated calcium carbonate consumption continues to be driven by the pace of conversions to alkaline sizing by the paper industry. One industry estimate sees alkaline papermaking capturing 60% of the total domestic paper market in the next 2 years. The North American market has the potential for 35 to 40 satellite plants. Pfizer plans to build an additional 10 plants in 1991.

The many benefits of PCC use by the paper industry have recently been balanced by criticism that, as paper filler levels increase, PCC performance will deteriorate because of poor drainage and increased water retention. Pfizer, which has reinvested much of its PCC profits into research and development, reports that new products with increased filler-loading levels will be available in the near future.

Although most paper markets are expected to slow down during 1991, long-term growth is expected when the economy turns around. Because paper accounts for the largest portion of PCC consumption, this growth will be reflected by increased PCC sales. The outlook for PCC consumption in paints and plastics is tied to the health of the economy, the construction industry, and the automobile industry. Both markets are expected to be flat through 1991 and then grow at a rate of 4% per year for paints and 4% to 7% for plastics.

CEMENT

By Wilton Johnson

Mr. Johnson, a minerals industry specialist with 29 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for cement since 1983. Domestic survey data were prepared by Howard L. Sullivan, mineral data assistant; and international survey data were prepared by Audrey D. Wilkes, international data coordinator.

ement is the primary ingredient for making concrete. Concrete is used extensively in a variety of construction structures, including buildings, highways and streets, bridges, and water supply and sewerage disposal systems. Substitute materials such as aluminum, steel, fiberglass, wood, stone, and clay products are not expected to impact concrete as the principal building material.

In 1990, U.S. demand for cement declined slightly for the third year following 5 consecutive years of growth. Corresponding declines were experienced in residential and commercial construction. Gains in the public construction sector continued to offset declines in other segments of the construction industry.

Domestic production of portland cement increased slightly, while masonry cement experienced marginal decline. Cement imported for consumption declined for the third year, making up 14% of apparent consumption compared with 19% experienced in the record year of 1987.

After approximately a decade of filing petitions alleging that foreign cement was being dumped in U.S. markets, the industry received a favorable ruling from the International Trade Commission (ITC) on Mexican cement imports.

Cement prices improved for the second straight year following 6 years of depression.

DOMESTIC DATA COVERAGE

Domestic production and consumption data for cement are developed by means of the portland and masonry cement voluntary survey. Of the 125 cement manufacturing plants to which an annual survey collection request was made, 123 responded, representing 98.4% of the cement production and consumption data shown in table 1. Estimates were made for nonrespondents using monthly survey data and data received from previous annual surveys.

BACKGROUND

Definitions, Grades, and Specifications

Section 4 of the Annual Book of the American Society for Testing and Materials (ASTM) publishes standards, test methods, definitions, recommended practices, classifications, and specifications for cement, lime, and gypsum. Following is a brief discussion of various types of hydraulic cements and the materials from which they are made.

^eEstimated. ^PPreliminary. ^rRevised

Excludes Puerto Rico and the U.S. Virgin Islands.

²Portland and masonry cement only.

³Includes imported cement shipped by domestic producers.

Value received, f.o.b. mill, excluding cost of containers.

⁵Quantity shipped plus imports minus exports.

⁶Adjusted to eliminate duplication of imported clinker and cement shipped by domestic cement manufacturers.

Clinker.—Clinker is produced by heating a properly proportioned mixture of finely ground raw materials containing calcium carbonate, silica, alumina, and iron oxide in a kiln to a temperature of about 2,700° F at which partial fusion occurs. The fused material, which ranges from fine sand grains to walnut size, is ground with small amounts, 3% to 5%, of calcium sulfate, usually gypsum or anhydrite, to make portland cement.

Portland Cement.—ASTM specification C-150 covers five types of portland cement: Type I, for use when special properties specified for other types are not required; Type II, for general use, especially when moderate sulfate resistance or moderate heat of hydration is desired; Type III, for use when high early strength is required; Type IV, for use when a low heat of hydration is desired; and Type V, for use when high sulfate resistance is required. ASTM specifications also include Type IA, Type IIA, and Type IIIA for the same uses but with the addition of air entraining compounds to protect concrete against freeze-thaw damage.

White Cement.—White cement is made from iron-free materials of exceptional purity, usually limestone, china clay or kaolin, and silica. The clinker is burned with a reducing flame in the kiln and rapidly quenched in a water spray to keep any iron in the ferrous state to avoid coloration by ferric ions. The clinker is then ground with high-purity white gypsum using ceramic balls and liners in grinding mills. White cement is used in decorative concrete, including terrazzo, highway lane markers, and architectural concrete.

Masonry Cement.—Masonry cement is a hydraulic cement used in mortars for masonry construction. It contains one or more of the following materials: portland cement, portland-pozzolan cement, slag cement, or hydraulic lime, usually with hydrated lime, limestone, chalk, calcareous shale, talc, slag, or clay interground for plasticity. ASTM designation C-91 contains specifications for masonry cement.

Blended Hydraulic Cement.—ASTM designation C-595 covers four kinds of blended hydraulic cements, each with an optional provision for air entraining.

Portland-Blast Furnace Slag.—This is

essentially an intimately interground mixture of portland cement clinker and granulated blast furnace slag, or an intimate and uniform blend of portland cement and fine granulated blast furnace slag in which the slag constituent ranges between 25% to 70% of the total weight of the cement.

Portland-Pozzolan Cement.—Portland-pozzolan cement is produced by intergrinding portland cement clinker and pozzolan, by blending portland cement or portland-blast furnace slag cement and finely divided pozzolan, or a combination of intergrinding and blending in which the amount of the pozzolan is between 15% and 40% of the total weight of the cement.

Pozzolan-Modified Portland Cement.— The constituents in this type of cement are the same as those for portland-pozzolan cement, and the methods of production are also the same. However, pozzolan makes up less than 15% of the total weight of the blended cement.

Slag Cement.—Slag cement is a finely divided material made from a uniform blend of granulated blast furnace slag and hydrated lime. The slag constituents at least 70% of the total weight of the blended cement.

Pozzolan.—Pozzolan is a siliceous and aluminous material that in itself possesses little or no cementitious value but will, in a finely divided form and in the presence of moisture, chemically react with calcium hydroxide at ordinary temperatures to form compounds possessing cementitious properties. Fly ash is a pozzolanic material obtained from flue gases produced by coal combustion. Natural pozzolans are naturally occurring materials such as diatomaceous earths, opaline cherts and shales, tuffs, volcanic ash, and pumicites. ASTM C-618 covers fly ash and natural pozzolans.

Oil-Well Cement.—Oil-well cement was developed to seal oil and gas wells under pressures up to 1,800 pounds per square inch and temperatures up to 350° F. This cement must remain fluid up to about 4 hours to be effective.

Expansive Cement.—Expansive cement is a hydraulic cement that tends to increase in volume after setting during the early hardening period. There are three types of expansive cements, Types K, M,

and S. Expansive cements are used primarily in shrinkage-compensating concrete. ASTM specification C-845 covers all expansive cements.

Aluminous Cement.—Sometimes known as calcium aluminate cement, high alumina cement, or "Ciment Fondu," aluminous cement is a hydraulic nonportland cement. Special applications of aluminous cement are based on its rapidhardening qualities, resistance to sulfate action, and refractory properties when used as "castable refractories" and mortars for furnaces and kilns.

Concrete.—Concrete is a proportioned mixture of coarse mineral aggregates of sand and gravel or crushed stone, bound together by a paste of hydraulic cement and water. Volume 04.02 of ASTM standards covers concrete and aggregates.

Products For Trade and Industry

Portland cement makes up 96% of total domestic output; the remainder is mostly masonry cement. About 92% of total portland cement production in 1990 comprised Types I and II cement, and 4% was Type III. Type V and oil well cements accounted for 1% each. White, expansive, portland slag and pozzolan, waterproof, and a variety of miscellaneous cements accounted for the balance. Each product requires either a change in proportion of raw materials mixed for kiln feed or additives to make clinker.

Industry Structure

The industry is composed of 125 cement-producing plants in 39 States. Multiplant operations were being run by 23 companies. Because of overall poor financial performance by the industry during the 1980's, many companies have left the cement business or closed plants and began importing finished cement or clinker for grinding into finished cement. Fifteen independent importers have constructed terminals to receive foreign cement for markets near coastal areas. The industry has also undergone dramatic changes in ownership. At yearend, foreign investors controlled approximately 65% of U.S. production capacity.

Resources

Primary raw materials required for ce-

ment clinker production are, in order of importance, limestone, clay and shale, and iron ore. In instances where essential chemical components are not present in primary raw materials in the required amount, other mined materials or industrial products may be used as additives to correct these deficiencies. Gypsum is added during the clinker grinding process to make finished portland cement.

Although raw materials for cement manufacturing have not been quantified, they are abundant in most countries. Some countries deficient in raw materials meet their requirements by importing. Many domestic companies have reported reserves of raw materials exceeding 100 years of supply.

Technology

Principal steps in manufacturing portland cement consist of crushing, grinding, mixing, and burning raw materials and grinding the resultant clinker. About 1.8 tons of raw materials is required to make 1 ton of cement.

Raw Material Grinding.—Both dry and wet grinding are used to obtain a fineness that may range from 75% to 90% passing through a 200-mesh sieve. In wet milling, water is added with the mill feed to produce a slurry containing about 65% solids. The raw material is then dried and ground for burning.

Burning.—Burning is the most important operation in manufacturing cement because fuel consumption is a major expense, plant capacity is measured by kiln output, and strength and other properties of cement depend on the quality of the clinker. Burning takes place in a rotary kiln that is a refractory-lined steel cylindrical shell. It rotates on an axis inclined at ¾ to ½ inch per foot toward the discharge end. U.S. kilns range in size from 116 to 760 feet long and 8 to 24 feet in diameter.

Byproducts and Coproducts

There are no major byproducts and coproducts in manufacturing hydraulic cement in the United States. Flotation, a method of beneficiation used by some companies to remove undesirable constituents from raw materials and usually to increase the calcium carbonate content of the kiln feed, produces waste such as silica sand or mica fines that may be marketed. Waste rock quarried in selective mining of usable raw material has been sold for riprap and fill materials or crushed and sold as aggregate for concrete or for road base. Some kiln dusts with high alkali content have been collected and used as fertilizer or processed to recover potash.

Economic Factors

Prices.—Cement prices are greatly influenced by local or regional markets and by the availability of energy and raw materials required for cement manufacturing. Discounts for cash and large quantity purchases, absorption of freight charges, and the cost of packing bags and pallets add to the complexity of cement price patterns. Extreme competition among producers and, in some instances, stiff competition from imports are also factors that contribute to depressed prices and ultimately limit investment dollars available for capital improvement or expansion.

Costs.—Cement production costs are determined by such factors as plant location, plant age and level of modernization, type of production process used, the availability of raw materials, and labor. Energy represents by far the largest portion of production costs, accounting for up to 40% of the total. The industry has had considerable success in stabilizing production costs by undertaking modernization projects that not only conserve energy but increase production capacity.

Tariffs.—For countries with most-favored-nation status, duties are imposed only on white cement in the amount of 22 cents per metric ton, including the weight of containers. Other hydraulic cement and clinker are duty free. The statutory import duty for countries without most-favored-nation status is \$1.76 per metric ton and \$1.32 per metric ton for all other types of cement and clinker, respectively.

Operating Factors

Environmental Requirements.—Since the 1970's, the U.S. cement industry has been required to make substantial capital investments in order to comply with environmental restrictions. The biggest source of pollution associated with cement production is controlling dust from kilns and clinker coolers. That requires the in-

stallation of dust collectors such as bag houses and electrostatic precipitators, both of which add considerably to operating costs without improving production. In addition to meeting air quality standards, the industry must also comply with water quality, land use, health and safety, and noise requirements. It has been estimated that capital costs for meeting these requirements can account for 20% to 25% of the capital expenditures for new plants and major additions.

Employment.—In 1990, the U.S. cement industry employed approximately 19,900 workers, including individuals employed in mining and milling operations. Employment in the industry has continued to decline primarily because automated process control technology permits greater productivity with fewer employees.

Energy Requirements.—The U.S. cement industry is one of the largest users of energy, consuming about 283 trillion British thermal units (Btu's) in 1990, Substantial energy savings have been achieved since the Federal Government implemented the voluntary energy conservation program in 1972. The installation of improved raw material grinding and processing technology, the use of preheaterprecalciner systems for burning raw materials, the conversion from wet to dry process, and the conversion from oil and gas to coal for kiln firing all contributed to improved energy efficiency. Further improvements in energy consumption will result as technological and institutional barriers to the use of municipal, industrial, and hazardous wastes for kiln firing are removed.

ANNUAL REVIEW

Issues

The primary issue facing the cement industry is a lack of investment capital for new plant construction or capacity modernization and expansion. Foreign import penetration into coastal markets and regional competition among domestic producers have combined to reduce the profitability of the U.S. industry. The lack of domestic investment capital has opened the door for foreign investors who now own more than two-thirds of U.S. cement production capacity.

Production

One State agency and 49 companies operated 125 plants in 39 States. In addition, two companies operated two plants in Puerto Rico, manufacturing hydraulic cement. The production data obtained are arranged by State or groups of States that form cement districts. A cement district may represent a group of States or a portion of a State. The States of California, Illinois, New York, Pennsylvania, and Texas are divided to provide more definitive marketing information within those States as follows:

California, Northern.—Points north and west of the northern borders of San Luis Obispo and Kern Counties and the western borders of Inyo and Mono Counties.

California, Southern.—All other counties in California.

Chicago, Metropolitan.—The seven Illinois counties of Cook, DuPage, Kane, Kendall, Lake, McHenry, and Will.

Illinois.—All other counties in Illinois.

New York, Western.—All counties west of a dividing line following the eastern boundaries of Broome, Chenango, Lewis, Madison, Oneida, and St. Lawrence Counties.

New York, Eastern.—All counties east of the aforementioned dividing line, except Metropolitan New York.

New York, Metropolitan.—The five counties of New York City (Bronx, Kings, New York, Queens, and Richmond) plus Nassau Counties, Rockland, Suffolk, and Westchester.

Pennsylvania, Eastern.—All counties east of the eastern boundaries of Centre, Clinton, Franklin, Huntingdon, and Potter Counties.

Pennsylvania, Western.—All other counties in Pennsylvania.

Texas, Northern.—All counties north of a dividing line following the northern borders of Burnet, Crockett, Jasper, Jeff Davis, Llano, Madison, Mason, Menard, Milam, Newton, Pecos, Polk, Robertson, San Jacinto, Schleicher, Tyler, Walker, and Williamson Counties.

Texas, Southern.—All counties south of the aforementioned dividing line.

Clinker Production.—Clinker production in the United States, excluding Puerto Rico, increased slightly to 69.8 million tons. California continued to lead all States in clinker production, followed by Texas, Pennsylvania, Michigan, and Mis-

souri. Together these five States accounted for 46% of total U.S. clinker production.

By yearend, multiplant operations were being run by 23 companies. The size of individual companies, as a percentage of total U.S. clinker production capacity, ranged from 0.3% to 6%. The 5 largest producers provided 30% of total clinker production; the 10 largest producers provided a combined 52%. The 10 largest companies, in decreasing order of size of clinker production, were Holnam Inc., Lafarge Corp., Southdown Inc., Lone Star Industries Inc., CalMat Co., Lehigh Portland Cement Co., Ash Grove Cement Co., Blue Circle Inc., Medusa Cement Co., and Gifford-Hill and Co.

Portland Cement.—Portland cement production increased slightly to 73.9 million tons. This was the second year that production increased after 2 consecutive years of decline. The increase was attributed to less reliance on imports of finished cement to satisfy demand primarily in the north-central and south-central areas of the United States.

The industry operated 120 plants, including 8 grinding facilities, to produce various types of finished hydraulic cement compared with 122 plants in 1989. California continued to lead all States in the production of cement, followed by Texas, Pennsylvania, Michigan, and Missouri. Together these five States accounted for 46% of total U.S. cement production.

The size of individual companies, as a percentage of total U.S. finished cement production capacity, ranged from 0.4% to 7.0%. The top 10 producing companies, in declining order of production, were Holnam Inc., Lafarge Corp., Southdown Inc., Lone Star Industries Inc., Lehigh Portland Cement Co., Ash Grove Cement Co., Blue Circle Inc., Gifford-Hill and Co., CalMat Co., and Medusa Cement Co.

Masonry Cement.—Production of masonry cement declined 3% to 3.2 million tons. At yearend, 80 plants were manufacturing masonry cement in the United States. Two plants producing masonry exclusively were Chaney Lime & Cement Co., Algood, AL; and Riverton Corp., Riverton, VA.

Aluminous Cement.—Aluminous cement continued to be produced by Lehigh, Buffington, IN; Lone Star Lafarge, Chesapeake, VA; and Aluminum Co. of America, Bauxite, AR.

Fuel Consumption.—The average energy consumption per ton of clinker produced was 3.9 million Btu, about the same as that required in 1989. Coal accounted for 92% of the fuel used. Oil and gas accounted for 4% each. The consumption of electrical energy remained at the equivalent of 1.1 million Btu per ton. Average fuel consumption for kiln firing plus electricity for grinding was 5.0 million Btu per ton. Fuel used in wet-process plants was 4.5 million Btu per ton, 27% higher than the dry process of 3.3 million Btu per ton. Approximately 65% of clinker was produced by the dry process method.

The industry reported 61 suspension and 10 grate preheaters in use during the year. Kilns without preheaters averaged 4.6 million Btu per ton, those with suspension preheaters averaged 3.3 million Btu per ton, and those with grate-type preheaters averaged 4.9 million Btu per ton.

Corporate Changes.—Lone Star Falcon, an import terminal owned by a joint venture between Lone Star Industries and Falcon Cement Co., was leased by Gulf Coast Portland Cement Co. Gulf Coast also acquired Sun Star Cement Co., an affiliate of Cementos Mexicanos, Mexico's largest cement company. Cementos Mexicanos also purchased the remaining 50% interest in Pacific Coast Cement Co., an import terminal in Long Beach, CA. Ciment Français, a French-based company, acquired two plants from Carlow Group Companies-Bessemer, PA, and Middlebranch, OH. Carlow retained its Zanesville, OH, plant. Onoda Cement Co. of Japan acquired Lone Star Industries interest in their joint venture, Lone Star Northwest, which included cement distribution terminals in Alaska, Oregon, and Washington. Onoda also purchased the Los Angeles-based CalMat Co., including plants and terminals in Arizona and California. Pioneer Concrete Co. of America Inc. acquired 50% interest in the Midlothian, TX, plant of Beazer PLC of Great Britain. The plant was formerly owned by Gifford-Hill and Co. The plant name was changed to North Texas Cement Co.

Consumption and Uses

Consumer demand for cement in the United States, excluding Puerto Rico, declined slightly to 89.6 million tons. This was the third year of decline following 5 consecutive years of growth after the 20-year low experienced at the depth of the

recession in 1982. Cement consumption mirrored construction activity in most segments of the building construction industry throughout the country. According to U.S. Department of Commerce data, housing starts declined 13% to 1.2 million units. The value of new construction put in place was virtually unchanged at \$434 billion. The value of residential construc-

tion put in place declined 5% to \$186 billion, primarily in single-unit structures. The value of nonresidential construction put in place declined slightly to \$102 billion, owing primarily to decreases in office and other commercial building construction. Public construction experienced the biggest increase, 15%, caused primarily by increases in spending for public buildings,

highways and streets, military facilities, sewer systems, and water supply facilities.²

Among the consuming States, California continued to lead all areas in the amount of portland cement consumed, followed by, in order of shipments received, Texas, Florida, Illinois, Ohio, and Pennsylvania. Together, these States consumed 42% of total U.S. tonnage.

TABLE 5

RAW MATERIALS USED IN PRODUCING PORTLAND CEMENT IN THE UNITED STATES¹

(Thousand short tons)

Raw materials	1988	1989	1990
Calcareous:			
Limestone (includes aragonite, marble, chalk)	79,517	81,792	86,098
Cement rock (includes marl)	23,398	21,920	20,239
Coral	783	911	1,128
Other	9	- 13	17
Argillaceous:			
Clay	4,784	4,801	4,661
Shale	4,126	4,289	4,447
Other (includes staurolite, bauxite, aluminum dross, alumina, volcanic material, other)	310	436	565
Siliceous:			
Sand and calcium silicate	2,011	1,991	1,839
Sandstone, quartzite, other	993	605	770
Ferrous: Iron ore, pyrites, millscale, other iron-bearing material	1,036	1,026	1,031
Other:			
Gypsum and anhydrite	4,174	4,254	3,858
Blast furnace slag	86	181	168
Fly ash	940	905	696
Other, n.e.c.	348	356	317
Total	122,515	123,480	² 125,835

¹Includes Puerto Rico.

On a regional basis, only three of the nine Census regions, East South Central, West South Central, and West North Central, experienced increases in consumption. The East North Central and Mountain regions remained unchanged, while the remaining regions experienced marginal declines.

Shipments of domestically produced portland cement from U.S. mills improved slightly, while masonry cement shipments

were virtually unchanged. Cement imported for consumption declined by 17%. This was the third consecutive year that imports declined and accounted for only 14% of apparent consumption compared with 17% in 1989.

Ready-mix concrete producers were the primary consumers of cement, accounting for about 72% of the total, followed by concrete product manufacturers with 12%, highway contractors with 5%, build-

ing material dealers with 4%, and other contractors with 3%. Smaller amounts were consumed by Federal, State, and other government agencies and by a variety of other miscellaneous users.

Transportation

The pattern of cement transport did not differ significantly from that of recent years. U.S. shipments of portland cement to consumers were primarily in bulk, 96%;

²Total number in operation at plants.

²Data do not add to total shown because of independent rounding

Markets and Prices

The average mill value of portland cement increased slightly for the second straight year following 5 consecutive years of decline. The increase can be attributed to higher production levels and a reduc-

tion of imports. Import prices also improved because of increases in transportation costs and the result of antidumping petitions filed by domestic producers. Masonry cement prices declined slightly while the industry experienced a corresponding decline in demand. The average value of cement as reported by Engineering News—Record (ENR) declined slightly to \$62.10 per ton. The ENR prices are based on an average per ton value of cement delivered to 20 cities. The prices ranged from a low of \$46.00 in Dallas, TX, to a high of \$76 in Detroit.³

¹Includes Puerto Rico.

²Data may not add to totals shown because of independent rounding.

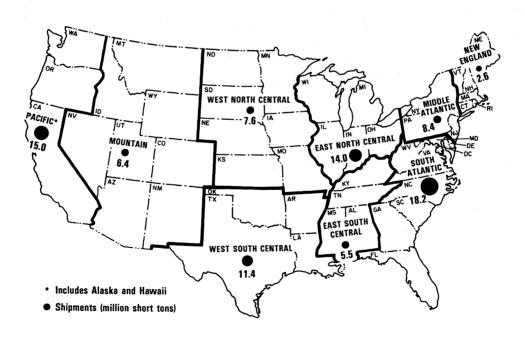

³Cement imported and distributed by domestic producers only. Source of imports withheld to avoid disclosing company proprietary data.

²Masonry cement made at cement plants only.

Foreign Trade

According to trade data reported by the U.S. Department of Commerce, Bureau of the Census, cement imported for consumption into the United States and its possessions and territories was 13.3 million tons or 16% below the level of 1989. This was the third year of decline following 3 consecutive years of record-high imports. The decline corresponded to the marginal decrease in total demand resulting from reduced construction activity. Canada, Mexico, Japan, and Venezuela were the principal import sources, accounting for 69% of the total. The industry continued to find it more economical to import finished cement instead of clinker for grinding. Clinker accounted for 14% of total imports compared with 32%

reached in the peak year 1985. This was the fifth consecutive year that clinker imports declined, reaching its lowest level since 1983. The average value of foreign cement and clinker, including cost, insurance, and freight, delivered to American ports averaged \$41.67 per ton, up 8% from that of 1989.

Florida led all States in the amount of imports received, accounting for 22% of the total. Sixty-five percent or 1.9 million tons of the Florida imports was shipped through the Tampa Customs District. Imports made up about 46% of Florida's portland cement consumption compared with 14% of apparent consumption nationally. Thirty-nine percent of imports into Florida came from Venezuela. Los Angeles was the second largest recipient of imported cement, receiving 1.9 million

tons or 14% of the total, most of which was received from Japan.

Exports of hydraulic cement and clinker as reported by the Bureau of the Census increased 8% to 554,000 tons. Cement was shipped to 63 countries, with Canada receiving 81% of the total.

In other trade developments, in August, the ITC issued a final determination on a petition filed by cement producers from Arizona, California, Florida, New Mexico, and Texas alleging that cement from Mexico was being sold in these areas at less than fair value. The ITC concluded that the industry was being materially injured by Mexican imports. Consequently, antidumping duties ranging from 3.7% to 58.4% were placed on cement imported from Mexico.

Concurrent with ITC's final investiga-

tion of imports from Mexico, an ad hoc committee of southern California producers of gray portland cement filed a petition against imported cement from Japan. The petition alleged Japanese cement was being sold in their market areas at less than fair value. The ITC immediately instituted a preliminary investigation. A final determination was expected in spring 1991.

World Review

World cement production was essen-

continued to lead all nations with 18% of production, followed by the U.S.S.R. with 12%, Japan with 7%, and the United tially unchanged at 1.3 billion tons. China | States with 6%. Countries with excess ca-

pacity continued to export cement to the United States. Twenty-eight countries exported cement to the United States in 1990, essentially the same as in 1989. The

Data may not add to totals shown because of independent rounding.

²Less than 1/2 unit.

Source: Bureau of the Census.

amount of cement imports declined by 16% because of increased demand within exporting countries and because of a continued decline in demand in certain U.S. markets.

There was considerable activity in plant modernization or expansion by industry throughout the world. The international issue of Rock Products magazine describes individual plant activities of the cement-producing nations.4

Capacity.—Data in table 23 are estimated and were obtained from a number of different sources, including Government representatives, cement associations, producers, and consultants. Capacity is defined as the maximum quantity of cement that can be produced in a period of time on a normally sustainable basis taking into consideration downtime required for maintenance and repair. Capacity includes operating plants and plants temporarily closed that can be brought into production within a short period of time with minimum capital expenditure.

During 1990, clinker-producing plants in an estimated 132 countries had a combined annual capacity of about 1.4 billion tons. The seven leading countries, China, the U.S.S.R., Japan, the United States, India, Brazil, and the Federal Republic of Germany, Western states, controlled 51% of world capacity.

In the United States, 46% of the clinker production capacity was concentrated in five States: California, Texas, Pennsylvania, Michigan, and Missouri. At yearend, 223 kilns at 112 plants were being operated, excluding Puerto Rico. The average downtime experienced by the industry for maintenance was 52 days, slightly less than that in 1989. The average annual kiln capacity decreased slightly to 365,000 tons. The average annual plant capacity decreased slightly to 727,000.

Canada.—Canadian cement production declined for the second consecutive year. Canada regained its position as the largest supplier of foreign cement to the United States with 3.2 million tons. Mexico had replaced Canada in that capacity in 1987. Canadian cement comes into U.S. markets through 15 ports, primarily along the northern borders of the United States from Anchorage, AK, to St. Albans, VT. Buffalo, NY, Detroit, MI, and Seattle, WA, received 61% of all Canadian imports.

^eEstimated. ^pPreliminary. ^rRevised.

China.—China continued to be the world's largest producer of cement. Its production stabilized in 1990 after reaching a record level 228 million tons in 1989. The industry continued to flourish amid new plant construction, modernization, and expansion projects, as well as the formation of joint ventures with Japanese cement producers.

India.—The Indian cement industry continued to aggressively expand its production capacity through new plant construction, modernization, and expansion activities. It is anticipated that demand will continue to increase. Cement production in India reached an alltime high of

48.5 million tons. This was the eighth consecutive year of reported production growth.

Japan.—Japan continued to maintain its position as the third highest cement producer in the world, producing just over 90 million tons, slightly more than in 1989. Japanese exports to the United States declined 13% to 2.1 million tons in 1990. Fifty-six percent of Japanese exports to the United States was shipped to the Los Angeles area. Japan was again the subject of an antidumping petition filed by southern California producers. A final determination on the petition was expected to be made by the International Trade

Commission in spring 1991.

Korea, Republic of.—Korea's cement production increased 44% over the past 5 years, to 37 million tons in 1990, in response to unprecedented growth in demand. Korea continued to expand its production capacity through new plant construction, modernization, and expansion projects, including building one of the largest plants in the world. Korea was once a major exporter of cement to the United States, primarily to the Los Angeles and San Francisco areas. Because of increased demand at home, however, cement exports to the United States have declined significantly.

¹Table includes data available through June 29, 1991.

²In addition to the countries listed. Cameroon produces cement, but available information is inadequate to make reliable estimates of output levels.

³Reported figure.

Less than 1/2 unit.

⁵Data are for the year ending June 30 of that stated.

Mexico.—Cement production in Mexico remained essentially unchanged from that of 1989. Production capacity, however, continued to grow as a result of modernization and expansion projects currently underway. Since 1987, Mexico had been the principal supplier of imported cement to the United States, replacing Canada. As a result of antidumping allegations and an affirmative determination by the International Trade Commission that domestic cement producers were being injured by cement from Mexico, imports from Mexico declined by 48% in 1990. However, given the rapid growth of the Mexican cement industry, the proximity of plants to U.S. markets, and the acquisition of import terminals in the United States, it is only logical to assume that Mexican cement will play a major role in supplying U.S. requirements for many years to come.

Current Research

Passamaquoddy Technology LP, USA, developed a new scrubbing system that recycles waste cement kiln dust (CKD) and reduces sulfur dioxide (SO₂) emissions. The process, named the Passamaquoddy Technology Recovery Scrubber, uses 90% of the SO₂ and a portion of the carbon dioxide (CO₂) in the kiln exhaust gas to recycle 100% of the plant's CKD into kiln feed, potassium fertilizer, and distilled water. The system can also be used to reclaim landfilled CKD. The sys-

tem was installed at the Thomaston, ME, plant of Dragon Products Co. The plant is the only one in the State and was formerly owned by the Passamaquoddy Indian Tribe.⁵

OUTLOOK

The recession that began in 1990 is expected to carry through 1991, causing cement consumption to decline to about 81 million tons. The decline will continue to be precipitated by weakness in the residential and in nonresidential building construction markets. Gradual increases in demand are anticipated for 1992 and 1993 as the economy is relieved of some of the existing recessionary pressures. It is estimated that demand for portland and masonry cement will reach 95 million tons by 1994. The projected increase will be influenced by new construction activity primarily in the public construction sector. The Portland Cement Association makes a more optimistic forecast of 98.5 million and about 100 million tons by 1994 and 1995, respectively.6

There has been considerable attention given to repairing or rebuilding the Nation's infrastructure. These cement consumption forecasts could be altered dramatically depending on the level of spending authorized for this undertaking.

Imports will continue to be a significant source of supply. The trend toward in-

creased world consumption of cement, however, could impact the amount of cement available for export to U.S. markets, particularly given the political and economic changes taking place in Eastern Europe.

Cement prices could benefit from a restricted supply of foreign cement. Recent antidumping duties imposed on cement from Mexico and Japan by the ITC could dramatically impact the pricing structure of domestic cement.

CHROMIUM

By John F. Papp

Dr. Papp, a physical scientist with 20 years U.S. Bureau of Mines experience, has been the commodity specialist for chromium since 1983. Domestic survey data were prepared by Lillian Wood and Robin Johnson, mineral data assistants; chromite world production data by country were prepared by Audrey D. Wilkes, international data coordinator. Cost of production data were prepared by the Minerals Availability Field Office, Division of Statistics and Information Services. (All tonnages are in metric tons unless otherwise specified.)

hromium has a wide range of uses in metals, chemicals, and refractories. It is one of the Nation's most important strategic and critical materials. Chromium use in iron, steel, and nonferrous alloys enhances hardenability and resistance to corrosion and oxidation. The use of chromium to produce stainless steel and nonferrous alloys are two of its more important applications. Other applications are in alloy steel, plating of metals, pigments, leather processing, catalysts, surface treatments, and refractories.

Because the United States has no chromite ore reserves and a limited reserve base, domestic supply has been a concern during every national military emergency since World War I. World chromite resources, mining capacity, and ferrochromium production capacity are concentrated in the Eastern Hemisphere. The National Defense Stockpile (NDS) contains chromium in various forms, including chromite ore, chromium ferroalloys, and chromium metal in recognition of the vulnerability of long supply routes during a military emergency.

Research is conducted by the Federal Government to reduce U.S. vulnerability to potential chromium supply interruption. That research covers both domestic resource utilization and alternative materials identification. Domestic chromium resources include mineral deposits and recyclable materials. The U.S. Geological Survey and the U.S. Bureau of Mines evaluate U.S. territory for chromium mineral deposits. The U.S. Bureau of Mines also studies minerals extraction and processing and materials substitution and recycling. Alternative materials research is also conducted by the National Aeronautics and Space Administration, the National Institute of Standards and Technology, the Department of Defense, and the Department of Energy.

World chromite ore reserves are more than adequate to meet anticipated world demand.

DOMESTIC DATA COVERAGE

Domestic data coverage of the primary consuming industries—metallurgical, refractory, and chemical—are developed by the U.S. Bureau of Mines by means of the voluntary monthly "Chromite Ores and Chromium Products" survey. The companies listed in table 10 by industry accounted for 100% of the chromite consumption data by industry in the current year of table 12. All of the refractory companies and all of the chemical companies that consumed chromite in 1990 reported to the Bureau, while 75% of the metallurgical companies reported. Consumption was estimated for the remaining 25% of the metallurgical firms.

Domestic production data for chromium ferroalloys and metal are developed by the U.S. Bureau of Mines by means of two separate voluntary surveys. These two surveys are the monthly "Chromium Ores and Chromium Products" and the annual "Ferroalloys." Production by the metallurgical companies listed in table 10 represented 100% of the domestic production shown in the current year of table 11. Seventy-five percent of those companies responded to both surveys. Production for the remaining 25% was estimated.

BACKGROUND

Chromium is primarily used in the metallurgical industry as an alloying

element. That is, it is mixed with a base metal to form an alloy. Chromium confers properties on the alloy that are not achievable with the base metal alone. The most common use of chromium is with iron to make stainless steel, an ironchromium alloy that contains chromium by definition. Chromium confers oxidation resistance to stainless steel, making it "stainless." Stainless steel, in addition to being commonly found in home and commercial kitchens, is an important engineering alloy used throughout industry in machinery and pipes. Chromium is also used in chemicals for a variety of purposes. Chromite, the mineral from which chromium is derived for use in the metallurgical and chemical industries, is used directly by the refractory industry to produce heat-, spalling-, corrosion-, and abrasion-resistant bricks for metallurgical and high-temperature industrial mineral processing applications. Chromite is not mined domestically; thus, the United States is 100% import dependent to meet domestic chromite demand. Some domestic chromium demand is met by recycling. Chromium is a critical and strategic material contained in the NDS to ensure adequate supply in the event of a national defense emergency.

Definition, Grades, and Specifications

U.S. industry sets chemical and physical specifications for chromium materials through the American Society for Testing and Materials (ASTM). Other organizations also make specifications for chromium materials. The Defense Logistics Agency (DLA), in cooperation with the Department of Commerce, maintains purchase specifications for chromium materials contained in the NDS. The Treasury Department, in cooperation with the Department of Commerce and

participants in the General Agreement on Tariffs and Trade, maintains definitions of chromium materials for the purpose of recording trade and applying tariff duties.

For the purpose of importation, chromite ore and concentrates made therefrom are classified by their chromic oxide content. Ore and concentrate is divided into three categories: containing not more than 40% chromic oxide, containing more than 40% and less than 46% chromic oxide, and containing 46% or more chromic oxide. Producers of chromite ore and concentrate typically specify chromic oxide content; chromium-to-iron ratio; and iron, silica, alumina, magnesia, and phosphorous contents. They also specify the size of the ore or concentrate. Typically, chromic oxide content ranges from 36% to 56%, with values in the 40% to 50% range being most common. Chromium-to-iron ratios typically range from about 1.5:1 to about 4.0:1, with typical values of about 1.5:1 to 3.0:1. In trade, the chromite ore is also called chromium ore, chromite, chrome ore, and chrome.

For the purpose of importation, chromium ferroalloys are classified as

ferrochromium and ferrochromiumsilicon. Ferrochromiumsilicon, also called ferrosiliconchromium and chromium silicide, is not further classified. Ferrochromium is classified by its carbon content as containing not more than 3% carbon, more than 3% but not more than 4% carbon, or more than 4% carbon. Producers of ferrochromium typically classify their material as low- or highcarbon or charge-grade ferrochromium. Charge-grade ferrochromium is also called charge chrome. Producers of chromium ferroalloys typically specify chromium, carbon, silicon, phosphorous, and sulfur contents and material size. Ferrochromiumsilicon typically contains 24% to 40% chromium, 38% to 50% silicon, and 0.05% to 0.1% carbon. Ferrochromium typically contains 50% to 75% chromium and 0.05% to 8% carbon. Low-carbon ferrochromium typically contains 55% to 75% chromium and 0.02% to 0.1% carbon. High-carbon ferrochromium typically contains 60% to 70% chromium and 6% to 8% carbon. Charge-grade ferrochromium typically contains 50% to 55% chromium and 6% to 8% carbon.

Products for Trade and Industry

Chromium is primarily used in the metallurgical industry as an alloying element. Small quantities of chromium are alloyed with (i.e., added to) a base metal to achieve certain desired properties not attainable with the base metal alone. Before its use as an alloying element, chromium was used predominantly in chemicals to make pigments or to plate metals. Chromite was used as a refractory material. As a pigment, chromium provided color to many end products and corrosion protection to ferrous metals. As a plating material, chromium provided a lustrous or a hard finish and corrosion protection to the substrate metal. As a refractory, chromite found major use in blast furnace iron production. The decline in use of this process has resulted in a corresponding decline in chromite refractory use. Environmental concern over hexavalent chromium contamination has resulted in reduced use or increased expense of chromium use in pigments and plating. Chromium is traded primarily as chromite ore or as ferrochromium. Substantial amounts of chromium chemicals, pigments, and metal are also traded.

²Minimum, except where range of values indicating minimum and maximum appears.

³Maximum, except where range of values indicating minimum and maximum appears.

Health and Nutrition¹

Chromium is a trace mineral required by the human body. A daily intake in the range of 50 to 200 micrograms has been recommended. Chromium is a cofactor for insulin, a hormone that participates in carbohydrate and fat metabolism. A cofactor is a material that acts with the material. The dietary chemical form of chromium is as trivalent compounds. Because humans cannot convert trivalent chromium to hexavalent chromium, the carcinogenicity of hexavalent chromium compounds bears no relevance to the nutritional role of trivalent chromium. (See Toxicity section of this report.)

Industry Structure

Stainless steel was developed in about 1900. Since then, stainless steel has grown to become the major end use of chromium. Chromium is used in stainless steel production in the form of ferrochromium, a product of smelting chromite ore with a carbonaceous material (chemical reductant) and silicious materials (flux material). The production of stainless steel evolved in association with the major steel-producing centers. The production of ferrochromium developed in conjunction with the production of stainless steel at those steel-producing locations.

In a trend toward vertical integration, chromite-producing countries have been developing ferrochromium and stainless steel production capacity. This trend has worldwide impact. Formerly, ferrochromium was produced mainly by the United States, Europe, and Japan, the major steel producers. The U.S. trend to obtain chromium in the ferroalloy form is a result of the world trend to produce ferrochromium in chromite-producing countries.

The structure of the chromium industry from a material processing perspective begins with mining of chromite ore. (See figure 1, chromium material flow.) Once mined, the ore is beneficiated. The resulting chromite ore or concentrate made therefrom may be consumed in the refractory, chemical, or metallurgical industry. Chromite ore is consumed in the refractory industry for its chromite mineral content. The chromite is typically crushed, ground, and sized. It is then mixed with magnesite to make chromemagnesite bricks that are subsequently consumed in the steel, glass, or cement

industry. The chromite refractories are used to line steelmaking furnaces, cement kilns, or heat exchangers associated with glass production.

Chromite ore consumed in the chemical or metallurgical industry is processed to extract the chromium from the chromite mineral. Chromite ore consumed in the chemical industry is kiln roasted, and the chromium is leached out in the form of sodium bichromate. The sodium bichromate is further processed to make chromic acid and other chromium chemicals and pigments. Chromic oxide is a chemical industry product. Chromite ore consumed in the metallurgical industry is smelted to produce ferrochromium. In effect, the oxygen is removed from the iron-chromium-oxygen mineral, leaving an iron-chromium alloy, ferrochromium. Ferrochromium is produced to meet a variety of chemical and physical specifications. Several variations of the ferrochromium production process are practiced; the submerged electric arc furnace is central to each process. Ferrochromium is the source of chromium units for alloys, especially ferrous alloys. When nonferrous alloys require chromium and the iron is undesirable, chromium metal is used. Chromium metal is produced from ferrochromium by an electrolytic process or from chromic oxide by an aluminothermic process.

The major vertical structure of the chromium industry is mining-smelting-stainless steelmaking. In some instances, the ownership of mining operations, smelters, and stainless steel production facilities is integrated. In many other cases, integration is limited to mining and smelting or to smelting and stainless steelmaking. Often the ownership of operations is shared. Major mining, smelting, or stainless steel production facilities are typically privately owned by large companies or groups of companies.

Geology-Resources

The geology of many chromium deposits has been characterized.²

The data in table 22 are rated reserves and reserve base for major chromite ore-producing countries.³ The data on chromite reserves and resources are categorized according to a general U.S. Bureau of Mines-U.S. Geological Survey classification system applicable to all minerals. The definition of reserves and reserve base are published in Geological Survey Circular 831, "Principles of a Resource/

Reserve Classification for Minerals." The distribution of chromite deposits into reserves, reserve base, and resources categories is determined by the physical and chemical nature of the ore and by mining and market economies. The reserve base is the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. The reserve base includes those resources that are currently economic, marginally economic, and some of those that are currently subeconomic.

Reserves are that part of the reserve base that could be economically extracted or produced at the time of determination. Reserves include only recoverable materials. Reserve values are included in reserve base values.

The term "reserves" is commonly used with a variety of definitions. Even when the definition given here is used, the quantitative value of reserves will vary owing to differing physical and economic criteria applied to a deposit by different analysts.

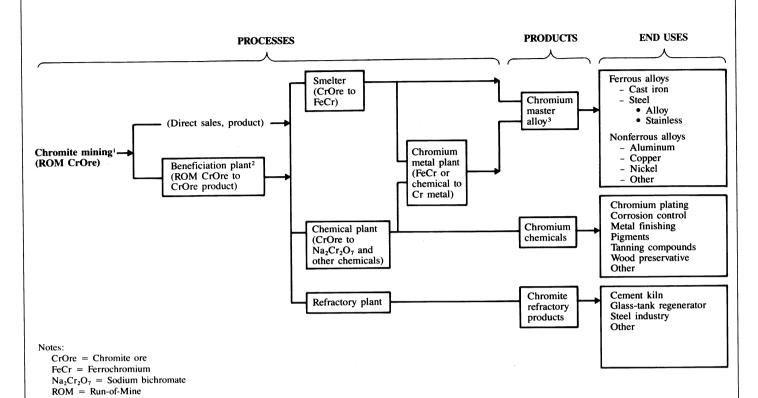

Technology

Mining.—A wide variety of mining technology is applied to the surface and subsurface mining of chromite ore. Most ore comes from large mechanized mines. However, small labor-intensive mining operations contribute to world supply.

Beneficiation.—The amount of beneficiation required and the techniques used depend on the ore source and end-use requirements. When the chromite is clean, only hand sorting of coarse material and gravity separation of fine material may be required. When the ore is lumpy and mixed with host rock, heavy-media separation may be used. When the chromite mineral occurs in fine grains intermixed with host rock, crushing may be used in conjunction with gravity separation and magnetic separation.

Smelting.—The smelting of chromite ore to produce ferrochromium requires electric arc furnace technology. Early electric furnaces having power ratings in the kilovolt-ampere range have developed into modern furnaces having power ratings of about 50 megavolt-amperes. Closed and partially closed electric arc furnaces replaced open furnaces in the 1970's to improve pollution control, efficient furnace operation, and safety. Industry is developing new production

FIGURE 1 CHROMIUM MATERIAL FLOW

¹Mining includes screening and hand sorting.

³Master alloy is an alloy used as a feedstock to produce other alloys.

technologies using high-temperature plasmas or using alternatives to electrical power supply. The new production technologies are expected to be more cost competitive than traditional production technology.

Technological change in stainless steel production permitted the replacement of expensive high-chromium, low-carbon ferrochromium by less expensive

low-chromium, high-carbon ferrochromium. This change permitted the use of low chromium-to-iron ratio ore for smelting to ferrochromium, which is subsequently alloyed to produce stainless steel. The Republic of South Africa is the most abundant and low-cost source of such ore. Unfortunately, this ore is friable (breaks easily into small pieces), and the finer fractions of such ore are blown out

of a furnace before it can be smelted. Agglomeration technology has been developed to permit the use of fine chromite ore in the electric arc furnace. Both briquetting and pelletizing are practiced. Efficient production technology uses prereduced and preheated pelletized furnace feed. Advanced smelting technologies have been designed to use fine ore.

²Beneficiation includes crushing, grinding, and separation techniques, including gravimetric, heavy media, and magnetic.

Recycling.—Recycling is the only domestic supply source of chromium. Stainless steel and superalloys are recycled, primarily for their nickel and chromium contents. As much as 50% of electric furnace stainless steel production can result from recycled prompt and purchased stainless steel scrap. Advanced stainless steel production technology like continuous casting reduces prompt scrap generation and permits a higher product yield per unit of raw material feed.

Byproducts and Coproducts

Chromium is mined as a primary product. Chromium is not a byproduct or coproduct of the mining of any mineral, nor are there byproducts or coproducts associated with chromium mining. Chromium has the potential of becoming a byproduct of platinum mining in the Republic of South Africa or of lateritic nickel mining. Platinum and chromite are both present in the UG2 seam of the Bushweld Complex in the Republic of South Africa. At present, most platinum mining is from the Merensky Reef. However, as platinum mining from the UG2 seam continues and as new mining operations that exploit the UG2 seam are developed, chromium-containing tailings will continue to grow. The feasibility of utilizing these resources has been demonstrated, and new ferrochromium production facilities under development by Middelburg Steel and Alloys are designed to permit the use of these resources. It appears to be only a matter of time before economic conditions favor the use of those tailings, thereby making chromium a byproduct of some platinum operations.

Economic Factors

Prices.—Inadequate supplies of ferrochromium in the late 1980's resulted from strong demand for stainless steel in all three major producing regions: the United States, Japan, and Europe. This inadequate supply resulted in increasing ferrochromium prices until mid-1989, when supply exceeded demand and prices began to decline. In 1989 and 1990, new ferrochromium plants and plant expansions were under construction or being completed. Reduced stainless steel production permitted ferrochromium producers, traders, and consumers to rebuild stocks after about 3 years of generally increasing production. Reduced demand for ferrochromium, resulting

from decreased stainless steel production, and increased supply of ferrochromium, resulting from producer expansions and new plant construction, have resulted in declining ferrochromium prices through 1990.

The historical value of chromite ore by grade, ferrochromium by grade, and chromium metal imported to the United States is shown in tables 4 and 5. These values show that as chromite ore is processed to ferrochromium and to chromium metal, the added value is quite large. On a per unit of contained chromium basis, the value of ferrochromium is about 7 times that of chromite ore: the value of chromium metal is about 30 times that of chromite ore. Variations of the value of ore are shown to follow those of ferrochromium, indicating values of chromite ore change in response to demand with ferrochromium value first to reflect demand changes.⁴ Ferrochromium values show greater variation than those of chromite ore. The unit value of chromium materials has increased by 10% to 15% per year in actual value since 1963.

Costs. 5—Operating and transportation are the two major components of chromite ore cost in the market place. Operating cost includes mining (the production of run-of-mine ore) and beneficiation (the production of marketable chromite ore or concentrate from the run-of-mine ore). Mining cost is typically in the range of 70% to 90% of operating cost but exceeds 90% in some cases. Labor cost is the major component of mining and of beneficiation cost. Labor cost is typically in the range of 20% to 70% of mining cost and from 25% to 90% of beneficiation cost, but can be higher.

Electrical energy, raw materials, and labor are the major components of smelting (i.e., production of ferrochromium from chromite ore) cost. (Note that smelting cost excludes the cost of chromite ore feed material.) Electrical energy cost is in the range of 20% to 55% of smelting cost; raw materials (excluding chromite ore), 15% to 35%; and labor, 10% to 30%.

Tariffs.—Import tariffs are typically imposed to protect domestic industry. Where there is no domestic industry, such as chromite ore production in the United States, there is no tariff. (See Foreign Trade section of this report for U.S. tariff

duties on chromium materials.) In some cases, such as ferrochromium imports to the European Community, import tariffs are used along with import quotas. That is, a duty-free quota is allocated to member countries. The quotas may be revised as necessary to meet the needs of domestic consumers and producers. Only in a few cases, such as ferrochromium exports from China and certain grades of chromite ore exports from India, are export duties applied.

Operating Factors

Environmental Requirements.—Chromium releases into the environment are regulated by the Environmental Protection Agency (EPA). Workplace exposure is regulated by the Occupational Safety and Health Administration.

Toxicity.6—The toxic effect of an element depends on its chemical form and concentration, and on the conditions and

NOTE.—1982 value is actual value multiplied by gross national product (GNP) ratio. GNP ratio is annual GNP divided by 1982 GNP. GNP ratio calculated as the ratio of GNP index reported in Economic Report of the President, U.S. Government, February 1990, available from Superintendent of Documents, U.S. Government Printing Office.

duration of exposure. At about 200 parts per million, chromium is the sixth most common element in the Earth's crust; at 1 to 2.5 parts per billion, the fifteenth most common element in seawater. Chromium generally forms chemical compounds in which chromium has either the hexavalent or trivalent oxidation state. Hexavalent chromium compounds are generally recognized as toxic. Chronic occupational exposure to hexavalent chromium has been associated with an increased incidence of bronchial cancer. The toxic status of trivalent chromium compounds is not clear. However, trivalent chromium compounds are less toxic than hexavalent chromium compounds. Chemical compounds containing chromium in lower valence states are generally recognized as benign. (See Health and Nutrition section of this report.)

Energy Requirements.—Ferrochromium production is an energy-intensive process, requiring about 3,800 kilowatt-hours per metric ton of product. Currently available technology can reduce the electrical energy requirement to about 2,000 kilowatt-hours per ton by thermal energy recovery and recycling. Traditional technology uses electricity to supply the energy required to smelt chromite ore. Advanced production technology permits the use of liquid or gas fuel to substitute

for part of the energy required. Alternative production technology is being developed that would permit nonelectrical energy sources to supply a significant fraction of the energy required to smelt chromite ore.

Transportation.—Chromite ore is typically transported by trackless truck or conveyor belt from the mine face to storage or processing facilities on the mine site. From there, it is transported by truck from the mine site to the local railhead. It is then transported by rail to ports or to smelters. Smelters that do not have associated loading and unloading facilities for ships transport their product by rail to ports. Following transport by ship to consumer countries, chromium materials are typically barged or hauled by truck to end users who have no loading and unloading facilities for ships.

ANNUAL REVIEW

In 1990, chromium apparent consumption was 447,000 metric tons of contained chromium. The reported consumption of chromite by the chemical and metallurgical industry and by the refractory industry decreased. Metallurgical industry chromite consumption includes material

consumed as part of the NDS program to convert chromite to ferrochromium. Imports of chromite decreased, while imports of chromium ferroalloys increased compared with those of 1989.

U.S. supply consisted of recycled and imported chromium materials. The United States recycled about 561,000 tons, gross weight, of stainless steel scrap and imported about 742,000 tons of chromite ore, ferroalloys, chemicals, and pigments valued at about \$338 million. The United States exported about 25,000 tons of chromium materials valued at about \$36 million.

Legislation and Government Programs

In accordance with the President's November 1982 directive and Public Law 99-591, the DLA continued to upgrade NDS chromite ore to high-carbon ferrochromium. The Agency reported conversion of chromite ore to ferrochromium on a calendar year contract basis. DLA signed a contract with Macalloy Corp., Charleston, SC, in 1990 to upgrade NDS chromite ore. The contract period covers the years 1990 through 1994, the last 2 years of which are optional for DLA.

As part of its plan to modernize the NDS, DLA contracted with Elkem Metals Co., Marietta, OH, to upgrade

¹Customs value per ton of chromium contained in imported material.

Carbon not more than 4%.

³More than 4% carbon.

NDS nonspecification-grade low-carbon ferrochromium into electrolytic (vacuum melting-grade) chromium metal. In 1989, Elkem was awarded a \$7.2 million contract to convert 2,129 metric tons of lowcarbon ferrochromium to about 1,043 metric tons of chromium metal during a 1-year period starting in December 1989. That contract was completed in December 1990. In 1990, DLA awarded a contract to Elkem to convert about 1,090 tons of low-carbon ferrochromium to about 779 tons of chromium metal at a cost of about \$7.0 million, with completion scheduled for 1991. A second year of this contract is optional for DLA.

DLA continued a program to evaluate plasma smelting technology. The program was being carried out by South Carolina Research Authority (SCRA), along with Macalloy Corp., Massachusetts Institute of Technology, Clemson University, and Arthur D. Little Inc. In 1990, a pilot-scale (2,000 kilowatt) furnace, capable of producing about 500 kilograms of ferrochromium per hour, was built at Macalloy's smelting facility in Charleston, SC. After successful test firings of the furnace, several production campaigns were run by SCRA and Macalloy. The group is expected to now plan, develop, and construct a larger prototype furnace.

DLA revised the goal for refractory-grade chromite ore in the NDS to 630,000 metric tons as authorized by Congress in the National Defense Authorization Act for Fiscal Years 1990 and 1991. This revision represents a goal reduction of 18%. The stockpile inventory remains unchanged at a level equivalent to about 56% of the revised stockpile goal.⁷

EPA completed its rulemaking on chromium containing treated residues from roasting and/or leaching of chrome ore with the publication of its final rule. EPA recommended treated residues from roasting and/or leaching of chrome ores to be regulated under subtitle D of the Resource Conservation and Recovery Act. EPA found no significant danger associated with treated residue from roasting and/or leaching of chrome ore based on waste characteristics, management practices, and damage case investigations. 9

Chromite refractory use could be significantly impacted by EPA regulation of waste containing chromium. EPA has determined that chromium-containing

¹High-, medium-, and low-carbon ferrochromium plus ferrochromium-silicon

²Includes chromium metal, exothermic chromium additives, and other miscellaneous alloys.

³As reported in the 1989 Ferroalloys annual report.

wastes exhibit toxicity. EPA has, therefore, established a policy that, if the extract from a representative waste sample contains chromium at a concentration greater than or equal to 5.0 milligrams per liter (total chromium), it is hazardous. EPA has promulgated a treatment standard for chromium-containing refractory brick wastes based on chemical stabilization. (Stabilization is a process that keeps a compound, mixture, or solution from changing its form or chemical nature.) EPA has also determined that some chromium-containing refractory brick wastes can be recycled as feedstock in the manufacture of refractory bricks or metal alloys. EPA recognized that there is insufficient capacity to process inorganic solid debris (i.e., treatable material that is greater than 9.5 millimeters in size and requires cutting or crushing and grinding in mechanical sizing equipment) prior to chemical stabilization. As such a material, chromite-containing refractory bricks were granted a 2-year capacity variance (i.e., a variance until May 1992).¹⁰

Congress enacted the Clean Air Act Amendments Law of 1990 (Public Law 101-549), completely revising the Air Toxics Program. Congress identified 189 hazardous air pollutants to be regulated. Chromium compounds—defined as any unique chemical substances that contain chromium as part of their infrastructure-were included among those hazardous air pollutants. Under the revised Air Toxics Program, Congress instructed EPA to regulate hazardous air pollutants by regulating the source of those pollutants. Congress required EPA to identify pollution sources by November 1991. then to set emission standards for those sources. The Act included a provision for EPA to review petitions to delete specific pollution sources or chemicals identified as hazardous air pollutants from those identified by Congress or EPA.¹¹

Motion pictures and videotape programs distributed by the U.S. Bureau of Mines are designed to inform viewers of the importance of minerals in our society and of the need for conservation of these finite resources. The Bureau made "Chromium," a new video recording, available to the public.¹²

Strategic Considerations

U.S. strategic minerals policy and practice has recently been reviewed and analyzed. The United States is import dependent for its chromium needs. This dependence results from our economic system, a system that requires most economically exploitable resources to be used first. The economic system that causes dependence also benefits all consumers by providing low-cost materials. Dependence was found to result in supply vulnerability due to long supply routes between chromium sources and the United States. U.S. policy is to reduce the risk of supply disruption in the event of a national emergency by maintaining a stockpile. Other policy alternatives not currently practiced include resource sharing, diversifying supply sources, and technological changes. 13

Supply Security.—There is no production of chromite ore in the United States; primary consumption of chromium by U.S. industry is by companies that use chromite ore to produce ferrochromium, chromium chemicals, and chromite

refractories and by chromium metal producers that use ferrochromium or chromium chemicals (i.e., chromic oxide). Chromite ore reserves are abundant, ensuring adequate long-term supply. However, supply sources are few and remote from the United States, making supply vulnerable to disruption. The problem for the United States is one of national security. Ferrochromium is essential to stainless and some alloy steel production, which are in turn essential to both the domestic economy and to the production of military hardware.

U.S. supply of chromium (contained in chromite ore and chromium ferroalloys and metal) was predominantly from the Republic of South Africa (50%), Turkey (11%), Zimbabwe (11%), and Yugoslavia (9%). Imports from the Republic of South Africa are currently restricted by the Comprehensive Anti-Apartheid Act (Public Law 99-440). In 1987 and again in 1989, the Department of State determined chromium (including ferrochromium) to be a critical and strategic material unavailable from reliable alternative sources, making it possible to import chromite ore and ferrochromium from the Republic of South Africa. Figure 2 summarizes world chromite ore and ferrochromium production capacity and chromium consumption, comparing centrally planned economy countries with market economy countries. The figure also shows NDS inventory.

Stockpile.—The NDS contains the following chromium materials: chromite ore, chromium ferroallovs, and chromium metal. The purpose of the NDS is to supply military, essential civilian, and basic industrial needs of the United States during a national defense emergency, and by law the stockpile cannot be used for economic or budgetary purposes. In addition to private and Government stocks, there exists a large unreported inventory of chromium contained in products, trader stocks, and scrap. The amount of these stocks varies with demand and price of the material. Under severe price pressures resulting from primary chromium shortages, recycling of consumer materials could add to the supply.

Chromite ore must be converted to ferrochromium before it can be used to make steel. Prompt response during a national defense emergency requires that conversion be carried out by domestic industry. However, domestic ferrochromium production capacity is not adequate

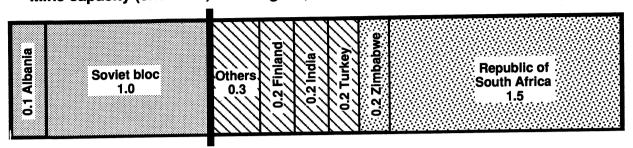

¹Nonspecification grade.

to meet anticipated domestic demand under mobilization conditions. To ensure prompt NDS response to a national defense emergency, the President chose to convert stockpiled chromite ore to ferrochromium. Changes in industrial capacity and new manufacturing and technological developments have rendered selected chromium materials in the NDS inventory obsolete, either in quality or form or both, and in need of upgrading. Subsequent to legislative mandate, DLA began modernizing chromium materials in the NDS by converting nonspecification-grade low-carbon ferrochromium into chromium metal. (See Legislation and Government Programs section of this report.)

Issues

World ferrochromium production capacity in 1990 increased significantly. Strong demand for ferrochromium, resulting from high levels of stainless steel production worldwide in 1987-89, resulted in ferrochromium plant expansions and new plant construction. Since 1970. the trend has been for ferrochromium production capacity to move from major stainless steel-producing countries (e.g., Japan, Western Europe, and the United States) to major chromite ore-producing countries (e.g., Finland, the Philippines, the Republic of South Africa, Turkey, and Zimbabwe). This has occurred through the creation of new plants or furnaces in chromite ore-producing locations and the closure of furnaces in other geographic areas where ferrochromium

production was formerly strong. The increase in and change in location of world annual gross weight production capacity, including net expansion by about 400,000 tons in 1989 and about 240,000 tons in 1990, has continued that trend. (Some new production facilities were completed but not put into production. Thus, there are production facilities that could be started up quickly, resulting in prompt production expansion when it is needed.) About 80% of added capacity was in chromite ore-producing countries in 1989 and 100% in 1990. All of capacity contraction was in nonchromiteproducing countries. The largest addition to national annual capacity was in the Republic of South Africa, where about 120,000 tons was added in 1989 and 280,000 tons was added in 1990, increasing The Republic of South Africa's capacity by about 30% in the 1989-90 time period. The supply shortage in 1988 was estimated to have been about 200,000 tons or about 5% of 1988 world production capacity. The expansion of 1989 and 1990 represented about 16% of 1988 world production capacity.

Stainless steel is the major chromium end use. In 1990, reduced demand for ferrochromium, resulting from decreased stainless steel production, and increased supply of ferrochromium, resulting from producer expansions and new plant construction, caused excess ferrochromium production capacity. Despite strong demand for ferrochromium resulting from production of stainless steel, excess ferrochromium production capacity caused

declining ferrochromium prices since their peak values in 1988. In 1990, world ferrochromium production was limited by delaying the startup of new furnaces, the idling of some furnaces, the conversion of some furnaces from ferrochromium to other ferroalloy production, and the closure of one plant.

Thus, by mid-1990, a combination of marginally reduced demand and added production capacity resulted in a large imbalance between demand and production capacity. With stainless steel production growing at a long-term average annual rate of 3% to 4%, it is estimated that it will take about 5 years for demand to catch up with added capacity. Experience shows that short-term variations in chromium consumption and production can be significantly larger than long-term trends.

Production

The major marketplace chromium materials are chromite ore and chromium metal, ferroalloys, and chemicals. In 1990, the United States produced chromium metal, ferroalloys, and chemicals, but no chromite ore.

Chrome Corp. of America, a subsidiary of Boulder Gold (Australia), entered a joint venture with Phelps Dodge to explore chromite at the Stillwater Complex (Montana) and to study the possibility for mining and producing ferrochromium. The study was planned to be completed in 1991. Chrome Corp. estimated that production could start in 1993.

Macalloy Corp. converted chromite ore to high-carbon ferrochromium for the NDS under a contract with the DLA. Elkem Metals Co. converted nonspecification-grade low-carbon ferrochromium into chromium metal for the NDS under a contract with the DLA. (See Legislation and Government Programs section of this report).

Consumption and Uses

Domestic consumption of chromite ore and concentrate was 402,290 tons in 1990. Of the total chromite consumed, the chemical and metallurgical industry used 358,620 tons, and the refractory industry, 43,670. Much of the chromite consumed and ferrochromium produced by the metallurgical industry were part of the NDS conversion program. (See Legislation and Government Programs section of this report.)

¹Data may not add to totals shown because of independent rounding.

Chromium has a wide range of uses in the three primary consumer groups. In the metallurgical industry, its principal use in 1990 was in stainless steel. Of the 388,916 tons of chromium ferroalloys, metal, and other chromium-containing materials reported consumed, stainless steel accounted for 78%; full-alloy steel, 9%; and other end uses, 13%. The primary use of chromium in the refractory industry was in the form of chromite to make refractory bricks to line metallurgical furnaces. Chromite consumption by the refractory industry decreased to 43,670 tons.

The chemical industry consumed chromite for manufacturing sodium bichromate, chromic acid, and other chromium chemicals and pigments. Sodium bichromate is the material from which a wide range of chromium chemicals are made.

Stocks

Reported consumer stocks of chromite in the United States decreased from 392,273 tons in 1989 to 354,661 tons in 1990. Chemical and metallurgical industry stocks decreased as did refractory industry stocks. At the 1990 annual rate of chromite consumption, consumer stocks represented about 11 months of supply in the chemical and metallurgical industry and 6 months of supply in the refractory industry. Producer stocks of chromium ferroallovs, metal, and other materials decreased from 20,475 tons in 1989 to 14,935 tons in 1990. Consumer stocks decreased from 19,486 tons in 1989 to 17,371 tons in 1990. At the 1990 annual rate of chromium ferroalloy and metal consumption, producer plus consumer stocks represented about a 5-week supply.

Prices

The price of chromite decreased steadily in 1990. The published price of the Republic of South African Transvaal chromite, 44% Cr₂O₃ (no specific chromium-to-iron ratio), decreased from a range of \$60 to \$65 per ton, f.o.b. the Republic of South African ports, to a range of \$55 to \$60 in June and a range of \$50 to \$55 in November, where it remained for the rest of the year. The published price of Turkish ore started the year by decreasing from a range of \$175 to \$185 per ton, f.o.b. Turkish ports, to a range of \$160 to \$170 in January. It then decreased to a range of \$145 to \$160

in June, followed by a further decrease in November to a range of \$120 to \$135, where it remained for the rest of the year.

Ferrochromium prices declined in 1990 as significant ferrochromium production

reductions were implemented to help move ferrochromium production and consumption toward balance. The published price of domestic high-carbon ferrochromium (50% to 55% chromium)

increased from 50.25 to 54.5 cents per pound (¢/lb) of chromium content in January, where it remained for the rest of the year. The published price of domestic low-carbon [0.05% and 0.015% (Simplex) carbonl ferrochromium remained unchanged. The published price of domestic chromium metal declined. The published price of electrolytic chromium metal declined from 395 ¢/lb to 350 ¢/lb in January, after which it increased to 370 ¢/lb, where it remained for the rest of the year. The price of elchrome declined from 462 ¢/lb to 422.5 ¢/lb in August, where it remained for the rest of the year. (Elchrome is a vacuum degassed chromium metal product produced by Elkem Metals Co.)

The price of imported high-carbon (50% to 55% and 60% to 65% chromium) ferrochromium declined until November, when it made a marginal recovery. The published price of imported 50% to 55% high-carbon ferrochromium started the year at a range of 50 to 52.25 ¢/lb-Cr from which it declined to a low range of 45 to 46 ¢/lb-Cr in November, after which it increased to a range of 46 to 47.5 ¢/lb-Cr. The published price of imported 60% to 65% highcarbon ferrochromium started the year at a range of 51 to 54.5 ¢/lb-Cr from which it declined to a range of 42.25 to 45.5 ¢/lb-Cr in December. The published price of imported low-carbon (0.05% carbon) ferrochromium varied throughout the year.

Foreign Trade

Chromium material exports from and imports to the United States included chromite ore and chromium metal, ferroalloys, chemicals, and pigments.

World Review

The council of the Chromium Association (Republic of South Africa) and the directors of the Chromium Centre (France) merged their respective organizations into a single organization, the International Chromium Development Association (ICDA). Each organization had been in operation for 6 years. The objective of the new organization is to promote the growth of chromium use in its traditional markets and the development of new end-use markets. Stainless steel in general and ferritic stainless steel in particular have been materials targeted for development. Structural and corrosion resistant end uses were the targeted

Low-carbon ferrochromium contains less than 3% carbon.

²High-carbon ferrochromium contains 3% or more carbon.

³Data may not add to totals shown because of independent rounding of converted units.

⁴Includes structural and hard-facing welding material.

⁵Includes cutting materials and magnetic, aluminum, copper, nickel, and other alloys.

⁶Includes estimates.

⁷Includes 4,290 tons of chromium metal.

⁸Includes 330 tons of chromium metal.

⁹Includes 4,920 tons of chromium metal.

¹⁰Includes 497 tons of chromium metal.

markets. The Chromium Review and bimonthly news bulletins are the communication tools to be used by the new organization. The ICDA has offices in Paris, France, and Johannesburg, the Republic of South Africa.

The German Ministry of Economic Affairs, in cooperation with the World Mining Congress, reviewed the world chromium industry. Information on company, location, product quality, geology and resources, and mining

methods were prepared by country and mine. 14

Industry Structure.—The chromium industry is composed primarily of chromite ore producers, ferrochromium producers, and stainless steel producers. Other industry components are chromium chemical and chromite refractory producers.

Brazil, Finland, India, the Republic of South Africa, and the U.S.S.R. are countries that mine chromite, produce ferrochromium, and produce stainless steel. In Finland, Outokumpu Oy, a major share of which is state-owned, owns and operates chromite mining, ferrochromium production, and stainless steel production facilities, making it completely vertically integrated. In the Republic of South Africa, Barlow Rand, an investment company, owns chromite mining operations (Rand Mines) and ferrochromium and stainless steel production facilities (Middelburg Steel and Allovs). making it the only completely vertically integrated chromium producer in the Republic of South Africa. Gencor, an investment company, owns chromite mining operations and ferrochromium production facilities through South Africa Manganese Amcor Ltd. (Samancor). Samancor owns chromite mining operations through its subsidiary Cromore and owns ferrochromium smelters (Tubatse and Ferrometals). Anglovaal, an investment company, owns chromite mines through Associated Ore and Metal Corp., which operates a ferrochromium smelter (Ferallovs) through Associated Manganese Mines. Anglo American and Johannesburg Consolidated Investment. investment companies, have shared interests in chromite mines and ferrochromium smelters (Consolidated Metallurgical Industries and Purity Ferrochrome). One other company in the Republic of South Africa, Chromecorp Technology, has chromite mining and ferrochromium production operations. Chromium chemical and chromite refractory production in the Republic of South Africa is also vertically integrated from mine production through product production. Bayer AG (Federal Republic of Germany) owns a chromite mine and chromium chemical plant. Vereening Refractories operates a chromite mine and produces chromite refractories. In the Republic of South Africa, the chromium-related companies are privately owned. Typically, major shares of a company are owned by other

Includes chromium briquets, chromium metal, exothermic chromium additives, and other miscellaneous chromium alloys.

companies, and the remainder, if any, is openly traded. (See figure 3.)

In Brazil, the mining and smelting of chromium is vertically integrated, but stainless steel production is independent of the mining-smelting operations. The major mining companies are subsidiaries of Cia. de Ferro Ligas da Bahia S.A. (FERBASA). Stainless steel is produced primarily by Companhia Acos Especiais Itabira (ACESITA). Other chromite operations in Brazil are also vertically integrated. Bayer AG (Federal Republic of Germany) owns a chromite mine and chromium chemical plant. Refractory chromite operations are also vertically

common needs such as insurance, banking, transportation, international trade. real estate, etc. Companies within a group are frequently part owners of other companies within the group, but shareholding between groups is also common, especially by banking and trust companies. The Japanese ferrochromium producers are typically associated with stainless steel producers and may be part

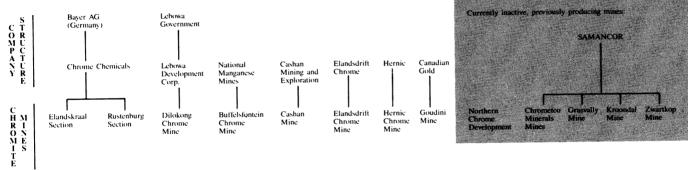

of a group. Association means the stainless steel producer takes the output of the ferrochromium producer. Because Japanese industry is typically both forward and backward integrated, stainless steel and ferrochromium may each be partial owners of one another. The chromium industry of Turkey is composed of both large and small chromite ore producers, with one major producer.

Etibank, integrated from mining through ferrochromium production. The chromium industry of Zimbabwe is composed of large companies vertically integrated from chromite mine production through ferrochromium production, small independent chromite mines, and chromite mines operated independently on behalf of the large vertically integrated companies.

Capacity.—The data in table 15 are rated capacities for major countries that mine chromite ore and produce ferrochromium, primary chromium chemicals, and chromium metal as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time at a normally sustainable long-term operating rate, based on the physical equipment

of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Because not all countries or producers make production capacity information

available, historical chromium trade data have been used to estimate production capacity. Rated production capacity changes result both from changes in facilities and changes in knowledge about facilities.

Reserves.—The United States has no chromite ore reserves. However, the United States has a reserve base and resources that could be exploited. (For

NA Not available.

further information on domestic reserves, reserve base, and resources, see Geology-Resources section of this report.)

Albania.—Albania continued construction of a ferrochromium plant at Elbasan. The plant was planned to have a production capacity in the range of 40,000 to 60,000 tons per year from three furnaces. The first of three furnaces was to have been completed in 1990. Albania produces most of its electrical energy at hydroelectric power stations that have had their output limited by water supply shortages resulting from drought. Because ferrochromium production is electrical energy intensive, ferrochromium production capacity has been limited by electrical energy supply.

Australia.—Dragon Resources Ltd. continued to develop its Range Well chromite in a laterite deposit near Cue in Western Australia. The company reported favorable results from a feasibility study for producing high-chromium cast iron grinding balls from its chromite resource. The study was carried out in cooperation with Crooks Mitchell Peacock Stewart (WA) Pty. Ltd. by shipping ore to Geraldton, where it was smelted and cast.

Bolivia.—Bolivia accepted applications for concessions for mineral exploration in the Rincon del Tigre. This 240,000-hectare area has been reported to contain chromite resources.

Brazil.—Companhia Ferroligas do Amapá's Vila Nova Mine produced chromite in Amapá Territory. The Vila Nova

Mine estimated its inferred chromite reserves at 7 million tons. Chromite production capacity was 50,000 to 60,000 tons per year of beneficiated product. The company planned to increase beneficiation capacity to 120,000 tons per year when an expansion was justified by chromite demand. Open pit mining resulted in run-of-mine (ROM) ore that typically graded 35% to 44% Cr₂O₃ with a chromium-to-iron ratio of 1.7:1, while beneficiated product typically graded 50% Cr₂O₃ with a chromium-to-iron ratio in the range of 2.0:1 to 2.3:1. ROM ore was beneficiated at the mine site from which it was transported by truck to the Cupixi railroad station, then by train to Santana for export.

Cia. de Ferro Ligas da Bahia S.A. (FERBASA) planned to construct four hydroelectric powerplants. FERBASA planned to construct two of those hydroelectric powerplants on the San Francisco River in Bahia State. Each was planned to have a production capacity of 50 megawatts. The first of these plants was planned to be completed in 1993. FERBASA planned to finance this project through Federal Government financial institutions. Owing to reduced world demand relative to supply, FER-BASA reduced production by about 20% (from about 110,000 tons to about 80,000 tons) in 1990.

Companhia Ferroligas do Amapá (CFA) completed construction of its ferrochromium smelter at Porto de Santana at a cost in the range of \$14 to \$16 million. CFA's 12-megavolt-ampere furnace has a ferrochromium production capacity

of 20,000 tons per year. Ferrochromium production would be interchangeable with ferromanganese and ferrosilicon production, with the choice of product determined by market conditions.

Anuário da Indústria Brasileira de Ferroligas (ABRAFE), the Brazilian ferroalloy producers association, reported 1990 production as follows: high-carbon ferrochromium, 73,105 tons; low-carbon ferrochromium, 10,684 tons; ferrochromium-silicon, 4,973 tons; and chromium metal, 37 tons. ABRAFE reported 1990 exports as follows: high-carbon ferrochromium, 16,143 tons; low-carbon ferrochromium, 345 tons; and ferrochromium-silicon and chromium metal, none.

Canada.—Canada studied the development potential of its chromium resources. Coleraine Mining Resources Inc. evaluated the resources of the Hall deposit in Ouebec. The Hall deposit was found to contain 1.04 million tons of chromite ore reserves graded at 4.5% Cr_2O_3 , of which 801,400 tons grading at 4.6% Cr_2O_3 was proven. Chromium-to-iron ratio of the chromite was found to be 2.6:1. The reserve was found to be exploitable by surface mining. The deposit remains open at depth, and the company planned to continue surveying to determine the deposit's lateral extent. Coleraine Mining also planned to conduct a feasibility study for the production of ferrochromium using low-cost hydroelectric energy from Québec.

Sherwood Metallurgical Corp. continued development of a low-carbon ferrochromium smelter in Vancouver, British Columbia. The plant was planned

¹World resources derived in consultation with the U.S. Geological Survey.

²Data and total rounded to nearest 100,000 metric tons.

³The reserve base includes demonstrated resources that are currently economic (reserves), marginally economic (marginal reserves), and some of those that are currently subeconomic (subeconomic resources).

Less than 1/2 unit.

⁵Less than 50,000 metric tons.

⁶Data may not add to totals shown because of independent rounding.

to have an initial production capacity of 30,000 tons per year of low-carbon ferrochromium containing 60% to 65% chromium. Producing at full capacity, the plant was planned to annually consume 300,000 megawatt hours of energy, 61,000 tons of chromite ore, 12,500 tons of lowsulfur reductant, and 22,000 tons of lowlime silica sand. A construction site was selected at Bear Cove in Port Hardy. The proposed plant was relocated to the Port Hardy area after local opposition was encountered at Mill Bay and Namaimo. The Port Hardy Ferrochromium Assessment Review Panel was expected to decide on whether or not to permit plant construction in 1991. The plant was opposed by the local Kwakiutl Indian tribe, which claims the proposed plant site and was concerned about the effect of a plant on local fishing. Sherwood also considered locating a low-carbon ferrochromium plant in New Brunswick.

Ferrochrome Canada, a joint venture including Showa Denko (Japan), Mitsui (Japan), Companhia Auxiliar Empresa Minerção SA (Brazil), and Société Général du Financement (Canada), planned an 80,000-ton-per-year-capacity high-carbon ferrochromium plant for Bécancour, Québec. The project was indefinitely postponed owing to the low price of ferrochromium (resulting from increased supply) and to the reduced likelihood of sanctions against the Republic of South African produced ferrochromium (resulting from improved performance of the South African Government in abandoning its apartheid policy).

China.—China reported chromite production from 1949 through 1988.¹⁵

China reported construction of the Norbusa Mine in Shannan district of Tibet Autonomous Region. Tibet has produced about 500,000 tons of chromite since 1979. The mine was planned to come into production in 1995, with an annual chromite production capacity of about 50,000 tons. The Lhobsa deposit is near the Yarlung Zangbo River. The development cost was estimated to be \$12 million and was to be financed by earnings from the Dongfeng chromite mine. The Dongfeng Mine was planned to close owing to consumption of reserves. Chromite from the Norbusa Mine was planned to be smelted to ferrochromium locally, and the ore was to be processed by the Tibet Chemical Works and smelted by the Lhasa Power Bureau and the Tibet Electrical Machinery Plant.

About 1,000 tons of ferrochromium was produced.

China deemphasized ferrochromium export owing to raw material supply shortages. Conversion contracts wherein foreign companies supplied ore for conversion were not effected.

The Chinese Ferroalloy Association reported Chinese high-carbon ferrochromium production in 1989 to have been in the range of 80,000 to 90,000 tons; low-carbon ferrochromium production was about 50,000 tons. Ferrochromium exports were reported to have been 8,000 tons in 1987, 24,000 tons in 1988, and 20,000 tons in 1989. Japan and the United States were the largest recipients of Chinese ferrochromium.

European Community.—European ferrochromium producers requested the European Commission to investigate U.S.S.R. and Albanian high-carbon ferrochromium imports to determine whether or not the ferrochromium was being dumped in the European Community. The European Commission opened an investigation, which it planned to complete in 1991. In July, the Council of European Communities increased the amount of high-carbon (more than 6% carbon) ferrochromium from nonmember states permitted to enter duty free from 300,000 tons to 450,000 tons.

Finland.—Outokumpu Chrome Ov operated a new concentrator at the Kemi Mine and a new pelletizing and sintering plant at its ferrochromium plant at Tornio. Construction of the new production facilities was completed in 1989, and these facilities were being brought up to full operating capacity, raising Outokumpu's sintered pellet production capacity to 300,000 tons per year and its ferrochromium production capacity to about 200,000 tons per year. The old sintering plant was to be dismantled. Outokumpu reported that Outokumpu Chrome Oy operated as an independent company and was a wholly owned subsidiary of Outokumpu Oy. Outokumpu planned to transfer ownership of Outokumpu Chrome Oy to Outokumpu Steel Oy effective January 1991. Outokumpu reported 1990 production of 1.1 million tons of chromite ore excavated (up from 0.8 million tons in 1989), 157,000 tons of ferrochromium (down from 169,000 tons in 1989), and 226,000 tons of stainless steel slab (up from 192,000 tons in 1989).

Greece.—Hellenic Ferroalloys SA (HFA) restructured its debt, power cost,

and ownership. HFA renegotiated its power rate from 10.2 to 4.75 drachmas per kilowatt-hour, to become effective in 1991. Also to become effective in 1991 was the new ownership structure wherein HFA was to be owned primarily by the Greek Finance Ministry (55%) and the state-run Public Power Corp. (35%). The Greek Government expressed interest in selling publicly owned companies, such as HFA, to the private sector. Interest in HFA was reported. However, no specific offers were revealed. The Greek Government was interested in developing stainless steel production in Greece through the sale of HFA and a sister nickel-producing company.

The National Bank of Greece granted HFA exclusive rights to mine chromite deposits near Domokos in central Greece. HFA planned to start mining the 1 million ton reserve at the rate of about 50,000 tons per year.

India.—National.—The large amount of ferrochromium production capacity licensed in 1989 stimulated debate over the best way for India to exploit its chromium resources. Some proposed development of India's ferrochromium industry so that India could benefit from supplying a higher value added commodity (i.e., ferrochromium instead of chromite ore) on the world market. Others proposed to develop the chromite ore-producing industry, but not the ferrochromium industry, reasoning that the ferrochromium plants are not cost effective. (The purpose of development is to earn hard currency. which could then be used for other Indian needs. The cost in hard currency, it was thought, of constructing ferrochromium plants would more than offset the income gain.) Yet others proposed limiting chromite ore exports for a variety of reasons, including the following:

(1) There was not adequate chromite ore production capacity in India to supply the ore required by licensed ferrochromium producers.

(2) Limiting chromite ore export could stimulate development of the electrical energy consuming industry (i.e., ferrochromium production) in States with excess electrical energy. Unfortunately, chromite ore resources and excess electrical power were not found in the same States.

(3) Limitation of chromite ore export from the major producing area (Orissa State) would stimulate industrial growth in that State.

Many motivations and constraints are shaping the development of the Indian chromium industry.

The Indian Government announced its chromite ore export policy for April 1, 1990, through March 31, 1993. The new policy prohibits the export of either lumpy chromite ore with Cr2O3 content greater than 38% or friable chromite ore with Cr₂O₃ content greater than 52% and silica content lower than 4%. The Steel and Mines Minister of India introduced a new minerals policy that reserves exploration and processing of chromite for the Government. The Orissa State Government sought to have the Indian Government ban export of chromite ore from the Orissa. Orissa State holds 97% of Indian chromite reserves and accounts for more than 90% of Indian chromite ore production. Such a ban would have reduced supplies to foreign consumers, reduced the likelihood of ferrochromium plant construction outside Orissa, and favored chromite ore and ferrochromium producers in Orissa State. Orissa Mining Corp. and OMC Allovs Ltd. are the State-owned enterprises currently producing chromite ore and ferrochromium. Tata Iron and Steel Co. is the major private producer of chromite ore and new ferrochromium producer in Orissa. Ferro Alloys Corp. Ltd. (FACOR) and Indian Development Corp. are private ferrochromium producers in Orissa State.

Chromite Ore.—FACOR continued development of the Lakshmi shaft at its Boula Mine. The company planned to complete the chromite ore haulage shaft in 1992.

Tata Iron and Steel Co. (TISCO) started production from its new beneficiation plant at Sukinda chromite mine. The plant cost about \$13 million¹⁶ and has an annual production capacity in the range of 70,000 to 80,000 tons of chromite ore graded at 48% Cr₂O₃ with a chromium-to-iron ratio of 2.7:1 and 20,000 to 30,000 tons of chromite ore graded at 52% to 54% Cr₂O₃ with chromium-to-iron ratio of 3.2:1. Product size is in the range of 150 to 200 mesh. Chromite feedstock to the plant is graded in the range of 20% to 30% Cr₂O₃.

Ferrochromium.—India's consumption of chromium materials was estimated to include about 60,000 tons of high-carbon ferrochromium and 10,000 tons of low-carbon ferrochromium annually. India is

virtually self-sufficient in ferrochromium supply. India operates a unique mixture of privately and publicly owned ferrochromium smelters. Larger smelters were licensed by the State, while smaller smelters operated without license. Licensed smelters are required to produce for domestic use or for export. It has been estimated that there is about 50,000 tons of ferrochromium production capacity at small (unlicensed) plants. Licensed production capacity nears 600,000 tons per year. However, substantially less production capacity is installed, and even less is available owing to insufficient electrical power availability from the national grid. India experienced electrical power shortages in Andra Pradesh and Karnataka States. Andra Pradesh reduced electrical power supply by 30% to 40%.

FACOR installed a captive electrical power generating facility (including a fuel oil storage facility) at its ferrochromium plant at Shreeramnagar in Andra Pradesh State. The electrical powerplant consisted of three 10.5-megawatt diesel-powered electrical generators. This captive power station is capable of supplying about 60% of FACOR's needs at Shreeramnagar. FACOR planned to install two 10.5-megawatt electrical generators at its charge-grade ferrochromium plant in Orissa State. FACOR added a vacuum oxygen decarburizing furnace of its own design and construction to its processing facilities to supply medium-carbon ferrochromium produced from high-carbon ferrochromium to India's steel industry.

Indian Charge Chrome Ltd. (ICCL), a subsidiary of Indian Metals and FACOR, started production operation of its 108-megawatt captive powerplant, briquetting plant, and ferrochromium smelter at Choudwar, Cuttack District, Orissa State. ICCL is an export-oriented unit with an annual production capacity of 62,500 tons. ICCL arranged for Tata Iron and Steel to supply chromite ore and to market its ferrochromium production.

Ispat Alloys Ltd. planned to construct a ferrochromium plant in Ohankale District of Orissa State, where chromite ore was readily available. Ispat Alloys planned to use a pelletizing process from Outokumpu Oy (Finland) and a 45-megavolt-ampere furnace from Demag (Germany) at the export-oriented plant. Ispat planned to complete construction of the plant in 1991.

OMC Alloys, a subsidiary of Orissa Mining Co. and a public-sector company,

experienced financial difficulties. OMC identified increasing electrical power rates and inflation as the major causes of its problems. Since the plant started producing ferrochromium, electrical power cost has increased from \$0.013917 per kilowatt hour to \$0.056618 per kilowatthour. The rising cost of production and declining price of ferrochromium has resulted in unprofitable operation for OMC. Rupee value dropped by 30% to 60% due to inflation. This inflation has increased the cost of the foreign component of OMC's debt. OMC planned to improve its position by increasing production from the current 70% of capacity to the range of 80% to 85% of capacity.

TISCO converted a ferromanganese furnace to ferrochromium and constructed an export-oriented ferrochromium plant. TISCO had Elkem (Norway) renovate a 9-megavolt-ampere ferromanganese furnace at its ferromanganese plant at Joda, Kendujhar District, Orissa State, to a 12-megavolt-ampere ferrochromium furnace with an annual production capacity of 20,000 tons.

Kolmak Chemicals planned to build a ferrochromium plant at Raigarh, Madhya Pradesh. The new ferrochromium producer, Standard Chrome, was planned to have an annual production capacity of 15,000 tons. TISCO was expected to supply chromite ore, handle export sales, and cofinance the new business.

Indonesia.—Aneka Tambang, Indonesia's state-owned mining company, developed a chromite mine near Wosu Port, Sulawesi Island. Commercial production started in 1990 and included chromite ore for metallurgical use and for foundry sand use. Aneka planned to ship the metallurgical-grade chromite ore to Japan and the foundry sand-grade chromite ore to Gebe Island for cast iron production. The metallurgical-grade chromite ore graded about 41% Cr₂O₃, 17% FeO, 18% Al₃O₃, and 11% MgO, with a chromium-to-iron ratio in the range of 1:1 to 1.6:1. The foundry-sand grade chromite ore contained about 52% Cr₂O₃.

Iran.—Following the end of the Iran-Iraq war in 1988, Iran has been developing its chromium industry. Chromite ore exports have increased since the end of the war.

Italy.—Italcromo purchased a site (the Stefana di Termoli, an industrial site used

to produce steel from 1972 to 1986) at a cost of \$5.4 million¹⁹ and planned to construct four furnaces. The first two were planned to be 24-megavolt-ampere furnaces for ferrochromium production (convertible to ferromanganese). The second two furnaces, planned for construction in 1994, were planned to be for silicomanganese production (convertible to ferrosilicon). The first furnace (planned to have been purchased from Demag in Germany) was to be brought into operation in the second quarter of 1991. It was noted that Italy consumed on the order of 160,000 to 170,000 tons of ferrochromium annually, an adequate level of demand to support a domestic plant. Italcromo planned to produce high-carbon ferrochromium from Albanian ore.

Japan.—Japan operated a two-part stockpiling program, Government and private. Japan's goal is to acquire a stockpile of chromium adequate to serve its needs for 60 days, of which 42 days was to be in the Government stockpile and 18 days was to be in the private stockpile. The Metal Mining Agency of Japan, under the supervision of the Ministry of International Trade and Industry, operated the Government stockpile, while Japan Rare Metals Association operated the private stockpile. As of March 1990, Japan had acquired a stockpile of chromium adequate to serve its needs for 35.3 days in the Government stockpile and 15.1 days in the private stockpile. Japan planned to increase its Government stockpile to 2.8 days of consumption, while increasing its private stockpile to

Japan reported stainless steel production of 2,410,725 tons in 1990, a decline of 11% compared with that of 1989. Japan's ferroalloy industry produced about 324,327 tons of ferrochromium, a decline of 9.0% compared with that of 1989. Japan's ferrochromium production has ranged from 260,000 tons to 360,000 tons per year in the 1980-90 time period. Japan imported 441,672 tons of ferrochromium in 1990, while it exported 2,811 tons, giving imports a 58% market share. Japan imported 789,225 tons of chromite ore with which to produce chromium ferroalloys and imported 550 tons of chromium metal.

Japanese ferrochromium producers suffered as a result of excess supply of ferrochromium in 1990. The Japan Ferroalloy Association studied the possibility of making an antidumping complaint against ferrochromium imports owing to the low price of that material relative to the cost of production in Japan.

Japanese stainless steel producers, NKK and Kawasaki Steel, reported implementing innovative production techniques. NKK started production of nickel-containing stainless steel at its Fukuyama works in September. NKK combined nickel and chromite ores with coke and blast furnace iron in a converter, then blew the mixture with oxygen and nitrogen to produce stainless steel. The stainless steel was then continuously cast. Kawasaki processed chromite ore in a kiln at its Mizushima works then supplied the chromium product to a converter at its Chiba works for the production of stainless steel. It was thought that stainless steel production by these blast furnace steel producers would increase competition and result in a lower priced and more competitive stainless steel product.

Korea, Repubic of.—Korea reported 1990 ferrochromium imports of 67,162 tons, consumption of 69,363 tons, and ending stocks of 11,953 tons.

Madagascar.—Kraomita Malagasy (Kraoma) mined 192,857 tons of chromite ore from which it produced 62,540 tons of marketable concentrate in 1989. Madagascar exported 134,338 tons of chromite in 1989.

New Caledonia.—Chromical Ltd., the chromite ore mining company that operates the Tiebaghi Mine in New Caledonia, continued mining until July 1990, while it prospected to extend chromite ore reserves. New Caledonia reported mining about 11,031 tons of run-or-mine chromite ore from which it produced about 6,207 tons of marketable concentrate.

Norway.—Elkem AS (Norway) purchased the fixed assets of Norsk Ferrokrom AS effective July 1990 and named the operation Elkem Rana AS. The assets included a briquetting facility and two ferrochromium-producing electric furnaces. One electric furnace started production in September 1989. Elkem planned to start the second furnace in 1991. The briquetting facility had an annual production capacity of 300,000 to 400,000 tons of chromite ore furnace feed. The operating furnace had a capacity of 45 megavolt amperes and was operated at 40 megawatts to produce about 70,000 tons of high-carbon ferrochromium

annually. Thus, with both furnaces in operation, Elkem could produce with an annual capacity of about 140,000 tons. Elkem planned to construct a concentrator to recover chromium from slag. Chromium recovery from slag would permit smelting-process-chromium recovery in excess of 80%. Norwegian sanctions against the Republic of South Africa prohibit importation of South African chromite ore.

Oman.—Oman Mining Co. (state owned) has mined chromite ore from deposits near Wadi Rajmi and exported about 8,000 tons of chromite between 1985 and 1989. Oman has identified more than 600 chromite occurrences. Detailed analysis of 36 deposits yielded 1 million tons of chromite ore reserves. Oman continues to explore for chromite in the area of Rajmi-Fizh and the Farfar-Hilti areas of northern Oman.

Philippines.—Chromite Ore.—At the request of the Philippine Government, the Japan International Cooperation Agency is conducting a 3-year study of chromite resources on Palawan Island. The study is funded by the Metal Mining Agency (Japan) and was estimated to cost about \$2 million.

Merlin Mining Co. (Australia) acquired 24.4% interest in Acoje Mining Co., owner of the Acoje Mine in Zambales Province. Merlin also holds leases near the Acoje Mine, from which it produces chromite fines from alluvial deposits and owns leases on Dinagat Island. Acoje Mining Co. started mining in the late 1930's, from which time it has produced about 3 million tons of chromite ore. As a result of excessive debt and labor problems, production has declined to about 36,000 tons per year. Merlin planned to invest in the Acoje Mine to bring the mine's production up to about 100,000 tons per year. In situ reserves were estimated at 4 million tons.

The Philippine Government signed an agreement with Benguet Corp. to develop a refractory chromite mine from deposits owned by Consolidated Mines Inc.

The Philippine Government and the United Nations Revolving Fund for Natural Resources Exploration (UNRFNRE) agreed to develop chromite deposits on Dinagat Island. The deposit was estimated to contain in the range of 1 to 2 million tons of massive metallurgical-grade chromite ore graded at 50% Cr_2O_3 .

Ferrochromium.—Ferrochrome Philippines Inc. operated a ferrochromium smelter with a production capacity of about 54,000 tons per year. Integrated Chrome Corp. operated a ferrochromium smelter with a production capacity of about 18,000 tons per year.

South Africa, Republic of.—Labor Relations.—The National Union of Metalworkers of South Africa (NUMSA) represents ferrochromium workers at Consolidated Metallurgical Industries, Ferrometals, Feralloys, Middelburg Steel and Alloys, and Tubatse. Contracts were renegotiated without work interruptions at Consolidated Metallurgical Industries, Feralloys, Middelburg Steel and Alloys, and Tubatse. Ferrometals experienced a strike during part of August and September before a new contract was agreed upon. Issues included job security and pay rates.

Chromite Ore.—High demand for chromium in 1989 resulted in the creation of new, independent chromite ore mining operations in the Republic of South Africa that utilize surface mining methods. As a result, the new operations can produce chromite ore at a cost less than that of established underground operations. The cost difference is expected to last until surface minable reserves are exhausted. Established South African chromite ore producers reported that wage increases, inflation, and rail transportation cost increases contributed to the increased cost of chromite ore. South Africa's Minerals Bureau reported 1989 chromite ore production (excluding Bophuthatswana) at 4,274,700 tons, an increase of 13% over that of 1988 and a record high for the second year in a row. The Minerals Bureau reported 1989 sales to have been as follows: domestic, 2,542,000 tons (up 19% over that of 1988); and foreign, 1,371,000 tons (up 3.5% over that of 1988). Domestic sales set a record high, exceeding the previous high in 1987 by 17.8%.

Lebowa Development Corp, owner of the Dilokong Chrome Mine in Lebowa, reported mine developments raising annual production capacity to 300,000 tons effective in 1990. The production composition was to include 69,000 tons of lumpy chromite ore, 58,000 tons of small lumpy ore, and 173,000 tons of fine chromite ore.

Hernic Pty. Ltd. started production late in 1989 from reserves of about 3.052

million tons and reached full potential in 1990. Ore reserves include 1.743 million tons in the GM-1 seam (primarily metallurgical grade) and 1.309 million tons in the GM-2 seam (primarily chemical and refractory grades). Open pit mining yields a range of 30,000 to 40,000 tons of chromite ore per month after removal of 25 meters of overburden and with an eventual change to underground mining when production capacity will shift to a range of 20,000 to 30,000 tons of chromite per month. A beneficiation plant under construction, at a cost of \$1.7 million, 20 was planned to produce 12,000 tons of lumpy chromite ore per month and 18,000 tons of chromite concentrate per month. A captive loading facility, under construction at Marikana station (11 kilometers from the mine), was to have a loading capacity in the range of 15,000 to 20,000 tons of chromite ore per month when completed in 1990. (Wolhuterskop station, 25 kilometers from the mine, was to be used until the Marikana facilities were completed.) Typical chromite ore specification were as follows: lumpy, 39.5% Cr₂O₃, chromium-to-iron ratio of 1.50:1; chemical grade, 46.54% Cr₂O₃, chromium-to-iron ratio of 1.55:1; concentrate, 45.0% Cr₂O₃, chromium-to-iron ratio of 1.51:1. Hernic's mine is south of Samancor's Mooinooi Mine in the Rustenburg district, Transvaal Province (western belt of the Bushweld Complex). Beneficiation includes crushing, screening, and spiral classifiers.

Goudini Mine started open pit production of chromite ore early in 1990, with reserves in the range of 70 to 75 million tons. Goudini Mine is in the western belt of the Bushweld Complex. Ore has an unusually high chromium-to-iron ratio of 2:1, with lumpy ore grading 40% Cr₂O₃ and concentrate, above 50% Cr₂O₃. Production was reported at the rate of about 80,000 tons per year in 1990, with a target production capacity of 200,000 tons per year.

Elandsdrift Chrome (Pty.) Ltd. was organized in September 1989 and started opencast mining in June 1990. The beneficiation plant was completed in February 1990. Chromite ore was mined from an inferred reserve of 1.5 million tons in the MG-1 seam. Run-of-mine ore grading 44% Cr₂O₃ was about 30% lump and 70% fines. The beneficiation plant, including a rod mill and spiral separators, produced about 9,000 tons per month, with expansion to 18,000 tons per

month planned. Shipping was by rail from the nearby Marikana station.

A new process, recovery of platinumgroup metals from chromite ore tailings, was being implemented. Temex, the mining exploration division of Genwest Group, erected a plant in western Transvaal Province. In addition to platinumgroup metals, the new plant was to produce chromite concentrate.

Ferrochromium.—The Republic of South Africa's Minerals Bureau reported 1989 ferrochromium production at 993,920 tons, an increase of only 0.02% over that of 1988 and a record high for the third consecutive year. The Minerals Bureau reported 1989 sales to have been as follows: domestic, 59,552 tons (up 2.4% over that of 1988 and a record high); and foreign, 930,571 (down 3.6% over the record high of 1988).

Chromecorp Technology (CCT) operated the two electric arc furnaces (electrical capacity, 30 megavolt amperes and production capacity, 50,000 to 60,000 tons per year each), while it completed construction in April 1990 of a third furnace like the first two. With completion of its third furnace, CCT had a production capacity in the range of 150,000 to 180,000 tons per year. CCT also operated a captive chromite mine, the Chroombronne Mine.

Consolidated Metallurgical Industries Ltd. (CMI), a subsidiary of Johannesburg Consolidated Investment Co. Ltd., started its third 32.5-megavolt-ampere furnace at its plant near Lydenburg, Transvaal Province. The additional furnace increased CMI's production capacity from a range of 150,000 to 160,000 tons per year to a range of 200,000 to 210,000 tons per year. CMI purchased the issued share capital of Purity Chrome Pty. Ltd. (a chromite ore mining and beneficiating company) and the assets of Purity Ferrochrome Pty. Ltd. (a ferrochromium producer) for \$49 million.²¹ At the time of purchase, Purity Chrome Mine had a production capacity of about 250,000 tons per year of chromite ore with chromium-to-iron ratio of 1.55:1. Chromite ore production included lumpy, grading 40% to 42% Cr₂O₃, and fines, grading 45% Cr₂O₃. Purity Ferrochrome included two electric arc furnaces of 33-megavolt-ampere power capacity and 120,000 tons per year charge-grade highcarbon ferrochromium production capacity. With this purchase, CMI acquired a captive chromite mine and additional ferrochromium production capacity, yielding a total capacity in the range of 320,000 to 330,000 tons per year for CMI and Purity combined.

Middelburg Steel and Alloys (Ptv.) Ltd. reorganized itself into MS&A Chromium (Pty.) Ltd. (MS&A), responsible for the chromium ferroalloy production and marketing, and MS&A Stainless (Ptv.) Ltd., responsible for stainless steel production and marketing. Middelburg Steel and Alloys (Pty.) Ltd. retains responsibility for the new companies' strategic planning. MS&A completed construction of a rotary kiln and electric arc furnace for application of the chrome direct reduction (CDR) process that MS&A developed with Krupp (Germany). The project will add 120,000 tons per year of ferrochromium production capacity during a 3-year period, while the new equipment and process is being brought to full capacity operation at a cost to MS&A of about \$97 million.²² The new process offers several cost-reducing features, including the following: (1) The CDR process uses chromite ore fines that are available at lower cost than chromite ore lumps, and (2) the CDR process uses coal as a source of energy for reducing a substantial fraction of the chromite ore before the partially reduced product is fed into an electric arc furnace for completion of the reduction process. Energy supplied from coal is less expensive than energy supplied from electricity.

Tubatse started production from its fifth furnace in February 1990. Tubatse started producing ferrochromium with three furnaces, each with electrical transformer capacity of 30 megavolt-amperes and production capacity of about 50,000 tons per year. Tubatse modified its furnaces, changing production capacity to about 60,000 tons per year for each furnace. Tubatse then added two furnaces, each with electrical transformer capacity of 37 megavolt-amperes and production capacity of about 60,000 tons per year. The fourth furnace was brought into production in 1989. Tubatse now has a production capacity of 300,000 tons per year.

South Africa Manganese Amcor Ltd. reported its analysis of the world chromium growth prospects. Samancor estimated world stainless steel production to have grown historically at a rate of 2.4%. At this growth rate, Samancor estimated the world chromium industry would be required to add about 100,000 tons of fer-

rochromium production capacity and about 300,000 tons of stainless steel production capacity annually. The Republic of South Africa was estimated to produce only about 1% of world stainless steel production. Samancor found these conditions encouraging to the development of stainless steel production capacity in the Republic of South Africa. Samancor and Highveld Steel & Vanadium planned a 300,000-ton-peryear capacity stainless steel plant. It was suggested that such a plant could be built at Witbank within a 3-year period. Expanded stainless steel production would be the next step in vertically integrating and expanding the Republic of South Africa's chromium industry.

Purity Ferrochrome, a subsidiary of Consolidated Metallurgical Industries Ltd., brought its first furnace into operation in June and its second in July 1990. Each furnace is of Tanabe Kakoki (Japan) design and has electrical capacity in the range of 30 to 33 megavoltamperes and production capacity of about 60,000 tons per year. (See Consolidated Metallurgical Industries Ltd. on previous page.)

Spain.—Empresa Nacional Adaro de Investigaciones Mineras S.A. (ENADIMSA), a state-owned Spanish company, in cooperation with the University of Madrid, reported the results of minerals exploration on the northwest coast of Spain. The exploration geologists targeted chromite because the Cape Ortegal Complex is composed of rock types known to be associated with chromite. The geologists found clear indicators of chromium mineralization in northwestern Spain. The mineral rights of the area are covered by ENADIMSA claims.

Sweden.—SwedeChrome AB closed its ferrochromium plant at Malm in January 1990. The plant was closed because of the declining price of ferrochromium, an unfavorable cost position due to the Swedish embargo toward South African chromite, and, to a lesser degree, uncertainty about electrical power rates. With SwedeChrome out of production, Sweden was left with one ferrochromium producer, Vargn Alloys AB. Vargn produces high-carbon ferrochromium with an annual capacity of about 160,000 tons.

Turkey.—Mine and smelter development was planned by Egemetal Madencilik AS in cooperation with three Korean

companies, Yukong Ltd., Sunkyong Ltd., and Korea Mining Promotion Corp. Mine development was planned to start in 1990 followed by smelter development in 1991, with completion in 1993 at a cost of \$34 million. The ferrochromium smelter was planned to have a production capacity of about 40,000 tons per year, of which 20,000 tons was planned to be supplied to Korea to meet about 20% of Korea's ferrochromium demand. The smelter was planned to be at the mine site in Bursa Province.

Etibank, Turkey's Government-owned company that owns chromite mines and the only ferrochromium smelters in Turkey, completed construction of two new furnaces in 1989, when one of those furnaces was brought into production. The second new furnace started trial operation in 1990. When both new furnaces are operating at full capacity, Etibank will have a high-carbon ferrochromium production capacity of 150,000 tons per year. Etibank considered reorganizing its sales operation in the United States. Etibank has sold its ferrochromium product quarterly on a tender basis to U.S. merchants, who then sell the material to consumers. Etibank may enter a jointventure arrangement to create an exclusive agent company for Etibank's ferrochromium in the United States.

U.S.S.R.—Donskoy Ore Dressing Complex is at Khromtau city, about 90 kilometers east of Aktyubinsk, Kazakhstan Republic. Ore was discovered there in 1936. The complex operated with a work force of 5,000 compared with a local population in Khromtau city of 25,000. Proven ore reserves were reported to have been 300 million tons at 43% to 44% Cr₂O₃; total ore reserves (including inferred), 1,000 million tons. Production was planned to increase to 4 million tons per year by the year 2000. Run-of-mine chromite ore was mined and then screened into lumps and fines. Tailings (material in the size range of 0 to 3 millimeters and containing 40% Cr₂O₃) were stockpiled and amounted to about 5.0 million tons by yearend. Upgrading tailings for export was planned.

Donskoy Ore Dressing Complex planned to expand its beneficiation facilities. The new beneficiation facility was planned to have a production capacity of 400,000 tons per year. Construction was planned to be completed in 1993, and shipments were planned to start in 1994. This additional production capacity

would increase the operation's production capacity from 3.6 to 4.0 million tons per year. The new beneficiation facility has been designed to utilize ore grades of 37% to 38% Cr₂O₃.

United Kingdom.—Metal Alloys Ltd. of South Wales ceased production of chromium metal when the company was sold, and its new owner elected to discontinue chromium metal production. United Kingdom is left with two chromium metal producers, London & Scandinavian Metallurgical Co. Ltd. and Murex—a division of SKW Metals UK Ltd.

Vietnam.—Vietnam operated the Nui Nua chromite mine in Than Hoa Province. Chromite was discovered there in 1927, and mining started in 1930. Production was about 8,000 tons per year until 1960. Production peaked at 36,000 tons in 1963, then dropped in 1980 to the range of 3,500 to 4,000 tons per year. Mining is from an alluvial deposit in which about 70% of the ore is in the size range of 0.07 to 0.28 millimeters. The chromite has a Cr₂O₃ content in the range of 47.3% to 51.5% and Al_2O_3 content of about 12%. Vietnam planned to replace current water-jet mining with modern dredging. There is an oversupply of modern tin dredges in Southeast Asia.

Zimbabwe.—The Government of Zimbabwe, Union Carbide (owner of Zimbabwe Mining and Smelting), and Zimbabwe Alloys are developing technology to mechanize the recovery of chromite from the narrow seams in the Mutorashanga area of the North Dyke. The objective is to make chromite recovery economic, thereby creating an estimated 500 million tons of chromite reserves for the country. The group will acquire and operate an Atlas Copco-Eikhoff (Federal Republic of Germany) roadheader on a narrow North Dyke chromite seam to test the feasibility of using such technology. The group planned to study a mechanized low-profile rock cutter for efficient stoping operations. Owing to a lack of economic recovery methods for narrow seam chromite mining, many northern Great Dyke mines are unmechanized and operated by cooperatives. Zimbabwe reviewed its chromium mining industry, reporting mine locations, cumulative production, and time period of operation.²³

eFstimated Revised.

Current Research

U.S. Bureau of Mines research provides fundamental scientific and technical information essential for advancing mineral science, processing technology, and conserving and developing domestic mineral resources. This research is conducted in support of the Strategic and Critical Materials Stock Piling Act of 1946 as amended, the Defense Production Act of 1950 as amended, the Mining and Minerals Policy Act of 1970, and the National Materials and Minerals Policy, Research and Development Act of 1980. Recent research related to chromium includes the study of chromite recovery from domestic deposits, the development of analytic techniques to study chromium alloys, and the recovery of chromium from waste.

The Bureau studied chromite recovery from California ores using physical concentration processes. Ore from three previously producing deposits was beneficiated in laboratory and pilot plant scale studies. Laboratory beneficiation

¹Table includes data available through May 7, 1991.

²In addition to the countries listed, Bulgaria and North Korea may also produce chromite, but output is not reported quantitatively, and available general information is inadequate for formulation of reliable estimates of output levels. Figures for all countries represent marketa-

ble output unless otherwise noted.

³Average Cr₂O₃ content is as follows; 1986—40.0%, 1987—40.0%, 1988—39.0%, 1989—39.5%, 1990—not available. Brazil also reports run-of-mine crude ore production (and Cr₂O₃ content) in metric tons as follows: 1986-762,599 (173,068); 1987-829,739 (172,215); 1988-779,258 (208,812); 1989-90-not avaliable

Direct-shipping lump ore plus concentrate and foundry sand.

⁵Exports of direct-shipping ore plus production of concentrates.

⁶India production for 1985 was, in metric tons, 569,475 (revised).

⁷Reported figure.

⁸Includes production by Bophuthatswana, which was as follows, in metric tons: 1986—451,900 (revised); 1987—522,900 (revised); 1988—536,500; 1989—676,154; and 1990—550,000 (estimated).

studies included tabling, vanning, spiraling, Reichert tray concentration, and froth flotation. The results of the laboratory studies were used to design the pilot scale studies. Pilot scale overall recovery ranged from 66% to 91% concentrating chromite ore with $\rm Cr_2O_3$ content in the range of 11% to 15% to a chromite ore concentrate with $\rm Cr_2O_3$ content exceeding 50% $\rm Cr_2O_3$ and a chromium-to-iron ratio of greater than 2:1.²⁴

The Bureau, as a result of numerous chromite ore and ferrochromium analyses, has developed analytical methods that are reliable yet rapid. The Bureau documented those procedures, materials, and supplies used to analyze for chromium.²⁵

The Bureau found that traditional etching methods did not yield stains satisfactory for accurate image processing system (IPS) analysis of chromium carbide volume fraction of high-chromium white cast irons. A successful etch procedure was developed by optimizing etching parameters of composition, temperature, and time to yield carbide contrast satisfactory for IPS analysis.²⁶

The Bureau studied the recovery of chromium from hardface alloy grinding waste and contaminated superalloy scrap. Researchers developed a hydrometallurgical process that recovers chromium in the form of chromic chloride solution from hardface alloy grinding waste and economically evaluated the process. About 79% of chromium contained in the hardface alloy grinding waste was recovered as commercial-grade chromic chloride. Economic evaluation resulted in estimated capital cost of \$4 million and operating cost of \$11.70 per kilogram of feedstock for a plant processing 200,000 kilograms per year.²⁷ The Bureau also developed a process for the recovery of chromium as a filterable precipitate from superalloy scrap. The mixed and contaminated superalloy scrap was first pyrometallurgically treated to produce a feed material for hydrometallurgical processing that produced the chromium as filterable precipitate ferroalloy.²⁸ In addition, Bureau researchers developed a process to recover chromium primarily in the form of insoluble chromium carbide anode sludge from mixed and contaminated superalloy scrap. The superalloy scrap is melt carburized to produce an anode containing the chromium carbide.²⁹

The Council for Mineral Technology (MINTEK) of the Republic of South

Africa developed chromite ore and ferrochromium reference materials. The reference materials are produced by crushing, milling, and blending bulk samples and are distributed.³⁰

Private industry researched more economic production and utilization processes. For example, private industry developed the hollow electrode system for use in the ferrochromium production process and applied it to chromite ore fines. The process was compared with other techniques for efficient finechromite ore consumption. In particular, the hollow electrode system was found to be a potential substitute for cost-intensive briquetting, pelletizing, or sintering processes. 31 Private industry implemented a chromium-aluminum hazardous waste recycling process. Chromium conversion chemicals are used in the aluminum metal finishing process generating a chromium-aluminum containing hazardous waste (EPA designation F019). The waste contains chromium hydroxide precipitate. About 15,000 tons of this waste, containing 3% to 15% chromium, has been generated annually. EPA permits the waste to be land filled after the contained chromium has been immobilized or fixed. However, the industry process recovers chromium from the material by first dissolving it, then precipitating chromium hydroxide, which is calcined to produce a material containing 50% to 55% chromic oxide.³²

OUTLOOK

On the average in the United States. about 70% of chromium is consumed by the metallurgical industry, and about 70% of metallurgical industry chromium consumption is for stainless steel production. Stainless steel, by definition, contains at least 11% chromium but may contain up to 36% chromium. Thus, stainless steel production accounts for about one-half of the chromium consumed in the United States. The remainder is consumed in the production of other ferrous and nonferrous alloys. chemicals, and refractories. Some of the chemical and refractory products are consumed in the steel production process.

On the average internationally, about 79% of chromium is consumed by the metallurgical industry, 13% by the chemical industry, and 8% by the refractory

industry. Of the chromium consumed in the metallurgical industry, about 60% is consumed in stainless steel. Thus, stainless steel production accounts for about one-half of the chromium consumed internationally.³³

The outlook for chromium consumption in the United States and internationally is the same as that for stainless steel. Stainless steel is estimated to be the major end use for chromium worldwide. Thus, stainless steel industry performance determines chromium industry demand worldwide.

The trend to supply chromium in the form of ferrochromium by chromite mining countries is expected to continue. The rate at which new ferrochromium plants come into production is expected to diminish now that all major chromite producers have such facilities. With new, efficient ferrochromium production facilities and excess capacity in chromiteproducing countries, both production and capacity are expected to diminish in traditional ferrochromium-producing countries, except where domestic industries are protected by quotas and tariffs. Further upward integration of the chromium industry is expected as chromiteproducing countries expand current capacity or develop new stainless steel production capacity.

A review of cement kiln refractories found that mag-chrome (magnesiachromite) refractories are used in the transition zones of cement kilns because chromite is inexpensive, provides resistance to acidic slags, and moderates thermal expansion that leads to excessive spalling. U.S. specific consumption of mag-chrome refractories was estimated to average about 0.31 kilograms per metric ton of clinker product. EPA regulation of used chromium-containing refractories (see Legislation and Government Programs section) was expected to increase the life-cycle cost of those refractories by increasing disposal cost. Increased disposal cost was expected to result in substitution of magnesia-spinel refractories for the mag-chrome refractories currently used.34

The world chromium markets were reviewed and classified as follows: structural and utilitarian stainless steels, stainless and heat-resisting steels, other metals and alloys, alloy steels, foundry sand, chemicals, and refractories. These markets were categorized as being growth or mature markets. (A mature market is a

market whose growth rate is less than that of gross national product. Similarly, a growth market is a market whose growth rate is greater than that of gross national product.) Growth markets for chromium were found to be structural and utilitarian stainless steels, stainless and heat-resisting steels, and other metals and alloys. The remaining markets were found to be mature. Each of the growth markets was described.³⁵

A review of the refractory and ceramic industries in the United Kingdom found that chromite ore has suffered a marked decline since 1950, when 150,000 tons was used. Chromite refractories are used primarily in steel production, but also in cement and glass production. This decline was found to be consistent with a general trend in the steel- and cement-producing industries toward smaller unit consumption of refractories (i.e., refractory consumption per unit of product). In addition to smaller unit consumption of refractories, these industries have experienced reduced growth rates in relation to gross national product. In particular, plastics have substituted for steel in automobiles and for glass in bottles.³⁶ A review of the foundry casting industry found the role of chromite to be particularly useful in sand casting of large castings for chilling rather than finish. It was

Calculated assuming chromite ore to average 44% Cr₂O₃ that is 62.48% chromium. ²Calculated assuming chromium content of ferrochromium to average 57%.

³Calculated from World Stainless Steel Statistics, 1990 ed. reported production, assuming chromium content of stainless steel to average 17%.

⁴Less than 1/2 unit.

Nonstockpile-grade material that was included before 1980 was deleted from stockpile count.

⁶Variation in stockpile quantity does not contribute to apparent industry demand because variation results from upgrading programs.

noted that in Europe, chromite has found a role as substitute material for zircon, the traditional material. Lack of suitable zircon has resulted in greater use of zirconchromite blends or chromite alone in greensand casting.³⁷

The world chromium metal market was reviewed and found to be a highly competitive market in which consumption and production are in near balance and production capacity far exceeds production. World production was estimated at 15,000 tons (13,500 Western World, 1,500 China and U.S.S.R.), of which about 70% was produced by the aluminothermic process and the remaining 30% by the electrolytic process. Japan was identified as the source of 37% of world production, leaving 53% for the remainder of the Western World. Consumption, however, was concentrated in the Americas (52%), Western Europe (31%), and Japan (13%). The end-use market for chromium metal was primarily superalloys (44%), aluminum alloys (16%), and welding and hard-facing materials (15%), followed by corrosion resistant alloys (9%), electrical wire (8%), and miscellaneous uses (8%). Chromium metal consumption prospects were optimistic. While there did not appear to be preeminent new uses, there also did not appear to be replacements in the traditional end user market, jet engines. In the United Kingdom, consumption prospects were optimistic because vacuum induction melting (the production route by which chromium metal is used to make superalloy castings) capacity was expected to increase. A significant change in the chromium metal industry has been the recent introduction of upgraded aluminothermic chromium metal, which now accounts for 5% of the world market. The price of high-grade electrolytic chromium metal has lead the price structure for chromium metal. The impact of this new upgraded aluminothermic chromium metal has been to reduce the high end price of chromium metal. The price of low-graded chromium metal has been pressured further downward by Chinese and Soviet produced material.³⁸

CLAYS

By Robert L. Virta

Mr. Virta, a physical scientist with 15 years of U.S. Bureau of Mines experience, has been the acting commodity specialist for clays since 1991. Domestic survey data were prepared by Rosa McGee, supervisory mineral data assistant. The international tables were prepared by Harold Willis and Virginia Woodson, international data coordinators.

he amount of clay sold or used by domestic producers increased slightly in tonnage to 43 million metric tons and 7% in value to \$1.6 billion. Production of bentonite, fuller's earth, and kaolin increased in 1990. Ball clay, common clay and shale, and fire clay production decreased. Common clays accounted for 61% of the tonnage, and kaolin accounted for 66% of the value of clays produced in 1990. Imports increased 7% in tonnage to 29,550 tons and 10% in value to \$12.0 million. Exports increased 10% in tonnage to 4.1 million tons and 6% in value to \$584.4 million. Clays were produced in 44 States and Puerto Rico. The seven leading producer States, in descending order, were Georgia, Wyoming, Ohio, California, Texas, Alabama, and North Carolina.

DOMESTIC DATA COVERAGE

Domestic production data for clays are developed by the U.S. Bureau of Mines from one voluntary survey of U.S. operations. Of the 1,080 operations covered by the survey, 944 responded, representing 88% of the total clay and shale production sold or used shown in table 1.

BACKGROUND

Definitions, Grades, and Specifications

Clays are categorized into six groups by the U.S. Bureau of Mines. The categories are kaolin, ball clay, fire clay, bentonite. fuller's earth, and common clay and shale. The definitions listed in this work for the high-alumina clays, kaolin, ball clay, and fire clay are similar to those in U.S. Bureau of Mines Information Circular 8335.1

Kaolin, or china clay, is defined as a white, claylike material composed mainly of kaolinite and other kaolin-group minerals, such as halloysite and dickite. Kaolin has a specific gravity of 2.6 and a fusion point of 1,785° C. Kaolin is classified according to the method of preparation (crude, air-separated, water-washed, delaminated, air-dried, calcined, slip, pulp, slurry, or water suspension) and on specific physical and chemical properties.

Ball clay is a plastic, white-firing clay used mainly for bonding in ceramicware. The clays are of sedimentary origin and consist mainly of the kaolinite, sericite mica, and organic matter. Ball clays usually are much finer grained than kaolins

²Includes Puerto Rico.

and are reknowned for their plasticity. They are classified according to the method of preparation (crude, shredded, airfloated, water-washed, or slurry) and specific physical and chemical properties.

Fire clay is defined as detrital material, either plastic or rocklike, that commonly occurs as underclay below coal seams. Low concentrations of iron oxide, lime, magnesia, and alkalies in fire clay enable the material to withstand temperatures of 1,500° C or higher. It is composed mainly of kaolinite. Fire clays also contain other clays such as diaspore, burley, burley-flint, ball clay, and bauxitic clay and shale. Fire clays generally are used for refractories or to raise vitrification temperatures in heavy clay products. The fired colors of fire clays range from buffs to grays. Fire clays are classified according to their physical and chemical properties and the characteristics of the products made from them.

Bentonite is a clay composed primarily of smectite minerals. The primary smectite mineral is usually montmorillonite. Swelling-type bentonite has a high-sodium ion concentration. Its volume increases 15 to 20 times its dry volume when wetted with water. Nonswelling bentonites usually are high in calcium. Bentonite is classified according to its physical and chemical properties, with particular emphasis on particle size and swelling index.

The term "fuller's earth" is derived from the first major use of the material, which was for cleaning textiles by fullers. Fuller's earth does not refer to a clay with a specific composition or mineralogy. It is defined as a nonplastic clay or claylike material, usually high in magnesia, that is suitable for decolorizing and purifying mineral and vegetable oils. They are composed mainly of the needle- and/or lath-shaped clay mineral attapulgite or varieties of montmorillonite. Fuller's earths containing opal or other forms of colloidal silica also are produced. Fuller's earths are classified according to their physical and chemical properties. Sepiolite-type clays are grouped with fuller's earths under the Bureau classification system.

Common clay is defined as a clay or claylike material that is plastic enough to mold easily. Its vitrification point is usually below 1,100° C. Shale is a laminated sedimentary rock that is formed by the consolidation of clay, mud, or silt. The common clays and shales are composed mainly of illite or chlorite. They also may contain kaolin and montmorillonite. Common clays and shales usually contain

more alkali, alkaline earth, and ferruginous minerals and less aluminum than high-quality kaolins, fire clays, and ball clays. Iron present in the clay usually imparts a reddish color to the final product after firing. There is no formal classification of common clays and shales, although a clay may sometimes be referred to as common, brick, sewer pipe, or tile clay. Clay and shale are used in the manufacture of structural clay products such as brick, drain tile, portland cement clinker, and expanded lightweight aggregates.

The American Society for Testing and Materials, American Foundrymen's Association, American Oil Chemist's Society, American Petroleum Institute, Technical Association of the Pulp and Paper Industry, and other national organizations have developed tests and set standards for some applications. Many producers and consumers, however, use nonstandardized tests that are applicable to their specific needs. Individual companies often set the acceptable limits of mineralogical composition, particle size, and other physical and chemical properties. Detailed data on specifications have been published by the U.S. Bureau of Mines.²

Products for Trade and Industry

Because of the many types of clay and different qualities within each type, the consumption pattern and the products for trade and industry are constantly changing. Consumption of kaolin in refractories has been growing since 1970 because of the increasing popularity of castable, ramming, gunning, and plastic mixes that use calcined kaolin aggregates (grog) in their formulations.3 The consumption of calcined kaolin grogs also has increased in refractory brick manufacturing, replacing imported calcined refractory-grade bauxite grogs. Consumption of bentonite has decreased for iron ore pelletizing and for more expensive drilling mud and foundry uses. Bentonite products for waterproofing and sealing in construction and reservoir uses also have gained in popularity. Attapulgite-type fuller's earth production, like bentonite, is finding increasing applications in the premium drilling mud industry.

Industry Structure

An estimated 350 companies operating more than 1,000 clays pits or mines reported production in 1990; of these, 50

companies, most with multiple operations, accounted for approximately 50% of the tonnage and 80% of the value for all types of clay produced and sold or used. Clay production was reported in all States and Puerto Rico except Alaska, Delaware, Hawaii, Rhode Island, Vermont, Wisconsin, and the District of Columbia.

The leading clay-producing States were Georgia, 9.9 million tons; Ohio, 2.5 million tons; Wyoming, 2.5 million tons; Texas, 2.3 million tons; Alabama, 2.3 million tons; North Carolina, 2.2 million tons; and California, 2.2 million tons. Most of the clay is mined by open pit methods. Less than 2% of U.S. clay output is from underground mines in 1990. Most of the underground production is in Pennsylvania, Ohio, and West Virginia, where the clays are mainly underclays associated with coal and suitable for refractory uses.

Forty-three firms operated 130 kaolin mines in 13 States. In 1990, three large, diversified firms accounted for about 60% of total domestic kaolin output. Most large kaolin producers have operations in Georgia, which accounted for 78% of the kaolin production.

The ball clay industry is small, with 6 producers operating 27 mines in 5 States in 1990. Three of the producers were large, diversified firms with widespread foreign and domestic mineral interests. Tennessee ball clay production represented about 69% of the total output.

Fireclay producers were mostly refractories manufacturers that used the clays in firebrick and other refractories. Seventytwo mines were operated in 1990 by 26 firms in 6 States.

Firms producing bentonite operated 132 mines in 13 States. Four producers were large, diversified firms with international mineral operations; three of the firms had interests in other types of clay in the United States. Wyoming was the leading State, accounting for 73% of the total output. Swelling-type bentonite is produced mainly in Wyoming and Montana, and nonswelling-type bentonite is produced in Mississippi and Texas. The United States is the world's largest producer and exporter of bentonitic clays.

Fourteen companies produced fuller's earth from 29 mines in 10 States. Fourteen of the mines were in the attapulgite-fuller's earth areas of Florida and Georgia. These two States accounted for 43% of domestic production. Most producers were small, independent firms, but three were large, diversified corporations with international

mineral interests. The world's fuller's earth needs are supplied from relatively few areas. The United States is the world's largest producer and user of fuller's earth.

Firms producing common clay and shale in 1990 were manufacturers of structural clay products, clay pipe, lightweight aggregates, and cement. Most companies mined the clays used in making their products. Private mining contractors and haulers were employed in many of the operations. Some producers were diversified firms having interests in metals and other nonclay products. Some companies owned and operated several clay pits and plants in order to cover a large market area. The economic radius for shipment of common clay or shale products is usually 200 miles or less. The high cost of transport promotes the development of local ownership companies, or in the case of a large firm, the ownership and operation of several strategically located pits and associated fabricating plants.

Geology-Resources

Clay is formed by the mechanical and chemical breakdown (weathering) of rocks. The weathering products consist of mineral grains and rock fragments of different size and different physical and chemical properties. The nonplastic portion consists of altered and unaltered rock fragments (grit), which are usually quartz, micas, feldspar, and iron oxides. The plastic portion usually is composed of clays and is low in grit.

Clays may be classified as residual or sedimentary. Residual clays are deposited in the same location in which they were formed. Sedimentary clays are those that have been transported, usually by water, and deposited elsewhere.4 Sedimentary clays often undergo further alteration and classification during transport. Kaolin deposits in Georgia and South Carolina are sedimentary. Kaolin deposits in North Carolina and English china or kaolin clay deposits are residual.5 The Kentucky and Tennessee ball clays and the Missouri fire clays are sedimentary deposits. Most bentonites, montmorillonites, and fuller's earth were formed in place through the weathering of volcanic ash or tuff. The attapulgite-type fuller's earth deposits of Florida and Georgia were probably not formed from volcanic ash or tuff. Geologists have never found any evidence of volcanic materials associated with these deposits.6

The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals." Reserves are the part of an ore body that can be economically extracted at the time of evaluation. Reserve base is the part of an ore body that meets specified minimum physical and chemical criteria related to current mining and production practices. Reserve base includes reserves, marginal reserves, and subeconomic resources.

Common clays and shale deposits are found throughout the United States. Clays and shale were mined commercially in 44 States and Puerto Rico. Domestic resources are almost unlimited. Not all deposits, however, are near potential markets, and most deposits are not suitable for all applications. For example, most common clay or shale deposits can be used to manufacture common brick, but the color or strength of the final product may not meet the requirements of the local market. Relatively few deposits are suitable for manufacture of lightweight aggregate. Even with these limitations of location and use, resources of common clay and shale are "virtually unlimited."

U.S. reserves of other types of clays that are owned or controlled by domestic producers are estimated to be about 700 million tons. U.S. reserves of kaolin are estimated to be 400 million tons; ball clay, 30 million tons; fire clay, 100 million tons; bentonite, 120 million tons; and fuller's earth, 60 million tons.

Large quantities of high-quality kaolin suitable for paper-coating and paper-filler are found in Georgia. A small area in Georgia and Florida contains sizable reserves of attapulgite-type fuller's earth. Most bentonite for iron ore pelletizing and oil-well-drilling muds is mined in Wyoming. Fire clay deposits, such as those found in Missouri, are widespread. Deposits of high-quality fire clay are nearing depletion. Kentucky and Tennessee are two of only a few States that have sizable deposits of ball clay.

Technology

Exploration.—Exploration begins with an understanding of the geological occurrence of the clays of interest. With this knowledge, potential economic deposits can be located. Auger or core drills are then made to deliniate the size and shape of the deposit and to obtain material for

testing.

Kaolins usually are evaluated for filler and ceramic applications. The grit, particle size, brightness, and leachability are determined. Air-floated clays normally require only grit and brightness determinations. Kaolin, ball clay, and fire clay for ceramic and/or refractory applications are analyzed for grit, brightness, green and dry strengths, fired color, and iron and alumina contents. The common clays and shales usually are tested according to the intended end use, such as brick, structural-drain tile, or lightweight aggregate. Usually, prepared specimens are tested for plasticity, green strength, shrinkage, vitrification temperature range, etc. For lightweight aggregates, the bloating range is determined. Bentonites and fuller's earth clays are difficult to evaluate because there is no standard testing procedures or specifications. Generally, they are processed to meet the purchaser's specifications.

Mining.—Most clays are mined from open pits using modern surface mining equipment such as draglines, power shovels, front-end loaders, backhoes, scraper-loaders, and shale planers. Some kaolin is extracted by hydraulic mining and dredging. A few clay pits are operated using crude hand-mining methods. A small number of clay mines, principally in underclays in coal mining areas, are mined underground using room-and-pillar methods. Clays usually are transported by truck from the pit or blending areas to the processing plants. Rail, conveyor belt, and in the case of kaolin, pipelines also are used.

About 100% of the clay is recovered from the minable beds in most open pit operations. Approximately 75% is recovered in underground operations. The waste-to-clay ratio is highest for kaolin, about 7:1, and lowest for common clay and shale, about 0.25:1.

Processing.—Clays are used in a large number of products so they must be treated in many different ways. Processing can consist of very simple and inexpensive crushing and screening for some common clays. It also can consist of very elaborate and expensive grinding, sizing, bleaching, delamination, etc., for paper-coating clays and high-quality filler clays for use in rubber, paint, plastic, and other products. In general, processing does not appreciably alter the chemical or mineralogical characteristics of the clays. The two exceptions are calcining and cation exchange.

Significant processing losses occur with kaolin and fuller's earth. About 40% of the kaolin and 30% of the fuller's earth delivered to the processing plants is discarded. Waste material from processing consists mostly of off-grade clays and small quantities of quartz, mica, feldspar, and iron-bearing minerals.

Kaolin.—Processing involves one or more of the following: crushing, blunging with dispersant, rough sedimentation, water fractionation, magnetic separation, ultraflotation, acid treatment, calcination, air floating, and attrition grinding, slurrying, and delaminating. Kaolins used for paper-coating applications may be bleached and further delaminated by grinding, deflocculation, and elutriation to special sizes. Ultraflotation or wet magnetic separation treatment may be used to remove iron- or titanium-bearing minerals to obtain a whiter product.

Ball Clay.—Processing involves drying, shredding, pulverizing, air floating, and slurrying.

Fire Clay.—Processing involves crushing, calcining, and blending.

Bentonite.—Processing involves weathering, drying, grinding, sizing, granulation, and the use of additives for cation exchange.

Fuller's Earth.—Processing involves blunging, extruding, drying, crushing, grinding, sizing, and dispersing.

Common Clay and Shale.—Processing involves crushing, blunging, extruding, and drying. Common bricks, tile, lightweight aggregate, etc., require firing in a kiln. The kiln firing or drying operation produces a finished manufactured product.

Processing costs for clays range from a few cents per ton for some common clays to more than \$400 per ton for some special paper-coating clays and high-quality clays that require very elaborate and expensive treatments.

Price schedules, although not complete, are available and are published regularly in trade journals such as the American Paint and Coatings Journal, Chemical Marketing Reporter, and Industrial Minerals (London).

Federal tax laws allow clay producers a depletion allowance on both domestic and

foreign gross income not to exceed 50% of net income with depletion deduction. Depletion allowances are as follows: ball clay, bentonite, kaolin or china clay, sagger clay, and clay used or sold for purposes dependent on its refractory properties, 14% domestic and 14% foreign; fuller's earth, 14% domestic and 14% foreign; clay used for extraction of alumina or aluminum compounds, 22% domestic; clay used or sold for use in manufacturing drainage and roofing tile, flower pots, and kindred products, 5% domestic and 5% foreign; and clay and shale used for making brick, tile, and lightweight aggregate, 7.5% domestic and 7.5% foreign. Severance taxes are levied by some producing States.

Byproducts and Coproducts

Firms in California, Florida, and Texas produce silica glass sand as a coproduct of its kaolin production. Flake mica is a byproduct in one kaolin operation in North Carolina. Bauxite is a coproduct in kaolin operations in Alabama and Georgia. Clay and limestone for cement manufacture are often produced from the same property and reported as coproducts or byproducts even though they are usually mined separately from different formations or beds. Sand, gravel, and stone aggregates are occasionally produced together with common clays.

Economic Factors

Economic factors affecting clays vary in importance with type, quality, and intended end use. The cost of transportation is an important factor for the common clay and fire clay industries; mines must be close to consumers to be cost competitive. Other types of clays are less abundant and have higher unit values. They can be shipped greater distances from the mines and still be cost competitive. For example, paper-coating clay from Georgia and attapulgite-type fuller's earth from Florida and Georgia can be shipped nationwide. Bentonite for iron ore pelletizing from Montana and Wyoming can be shipped a considerable distance to the iron ore centers. In some of these cases, the shipping costs exceed the value of the clays at the mine or processing plant.

Because most clays are relatively lowcost materials in the crude state, mining costs must be kept as low as possible. Cost of the crude clays ranges from less than \$3 per ton for some common clays to above

\$20 per ton for some of the higher quality materials.

Very little clay is imported because transportation costs would make the clays noncompetitive in price. Consequently, import duties have little impact on the amount of clays imported.

Operating Factors

To manufacture finished clay products, producers require equipment to mine and process the crude clay and a kiln for firing or drying their products. Mining, processing, and manufacturing are all energy-intensive operations. Many clay producers converted to coal from oil firing and gas firing. However, the conversion to coal and/or wood as a kiln fuel is gaining in popularity where feasible in heavy clay and refractory products manufacturing and in bentonite processing.

Losses in mining are extremely small, except in underground mining where recovery will average about 75%. Processing losses for material receiving, crushing, grinding, mixing, shredding, blending, and drying also are insignificant. Losses from washing, sizing, etc., reach 30% or 40%.

Clay mining lacks many of the hazards associated with other types of mining because only a few deposits require the use of explosives and most mines are open pit earth-moving operations. Domestic mine employment in 1990 was estimated to be 2,000 workers. Domestic mill employment was estimated to be 9,100 workers.

ANNUAL REVIEW

Issues

Clay mining has an environmental impact because of the disturbance to the land. Overburden is moved and clays are removed, leaving a depression or pit. State laws usually require leveling or recontouring of the disturbed area and planting trees or grasses to prevent or minimize erosion. For processing, the impoundment of slimes and dust control are usually required. The rules for disposal of coarse tailings are similar to or included with those laws governing reclamation of the mined area.

Many local governments are enacting stricter regulations. In some cases, they change the land use zoning. New regulations and land use changes sometimes force a mine to close or relocate to a more distant deposit. Moving to a more distant deposit increases costs to the community because of increased transportation charges.

Another important issue concerns crystalline silica. The World Health Organization classified crystalline silica as a possible human carcinogen in 1987. Additionally, the Occupational Safety and Health Adminstration (OSHA) must include crystalline silica under its Hazard Communication Standard (HCS). Products containing 0.1% or more crystalline silica must be labeled in accordance to the HCS, and employers must comply with the terms of HCS with regard to worker training. The Mine Safety and Health Administration has proposed a similar regulation. There is concern that States will consider crystalline silica a proven, rather than a possible, carcinogen when enacting legislation as a result of these findings.

Although domestic clay resources are more than adequate and clay is a mature industry, the average price for clays is expected to rise steadily. The increased prices reflect the demand for higher quality specialty clay by consumers and increased costs associated with land acquisition, severance taxes, land rehabilitation,

energy requirements, and environmental factors. These rising prices, if unchecked, will have an adverse effect on the clay industry by making competing materials more cost competitive.

Production, Prices, and Foreign Trade

Two articles reviewed clay production in the Southwest United States and Georgia. The article on the Southwest United States discussed the common clay and shale, kaolin, bentonite, and hectorite industries, including producers and end uses. The article on Georgia discussed the history of the clay industry within the State, the geology of deposits, end uses, and the outlook for the State's clay industry. §

Kaolin.—Domestic production of kaolin increased 9% to 9.8 million tons. The value of production increased 5% to \$1.07 billion. The unit value of kaolin decreased 4% to \$110 per ton. Filler- and refractorygrade kaolin had the highest reported values. Kaolin was produced in 13 States. Georgia accounted for 78%, and South Carolina accounted for 13% of total production. Georgia accounted for more than 91% of the total production value. Filler, refractory, chemical- and water-washed,

air-floated, and unprocessed grades were produced in Georgia. South Carolina produced only air-floated and unprocessed grades of kaolin. Arkansas and California produced refractory- and chemical-grade kaolins. Kaolin producers reported major domestic end uses as paper-coating, 28%; paperfilling, 15%; refractories, 9%; fiberglass and insulation, 5%; face brick and rubber, 4% each; and paint and chemicals, 3%.

Despite the overall slow economy, kaolin production increased. Sales of paper-, plastic-, and paint-grade kaolin increased. Exports also increased because of a continued weak U.S. dollar. Sales of kaolin for refractory grogs and calcines, and firebrick also increased. Sales to cement manufacturers decreased because of continued lower construction rates. Production of paper-grade kaolin increased slightly in 1990. U.S. sales of unprocessed kaolin almost doubled because large tonnages of low-value unprocessed kaolin were required for a special project in the Southeastern United States. Calcined, water-washed, and delaminated kaolin production increased 5%, 2%, and 13%, respectively. Air-float kaolin production decreased 8%.

The geology, mineralogy, and classification of major occurrences were dis-

cussed in a paper on kaolin. Mining methods and processing technology (including flotation, fractionation, bleaching, magnetic separation, flocculation, delamination, calcination, and surface treatment) were discussed. Applications and specifications also were featured.⁹

The Minnesota Department of Natural Resources collected mineralogical and geological data on clay deposits in the southwest section of the State for its data base on kaolin. The State is gathering the information to encourage exploration activities by mining companies. There are three operating kaolin mines in the region. The kaolin produced is for brick and cement manufacturing. 10

The Minnesota Valley Railroad (MNVA) announced plans to purchase a kaolin operation from Nova Natural Resources. The mine is near Belview and produces kaolin used in the production of cement. MNVA plans to expand the mine to include a higher grade deposit. 11 Minnesota Valley Minerals, Inc. announced

¹Includes high-temperature calcined.

²Includes low-temperature calcined and delaminated.

³Data may not add to totals shown because of independent rounding.

Includes electrical porcelain; floor and wall tile, ceramic; flue linings; glazes, glass, and enamels; high-alumina brick and specialties; kiln furniture; and refractory mortar and cement.

Includes animal oil; catalysts (oil refining); chemical manufacturing; ink; medical; sewer pipe; and unknown uses.

Includes ceramics; adhesives; paper filling; pesticides and related products; and rubber.

⁵Data may not add to totals shown because of independent rounding.

plans to mine and process kaolin in Belview. MN. The kaolin will be sold as a filler for soybean meal.12

Combustion Engineering Inc., a subsidiary of Asea Brown Boveri Inc., sold a portion of its Georgia Kaolin Co. to ECC Group. The sale included its mine and plants near Sandersville and Wrens, GA, and the Carbonate Div., which produced precipitated calcium carbonate. Combustion Engineering is the parent company of Georgia Kaolin Co., a major producer of water-washed and air-floated kaolins in Georgia.¹³ Combustion Engineering sold C-E Minerals Co. to IMETAL SA of France. C-E Minerals operates mines near Anersonville, GA, and is the world's largest calcined refractory clay producer.14 Asea Brown Boveri retained ownership of Georgia Kaolin's Dry Branch kaolin operation. Dry Branch Kaolin Co., a newly formed company, will operate the Dry Branch mine. 15

Despite strong foreign competition and a fluctuating U.S. dollar, exports of kaolin, reported as clays by the U.S. Department of Commerce, increased 21% to 2.83 million tons valued at \$428 million. The unit value of the exported clay decreased 5% to \$151.41 per ton. Kaolin, including calcined material, was exported to 67 countries. The major importers, in descending order, were Japan, Canada, Italy, the Netherlands, Finland, and Mexico. Exports to Finland increased 21% to 192,000 tons. Kaolin producers reported end uses for their exports as follows: paper-coating, 69%; paper-filling, 18%; rubber, 5%; paint, 2%; and other, including ceramics and refractories, 6%.

Kaolin imports for consumption decreased about 10% to 3,067 tons valued at \$1.4 million. The unit value increased about 8% to \$443.43 per ton, reflecting the continuing strong worldwide demand for premium-quality kaolin.

Kaolin prices quoted in the trade journals generally were unchanged from those of the previous year.

Ball Clay.—Production of domestic ball clay decreased 13% to 788,000 tons valued at about \$33 million. Tennesse supplied 69% of the Nation's output, followed by, in descending order of production, Kentucky, Mississippi, Texas, and Indiana. Production decreased in all the major producing States. The principal ball clay markets were dinnerware, floor and wall tile, pottery, and sanitaryware. Sales decreased because the slow overall economy depressed construction rates and housing starts.

United Clays Inc. of Tennessee announced that it would open a mine in Tennessee. The company will produce clay for the manufacture of ceramic fixtures and fiberglass.16

TABLE 12 PRICE QUOTATIONS FOR KAOLIN AND BALL CLAY, 1990

	Per tor
aolin:	
Waterwashed, fully calcined bags, carload lots, f.o.b. Georgia per ton	\$323.00
Calcined, paper-grade, same basis, per ton	470.00

The average unit value for ball clay reported by domestic producers increased 17% to \$52.77 per ton. Listed prices in the Chemical Marketing Reporter, January 7, 1991, per short ton, were unchanged from those of 1989.

Ball clay exports decreased 56% to 69,000 tons valued at \$3.1 million. Unit value increased to \$45.14 from \$43.62. Shipments were made to 24 countries, 1 less than in 1989. The major importer was Mexico, with 86% of the exports. The expanding Mexican ceramic markets continued to be supplied largely with domestic clays because of international financial difficulties. Mexican ceramic exports,

mostly to the United States, are made chiefly with U.S. and domestic clavs.

Ball clay imports for consumption, almost entirely from the United Kingdom, also decreased 4% to 1,417 tons valued at \$299,000. The unit value of these clays increased more than 12% to \$286.58 per ton.

Fire Clay.—Fire clay sold or used by domestic producers decreased 24% in tonnage to 625,808 tons and 23% in value to \$16.1 million. Missouri was the leading producing State followed by Ohio, Alabama, New Jersey, Pennsylvania, and New Mexico.

The clay refractory industry had been in a period of low production because of decreased demand brought about by technological changes and lower consumption levels by its major users-steel, non-ferrous metals, ceramics, glass, and minerals processing industries. The technological changes in steelmaking, away from integrated pig iron systems and toward electric furnaces and/or minimills, further compounded the problem by employing shapes and specialty refractories requiring less fire clay.

Radex Heraklith of Austria signed an agreement to acquire 50% ownership of National Refractories and Minerals Corp.

W Withheld to avoid disclosing company proprietary data included in "Other."

¹Includes catalyst (oil refining); fiberglass; glazes, glass, and enamels.

²Includes crockery and other earthenware; fine china and dinnerware.

³Includes animal feed; asphalt emulsions (1989); asphalt tile; pesticides and related products; rubber; wallboard (1989); other uses not specified.

⁴Includes electrical porcelain; firebrick, block and shapes; high-alumina brick and specialties.

Refractory uses only.

of California. National Refractories produces clays for refractory applications.¹⁷

Fire clay was produced again from mines in six States. Missouri, Ohio, and Alabama, in descending order of volume, accounted for more than 97% of the total domestic production. Output decreased in other producing States.

Exports of fire clay decreased 14% to 245,000 tons. The unit value of exported clay increased 3% to \$87.45 per ton. Fire clay was exported to 33 countries, 1 less than in 1989. The major recipients, in descending order, were the Netherlands, Japan, Mexico, Australia, and Canada. Fire clay imported from three countries amounted to 185 tons valued at \$16,200.

The unit value for fire clay, reported by producers, ranged from about \$25 to \$77 per ton.

Bentonite.—Bentonite production increased more than 12% to 3.5 million tons, while the value decreased 2% to \$123.0 million. Wyoming was the largest bentonite producer, accounting for 73% of production. Wyoming also was the leading producer of swelling bentonite. The three major end uses were drilling mud, foundry sand, and iron ore pelletizing with 24%, 32%, and 20%, respectively, of total sales. Consumption of bentonite for foundry sand and iron ore pelletizing applications increased in 1990.

Bentonite was produced in 11 States.

Most of the high-swelling or sodium bentonite was produced in Wyoming. Mines in Alabama and Mississippi produced more than one-half of the low-swelling or calcium bentonite. Calcium bentonite produced in Alabama and Mississippi was suitable for the production of absorbent, acid-activated, and foundry products.

American Colloid Co.'s request for bentonite mining in Thunder Basin National Grassland in Wyoming was still under review. American Colloid purchased the Thunder Basin bentonite operations owned by Federal Ore and Chemicals Inc. The company applied for permission to mine an additional 179 acres that had previously been disturbed by mining.¹⁸

A new plant that produces mats of bentonite sheeting was planned for Spearfish, SD. The company will use locally produced bentonite to produce the mats, which consist of bentonite sandwiched between layers of thick plastic. The company estimates that it will use approximately 500 tons of bentonite per month.¹⁹

The quoted price in the Chemical Marketing Reporter, January 7, 1991, for domestic bentonite, carload lots, f.o.b. mines, was \$28.60 per ton. The average unit value reported by domestic producers decreased 12% to \$35.42 per ton.

Bentonite exports increased 4% to 699,000 tons valued at \$57.1 million. The unit value of exported bentonite in-

creased about 4% to \$81.71 per ton. Bentonite was exported to 68 countries, 18 less than in 1989. The five major recipients, in descending order, were Japan, Canada, Singapore, Taiwan, and the Federal Republic of Germany. Domestic bentonite producers reported their exports were foundry sand, 55%; drilling mud, 24%; and others, 21%.

Bentonite imports for consumption consisted mostly of untreated bentonite clay and chemically or artificially activated materials. Bentonite imports increased 5% to 17,000 tons. Canada was the largest supplier of bentonite. The chemically activated category increased 15% to 15,000 tons valued at \$6.2 million. Mexico accounted for 92% of the chemically activated bentonite imported into the United States. This was an increase of 7% over that of 1989.

Fuller's Earth.—Production of fuller's earth increased 23% to 2.31 million tons valued at \$224 million. Reported production of fuller's earth is greater than that of 1989 because two producers were included under the fuller's earth category for the first time. They were reported under other clay categories in the past. The average unit value increased 10% to \$96.92 per ton. Production was reported in 10 States. Florida and Georgia accounted for nearly one-half of domestic production. Increases in consumption occurred in every

major absorbent product line. The, two major end uses were pet waste and oil and grease absorbents.

Production from the region that includes Attapulgus, Decatur County, GA, and Quincy, Gadsden County, FL, is composed predominantly of the lath-shaped amphibolelike clay mineral attapulgite. Most of the fuller's earth produced in other areas of the United States contains varieties of montmorillonite and/or other clays.

Attapulgite, a fuller's earth-type clay, finds wide application in both absorbent and gelling and/or thickening areas. The thixotropic properties of attapulgite clays

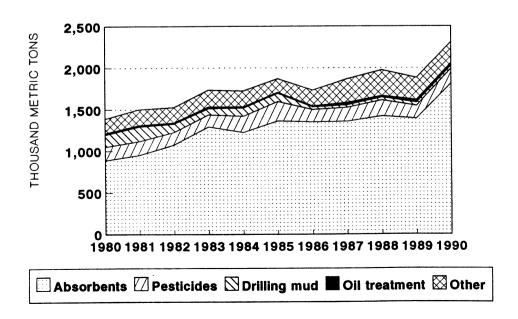

provide the important thickening and viscosity controls necessary for suspending solids. Mineral thickeners are used in such diverse markets as paint, joint compound cement, and saltwater drilling mud.

Fuller's earth was exported to 30 countries, 4 more than in 1989. The quantity decreased 50% to 46,000 tons. The unit value of exported fuller's earth rose 45% to \$129.07. The increase was attributed to a larger percentage of high-cost gelling and drilling mud grades shipped. Most of the fuller's earth was shipped to Canada (15%) and the Netherlands (43%). Small amounts of decolorizing fuller's earth were

imported from Canada and the Federal Republic of Germany.

Common Clay and Shale.—Domestic sales or use of common clay and shale decreased 2% in tonnage to 26.1 million tons and increased 8% in value to \$152 million. Of the nine major producing States, production increased in Alabama, Indiana, and Missouri, and decreased in California, Georgia, Michigan, North Carolina, Ohio, and Texas. Common clay and shale represented about 61% of the quantity but only 9% of the value of total domestic clay production.

FIGURE 3
FULLER'S EARTH SOLD OR USED BY DOMESTIC PRODUCERS FOR SPECIFIED USES

¹Data may not add to totals shown because of independent rounding.

²Includes data for asphalt emulsions; asphalt tile; cement, portland; ceramic floor and wall tile; face brick; fertilizers; firebrick, blocks and shapes; gypsum products; ink; kiln furniture; mineral wool and insulation; oil well sealing; paper coating and filling; plastics; pottery; roofing tile: rubber; uses not specified; and data indicated by symbol W.

Includes absorbents; animal feed; asphalt emulsions; cement; filtering, clarifying, decolorizing; paint; plastics; waterproofing and sealing; and uses not specified.

Domestic clay and shale are generally mined and used captively to fabricate or manufacture products. Less than 10% of the total output is usually sold. The average unit value for all common clay and shale produced in the United States and

Puerto Rico increased 11% to \$5.82 ton. The reported unit value ranged from \$5 per ton to \$36 per ton.

The Department of Commerce reviewed ceramic tile imports from Mexico for January 1, 1987, to December 31,

1987. It concluded that duties will be zero for 47 companies and 1.29% ad valorem for all other firms. The Agency also reviewed brick imports for January 1, 1986, to August 23, 1986. It concluded that duties will be zero for 22 firms and

cotta, and other tile; (2) portland cement clinker; and (3) lightweight aggregate, accounted for 47%, 17%, and 10%, respectively, of total domestic consumption.

Kaolin has many industrial applications, and many grades are specifically designed for use as a filler in paper, paint, rubber, plastics,24 and ceramics.25 New uses are constantly being developed. Kaolin is a unique industrial mineral because it is chemically inert over a relatively wide pH range, is white in color, and has good covering or hiding power when used as a pigment or extender in coated films and filling applications. It also is soft and nonabrasive, has low conductivity of heat and electricity, and costs less than most materials with which it competes. Fillers and extenders must meet very rigid specifications such as particle size, color, brightness, and viscosity.26

Ball clays are extremely refractory and their use, largely in whitewares, imparts a high green strength as well as plasticity to the bodies. Although white-firing ball clays are preferable, fired products that range to cream or buff colors do not generally impair the quality of the whiteware products.

Fire clays are used mostly in commercial refractory products such as firebrick and block of many shapes, insulating brick, saggers, refractory mortars and mixes, ramming and gunning mixes, grog and crude aggregates, and many other products. Fire clays are also added to common clays to increase the vitrification range of sewer pipes and bricks.

The swelling sodium bentonites are used largely in drilling muds, in foundry sands, and in pelletizing taconite iron ores. The nonswelling or calcium bentonites are used mostly in conjunction with the swelling bentonites in foundry sand mixes in which the sodium bentonites provide dry strength and the calcium bentonites provide high green strength. Fuller's earth and calcium bentonites find application in decolorizing and purifying mineral, vegetable, and animal oils. Clays used to process animal or vegetable oils usually are activated by acid treatment. Acid treatment produces a highly absorbent sievelike structure. Attapulgite is used in drilling muds instead of sodium bentonites for drilling saltwater formations. Sodium

bentonite "breaks the emulsion" or flocculates in brine, thereby destroying the gellike colloidal suspension required for drilling. The major uses for attapulgite and montmorillonite types of the fuller's earths are in pet waste and oil and grease absorbents because of their absorbent properties.

Bentonite also is used for foundry casting by the steel, iron, and nonferrous casting. The bentonite provides good green strength and desirable dry strength characteristics. Sodium bentonites are used in steel casting. Ion-exchanged bentonites are used for iron and nonferrous casting. There is increased use of mixtures of ion exchanged and sodium bentonites to meet the more stringent demands of the casting industry.²⁷

Construction.—Common clays and shales are used to manufacture a wide variety of construction materials such as structural clay products, cement, and expanded aggregates.

Structural Clay Products.—Structural clay products such as building brick, drain

tile, and vitrified sewer pipe are used in building construction, for sewer systems, to drain farmers'fields, and for many other uses. Other clays, such as kaolin, fire clay, or ball clay, could in many cases be used to produce equally suitable "heavy clay" products, but they are generally more refractory and valuable for other uses. Of the total clay produced, about one-third is consumed in the manufacture of these structural products.

Hydraulic Cement.—The portland cement industry requires alumina and silica as constituents in the manufacture of portland cement. Common clays provide a low-cost source of these materials.

Expanded Clay and Shale.—For this purpose, certain bloating qualities and strength are required. Lightweight concrete blocks, floors, walls, and other shapes made from expanded clay and shale have a lower overall weight, which results in savings in the design of the supporting framework. Also, products made from expanded clay and shale have better insulating qualities than equivalent products made with sand and gravel and crushed stone aggregates.

Refractories.—Refractories require strength at high temperatures, resistance to corrosion, low coefficient of expansion, and many other physical and chemical properties, depending on application. Clays with physical properties most suitable for general refractory use have been classed as fire clays. The current trend is for refractories designed for a specific use and castable mixes containing refractory aggregates and calcium aluminate cements.²⁸

Paper Products.—Demand for clays for use as filler and coater in paper has followed the rapid increase in demand for paper. Kaolin is the principal clay used.

Other Uses.—Pottery and related products require good ceramic qualities, including plastic formation, desirable firing temperatures, color, etc. The principal clays meeting these and other specifications are ball clay and kaolin. Kaolin also is used as a raw material feed in formulating bottle and plate glass batches. Drilling mud is a scientifically designed mixture of several items. It contains, in addition to bentonite or attapulgite, ground barite for its high specific gravity.29 Demand for bentonite in iron and steel production is based on its ability to form strong iron ore pellets from fine-grained taconite concentrates. Easily handled hard pellets are essential for efficient blast furnace operation.

Heavy Clay Products.—The value reported for shipments by the Bureau of the Census for heavy clay products remained the same at \$1.8 billion. The million

standard brick count for building or common face brick increased slightly. Shipments of clay floor and wall tile decreased 6% while vitrified clay and sewer pipe fittings decreased 5%.

Lightweight Aggregates.—Consumption of clay and shale in the production of lightweight aggregate increased 12% to 3.8 million tons. Concrete block, the largest category (66% of total production), increased 22% while the second biggest consuming area, structural concrete (22% of total production), increased only slightly. The third largest segment, highway surfacing (7% of production), declined significantly. The other category, the smallest segment consisting essentially of market areas such as recreational and horticultural uses, increased 5%.

Refractories.—All types of clay, except for fuller's earth, were used in manufacturing refractories. Kaolin, bentonite, and fire clay accounted for 32%, 31%, and 19%, respectively, of total clay used for this purpose. The remainder, ball clay and common clay and shale, was used chiefly as bonding agents. Bentonite, both swelling and nonswelling, was used as a bonding agent in proprietary foundry formulations imparting both hot and green strength to the sand.

The tonnage of clays used for refractories increased 6% and constituted 8% of

¹Include extruded and other brick.

total clay produced. The continued use of high-alumina clay-base refractories, mostly calcined kaolin grogs in monoliths, and the upturn in demand for the more conventional refractory bricks and shapes were largely responsible. The major refractory consuming industries—cement, foundry, glass, and ferrous and nonferrous metals—continued to undergo major changes in technology and production levels for their products.

Filler.—Bentonite, fuller's earth, and kaolin are the principal filler clays. Kaolin, either air-floated, water-washed, low-temperature calcined, and/or delaminated, was used in the manufacture of adhe-

sives, paint, paper, plastics, and rubber. Fuller's earth was used primarily in pesticides and fertilizers. Clays were used in pesticides and fertilizers as either thickeners, carriers, diluents, or prilling agents. Bentonites were used mainly in animal feeds.

Of the total clay produced, 13% was used in filler applications; of this, kaolin accounted for 87%; fuller's earth, 6%; bentonite, 3%; and ball clay, common clay and shale, and fire clay, 4%. Kaolin consumed as fillers increased 3% to 5.1 million tons. Use of paper-coating-grade kaolin increased 7%, and the use of paper-filler-grade kaolin decreased 6%. These two categories accounted for 84% of the

total filler and extender category.

Absorbent Uses.—Absorbent uses for clays accounted for about 2.1 million tons or 5% of total clay consumption. Demand for absorbents increased 10%. Fuller's earth was the principal clay used for absorbent purposes. This application accounted for 83% of its entire output. Demand for clays in pet waste absorbents increased. The use of fuller's earth in floor or oil and grease absorbents, chiefly to absorb hazardous oily substances, accounted for 17% of the absorbent demand.

Drilling Mud.—Demand for clays in rotary-drilling muds decreased to about

²Extruded brick only.

Other brick only.

⁴Includes 1.5 million tons used in other brick production.

⁵Data may not add to totals shown because of independent rounding.

747,000 tons and accounted for 2% of total clay production. Oil- and gas-well-drilling activity increased at the end of the year because of firmer oil prices brought about by Middle Eastern difficulties. Swelling-type bentonite remained the principal clay used in drilling mud mixes, although fuller's earth, used mostly in saltwater drilling techniques, and non-swelling sodium-activated bentonites were also used to a limited extent. Bentonite and fuller's earth accounted for 100% of the total amount of clay used in this category.

Floor and Wall Tile.—Common clay and shale, ball clay, and kaolin, in order of volume, were used in manufacturing floor, wall, and quarry tile. This end-use category accounted for 2% of the total clay production.

Pelletizing Iron Ore.—Bentonite continued to be used as a binder in forming indurated iron ore pellets. Demand in-

creased 32% to 732,000 tons.

Ceramics and Glass.—Total demand for clay in the manufacture of pottery, sanitaryware, china and dinnerware, and related products (excluding clay flower pots) accounted for 1% of the total clay output. This demand, principally ball and kaolin clays, increased 3% to 1.41 million tons. The downturn in new residential housing construction, large consumers of whiteware and sanitaryware, was partially offset by the strong demand for these products in the remodeling areas.

World Review

Capacity.—The data in tables 27, 28, 29, 30, and 31 are rated capacity for mines as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced on a normally sustainable long-term operating rate based on physical equipment of the plant, and given acceptable routine oper-

ating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Mine capacity for domestic clay production was aggregated from data voluntarily supplied by producers. The rated capacity data for the foreign mines were estimated from previous years' production in cooperation with the Division of International Minerals.

Algeria.—A 50,000-ton-per-year kaolin processing plant will be constructed at El Milia by the State Organization for Non-Ferrous Minerals and Useful Substances. Approximately one-half of the production will be used in sanitaryware, one-fourth in tableware, and one-fourth in paper.³⁰

Australia.—Commercial Minerals Ltd.

acquired Australian China Clays Ltd. The purchase enables Commercial Minerals to offer a full range of dry processed and wet refined kaolin and ball clays.31

Brazil.—Companhia Vale do Rio Roce and Caulim da Amazonia (Cadam) announced plans to mine kaolin in eastern Para. The deposits have an estimated reserve of 300 to 400 million tons. 32

Chile. - Minera Pacifico provided all of the kaolin for the paper industry. The kaolin produced is suitable only as a filler. Ball clay and kaolin for the ceramics industry is provided by Ceramicas Cordillera SA (Eternit Group). The clay is produced near Pichilemu.3

China.—A large kaolin deposit was discovered in Shaanix Province. Reserves are estimated at 360 million tons.34 A large bentonite deposit was discovered in Xianiiang. The deposit has reserves of 1.2 billion tons.35

Denmark.—Denmark is the only producer of moler, which is a mixture of diatomite and plastic clay. The clay acts as a binder, while the diatomite acts as an

insulator. Moler is used to make insulating bricks. In powder and granular form, some of its uses are in animal feed, for filtration, as a chemical carrier, for acid treatment, as an insulating board, as a pet litter, and in fertilizers. Denmark also produces kaolin for the tile industry.36

Iraq.—The Ina-Petrokemija enterprise of Yugoslavia will develop a bentonite deposit and build a 50,000-ton-per-year processing plant in Iraq.37

Japan.—Hojun Kogyo built a new bentonite processing plant in Chiba pre-

fecture. The plant, which has a capacity of 5,000 tons per month, will process high-grade sodium bentonite from Wyoming for foundry and soil sealing and other civil engineering applications.³⁸

Malaysia.—The ball clay, common clay, and kaolin industries were reviewed. The country produces medium-grade ball clay and common clay for manufacturing pipe, tile, brick, sanitaryware, etc. Malaysia produces kaolin for the ceramics, paint, rubber, and fertilizer industries. The outlook for these industries is good because of anticipated expansion of the Malaysian ceramics industry and increased exports of ore and finished products.³⁹

New Zealand.—A report covered the halloysite, common clay, and bentonite industries. Halloysite is produced from two mines on the North Island. The deposit is approximately 50% halloysite and 50% silica. A 142-hectare deposit currently is being investigated. Halloysite is used primarily in porcelain. 40

Philippines.—A clay deposit that is suitable for whiteware production was discovered. The deposit is in an altered gabbroic rock. Further exploration will be undertaken to determine if the deposit has sufficient reserves to be mined economically.⁴¹

South Africa, Republic of.—A new deposit of kaolin was discovered at Klipheuwel. Preliminary study indicates that the deposit may contain up to 40 million tons of kaolin.⁴²

United Kingdom.—ECC Group announced plans to reduce its work force and focus on its kaolin, ball clay, calcium carbonate, and aggregates industries. The company will phase out its activities in other industries. The reduction in work force is not expected to affect production capacity.⁴³

Current Research

A paper reviewed the use of superconducting separators for processing kaolin. The report covered applications, superconductivity, magnet design, power requirements, cycling, and reliability.⁴⁴

A report reviewed the acid-activated bleaching industry. The report covered the activating process, worldwide pro-

ducers of activated clays, the refining processes (chemical process, physical process, and hydrogenation), and desirable properties of bleaching clays.⁴⁵

The sorption of hydrophobic organic compounds (HOC's) onto humic-coated minerals may affect the concentration of HOC's in low-carbon aquifer materials. A study investigated how humic and fulvic acid affected the sorption of HOC's on kaolin. The sorption of HOC on kaolin was greater for kaolin treated with humic acid than with untreated kaolin or kaolin treated with fulvic acid. The sorption of HOC's was different for kaolin and hematite. 46

Treated bentonite may increase the sorption of nonionic organic contaminants when used as a liner at waste-disposal facilities. The sorption of tetrachloromethane by Wyoming bentonite treated with 10 ammonium compounds was tested. Bentonite treated with tetramethyl-, tetraethyl-, benzyltrimethyl-, and benzyltriethylammonium exhibited the greatest sorption.⁴⁷

Montmorillonite treated with alkylammonium compounds may be suitable for sampling organic vapors from the air. The tetramethylammonium montmorillonite exhibited better characteristics than the other treated montmorillonite samples and some other adsorbents. It exhibited favorable breakthrough and sampling volumes. The recovery and desorption efficiencies were comparable to those of a reference adsorbent.⁴⁸

OUTLOOK

U.S. clay demand between 1980 and 1990 has rebounded slowly from the recessionary years of 1981-82 to 43 millon

tons. Despite the rebound, production still is well below the levels of the early 1970's. In general, there has been a decrease in construction activity in the public, private, and commercial sectors. Higher mortgage rates in the late 1970's and early 1980's and the limited availability of affordable housing and funds for public and business ventures contributed to the problem. The slow economy of recent years continued to depress construction activities despite declining interest rates and increased availability of capital. Demand for common clay and shale, which are strongly tied to the construction industry, has declined over the past 10 years. Kaolin, ball clay, and fuller's earth have fared better than their common clay and shale counterparts because they are used in more diversified applications and industries. Domestic demand for specialty clays should remain strong in the near

The weakening U.S. dollar in the latter part of the decade encouraged specialty clays producers to expand their share of export markets. Exports of domestic clays, mostly kaolin, bentonite, ball clay, and fuller's earth, are restricted to the higher valued specially treated varieties for use in drilling muds, paper-coating, and iron ore pelletizing and by the foundry industry. Export markets should continue to remain strong in the near future. Imports of clays, except for English china and ball clays and acid-activated bentonites, are minor. The English clays enjoy a small prestige-dictated market, while the activated clays are confined to use in the Southern and Northern States.

¹Includes capacity at operating plants as well as at plants on standby basis.

COBALT

By Kim B. Shedd

Ms. Shedd, a physical scientist with more than 11 years of U.S. Bureau of Mines experience, has been the commodity specialist for cobalt since 1988. Domestic survey data were prepared by Jo-Ann S. Sterling, supervisory mineral data assistant, and trade data were prepared by Barbara J. McNair, mineral data assistant, Section of Ferrous Data. International production tables were prepared by William Zajac, Chief, Section of International Data.

obalt is a strategic and critical metal used in many diverse industrial and military applications. The largest use of cobalt is in superalloys, which are alloys designed to resist stress and corrosion at high temperatures. The main use for superalloys is in jet engine parts. Another important use of cobalt is to make permanent magnets, which are used in a wide range of electrical devices. Cobalt acts as a binder in cemented carbides and diamond tools, which are used for metal cutting and forming, mining, and oil and gas drilling. Cobalt chemicals have diverse uses. including catalysts for the petroleum and chemical industries: drving agents for paints, varnishes, and inks; additives to ground coats for porcelain enamels; and pigments for ceramics, paints, and plastics.

The United States is the world's largest consumer of cobalt, but has no domestic production, so it relies on imports to meet its primary cobalt needs. The United States stocks significant quantities of cobalt metal in the National Defense Stockpile (NDS) for military, industrial, and essential civilian use during a national emergency.

U.S. cobalt demand remained strong in 1990. For the third year in a row, Western World cobalt demand exceeded Western World production, resulting in a further reduction in producers' stocks. Concerns over adequate supply caused market prices to rise significantly in 1990, ending a period of market stability that began in late 1986. This increase was followed by a 31% increase in the producer price late in the year.

DOMESTIC DATA COVERAGE

Domestic data on cobalt processing and

consumption are developed by the U.S. Bureau of Mines from three separate, voluntary surveys of U.S. operations. In the cobalt processors survey, seven of the eight companies canvassed responded. Most of the data on cobalt used in chemicals were obtained from this survey. The second survey covers a broad range of metal-consuming companies, such as superalloy producers, magnetic alloy producers, and tungsten carbide producers. The U.S. Bureau of Mines also surveys superalloy scrap recyclers to determine the consumption of secondary cobalt in superalloy producers. The data in tables 3 through 6 contain estimates to account for nonrespondents.

BACKGROUND

Definitions, Grades, and Specifications

Cobalt is a metallic element. It is silvery gray in color, hard, ductile, somewhat malleable, and magnetic. Other properties include atomic number, 27; atomic weight, 58.93; melting point, 1,493° C; boiling point, 3,100° C; and Curie temperature, 1,121° C. Cobalt-60 (60°Co) is produced by irradiating cobalt metal in a nuclear reactor. This radioactive isotope is used in radiation therapy and sterilization of medical supplies.

Currently there are no internationally recognized specifications for cobalt metal. The two leading Western World producers, La Générale des Carrières et des Mines du Zaire (Gécamines) and Zambia Consolidated Copper Mines Ltd. (ZCCM), have proposed specifications for five grades of cobalt. The U.S. Government has purchase specifications for NDS cobalt. The current NDS specification, P-13-R6, provides physical and chemical

requirements for three grades of refined cobalt metal. Grades A and B must be in the form of electrolytic cathode; grade C can be either cathode or granules. Chemical requirements specify the weight percentage, in order of abundance, of cobalt, nickel, iron, and manganese, as well as maximum levels of 26 impurities.

Products for Trade and Industry

More than one-half of the cobalt used in the United States is consumed as primary cobalt metal. This is either in the form of electrolytic cobalt (cathode or rounds), granules (shot), or metal powder. Secondary cobalt is cobalt recovered from scrap. Purchased scrap constitutes about 16% of U.S. consumption. The remainder of the cobalt used, about 30% is in the form of cobalt chemical compounds. This includes cobalt oxide, which can be either gray oxide, with 75% to 78% cobalt content, or black oxide, with 70% to 74% cobalt content. The percent cobalt content in the oxides depends on the relative amounts of cobalt(II)oxide and cobalt(II)dicobalt(III)tetroxide present. Commercially available inorganic cobalt compounds include carbonate, chloride, hydroxide, nitrate, and sulfate (either as heptohydrate or monohydrate). Most of the inorganic compounds are sold in crystalline form, but some are also available in solution. A variety of organic cobalt compounds are also available.

Industry Structure

Cobalt mine and refinery production are limited to a few countries. The United States is not currently a cobalt producer. U.S. mine production of cobalt ceased at the end of 1971, and the sole U.S. cobalt refinery discontinued processing imported nickel-cobalt matte in late 1985. In 1990,

Zaire was the world's leading producer of refined cobalt, followed by Zambia, the U.S.S.R., Canada, Norway, and Finland. These six countries represented 95% of world cobalt refinery production. Zairian and Zambian production was from domestic ores. Canada and the U.S.S.R. produced cobalt from both domestic and imported raw materials. All of the cobalt produced in Norway and most of the cobalt produced in Finland was from imported raw materials. World producers of refined cobalt and producers of intermediate cobalt-containing products are listed in tables 1 and 2.

Cobalt processors represent an important source of supply for various industries. Processors differ from producers primarily in the feed materials they use. Cobalt producers refine cobalt from ores. concentrates, mattes, or residues originating from mining or refining operations. Some refiners also use scrap as a feed material. Producer products include cobalt cathode, granules, metal powder, oxide, and salts. In contrast, cobalt procescathode or granules. The world's largest

sors begin with refined cobalt metal or cobalt-containing scrap and make metal powder, oxide, and/or salts, but not

Companies with production during 1990; excludes companies producing refined cobalt ²Cobalt may not be recovered.

cobalt processor is Metallurgie Hoboken-Overpelt S.A. (MHO) in Belgium. Other cobalt processors are in Europe and the United States (see Production section of this report).

Byproducts and Coproducts

Cobalt is rarely produced as a primary product from a mining operation. Most of Western World cobalt supply is produced as a byproduct of copper production in Zaire and Zambia. With the exceptions of Morocco, where small amounts of cobalt are produced as a primary product, and the Republic of South Africa, where cobalt is produced as a byproduct of platinum mining and refining, cobalt production in most other countries is a byproduct of nickel production.

Economic Factors²

Most of cobalt's production costs are attributed to the primary metal produced at a given operation. The incremental costs applied to cobalt production include costs to separate cobalt from the primary metal, usually during the refining stage; transportation costs; and marketing costs. The U.S. Bureau of Mines Minerals Availability Program estimated 1989 direct operating costs for cobalt refining in market economy countries to range from less than \$1.00 per pound for cobalt cathode production at Falconbridge Ltd.'s Kristiansand, Norway, refinery to about \$3.00 per pound for production of cobalt powders at Sherritt Gordon Ltd.'s refinery in Alberta, Canada. Cobalt refining costs in Zaire and Zambia are estimated to average about \$2.50 per pound. However, additional capital improvements, transportation, and marketing expenses in these two countries may increase total costs to about \$4.00 per pound. Most of the nonproducing properties evaluated in the study would require a total cost per pound, including a 15% discounted cashflow rate of return, in excess of January 1989 market prices for the primary commodity (copper, nickel, or cobalt).

Operating Factors

Environmental Requirements.—The Environmental Protection Agency (EPA) regulates releases of cobalt into the environment under various programs. The Occupational Safety and Health Admin-

Companies with production during 1990.

istration (OSHA) regulates workplace exposures by setting permissible exposure limits for cobalt metal, dust, and fume; cobalt carbonyl; and cobalt hydrocarbonyl.

Toxicity.—The International Agency for Research on Cancer (IARC) adopted a classification for cobalt and its compounds at a meeting in Lyon, France, during the week of July 12-19, 1990. The IARC classifies materials into one of four groups: group 1, sufficient evidence of carcinogenicity in humans; group 2A, probably carcinogenic to humans; and group 3, not classifiable as to carcinogenicity to humans. The IARC classified cobalt as group 2B, possibly carcinogenic to humans.³

ANNUAL REVIEW

Legislation and Government Programs

The NDS cobalt inventory did not change significantly during 1990. The only stockpile activity was the fulfillment of the cobalt upgrading contract awarded to Sherritt Gordon Ltd. the previous year. Under the contract, the Defense Logistics Agency (DLA) shipped 148 metric tons, contained cobalt, of cobalt metal from the stockpile to Sherritt in Canada. In return, Sherritt supplied 186 metric tons, gross weight, of cobalt cathode from Falconbridge's Kristiansand refinery in Norway. Sherritt provided cobalt from Falconbridge because the DLA contract required cobalt cathode, which Sherritt does not produce. The DLA reported a yearend cobalt inventory of 23,940 metric tons, contained cobalt. This inventory did not include the cobalt received from Sherritt, which was on hand but awaiting a final accounting transfer. The NDS goal of 38,737 metric tons cobalt metal remained in effect during 1990. No actions were taken during the year to increase the inventory level to meet the goal.

The General Accounting Office (GAO) reviewed DLA's 1989 contract with Sherritt in response to a protest from The Hall Chemical Co.⁴ The GAO determined that the contract had been properly awarded to Sherritt. While Sherritt was the highest bidder, it was also the only company to offer cobalt from a designated country, as required by the Trade Agreements Act.

^eEstimated. ^pPreliminary. ^rRevised.

In August, the Minerals Management Service and the State of Hawaii completed a final Environmental Impact Statement (EIS) for the possible future development of cobalt-rich manganese crusts in the Exclusive Economic Zone (EEZ). The EIS evaluated 26,910 square kilometers of EEZ lands adjacent to Hawaii and Johnston Island for a proposed lease sale and gave the following preliminary estimates of potential metal resources: 2.6 million metric tons of cobalt, 1.6 million metric tons of nickel, and 81 million metric tons of manganese. The pollution risks of exploration and development of the areas were addressed in the EIS, and several alternatives to the proposed lease were presented. No date was set for the lease sale.

On November 15, Congress amended the Clean Air Act (Public Law 101-549), completely revising the act's hazardous air pollutants program. As part of the new program, Congress established a list of hazardous air pollutants to be regulated. Cobalt compounds—defined as any unique chemical substances that contain cobalt as part of their infrastructure (composition)—were included on the list. Congress instructed EPA to establish emission standards for sources that emit hazardous air pollutants, rather than for the pollutants themselves. Congress required EPA to develop a list of source categories by November 15, 1991. The act included a provision for EPA to review petitions to delete specific chemicals or pollution sources from the lists.⁵

Strategic Considerations

Cobalt is considered a strategic and critical metal because of its many industrial and defense-related uses and because the United States is highly dependent on imports for its supply. The United States is the world's largest consumer of cobalt. In 1990, the United States consumed 31% of estimated world refinery production. There was no domestic production, so demand was met primarily from imports, with the exception of about 16% from purchased scrap.

To ensure an adequate supply for military, industrial, and essential civilian needs, cobalt metal is included in the NDS. Stockpile quantities are intended to sustain the United States for a period of not less than 3 years during a national emergency situation. Most of the cobalt in the stockpile was purchased prior to 1980 and does not meet current quality requirements for vacuum-melted superalloys. Upgrading of stockpile cobalt began in 1990. (See the Legislation and Government Programs section of this report.)

World cobalt production is concentrated in a limited number of geographic areas. More than one-half of the world's supply of refined cobalt comes from cen-

¹Stocks held by consumers and chemical processors.

²Market price based on weighted average of Metals Week prices.

tral Africa, primarily Zaire and Zambia. Since 1987, all of the cobalt produced in Zaire has been transported through the Republic of South Africa. Cobalt produced in Zambia was formerly transported through the Republic of South Africa, but has been exported through Dar es Salaam, Tanzania, in recent years. Therefore, while the Republic of South Africa is not a major cobalt producer, its potential influence on supply is great because of the large amounts of cobalt exported using its transportation system. As part of the Comprehensive Anti-Apartheid Act of 1986 (Public Law 99-440), the United States prohibits imports of products "produced, manufactured by, marketed, or otherwise exported by a parastatal organization of South Africa." Because of our high reliance on cobalt imports from southern Africa, the U.S. State Department has certified cobalt as a strategic mineral so that it is exempt from this prohibition.6

An overview of the issues related to U.S. supplies of strategic minerals was published in 1990.⁷ Many interesting points were addressed regarding the U.S. dependence on foreign supplies; ways to reduce disruptions in strategic mineral supplies; and the quality, quantities, and management of materials in the NDS. Articles by individuals from private industry and the Government were included in the text.

Production

There was no domestic mine or refinery production of cobalt in 1990. Plans by Blackbird Metals Inc. to initiate U.S. cobalt production were delayed. Delays in obtaining financing resulted from the economic slowdown. A second complicating factor was an ongoing environmental lawsuit by the State of Idaho against Noranda Mining Inc. and the M. A. Hanna Co., current owners of the Blackbird cobalt mine in Lemhi County, ID.

Black Hawk Mining Inc., of Toronto, Canada, bought China First Capital Corp., owner of a nickel-copper deposit near Warren, ME. The deposit, formerly known as the Union or Crawford Pond deposit, was renamed the Knox deposit. During 1990, Black Hawk spent \$400,000 on core drilling and metallurgical testing. The company estimates reserves at 3 million metric tons ore grading 1.47% nickel, 0.66% copper, and 0.1% cobalt.8 Annual production was anticipated to be 3,600 to

4,000 metric tons (8 million to 9 million pounds) nickel, 2,500 metric tons (5.5 million pounds) copper, and 400 metric tons (900,000 pounds) cobalt. Late in the year, Black Hawk began a feasibility study on mine and mill design and cost estimates. At yearend, the company was awaiting new State of Maine mining regulations before proceeding.

U.S. cobalt supply included secondary cobalt from the recycling of superalloy and other forms of scrap. Cobalt was recovered from spent petroleum catalysts at the AMAX plant in Braithwaite, LA, and at Gulf Chemical and Metallurgical Corp. in Freeport, TX.

Two cobalt processors produced extrafine cobalt metal powder in the United States. Carolmet, owned by MHO of Belgium, produced extra-fine powder from imported primary metal at its Laurinburg, NC, plant. GTE Products Corp. produced extra-fine powder from recycled materials in Towanda, PA. Production and shipments of extra-fine cobalt metal powder are withheld to avoid disclosing company proprietary data.

Domestic chemical processors pro-

duced 2,123 metric tons of cobalt oxide. cobalt hydroxide, inorganic cobalt compounds, and organic cobalt compounds in 1990. Because this figure includes production of intermediate forms, it does not represent net production. Shipments are defined as sales, transfers, or consumption to make end-use products such as paint driers or catalysts. In 1990, domestic chemical processors shipped 1,963 metric tons of cobalt oxide, cobalt hydroxide, inorganic cobalt compounds, and organic cobalt compounds. Production and shipments in 1990 are not comparable with those published for prior years because of a correction in survey response that began in 1990.

Consumption and Uses

Apparent consumption, as calculated from net imports, consumption from purchased scrap, and changes in Government and industry stocks, was 7,885 metric tons. Total U.S. reported consumption of cobalt increased 4% in 1990 compared with that of 1989. Consumption of cobalt in superalloys, the largest

cobalt-consuming industry, increased significantly in 1990. Consumption of cobalt in paint driers and in cutting and wearresistant materials also increased. In contrast, cobalt use in tool steels and magnetic alloys decreased.

Stocks

Total yearend cobalt stocks held by U.S. chemical processors and consumers were higher than 1989 yearend stocks. The increase paralleled a gradual rise in cobalt metal inventories during 1990. Yearend stocks of cobalt chemicals and cobalt-containing scrap were lower than 1989 yearend stocks (table 6).

Markets and Prices

The producer price of \$8.40 per pound of electrolytic cobalt established in November 1988 was maintained during 1989 and 1990. On September 27, Gécamines and ZCCM, the Western World's two

largest cobalt producers, announced a 31% increase in the producer price to \$11.00 per pound, to be effective for 1 year beginning January 1, 1991.

The free market price for cobalt metal (also referred to as market, merchant, or spot price) increased significantly during the second half of 1990, ending a period of relative stability that began in late 1986. Market analysts suggested that much of the increase was trader-driven, with many of the transactions at the high prices between traders, as opposed to sales to consumers. The price increases were fueled by press reports emphasizing a decrease in availability of free market cobalt coupled with concerns over adequacy of supply and possible supply disruptions during a period of steady demand. Early in the year, reports focused on delayed shipments from African producers, the effect that planned cutbacks in nickel production by Canadian nickelcobalt producers would have on cobalt output, and tightening of supplies on the

free market. Market prices during this period gradually increased from \$7.50 per pound in January to approach the producer price of \$8.40 per pound in April. In July, the market price jumped above the producer price following reports of strikes in Zaire and political unrest in Zambia. Market prices increased steadily over the summer, approaching \$13.00 per pound by late August. Following the announcement of the new producer price in late September, news of a cave-in at one of Gécamines' copper-cobalt mines caused the market price to jump again, exceeding \$14.00 per pound. Between mid-October and early December, the market price decreased steadily to approximately \$12.50 per pound. However, in December, prices increased again, and the year ended with a market price range of \$15.25 to \$15.75 per pound. The weighted average market price for the year was \$10.09 per pound. Prices for cobalt-containing materials are presented in tables 3 and 7.

A significant change in the world cobalt market was noted.9 During 1990, Western World cobalt sales to Eastern Europe and the U.S.S.R. decreased as a result of reduced consumption during economic and political restructuring in those countries. A 50% decrease in exports to Eastern Europe and the U.S.S.R. was reported. In addition to reducing their consumption of imported cobalt, the Soviets also exported cobalt ingot produced in the U.S.S.R.10 to Europe, the Far East, and the United States (see table 9).

Foreign Trade

U.S. imports of unwrought cobalt and cobalt chemicals increased 13% to an estimated 6,529 metric tons, valued at \$119 million. One-third of these imports was from Canada and Norway. Much of the cobalt produced in Norway was from Canadian ores. Fifty-nine percent of U.S. cobalt imports in 1990 was from ores originating in the south-central African countries of Zaire and Zambia. This includes cobalt imported from Belgium, where Zairian cobalt metal is processed into metal powder, oxides, and salts by MHO.

In 1990, the United States began importing minor amounts of cobalt metal from Brazil and the U.S.S.R. Brazil is a new cobalt producer. Its production of cobalt metal began in 1989 with the installation of an electrolytic cobalt circuit at Cia. Niquel Tocantins' nickel refinery.

Source: Bureau of the Census; minor adjustments by the U.S. Bureau of Mines.

Cobalt originating from Brazilian ores was formerly refined at Falconbridge Nikkelverk in Norway. The U.S.S.R. has been a major cobalt producer, but was considered a net importer of cobalt until recently. Decreased domestic consumption and the need for hard currency are

assumed to be the reasons for sales of Soviet cobalt to Western World markets.

U.S. net import reliance as a percentage of apparent consumption was estimated to be 84% in 1990. The net import reliance would be 100% if no cobalt were recovered from secondary sources (scrap).

In 1990, the United States exported an estimated 1,340 metric tons of unwrought cobalt and cobalt contained in chemicals, valued at \$18.1 million. This represented a 51% increase as compared with exports in 1989. Major recipients were Canada (27%), Mexico (10%), Taiwan (9%), and Japan (8%). The remaining 46% was shipped to 44 other countries.

Exports also included 481 metric tons, gross weight, of wrought metal and cobalt articles, valued at \$12.3 million. The majority of these materials was sent to four countries: the United Kingdom (54%), Canada (12%), France (8%), and the Netherlands (8%). The remainder was shipped to 22 other countries. In addition, the United States exported 49 metric tons, gross weight, of material under the category entitled, "Cobalt ores and concentrates." Canada was the major recipient of this material.

World Review

Estimated world refinery production was relatively unchanged from production in 1989. Increases in production by major producers Zaire and Zambia and minor producers Brazil, Japan, and France were balanced by decreases in estimated Soviet production and production reported for Canada and Norway. Refinery production reported by the seven Cobalt Development Institute (CDI) member producers11-Falconbridge, Gécamines, Inco Ltd., Outokumpu Ōy, Sherritt Gordon, Sumitomo Metal Mining Co. Ltd., and ZCCM—was 5% greater than production in 1989. Sales by CDI producers were estimated at 23,500 metric tons, a 10% increase over sales in 1989. However, only 22,500 metric tons of these sales was believed to represent actual Western World consumption. For the third year in a row cobalt production was less than demand, resulting in a significant decrease in producers' stocks.

Capacity.—The data in table 13 are rated capacity for refineries as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the

judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Australia.—Nickel-cobalt sulfide and cobalt sulfide were produced as byproducts of nickel mining and refining by Western Mining Corp. (WMC) in Western Australia and Queensland Nickel Pty. Ltd. in Queensland, respectively. Minor amounts of cobalt oxide were produced as a byproduct of zinc production by Pacific Smelting and Mining Co. Ltd. in Risdon, Tasmania.

WMC reached an agreement to acquire a 70% share in the Bulong nickelcobalt project from Resolute Resources Ltd. of Perth, Western Australia, and Energy Oil and Gas NL, also from Australia. The Bulong deposit is a nickeliferous laterite 35 kilometers east of Kalgoorlie, Western Australia. The deposit reportedly contains a resource of 108 million metric tons, with measured reserves of 9.8 million metric tons ore grading 1.05% nickel and 0.07% cobalt.12 As part of the agreement, WMC planned to build a pilot plant and to conduct a feasibility study on technical and economic aspects of the project. The study was to include nickel and cobalt extraction by pressure acid leaching. The use of sulfuric acid manufactured from sulfur dioxide generated at WMC's Kalgoorlie smelter was to be investigated. Previous studies projected annual production rates of 12,000 metric tons nickel and 800 metric tons cobalt.

In January, the Queensland government increased its stake in Queensland Nickel to 28%. Dallhold Investments Ptv. Ltd. held the remaining 72% interest in the joint venture. Queensland Nickel's plans to increase the capacity of its Yabulu nickel-cobalt processing plant at Townsville, Queensland, were delayed when approval to build an ore-handling facility at Halifax Bay was denied by the Great Barrier Reef Marine Park Authority. The Marine Park Authority rejected the proposal because of concerns over the impact of potential ore spills on the marine environment. The ore-handling facility was part of a plan to replace diminishing supplies of feed from the company's Greenvale Mine with increased imports of higher grade ore from New Caledonia, Indonesia, and the Philippines. At yearend, Oueensland Nickel had lodged an appeal with the Administrative Appeals Tribunal and was discussing alternatives to importing through Halifax Bay with the Queensland government. Cobalt sulfide produced at the Yabulu refinery was refined by Outokumpu Oy in Finland.

Botswana.—BCL Ltd. continued development of a new copper-nickel mine in the Selebi North deposit, with the intention of maintaining current production levels into the future. Copper-nickel-cobalt matte produced by BCL was sent to refineries in Norway and Zimbabwe to be refined.

Brazil.—Cia. Niquel Tocantins was reported to have produced roughly 5 tons per month of cobalt cathode during 1990. Much of the cobalt produced was exported to the United States and Europe. The company planned to increase production to 15 to 20 tons per month in 1991.¹³

Canada.—In 1990, Falconbridge produced approximately 800 metric tons of cobalt from nickel ores at its Sudbury, Ontario, operations. An additional 500 metric tons of cobalt was produced in 1990 from custom feed smelting. ¹⁴ Cobalt-containing nickel-copper matte from Sudbury was refined at the Falconbridge Nikkelverk refinery in Norway.

Inco produced cobalt oxide at its Thompson, Manitoba, refinery and cobalt cathode at its Port Colborne refinery. Feed materials for the two refineries originated from mines in Thompson, Manitoba, and Sudbury, Ontario, respectively. Inco's production of refined cobalt decreased 9% in 1990. The company produced 1,380 metric tons of cobalt, as compared with 1,510 metric tons in 1989. Inco's 1990 cobalt deliveries, including cobalt contained in alloys and engineered products, were relatively unchanged from deliveries in 1989 at 1,447 metric tons. Incomparison of cobalt contained in alloys and engineered products, were relatively unchanged from deliveries in 1989 at 1,447 metric tons. Incomparison of cobalt contained in alloys and engineered products, were relatively unchanged from deliveries in 1989 at 1,447 metric tons. Incomparison of cobalt contained in alloys and engineered products, were relatively unchanged from deliveries in 1989 at 1,447 metric tons.

Sherritt Gordon refined cobalt-containing materials from Canada and elsewhere at its nickel-cobalt refinery at Fort Saskatchewan, Alberta. Sherritt produced 688 metric tons of cobalt powder in 1990.17 This represented a 12% increase over 1989 production, but remained below the high production levels achieved prior to 1989. During the third quarter, Sherritt closed its nickel-cobalt refinery in Edmonton, Alberta, for 2 months owing to a lack of nickel-cobalt feed. In September, a shareholders meeting was called by Canada SherGor Enterprises Inc., a private company formed by Sherritt shareholders dissatisfied with the way the company was being run. At the meeting, shareholders voted by a narrow margin to replace Sherritt's board of directors and executive managers with representatives from SherGor. At yearend, the company continued in its efforts to obtain new feed supplies.

Finland.—Outokumpu produced 1,220 metric tons of cobalt metal powder and salts, a 5% decrease from the 1,290 metric tons produced in 1989. In 1990, Outokumpu purchased Vasset S.A. in France. Vasset converts cobalt chemicals to organometallic soaps for use by the tire and chemical industries.

India.—Hindustan Zinc Ltd. continued construction on a cobalt recovery unit at the Debari zinc smelter in Udaipur, Rajasthan State. The unit was to recover cobalt from zinc smelting residues.

Japan.—Sumitomo produced cobalt metal and salts as a byproduct of nickel production at its Niihama Nickel Refinery in Ehime Prefecture. The large increase in cobalt metal production in 1990 resulted from processing cobalt precipitates stockpiled during the previous year.

¹Includes salts.

²Cobalt chloride.

³Includes standby capacity of 1,200 metric tons.

⁴Based on estimated production.

⁵Standby capacity.

⁶Does not include Albania or China.

The precipitates were stocked during construction to expand nickel capacity at the Niihama refinery.

According to Japan's Ministry of International Trade and Industry, Japanese reported cobalt consumption increased 16% in 1990 to 2,994 metric tons. Cobalt use increased in all industry sectors: catalyst use increased 12% to 416 metric tons; cobalt in hard metal tools increased 14% to 345 metric tons; cobalt in special steels increased 13% to 890 metric tons; cobalt in magnetic materials increased 17% to 647 metric tons; and cobalt in other uses increased 23% to 696 metric tons. Demand was met primarily from imports, which increased 36% in 1990 to 4,537 metric tons.

Norway.—The Falconbridge Nikkelverk refinery produced 1,830 metric tons cobalt cathode in 1990, a 6% decrease from the 1,946 metric tons produced in 1989. Feedstock for the refinery was in the form of matte, from company operations in Sudbury, Canada; BCL Ltd. in Botswana; and Noril'sk in the U.S.S.R. During 1990, cobalt from Falconbridge Nikkelverk was supplied to the NDS under the cobalt upgrading program (see Legislation and Government Programs section of this report).

Philippines.—In October, the Philippine Government signed a final agreement with the Philippine Nickel Co. (Philnico) for the sale of the Nonoc Mining and Industrial Corp. nickel production facility. During the year, Philnico continued rehabilitation of the idled plant. This work was begun under a memorandum of understanding signed in August 1989. Cobalt production at the plant would be in the form of mixed nickel-cobalt sulfide. Previous peak production at the facility was 1,374 metric tons of cobalt in mixed sulfide in 1979.

South Africa, Republic of.—Cobalt was produced as a byproduct of the Republic of South Africa's platinum mining and refining industry. Refined cobalt was produced by two companies: Rustenburg Base Metal Refiners Pty. Ltd. produced cobalt sulfate, and Impala Platinum produced cobalt metal powder. A third company, Western Platinum Ltd., produced nickel sulfate containing minor amounts of cobalt. Most of the cobalt produced in the Republic of South Africa was exported. Exports were expected to

increase in the future as a result of increases in mine production.

In terms of South African consumption, a significant shift in cobalt use was reported in 1990. In 1989, the largest use of cobalt was in paint and ink driers (55% of total use), followed by enamels and glazes (25%), then cemented carbides (15%). In previous years, the primary use of cobalt in the Republic of South Africa was in cemented carbides, followed by paint and ink driers, then enamels and glazes.²⁰

Sweden.—In March, the Swedish Government sold 33 metric tons of extra-fine cobalt powder from its stockpile. The cobalt was purchased by MHO, the Belgian processor that had originally supplied it to the stockpile 10 years ago. MHO reportedly bought the cobalt to prevent it from reentering the market because it was not equivalent in quality to powders currently available.

Tanzania.—Sutton Resources Ltd., a Canadian exploration company, acquired Romanex International Ltd., owner of the Kabanga Nickel project in Tanzania. Exploration of the property was underway to confirm previous reserve estimates and provide samples for mineralogical and metallurgical studies. A United Nations Development Program study in the mid-1970's resulted in indicated and inferred reserve estimates of 40.5 million tons of sulfide ore grading 1.05% nickel, 0.21% copper, and 0.11% cobalt.²¹

Zaire.—Gécamines remained the world's largest cobalt producer, providing about 40% of estimated world refinery production. The company's cobalt production increased 8% in 1990, reversing a downward trend in production that began in 1987. An overview of Gécamines cobalt production was presented.²² Materials flow from mines to refineries, refining practices, enhancement or suppression of cobalt production, and mediumand long-term plans were discussed.

In January, Gécamines Commerciale and Sogem-Afrimet Inc. announced the formation of a joint-venture company. The company, named African Metals Corp., was created to act as the exclusive agent for the importation and sale of all cobalt metal produced in Zaire and sold in the United States and Canada.

In September, Gécamines' Kamoto underground mine suffered a major cave-in.

The Kamoto Mine, in Gécamines Western Group near the town of Kolwezi, is the company's largest underground copper-cobalt mine. It provides concentrates to the Shituru and Luilu refineries and the Lubumbashi smelter. Before the cave-in. the mine had been a significant source of cobalt because of its high output levels and the high cobalt content of its ores. At the time of the cave-in, estimates of projected cobalt losses varied widely, but were likely to be on the order of 100 to 150 metric tons per month. Gécamines announced that it would meet its sales commitments and that the loss of cobalt concentrates from Kamoto could be "made up from other sources." Increased output from the Siège de Kolwezi Mines open pit operations was anticipated. No injuries were reported from the accident. However, news of the cave-in caused U.S. cobalt market prices to increase temporarily to more than \$14.00 per pound.

While cobalt production at Gécamines is ultimately tied to copper production, there are various stages during mining. concentrating, and hydrometallurgical processing where cobalt recovery can be either enhanced or suppressed in favor of copper recovery. Emphasis on cobalt production at a given time depends on a balance between market demand, production, and stock levels. For many years Gécamines had been precipitating excess cobalt from its hydrometallurgical plants' cobalt leach circuits and stockpiling cobalt hydrates for later use. In late 1990, Gécamines decided to augment its cobalt production by reprocessing the stockpiled hydrates. Cobalt recovered from the hydrates offset production losses from the Kamoto Mine cave-in.

In a related project, in late 1990, Gécamines signed a contract with Techpro Mining and Metallurgy of the United Kingdom for a turnkey project for the recovery of cobalt and copper from current leach residues. Techpro was to construct a horizontal belt filter and two flotation columns at the Shituru plant and a horizontal belt filter at the Luilu plant, then train operations and maintenance staff in their use. The filters were intended to increase cobalt recovery by providing improved washing of the leach residues.

Zambia.—Production of refined cobalt metal from January to December 1990 increased 8% over that of the same period in 1989 to 4,844 metric tons.²³

Zimbabwe.—Minor amounts of impure cobalt oxide were produced in Zimbabwe as a byproduct of nickel mining and refining. In 1990, the Bindura Nickel Corp. Ltd. produced 123 metric tons of contained cobalt from company nickel ores and toll-refined material.²⁴ The cobalt oxide was exported to be refined.

In October, BHP-Utah Minerals International, a subsidiary of Broken Hill Pty. Co. Ltd., formed a joint venture with Delta Gold NL to study the Hartley platinum deposit. The deposit is part of the Great Dyke, a 500-kilometer-long precious metals and chromite deposit that crosscuts Zimbabwe north to south. As

part of the joint-venture agreement, BHP-Utah was to complete a 2-year feasibility study, then decide on the development of an underground mine. A 1989 feasibility study for Delta Gold showed 37 million metric tons proven and probable reserves. Based on a 2-million-ton-per-year underground mine, annual production was estimated to be in excess of 200,000 ounces of platinum-group metals and 15,000 ounces of gold. In addition, 2,450 metric tons of nickel, 1,570 metric tons of copper, and about 47 metric tons of cobalt could be produced from nickel-copper matte that was to be toll refined in Zimbabwe.

 $^{^{\}rm e}$ Estimated. $^{\rm p}$ Preliminary.

Current Research

The U.S. Bureau of Mines evaluated the availability of cobalt from 27 deposits or districts in 11 market economy countries. An economic evaluation of each deposit or district resulted in an estimation of quantities of cobalt that could be produced at various cobalt, copper, or nickel prices. The study concluded that an adequate supply of cobalt was available from market economy countries to meet their anticipated demand. The study also addressed issues that could affect cobalt availability, including the dependence of cobalt production on production of the operation's primary commodity and transportation routes used by major African producers.25

The U.S. Bureau of Mines published two studies on the processing of cobaltrich manganese crusts from the United States' EEZ surrounding the Hawaiian Islands and Johnston Atoll. In one study,²⁶ froth flotation parameters were optimized to maximize separation of manganese crust from substrate waste rock. Flotation in seawater with diesel fuelcrude tall oil-sulfonate collectors resulted in recoveries of 89% to 95% and produced concentrates grading 15% manganese, 0.58% cobalt, and 0.32% nickel. Flotation tailings were subjected to the EPA Extraction Procedure Toxicity Test to evaluate the environmental impact of tailings disposal. Leachable metal ions were below maximum allowable concentrations established by EPA.

In the second study,²⁷ the Bureau researched the hydrometallurgical processing of cobalt-rich manganese crusts. Conditions were optimized for a hydrogen peroxide-sulfuric acid leach followed by a three-stage selective precipitation. Cobalt was recovered as a mixed cobalt-nickel sulfide precipitate. The EPA Extraction Procedure Toxicity Test was performed on flotation tailings, leach residue, and the iron precipitate to evaluate potential environmental impact. Metal ions leached from the process wastes were below EPA's maximum allowable concentrations.

Three examples of Bureau research on the recovery of cobalt from superalloy scrap were presented at a symposium on recycling held by the Minerals, Metals and Materials Society of the American Institute of Mining, Metallurgical and Petroleum Engineers (AIME). In two studies, superalloy scrap was melt-carburized

Table includes data available through May 31, 1991. Figures represent recoverable cobalt content of ores, concentrates, or intermediate products from copper, nickel, platinum, or zinc operations. Morocco was the only country where cobalt was mined as a primary product.

In addition to the countries listed, Bulgaria, China, the Eastern states of the Federal Republic of Germany, Indonesia, and Poland are known to produce ores that contain cobalt, but information is inadequate for reliable estimates of output levels. Other copper-, nickel-, platinum-, or zinc-producing nations may also produce ores containing cobalt as a byproduct component, but recovery is small or nil.

Calculated from reported and estimated weight of nickeliferous ore.

Figures represent quantities of cobalt contained in intermediate metallurgical products (cobalt oxide and nickel-cobalt sulfide). Cobalt content of lateritic nickel ore, nickel concentrate, and zinc concentrate was as follows, in metric tons: 1986—2,914; 1987—2,715; 1988—2,574 (revised, estimated); 1989—2,375 (estimated); and 1990—2,375 (estimated).

SReported cobalt content of pelletized nickel-copper matte.

⁶Reported figure

⁷Figures represent total cobalt content of all products derived from ores of Canadian origin, including cobalt oxides shipped to the United Kingdom for further processing and nickel-copper-cobalt mattes shipped to Norway for further processing.

Determined from reported nickel-cobalt content of granular and powder oxide, oxide sinter, and sulfide production

⁹Cobalt content of concentrates.

¹⁰Series represents estimated recoverable content of ores and intermediate metallurgical products exported from New Caledonia to France and Japan. The estimated cobalt content of total ores mined is as follows, in metric tons: 1986—5,000; 1987—5,800; 1988—6,000; 1989—6,000; and 1990—6,000.

¹¹Fiscal years beginning Apr. 1 of that stated. Cobalt content of ore milled was as follows, in metric tons: 1986—8,656; 1987—11,198; 1988—10,687; 1989—10,590; 1990—10,700 (estimated).

²Estimated cobalt content of ore.

and cast into anodes. Cobalt and nickel were then recovered hydrometallurgically from the anodes in one of two ways: as high-purity cobalt or nickel in separate double-membrane electrolytic cells,28 or as a mixed nickel-cobalt alloy using controlled-potential electrolysis.29 A third study detailed a chloride-based hydrometallurgical process to recover cobalt, chromium, manganese, nickel, and tungsten from hard-face alloy grinding waste. Ninety-seven percent of the cobalt in the grinding waste was recovered as a cobalt chloride solution using solvent extraction. An economic analysis of the process was also reported.30

A review of four methods for the identification of scrap metals was also published. The methods described were thermoelectric measurements, optical emission spectroscopy, X-ray fluores-

cence spectroscopy, and spark testing. Results of a large-scale field study using these and other techniques at a Department of Defense scrapyard were presented.³¹

The Bureau published a material flow model for the U.S. cobalt industry. The model addressed cobalt consumption, losses, and recycling for eight industry sectors: superalloy; magnetic alloy; cemented carbide: tool steel; stainless steel, heat-resistant steel, and other alloys; miscellaneous alloys; catalyst; and other chemical uses. A combined material flow for the eight sectors gave the following results, based on an estimated consumption of 8,085 metric tons in 1987: 1,139 metric tons of cobalt in recycled obsolete scrap, 1,017 metric tons of cobalt in recycled prompt scrap, 1,385 metric tons of cobalt lost to downgraded scrap, 582 metric tons of cobalt lost as waste, and 6,118 metric tons of cobalt reporting to final products.³²

The Cobalt Development Institute of Wickford, Essex, United Kingdom, published abstracts on cobalt research, articles on selected cobalt uses, and annual and semiannual data on cobalt production by Institute members in quarterly issues of Cobalt News.

OUTLOOK

The outlook for cobalt consumption is dependent on the performance of a variety of industries. The largest single use of cobalt is in superalloys, which are used primarily in turbine engines for both commercial and military aircraft. Decreases in military spending are expected to result in a decline in demand for superalloys in military aircraft. In contrast, demand in the commercial aviation sector is expected to remain strong because of a record backlog of aircraft orders. Areas of potential growth for cobalt-containing superalloys include industrial applications requiring the alloys' ability to withstand corrosive conditions at high temperatures. While these nonaerospace applications represent a small fraction of total superallov use, certain applications, such as waste incineration, have been cited for their growth potential.

Table includes data available through May 31, 1991. Figures represent cobalt refined from ores, concentrates, or intermediate products and do not include production of downstream products from refined cobalt.

²In addition to the countries listed, Belgium, Czechoslovakia, and the Western states of the Federal Republic of Germany may recover cobalt from imported materials, but production is not reported, and information is inadequate to make reliable estimates of production.

³Reported figure.

COLUMBIUM (NIOBIUM) AND TANTALUM

By Larry D. Cunningham

Mr. Cunningham, a physical scientist with 11 years of U.S. Bureau of Mines experience, has served as the commodity specialist for columbium and tantalum since 1983. Domestic survey and trade data were prepared by Cheryl M. Mack, mineral data assistant; and columbium and tantalum world production data, by country, were prepared by Audrey D. Wilkes, international data coordinator.

olumbium is vital as an alloving element in steels and in superalloys for aircraft turbine engines and is in greatest demand in industrialized countries. Columbium is critical to the United States because of its defense-related uses in the aerospace. energy, and transportation industries. Acceptable substitutes are available for some columbium applications, but in most cases they are less desirable. Tantalum is used mostly in the electronics industry. mainly in capacitors, and in aerospace and transportation applications. Tantalum is also critical to the United States because of its defense-related applications in aircraft, missiles, and radio communications. Substitution for tantalum is made at either a performance or economic penalty in most applications. Domestic columbium and tantalum resources are of low grade and are not commercially recoverable. The last significant mining of columbium and tantalum was during the Korean conflict when increased military demand resulted in columbium and tantalum ore shortages.

The United States continued to be dependent on imports of columbium and tantalum materials, with Brazil remaining the major source for columbium imports and the Federal Republic of Germany the major source for tantalum imports. Columbium price quotations were unchanged for the year, and tantalum prices remained stable.

The National Defense Stockpile (NDS) requirement (goal) for the columbium group nearly tripled in accordance with the National Defense Authorization Act for Fiscal Years 1990 and 1991. Also, to ensure future availability to the United States, the Defense Logistics Agency

(DLA) awarded contracts for purchase of tantalum minerals for the NDS.

Overall reported consumption of columbium in the form of ferrocolumbium and nickel columbium rose slightly, with demand for columbium in superalloys at the highest level since 1986. Tantalum consumption was up for the year, aided by increased demand from the electronics industry.

DOMESTIC DATA COVERAGE

Domestic production data for ferrocolumbium are developed by the U.S. Bureau of Mines from the annual voluntary domestic survey for ferroalloys. Of the four operations to which a survey request was sent, three responded. Thus, ferrocolumbium production data for 1990 were incomplete at the time this report was prepared.

BACKGROUND—COLUMBIUM

Columbium and niobium are synonymous names for the chemical element with atomic number 41; columbium was the first name given, and niobium was the name officially designated by the International Union of Pure and Applied Chemistry in 1950. The metal conducts heat and electricity relatively well, has a high melting point (2,480° C), is readily fabricated, and is highly resistant to many chemical environments. Columbium exhibits superconductivity at about 9° K.

a temperature still too low for most commercial applications. (Superconductivity is the virtual loss of electrical resistance that occurs at a specific material dependent temperature and results in energy conservation and more rapid operation of electrical circuits.)

Definitions, Grades, and Specifications

Columbium pentoxide (oxide) is a stable, white- to buff-colored compound that is produced in metallurgical, ceramic, and optical grades. Purity of oxide generally exceeds 99%.

Ferrocolumbium is categorized into three grades by American Society for Testing and Materials (ASTM) Specification A550: low-alloy steel grade, alloy and stainless steel grade, and high-purity grade. For all grades, the composition is approximately 65% columbium, with the balance iron; principal impurities are aluminum, silicon, and tantalum. Nickel columbium typically contains 63% columbium, with the balance being nickel. Aluminum, iron, silicon, and tantalum are the principal impurities.

Columbium carbide is available as a powder containing about 87% columbium and the balance as carbon.

Columbium metal is available in many forms and shapes. Purity of unalloyed metal is usually more than 99%, with attention mainly given to iron, tantalum, and zirconium as metallic impurities and carbon, hydrogen, nitrogen, and oxygen as interstitial impurities. Alloys with hafnium, tantalum, titanium, tungsten, and zirconium are of most commercial importance. Chemical and physical standards for columbium and columbium alloy mill shapes are given in ASTM

Specifications B391-B394, B652, and B654-B655.

Products for Trade and Industry

Columbium, in the form of ferrocolumbium, is used worldwide, principally as an additive to improve the strength and corrosion resistance of steel. Columbiumcontaining high-strength and corrosion resistant steel is used in applications such as high-strength linepipe, structural members, lightweight components in cars and trucks, and exhaust manifolds. Because of its refractory nature, appreciable amounts of columbium in the form of high-purity ferrocolumbium and nickel columbium are used in nickel-, cobalt-, and iron-base superalloys for applications such as jet engine components, rocket subassemblies, and heat-resisting and combustion equipment. Columbium-base alloys are also used in aerospace applications such as rocket nozzles. Columbium carbide is used in cemented carbides to modify the properties of the cobaltbonded tungsten carbide-base material. It is usually used with carbides of metals such as tantalum and titanium. Columbium oxide is the intermediate product used in the manufacture of high-purity ferrocolumbium, nickel columbium, columbium metal, and columbium carbide.

Geology-Resources

Columbium is almost always found in nature as an oxide in association with other minerals, but not in elemental form nor as a sulfide. Columbium has an overall crustal abundance estimated as 20 parts per million and a strong geochemical coherence with tantalum. Pyrochlore and bariopyrochlore (also known as pandaite), its barium analog, have become the main sources of columbium. The minerals contain little tantalum, having a columbium oxide-to-tantalum oxide ratio of 200:1 or greater. Pyrochlore and bariopyrochlore are commonly found in the interior parts of alkalic rock complexes, frequently in association with minerals of such other elements as thorium, titanium, uranium, and those of the rare earths. Columbite, the columbium-rich member of the columbite-tantalite isomorphous series, is normally found in intrusive pegmatites and in biotite and alkalic granites. However, because most such deposits relatively high in columbium content are small and erratically distributed, most columbite has been obtained as a byproduct of mining for other commodities, mainly tin.

Reserve and reserve base data for columbium are shown in table 1 and are based on a judgmental appraisal of current information. Reserve base is defined as the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. The reserve base may encompass those parts of the resources that have a reasonable potential for becoming economically available within planning horizons beyond those that assume proven technology and current economics. Reserves are defined as that part of the reserve base that could be economically extracted or produced at the time of determination.

Technology

Exploration.—Columbium deposits of economic interest are most likely to be found in alkalic rock complexes and associated carbonatites. Aerial photography and geological mapping can be used to reveal alkalic complexes, which frequently occur with circular geometry and concentric rock arrangement. Test pitting and panning can be used to explore placer deposits for columbium by virtue of the high specific gravity of columbium minerals. The columbium content of samples can be determined rapidly by means of truck-mounted spectrographic equipment and X-ray fluorescence spectroscopy.

Mining.—Pyrochlore has been mined mainly by mechanized open pit, under ground stoping methods, or a combination of both. Currently, all mining for pyrochlore in Brazil is open pit, whereas in Canada, underground mining is being done via a large-diameter blasthole method. Ore, with host rock, is usually dislodged from a working face with explosives. Beneficiation of the ore, after it has been finely ground, is achieved primarily by various flotation procedures combined with magnetic separation to remove iron minerals. A chloridizing and leaching process can also be employed to lower barium, lead, phosphorus, and sulfur contents. Methods used to mine columbite have ranged from simple hand operations in small pegmatite mines to hydraulic monitors and dredges at placer deposits.

Beneficiation.—Pyrochlore concentrates are used solely in the manufacture of ferrocolumbium for steelmaking. Aluminothermy, the process being used for making steelmaking-grade ferrocolumbium from pyrochlore concentrates, is carried out in batches. As practiced by Cia. Brasileira de Metalurgia e Mineração (CBMM) in Brazil, a mixed charge of concentrate, iron oxide (as hematite), fine aluminum powder, and slagging agents is reacted to produce ferrocolumbium in a refractory-lined, cylindrical steel shell open at the top and resting upon a lined silica sand bed. Also, processes have been developed for production of columbium oxide through treatment of ferrocolumbium produced from pyrochlore concentrates. This technology is being used to produce commercial quantities of columbium oxide suitable for the manufacture of highpurity ferrocolumbium, nickel columbium, and columbium metal.

TABLE 1 WORLD COLUMBIUM RESERVES AND RESERVE BASE, 1990

(Thousand pounds columbium content)

Country	Reserves	Reserve base ¹
Brazil	7,300,000	8,000,000
Canada	300,000	900,000
Nigeria	140,000	200,000
United States		(2)
Zaire	70,000	200,000
Other market economy countries	14,000	19,000
World total (rounded)	7,800,000	9,300,000

The reserve base includes demonstrated resources that are currently economic (reserves), marginally economic (marginal reserves), and some of those that are currently subeconomic (subeconomic resources). 2 Negligible.

In the extraction of columbium from other mineral concentrates and tin slags, modern technology makes use mainly of digestion with hydrofluoric acid followed by liquid-liquid extraction with methyl isobutyl ketone (MIBK). This procedure efficiently recovers both columbium and tantalum in the form of separate streams that then can be further processed individually into oxides and metal. Columbium oxide is precipitated from the columbium stream by ammonia and then purified and calcined.

Columbium oxide is aluminothermically reduced batchwise to produce highpurity ferrocolumbium, nickel columbium, and columbium metal. Aluminothermically produced columbium metal is commonly purified to remove aluminum and other contaminants by remelting it in an electron-beam furnace. Several remelts may be required before the desired level of purity is reached and a ductile ingot has been produced. The basic method for production of columbium carbide is reduction of columbium oxide by carbon at high temperature under vacuum or a protective atmosphere.

Recycling.—Columbium used in steel-making and in superalloy manufacture is essentially a dissipative use, and little is reclaimed. However, when strict scrap segregation practices are followed, small quantities of columbium-bearing superalloy scrap are recycled. Aside from sales to alloy melters, columbium metal scrap has not been recycled to any extent other than in-house as home scrap by processors.

Byproducts and Coproducts

In Africa, Australia, Brazil, Malaysia, and Thailand, columbium, as well as tantalum, is produced as a byproduct and/or coproduct of tin mining. Columbium and tantalum can also be recovered economically from some tin slags, which constitute an important raw material source for high-purity columbium and tantalum. Other elements frequently associated with columbium deposits include rare earths, thorium, titanium, and uranium; some of these have been recovered along with columbium in the past and may be coextracted in the future.

Substitutes

For established applications of both columbium-bearing steels and superalloys, substitution of some alternative steel or alloy requiring less columbium ordinarily lowers performance and/or cost effectiveness. In some high-strength lowalloy (HSLA) steels, use of columbium as a microalloying element competes with use of such elements as molybdenum, titanium, and vanadium. In other HSLA steels, it may be desirable to use one or more of these elements along with columbium in complementary fashion. Tantalum is a costly potential substitute for columbium in superalloys. Titanium can be used instead of columbium in stainless steel to improve corrosion resistance.

Economic Factors

Prices.—The price of columbium contained in concentrates, in terms of actual prices and in constant 1982 dollars, has been relatively stable for the period shown in table 2. Actual prices reported are based on historical price quotations or best available information from producers. Additionally, prices for products based on columbium concentrates have been stable over the past decade. At yearend 1990, the published price for columbium oxide was \$7.64 per pound of oxide, the published price for regular-grade ferrocolumbium was \$6.58 per pound of contained columbium, the published price for high-purity ferrocolumbium was \$17.50 per pound of contained columbium, the published price for nickel columbium was \$19.50 per pound of contained columbium, and the published price for columbium metal was at a range of \$30 to \$50.

Depletion Provisions.—U.S. columbium-producing companies are granted a depletion allowance of 22% for domestic production of columbium minerals and 14% on foreign production.

BACKGROUND— TANTALUM

Tantalum is a refractory metal that is ductile, easily fabricated, has a high melting point (2,996° C), is highly resistant to corrosion by acids, and is a good conductor of heat and electricity. It combines readily with other refractory metals such as hafnium and tungsten to form alloys having high-temperature strength and stability. Tantalum forms highly stable anodic films and exhibits a rectifying, or electronic valve, action in an electrolyte. Tantalum is twice as dense as steel with a specific gravity of 16.6.

Definitions, Grades, and Specifications

Metallic forms of tantalum are produced chiefly in unalloyed form or alloyed with up to about 10% tungsten.

Unalloyed metal and alloys with tungsten are available as ingot, plate, sheet, strip, bar, rod, wire, and tubing in accordance with ASTM Specifications B364, B365, and B521. Allowable impurity levels do not exceed 0.3% in most cases; the main impurities are columbium and oxygen, plus tungsten in the case of unalloyed tantalum. Purity of tantalum metal powder is usually about 99.9%. Depending on powder usage, impurities that must be controlled consist mainly of calcium, carbon, columbium, iron, nickel, nitrogen, oxygen, silicon, and sodium. Commercial tantalum carbide usually contains about 93% tantalum and about 6.3% carbon.

Products for Trade and Industry

The major end use for tantalum, as tantalum metal powder, is in the production of electronic components, mainly tantalum capacitors. Applications for tantalum capacitors include computers, communication systems, and instruments and controls for aircraft, missiles, ships, and weapon systems. The tantalum capacitor exhibits reliable performance and combines compactness and high efficiency with good shelflife. Because of its high melting point, good strength at elevated temperatures, and good corrosion resistance, tantalum is combined with cobalt, iron, and nickel to produce superalloys that are employed in aerospace structures and jet engine components. Tantalum carbide, used mostly in mixtures with carbides of such metals as columbium, titanium, and tungsten, is used in cemented-carbide cutting tools, wear-resistant parts, farm tools, and turning and boring tools. Because of its excellent corrosion resistant properties, tantalum mill and fabricated products are used in the chemical industry in applications such as heat exchangers, evaporators, condensers, pumps, and liners for reactors and tanks.

Geology-Resources

The principal source of tantalum is an isomorphous series of minerals containing columbium, iron, manganese, and tantalum oxides. Tantalum and columbium have strong geochemical affinity and are found together in most rocks and minerals in which they occur. Tantalitecolumbite occurs mainly as accessory minerals disseminated in granitic rocks or in pegmatites associated with granites. The microlite-pyrochlore mineral series is also a source of tantalum. These minerals consist essentially of complex oxides of calcium, columbium, sodium, and tantalum in combination with hydroxyl ions and fluorides. Microlite occurs mainly in the albitized zones of granite pegmatites, often associated with tantalite or columbite. Struverite is a low-grade source of tantalum recoverable from tin mining wastes in Southeast Asia. Struverite is a variation of the titanium mineral rutile. Tantalum is also obtained through byproduct recovery from tantalum-bearing tin slags, principally from smelters in Brazil and Southeast Asia.

Reserve and reserve base data for tantalum are shown in table 3 and are based on a judgmental appraisal of current information. Reserve base is defined as the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. The reserve base may encompass those parts of the resources that have a reasonable potential for becoming economically available within planning horizons beyond those that assume proven technology and current economics. Reserves are defined as that part of the reserve base that could be economically extracted or produced at the time of determination.

Technology

Exploration.—Exploration for tantalum is generally pursued on the basis of its known frequent association with tin and certain other elements in pegmatite environments, some features of which can be distinguished by aerial photography. Application of X-ray fluorescence analysis techniques has been helpful in measuring tantalum at the low concentrations at which it occurs. The high specific gravity of tantalum minerals makes it possible to reveal their presence in placer deposits by test pitting and panning.

Mining.—Most tantalum-related mining developments in the past generally were small, relatively high-cost intermittent operations that depended on the recovery of byproduct or coproduct minerals for economic viability. Future mine development will shift more to primary tantalum sources, notably operations in Australia.

Both alluvial and residual tantalum and tantalum-containing tin deposits are normally mined by hand, by hydraulic monitors, by dredges, or by mechanized open pit mining. The mining of pegmatite deposits, which may be either open pit or underground, is carried out by blasting, transporting, and crushing the rock to free the tantalum and associated coproduct minerals. The materials are then concentrated by wet gravity methods (sluices, jigs, spirals, and tables) and finally separated from associated minerals by gravity and electrostatic and electromagnetic processes.

TABLE 3 WORLD TANTALUM RESERVES AND RESERVE BASE, 1990

World total	48,000	76,000

¹The reserve base includes demonstrated resources that are currently economic (reserves), marginally economic (marginal reserves), and some of those that are currently subeconomic (subeconomic resources) 2 Negligible.

Tantalum is recovered from slags produced at tin smelters throughout the world. Tantalum content varies in tin slag depending on ore and smelting practice.

Beneficiation.—Tantalum mineral concentrates and tin slags are the predominant feed materials for preparation of tantalum metal and compounds. Both raw materials usually contain recoverable amounts of columbium as well. Depending on circumstances, tin slags may be used directly for extraction of tantalum or they may be first upgraded. Upgrading is typically performed by means of an electric furnace process that yields a synthetic concentrate.

In the extraction of tantalum from these source materials, technology makes use mainly of digestion with hydrofluoric acid followed by liquid-liquid extraction with MIBK. This procedure efficiently recovers both tantalum and columbium in the form of separate streams that then can be further processed individually into salts, oxides, and metal. The two streams are produced by a series of countercurrent extractions that also remove impurities. The tantalum product stream is a fluotantalic acid solution from which either potassium fluotantalate (K-salt), by addition of potassium chloride or fluoride, or tantalum pentoxide, by addition of ammonia, can be precipitated. Reducing K-salt by sodium is the standard commercial method for making tantalum metal. The product of sodium reduction is a powder that is consolidated by a pressing, vacuum sintering, and melting sequence.

Tantalum carbide can be manufactured by several methods, the most common being solid-state reaction between tantalum oxide and carbon. Tantalum carbide can also be made by reacting metallic tantalum directly with carbon.

Recycling.—Recycling of tantalum largely takes place within the processing and product-producing industry and is mostly runaround or home scrap that is consumed internally. In addition, quantities of tantalum are recycled indirectly in the form of used tantalum-bearing cutting tools and high-temperature alloy melting scrap.

Byproducts and Coproducts

Economic exploitation of tantalum minerals often is dependent on the price of associated recoverable byproduct or coproduct minerals, principally tin and

columbium. Tantalite-columbite minerals occur in deposits associated with beryllium, lithium, rare-earth, tin, titanium, tungsten, uranium, and zirconium minerals. Minerals associated with tantalum in pegmatite deposits include beryl, feldspar, lepidolite, mica, pollucite, and spodumene. Tantalum and columbium can also be recovered economically from some tin slags, which constitute an important raw material source for tantalum and high-purity columbium. Tantalum is usually extracted in conjunction with columbium in much the same type of equipment.

Substitutes

Substitution for tantalum is usually made at a performance or economic penalty for most uses. Also, substitution requires both investment and experimentation and does not necessarily occur quickly. Aluminum and ceramics compete strongly with tantalum for use in electronic capacitors. In cemented carbides, columbium carbide and columbiumhafnium carbide can take the place of tantalum carbide in some cutting tools. Replacements for tantalum in corrosionresistant equipment are columbium, glass, platinum, titanium, and zirconium. Columbium, hafnium, molybdenum, tungsten, and some platinum-group metals can be substituted for tantalum in high-temperature applications.

Economic Factors

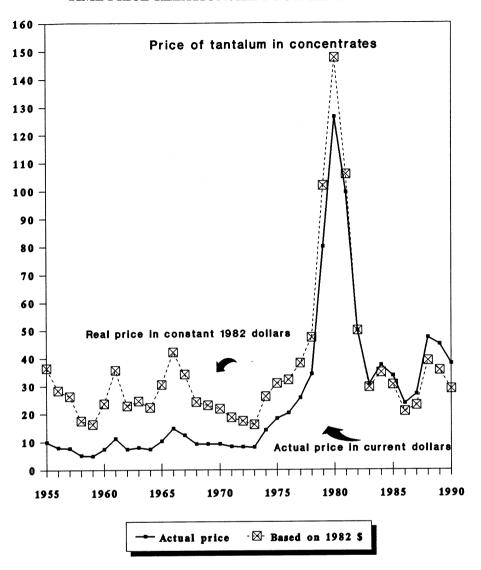

Prices.—Time-price relationships for tantalum contained in concentrates in terms of actual prices and in constant 1982 dollars are shown in table 4. Actual prices reported are based on historical price quotations or best available information from producers. The prices show large swings between the high and low in response to market conditions, with recent year pronounced maximums occurring in 1980 and 1988. A 7-year trend of declining price, 1967–73, was followed by a trend of rapid price increase that was sustained through midyear 1980. The record price levels during this period were attributed in part to a state of panic buying influenced by anticipated greater tantalum demand, amidst concerns at the time of a shrinking world tantalum supply. The high prices brought about substitution for tantalum and more widespread search for and development of new tantalum sources. However, prices | 160% basis, combined tantalum and columbium pentoxides.

began declining by yearend 1980 and, by midvear 1986, were the lowest since first quarter 1977, hastened by a weak

tantalum demand and an increase in tantalum material stockpiles. Subsequently, prices rebounded through yearend 1988 and were at the highest level since the third quarter of 1981, responding to increased demand for feed materials along with the drawdown of stockpiles.

Depletion Provisions.—U.S. tantalumproducing companies are granted a depletion allowance of 22% for domestic production of tantalum minerals and 14% on foreign production.

ANNUAL REVIEW— COLUMBIUM AND TANTALUM

Legislation and Government Programs

Under the offset concept for the NDS, less than 25% of the goal for columbium concentrates and 37% of the goal for tantalum minerals were met (table 7).

In June, the goal for the columbium

group in the NDS was raised to 12,520,000 pounds of contained columbium from 4,850,000 pounds of contained columbium. The action to nearly triple the columbium stockpile goal was taken under the authority vested in the Assistant Secretary of Defense and in accordance with the National Defense Authorization Act for Fiscal Years 1990 and 1991. This followed the U.S. Department of Defense findings concerning military requirements for strategic and critical materials.

Also in June, the DLA awarded contracts to purchase 200,000 pounds of tantalum pentoxide (Ta_2O_5) contained in tantalum natural minerals and concentrates for the NDS. The minerals and concentrates were to be grade 1 as defined in National Stockpile Purchase Specification P-113a, effective August 3, 1981, requiring a minimum Ta_2O_5 content of 25% and a minimum combined Ta_2O_5 plus columbium pentoxide (Cb_2O_5) content of 55%.

The awards were made to O'Dell Construction Co., Prattville, AL, a domestic producer, and Sogem-Afrimet, New York, NY, for two allotments of 100,000 pounds each for placement in the NDS storage depot at New Haven, IN, and Somerville, NJ, respectively. The tantalum materials are to be delivered to the NDS within 2 years of contract award. The material to be provided by O'Dell Construction reportedly will be produced at a mine in Rockford, AL.

Offers for the first allotment ranged from \$37.00 to \$45.00 per pound of contained tantalum pentoxide. O'Dell Construction Co. was the low bidder. Offers for the second allotment ranged from \$36.62 to \$47.00 per pound of contained tantalum pentoxide. Sogem-Afrimet was the low bidder.

At about the time the bids were opened, the Metals Week and Metal Bulletin published price for tantalite ore ranged from \$27.00 to \$28.50 and \$27 to \$33 per pound of tantalum pentoxide, respectively.

The U.S. Department of Defense's planned targets of opportunity for fiscal year 1991 included the purchase of an additional 200,000 pounds of tantalum pentoxide contained in tantalum natural minerals and concentrates for the NDS.

Strategic Considerations

The high degree of import reliance for columbium and tantalum continues to be the principal strategic problem faced by the United States. In the case of both columbium and tantalum, there has been no significant mining since the 1950's. Domestic columbium and tantalum resources are of low grade, some mineralogically complex, and most are not currently commercially recoverable. To ensure a supply of columbium and tantalum during an emergency, goals for both materials have been established for the NDS. However, inventories for both materials are substantially under set

A small unreported quantity was produced.

goals. Consequently, a degree of vulnerability still remains.

Issues

At the start of the 1980's, there were four major processors of columbium- and tantalum-bearing source materials (feedstocks). One of the operations was shut down in 1985, and another shut down its processing operation at yearend 1989. Of the remaining two companies, one is dedicated solely to the processing of columbium materials, whereas the other company processes both columbium and tantalum materials. The NDS goals and inventory for both columbium and tantalum are mostly for source materials. Thus, it is assumed that the United States would have on hand in an emergency adequate processing capacity for conversion of the material to an upgraded form and quality required by the critical end uses. However, the United States has become more reliant on the processing capability of foreign sources and the availability of intermediate products from those sources.

Production

In 1990, there were only two processors

of columbium- and tantalum-bearing source materials that were integrated from raw material processing to columbium and tantalum end products: Cabot Corp. for columbium and tantalum processing and Shieldalloy Metallurgical Corp., dedicated solely to columbium processing. NRC Inc. was a major producer of tantalum products, and Reading Alloys Inc. and Teledyne Wah Chang Albany were major producers of high-purity columbium products. Kennametal Inc. was the major producer of columbium and tantalum carbides.

Additionally, Thai Tantalum Co. Ltd. (TTA), formally Thailand Tantalum Industry Corp. Ltd. (TTIC) of Bangkok, reportedly began production of a range of precursor powders at its tantalum facility in Muskogee, OK, in late 1990. The powders produced at Muskogee were to be shipped to TTA's other tantalum facility in Gurnee, IL, where the powders will be upgraded to capacitor-grade quality. Commercial-scale production of the capacitor powders at Gurnee was to commence in early 1991.

Buttes Gas & Oil Co. reportedly entered into an agreement with Teck Corp., Vancouver, British Columbia, to develop Buttes' Powderhorn titanium property in

Gunnison, CO. Teck would earn a 60% interest in Powderhorn by taking the property to commercial production. The property reportedly contains significant quantities of columbium in the form of the mineral perovskite.

Consumption and Uses

Overall reported consumption of columbium as ferrocolumbium and nickel columbium rose by 6% compared with that of 1989. Consumption of columbium by the steelmaking industry was up slightly in line with a small increase in raw steel production, with virtually no change in the percentage of columbium usage per ton of steel produced. Consumption in all reported steel end-use categories was down with the exception of carbon steels, which increased by 15%. Demand for columbium in superalloys was up by 27% to the highest level since 1986. That portion used in the form of nickel columbium increased to more than 470,000 pounds to the highest level since 1985. U.S. columbium consumption, by end use, is shown in figure 2.

Overall consumption of tantalum was up from that of 1989, aided by increased demand from the electronics sector in the form of tantalum capacitor-grade powder. Tantalum shipments data were no longer available from the Tantalum Producers Association (TPA). The TPA was dissolved in December 1990. Factory sales of tantalum capacitors rose by 10%, as reported by the Electronic Industries Association. Additionally, the trend in recent years toward miniaturization of tantalum capacitors in the electronics industry continued. U.S. tantalum consumption, by end use, is shown in figure 3.

Markets and Prices

A published price for pyrochlore concentrates was not available. The published price for pyrochlore produced in Canada was suspended in early 1989, and a price for Brazilian pyrochlore has not been available since 1981 when exports were stopped. Unchanged since midyear 1989, the Metals Week published price for regular-grade ferrocolumbium was \$6.00 to \$6.58 per pound of contained columbium, f.o.b. shipping port.

The Metals Week published price for high-purity ferrocolumbium containing 62% to 68% columbium remained at \$17.50 per pound of contained columbium, f.o.b. shipping point, and the

metal group. 3 All surplus tantalum carbide powder and tantalum metal were used to offset the tantalum minerals shortfall. Total offset was 271,000 pounds. 4 100 pounds.

published spot price for columbite ore continued at a range of \$3.00 to \$3.50 per pound of contained Cb₂O₅ and Ta₂O₅, c.i.f. U.S. ports. Also unchanged for the year, the published price for nickel columbium was \$19.50 per pound of contained columbium, the published price for columbium oxide was \$7.64 per pound of oxide, and the published price for columbium metal was at a range of \$30 to \$50.

The Metals Week published spot price for tantalite ore, on the basis of 60% combined Cb₂O₅ and Ta₂O₅, c.i.f. U.S. ports, began the year at \$26 to \$28 per pound, rose to \$34 to \$36 by midyear, and then widened in the fourth quarter to finish the year at \$31 to \$35. The Metal Bulletin published price for tantalite rose from \$29 to \$35 per pound of contained Ta₂O₅ to \$34 to \$37 by yearend. The Metal Bulletin published price for tantalite produced by Greenbushes Ltd. of Australia, on the basis of 40% contained Ta₂O₅, remained unchanged at \$50 per pound. A published price for tantalite from the Canadian producer, Tantalum Mining Corp. of Canada Ltd. (TANCO), was not available. Tantalum capacitor-grade powder reportedly sold for about \$120 per pound, and tantalum mill products reportedly sold for about \$160 per pound.

Foreign Trade

Net trade for columbium and tantalum remained at a deficit, but closed to about one-half the 1989 deficit. Overall trade value for exports was relatively unchanged, with total volume up by 25%,

owing to a significant increase in the volume of ferrocolumbium exports to Canada. Exports of columbium and tantalum ores and concentrates decreased substantially to 108,000 pounds valued at \$365,000. Germany was the principal recipient, with more than 50% of total shipments. For imports, trade volume and value were down appreciably for most items, the major exception being a significant increase in columbium oxide imports from Brazil.

Imports for consumption of columbium mineral concentrates were virtually unchanged from those of 1989. Canada remained the leading supplier, providing almost all of both total quantity and total value. Imports at an average grade of approximately 61% Cb₂O₅ and less than 1% Ta₂O₅ were estimated to contain 2.12 million pounds of columbium and a small quantity of tantalum.

Imports for consumption of tantalum mineral concentrates declined substantially, with the average unit value for overall imports decreasing by more than 15%. Imports from Belgium-Luxembourg and the Federal Republic of Germany, both nonproducing countries, together accounted for about 50% of total quantity and value. Imports at an average grade of approximately 35% Ta₂O₅ and 23% Cb₂O₅ were estimated to contain 640,000 pounds of tantalum and 360,000 pounds of columbium.

Imports for consumption of synthetic tantalum-columbium concentrates declined significantly: 113,000 pounds valued at \$1.5 million compared with

170,000 pounds valued at \$2.2 million in 1989. These figures are not included in the salient statistics data.

Brazil continued as the major source for U.S. columbium imports, and the Federal Republic of Germany remained the major source for U.S. tantalum imports (see figures 4 and 5).

World Review

Industry Structure.—Brazil and Canada remained as the major producers of columbium raw materials feedstock, while tantalum raw materials continued to be produced mainly in Australia, Brazil, Canada, and in Thailand in the form of high-grade tantalum-bearing tin slags. Synthetic concentrates, produced from low-grade tin slags, from the Federal Republic of Germany were an additional source of columbium and tantalum raw material supply. Principal world raw material and product producers are shown in tables 15 and 16, respectively.

Capacity.—The data in table 17 are rated capacity for mines and mills as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgement of the author, can be brought into production

within a short period of time with minimum capital expenditure. Mine capacity for columbium and tantalum is based on published reports, maximum production statistics, and estimates where capacity information is either incomplete or unavailable.

Australia.—For its fiscal year ending June 30, 1990, Gwalia Consolidated Ltd. reported that, as a result of mergers, all company operations at Greenbushes have been consolidated and will be conducted as a single business unit known as the "Greenbushes Mine." Ore treated at Greenbushes was down by about 30% to 1.7 million tons, with tantalum oxide production in tantalum concentrates decreasing to about 203,000 pounds. The tailings retreatment plant produced 99,400 pounds of Ta₂O₅ contained in tantalum concentrates, and tantalum oxide contained in tantalum glass (slag) production rose to 87,000 pounds. The mine's chemical plant produced 12,300 pounds of Ta₂O₅ and 4,700 pounds of Cb₂O₅, both down from the production levels of 1989. Feasibility and marketing studies were being conducted to make a decision, prior to March 1991, with respect to future mine operation and the marketing of products produced.1

Brazil.—Production of ferrocolumbium was 17,747 tons, 14,440 tons produced by Cia. Brasileira de Metalurgia e Mineração (CBMM) and 3,307 tons produced by Mineração Catalão de Goiãs S.A. (CATALAO). CBMM also produced 1,709 tons of columbium oxide, up considerably from the 418 tons produced in 1989. CBMM reportedly started construction of a new ferrocolumbium plant in Araxa. With a planned annual ferrocolumbium capacity of about 25,000 tons, the plant will cost about \$8 million to construct. The new facility is said to be more cost effective, will allow for production of ferrocolumbium to a tighter specification, and will eliminate atmospheric pollution.

Canada.—As reported by Teck Corp. (operator) and Cambior Inc. (product marketing and sales), production of Cb₂O₅ at the Niobec Mine at St. Honoré, Quebec, a 50-50 joint venture, was down from the record level in 1989 to 7.5 million pounds. Ore milled was virtually unchanged at 876,000 tons, as the mill operated on the average of 2,399 tons of ore per day. Average recovery was

³Rounded.

Sources: Bureau of the Census and U.S. Bureau of Mines.

down to 60.4% with Cb₂O₅ grade of concentrate at 71%. Lower recovery was attributed to treatment of more refractory ore. Yearend ore reserves decreased to 11 million tons assaying 0.65% Cb₂O₅, reportedly sufficient for 14 years of production. Expansion of the mine's tailings storage capacity is scheduled for late 1991. When construction is completed on the tailings pond, the mine will have an additional 12 years of storage capacity.

Germany, Federal Republic of.— Hermann C. Starck Berlin KG announced that it had increased its holding in V Tech of Japan, a tantalum capacitor powder producer, to 92%, with the balance being held by V Tech management. Starck had acquired a 54% interest in V Tech from Fansteel Inc. (USA) in December 1989, when Fansteel sold most of its domestic and foreign tantalum business.

Japan.—Production of ferrocolumbium was 1,085 tons, up considerably from the 812 tons produced in 1989. Columbium ore imported for ferrocolumbium production increased by 70% to 1,291 tons, with Canada providing more than 80% of the total. Ferrocolumbium imports fell to 3,876 tons from the 3,957 tons reported in 1989. The bulk of

ferrocolumbium imports continued to come from Brazil.

Thailand.—Thai Tantalum Co. Ltd. (TTA), formerly Thailand Tantalum Industry Corp. Ltd. (TTIC) of Bangkok, reportedly commenced civil work for construction of a tantalum-processing plant at the Map Ta Phut Industrial Estate in Rayong Province east of Bangkok. The new facility will replace TTA's tantalum plant that was destroyed by fire in June 1986. The fire followed demonstrations by protestors against the opening of the chemical plant because of environmental concerns over the plant's waste treatment facilities and acid storage areas.

Completion of major civil work is planned by third quarter 1991, with production of columbium oxide and potassium fluotantalate to commence first quarter 1992. Availability of high-quality tantalum capacitor-grade powders is anticipated by first quarter 1992. The cost of the facility has been estimated at \$30 million and will have a combined columbium and tantalum product annual capacity of about 600 tons. The plant will use domestically produced columbium and tantalum feedstock materials, and product production will be exclusively for export.

Laporte Ltd. of Thailand reportedly began construction of a hydrofluoric acid plant at Map Ta Phut. TTA indicates that the plant will supply the tantalum plant with all of its hydrofluoric acid requirements.

OUTLOOK

Columbium

Columbium is used principally as an additive in steelmaking, which has accounted for about 80% of the reported consumption in the United States in recent years. No significant change to this trend is expected in the near term for there are few other growth markets and/or uses for columbium. Thus, future columbium demand growth will continue to be directly related to the worldwide performance of the steel industry. The outlook for steel is discussed in the annual report for Iron and Steel. A boost for columbium consumption in steelmaking has been the price volatility in recent years for competing ferroallovs of titanium and vanadium. Some steel companies reportedly have initiated projects for the substitution of columbium for titanium and vanadium in steelmaking. Domestic columbium consumption in the production of superalloys is currently about 15%. Future growth for this end use will be affected mainly by the demand for columbium-containing superalloys from the aircraft industry, which continues to have an up and down cyclical history. The major components of U.S. supplydemand relationships for columbium in 1980-90 are given in table 19.

Tantalum

During the 1980's, more than 60% of the tantalum consumed in the United

Oceania: Australia	200	400		
World total (may be rounded)	47,000	2,400		

¹Includes capacity at operating facilities as well as facilities on standby basis.

States was used to produce electronic components, mainly tantalum capacitors, with major markets in recent years being computer and communication systems. However, overall tantalum demand growth in this sector has been slowed because of the industry's continued emphasis on higher capacitance powders and the miniaturization of electronic components resulting in less tantalum used per unit. A similar situation exists for tantalum in cemented carbide use. Tantalum demand in this market has been affected by the growing use of mixed carbides, coated cutting tools, improved tool life, and the down-sizing of components. Additionally, the demand and price for tantalum has had a cyclical and somewhat volatile history. Thus, the future growth for tantalum will continue to depend not only on the fortunes of the electronic and carbide industries but also on tantalum's price stability. The major components of U.S. supply-demand relationships for tantalum in 1980-90 are given in table 20.

²A wholly owned subsidiary of Metallurg Inc., New York.

³A joint venture between Showa Denko and Cabot Corp.

⁴A subsidiary of Hermann C. Starck Berlin KG.

⁵Jointly owned by Bayer U.S.A. Inc. and Hermann C. Starck Berlin KG.

²Includes estimated byproduct recovery as tin slag.

¹Excludes columbium and tantalum bearing tin slags. Production of tantalum contained in tin slags was, in thousand pounds, 1986—623; 1987—543; 1988—1,145; 1989—799; and 1990—756 according to

data from the Tantalum-Niobium International Study Center. Table includes data available through June 21, 1991.

In addition to the countries listed, China, the U.S.S.R., and Zambia also produce, or are believed to produce, columbium and tantalum mineral concentrates, but available information is inadequate to make

The addition of the content levels.

3 Data on gross weight generally have been presented as reported in official sources of the respective countries, divided into concentrates of columbite, tantalite, and pyrochlore where information is available to do so, and reported in groups such as columbite and tantalite where it is not.

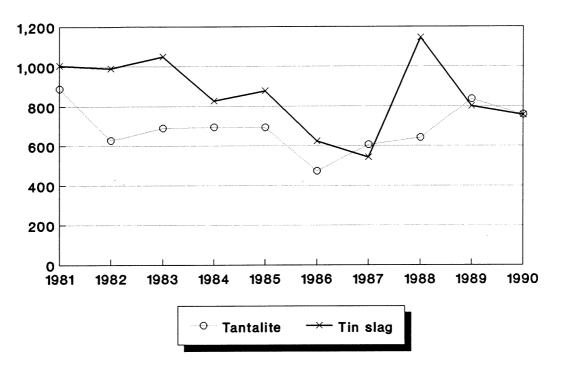

4Unless otherwise specified, data presented for metal content are U.S. Bureau of Mines estimates based on, in most part, reported gross weight and/or pentoxide content. Metal content estimates are revised

as necessary to reflect changes in gross weight and/or pentoxide data.

Reported in and/or by official country sources.

⁶Less than 1/2 unit.

COPPER

By Janice L. W. Jolly and Daniel L. Edelstein

Mrs. Jolly is a physical scientist (geologist) with more than 30 years in the mining industry, including 17 years with the U.S. Bureau of Mines. She worked as a research geologist on mineral deposits with the U.S. Geological Survey and Roan Selection Trust, Ltd., of Zambia and as a consultant on mineral affairs with the U.S. House of Representatives Armed Services Committee and the World Bank. Mrs. Jolly is currently the copper specialist for the U.S. Bureau of Mines, a position she has held since 1983.

Mr. Edelstein is a physical scientist (geologist) with more than 16 years of combined experience working for the U.S. Bureau of Mines in mineral processing research, process evaluation, and mineral commodities. He has been a copper commodity specialist for 8 years as well as the specialist for the copper byproduct metals, selenium and tellurium.

Domestic survey data were prepared by Lisa Conley, Lisa Christian, and Wannette Davis, mineral data assistants, and Jean Moore, data controller. The world production tables were prepared by Audrey D. Wilkes, Harold Willis, and Virginia Woodson, international data coordinators, from data provided by the foreign mineral specialists.

orld copper mine production of almost 9 million tons and refined consumption of 11 million tons were at record levels. World supply and demand was more or less in balance throughout the year. Copper demand by U.S. semifabicators was higher during the first half of the year, but declined in the last 3 months of the year as a result of the recession in domestic markets. Increased world demand continued to be driven by increased consumption in the Asian countries. Increased supplies from new capacity in Chile, Indonesia, Portugal, and the United States were offset by disruptions at other sources and the continued closure of the Bougainville Mine, Papua New Guinea. Serious mine accidents in both Chile and Zaire and sporadic labor disputes also restrained the flow of copper. At yearend, visible refined inventories increased slightly to an estimated 684,000 tons, slightly more than 4 weeks of market economy countries (MEC) consumption. The U.S. producers' average annual price, at \$1.21 per pound, was lower than that of 1989, reflecting more pessimism about the economy and the future copper market than actual surplus supply of the time. U.S. exports of scrap, concentrates, and refined copper continued to be high; most were destined for Far Eastern markets in Japan, Taiwan, and the Republic of Korea.

In the United States, ownership changes and modernization continued, but were more prevalent on the copper consuming and secondary processing side of the industry. Permits were received to begin building a new mine in Wisconsin, and the first underground mine to open in Oregon

since World War II started production during the year. Several older mines in Arizona and New Mexico were being prepared for reopening; the Superior Mine, AZ, reopened late in the year.

DOMESTIC DATA COVERAGE

Domestic production data for copper were developed by the U.S. Bureau of Mines from seven separate surveys of U.S. operations. Typical of these surveys is the mine production survey. Of 119 operations to which a survey request was sent in 1990, 91% responded and 71 reported copper production, representing an estimated 99.7% of the mine production shown in tables 1, 12, 15, and 16. Production for the remainder was estimated using other surveys.

BACKGROUND

Definitions, Grades, and Specifications

Copper is traded in its many forms that relate to differing stages of processing. For example, at the mine, copper may be sold as ore, concentrates, or precipitates. Copper ore may contain as little as 0.40% copper or more than 10% copper, depending upon its source. Copper concentrates are produced by milling and concentrating copper ore and may contain between 18% and 40% copper. Copper precipitates, or cement copper, are recovered from leach solutions by chemical precipitation with scrap iron and may contain as much as 90% copper.

Smelter products include copper matte, blister, slag, and anode. Slag is the waste

formed in smelting through the combination of a flux, such as limestone and silica, with the gangue or waste portion of the ore and, though it may contain small amounts of copper, is high in silicon and iron. Copper matte contains between 15% and 65% copper, together with much of the sulfur and other nonferrous and precious metals. The newer flash smelting technologies result in a much lower sulfur content in the matte than was possible in the reverberatory furnaces. Copper matte is transferred to a converting furnace, where the sulfur and iron are oxidized and removed as sulfur dioxide gas and slag, respectively; the enriched copper melt (97% to 98.5% copper) is poured as blister copper. The blister is then fire-refined by oxidizing the impurities in a reverberatory furnace, followed by removal of the excess oxygen by a process called poling. Poling may be done by insertion of green logs or a reducing gas into the melt. The blister is then cast into anode shape and further treated in an electrolyte bath to form refined copper cathode through electrolysis, a process in which the copper ions of the anode are transferred by electrical current to the negatively charged cathode. Impurities in the copper anode, such as gold, selenium, and silver, are collected at the bottom of the electrolytic tank as a residue and are recovered in a later process. Cathode copper may also be obtained from an electrowinning process. In this process, cathode copper is plated directly from copper-bearing solutions obtained from leaching copper-bearing ore, matte, scrap, or other material and enriched by solvent extraction methods. Alternatively, the fire-refined blister, or scrap, may be cast into ingots, bars, billets, or cakes, and

not processed electrolytically in a refining tank before direct use.

Refined copper cathode, which contains greater than 99.3% copper, is the predominant form traded. *Tough-pitch copper* is refined copper cast into shapes. *Oxygen-free copper*, which is preferred for special electrical uses, is refined copper melted and recast in a deoxidizing atmosphere. *Deox*

idized copper is refined copper treated with deoxidizers to reduce cuprous oxide and remove oxygen. Normal refinery shapes cast from cathodes and fire-refined copper are wire bars, billets, slabs, ingots, and bars. Since the late 1970's, the continuous cast wire rod nearly has eliminated the wire bar as an intermediate shape used for making wire rod from refined copper. Wire rod

is used to make wire of all types. Wire bar currently comprises less than 1% of the copper market. Billets typically are large cylindrical shapes often used for extruding tubing, or sometimes wire rod. Slabs are the precursors to flat products such as sheet. Ingots are small shapes that are usually remelted and used for making alloys.

¹Includes copper content of blister and anodes produced from foreign ores and concentrates.

²Includes primary copper produced from foreign ores, matte, etc., to avoid disclosing company proprietary data

³Data do not add to total shown because of independent rounding.

⁴Includes copper content of alloy scrap. Copper content of alloy scrap imported and exported in 1989 and 1990 was estimated from gross weight.

⁵High-grade prior to 1988.

There are more than 370 copper and copper alloys divided into broad categories of wrought and cast metals. A Unified Numbering System (UNS) for Metals and Materials was developed by the American Society for Testing and Materials (ASTM) and the Society of Automotive Engineers. This system designates each alloy by five digits preceded by the letter C. The UNS system is administered by the Copper Development Association (CDA) and is widely used by ingotmakers, brass mills, and foundries in the United States. The major classes are: coppers, which contain greater than 99.3% copper; high-copper alloys, which contain at least 94% copper: brasses, which contain zinc as the dominant alloying agent; bronzes, which normally contain tin as the dominant alloying agent, but which also may contain such other metals as aluminum, lead, phosphorous, and silicon, but only small amounts of zinc; copper-nickels, which contain nickel as the principal alloy metal; nickel silver, which contains copper, nickel, and zinc as the principal metals; leaded coppers, which are cast alloys containing 20% or more of lead, but no zinc or tin; and special alloys, which are copper alloys with compositions not covered in the above groups. Master alloys and hardeners are copper-base alloys cast with a high alloying element content and are used in producing copper alloys. Hardeners and master alloys not only permit closer composition control than possible by addition of pure metals, but also permit easier introduction of a deoxidizer, such as phosphorus. Beryllium copper master alloy, containing 7% to 10% beryllium, and phosphor copper, containing 10% to 14% phosphorus, are examples. The ASTM specifications for refined copper are designated in part 6, section B5-77 of the ASTM specifications and are under the jurisdiction of ASTM Committee B-5 on copper and copper alloys.

Geology

According to their mode of origin, copper deposits may be grouped in the following broad genetic classes: (1) porphyry copper deposits and their associated skarn, hydrothermal veins, and replacement breccia deposits; (2) deposits associated with ultramafic, mafic, and alkaline ultrabasic and carbonatite rocks; (3) volcanogenic and metavolcanogenic deposits; (4) sedimentary and metasedimentary deposits; and, (5) veins and replacement bodies associated

with metamorphic sequences, not otherwise classified. As a percent of total world capacity, the predominant types mined were the porphyry copper and associated deposits (59%), stratiform sedimentary replacement and metasedimentary deposits (24%), volcanogenic massive sulfide deposits (7%), veins and replacement bodies (7%), and ultrabasic massive sulfide and carbonatite deposits (4%). Though the massive sulfide and vein and replacement deposits were much more numerous than the porphyry and stratiform sedimentary deposits, they tended to be smaller in both capacity and reserves, but generally contain a wider variety of other mineral coproducts. In the United States, porphyry copper deposits comprised about 93% and stratiform sedimentary and metasedimentary deposits about 6% of established mine capacity.

In recent years, plate tectonic theory has been emphasized in defining copper deposits as they relate to the Earth's lithospheric plates, their edges, subduction zones, and spreading axes in space and time. For example, deposits of the porphyry copper type occur mainly in magmatic, volcanic arc, and back-arc regions of plates overlying subduction zones; hence, their predominant location along areas such as the continental edges of North and South America. Copper deposits found in ultramafic sequences are characteristic of oceanic plate settings and ophiolite rock groups. Alkaline ultrabasic rocks and carbonatites intrude stable continental cratons and are presumed to have come from mantle-derived magmas contaminated with crustal rocks. At Palabora, the Republic of South Africa, a carbonatite is host to a copper deposit; as a significant producer of copper, this is a unique occurrence. Sedimentary copper deposits generally occur in rocks typical of passive continental margin and interior environments and intracontinental rift systems. In addition, these deposits may have been redistributed by later diagenetic or metamorphic hydrothermal systems, but retain their stratiform identity. Stratiform applies to a layered mineral deposit of any origin. Stratibound refers to a deposit confined by a single stratigraphic horizon.

Copper occurs in about 250 minerals; however, only a few are commercially important. The most common are chalcopyrite (CuFeS₂), covellite (CuS), chalcocite (Cu₂S), bornite (Cu₅FeS₄), enargite (Cu₃AsS), and tetrahedrite (3Cu₂S•Sb₂S₃). Metals may be leached out of the rock above the water table by

circulating ground water, oxidized, and enriched in the underlying supergene zone. The supergene capping of an ore body often contains the highest concentration of copper as chalcocite or as various copper oxide and silicate minerals. Native copper also occurs in the oxidized or supergene zones.

Technology

Exploration.—Exploration for copper deposits may take place in potential areas within which the anticipated copper deposit is masked by post-ore cover in the form of alluvium and volcanic or sedimentary rock. Following discovery of a potential deposit by geophysical and geochemical means, successively and increasingly intensive drilling campaigns to characterize and quantify the deposit are undertaken before a decision is made to bring a deposit into production. Continued drilling programs to extend identified reserves may continue throughout the production life of the deposit. As a result of ongoing exploration and acquisition programs, a mining company develops an inventory of exploration properties. As properties are explored and evaluated, they move up the development chart. As a potential property is better defined, it may become a candidate for development. Economic conditions determine whether there is a hiatus at this stage or whether the property can move on to development. Taking a prospect through all stages to a producing mine is full of risks and requires complex analyses in geology, metallurgy, engineering, and finance. Environmental considerations are also important in today's decision process.

Good geological concepts will lead an exploration team into a regional environment with the highest probability of economic discovery. In addition, before exploration or development occurs, political and economic factors also will be considered. These factors include the potential for expropriation, availability of land, ease of land acquisition, and local attitude of people toward mining, including environmental concerns. Economic factors include tax policy, transportation facilities, infrastructure power costs, availability of labor force, development incentives, and environmental and reclamation requirements. One analyst reported2 that non-U.S. companies were exploring in the United States for two reasons: (1) the political environment was thought to be more attractive than the rest of the world, and (2) the geologic opportunity was

perceived as high. Other inducements were availability of markets, infrastructure, good work force, and the fact that North Americans were good explorationists. In the United States, recent exploration and development has focused on oxide ores suitable for processing by low-cost, leaching solvent extraction-electrowinning (SX-EW) technology and on the stratiform ores of Montana.

Copper exploration was seriously lacking through most of the 1970's and 1980's, not only owing to a lack of available funds, but also to an increasingly hostile public point of view about the need for mining. For at least two decades, the socioeconomic and political trends of the United States have been effective in preventing rapid exploration and development of new ore deposits. Creeping urbanism, a desire to preserve pristine wilderness areas, and prevention of environmental pollution have all had effect on the success of companies in getting exploration and mining permits in the United States.

No old mining district is positively dead in a geologic sense; the next minor geologic revelation may bring it to life. Further elucidation of ore genesis theory could revolutionize exploration. As a result, collective data pools, core storage facilities, and increased availability of all types of geological and geochemical information through improved data base reliability and accessibility could dramatically increase the numbers of deposits discovered. Improved exploration techniques on the horizon include: improved spatial and spectral imagery resolution for penetration of foliage and surface cover; increased digital geophysical coverage of the United States (magnetically, gravitationally, radiometrically, and spectrally), and improved drilling, sampling, and analytical methods. With geosensing, the ability to predict ore body variations, geological disturbances, and in situ ore-grade variations, can be improved. Estimates have varied as to the frequency of success as the result of exploration programs. Prompted by the rapid economic growth era accompanying the Korean and Vietnam wars, the exploration tempo began to pick up in the 1950's with the maximum exploration rate occurring in 1962. Thereafter, the deposit discovery rate gradually declined to the present. The data indicate that, despite worldwide exploration expenditures for all mineral deposits that exceeded several hundred million dollars each year, there was a significant decrease in the exploration success ratio. For example, \$70 million was spent for each deposit discovery in the early 1960's, compared with \$225 million in the late 1970's.³

World class deposits have been defined as those that consistently returned a profit even in periods of low metal prices, that are of a magnitude to significantly affect a medium-sized company's profit, and that are in the lower one-third of cost per unit of metal sold. Using this definition, it was estimated that in more than 30 years (720 combined corporate years) of effort, only 69 world class deposits were found. A rough ratio might be 1:100; i.e., that for every 1 ore body of any type, 100 raw prospects will have to be tested. Substantial ore bodies that are large enough to return exploration expenditures and provide a profit are much more scarce. The ratio for world class deposits to all deposits has been estimated to be more like 1:1,000.4 Using a revised criteria relating to size and profitability, i.e., a deposit yielding more than \$500 million in revenue, the number of successful, large discoveries could be increased from 70 to 166 between 1950 and 1986.5

Base metal exploration in Canada during the 1951-74 period involved an expenditure of about \$2 billion and resulted in the discovery of 87 economic deposits. About 2,100 base metal deposit occurrences were discovered at an average cost of \$450,000 each. An economic mineral deposit in the Canadian study was defined as one that realizes a total revenue of at least \$20 million and a rate of return of at least 8%. In this context, about 1 economic mineral deposit was found for every 40 mineral occurrences discovered. The average exploration cost required to find and delineate an average economic deposit was \$16 million, compared with an average return of \$77 million for each deposit. The potential value of an economic deposit was therefore estimated to be \$61 million.6

Mining.—Since the turn of the century, the evolution of technology for large-scale mining, milling, and concentrating low-grade ores has resulted in a continued shift away from mining small, high-grade, massive sulfide deposits by labor-intensive underground methods. Today, open pit mining accounts for almost 60% of MEC production and more than 80% of domestic production. Open pit mining requires a relatively shallow deposit with typical stripping, waste-to-ore, ratios between 1:1 and 2:1. A typical surface copper mine uses

rotary blasthole drills and a shovel-truck combination for the loading and hauling operation. Underground mining methods vary with the physical nature of the ore and host rock, but typically have lower waste-to-ore ratios and higher grades and employ some form of large-scale block caving, such as that employed at San Manuel in the United States and El Teniente in Chile. Following extraction, run-of-mine ore is crushed and ground to liberate the copper sulfide minerals and beneficiated or concentrated via froth flotation to produce a concentrate containing about 30% copper suitable for smelting.

Faced with higher energy costs, deeper mines with longer haul distances, high labor rates, and lower ore grades, the domestic industry has strived to maintain and/or lower production costs over the past few decades. Major improvements in energy use and labor management in mining and milling technology have been made in recent years through improved methods of materials transport, grinding, and concentration. Technological improvements include: in-pit crushing and conveying systems to replace truck haulage to the mill; semiautogenous and autogenous grinding circuits; column and cyclone flotation cells; larger scale equipment, including trucks and flotation cells; computer-controlled truck dispatch systems; and improved online sampling and automated regent control in the mill. A microwave system for communications was being used by Phelps Dodge at the Morenci Mine. Microwave was chosen over cable because of the changing mining contour, the distances to be covered, and potential for equipment damage by lightning to the older systems. In mining, further improvements were anticipated in automated mining, nonexplosive rock fragmentation, and process and extraction technologies that result in minimal hazardous conditions. The clean plant concept (hazardous free) should be built into design criteria.

An important factor in domestic mine cost savings has been the development and rapid expansion of SX-EW technology for the treatment of acid soluble oxide or chalcocite ores. In this process, dilute sulfuric acid is percolated through the ore, either in dumps, pads, or in situ. The copper-bearing solution (leachate) is collected and processed by solvent extraction methods to concentrate the copper, which then is recovered by electrowinning, plating copper directly from solution onto a starter cathode. The resultant pure copper cathode

thus bypasses the traditional smelting and refining steps. Recent advances in the organic extractants and in electrowinning have improved the economics of this process. In addition to being able to process oxidized ores, mines have realized tremendous cost savings by being able to leach existing waste and ore dumps as well as lower grade mined ore and by adjusting cutoff grades to the concentrator upward. Growth in SX-EW capacity has been rapid since the mid-1970's. In the United States, SX-EW capacity increased from only 37,000 tons in 1974 to 405,000 tons of copper in 1990. Similarly, SX-EW capacity for the world, which was estimated to be 950,000 tons of copper per year in 1990, was expected to exceed 1.7 million tons by the year 2000.

Only one U.S. company, Cyprus Minerals, was using a roast-leach process to extract copper. In this process, copper sulfide concentrates are roasted, with the sulfur recovered as sulfuric acid, and then placed in a large vat for leaching, followed by SX-EW recovery.

Smelting-Refining.—Most copper concentrates are processed through three-stage smelting to produce anode suitable for electrolytic refining. Concentrate first is processed in the primary smelting reactor to produce a copper sulfide-iron sulfide matte containing up to 60% copper. The matte is passed to a converter where it is oxidized. Sulfur is removed from the matte as sulfur dioxide in the gas streams, and iron is removed in the converter slag. Blister copper from the converter is fire refined in an anode furnace to remove oxygen and other impurities. The anode shapes are interspersed with either copper, stainless steel, or titanium starter sheets in an electrolytic cell or tank, and copper is plated from the anode to the cathode. Valuable impurities, including the precious-metal values, collect as sludge in the bottom of the electrolytic cell.

In the 1970's, environmental constraints and energy costs became a prime concern of the domestic smelting industry. Through the late 1970's and mid-1980's, smelters were able to use interim methods, such as tall stacks and intermittent operation to meet sulfur dioxide emissions standards. However, by 1987, most remaining smelters had abandoned traditional batch reverberatory smelting and had adopted one of the various continuous, flash, and oxygen-enriched methods (Outokumpu flash, Noranda, Inco flash, and Mitsubishi continuous). These furnaces require lower

energy input and provide a more concentrated sulfur dioxide gas stream, which allows for sulfuric acid production as a means of sulfur dioxide capture. In some instances, the byproduct sulfuric acid not only became an inexpensive source of acid, but also contributed to the expansion of the SX-EW capacity. However, its overall economic value to a smelter has varied.

Flash smelting involves the blowing of concentrate, flux, and oxygen into a hot furnace. The concentrate reacts rapidly with oxygen, releasing a tremendous amount of heat. As a result, flash processes are generally autogenous, requiring no external fuel input after firing-up. In 1988, Magma Copper Co. commissioned the world's largest single-furnace Outokumpu flash smelter with a 272,000-ton-per-year blister capacity. The majority of new smelters constructed worldwide since 1970 have been Outokumpu flash smelters. However, in the United States, two new Inco furnaces, Hayden and Hurley, have been commissioned since 1980. The Noranda process smelter, installed by Kennecott, was not autogenous, but had the advantage of being able to process larger size material, including scrap, and to produce a higher grade copper matte. Many copper smelters have found that the limit on environmental improvement at an acceptable cost rested with upgrading the converting process. Most plants have operated Pierce-Smith converters adapted for high-sulfur capture, but generally at high cost. A switch from the present batch mode of matte processing to one of continuous operation without converters is expected to be a major improvement for the future.

Canada pioneered the use of oxygen in smelting during the 1960's, and some forecast that this is the trend of the future. The use of oxygen in copper smelting was borrowed from steelmaking technology. If the smelter complex (smelting furnace, converters, and anode furnace) are considered one operation, the smelting process would use a typical ratio of total oxygen tonnage to concentrate of about 1:4. A 100,000-ton-per-year smelter, treating typical southwestern U.S. concentrates, would require about 300 tons of oxygen per day. The trend is toward higher levels of oxygen enrichment in smelting; this ratio is expected to increase through the next decade to more than 0.35 ton of oxygen per ton of concentrate. In the future, most smelters are likely to process all of their primary copper sulfides by oxygen enrichment processes, whether by flash or bath smelting, by the end of the decade.⁷

The Contop (Continuous Top-Blowing process) smelter is an autogenous process in which concentrate is continuously melted in a cyclone furnace on top of a large settling chamber. The high temperature of the flash smelting, combined with top blowing of the slag in the settling chamber, volatilizes most of the impurities, such as lead, arsenic, etc., and is well suited to ores having high impurity levels. It also provides for a low-copper slag that can be dumped without further treatment. Because of its relatively low capital requirement and compact size, it was reportedly well-suited for retrofit installation at reverberatory furnaces.

Cyprus Minerals Co. was building the first Isasmelt-process smelter in the United States. Developed by Mount Isa Mines (MIM) Co. and the Commonwealth Scientific and Industrial Research Organization (CSIRO) of Australia, this process used a single cylindrical reactor and a submerged Sirosmelt smelting lance in an easily controlled oxygen-enriched, high-intensity smelting process. The Isasmelt process has considerably lower energy needs than Cyprus' existing Miami, AZ, electric plant. The system offered capital and operating cost advantages, in addition to resolving some environmental problems. Associated with a 500-ton-per-day oxygen plant, the process also will allow a significant increase in concentrate capacity at the Cyprus plant. Slag from the new smelter will be cleaned in the existing electric furnace, and the existing acid plant will handle all of the sulfur dioxide process streams. The Cyprus smelter is the only remaining electric primary copper smelter in the United States.

The foam smelting process developed in the U.S.S.R. was being used on an industrial scale at three Soviet plants; enriched air was injected into the slag melt, and smelting occurs in the resulting slag foam. At present, this process is only used in the U.S.S.R.⁸

Technical improvements at the refinery level have included the use of permanent stainless steel or titanium starter sheets, improved solution chemistry, and automated system control leading to greater current efficiency and reduced impurity levels. As a result of reagent and production refinements, almost all domestic SX-EW production is high-quality cathode that does not require further refining. Continuous cast rod technology, in particular, requires

high-quality refined copper. The rapid increase in continuous cast technology for rod, since the middle 1970's, has rendered the wire bar, an intermediate cast shape for wire rod, almost obsolete and has effectively shifted intermediary casting from the refinery to the wire mill. Though it has not replaced deep well casting of intermediate cake, slab, and billet at brass mills, continuous casting technology also has been developed for some aspects of the sheet and tube sectors.

Recycling.—Scrap Consumption and Type.—The Institute of Scrap Recycling Industries Inc. (ISRI) recognized about 53 classes of copper and copper alloy scrap and published a booklet describing them. Although there were several grades of scrap within each, the major unalloyed scrap categories were known generally as No. 1 copper, which contained greater than 99% copper and often is simply remelted, and No. 2 copper, which, while clean and containing 94.5% to 99% copper, usually must be re-refined. In 1990, about 1.6 million tons of copper-base scrap, containing an estimated 1.3 million tons of copper, was consumed in the United States. The largest scrap categories were: No. 1 copper, 26%; No. 2 copper, 21%; leaded yellow brass, 15%; yellow and low brass, 7.5%; cartridge cases, 6%; automobile radiators, 6%; red brass, 5%; and low-grade ashes and residues, 8.5%. A wide variety of alloys made up the remaining 5%. Brass and copper tube mills processed 60% of No. 1 copper and most of the cartridge cases and yellow brass, while the secondary smelters and ingotmakers processed 79% of the No. 2 scrap and most of the auto radiators and red brass scrap. With a few exceptions, U.S. wire rod mills did not consume purchased scrap directly. One U.S. wire rod-producing company constructed a continuous-process scrap refining and wire rod casting plant, in which No. 1 return scrap from its own plants was processed. Scrap is classified into two general categories called old and new scrap. New scrap, or manufacturing scrap, is generated during the fabrication of copper products and returned to the mill for reprocessing, or sold, and is not considered a new source of copper supply. New scrap is termed "run-a-round" or home scrap when it was generated internally at the plant reusing it, or it may be called purchased return scrap, when returned by a customer from a plant external to that purchasing and reusing it.

Old scrap is generated from worn out, discarded, or obsolete copper products and, thus, is considered to be a new source of supply. Since World War II, the everincreasing reservoir of copper products in use, much of which was eventually recycled as "old" copper, provided annually between 19% to 33% of U.S. apparent demand and, on average, provided about 18% of world copper demand. It is estimated that the world copper reservoir of old scrap items, in use or abandoned in place, exceeded 173 million tons. The U.S. scrap reservoir is estimated to exceed 66 million tons or 38% of the world's total.

The rate of old scrap recovery is limited by copper's long life and its essential uses. On average, the rate of old scrap recovered in the United States, as a percentage of total scrap consumption, declined from 50% to 60% in the 1940's to about 40% in the 1980's. The decline in the old scrap component was the result of an increasing manufacturing base from which to generate new scrap and also of a changing demand pattern to one dominated by electrical uses. Electrical items, which now account for greater than 70% of copper consumed, were less likely to be substituted, replaced, and scrapped than items in other end-use sectors. The long service life for utility and building cable, among other reasons, results in a practical limit to the amount and rate at which old scrap from this source can be recovered. The average life for old copper items has been estimated at about 20 years. Historically, old scrap recovery not only improved during periods of high refined copper prices, but also increased at any time that primary supplies became scarce, including the deep recessionary years of the 1930's.

According to one source, using a definition for "recycling rate" as the ratio of copper scrap consumed to copper produced annually, copper has a recycling rate of 50% in Europe, 60% in the United States, and 47% in Japan. By comparison, aluminum has a recycling rate of 30% in Western Europe, 28% in the United States, and 36% in Japan. Zinc recovery is similar to aluminum, while lead is similar to copper. The average life for copper recovery in Germany, according to this same source, was cars, 8 years; small electric motors, 12 years; cables, about 42 years; and buildings, exceeding 80 years.9 In the United States, about 44% of total annual copper consumption was from copper in old and purchased new scrap. Copper scrap accounted for a similar percentage, 36%, in the countries of the European Community (EC), which collectively comprises one of the largest sources of copper scrap in the world.

Parts of the copper industry are very scrap intensive. For example, nearly all of the copper raw material used to make specialty alloy ingot for use in foundries was scrap. Scrap also was the dominant feed for yellow and leaded yellow brass rod mills and for many copper tube mills. In both Europe and the United States, many smelters and refiners used scrap as feed. a trend that has been increasing along with the need for purer forms of copper. In recent years, about 40% of refined copper produced in Western Europe and about 22% of refined copper in the United States was derived from copper scrap. Copper scrap accounts for about 19% of the world's refined copper production. Direct melt copper and copper alloy scrap, used mostly by brass mills and foundries, was more than double that used to make refined copper.

Scrap Processing.—Impure old copper scrap from sources such as radiators, electronics, cable, or tubing generally is processed by smelters and refiners. Alloy scrap, such as brass and bronze, is refined in a special scrap converter that enables alloying metals such as zinc, tin, and nickel to be removed by reduction and evaporation, or by oxidation and elimination, in the slag phase. The flue dust of the converter process contains mainly zinc, tin, and lead, most of which is recovered when the dusts are processed. A Pierce Smith converter or a Top Blow Rotary Converter (TBRC) can be used for the converting process of alloy scrap. The TBRC consists of a cylindrical vessel that rotates on its midaxis. Processing of complex copper-containing materials, such as drosses, flue dust, catalysts and collector dust, slimes from electroplating wastewater, and metal-rich slags from converter processes also require versatile production processes. Reverberatory or electric rotary melting furnaces are used for casting various copper forms, such as slabs, cakes, or billets, ASARCO Incorporated shaft furnaces may be used with holding furnaces in conjunction with continuous casting systems.

Problems.—Problems on the horizon for recyclers include stricter regulations for emissions, higher costs for waste disposal, legislation limiting the lead content of alloys and in drinking water, and the Basel

Convention. The cost for dumping hazardous materials, such as lead-containing plastic wire coverings and fluff, is high. While acceptable in some other nations, such as in Japan, incineration to destroy some of the unwanted plastics in the United States does not appear to be an acceptable solution. Cable scrap is an important source of metal, and whereas the plastic parts of the cable were removed previously by burning, stringent legislation on emissions has restricted this procedure. Thus, mechanical dismantling of cables has become common. An estimated 340,000 tons of cable is chopped every year in the United States, resulting in about 158,000 tons of plastic waste that must be disposed in some way. Thermoplastic resins are recyclable, but some high lead-containing plastics are not. Lead is used as a stabilizer in plastic cable coverings. Legislation limiting the content of lead in copper alloys was also being considered in the United States and may create many problems for both producers of these alloys and their consumers. Improperly applying wastehandling laws to scrap could have a stiffling effect on recycling.

The Basel Convention, negotiated in 1989 under the auspices of the United Nations Environment Program (UNEP), eliminates uncontrolled transboundary movement of hazardous and other wastes between nations, provides for accountability for waste movement, and encourages self-sufficiency in waste treatment. As currently written, the convention separates recyclables from other waste and recognizes the international community's need to trade in recyclables; however, "hazardous waste" is defined much broader than that in current U.S. law and regulations. The convention becomes effective 90 days after 20 countries ratify the document. EC ratification and implementation was not expected until early 1992. Eleven countries had ratified the treaty by yearend 1990. Another 53 countries, including the United States, have signed a UN document indicating an interest in ratifying the agreement. While the United States was a signatory to the convention, the ratification process will take 3 years or more. Because the convention would prohibit trade in wastes between nonparticipants, trade, which includes metal scrap, could be limited between the United States and other countries if the convention is activated prior to U.S. ratification. In addition, the regulatory scheme under Basel could be cumbersome, and documents may

duplicate existing procedures. The Organization for Economic Development (OECD) was developing a protocol for issues relating to the convention.

Economic Factors

Each copper product, including scrap, from mine through refinery has a distinct pricing procedure linked, for the most part, to its copper content and the market price for copper. For example, copper concentrates, which contain between 20% and 40% copper, are purchased on the basis of recoverable copper content and anticipated smelter and refinery charges for processing.

Copper concentrates were sold predominantly under long-term contracts and included provisions for the delivery of specified quantities and the formula by which the price paid was to be calculated. Contracts tended to be for periods as long as 10 years, though various terms were renegotiated at shorter intervals, and thus provided smelters with secure sources of feed material. Without such contracts, new mines would find development financing difficult. Contracts provided for two types of charges. A treatment charge was made for every ton of concentrate by the smelter, and a refining charge was made for every pound of recoverable copper. There was generally a provision for the participants to benefit from copper price rises. There also may be penalties for undesirable impurities, such as antimony, arsenic, and bismuth. The basis for additional payment for precious metals in the concentrates was generally slightly less than the amount actually contained.

Refined copper prices vary according to form and purity. Historically, the price for refined wirebar was the "bellwether" price for refined copper, because this was the dominant form traded. With the advent of continuous casting for wire rod, however, high-grade cathode became the dominant form traded. Copper wire rod prices are based on the refined copper cathode price plus a processing premium. The price spread between copper scrap and refined copper must be sufficient to allow for processing costs. Refined prices not only relate to the refined shape and its quality, but also to the manner in which it was priced; i.e., through producer's annually negotiated contracts, or through the commodity exchanges of the London Metal Exchange (LME), Commodity Exchange of New York (COMEX), and Mid-America

Commodity Exchange (MACE). Trading in copper began on the LME, January 1, 1877, and on the COMEX, May 15, 1929. A futures exchange, such as COMEX, is a centralized market where contracts for the future delivery of the commodity are bought and sold by competitive auction. Each contract for a particular commodity is identical, representing a specific amount and grade of a commodity designated for delivery at a specified date, which may be as far as 2 years in the future. Because all futures contracts are standardized, the only negotiable aspect of a contract is price. Futures contracts changed gradually over the years to correspond to the most active markets. The LME dropped its wire/bar and standard cathode contracts and, beginning January 1989, traded only the Grade A (high-grade) cathode contract. Similarly, COMEX converted to the High-Grade cathode contract on January 1, 1990. The spot, or first position, price is most often quoted for the exchanges. To this price, however, various premiums and other charges were added to determine the actual price paid by the buyer. Historically, the U.S. copper producers' price series was related to annually negotiated contract sales with price changes occurring at frequent intervals. When quoted, this price normally included a charge for delivery and insurance. Most U.S. producers abandoned classic producer pricing during the 1970's and 1980's, as inventories accumulated on the exchanges and the COMEX price became more influential. Producers adopted the custom of using the first position COMEX price as a basis for contract pricing. During tight markets, however, such as that which has existed since late 1987, the speculative influence of a COMEX-based pricing system has proved to be less than satisfactory for the consumer, owing to price volatility. The conventional producer pricing system tended to provide more stability to the market. Periods of speculative interest have usually been brief, however. The long period of stock surpluses since 1982 dampened speculative interest until the end of 1987. Since that time, both producers and consumers have increasingly used futures contracts and the newly introduced copper options to hedge their sales and purchases.

Based on constant dollars, one must look to the depression era of the 1930's to find prices as low as those occurring between 1981 and 1988. Since that time, current prices have been within the range of the constant dollar average for all prices,

1901-90. Copper prices not only responded to changes in the world economy, but also to the effects of large copper inventory accumulation; to copper cartel actions to restrict production, which were most effective prior to World War II; and from time to time, to speculative influences on the commodity exchanges.

Refined copper inventories are kept on hand by consumers and producers as a means to meet demand. A just-in-time inventory philosophy in recent years has been assisted by the advent of the computer, allowing a more accurate analysis and timing of production and shipments. Normally, about 4 weeks of supply is considered adequate to meet market needs and prevent excessive speculation. Whenever inventories exceed this mark, prices tend to be lackluster, and conversely, whenever inventories are below this mark, speculation can drive market prices up. Surplus inventories may find their way to the commodity exchanges where their high visibility tends to depress prices. The exchanges also provide a mechanism for hedging production and consumption, providing liquidity to the market. The primary economic purpose of futures trading is to provide a marketplace for hedging against the financial risk associated with volatile fluctuations in prices by transferring that risk to speculators.

Surplus refined copper inventories not only have accumulated periodically in response to periods of economic recession, but also as a result of U.S. Government purchases for the National Defense Stockpile (NDS). There is an inverse relationship between the amount of commercial stocks on hand and the market price for copper. High inventory levels have had a depressing effect on prices when these surplus supplies were released onto the market to compete with newly mined copper. Trends in U.S. copper inventories since 1955 are shown in table 2.

The U.S. Government has been historically a large holder of refined copper inventories, but since the final large elease of 1974 has not attempted to refill the NDS, which was released for the most part in response to the shortages of the Vietnam war years. From time to time, other nations, such as Japan, also have held refined copper stocks for strategic reasons. Materials shortages created during World War II prompted the creation of the NDS late in the 1940's. Beginning in the 1950's, the NDS became a vehicle for controlling the flow of mineral supplies during an emergency, buying copper in times of

TABLE 2 U.S. REFINED COPPER INVENTORIES, END OF YEAR'

rRevised.

¹Semifabricated forms such as rod, sheet, etc., at consumers are not included. Data may add not to totals shown because of independent

²Stocks held by miscellaneous manufacturers, foundries, and chemical plants. Data for the years 1955-64 estimated based on partial data. ³Inventories held by primary and secondary refineries.

⁴Data from Commodity Exchange Inc., New York.

⁵General Services Administration Inventory of the National Defense Stockpile

surplus (524,000 tons was purchased between 1953 and 1958; very little has been purchased since), and selling copper in times of shortage (808,000 tons was sold between 1965 and 1969 and 229,000 tons in 1974). The stockpile currently holds 26,352 tons of copper materials, including 20,000 tons of refined copper, 6,124 tons of copper in brass scrap, and 548 tons of nonstockpile copper.

ANNUAL REVIEW

Legislation and Government Programs

Copper Study Group.—The United States notified the United Nations, on March 15, of its provisional acceptance of the terms of reference of the International Copper Study Group (ICSG). Because the United States had led the movement to establish the study group, other countries were waiting for this signal to indicate their own interest. There was a June 30, 1990. deadline for acceptance of the terms of reference by countries representing 60% of the world copper trade. However, by the end of June, only Chile, Greece, Peru, and Poland had notified the United Nations that they had accepted the terms of reference. Even so, by yearend, several other nations and the EC were viewing the study group positively. A followup meeting by interested nations was to be held, in late 1991, to discuss objections by Japan and consider bringing the organization into force.

Environmental Legislation.—In late 1990, the U.S. Environmental Protection Agency (EPA) issued a strategy for reducing lead exposure based on a goal of reducing lead exposures to the fullest extent through market-based incentives to limit or eliminate lead use. The strategy included application of regulatory mechanisms, such as the Toxic Substances Control Act (TSCA), which would be used to reduce the use of lead in current and future products; combined with efforts to identify and encourage cleaner technologies for mining, smelting, and processing lead. Studies were to be made on potential hazardous exposures that might occur in the future, after disposal of any lead-bearing product, including copper alloys. The EPA planned to explore the desirability and feasibility of discouraging overall consumption of lead in any form.

The Lead Exposure Reduction Act (S. 2637 and H.R. 5372) and Lead Ban Act of 1990 (S. 2593) were introduced, but not passed. These bills were viewed by the scrap industry as having the potential to impede copper alloy recycling in the United States. Restrictions would have been placed on solder (greater than 0.1% lead), copper alloy plumbing fixtures (greater than 2% lead), and many other items, such as soldered copper pipe, many lead-containing plastics, wire coatings, and brass and copper plumbing fittings and construction materials, as well as the scrap

materials derived from them. The Brass and Bronze Ingotmakers testified that these bills, which sought to restrict all leadcontaining products, could actually result in more lead being released into the environment if such laws were passed. Currently, much of the lead-bearing copper alloy material is safely recycled, but the legislation could result in at least 6 to 10 million tons per year going to landfills. where lead could leach into the ground waters. The industry asked for rewording of the legislation to state clearly that it does not apply to the processing or distribution of copper alloy products of the recycling process. A new organization, Recyclers of Copper Alloy Products (RECAP), was formed to make the industry's views known. Among the members were the Brass and Bronze Ingot Manufacturers Inc., the Copper Development Association (CDA), the Copper and Brass Fabricators Council (CBFC), the ISRI, the American Foundrymen's Society, the American Cast Metals Association, the Non-Ferrous Founders' Society, the Plumbing Manufacturers Institute, the Air-Conditioning and Refrigeration Institute, and the American Pipefittings Association.

On October 19, 1990, the EPA solicited comments for the proposed final rule (published August 18, 1988) for the National Primary Drinking Water Regulations and Maximum Contaminant Level Goals for lead and copper in drinking water. Under the proposed rule, water delivery systems would be required to optimize corrosion control treatment if one of the following action levels were exceeded at consumers' taps: an average lead level greater than 0.010 milligrams per liter (mg/l); a copper level in 5% of the samples exceeding 1.3 mg/l; or a pH of less than 8.0 in 5% of the samples. In addition, water delivery systems would be required to implement public education, as specified, if the level of lead exceeded 0.02 mg/l in 5% of the tap samples. The final rule under consideration would apply the lead and copper action levels as a trigger for corrosion control treatment only to systems serving less than 50,000 persons. Larger water systems would have to install treatment to minimize lead and copper levels at consumer taps. Based on source water and tap water monitoring, a State may determine that source water treatment is necessary to minimize lead and/or copper levels.

Federal Actions.—The Small Business Administration (SBA) published a notice

that established a waiver of the "nonmanufacturer rule" for copper cathodes. The basis for the waiver is that no small business manufacturer is supplying these classes of products to the Federal Government. The effect of the waiver would allow an otherwise qualified regular dealer to supply the product of any domestic manufacturer on a Federal contract set aside for small business or awarded through the 9(a) program (SBA regulations 13 CFR 121.906 (b) and 121.1106 (b). Included were copper cathodes and five nonferrous base metal refining and intermediate forms, including ingots and slabs (PSC-9650), and nickel cathodes and brickettes.

The U.S. General Accounting Office issued a report in May 1990 (GAO/CD-90-88), commissioned by the House of Representatives Committee on Banking, Finance, and Urban Affairs, that analyzed the feasibility and effects of replacing the dollar bill with a dollar coin and the possibility of eliminating the penny and half dollar. The report concluded that a dollar coin could save the Government \$318 million annually in printing costs by replacing the \$1 note. The proposed coin would contain 80% to 90% copper. The report also concluded that there is no compelling reason to eliminate the penny or half dollar.

State Legislation.—Fearing that State approval of the open pit copper and gold mine near Ladysmith, WI, would result in a rush of mines being developed in northern Wisconsin, a State mining moratorium bill was proposed that would be a "yellow light" to mining in the State. The moratorium would have enforced stricter State regulations, requiring regional environmental and economic impact statements, and the so-called "local agreement" provision of the current mining law would be repealed. This provision essentially granted mining companies a short cut through the permit process. According to mining opponents, about 25 multinational mining corporations have bought or leased more than 500,000 acres of land in northern Wisconsin since the mid-1970's. The bill was not expected to pass the Wisconsin legislature, but was symptomatic of the current antimining movement in the United States.

A higher severance tax on minerals in Utah was passed (Senate bill 1991) in March 1990. The severance tax on copper was increased by 60%.

A large number of bills were introduced during the 1990 session of the Arizona

legislature that addressed environmental issues, particularly in the areas of hazardous waste and air and water pollution. One of the most significant laws passed was Arizona House bill 2007, which established penalties of up to \$10,000 per day for each air pollution violation committed by anyone in metal mining. The Arizona Desert Wilderness Act of 1990 incorporated about 1.1 million acres of Bureau of Land Management land and 1.3 million acres of Fish and Wildlife Service land into the National Wilderness Preservation System.

Trade Legislation and Actions.—By October 1990, Mexico had exceeded its General Selected Preference (GSP) competitive-need limit for unrefined copper and copper anodes exports to the United States. U.S. imports from Mexico through October totaled \$43 million or 38.2% of the total product imports. GSP competitive-need limits are based on a dollar figure tied to the Gross National Product (GNP) or to the percentage of total U.S. imports of the item. For 1990, the dollar limit was expected to be about \$93 million. Also, GSP imports normally could not exceed 50% of the total imports for the item. The limits were lowered for countries found to be sufficiently competitive in a product. Mexico exceeded its limit of 25% of total U.S. imports for unrefined copper and copper anodes. The import data are reviewed annually, and decisions about removing or renewing GSP status are announced on or about April 1. Other metal items likely to exceed the percentage limit are some types of copper wire cables from Mexico, as well as copper wirebars and stranded copper cables from Peru. GSP duty-free status was to be granted for U.S. imports of stranded copper wire from Peru, removing the 4% ad valorem duty. Legal procedures delayed any action until January 1, 1991.

A bill was passed, attached to the Commerce Department Appropriations bill, to establish a foreign trade zone in Cedar Rapids, IA. Designation as a foreign trade zone would enable Poongsan Inc. to build a copper and brass rolling mill in Cedar Rapids for the purpose of shipping finished copper products around the world, especially to Canada, using coils of copper and brass made in the Republic of Korea. The International Trade Administration (ITA) had determined that brass sheet and strip from Poonsgan Metal of Korea was dumped in the United States

at a margin of 25.58% during the period August 22 through December 31, 1986. As a result, Poongsan was required to pay a duty of 7.2% on any brass or copper it shipped to this country, which would have made Poongsan noncompetitive. Establishing the free trade zone would allow Poongsan to avoid this obligation at its mill in Iowa. The mill was to employ 800 workers and, thus, the bill received full support of Iowa legislators in the U.S. Congress.

The Non-Ferrous Metals Producers Committee (NFMPC), an industry group formed in 1988 to represent the domestic copper, lead, and zinc industries, petitioned the U.S. Trade Representative (USTR) to provide information under section 409/(b) of the United States-Canada Free-Trade Agreement (FTA) and section 308 of the Omnibus Trade and Competitiveness Act (OTCA). The NFMPC, and individually, ASARCO Incorporated, The Doe Run Co., Magma Copper Co., Phelps Dodge Inc., and Zinc Corp. of America, sought identification of the domestic copper, lead, and zinc industries as industries that could face increased competition from subsidized Canadian imports. The NFMPC believed these industries could be adversely affected by elimination of import tariffs on goods traded between the two countries. In particular, the NFMPC requested information about Canadian Federal and Provincial government assistance to the Canadian copper, lead, and zinc industries. In July 1990, based on the committee's recommendations, the USTR, in consultation with the Department of Commerce, found that the copper and lead industries should be "identified" as industries that could face increased competition from subsidized Canadian imports with which they compete as a result of the FTA.

The ITA determined that five West German companies were dumping brass sheet and strip in the United States at margins from 7.30% to 16.18% between 1986 and 1988. The companies, with new preliminary findings and current applied duties, in parenthesis, were Wieland Werke Ag (7.94%, 3.81%), Langenberg Kupfer und Messingwerke (7.94%, 16.18%), Metallwerke Schwarzwald (7.94%, 7.3%), William Prym (16.18%, 7.3%), and Schwermetall Halbzeugwerke (7.3%, 7.3%).

Issues

Industry Investments, Earnings, and Ownership Changes.—Arizona's copper

industry, growing and expanding since the mid-1980's, contributed \$6.3 billion to the State's economy in 1990, according to the Arizona Mining Association. 10 Direct contributions amounted to \$1.54 billion, up from \$1.25 billion in 1989 and \$1.08 billion in 1988, but as that money recirculated throughout the State economy, it made an indirect impact of \$4.8 billion, according to an analysis by the Western Economic Analysis Center in Arizona. The industry showed increases in several categories. including property tax payments, numbers of Arizonians employed, earnings of employees and, specifically, a 38% increase in purchases from Arizona suppliers.

According to the U.S. Bureau of Mines, Arizona led the Nation in the value of nonfuel minerals produced in 1990, equaling about 10% of the Nation's total. Of the State's \$3.1 billion in nonfuel minerals, \$2.8 billion was generated by the copper industry, about \$100 million more than the previous year, despite lower copper prices. The Arizona copper industry paid almost \$106 million in 1990 in direct support of State, county, municipal, and local governments in the State. This was about 5% more than in 1989. The largest payments were as property taxes levied on the industry's land, ore reserves, production facilities, and equipment. Property taxes were \$34 million. Second was severance taxes, a tax paid only by mining firms and timber producers. The severance tax on net value of copper production made up 29% of the industry's total State and local government tribute. Sales taxes paid on Arizona purchases of products and services were about 16% of the copper industry's direct payments, most of which went to the State's school districts, with the remainder going to State, counties, and incorporated cities and towns. Corporate State income taxes were almost as much as sales taxes, amounting to almost \$13 million. Payroll taxes, including both unemployment and worker's compensation premiums, comprised 7%. Rents and royalties paid for land use owned by the State accounted for less than 3% of industries tax payments.

Asarco reported net earnings of \$122 million on sales of \$2.2 billion in 1990. Harkets for the company's metals held up well in 1990, despite the slowing of economic activity in the United States late in the year. Asarco's strategy since the mid-1980's has been to transform the company from principally a custom smelter and refiner of ores and concentrates produced

by others into an integrated producer and processor on its own account. The company planned to invest about \$250 million in acquisitions and expansion programs to accomplish this goal by 1992. In 1990, Asarco committed \$75 million to expand and modernize its copper production facilities at the Ray and Mission Mines in Arizona. Other investments included \$213.3 million for Southern Peru Copper Corp. (SPCC), of which \$176.9 million is equity in restricted net assets. Peru had placed currency control restrictions on SPCC net assets of about \$331.2 million.

Copper Range Co., of White Pine, Michigan, owned 96.1% by Metall Mining Corp., reported operating earnings of \$2.0 million in 1990 compared with \$18.7 million for 9 months of 1989. Lower realized copper prices of \$1.09 per pound in 1990 were a key factor in the reduction of operating profits, from \$18.7 million in 1989 to \$2 million in 1990. The costs of mining reorganization were higher than anticipated, and the benefits only began to materialize late in the year. In 1990, the first phase toward modernizing the mill was started. In May, Copper Range purchased a mill section from Echo Bay Inc. for \$4 million at its mine in White Pine, MI. Copper Range owned five sections of the existing mill equipment at White Pine, while Echo Bay, the previous owner, still owned one idle section in the mill.

Cox Creek Refining Co. became 80% owned by Mitsubishi Metal Corp. during the year; Southwire Corp. retained a 20% share. Mitsubishi's move to increase its original 60% share in the Baltimore, MD, facilities was seen as a move to enable a direct link with planned output from the company's Texas City, TX, smelter, which was scheduled to start construction in 1992, providing environmental permits were obtained in a timely manner. Cox Creek was principally a tolling firm for imported copper anode.

Cyprus Minerals Co. had a net income from its copper-molybdenum-gold mining segment of \$111 million in 1990 compared with \$165.9 million in 1989. Profits for the year were reduced by asset write-downs of about \$63 million, including the Tonopah, NV, molybdenum-copper mine. In addition, lower metal prices and higher costs reduced earnings, although revenues of \$1.9 billion were higher than those in 1989. The earning levels of recent years reflect both strong metals prices and Cyprus Minerals' growth resulting from acquisitions of 22 properties from 1985 through 1989, at a

cost of about \$500 million. The emphasis during these years was growth through acquisitions, but the focus in 1990 shifted to increasing operating efficiencies. Cyprus Minerals Co. completed the purchase of MCR Products' wire-rod mill in Chicago, IL, from Magma Copper Co. The mill, shuttered since late 1989, began production in March. Full capacity of about 125,000 tons of wire rod per year would probably not be reached until next year.

Gold Express Corp. of Denver, CO, estimated that \$53 million would be needed for startup costs at the Copper Flat Mine, including repayment of capital already spent by previous operators. Costs reportedly were to be partially financed by Paribas Corp. of New York. Quintana Corp. operated the mine and mill at Copper Flat only a few months in 1982, before giving up the project because of depressed prices.

In 1990, Magma Copper Co. began to benefit from the prior 2 years of restructuring, consolidation, and employee team building. Magma Copper was made up by the San Manuel Mining Div., Pinto Valley Mining Div., Smelting & Refining Div., and three new divisions formed during 1990: Superior Mining Div., McCabe Mining Div., and the Robinson Mining Ltd. Partnership. Record financial and production levels were achieved despite lower copper prices. Net income increased by 44% to a record \$84 million. International sales increased to 34% of total copper sold. Earnings increased primarily owing to the attainment of full-capacity smelter performance and increases in productivity and copper production. Magma's refined copper cathode sold (excluding rod conversion premiums) at \$1.17 per pound in 1990 compared with \$1.19 in 1989. The company acquired 54% of the Robinson Mining District, NV, from Kennecott Corp. at a cost of \$21 million; \$18 million was spent on the development of the Kalamazoo and Superior mines; and \$37.5 million went to repay bank debts. Gross profit from custom smelting and refining was \$18 million in 1990. Magma started selling 25% to 30% of its cathode on a spot basis in 1990, permitting the company to take advantage of higher prices in Asian markets owing to the closure of Taiwan's sole copper smelter and falling concentrate stocks at Japanese smelters. The strategy also cut the company's need to hedge in the futures market. In order to free material for planned spot sales, Magma sold its rod mill near Chicago to Cyprus Minerals.

Magma and Alta Gold Co. completed the purchase of the Robinson Mining District near Ely, NV, at yearend. Magma acquired 51% interest in the property, consolidated through payments of \$10.5 million each to Kennecott and to the Alta Gold and Echo Bay Inc. gold mining partnership. Alta Gold acquired 49% in the partnership through a \$2 million payment to Kennecott. The 12,500-acre Robinson Mining District included a large high-grade ore body that greatly strengthened Magma's reserve position. Alta Gold had been paying royalties to Kennecott for its gold operations on the property. Echo Bay Mines Ltd., which had been in a gold venture with Alta Gold in the district, also sold its stake in the gold mining lease to Alta Gold and Magma for \$2.0 million. Magma agreed to invest \$1.5 million on a feasibility study to confirm estimated reserves of 248 million tons of ore grading 0.6% copper.

Phelps Dodge Corp. had a net income of \$454.9 million, after \$237 million in writedowns, compared with \$267 million net income in 1989. The company invested \$290 million in capital improvement and cost reduction programs and paid \$98 million of debt. Record copper production and sales, favorable prices, low production costs. and a strong international investment contributed to the record net income. The \$237 million after-tax charge to earnings was for certain nonproducing assets. Phelps Dodge Mining Co. had pretax earnings of \$594.4 million compared with 1989 earnings of \$290.6 million. The company's exploration efforts focused on increasing worldwide reserves. New resources were added at Morenci, Lone Star, and Bisbee in Arizona. and at Ojos del Salado in Chile. Discussions were entered into with potential partners in the La Candelaria Project of northern Chile for up to 30% of the project. Project structuring and financing options were expected to be completed by yearend 1991. The company expended \$55 million in exploration, advance mine evaluations, and research and development in 1990.

In 1989, Phelps Dodge recorded a nonrecurring pretax charge of \$374.6 million for the Morenci smelter (\$145 million); the Ajo Mine, concentrator, and smelter (\$50 million); the Dos Pobres underground mine development costs (\$115 million); and certain other facilities rendered obsolete by environmental requirements or other economic considerations. Other provisions included in this charge related to the planned shutdown of the Tyrone, NM, mine and concentrator

in the early 1990's and reserve for estimated environmental costs associated with other previously closed facilities. In 1988, the corporation corrected a previous pretax charge of \$50 million for anticipated obsolescence and closure costs of certain closed facilities.

RTZ Corp., although British based, was an international company with one-half of its assets in North America. Production from its principal U.S. investment, Kennecott's Bingham Canyon Mine, UT, was up by 3%, but earnings were less than in 1989, as a result of the lower copper price, timing of stock sales, and increased operating costs. A major part of the debt incurred for the acquisition of BP Minerals in 1989 was refinanced, resulting in lower interest costs. Exploration costs (\$171 million) were higher, but were spent mainly in Queensland, Australia, and Papua New Guinea. Net profits from RTZ's U.S. companies were \$459.3 million for 1990, comprising 43.7% of total corporation profits. Capital expenditures for 1990 were \$540.6 million, with a significant amount (\$227 million) being spent for the Bingham Canyon expansion. Copper and gold remained the largest contributors to RTZ's earnings in 1990, most of which came from its Bingham Canyon copper mine.

RTZ continued to use currency exposure management to reduce possible adverse effect of long-term currency changes by diversifying the risk among a wide range of currencies by decreasing exposure to key currencies to acceptable levels. The U.S. dollar's weakness against most major currencies in 1990 had an impact on RTZ's results. Metal and mineral prices were determined by the company from a basket of currencies, even when they were denominated in U.S. dollars. Whenever the dollar declined, there would be some partial offsetting increase in U.S. dollar prices. RTZ also managed its portfolio of cash and debt to take account of the currencies in which its costs and revenues were incurred. In this respect, the U.S. dollar was the most important net revenue exposure, and this was offset by dollar debt. If, for example, the dollar weakened, not only would the sterling value of revenues decrease, but the sterling value of dollar debt to be repaid would also decrease.

Sindor Resources negotiated a new sublease arrangement on the Lisbon Valley, UT, copper property that eliminated large preproduction payments and improved the likelihood for development of the 10 million tons of leachable ore reserves.

Court approval was granted in late 1990 for bankrupt Tennessee Chemical Co. to sell its Copperhill, TN, sulfuric acid and copper sulfate operations to Boliden Intertrade AG of Sweden. Approval was granted only after Boliden and the EPA reached a settlement on Boliden's obligation regarding past environmental damage at the site resulting from mining, roasting, and smelting operations. The agreement called for Boliden to spend about \$8 million over the next 10 years on an environmental improvement plan. Boliden assumed management of the operation in March 1990. Mining of sulfide ore ended in 1987. There were no immediate plans to reopen the mines. A new firm, Gaston Copper Recycling Corp. (GCRC), owned by Southwire (87.5%) and the Bank of Montreal (12.5%), purchased AT&T's Nassau Metals Corp.'s Gaston, SC, rod mill and integrated scrap processing plant (processing, smelting, and refining). The change in ownership resulted in a curtailment of operations during the third quarter.

A plan was approved for Sharon Steel Corp., owner of the shuttered Continental Mine, NM, and Mueller Brass Co., Port Huron, MI, to split into two companies, as part of its reorganization under chapter 11 creditor protection. The company's nonsteel assets would be transferred to unsecured creditors led by Quantum Overseas N.V. Quantum expected to sell shares in the spinoff segment, to be named Mueller Industries Inc., after the group's largest company.

Restructuring of the U.S. brass mill industry continued, as the trend toward modernization and specialization continued. BP America withdrew entirely from the copper industry. Chase Brass & Copper Co.'s, Montpelier, OH, copper alloy rod mill was sold by BP America for an estimated \$91 million to an investment group that included Martin V. Alonzo, Citicorp Venture Capital, and Westinghouse Credit Corp. The modern plant was North America's largest supplier of copper alloy rod. Talco Metals Co. of Philadelphia, PA, reportedly purchased Chase Brass and Copper Co.'s 50,000-ton-per-year copper and brass narrow strip plant at Shelby, NC. The plant was to be renamed Metals America, and the melting and casting facilities were to be used to produce special copper and copper alloy plating anodes. The strip rolling facilities will reportedly remain idle. Talco Metals created a new commodities and trading unit aimed at reducing the risk associated with the company's increased investments.

JPS Ltd., of Japan, through its newly formed subsidiary Great Lakes Metal Corp., signed a letter of intent to purchase the brass mill facilities of the closed North Coast Brass and Copper Co., near Euclid, OH. The new owners reportedly would operate the plant as a reroll mill, but would not operate the casting plant.

American Brass Co., Buffalo, NY, signed an agreement for the sale of all assets to Outokumpu Oy copper group of Finland, including its brass and tube mills in Buffalo, NY, Kenosha, WI, and Franklin, KY. Outokumpu already owned the rod mill facilities of Valleycast Inc., WI, and Nippert Co., OH.

Hussey Copper Ltd. launched a \$10 million expansion and quality improvement program, including installation of three new casting furnaces at its Leetsdale, PA, plant. The improvements would enable the company to expand its variety of alloys and to rely less on outside sourcing. A continuous strip annealer was also installed, and two rolling mills were to be upgraded with new automatic controls.

Halstead Industries Inc., Greensboro, NC, closed its Zelienople, PA, copper tubing plant in September, mainly because of continued weak construction markets. All production previously handled by the plant was assumed by the company's newer facilities in Arkansas and North Carolina.

Cerro Copper Tube Co., IL, selected a northeast Missouri location for its \$30 million integrated copper tube mill, scheduled for completion in mid-1991. The new mill would boost the producer's capacity by more than 50%. Cerro was to spend more than \$12 million in cleaning up a contaminated creek, known as Dead Creek, that crossed its Sauget, IL, property. The creek had been polluted by years of industrial waste from manufacturing companies in the Sauget, IL, area. As part of a consent decree with the Illinois Environmental Protection Agency, the company agreed to stop all discharge into the 1,600-foot creek segment crossing its property, construct an alternate storm water collection and retention system, and remove contaminated sediment from the creek bed.

Environmental Issues.—Secondary Materials.—Brass and bronze foundries and ingotmakers scored a minor victory when the U.S. District Court of Appeals ruled in early 1990 that OSHA Lead Standard would remain at 200 micrograms throughout the pending legal challenge of

OSHA's current recommendations. Labor unions had sought to remove the court's stay and to start the 5-year phase-in period for eventual compliance with the 50/75 microgram airborne lead standard as outlined in OSHA's January 22, 1990, ruling on Non-Ferrous Foundries and its June 28, 1989, recommendation for Brass & Bronze Ingot Manufacturers. The court's action was an acknowledgment that there were valid concerns over whether or not nonferrous foundries can meet OSHA's proposed regulations.

The secondary processing industry claimed that a major portion of the scrap export market could be curtailed if the Solid Waste Disposal Act (SWDA)(H.R. 3736) was implemented. If scrap metals are found to be hazardous waste under section 201 of the SWDA, then the export controls of SWDA would govern their entry into international trade. In addition to adverse scrap export effects, at proposed 0.1% heavy-metal concentration, the legislation defined many discarded consumer goods as hazardous, even though these same goods currently were being recycled safely with no harmful release of hazardous constituents. Metallic products that would come under the hazardous definition included such commonly used items as stainless steel flatware and foil wine wrappers. For many, if not most, metals recyclers, becoming classified as hazardous waste facilities would be disastrous. The legislation defined as hazardous many millions of tons of metals recycled each year, based upon the mere presence of certain heavy metals, with no reference to the toxicity of these metals. This legislation would deem as hazardous waste any discarded material that contained more than 0.1% of any heavy metal, such as beryllium, cadmium, chromium, lead, mercury, and nickel. This proposal grew out of concern that wastes bearing heavy metals could expose those metals to the environment. Thus, stainless steel, with far more than 0.1% nickel and chromium, would be deemed hazardous regardless of whether it could escape into the environment. Copper, brass, bronze, galvanized steel, and other metals that are commonly and safely recycled also would not pass this arbitrary test.

The ISRI warned against movements toward laws and regulations that do not recognize the unique role of recycling. Current law would treat scrap as solid waste, not as a raw material, and it failed to define what constituted recycling and what did not. Metals should be viewed as renewable

resources in that they can be used again and again in new products, conserving scarce resources and preventing pollution. The industry viewed one of the biggest barriers to increased use of recycled materials had been the governmental failure to give recycling priority over disposal. ISRI recommended that any new rules should be studied to determine their effect on scrap supply and processing. A regulatory program should, ideally, encourage legitimate recycling. State and local governments. when passing rules, often had failed to look at the interplay of markets, commodities, and regulation before putting into effect their own recycling regulations. The recycling program often ended up being a very costly storage, and in some cases, disposal program. 12

Claiming to protect the environment by preventing the production of waste and by "organizing" its disposal or recycling, administrations and legislators worldwide have decided to take charge of all aspects of waste management-whether hazardous or not-including those recyclable raw materials that the industry reclaims, processes, and sells. Legislators tend to confuse "recyclable raw materials" with "waste," and, in the process, create enormous obstacles to trade for the entire reclamation and recycling industry. In 1990, there were reports of cases in which entire shipments of nonhazardous recyclable raw materials were detained at borders, even though there was no doubt whatsoever regarding their end use or the ecological credibility of their consignees. The Bureau Internationale de la Recuperation (BIR) and national federation members, as well as large multinationals, were to provide as concise a definition as possible for the term 'recyclable raw materials" as opposed to 'waste." 13

Mines.—At the Sierrita Mine, Cyprus Minerals continued to look for a practical way to eliminate dust blown by high winds from its active mill-tailings pond. Remedies used by other copper producers included covering inactive tailings areas with crushed rock or soil and vegetation to prevent dust pollutions. In Arizona, several exploration or developmental programs were reportedly canceled or postponed because of environmental constraints. Bond Gold Corp. had planned drilling in the Prescott National Forest, but after lengthy regulatory delays and issuance of an exploration permit that was too restrictive, the company terminated its plans. Strong local opposition to proposed exploration in the Coronado National Forest forced Newmont Mining Corp. to postpone drilling on its claims. Phelps Dodge withdrew its request to trade land with the Forest Service so that it might develop its Copper Basin deposit in Yavapai County. After spending \$93,000, the company decided the projected cost of \$2.5 million for an environmental impact study was unacceptable at this time.

Asarco and a subsidiary received notices from EPA that they and, in most cases, other parties, were potentially responsible to remediate alleged hazardous substance releases at certain sites under Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA). The company anticipates to spend significant capital and other expenditures over the next several years to comply with environmental laws and regulations, including required remediation at various Superfund sites. Based on developments in 1990 at a number of Asarco's properties, the company added \$75.5 million to its closed plant and environmental liability reserves. At the end of 1990, such reserves totaled \$129 million. Cash expenditures charged to these reserves were \$15 million in 1990, \$13 million in 1989, and \$14 million in 1988.14

The U.S. EPA and Boliden Intertrade A.G. of Sweden reached an agreement regarding cleanup and liability for past contamination at Tennessee Chemical Co. in Copperhill, TN. Under the agreement, Boliden, which purchased the bankrupt Tennessee Chemical facilities in 1990, will spend \$8 million over the next 10 years on an environmental improvement program that will include reforestation, installation of sediment traps, continued operation of wastewater treatment plants for runoff, installation of a sulfur burner, and remediation of soil contamination. Boliden will not be held liable for any contamination that occurred prior to its assumption of management. Most of the environmental damage was caused by waste dumped along Davis Mill Creek by the plant and associated copper mine, which closed in 1987. Acid emissions from the plant destroyed much of the surrounding vegetation.

Smelters.—Kennecott's plans to comply with environmental requirements by 1994 included a possible investment of \$200 million in pollution control equipment. However, even these measures would be insufficient to meet particulate emissions standards proposed by the Utah

Bureau of Air Quality under its draft State Implementation Plan (SIP). Other options included construction of a new, larger smelter.

Mine and Plant Labor.—Productivity at all mines that produced copper as a principal production was 16.8 worker-hours per ton of recoverable copper produced by open pit, underground, and leach methods. Average productivity, including mine, mill, and leach operations, was 54 worker-hours per ton for 4 underground operating mines and 14 worker-hours per ton of recoverable copper for 12 open pit mines. The number of workers at U.S. copper mines and mills averaged 12,924 in 1990. Arizona (8,759 workers) led in the average number of mine and mill workers, followed by New Mexico (1,585 workers), Utah (1,173 workers), and Michigan (928 workers).

Arizona's copper production exceeded the high level achieved in 1973, with slightly less than one-half of the 21,000 persons employed at that time. This reduction of labor force and equivalent increase in productivity was accomplished through large capital investments on larger and more efficient equipment and on new labor- and

energy-saving techniques to increase production and lower costs. The SX-EW process can be applied to certain lower grade ores and produces market-ready copper while requiring far fewer workers. One SX-EW plant, for example, needs only 26 workers to produce 100 million pounds per year. Copper industry workers continued to be the highest paid industrial workers in the State of Arizona, with average earnings of \$36,608 per year. In addition, copper industry workers enjoy generous fringe and retirement benefits.15

In the United States, talks were carried out between management and unions at Asarco's Ray, AZ, mine; Kennecott's Bingham Canyon, UT, mine, mill, and smelter complex; and Phelps Dodge's Chino, NM, mine, mill, and smelter complex. Four-year contracts negotiated by Kennecott in 1986 expired in June 30, 1990. Following the ratification of a 3-year contract at Kennecott's Bingham Canyon Mine, members of the United Steelworkers Union ratified a 3-year contract at Phelps Dodge Corp.'s Chino Mine on June 12. A short strike at Asarco's Ray Mine, AZ, was ended with the ratification of a new 3-year labor agreement on July 21 that provided

increased wages and improved insurance and pension benefits. The new contract provided for a \$2.00 per hour increase for the first year and an average of 25 cents per hour increase for each of the following 2 years. A \$400 lump-sum payment in the third year was part of the Phelps Dodge contract.

In 1990, the White Pine Mine employed a total of 1,113 workers compared with 1,069 in 1989, according to the company annual report. Although under new ownership, employees of Copper Range still participated in an Employee Stock Ownership Plan and had representation on the board of directors. Copper Range has a collective agreement with the United Steelworkers of America, representing the unionized employees at Copper Range, which expires in November 1993. No further wage increases will be granted under the current contract.

Production Costs.—The weightedaverage cash cost, including byproduct credits and taxes but excluding depreciation, of producing refined copper in the United States was estimated to have remained nearly the same, at 54 cents per pound

in 1990, according to the U.S. Bureau of Mines Minerals Availability System (MAS) estimates. Including recovery of capital, the average production cost was 60 cents per pound. Even so, the massive restructuring program undertaken by the U.S. copper industry was now paying off; although it had taken immense amounts of capital, the producers were positioned favorably for international competition and lower prices.

Asarco's administrative costs rose by \$15 million in 1990, as a result of higher marketing costs in the specialty chemicals business and other corporate expenses. Depreciation and depletion increased \$11 million in 1990 on higher metal production rates and increased capital spending. Research and exploration costs rose \$2.8 million in 1990 compared with those of

1989, reflecting the second year of increased exploration activity. Interest expense was \$9 million higher in 1990 than that in 1989, because of increased borrowing. In 1990, lower prices for copper, silver, and zinc were largely offset by higher lead prices, higher copper sales volume, and specialty chemical sales.

Copper Range's cash costs were reported by the company to be 96 cents per pound in 1990 compared with 88 cents per pound in 1989. Total costs were \$1.08 per pound in 1990 and \$1.00 per pound in 1989. Metall Mining began significant investment in the White Pine Mine to reorganize and modernize the mine in order to increase production and lower operating costs. The underground mine was reorganized into two distinct operations, the Northeast and

Southwest Mines. The priority in 1990 was to replace the aging equipment in the Northeast Mine and to develop additional headings to achieve higher production levels. These measures increased the mine output to its highest rates since the restart of operations in 1985. The production increases and productivity improvements had not yet translated into higher earnings because of the high costs associated with this program as well as a fall in copper prices in 1990. The priority for 1991 was to be the modernization of mining equipment in the Southwest Mine and consolidation of mining activities.

Copper Range developed the "super unit" concept by creating larger production areas with the intent of improving productivity and achieving economies of scale. All

new equipment was mobile, to allow for a more efficient and uninterrupted process of drilling, blasting, mucking, and removal of ore. New techniques at the White Pine Mine have increased drilling flexibility; primary crushing was moved closer to the production face, and haulage distances were shortened through the extension of conveyor systems to the working areas. The Northeast and Southwest Mines each will have its own management structure and equipment fleet.

The emphasis during Cyprus' previous 5 years was growth through acquisitions, but the focus in 1990 shifted to increasing operating efficiencies. To increase productivity, lower operating costs, and maintain capacity, Cyprus spent more than \$200 million in 1990. A similar expenditure was planned for 1991. Over the past 5 years, Cyprus had invested almost \$700 million to sustain and improve operations and develop new mines, with about \$180 million being spent on copper.

Cyprus Minerals planned to modernize and expand its electric Miami, AZ, smelter to reduce the company's overall costs. Addition of an oxygen enrichment combustion process was expected to reduce electrical costs. The increased throughput also would result in additional sulfuric acid, decreasing the company's need to purchase sulfuric acid for its leaching projects. The additional mill capacity at Bagdad, which was completed during the year, was designed to reduce production costs through added processing capacity and improved productivity.

Kennecott reported operating costs were up at its Bingham Canyon Mine during the year, as a result of higher labor rates and reduced smelter production. ¹⁶ Construction of the fourth concentrator line was 25% completed by yearend and was scheduled for commissioning in early 1992. Although exact costs were not made public, Kennecott officials cited costs at Bingham of about 35 cents per pound after credit for byproducts. This would make the mine one with the lowest cost in the world. ¹⁷

Production costs at Phelps Dodge operations were reduced to between 55 and 60 cents per pound of copper, from a high of more than 80 cents in 1981. Substantial capital programs underway or planned will cost another \$365 million over the next 3 years, further supporting the company's cost-reduction goal. Incremental production costs at the Tyrone SX-EW plant have been below 30 cents per pound of copper cathode; similar costs have also been

experienced at the Morenci plant. The Morenci plant was being doubled in size.

Phelps Dodge's planned capital expenditures for 1991 were budgeted at about \$290 million, very near the 1990 level of investment. The more important projects in 1990 included the completion of the Northwest Extension at Morenci, additional in-pit crushing and conveying equipment to support reentry into the Metcalf area of the Morenci Mine, and expansion of Tyrone's SX-EW facility. Phelps Dodge Mining Co. had capital expenditures in 1990 of \$182.5 million. With unit costs substantially below combined conventional methods, the SX-EW method of copper production was a major factor in cost reduction by Phelps Dodge. The in-pit crusher and conveying project allowed the company to phase out rail haulage and reduce haulage costs in the Morenci pit.

Magma Copper's strategy for the future was to continue to reduce costs and increase production. Within the next 5 years, Magma planned to develop electrowon cathode production of 72,575 tons per year from existing and new properties at a fully loaded cost of less than \$0.65 per pound. Coupled with cost reductions and productivity increases from sulfide copper sources, Magma anticipated an overall average cost at its mines of \$0.70 per pound could be achieved. San Manuel mine is deep, hot, and labor intensive, making it high cost. However, these costs were expected to decline significantly once primary development of the Kalamazoo is completed in 1991. Additional cost reductions were expected from productivity and other cost reduction programs. Other production outside of the underground mine have a break-even cost of \$0.59 per pound, including general, administrative, and marketing costs. As the last of the technical problems were resolved and Magma's smelter was operating at full capacity, the company reported cash operating costs had been reduced substantially from about 80 cents per pound in the first quarter to 71 cents per pound in the fourth quarter. 18

In a recent study, the U.S. Bureau of Mines estimated direct operating costs for smelting facilities with emission controls. Retrofit capital costs were estimated to be on the order of \$150 million per facility or 5.6 cents per pound of copper produced. The overall cost penalty, including capital invested, to the producer for implementing the new smelting and sulfur dioxide capture facilities was estimated to be 7.5 cents per pound after deductions of a 1.3 cent

per pound acid credit. The realized benefit derived from providing a cleaner air could not be evaluated in monetary terms. The operating costs for the individual smelters studied ranged from 10 to 15 cents per pound of copper, and the average operating cost in 1987 was 12.3 cents per pound. This operating cost included 3.2 cents, or 26% of the total, as the cost burden of compliance with environmental, health, and safety regulations. Installation of the new processes led to some savings in operating cost as well as increased production capacity, but the study concluded that the retrofits would not have been economically justified had not compliance with regulations been dictated.19

Production

Mine Production and Reserves.— Copper was mined in 13 States during 1990, with Arizona maintaining its lead with 60% of the total, followed by New Mexico and Utah. There were 62 copper-producing mines, down from 68 mines in 1989. Of these, 36 were copper mines and 26 were mines from which copper was produced as a byproduct or coproduct of gold, lead, silver, or zinc. Total U.S. operating mine capacity, in terms of recoverable copper per year, was estimated to be 1.86 million tons in 1990 compared with 1.79 million tons in 1989. The growth was largely the result of further increases from SX-EW recovery, but also was from the startup of several new mines. Annual SX-EW capacity was expanded to 405,000 tons during the year compared with 353,000 tons of copper in 1989. Reserves at the major producing companies were reevaluated with some significant increases, as shown in table 5.

South Atlantic Ventures Ltd.'s Oracle Ridge reportedly was the first underground mine to open in Oregon since World War II. Costing \$6 million to construct, the mine would produce at the rate of 5,400 tons of copper per year, starting in January 1, 1991. Underground development encountered massive sulfide ore containing values as high as 21.53% copper and 4.45% zinc. Reserves were listed as 417,300 tons of ore grading 3.04% Cu, 2.92% zinc, 0.038 ounce per ton gold, and 1.10 ounces per ton silver. Magma Copper reopened its Superior Mine, AZ, Arimetco opened the Johnson Camp Mine, AZ, and Formosa Mining opened the Silver Butte Mine, OR. Kennecott received development and mining permits for the Flambeau, WI, project. A setback occurred

in the development of the Montanore silvercopper project near Libby, MT, when Montana Reserves Co. encountered difficulties in financing its 45% stake in the project.

Gold Express Corp. of Denver, CO, announced plans to reopen the Copper Flat Mine in New Mexico. Expected to begin production in 1991, the mine would produce about 18,000 tons of copper in concentrates annually. The mine would also produce some gold, silver, and molybdenum. Since the old mill had been sold and moved to Papua New Guinea, a new mill was to be built. Michcan Inc., a Michigan investment group that included Peninsula Copper Industries, was proceeding on schedule with dewatering the Centennial Mine, MI.

Butte Hill Mine, MT, closed in 1990 because of low zinc prices. Copper Cliff Mine, ID, also closed in the third quarter owing to lower silver prices. Although new investors were examining its potential, the Van Dyke Mine, AZ, remained closed during the year.

Asarco, or its associated companies, operated mines in Australia, Canada, Mexico, Peru, and the United States. According to the company's annual report, Asarco and its associated companies together in 1990 accounted for about 12% of free world mine production of copper, 14% of silver, 14% of lead, and 9% of zinc. Five years ago the company supplied less than 25% of its copper and 5% of lead concentrate requirements; in 1990, it supplied about 70% of its copper needs and more than 50% of its lead requirements. By the time the copper mine expansion programs are completed in 1992, the company planned to be self-sufficient in copper concentrate requirements.

Asarco continued to expand and modernize its copper operations in Arizona. Copper production will be increased at the Ray Mine, AZ, by 58% to 165,000 tons per year and at the Mission Mine, AZ, by 42% to 112,000 tons per year. A \$54 million plan to build a SX-EW plant at the Silver Bell Mine was announced. Silver Bell, which opened in 1952, was Asarco's first domestic open pit copper mine. Mining stopped there in 1984, owing to high operating costs. The new facility will produce 16,300 tons of cathode annually. Earlier plans to expand Ray Mine production had been modified to fund premine stripping and construction of a new tailings pond. An originally planned 18-mile tailings pipeline was canceled. The total cost of the Ray

expansion was reset to \$194 million. Late in the year, construction of a new concentrator was suspended because of unexpected permitting delays. These projects will allow Asarco to have a total mine output of 327,000 tons of copper per year.

In 1990, Asarco mined for its own account 218,000 tons of copper, compared with 198,000 tons in 1989, increasing the proportion of copper concentrates supplied to its smelters from internal sources to 70% of production from 67% in 1989. According to the company annual report, production at Asarco's mines was as follows in 1990: Mission, 72,400 tons; Ray, 110,500 tons; Continental, 37,100 tons; Silver Bell, 3,800 tons; Troy, 15,300 tons; Coeur, 800 tons; and at Galena, 800 tons.

Asarco was defendant in lawsuits in Arizona brought by Indian tribes and some other Arizona water users contesting the right of the company and numerous other individuals to use water and, in some cases, seeking damages for water usage. The lawsuits potentially affect the company's use of water at its Ray Unit, Hayden Plant, Mission complex, and other Arizona operations.²⁰

According to the company's annual report, the White Pine Mine produced 42.800 tons in 1990 compared with 29,600 tons in 1989. The average grade of ore milled was 1.10% copper. Tons of ore milled in 1990 was 4.6 million, an average of 12,900 tons per day, compared with 11,700 tons per day in 1989. Production improvements continued, with average milling rates in excess of 14,500 tons per day for the final quarter. Copper Range spent about \$17.2 million on replacing older mining equipment such as drill jumbos, loadhaul dump equipment, and bolters. Copper Range also acquired an additional mill section that will increase milling capacity in excess of 5,400 tons per day to process the higher mine production anticipated for future years. The target output was 60,000 tons of copper per year within the next 3 years.21

Cyprus Minerals announced that the mill expansion at its Bagdad, AZ, copper mine had been completed and began operating August 20. The expansion increased Bagdad's annual copper production by 18,000 tons, to more than 100,000 tons. The addition of a fifth grinding line increased daily mill throughput from 54,400 tons to 68,000 tons of ore.

Copper output of 236,100 tons at Kennecott's Bingham Canyon Mine, UT, was up 3% compared with that of 1989,

according to the company's annual report. In addition to gold and copper, 3.4 million ounces of silver and 5,200 tons of molybdenum were produced. Construction of the fourth concentrator line was 25% complete by yearend and was scheduled for startup in 1992. During its first 5 years of operation, the fourth line will increase production by about 32,000 tons per year of copper and 84,000 ounces per year of gold. Bingham Canyon was RTZ's largest producer of gold, even though production was 17% below that in 1989 as a result of lower grade ore being mined. RTZ reported 420,000 troy ounces of gold produced from the Bingham Canyon Mine in 1990.22 The Wisconsin Third District Court of Appeals upheld an agreement between the town of Grant in Rusk County, WI, and Kennecott Corp. for mining copper near Ladysmith, paving the way for mine development. The ruling resolved another dispute between Kennecott's subsidiary, Flambeau Mining Co., and its environmental critics. The State of Wisconsin was expected to approve a series of permits needed to operate the 32-acre open pit mine in early 1991. Mine opponents were expected to continue to seek court injunctions to stop the mine, but company officials felt they would be able to start work at the site by mid-1991. Magma Copper's Pinto Valley Mining Div. near Miami, AZ, operated an open pit sulfide ore mine and concentrator. The open pit had an average grade of 0.41% copper. During 1990, the concentrator produced 260,400 tons of concentrate, containing 76,200 tons of copper. Pinto Valley's flotation capacity was improved in 1989, and in 1990, 14 haulage trucks were replaced with larger equipment, increasing productivity and reducing costs despite lower ore grades. Pinto Valley also had three leach operations; an in situ leach in the old Miami underground mine, closed since 1959; tailings treatment; and conventional leaching of sulfide waste from the open pit. Solutions from these three sources feed two SX-EW plants. SX-EW copper production was 14,500 tons in 1990. Magma's strategy was to supply 50% or more of the concentrate feedstock to its smelter from its own resources. To do this, Magma must develop new sulfide copper reserves, capable of supplying at least 245,000 tons of concentrates per year by 1997, when the San Manuel underground reserves will be depleted.

San Manuel underground mine has been in operation since 1956. The current underground plan extends into 1997, at a

rate of 42,000 tons per day, with an average ore grade of 0.65% copper. The plan included limited development and production from the Kalamazoo Mine. The Kalamazoo Mine started production in the third quarter of 1990 and was operating at 5,400 tons per day at yearend. Refined copper from this source will average 86,200 tons per year over the mine plan period. Magma also produced about 26,700 tons of SX-EW copper cathode from an open pit mine at San Manuel, from which copper oxide was mined for pad leaching, and from an in situ leaching operation that extracted copper from San Manuel underground oxide ore reserves. Production from the in situ leach operation, originally plagued with recovery problems, was 11,400 tons. This improvement was achieved as a result of an innovative well-to-well leaching technology.²³ Magma Copper's Superior Mining Div., near Superior, AZ, produced concentrates that were trucked to the San Manuel smelter. The underground mine and mill were closed in August of 1982 and, although the ore grade averaged 3.5% copper, the operation was too labor intensive to be profitable at the time, with about 1,400 employees producing 2,700 tons of ore per day. The current mine plan had an average ore grade of 6% copper. The operations were designed to use productive teamwork with employee participation in all development aspects. This permits only 312 employees to produce more than 1,000 tons of ore per day. The company planned to increase the production rate to 1,400 tons per day by the end of 1991, at which time the mine was expected to produce more than 63,500 tons of concentrate per year, with more than 18,000 tons of copper. An exploration program to develop new reserves was also underway.

Phelps Dodge Mining Co., the mining and metals division of Phelps Dodge Corp., was the world's second largest producer of copper. The corporation's U.S. mines produced 532,500 tons of copper, including partner shares, or about one-third of the copper mined in the United States.²⁴ Phelps Dodge operated open pit mines at Morenci, AZ, and at Tyrone and Santa Rita Mines, NM, and at two underground mines near Copiapo, Chile. Phelps Dodge owned an 85% interest in the Morenci complex. The Santa Rita Mine and Hurley. NM, smelter are owned by Chino Mines Co., a general partnership in which Phelps Dodge holds a two-third interest; Sumitomo Mining of Japan owns one-third. According to the company's annual report,

recoverable copper production at Phelps Dodge mines was as follows: Morenci, 304,500 tons; Tyrone, 144,500 tons; Chino, 123,700 tons; and at Bisbee, 5,200 tons. Bulk sampling and metallurgical testing of ores were conducted at the Cochise Project near Bisbee, AZ. Tests are underway to estimate SX-EW recovery potential.

Phelps Dodge discovered additional mineralized material at its Coronado deposit near Morenci. The Coronado deposit contained combined sulfide and oxide mineralization in excess of 136 million tons grading 0.7% copper. Additional mining resources were also identified at Tyrone, which will allow this copper operation to continue at least through 1991. The average grade of ore mined at Morenci was 0.74% copper; at Tyrone, 0.79% copper; and at Chino, 0.67% copper. When the ore body at Phelps Dodge's Tyrone Mine, NM, is exhausted early in the 1990's, SX-EW production will continue for about 15 years more. The company planned for the Northwest Extension Project at Morenci to replace the Tyrone sulfide production lost when Tyrone closes in 1992. Phelps Dodge made progress on the \$112 million expansion at Morenci, which was started in 1989 and scheduled to be complete by mid-1991. By 1993, about 50% of the production at Morenci may come from lowcost SX-EW facilities. The SX-EW capacity at Morenci will be expanded by 63,500 tons of cathode annually, beginning in mid-1991 and continuing through the end of the decade. A major part of this will be from the Northwest Extension Project. About \$48 million also was spent on an in pit crushing and conveying system at the Morenci Mine. This system allowed the mine to phase out rail haulage and reduce haulage costs in the Morenci pit.

Phelps Dodge announced that it would cease work on its Copper Basin Project near Prescott, AZ, and would focus efforts on other sites, including the Cochise copper project in Bisbee, AZ, and La Candelaria in Chile. Phelps Dodge had terminated a proposed land exchange with the Forest Service and preparation of its related Environmental Impact Statement for the Copper Basin Project. The corporation had been attempting for about 20 years to complete a land exchange with the Forest Service adjoining its copper property for use in building surface facilities and a tailings impoundment. Environmental protests concerning the mine itself and rumors of a new smelter being constructed here were in

large part responsible for disinterest in continuing the project at this time. The Copper Queen Branch completed test mining and leaching investigations at its Cochise Project. An open pit mine with heap leaching and an SX-EW plant were planned. Cost to construct this project was estimated as \$80 to \$90 million. Planned recovery rates were about 41,000 tons per year of copper cathode. Limited precipitate production was currently from leaching of the old Lavender Pit No. 7 dump.

Smelter Production.—Primary and secondary smelter production increased in 1990 compared with that of 1989. Eight primary smelters with a combined capacity of 1.37 million tons operated during the year. In addition, five secondary smelters with a combined capacity of 420,000 tons operated; however, one smelter was closed for nearly half of the year, reopening under new ownership.

According to the company's annual report, Asarco produced 258,800 tons of copper at its El Paso, TX, and Hayden, AZ, smelters. Hayden produced 164,700 tons, and El Paso produced 94,200 tons of copper.

Cyprus Minerals planned to use Mount Isa Mines' (MIM) Isasmelt process in a major modernization project at its Miami, AZ, smelter. The Isasmelt process was developed by MIM and the Commonwealth Scientific and Industrial Research Organization (CSIRO) of Australia.²⁵ The new system will bring the smelter more in compliance with OSHA and air quality regulations and provide both capital and operating cost advantages. The rennovation was expected to cost \$92.5 million and reduce operating costs. The copper concentrate capacity would increase, from 408,200 tons per year to 544,300 tons per year, and the copper capacity to 163,300 tons per year. The greater throughput of concentrates and increased use of oxygen would also increase acid recovery that would be used in leach operations at the Miami mining site and eliminate acid requirements from other sources. The matte grade also would be greatly improved by about 40%. The process used a single cylindrical reactor and a submerged Sirosmelt smelting lance in an oxygenenriched, high-intensity smelting process that was easily controlled and had considerably lower energy needs. The process also eliminated the need for a concentrate dryer, reducing energy requirements and eliminating problems associated with a

dryer. The electric furnace was to be retained, but only for separating matte and slag, since the feed into it would be molten matte and not cold concentrate. The addition of the oxygen-enriched combustion process was expected to reduce the consumption of high-cost electric power for smelting. The smelter had been affected when, in January 1990, the Salt River Power Authority increased electric power rates by more than 100%. If the necessary State and Federal approvals are obtained, startup was anticipated by mid-1992.

At yearend, Kennecott Corp. had yet to reach a final decision on modernization of its Utah smelter. Kennecott reportedly was considering an investment of \$200 million in pollution control equipment, including a double-contact acid plant by 1994, in an effort to reduce particulate emissions. Kennecott was also considering a new smelter with increased capacity since current capacity was insufficient to handle the expanded concentrate production at Bingham Canyon.

According to the company annual report, Magma Copper achieved a record smelter production of 253,000 tons of copper anode as the last of the technical problems associated with commissioning of its flash furnace were resolved. As a result, cash operating costs decreased substantially. from 80 cents per pound in the first quarter to 71 cents per pound in the fourth quarter. The flash furnace has a capacity to process more than 907,000 tons of new concentrate per year. Magma had about 21% of the copper smelting capacity in the United States and could produce more than 272,000 tons of refined copper per year. The company reported the smelter as the lowest cost smelting facility in the United States and among the lowest cost in the world; in addition, it met and exceeded all regulatory environmental requirements. The smelter operated at 100% of capacity for 1990, achieving 107% for the fourth quarter of the year. Other facilities using the Outokumpo flash smelting process reportedly undergo a furnace rebuild after processing 1 million tons of concentrates. Magma's smelter had processed more than 2.3 million tons of concentrate without a rebuild, and the company felt it would not be needed until 1992. About 903,500 tons of concentrate was processed in 1990. Magma provided 63% of feed stock.

Nassau Metals Corp., Gaston, SC, closed its secondary smelter and associated wirerod mill in August while undergoing ownership changes. Renamed Gaston Copper

Recycling Corp., the new company reopened near yearend under new ownership.

Texas Copper Corp. continued to acquire permits for construction of a new smelter in Texas City, TX. Final permits were anticipated by early 1992.

Refinery Production.—Ten electrolytic. 6 fire refineries, and 14 electrowinning plants operated during the year. Total U.S. refinery capacity was 2.47 million tons of copper. Refinery production from primary sources increased markedly as a result of increased SX-EW capacity, continued higher imports from Mexico by Magma Copper to feed its San Manuel facilities, and higher input from domestic blister. Refined copper from scrap was lower, largely owing to a temporary shutdown by one secondary plant and a decision by another plant to switch from smelting scrap at yearend. Refined imports were lower, and exports were nearly double that of 1989.

According to the company annual report, Asarco produced 437,600 tons of refined copper in 1990 compared with 447,100 tons in 1989. Asarco announced plans in 1990 to build a new, \$54 million SX-EW plant at the Silver Bell Unit near Tucson, AZ. The facility was to have a capacity of 16,300 tons per year of copper cathode.

Magma's refined copper production, excluding copper from purchased and toll concentrates, increased by 34% to 213,200 tons in 1990 compared with 158,800 tons in 1989.26 The company expected production from Magma sources to exceed 227,000 tons in 1991 owing to increased production from the Kalamazoo and Superior Mines, which began production in 1990. According to the company annual report, custom refining operations produced 89,800 tons of copper in 1990 compared with 78,926 tons in 1989. Several operating records were achieved, including an electrowon copper production of 52,600 tons, which compared with 42,200 tons in 1989. The increase was due to startup of the new well-to-well in situ leaching technology developed at San Manuel.

All three of Phelps Dodge Mining's mines achieved record SX-EW cathode production, according to the company annual report. Production from SX-EW plants comprised almost 40% of the company's total copper production and was expected to be about 45% in 1992. SX-EW production was 185,973 tons, including partner share, and increased 47% compared with that of 1989. Eventually, the

company planned for SX-EW production to comprise about 50% of its copper production. The company's electrolytic refinery in El Paso had the capacity to produce about 390,000 tons of copper cathode per year. Refinery production at Phelps Dodge facilities totaled 383,900 tons in 1990. The company also produced 55,500 ounces of gold and 2.9 million ounces of silver as a byproduct of copper mining.

Phelps Dodge was undertaking a \$9 million modernization program at the El Paso refinery. This was the first full year of production at the expanded Morenci SX-EW plant, which produced 91,000 tons of copper, according to the company annual report. The Chino Mines SX-EW plant produced about 41,000 tons of copper. A \$112 million project to expand Morenci's capacity by an additional 63,500 tons of SX-EW cathode per year was expected to begin in mid-1991 and continue through the decade. The Tyrone plant began in 1984 at 13,600 tons per year and has been expanded three times to its current 49,900-tonper-year capacity. The company planned to expand Tyrone SX-EW production in early 1992 to about 63,500 tons per year.

Other Copper Products.—Peninsula Copper Industries Inc. of Hubbell, MI, manufactured high-purity copper oxide using copper-bearing scrap in the form of electronic circuit board trimmings and copper-clad bimetallics. The bimetallic scrap is usually stainless steel or conventional mild steel that can be resold after the copper is removed. However, circuit board trimmings yield a metal-free, glass-fiber epoxy laminate that was unusable and was being sent to landfills. To resolve this problem, the firm was awarded a \$208,000 State grant to build a production-scale plastics recycling plant to process about 8 million pounds of fiberglass-reinforced board scrap per year. Peninsula pilot tested a method using a heat-cleaning process to clean the glass fiber and produced sufficient quantities for testing in plastics compounding and molding equipment. Initial results indicated that the fibers can impart reinforcement properties that compared favorably with virgin chopped strand. Peninsula was planning on doubling its copper oxide capacity, but hoped to derive much of its additional copper from the nearby Centennial Mine, currently under development. Peninsula's oxides were used as ingredients in wood preservatives for pressure-treated lumber and for other in dustrial and agricultural applications.27

Mitsui Mining and Smelting Co. announced intention to expand its electrolytic copper foil plant at Hoosick Falls, NY. Oak-Mitsui Inc., a joint venture with Allied Signal Inc., was to operate the 7,000-tonper-year copper foil plant. Mitsui Mining produced about 25% of the world's copper foil for printed circuits and other electronic uses. Prior to 1988, the United States and Canada comprised about one-third of the 60,000-ton-per-year market. Since that time, however, several Japanese companies have increased their share of the market so that by 1991, according to some analysts, the Japanese companies will collectively control about 90% of the world's production of electronic copper foil.

Copper Chemicals.-Of the many known copper compounds, only a few were used on a large scale. Copper sulfate, from a tonnage aspect, was the most important and was a feed stock for producing many other copper chemicals. Anhydrous copper sulfate (CuSO₄) is a white crystalline substance, but the usual commercial form is the pentahydrate (CuSO₄•5H₂O), which contains about 26% copper. Copper sulfate was used as an algacide and fungicide and as a source of copper for plant and animal feed. Copper sulfate was also used to activate zinc and other sulfide minerals in froth flotation, as a print toner in photography, and in dyes, galvanic cells, and antiseptics. In recent years, agricultural uses, including fungicides and animal feed, accounted for the growth in demand. Domestic apparent demand for copper sulfate was about 48,000 tons in 1990. The estimated end-use distribution of shipments from domestic producers, which accounted for about 75% of demand, was 65% for agricultural uses, 28% for industrial uses. and 7% for water treatment.

Copper carbonate, once used widely for production of wood preservatives, is now used primarily as a chemical intermediate, competing with industrial-grade copper hydroxide. Copper oxide has replaced carbonate in wood preservatives, and zinc carbonate has replaced copper carbonate in drilling muds. Copper sulfate was produced from copper scrap, blister copper, copper precipitates, electrolytic refinery solutions, and spent electroplating solutions by at least six companies. Prior to the 1970's, most domestic production was from copper mine producers, but as new production began from scrap, other production became significant. Although organic fungicides largely replaced copper fungicides

during the 1960s, greater concern for the environment has resulted in a return to increased use of copper. Copper hydroxide fungicides, first developed in the 1970's, have become favored for most fungicide applications. Copper sulfate and, in some instances, copper chloride are used as a starting material to make hydroxides; direct copper sulfate use is declining. The main U.S. markets for copper fungicides are California and Florida citrus production.

Though demand has been increasing in recent years, domestic production of copper sulfate has stabilized at about 34,000 tons per year. Thus, the market has become increasingly import dependent, as shown by the quadrupling of U.S. imports of copper sulfate, copper oxides, and hydroxides since 1985. According to the Bureau of Census statistics, U.S. imports were 380 tons of oxides and 335 tons of copper sulfate in 1970 and increased to 2,957 tons of oxides and 13,458 tons of copper sulfate in 1989. Imports of sulfate declined slightly in 1990 as domestic production increased. The largest U.S. import sources for copper sulfate have been Mexico and Peru; Australia for copper oxide; Australia and Norway for cuprous oxide pigment; and Mexico for other copper chemicals. Most U.S. exports of copper chemicals went to Canada and Far Eastern countries such as Korea, Singapore, and Taiwan. The European nations comprise the largest import market for copper sulfate. Among the world's consumers of copper sulfate, the Federal Republic of Germany was one of the largest importers, importing an average of 10,000 tons per year since 1982. Countries that have been significant producers of copper sulfate include France, Italy, Japan, Mexico, Peru, Spain, the United Kingdom, the United States, the U.S.S.R., and Yugoslavia. Japan, one of the few countries to report its production of copper sulfate, has more than doubled its

production since the early 1950's, but consumes most of it domestically. At the same time, the United Kingdom has reduced its production of copper sulfate from about 56,000 tons in 1950 (almost all was exported) to less than 10,000 tons (2,500 tons exported) in 1987.

Sulfuric Acid.—In 1990, a total of 3.96 million tons of byproduct sulfuric acid was produced, up from that of the previous year, and from 1.86 million tons in 1973, a record year of copper production. About two-thirds of all sulfuric acid production was used by the U.S. fertilizer industry. Petroleum refining and petroleum products were next in importance, followed by use in leach extraction of copper ores. Leaching of copper ores used 1.8 million tons of sulfuric acid in 1989 and 2.0 million tons in 1990. Acid for copper leaching accounted for about 8% of total acid market.28 Sulfuric acid, the waste product scourge of the 1970's, now has evolved into a more viable byproduct for many copper smelters in the United States. The domestic industry had feared oversupply when forced to install acid plants to contain sulfur dioxide emissions. The cost to neutralize the highly caustic liquid for lack of sufficient markets also was of concern. In 1990, the acid supply and demand was nearly balanced, aided by the increase in acid leaching of copper ores. For many copper producers, acid has become a viable coproduct, and they have become major suppliers; for others, however, it was still a liability. Producing the product was extremely capital intensive. The copper industry overall has had to absorb a cost penalty of about 7.5 cents per pound, according to figures from a recent U.S. Bureau of Mines study.²⁹ Retrofit capital costs were estimated to be on the order of \$150 million per facility. Overall, they were of little economic benefit, even though they

TABLE 6
COPPER SULFATE PRODUCERS IN THE UNITED STATES IN 1990

Company	Plant location			
BIT Manufacturing Inc.	Copperhill, TN.

did provide for cleaner air, a benefit that was hard to evaluate monetarily. Neutralization—a worst case scenario for the smelters—reportedly would cost about \$20 million per year. Some smelters have been in the situation where acid sales did not even cover the transportation costs. In fact, some producers of the 1970's paid part of the shipping costs in order to keep the acid moving; however, the market has improved since then for some producers. For example, Asarco has created its own acid sale force and reported that it can sell all it produces. Potential new acid supplies from the new smelter in Texas were expected to be absorbed by industry in Florida, Texas, and the Southwest.³⁰

The economics of acid production varies between producers, but most find that transportation costs are a major factor in sales. At Magma, acid production was reportedly not profitable because of shipping distances and competition. However, Magma used about 310,000 tons in the company's own leach operations; about 500,000 tons was sold under long-term contracts. The largest percentage of Magma's sales were to other mining companies for leaching ores in Arizona. Asarco used about 40% of its acid from the Hayden, AZ, smelter for leaching ore at the nearby Ray Mine Project. Kennecott sold all of its acid within the United States. The company itself used no acid for leaching. Kennecott was planning an acid transloading facility that would provide acid storage as well as serving as a distribution point to Western State area customers. Kennecott reportedly was breaking even with its acid production.31

Phelps Dodge reported that acid sales had been largely unprofitable. Costs at smelters were incurred in capturing the fugitive gases within the smelter and beyond the acid plants, and high capital and operating costs were incurred for the treatment and storage of the effluent generated from the acid plant gas scrubbing system.³²

Of concern to the copper producers was the U.S. Government's plans to increase air quality regulations. The cost to recover an additional 5% sulfur could equal the cost to recover the 90% already being recovered. One hundred percent recapture was deemed impossible by the industry. In the Clean Air legislation under consideration in Congress, additional regulation of sulfur dioxide and particulates through taxation has been proposed. The industry could be taxed up to \$60 per ton of

pollutants emitted. Costs and problems associated with capturing 90% of the sulfur were seen as manageable by industry, but further control was seen as having a serious effect on the copper smelting industry.

World supplies of smelter-produced sulfuric acid were rising and were forecast to increase much faster than that produced from native sulfur. Over the 5-year period starting in 1989, one analyst predicted that overall smelter acid production capacity would increase by 14% to almost 33 million tons per year. Smelter acid from South American countries was forecast to rise by 48% to 4.5 million tons per year, 70% of which was expected to be from copper smelters. This was considered important since smelter acid production was inflexible, deriving from a desire to produce copper, and was not related to the state of the sulfur market. In conditions of oversupply, unwanted tonnages of acid cannot sit around, but must be disposed of and will have a marked effect on overall acid market prices. This situation was forecast to occur within the next 2 to 3 years, if all new smelters under consideration come on-stream.33

Consumption

Though U.S. reported and apparent consumption for copper plummeted during the fourth quarter in response to an overall downturn in the economy, annual consumption declined only slightly. According to data compiled by the Copper Development Association (CDA), total (domestic mill shipments plus net imports) copper and copper alloy shipments to the domestic market declined by almost 4%. This followed a decline of 3% in 1989. In general, semifabricator demand for unwrought copper outperformed the market sectors in which it was consumed. For example, while annual apparent consumption for copper declined by less than 1%, housing starts declined by 13%, and investment in private and residential construction declined by 3%. Building construction was the largest end-use market for copper. The relatively strong unwrought copper demand was attributed to an increase in exports, recapture of domestic markets, and growth in the electronics and electronics product market sector. As a result, net imports of brass and wire mill products declined.

In addition to increased self-reliance on brass mill products, the 4-year trend toward increasing self-sufficiency for unwrought copper continued. Primary refined

production plus copper recoverable from old scrap accounted for more than 97% of domestic demand. During the second half of the year, the United States was a net exporter of refined copper. While eastern consumers of copper continued to import copper from Canada, western producers became significant exporters of refined copper to Asian markets. Shorter transit times and higher reliability, compared with producers in Africa and South America, encouraged Asian consumers to buy their refined copper in the United States.

According to CDA shipment data, demand for mill products in building construction, industrial machinery, consumer and general products, and transportation equipment declined by 8%, 8%, 6%, and 1%, respectively; shipments to electrical and electronic products increased by 4%. According to CDA data, building construction was the largest market sector for copper products, accounting for 40% of demand, followed by electrical and electronic products, 26%; industrial machinery and equipment, 14%; transportation equipment, 11%; and consumer and general products, 9%.

Refined copper or directly melted scrap was consumed at about 20 wire rod mills, 40 brass mills, and more than 700 foundries, chemical plants, and miscellaneous manufacturers. According to U.S. Bureau of Mines estimates, as a percentage of apparent demand, 72% of the copper used in all market sectors was consumed in electrical applications; 15% in construction; 5% in machinery; 3% in transportation; 1% in ordnance; and 3% in miscellaneous uses. Following a significant growth in electrical applications during the 1970's and 1980's, this demand pattern stabilized over the past several years.

Prices and Stocks

On average, the price for refined copper remained relatively high during 1990, though it fell below that of record-high prices set in 1989. Though volatile by historical standards, with the producer price ranging from a low of \$1.02 in January to a high of \$1.40 in September, prices were more stable in 1990 than those in 1989, when the spread between high and low was \$0.57 per pound. Domestic inventories continued to remain low throughout the year, and at the average prevailing rate of consumption, accounted for only about a 15-day supply. Thus, even small changes in availability, or perceived availability of

TABLE 7

^rRevised.

¹Copper Development Association (CDA) categories have been redistributed on a copper content basis (the alloy component has been subtracted). The electrical component has been extracted from all end-use categories except electrical and ordnance. Adjustments were also made for the new scrap component, which was subtracted. Ordinance data reflect U.S. Department of Commerce ACM military shipments to 1983; estimated data, thereafter, reflect CDA data for 1989.

copper, significantly affected prices. Prices were at the lowest level of the year in January, having fallen sharply during the fourth quarter of 1990. Prices rose during the first three quarters of the year, though prices dipped temporarily in June owing to a modest rise in the more readily visible COMEX stocks. Prices during the first three quarters of the year were buoyed by global disruptions to supply rather than by strong demand. Production shortfalls in Chile, Peru, and Zaire, along with the

continued shutdown of the Bougainville Mine in Papua New Guinea, all contributed to global tightness in supply.

The buildup in domestic inventories was moderated by changing trade patterns, the United States having become a net exporter of refined copper during the second half of the year. Increasing U.S. exports of refined copper to Asian markets resulted in continued low domestic inventories despite weak domestic consumption and record production. Though COMEX inventories

remained low throughout the year, peaking at only 20,000 tons in December, LME inventories were more sensitive to foreign supply-and-demand imbalance. LME inventories, which rose to more than 130,000 tons in November 1989, declined through the first half of 1990. In early July, with spot prices on LME exceeding those on COMEX by about 6 cents per pound, surplus copper began to accumulate preferentially on the LME, more than doubling by the end of the month to 105,000

²Includes wire and other forms used in electrical, communications, and other special usés.

³Data may not add to totals shown because of independent rounding

tons. However, this sudden rise did not have an immediate impact on world prices, as prices remained strong through September. Copper prices fell throughout the fourth quarter as world inventories rose to the highest level since 1986. Domestic demand dropped throughout the fourth quarter, demand in December being at the lowest monthly level in more than 4 years, and domestic inventories rose to the highest level of the year.

World Review

Industry Structure.—Market Summary.—World production of refined copper increased only nominally in 1990, while demand, which had risen steadily following the 1982 recession, remained unchanged. For the third consecutive year, the balance between supply and demand for refined copper remained very close. World mine production, which had been expected to rise during the year, was essentially unchanged, as production increases in the United States and Europe were offset by production shortfalls in Africa, Chile, and Indonesia.

Stocks of refined copper held on COM-EX and the LME declined slightly during the first half of the year before rallying in the second half to register a net yearend gain of about 70,000 tons. World producer and consumer inventories were estimated to have remained unchanged. Though overall stock levels increased slightly, they remained low by historical standard and represented only about a 5-week supply at the prevailing rate of consumption.

While overall world consumption of refined copper remained unchanged or even declined slightly, there were distinct regional differences. By yearend, economic recession in Canada and the United States was well documented. In the United States, weak automobile sales and a decline in new home and commercial construction led the overall economic decline. During the fourth quarter of the year the GNP declined by about 2%.

In Europe, overall copper demand was stagnant. Demand in the Federal Republic of Germany declined slightly, as a more than 2% growth in the Western states' demand was more than offset by a dramatic decline in the Eastern states. Unification buoyed demand for housing and consumer goods in the Western states, where residential construction was estimated to have increased by about 10%. The overall consumption decline in Germany was balanced

by growth in Belgium, France, and Italy. Consumption in the United Kingdom was unchanged, despite a steep decline in residential and commercial construction. Increased exports to other EC countries served to stabilize their demand.

In Asia, according to preliminary data published by the World Bureau of Metal Statistics (WBMS), demand grew by about 8%. Consumption in Japan grew by almost 9%, as demand for wire mill products surged owing to growth in residential and commercial construction and increased automobile production. Demand declined in Taiwan. Taiwan's demand had surged in 1989, owing to increased exports afforded by strikes at Korean rod producers. Conversely, Korean consumption, according to WBMS, surged by almost 30% in 1990.

Mine Production.—Despite continued projections of a significant increase in world production from new and expanded projects, mine production of copper increased by less than 1% during 1990. Significant setbacks in Africa and Chile and the continued closure of the 180,000-ton-per-year Bougainville Mine in Papua New Guinea resulted in production falling below many analyst's projections.

In Chile, mine production, which had risen continuously for more than 10 years, declined slightly, principally owing to production problems at CODELCO-Chile's four mining divisions. Production by CODELCO-Chile, the world's largest copper-producing company, declined by about 50,000 tons to 1.195 million tons. Production by CODELCO-Chile was expected to remain stable or even decline further over the next several years. At the Chuquicamata Mine, a motor fire in February placed one of four ball mills in its No. 2 concentrator out of commission for most of the year. That, coupled with mine stability problems, and a 10-day slowdown by haulage truck drivers resulted in a 25,000-ton shortfall in production. Highgrade slag piles from the Chuquicamata smelter, which were being reprocessed at the El Salvador division, were exhausted. The production decline at Chuquicamata was moderated by a concentrator expansion, completed in 1989, which had its first full year of operation.

At the El Teniente Mine, the world's largest underground copper mine, a series of three major rock bursts, beginning in January, led to the closure of sublevel six at midyear and an almost 9% (28,000 tons) drop in production. The section was not

opened until April 1991, following a \$60 million investment in concrete arch supports. As a result of the investment and lost production, the newly expanded mill operated at only about 75% of capacity, and production costs rose significantly. A permanent loss of sublevel six would have had serious implications for El Teniente as a significant portion of future production was expected to come from this area of the mine. Though final go-ahead had not been given, CODELCO-Chile was considering several new projects to compensate for declining production. The most ambitious was the 150,000-ton-per-year Chuqui Norte Project, an open pit oxide leach project 2 kilometers from the current pit. Other potential projects were: a second oxide dump-leach project and a low-grade, heapleach project at Chuquicamata; development of an open pit in the Quebrada sulfide deposit east of El Teniente; an in situ oxide leach project in the caved area above El Teniente; and expansion of Andina's concentrator and tailings capacity by onethird to 180,000 tons of copper per year.

Despite the prognosis for a decline in production from CODELCO-Chile, growth in private-sector copper production was expected to result in continued growth in Chilean mine production. La Escondida Mine began operations during the fourth quarter of the year, and the first concentrate shipments left Chile in December, approximately 6 months ahead of schedule. The mine was expected to reach its 320,000-ton-per-year capacity by mid-1991. The \$400 expansion of Exxon's Los Bronces copper project was expected to be completed by June 1992. Other major copper projects still in the formative stage, but likely to come on-stream within the next several years, included: the 75,000-ton-pervear Ouebrada Blanca oxide leach project: Rio Algom's 40,000-ton-per-year Cerro Colorado sulfide-bacterial leach project; the Zaldivar underground heap-leaching and electrowinning project, purchased by Outokumpu Oy of Finland in November 1989 and projected to produce 40,000 tons of cathode per year by mid-1993; and Phelps Dodge's large La Candelaria project, projected to produce 100,000 tons of copper per year in concentrate by 1995. A detailed engineering and feasibility study was completed for La Candelaria in May, though the project had been delayed because of a legal dispute concerning improper land claim documents.

Mine production in Canada rose substantially, owing to continuous operations at

Highland Valley, Canada's largest copper mine, where an extended strike in 1989 resulted in an estimated 56,000 tons of lost production. Increased production from a group of smaller mines that started or restarted production in 1989 also contributed to the production increase and offset closure of Noranda's Brenda Mine in June, as well as production disruptions at several other mines. Canada was the site of extensive exploration and development activity during the year. In British Columbia, Geddes Resources Ltd. continued work on its Windy Craggy deposit, where reserves of at least 165 million tons grading 1.95% copper had been identified. In October, the company announced the discovery of a new Ridge Zone, which contains additional reserves. In January, the Provincial government rejected a stage 1 environmental and socioeconomic impact assessment for the project on the basis that measures to guard against potential acid mine drainage were inadequate.

At yearend, a revised mine plan was submitted that called for expansion of underground operations at the expense of open pit mining in an effort to reduce generation of acid-generating waste rock. Windy Craggy is in a sensitive wilderness area near the Alaskan border.

Other exploration activity in British Columbia included work at the Expo and Red Dog properties near Island Copper, and the Mount Milligan property, where reserves were estimated at more than 400 million tons grading 0.2% copper. In Manitoba, Hudson Bay Mining and Smelting Co. announced the discovery of new reserves at its Trout Lake Mine, and in Ontario, Minnova Inc. discovered a deep massive sulfide deposit at its Winston Lake Mine. New reserves were also identified in New Brunswick, Newfoundland, Ontario, Quebec, Saskatchewan, and the Yukon.³⁴

In Peru, prolonged strike activity resulted in an 11% drop in mine production and an even greater drop in refined production. Southern Peru Copper Corp.'s Toquepala and Cuajone Mines were closed for more than 50 days over the March-May period, and Tintaya was closed for 26 days in March and April. Centromin Peru's Cobriza Mine was closed for a week in October, and Minero Peru's Cerro Verde Mine was closed for almost 4 weeks beginning in mid-August.

In Mexico, production rose owing to the continuous operation of the Cananea open pit, which had been closed for several months in 1989 when the Government

declared the mine bankrupt, shut the mine, and dismissed the workers. After three failed attempts over the past several years, the Government was successful in selling the assets of Cia Minera de Cananea to a partnership between Grupo Industrial Minera Mexicana (79%), owner of Mexico de Cobre, which operates Mexico's La Caridad Mine, and Acec-Union Miniere of Belgium. The sale price was reported to be \$475 million in cash.

In Papua New Guinea, the Bougainville open pit remained closed throughout the year. Initially closed in May 1989 owing to rebel activity, the mine was placed on care and maintenance in January 1990. Peace talks were scheduled to resume in January 1991 following removal of a Government economic blockade of the island, though there was little optimism regarding the near-term reopening of the mine.

In the Philippines, mine production declined slightly from the low level of the previous year as natural disasters continued to plague production. An earthquake in Benguet Province on Luzon forced the closure of Philex Mining's Santos Tomas Mine in July for 9 days, and typhoons caused a second closure in August. In November, a typhoon resulted in the shutdown of Atlas Consolidated Mining's operations on Cebu Island. Production was not fully restored until the end of December. Near yearend, Marcopper announced that its Tapian copper mine will close prematurely in 1991, about 1 year earlier than anticipated. The 26,000-tonper-year San Antonio Mine, which was under development and would replace the lost capacity at Tapian, was not expected on-stream prior to the shutdown of Tapian. At yearend, Marcopper was seeking the necessary \$40 million to complete development of San Antonio.

In Indonesia, production from Freeport-McMoRan Copper Co. Inc.'s Ertsberg complex rose significantly, with startup of production of the new Grasberg coppergold ore body. In November 1989, Freeport announced that it had secured \$550 million in financing for debt restructuring of Freeport Indonesia Inc. and mine expansion. By the third quarter of 1990, a first stage mill expansion, from 20,000 to 32,000 tons of ore per day, had been completed, and work was underway to further expand production to 52,000 tons per day. Proven reserves at Grasberg continued to be expanded, with 10.9 billion pounds of payable copper having been identified by midyear.

By the end of the third quarter, Grasberg was accounting for 45% of the ore milled at the Ertsberg complex.

In Europe, the major mine development was the increased production from Portugal's Neves Corvos underground mine. Neves Corvos, which started in 1988, produced 55% more copper in concentrate than during 1989, according to the RTZ Corp. annual report. RTZ, which owned 49% of Neves Corvo, has emerged as the world's leading international copper mining company with ownership of the Bingham Canyon Mine (100%) in the United States and interests in other major copper mines in other countries, including Bougainville (26%), La Escondida (30%). Highland Valley (17%), and Palabora (39%). The large increase in Neves Corvo production in part reflected the startup in the first quarter of 1990 of a copper-tin recovery plant, which had a capacity to produce 35,000 tons of copper in concentrate per year.

In Africa, mine production fell sharply owing to problems in Zaire. A cave-in in September at the Kamoto Mine of La Generale des Carrieres et des Mines du Zaire (Gecamines) resulted in the loss of about 50,000 tons of copper production. The mine, which had a capacity of 150,000 tons of copper per year, had accounted for about 30% of Gecamines production. At yearend, the mine was reported to be operating at about 15% of capacity, and the outlook for early restoration of production was bleak.

Mine production of copper in centrally planned, or formerly centrally planned economy countries, was relatively stable during 1990, having fallen significantly the previous year. Production probably declined in Bulgaria owing to the reported closure of the Medet Mine, though preliminary estimates for Bulgarian production indicated no decline. Environmental pressure at the smelters and refiners and opening of centrally planned economy countries to free market forces was expected to result in a near-term decline of copper mine production in those countries.

Mine production in Australia increased owing to increasing production from Olympic Dam, which began production during 1989, and new production from several smaller byproduct mines. The largest of the byproduct mines was the Thalanga copperlead-zinc mine, which began production in February. Thalanga, a joint venture between Pancontinental Mining Ltd. (50%), Agip Australia Pty. Ltd. (25%), and

Outokumpu Australia Pty. Ltd. (25%), was expected to produce about 10,000 tons per year of copper in concentrate over 20 years. Additional capacity was expected onstream in 1991 when the Boddington Project in Western Australia, Australia's largest gold producer, begins production of about 3,500 tons per year of copper in concentrates at its new flotation plant. Olympic Dam was considering a stage 2 expansion, which would boost capacity by about 20,000 tons.

Smelting and Refining.—Concern over the adequacy of world smelting capacity became a significant issue during 1990. World copper mine production was expanding with the opening of several major mines and the incremental increases in U.S. capacity. Smelter closures in the United States during the early and mid-1980's resulted in a deficit of domestic smelting capacity and the transformation of the United States to a significant exporter of copper concentrates. Though some countries in Africa and South America were experiencing setbacks in mine production, the remote location of their smelters resulted in only limited smelting capacity availability for other mines. In recent years, Zambia has been toll smelting a small amount of concentrates for Zaire.

Spot treatment and refining charges, which had been high by historical standards during most of 1989 owing to a surplus of concentrates, began to decline at yearend. The sustained closure of the Bougainville and other supply disruptions helped sustain lower prices through midyear, but by yearend, world stocks of concentrates showed signs of increasing, and spot treatment and refining charges in Japan, as reported by the Commodities Research Unit Ltd. of London, began to rise. Charges, which had dipped below 14 cents per pound during the second quarter, rose to more than 22 cents per pound by yearend. With the opening of La Escondida Mine at yearend and incremental expansions at several other major concentrate exporting mines, the concentrate surplus was expected to increase in 1991, along with treatment and refining charges.

Numerous new smelter or expansion projects came under consideration throughout the year. In the United States, Texas Copper Corp., a subsidiary of Mitsubishi Metal Corp., continued to seek the water and air discharge permits necessary to construct a 180,000-ton-per-year Mitsubishi continuous smelter in Texas City,

TX. Startup, initially scheduled for 1991, continued to be delayed by the permitting process. In Utah, Kennecott was considering alternatives, including total replacement, for its Noranda-type smelter, which had insufficient capacity to process Bingham Canyon's expanded capacity and was also facing increasingly stringent State environmental regulations. Other domestic smelter projects included furnace replacement at Asarco's El Paso smelter and renovation and expansion at Cyprus's Miami, AZ, smelter. In Chile, where significant growth in mine capacity has and is expected to continue to occur, both CODELCO and ENAMI pursued options for joint development with the private sector for new smelter capacity. ENAMI was considering expanding its Paipote smelter by 70,000 tons per year. In December, following completion of a joint feasibility study for a 200,000-ton smelter by RTZ, BHP, CODELCO, Anglo American, Outokumpu, and Billiton Metals, RTZ and BHP announced withdrawal of their support for the project. Higher-than-projected construction costs led to economic infeasibility, given prevailing treatment and refining charges. By yearend, it appeared that a similar option was still being considered by ENAMI and Brazilian, Chilean, and Canadian private interests. A feasibility study was to begin in 1991. Cia Minera Disputada de las Condes, which operated the 44,000-ton-per-year Chargres smelter, was reported to be studying the feasibility of expanding capacity to 125,000 tons. Increased production from its Los Bronces Mine, scheduled to come on-stream by 1992, would boost Disputada's concentrate production to about 200,000 tons of contained copper per year. Disputada currently markets its excess concentrate production. In Brazil, Cia Metalquimica do Maranho Ltda. (CMM) planned to construct a 100,000-ton-per-year smelter-refinery complex at Sao Luiz de Maranho to coincide with the 1993 startup of the Salobo Mine near Carajas. A planned expansion of Caraiba Metais' smelting-refining capacity, from 168,000 to 225,000 tons per year, was postponed indefinitely owing to depressed domestic demand. In addition, Brazilian tariff reductions on imported refined copper from 10% to 5% in October, with the tariff on imports from Chile and Peru being only 25% of the general tariff rate, adversely impacted Caraiba's treatment and refining margins.

Several other countries were also investigating the possibility of building

smelters to accommodate new or expanded mine production. In Portugal, Outokumpu, along with a consortium of seven Portuguese companies, was studying the feasibility of building a 200,000-ton-peryear Outokumpu smelter, scheduled for startup in 1994. Outokumpu, the Portuguese Government, and private Portuguese companies each would have a onethird interest in the operating company Metalurgia do Cobre Lda. (METCOB). About one-half of the smelter feed would come from the Neves Corvo Mine. In Indonesia, Metallgesellschaft, Freeport, and the state-owned petrochemical company, PT Petrokimia Gresik, were reportedly investigating the construction of a 120,000-ton-per-year smelter to handle expanding production from Grasberg. In Thailand, Padaeng Industry Co., in partnership with Mitsubishi, Mitsui, and Mount Isa Mines Co., was undertaking a feasibility study for construction of a 150,000-ton-per-year smelter, which would depend entirely on imported concentrate. In Canada, a feasibility study funded by local business and Federal and Provincial governments concluded that construction of a 200,000-ton-per-year copper smelter near the Alcan aluminum smelter in Kitimat, British Columbia, was economically viable. However, though determined to be economic and well-positioned to process local concentrates and export copper to Asian markets, some concerns were raised over possible environmental impact and markets for byproduct acid production. In Mongolia, the Government was soliciting financial assistance from Japan to construct a 60,000-ton-per-year smelter to treat about one-half of the concentrates produced at the Erdenet Mine.

Several existing smelters were undergoing or expected to undergo expansions. In the Philippines, Government approval was given to expanding capacity at the PASAR smelter and refinery from 138,000 tons per year to 172,000 tons per year.

In Australia, CRA Ltd.'s Electrolytic Refining and Smelting Co. of Australia Ltd. commissioned a new 80,000-ton-per-year smelter in March 1991 and officially changed its name to Southern Copper Ltd. The smelter replaced a 40,000-ton-per-year smelter that closed in September 1990. Startup had been delayed by about 6 months owing to labor, weather, and equipment problems. At the Mount Isa smelter, replacement of the reverberatory furnace with an Isamelt unit was planned for 1992. The new furnace was expected to boost

capacity by 15,000 tons of copper per year. In Japan, Mitsubishi began reconstruction of its Naoshimi smelter, where it was replacing two furnaces with a Mitsubishi system that would equal the 17,000 tons per month of combined capacity for both existing furnaces. Though no overall increase in capacity was announced, production costs were expected to be reduced by 20% to 40%. Modifications were planned at several other Japanese smelters that would collectively increase capacity by about 60,000 tons per year. In Hamburg, Germany, Norddeutsche Affinerie Aktiengesellschaft (NAA) was planning to replace its blast furnaces with an electric furnace that would boost its scrap-handling capacity by about 60,000 tons per year. In March, Taiwan's 50,000-ton-per-year Taipower smelter was closed owing to protests over sulfuric acid emissions. It appeared that the smelter would remain closed indefinitely. The 30,000-ton-per-year smelter planned for the Saindak, Pakistan, project was delayed owing to financial problems relating to infrastructure that was to be provided by the Pakistan Government. If the Government cannot build a powerplant by 1992, a fee of \$15,000 per day will be owed under contract to the Metallurgical Construction Corp. (MCC) of China, which is constructing the smelter.

Capacity.—Compared with that of 1989, world mine capacity increased by only 1.6%, smelter capacity by 3%, and refinery capacity by 2.7%. Copper mine, smelter, and refinery capacity for 1990 is shown in table 8. World capacity utilization (83%) at mines continued to be low in 1990, owing to continued disruptions at mines, discussed in the previous section. Since 1974, average annual world mine production has ranged between 79% and 85% of available capacity, being highest during periods of peak demand and low available capacity, such as existed in 1987, a year of high-capacity (85%) utilization.

The data in table 8 are rated annual production capacity for mines, smelters, and refineries as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routing operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author,

can be brought into production within a short period of time with minimum capital expenditure.

Capacity at mines represents the potential copper production contained in concentrates for many producers, but for some major producers—such as Chile, the United States, and Zambia—it represents copper recoverable at the smelter level, based upon known recovery factors. SX-EW capacity is counted as smelter-level capacity only when the material must be further refined. It is otherwise counted as mine and refinery capacity, bypassing the smelter level. Past and present production potential are taken into consideration when rating a mine, especially where an engineering estimation is not available or seems inappropriate in the case of decreased ore grades. Generally, the rated capacity is based upon 360 days per year and 2 to 3 shifts per day. For new facilities, capacity is prorated for the year in which it started, but the full capacity is used for the year in which a facility closes. Mines and plants generally are not counted if they are not operating at any time during the year, except where it may be reasonably expected that a shutdown may be temporary, i.e., usually less than 2 years. The closed mine at Bougainville, Papua New Guinea, was not counted as available capacity during the year, because its closure has exceeded 2 years. The cost to reactivate this mine was considered almost that of a new mine, and so clearly falls into the long-term closure category.

Reserves.—The definitions for reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals." In this system, the reserve base is the measured plus indicated (demonstrated) resource from which reserves are estimated. Reserves are that part of the reserve base thought to be economically recoverable with existing technology at operating or developing properties. Among individual countries, Chile (22%) has the largest share of the reserve base, followed by the United States (16%), the U.S.S.R. (9.7%), and Australia (7.3%). Peru, Zaire, and Zambia also have large copper reserves, with about 5% each.

More than 90% of U.S. copper reserves was in five States—Arizona, Michigan, Montana, New Mexico, and Utah. The U.S. Geological Survey estimated total world land-based copper resources, composed of the reserve base and a larger body

of less well characterized resource, was about 1.6 billion metric tons. Copper reserves reported at operating or developing properties were sufficient to meet a project cumulative demand of almost 118 million tons of primary copper through the year 2000. In addition, some of the material already identified in the reserve base, which was presumed to be uneconomic to mine, may become economic with new technology and/or higher copper prices. However, the rate of increase in the reserve base has declined since 1976. The world reserve base, including measured and indicated ore, increased by about 140% from 1965 to 1976, corresponding to a 56% growth in world production and 48% growth in consumption over the same period. Since 1976, however, the reserve base has increased by only 18% and production by only 24%, while consumption grew by an impressive 39%. Since the late 1970's the preoccupation with gold exploration and general neglect of base metal exploration led to a significant decline of reserves in Canada, Peru, the Philippines, and other countries. Unless substantial new discoveries are made immediately, some countries' output will decline by the late 1990's.

OUTLOOK

Trends in Consumption

U.S. refined copper consumption was almost 1% lower than that in 1989, reflecting the effects of depressed domestic construction, automobile, and other markets during the last 3 months of the year. World demand, on the other hand, increased by 1.2% compared with that of 1989. Demand growth rates for select periods within the 1950 to year 2000 time span have varied significantly, as shown in table 10.

Temporary, extreme changes in growth rates have occurred in response to war time demands, development and reconstruction efforts, and economic recessions. Growth rates in the United States have reflected these extremes over the years, but have generally continued along the longer term growth rate (1950-88) of 1.35% per year. As a result of the 1990-91 recession, U.S. consumption is anticipated to drop below the average growth trend line, but then is expected to rebound, resulting in an average annual growth rate of 1.96% between 1990 and the year 2000. World demand, on the other hand, while slowed by

the recession, is expected to average a 2.9% growth annually over the next decade. The lower growth rates typical of the 1970's and 1980's are not expected to prevail. Contrarily, there were many reasons to assume that copper consumption would follow higher growth rates than the previous two decades, as discussed below.

Any analysis of copper consumption at regional and country levels needs to recognize that the figures reported reflect the level of copper fabricating activity rather than that of "final" consumption by the country's society. Measured copper consumption at the semifabricate level does not take into account imports or exports of semifabricates or, more importantly, of manufactured goods containing copper. Since the early 1970's, copper consumption rates in the United States have been affected by loss of domestic market share to imports. The United States has been a net importer of copper semifabricates and of manufactured goods containing copper. A true measure of "societal" or per capita demand for copper would include copper contained in net imports of these goods. Countries such as Belgium, Germany, and Japan, and other net exporters of copper semifabricates should have their societal consumption reduced by these items. A recent study³⁵ by the University of Arizona indicated that the U.S. societal consumption could be increased in 1985 by as much as 500,000 tons of copper owing to imports of copper in semifabricates and finished goods. The sharp rise and subsequent fall in Japanese copper consumption in 1984 and 1985, respectively, reflected in part changes in the level of copper wire exports. A considerable part of world production

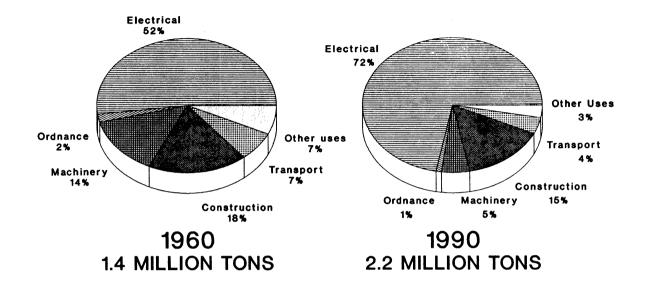

and trade in semifabricates takes place between developed countries. The less developed countries (LDC's) tend to be net importers of semifabricates.

Although consumption has been reduced in many traditional end uses owing to substitution, downsizing, and changes in technology, copper consumption for all electrical uses has expanded significantly, both in total amount as well as in percent market share. In the United States, as shown in figure 1 and table 6, copper in all electrical uses has expanded market share from 52% in 1960 to more than 70% in 1990. Not only was there no suitable substitute for copper in many of these uses. but there has been a proliferation of electrical gadgetry of all types. For example, while the nonelectrical uses in automobiles, such as in radiators, have decreased significantly, copper used in the wiring harness has been enough to actually increase the total amount of copper used per vehicle. This change in makeup of copper end-use distribution has had several effects. including an influence on the availability of old scrap and on the tight correlation of total copper consumption with the gross private domestic investment (GPDI) trend for the United States. The electrical sector historically has shown the highest correlation with the GPDI among all copper enduse sectors. A high demand for copper products is associated with the high standard of living associated with increased electrical uses.

Another way of looking at copper demand and its association with standards of living is to compare copper demand with population growths, as shown in figure 2. U.S. per capita demand for copper, while

FIGURE 1

U.S. COPPER CONSUMPTION, BY END USE, PERCENT OF TOTAL, 1960 AND 1990

Source: U.S. Bureau of Mines, Sept. 1991

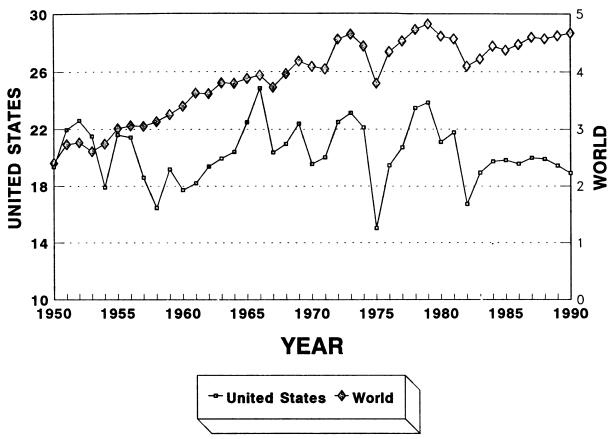

significantly affected by periodic recessions, has remained remarkably stable despite substitutions and loss of industry capacity to imports of manufactured goods. Global per capita use of copper, on the other hand, has exhibited an almost steady increase of 1.66% per year between 1950 and 1990. If this long-term growth trend in copper per capita demand continues, population pressure alone could result in requirements for about 15.7 million tons of copper in the year 2000, significantly above the current forecast. In recent years, per capita copper growth in demand has been less than 1% per year; if these lower rates prevail, demand in 2000 might be somewhat lower than the long-term trend would indicate. At the same time, however, the noticeable gap between the average 4.7 pounds per person consumed for the world and the 20 pounds per person for the United States illustrates the considerable growth potential for attaining an equivalent standard of living.

Trends in Supply

Based on the optimistic capacity projections, shown in table 11, world mine production, estimated at 85% of this capacity, could exceed 11 million tons of copper by 2000, with Chile and the United States contributing 21% and 17%, respectively. Most of the increases in mine capacity will be in South and North America, with Chile being the most important source. In Chile, several new projects are slated for development over this period, as well as anticipated mine expansions at mines such as Escondida, which may be expanded to nearly twice its original size. In the United States, expectations are that only a few new mines will be brought on-stream within this period. Several in Arizona, Montana, and Wisconsin are under consideration. In Canada, several projects are projected for this period, but some, such as Windy Craggy, could be delayed or even halted by strong environmental objections. Australia, Indonesia, and Papua New Guinea are also expected to markedly increase their respective shares of world mine capacity. Small shares are indicated than at present for Canada, Peru, Zaire, and Zambia. Most capacity in the year 2000 will come from mines now operating or being developed. The forecast capacity of table 11 is optimistic in that about 11% of the projected capacity for 2000 is highly speculative, and if successful, will come from deposits currently in exploration stages. These are known deposits that do not have firm commitment for development or financing, and their production status only can be postulated. Some reopened capacity from currently closed or uneconomic mines is also included for this period. World copper capacity from SX-EW production will increase to about 13% of total mine capacity compared with about 10% in 1992.

Historically, old scrap consumption for the world has averaged 18% of world demand, and it is dubious that this rate will

FIGURE 2
U.S. AND WORLD PER CAPITA DEMAND

Source: U.S. Bureau of Mines and Bureau of the Census, May 1991.

change over the forecast period. Primary copper has contributed more than 80% of world copper demand. The U.S. scrap resource from items in service is estimated to exceed 69 million tons or 38% of the world's total scrap resource. The rate of old scrap recovery, however, is limited by copper's long service life and use in durable goods. Historically, the largest smelters and refiners have been in or near the large refined copper-consuming industrialized countries to support their manufacturing industries. Since the early 1970's, however, several Asian and South American countries have been increasing their refined copper production capacity. The largest producer in Asia is Japan, followed by a rapidly growing China. In South America, the largest producer is Chile, which has developed its refined capacity principally for export. Australia has also begun to develop its refined copper industry in

recent years. The copper industry of central Africa, because of its isolated location, size of the mine production, and energy availability, developed smelting and refining facilities early in its mine development period; its production is mostly exported. Elsewhere, however, with ready access to ports, low-cost ocean transport, and lacking energy resources necessary for economic operation of a smelter and refinery, many mine-producing countries were initially encouraged not to develop downstream processing. This was further promoted by industrialized countries with poor copper resources that have invested heavily in mine development in other countries in order to ensure long-term concentrate supplies. This has resulted in significant Japanese and European ownership of the world's copper mines. However, as environmental requirements become more stringent in the industrialized nations and the mine-producer nations strive to develop their manufacturing industries, it is anticipated that there will be an increased move to build new smelters and refineries nearer to the mine source. Building a new greenfield smelter may be perceived as more affordable where the process of permitting is quicker and easier.

Forecast Supply and Demand Trends

The major refined copper-consuming countries, or areas, of the world in 1990 were Western Europe (28.5%), the United States (19.1%), Japan (14%), the U.S.S.R. (10.2%), and China (5.3%). Copper demand was forecast to grow at a 1.97% rate in the United States and at a 2.66% rate in the world between 1990 and 2000. While consumption in Europe, Japan, and the United States was expected to increase at a relatively lower rate, other countries were

expected to surpass these rates as their economies develop. The Asian and South American markets were forecast to show the fastest growth in copper manufactures during the 1990's, as shown by the consumption trends of figure 3. Between 1975 and 1990, demand for refined copper in Asia, the majority of which was composed of Japan (59%), rose by an impressive 176% to reach 2.6 million tons. The 20% growth in U.S. semifabricate production since 1975 seems negligible compared with that of the Asian countries. Japanese growth in copper consumption began in the late 1960's, whereas Korea and Taiwan started in the 1980's. Refined copper production and consumption in Japan and other Asian countries were developed largely to feed growing export-oriented semifabricate and manufacturing industries. These goods were largely destined for North American and European markets.

In 1990, the top importers of semifabricates were France, Germany, Italy, and the United States. Production of semifabricates in Japan totaled 2.3 million tons in 1990, but imports of like items were only about 33,000 tons while exports were 166,000 tons. U.S. net imports of brass mill semifabricates have increased steadily since the 1950's, as shown in figure 4. However, since 1984, this trend has been reversed, with domestic mills recapturing some domestic markets as well as increasing exports. The United States, while producing 2.7 million tons of copper and brass mill products in 1990, imported 195,000 tons while exporting 118,000 tons. This contrasts with U.S. imports of 247,827 tons and exports of 58,950 tons in as recent as 1987. U.S. exports of copper semifabricates have been largely to Canada, Mexico, and Europe.

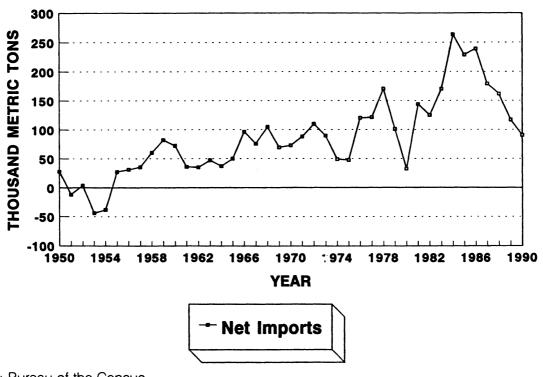

New opportunities for international trade in semifabricates, such as wire, bar, rod, sheet, and tube, will occur in the LDC's and developed countries alike over the forecast period. According to a United Nations

FIGURE 3
WORLD REFINED COPPER CONSUMPTION, PERCENT OF WORLD TOTAL, IN 1990 AND 2000

Source: U.S. Bureau of Mines, Sept. 1991.

FIGURE 4
U.S. NET IMPORTS OF COPPER AND BRASS MILL PRODUCTS

Source: Bureau of the Census. (Copper wire rod is excluded.)

report, many LDC's have become growing importers of semifabricates.³⁶ Developing country imports of semifabricates rose from an average of 90,000 tons gross weight in the 1970's to almost 400,000 tons in the early 1980's and made up most of the increase in world trade in these products over this period. Japanese imports of semifabricates also were anticipated to increase further because of increasing domestic production costs and a growing domestic consumption in all sectors, but especially the electrical sector.

Some restrictions on the demand growth also will continue over the short term. The North American, or world recession, will have a negative short-term effect on demand for copper because real industrial growth will be restrained. Political, monetary, and social problems for some of the African, East European, Southeast Asian, and South American countries could continue and could intensify further. Consumption in these countries, therefore, could be expected to exhibit minimal growth. However, world prospects for

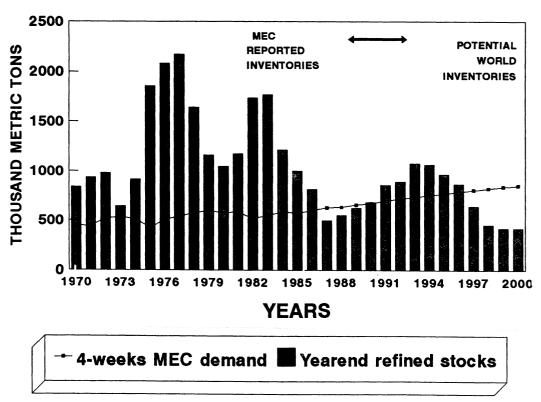

strong, continued growth in copper consumption can be anticipated as most nations continue to improve their standard of living. The domination of copper in the many electrical and electronic applications of modern society will counterbalance the effects of substitution by other materials in some uses. The main deterrent for growth would be that of economic stagnation.

The projected balance between supply and demand forecasts is shown in figure 5. Estimated refined inventories are compared to projected average monthly MEC consumption. This forecast indicates a period of inventory surplus over the period 1992-96. The current economic recession may heighten or lengthen the period, but it is expected to be of relatively short duration as consumption rises to exceed increased copper production. The near-term period of oversupply will be followed by a renewed period of supply deficit as available mine production capacity proves insufficient to meet demand growth, as a result of mine closings, decreased ore grades at some mines, and a lack of major expansions or new projects planned for the late 1990's. Projected cumulative mine production over the next 10 years might reach 113 million tons, but this optimistic goal is still 5 million tons short of the demand forecast for the same period.

Fully 21% of future world supply in 2000 must come from new deposit production. It takes between 5 and 12 years for planning, developing, commissioning, and achieving capacity for a new copper mine. In projecting supply, it was also assumed that mine development, expansions, and production would occur in an orderly fashion with few impediments. However, if the past few years are any example, numerous obstacles could reduce production below forecast production and further exacerbate the projected deficit. Obtaining environmental clearances and mining permits can delay project development for months, if not years. Uncertainty and disruption of supply has been a hallmark of copper production over history. Because almost 60% of MEC mine capacity is composed of 29 mines of greater than

FIGURE 5

REFINED COPPER INVENTORIES AND AVERAGE MONTH'S MARKET ECONOMY COUNTRY (MEC) DEMAND

Source: U.S. Bureau of Mines, Oct. 1991.

100,000-ton-per-year size each, a temporary mine shutdown can have significant impact on the market. There is currently no emergency stockpile of supplies, such as existed in the U.S. Government stockpile during the 1960's during the crisis years of the Vietnam war. Many market, monetary, and governmental regulatory problems are also on the horizon. Some trade practices in copper scrap, for example, may be hampered by regulations emanating from the Basel Convention.

eEstimated. PPreliminary. Revised.

Data represent copper content by analysis of concentrates produced except where otherwise noted. Table includes data available through June 28, 1991.

²Reported figure.

³Less than 50 tons.

⁴Copper content of pelletized nickel-copper matte produced in smelter.

⁵Anode copper recovered in Canada from domestic concentrates plus exports of payable copper in concentrates and matte.

Recoverable copper content by analysis of concentrates for export plus nonduplicative total of copper content of all metal and metal products produced indigenously from domestic ores and concentrates; includes leach production for electrowinning in Chile and Portugal.

⁷Copper content of cement copper. Includes copper content of pyrite for 1989-90.

⁸Recoverable content.

⁹Includes copper content of pyrite.

¹⁰Includes electrowon from concentrates roast-leached.

¹¹Copper content by analysis of ore mined.

¹³Data may not add to totals shown because of independent rounding.

eEstimated. PPreliminary. rRevised.

¹ This table includes total production of copper metal at the unrefined stage, including low-grade cathode produced by electrowinning methods. The smelter feed may be derived from ore, concentrates, copper precipitate or matte (primary), and/or scrap (secondary). To the extent possible, primary and secondary output of each country is shown separately. In some cases, total smelter production is officially reported, but the distribution between primary and secondary has been estimated. Table includes data available through June 28, 1991.

²Argentina presumably produces some smelter copper utilizing its own small mine output together with domestically produced cement copper, and possibly using other raw materials, including scrap, but the levels of such output cannot be reliably estimated.

³Reported figure.

⁴Data include electrowon production; estimated to be 35,000 to 45,000 tons per year that is fire-refined and cast into wirebars; detailed data are not available.

⁵Data may be for year ending Mar. 20 or beginning Mar. 21 of year stated. Only estimated production data are available. Secondary production is estimated to be about 5% of total.

⁶Figures for U.S. primary smelter production may include a small amount of copper derived from precipitates shipped directly to the smelter for further processing; production derived from electrowinning and firerefining is not included. Copper content of precipitates shipped directly to smelter are as follows, in metric tons: 1986—79,031 (revised); 1987—70,136 (revised); 1988—49,299 (revised); 1989—34,485; and 1990—19,817. Production from scrap prior to 1984 excludes data from secondary smelters processing only scrap.

7For fiscal year beginning Apr. 1 of year stated. Electrowon is total electrowon production reported, less the quantity reported as "finished production, leach cathodes." (See table 38).

⁸Refined figure; unrefined data not available. Includes production from low-grade electrowon cathodes produced in nickel processing.

⁹Data may not add to totals shown because of independent rounding.

eEstimated. PPreliminary. Revised.

¹This table includes total production of refined copper, whether produced by pyrometallurgical or electrolytic refining methods and whether derived from primary unrefined copper or from scrap. Copper cathode derived from electrowinning processing is also included. Table includes data available through June 28, 1991.

²Reported figure.

³Data may not add to totals shown because of independent rounding.

⁴Includes leach cathode from Zaire, which is processed.

⁵May include secondary.

⁶Excludes leach cathode exported for reprocessing in Belgium.

Data are for fiscal year beginning Apr. 1 of that stated. Electrowon covers only presumably high-grade cathodes reported as "finished product leach cathodes." Other, in addition to electrorefined cathodes, includes "finished product shapes" presumably cast from electrorefined cathodes, high-grade electrowon cathodes, or any blister-anodes and low-grade electrowon cathodes that were furnace- or fire-refined.

⁸May not include copper-nickel matte (copper content more than 6,000 tons per year) imported from Botswana for toll refining in 1986-89.

DIATOMITE

By Lawrence L. Davis

Mr. Davis, a physical scientist with 35 years of industry and U.S. Bureau of Mines experience, has been acting commodity specialist for diatomite since 1989. Domestic survey data were prepared by Blanche S. Hughes, mineral data assistant; the international data table was prepared by Audrey Wilkes, international data coordinator.

.S. sales of processed diatomite increased 2% to 631,000 metric tons valued at \$138 million. Seven companies processed diatomite at 11 plants in 5 States. California continued to be the leading State, followed by Nevada, Oregon, Washington, and Arizona. Major domestic producers were Manville Products Corp., with operations at Lompoc, CA; Grefco Inc., Dicalite Div., at Lompoc and Burney, CA, and Mina, NV; Eagle-Picher Minerals Inc. at Sparks and Lovelock, NV, and Vale, OR; and Witco Corp., Inorganic Specialties Div., at Quincy, WA. Other producers were Whitecliff Industries, Mammoth, AZ; CR Minerals Corp., Fernley, NV; and Oil-Dri Production Co., Christmas Valley, OR.

DOMESTIC DATA COVERAGE

Apparent domestic consumption of processed diatomite increased slightly to 488,000 metric tons. The major use of diatomite was in filtration to separate suspended solids in liquids. In 1990, domestic and export sales of filter-grade diatomite were 451,000 tons, slightly more than in 1989. Sales of diatomite as a filler, the second largest use, were about 90,000 tons, virtually the same as for 1989.

The average unit value of sales for processed diatomite was \$219 per ton, slightly less than in 1989. U.S. exports of processed diatomite were 144,000 tons, about 5% more than in 1989. The average unit value was \$293 per ton compared with \$302 per ton in 1989. Diatomite was exported to 72 countries. The following countries combined received 50% of the total exported: Canada, 20,600 tons; Japan,

Insulation	3	2	2	3	4
Other ²	13	13	12	11	11

¹ Includes exports.

16,300 tons; the Federal Republic of Germany, 13,200 tons; France, 11,100 tons; and the United Kingdom, 10,500 tons. U.S. exports represented 23% of domestic production. Imports of diatomite were 689 tons, of which 94% was supplied by Mexico.

OUTLOOK

World production was estimated to be 1,838 billion tons in 1990. The United States remained the world's leading producer, followed by Romania, the U.S.S.R, and France. These four countries accounted for 75% of world production.

FELDSPAR, NEPHELINE SYENITE, AND APLITE

By Michael J. Potter

Mr. Potter, a physical scientist with 24 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for feldspar since 1976. Domestic survey data were prepared by Linder Roberts, mineral data assistant; and international data table was prepared by Virginia Woodson, international data coordinator.

eldspars are major components in most igneous rocks and constitute a large part of at least the outer layers of the Earth and its moon. Feldspar, usually of the potash or soda type or in mixtures of the two, finds its principal end uses in the manufacture of glass and ceramics. Feldspar acts as a flux and lowers the melting temperature of a ceramic mixture. In glassmaking, feldspar provides a source of alumina, which enhances the workability of the product and increases its chemical stability.

Feldspar consumption in glass containers and pottery remained flat during the first half of 1990 and decreased in the second half of the year. Feldspar use in glass containers has been affected by mergers and consolidation of glass manufacturers, increased use of recycled glass (cullet), and competition from imported nepheline syenite. Fewer housing starts in 1990 resulted in reduced feldspar demand in whiteware such as plumbing fixtures and tile.

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on feldspar that are consistent with international usage, will henceforth report data in kilograms and metric tons unless otherwise noted.

DOMESTIC DATA COVERAGE

Domestic production data for feldspar are developed by the U.S. Bureau of Mines by means of a voluntary survey. Of the 13 active operations, 9 operations responded, representing 69% of the total canvassed. These nine respondents reported a production of 474,000 tons or about 75% of the total domestic production shown in table 1. The estimated production of nonrespondents, 158,000 tons, was derived from past years' production levels and trends.

BACKGROUND

Definitions, Grades, and Specifications

Feldspar is the general term used to designate a group of closely related minerals, especially abundant in igneous rocks and consisting essentially of aluminum silicates in combination with varying proportions of potassium, sodium, and calcium. The principal feldspar types are orthoclase or microcline, both $K_2O \cdot Al_2O_3 \cdot 6SiO_2$, and anorthite, $CaO \cdot Al_2O_3 \cdot 2SiO_2$. Specimens of feldspar closely approaching these ideal compositions are seldom encountered in nature, however, and nearly all potash feldspars contain significant proportions of soda feldspar. Albite, or soda feldspar, and anorthite are the theoretical end members of a continuous compositional series known as the plagioclase feldspars, none of which is ordinarily without at least a minor admixture of potash. Commercially speaking, "potash spar" is feldspar containing 10% or more K_2O ; "soda spar" contains 7% or more Na_2O .

Perthite is the name given to material consisting of orthoclase or microcline and containing crystals that are intergrown with crystals of albite. Most of the feld-spar of commerce can be classified most correctly as perthite.

Alaskite is a relatively coarse-grained,

granite-like feldspar ore that occurs in the Spruce Pine district of North Carolina. The principal mineral ingredients of this ore are approximately 45% plagioclase, 25% quartz, 20% microcline, and 10% muscovite mica. Minor amounts of other minerals are also present. Beneficiated feldspar from alaskite is a major portion of total U.S. feldspar output.

Feldspar for glass manufacturing, ordinarily ground to 20 to 40 mesh, usually contains 4% to 6% K_2O , 5% to 7% Na_2O , and approximately 19% Al_2O_3 . Material for this purpose may be sold as a feldspar concentrate low in free quartz or in the form of a mixture containing feldspar and quartz with harmful impurities removed. In glass-grade feldspar, the iron content, expressed as Fe_2O_3 , is approximately 0.08% for high-quality clear glass. Typically, 70 to 90 kilograms of ground feldspar is used to produce 1 ton of container glass.

Feldspar with a high potash-to-soda ratio is often preferred for pottery making, and spar for this purpose is usually ground to minus 200 mesh. Potash spar ground to 120 or 140 mesh is usually specified for use in porcelain enamel, and even traces of such impurities as garnet, hornblende, tourmaline, and biotite mica ordinarily are not tolerated. Both potash and soda feldspars, ground to minus 200 mesh, are used in glazing.

Pottery-grade feldspar for whiteware and similar ceramic products may range from 5% to 14% in K₂O content and usually is ground to 200 mesh or finer. Limitations on iron content may be even more stringent than for glass grade; Fe₂O₃ content may be 0.07%. Feldspar for use in filler applications, such as for foam rubber products, may be similar to pottery spar in fineness of grind and

chemical composition, although more free quartz is often accepted; sometimes material for this purpose may be held to particle-size specifications expressed in micrometers.

Geology-Resources

Feldspar, one of the most abundant minerals in the Earth's crust, is found in significant amounts in some sedimentary strata and in nearly all igneous formations. Workable deposits of feldspar are probably widely distributed throughout most of the world, and the total quantity of the mineral potentially available is very large.

It has been estimated that feldspar constitutes 60% of all crystalline igneous rocks. Granted sufficient demand and economic incentive, the mineral could be extracted from the world's granite, a source that is extremely large.

Data are not available on the quantity of feldspar in either domestic or foreign deposits. However, U.S. reserves are estimated to be quite large in the Spruce Pine district of North Carolina alone.

Feldspar concentrations of potential economic interest exist in many pegmatites, granites, and other granitic rocks and as accumulations of certain residual sands on ocean beaches or river banks.

Pegmatites are masses of coarsely crystalline rocks of igneous origin. Pegmatite bodies may range in size from small pods to extensive formations measuring hundreds or even thousands of feet. The principal feldspar ore bodies of pegmatitic type currently being exploited in the United States are in Connecticut, Georgia, North Carolina, and South Dakota. Potentially exploitable pegmatite bodies are known to exist in other areas.

The only feldspathic sand deposits now being mined in the United States are in California, Idaho, and Oklahoma. Other accumulations of feldspathic sands in the United States offer possibilities as future sources of feldspar supply.

Granites are widely distributed igneous rocks of plutonic origin. Granites are present as major components of whole mountain ranges, and the dimensions of granite bodies can often be stated in miles. The important constituent minerals in granites are much the same as those in pegmatites, although there are likely to be significant differences in the respective proportions. Because of economic and technologic considerations, commercial utilization of granite in the United

States as a source of feldspar is not presently taking place.

Technology

Most feldspathic rocks can be quarried by open pit procedures. High-grade, selectively mined feldspar from pegmatites may be dry processed, passing consecutively through jaw crushers, rolls, and pebble mills before being subjected to high-intensity magnetic or electrostatic treatment to bring the iron content down to an acceptable level.

The customary procedure applied to most massive deposits, such as alaskite, begins with drilling, blasting, and dropball breaking at the quarry, followed by primary and secondary crushing and fine grinding in jaw crushers, cone crushers, and rod mills, respectively. The sequence typically continues with acid-circuit flotation in three stages, each stage preceded by desliming and conditioning. The first flotation step typically depends on an amine collector to float off and remove mica, and the second uses sulfonated oils to separate iron-bearing minerals, most notably garnet. The third step, flotation with another amine collector, leaves behind a residue that consists chiefly of quartz. Sometimes the third step is bypassed, leaving a feldspar-silica mixture, which can be used with little or no additional processing as furnace-feed ingredients in the manufacture of glass.

The flotation-cake feldspar or feldsparsilica mixture is dewatered in filters or drain bins and dried in rotary driers for use as glass-grade feldspar. Some material is further ground in pebble mills as pottery spar and for other uses.

Byproducts and Coproducts

Feldspar was obtained as a coproduct in 1990 from two companies mining and processing lithium ores and one company treating weathered pegmatite ore containing mica and kaolin. Coproduct recovery of mica and silica sand was reported by some feldspar processors.

Economic Factors

Feldspar is largely sold in bulk and moved by rail hopper cars. Transportation can comprise 50% or more of the total delivered cost. Some shipments are by truck. Most feldspar products are shipped less than 1,000 miles. An exception is premium-grade high-potash feldspar.

ANNUAL REVIEW

Feldspar

Legislation and Government Programs.—According to provisions of the Tax Reform Act of 1969, which continued in force throughout 1990, the depletion rate allowed on domestic and foreign feldspar production was 14%.

Production.—Feldspar or feldspar-silica sand was mined in seven States, led by North Carolina and followed, in descending order, by Connecticut, California (estimated), Georgia, Oklahoma, Idaho, and South Dakota. North Carolina accounted for 66% of the total. Eleven U.S. companies operating 13 beneficiating plants and 1 grinding plant produced feldspar or feldspar-silica mixtures for shipment to more than 31 States and foreign countries, including Canada and Mexico. Of the 11 companies, 3 produced potash feldspar, and the remainder produced soda and/or potash feldspar or feldspathic sand mixtures. North Carolina had six plants, California had two, and Connecticut, Georgia, Idaho, Oklahoma, and South Dakota each had one. The grinding plant was in South Carolina.

The U.S. Bureau of Mines uses a criterion of 8% minimum K_2O content in collecting data for potash feldspar.

In late 1990, the two feldspar mines and processing plant in Spruce Pine, NC, owned by Indusmin Inc., were sold to Hecla Mining Co. The new name of the operation was KT Feldspar Corp.

Consumption and Uses.—Of the total feldspar sold or used in the United States, 56% went into glassmaking, including container glass and glass fiber, and 44% was used in pottery and other applications. Fewer housing starts in 1990 resulted in decreased feldspar usage in plumbing fixtures and tile compared with that of the previous year.

Processed feldspar is added to glass-making formulas for its alumina and alkali contents. Alumina enhances the workability of molten glass and improves the finished product by giving it better chemical stability. The increased workability facilitates the operation of automatic machines for shaping jars and bottles. Greater chemical stability broadens the usefulness of the containers. Feldspar is used in ceramic mixtures, such as those for the making of vitreous

china and porcelain enamels, principally as a flux. It fuses at a temperature below the melting point of most of the other ingredients. It also performs as a vitreous binder to cement particles of various crystalline substances present in ceramic mixtures. Feldspar serves advantageously in abrasives and scouring soaps. It forms a mild abrasive but is soft enough to avoid injury to the article being cleaned. Feldspar is also used as a filler in paint, foam rubber, and plastics.

The quantity of potash feldspar sold or used in 1990 was 60,600 tons with a value of \$5.8 million.

Whiteware is a significant end use of feldspar. In 1989, sanitaryware sales were 44% of total whiteware sales; floor and wall tile were 33%.² The mix for sanitaryware bodies is about 50% clay (ball clay and kaolin), 25% silica, and 25% feldspar or nepheline syenite. A typical glaze may contain about 30% feldspar and smaller proportions of several other ingredients.³

World Review.—Capacity.—The data in table 10 are rated capacity for mines and refineries as of December 31, 1990. Rated capacity is defined as the

maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Because actual capacity data were not available, recent peak production during the past 5 years for the United States

and foreign countries was considered to be equal to rated capacity.

Australia.—The domestic market of 10,000 tons per year was largely in the ceramic and welding rod manufacturing industries. The market was mainly on the eastern coast in Victoria and New South Wales.

The Mukinbudin pegmatite deposit owned by Commercial Minerals Ltd. was one of two major Australian feldspar operations. The mainly quartz-microcline (potash) feldspar deposit is near the town of Mukinbudin, which is 330 kilometers east of Perth, the capital of Western Australia. The quartz was crushed and screened as a decorative stone for the local building industry. The feldspar was crushed and shipped to clients or mills for further processing. Chemical analysis of the material was 11.5% K₂O, 2.6% Na₂O, and 0.1% Fe₂O₃. Both lump ore and milled feldspar were exported from the port city of Perth to Southeast Asia. Iron contents of 0.08% were achieved by processing selected high-grade ore; in 1990, a magnetic separation plant was being installed to produce feldspar with 0.04% Fe₂O₃ for use in glazes.

The country's second major deposit was the Pippingarra pegmatites, also owned by Commercial Minerals, 30 kilometers from Port Hedland on the northwest coast. The massive microcline feldspar deposit also contained muscovite mica, which was processed and sold for oil well drilling and other uses. An extensive drilling program was planned for early 1990 to delineate ore reserves. This deposit is well situated to serve the Southeast Asia market area.

Potash feldspar is not widely available in Asia, and a significant market for high-quality material exists in Japan, Korea, and Taiwan. The ceramic tile industry of Taiwan was reported to be the third largest in the world after Italy and Spain. Another outlet for potash feldspar in Southeast Asia was in welding rod manufacture for the heavy construction industry. The potash spar is able to improve the surface finish of the weld. Other end uses were in the television tube and neon tube glass industries.⁴

Nepheline Syenite

Nepheline syenite was produced by Indusmin Ltd., a division of Falconbridge Ltd., from two operations at Blue

Mountain and Nephton, Ontario, Canada. Output in 1989, the latest year for which information was available, was estimated to be more than 660,000 tons. End uses included glass, whiteware, and as a filler and extender in paint, plastic, adhesives, and rubber.⁵ In late 1990. Unimin Corp. of New Canaan, CT, acquired the Indusmin nepheline syenite operations. The new name of the company was to be Unimin Canada Ltd.6

In Norway, nepheline syenite was produced at the Elkem Nefelin A/S, underground mining operation on the arctic island of Stjernøy. Output was 287,000 tons in 1988, the latest year for which data were available. Sales were largely to markets in Western Europe.⁷

Prices for Canadian nepheline syenite listed in Industrial Minerals (London), December 1990, were approximately \$24 to \$31 per ton for glass grade, 30 mesh, bulk, carlots-trucklots, depending on iron content; \$74 per ton for ceramic grade. 200 mesh, bagged, 10-ton lots; and \$87 to \$100 per ton for filler-extender grade, bagged.

Aplite

Aplite is a feldspar mineral that has more than one geological definition. However, aplite from the one active U.S. operation contains lime-soda feldspar. Aplite, usually unsuitable for use in ceramics, has been used in the manufacture of glass when it is sufficiently low in iron.

Aplite of glassmaking quality was produced in the United States by The Feldspar Corp. near Montpelier, Hanover County, VA.

Domestic output was approximately the same as in 1989. The data are company proprietary and cannot be released for publication. Aplite traditionally has a somewhat lower price than feldspar. Industrial Minerals (London), December 1990, gave a value of \$25.75 per ton for glass grade, bulk, 100% plus 200 mesh, f.o.b. Montpelier, VA.

With an annual production of 500,000 tons to 560,000 tons in recent years, Japan has been the world's largest producer of aplite. Italy is the world's largest producer of feldspathic materials, including feldspar and aplite; published figures did not give the relative breakdown of the two minerals.

Includes potash feldspar (8% K2O or higher).

An estimated 68% of these data were obtained by survey forms; the remaining 32% were estimated.

³Because of a lack of actual data, an estimated 65% of these data were obtained from projections of previous years' data.

⁴Because of a lack of actual data, an estimated 67% of these data were obtained from projections of previous years' data.

OUTLOOK

U.S. feldspathic consumption has remained fairly constant for the past several years. Competition from imported nepheline syenite, as well as increased use of recycled glass (cullet) and lightweighting of glass containers, have impacted on the demand for feldspathic materials in glass manufacturing. Glass containers should at least maintain their market share in the near future in a field that includes metal cans and plastic containers.

Fewer housing starts in recent years have resulted in static feldspar demand in whiteware such as plumbing fixtures and tile and in glass fiber insulation for housing. Feldspar outlook in 1991 will be

affected, in part, by the level of construction activity and remodeling.

FERROALLOYS

By Clark R. Neuharth

Mr. Neuharth, a physical scientist with 8 years U.S. Bureau of Mines experience, has been a commodity specialist since 1986, covering silicon initially and ferroalloys currently. Domestic survey data were prepared by Jo-Ann Sterling, Robin Johnson, and Elizabeth Voyatzis, mineral data assistants, and Mr. Neuharth; the international data tables were prepared by William Zajac, Chief, Section, International Data.

erroalloys and related materials are essential to the production of many metals and alloys, including aluminum, iron, and steel.

The domestic ferroalloys industry has been in a state of decline since its peak production years in the early-1970's because of decreased demand and competition from low-priced imports. Since that time, many U.S. producers have gone out of business, leaving the domestic ferroalloy industry a lean but surviving element of the country's industrial base.

Overall domestic usage of ferroalloys and related materials was little changed compared with that of 1989 because the steel industry, the major consumer of ferroalloys, produced at a rate just slightly higher than that of the previous year. Domestic shipments of ferroalloy were slightly lower than those of 1989, while overall ferroalloy imports were somewhat higher.

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on ferroalloys that are consistent with international usage, will henceforth report data in kilograms and metric tons unless otherwise noted.

DOMESTIC DATA COVERAGE

Domestic production data for ferroalloys are developed by the U.S. Bureau of Mines by means of monthly and annual voluntary domestic surveys. Typical of these surveys are the three separate monthly surveys for chromium alloys and metal, manganese alloys and metal, and silicon alloys and metal, and the annual survey for ferroalloys. Of the 38 operations to which a survey was sent, 36 responded, representing an estimated 95% of the total production and/or shipments shown in table 4.

BACKGROUND

Ferroalloys impart distinctive qualities to steel and cast iron and serve important functions during iron and steel production cycles. The principal ferroalloys are those of chromium, manganese, and silicon. Manganese, used to neutralize the harmful effect of sulfur and as an alloying element, is essential to the production of virtually all steels and is also important to the production of cast iron. Chromium adds corrosion resistance to stainless steels. Silicon is used primarily for the deoxidation of steel and as an alloying element in cast iron. Boron, cobalt, columbium, copper, molybdenum, nickel, phosphorus, titanium, tungsten, vanadium, zirconium, and the rare earths are among the other elements contributing to the character of the various alloy steels and cast irons. Most of these elements are normally added to the molten metal as a ferroalloy. This report considers the ferroalloy industry as a whole and its role as a supplier of ferroalloys to the iron and steel industries.

Definitions, Grades, and Specifications

Ferroalloy is defined by the American Society for Metals and the U.S. Bureau of Mines as "an alloy of iron that contains a sufficient amount of one or more other chemical elements to be useful as an agent for introducing these elements into molten metal, usually steel." However, in practice, the term is used loosely to include addition agents and master alloys, sometimes containing very little or no iron, employed to introduce reactive elements to numerous alloy systems, and various other materials; for example, calcium-silicon, nickel-boron, and chromium, manganese, and silicon metal.

The bulk ferroalloys are produced in a variety of grades distinguished by (1) carbon level, (2) silicon level, (3) or aluminum level. Thus, ferromanganese is classified into three carbon ranges (high-, medium-, and low-carbon). Generally, ferrosilicon is classified by broad silicon ranges, but it is further classified by aluminum and calcium contents. Altogether, there are scores of different specifications applying to the ferroalloys used in the manufacture of steel and cast iron. Perhaps the most varied assortment of alloys is associated with silicon. These include silicon metal, with varying amounts of iron; five ranges of silicon in ferrosilicon; and magnesium ferrosilicon alloys and other inoculant-type alloys involving controlled additions of barium, calcium, zirconium, and rare-earth elements, some with magnesium, in alloys where silicon is the dominant element. The majority of

the specialized alloys involving another element or two elements in addition to silicon are utilized by the iron casting industry. In the United States, the most complete set of accepted ferroalloy specifications are those of the American Society for Testing and Materials.

Industry Structure

The ferroalloy industry is closely associated with the iron and steel industries, its largest customers. Domestically, 29 companies produced ferroalloy materials and/or silicon metal in 1990, although 4 of those produced only ferrophosphorus as a byproduct of elemental phosphorus production. The U.S. industry can be divided into three sectors according to the alloys produced, with only a few companies operating in more than one sector.

The first sector produces the tonnage or bulk ferroalloys of manganese, chromium, and silicon, and their respective metals. Except for manganese metal, chromium metal, and some specialty alloys, these products are made in submergedarc electric furnaces, and to a limited extent, the companies can switch their production among these products according to market conditions. Since 1977, there has been no blast furnace production of ferromanganese in the United States, and currently no ferroalloys are produced domestically within a steel plant. One primary aluminum company operates a captive plant to produce silicon metal for alloying aluminum. Authors and publishers usually include silicon metal among the ferroalloys because its production process (i.e., electric furnace) is very similar to that of most ferroalloys.

The second sector of the industry comprises companies producing the remaining ferroalloys other than ferrophosphorus. These companies generally produce low-tonnage materials with relatively high unit values, sometimes referred to as "specialty ferroalloys," such as ferroboron, nickel-boron, ferrocolumbium, ferromolybdenum, ferronickel, ferrotitanium, and ferrovanadium.

The third sector of the industry produces ferrophosphorus as a byproduct of elemental phosphorus production.

Most countries with well-established steel industries also produce ferroalloys, but a definite shift in the location of ferroalloy production has occurred in more recent years toward countries with relatively low energy costs. These include

Brazil, Norway, and Venezuela, as well as countries possessing substantial quantities of high-grade ferroalloy ores such as India and the Republic of South Africa. Development of a large export potential in countries such as these has decreased economic viability of small-scale ferroalloy production in some areas, particularly where stringent pollution abatement requirements have been established and power costs are high. Japan's ferroalloy industry, not unlike that in the United States, has been in a state of decline in more recent years because of high power costs.

Resources

The reader is referred to the respective commodity annual reports for complete discussions of ore reserves and potential sources of ferroalloy raw materials. The U.S. ferroalloy industry is dependent on imports for most of its primary supply of chromium, cobalt, columbium, manganese, and nickel. The United States has large reserves of silica, molybdenum ores, and raw materials for ferroboron, ferrotitanium, and the rare-earth additives. It also produces a substantial percentage of its vanadium requirements from domestic raw materials.

Technology

High-carbon ferromanganese, spiegeleisen, and silvery pig iron (containing 10% to 20% silicon) are produced in sev-

eral countries in the type of blast furnace used to produce pig iron. However, since 1977, U.S. production of alloys containing chromium, manganese, and silicon has been in electric arc furnaces exclusively. Most of these alloys are smelted in submerged arc furnaces (i.e., the electric arc is kept submerged within the charge of raw materials). Ores are smelted with carbon from coke, coal, or wood chips as reductant. The high temperature and added energy needed for the reaction are provided by the electric arc. Unlike the operation of electric furnaces in steelmaking. that of the submerged-arc furnace is continuous, with raw materials being fed from above and molten alloy and slag (if produced) being tapped through holes in the side of the furnace. For some grades, such as low-carbon ferromanganese and low-carbon ferrochromium, two or three processing steps are involved, and openarc as well as submerged-arc furnaces are used.

Modern ferroalloy electric furnaces evolved from calcium carbide furnaces, which became important in the 1920's. Initially, ferroalloy plants had several furnaces of small size that provided flexibility in producing a limited volume of a variety of alloys. The trend has been toward fewer but larger furnaces, with transformer ratings now up to 100 megavolt-ampere (MVA), and with some new plants consisting of just one or two furnaces. The larger furnaces are designed more for specific alloy production, and the use of the furnace for other alloys may

TABLE 1
GOVERNMENT INVENTORY OF FERROALLOYS, DECEMBER 31, 1990

(Metric tons of alloy, unless otherwise stated)

Alloy	Stockpile grade	Nonstockpile grade	Total
Ferrochromium:			
High-carbon	627,985	629	628,614
Low-carbon	272,373	16,738	289,112
Ferrochromium-silicon	51,699	1,242	52,941
Ferrocolumbium (kilograms contained columbium)	271,435	150,820	422,255
Ferromanganese:			
High-carbon	787,927		787,927
Medium-carbon	26,374		26,374
Ferrotungsten (kilograms contained tungsten)	381,359	536,778	918,137
Silicomanganese	21,386	_	21,386

require physical modification. Modern furnaces are equipped with automated materials handling equipment to reduce labor requirements and with computerized control systems to maintain more efficient production.

Some ferroalloys are produced in the electric furnace by metallothermic reduction. The reductant may be aluminum or silicon (often as ferrosilicon). The reactions are generally self-sustaining, but heat may be added by an electric arc to keep the molten alloy liquid until the slag can be separated.

Economic Factors

Prices.—Demand for ferroalloys is determined by the level of activity in the iron and steel industries, and prices for ferroalloys tend to vary, sometimes widely, with changes in demand or supply. For example, in 1987 and 1988, bulk ferroalloy prices rose steadily and, in some cases, more than doubled as U.S. steel production and that of stainless grades headed toward their highest levels in nearly 10 years. In 1989, as steel production fell slightly, most bulk ferroalloy prices also fell.

TABLE 2
HISTORICAL FERROALLOYS
PRICE TRENDS

(Weighted annual averages)

Year	FeMn ¹	FeCr ²	FeSi ³
1976	376.63	42.45	28.55

1990	644.27	47.51	39.94
1-			

¹Imported standard-grade ferromanganese—prices in dollars pellong ton of alloy.

Costs.—Principal elements in the cost of ferroalloy production are (1) delivered costs of the ore, (2) energy cost, (3) cost of reductant coke or low-ash coal, (4) cost of

iron in the form of steel scrap, if required, and (5) labor. The cost of all of these elements, and particularly the cost of energy, increased rapidly since 1970. In addition, new capital costs for pollution control equipment were added.

Energy costs are a dominant factor in the cost of producing ferroalloys in submerged-arc furnaces. Silicon alloys require the highest energy input, followed by chromium- and manganese-containing alloys. In the United States, energy costs account for up to 40% of the cost of silicon-containing ferroalloys. In addition, many national Governments are favoring less power-intensive industries by allocating power. Thus, countries with an adequate technology base, economy of large-scale operation, and ensured low energy costs will be favored to become larger factors in the ferroalloy industry. The United States will be in an intermediate energy cost position. However, energy costs and ore reserves continue to favor expansion in production of (1) chromium alloys in Albania, Greece, India, the Philippines, the Republic of South Africa, and Turkey; (2) manganese alloys in Brazil, Mexico, and the Republic of South Africa; and (3) silicon alloys in Australia, Brazil, and Norway. At the same time, such growth will tend to dampen growth in steel- producing countries such as the United States, Japan, and many Western European countries.

Tariffs.—Tariff schedules for ferroalloys and related metals can be found in the respective individual commodity annual reports.

Operating Factors

Environmental Requirements.—Air pollution is the principal environmental problem in the production of ferroalloys. Most developed countries, such as Japan, the United States, and those of Western Europe, have stringent environmental controls, requiring pollution control systems. Ferroalloy furnaces in the United States are generally equipped with baghouses; wet scrubbers and electrostatic precipitators are also in use. In some other countries, environmental controls are not always required by the Governments, but producers are equipping new furnaces with the most modern equipment commercially available to effect substantial removal of objectionable emissions.

Energy Requirements.—Bulk ferroalloys produced in submerged-arc electric furnaces are extremely power intensive, especially silicon metal and the siliconcontaining alloys, which can require up to 12,000 kilowatt-hours of electric energy per ton¹ of silicon contained in the final product. Standard ferromanganese is the least power intensive of the major ferroalloys, requiring approximately 2,500 kilowatt-hours per ton of alloy produced.

To buy power at low cost, many ferroalloy companies have long-term contracts with use-or-pay conditions that may restrict the companies' operational flexibility. Contracts that specify a high minimum charge limit the amount that costs can be reduced by cutting production during periods of weak demand. Under interruptible contracts, power can be cut off during power shortages.

ANNUAL REVIEW

Legislation and Government Programs

In November, the President signed into law Amendments to the Clean Air Act of 1977. It was expected that the new amendments would have both a direct and indirect impact on the domestic ferroallovs industry. A potential direct impact will be determined by new toxic emissions regulation. The Environmental Protection Agency placed all ferroalloy producers on a list of possible sources of toxic emissions subject to regulation. Indirectly, the industry could be impacted by the acid rain portions of the new law. New standards for the reduction of SO₂ emissions would almost certainly raise prices for electrical power, a major cost component in ferroalloy and silicon metal production.

The South Carolina Research Authority (SCRA), a public corporation created by the State's government to promote high-technology industries, completed phase I of a government-sponsored research project aimed at utilizing plasmaarc smelting technology for the production of ferrochromium. In 1989, SCRA received \$3.5 million in seed funding from the Defense Logistics Agency (DLA) for phase I. Macalloy Corp., Arthur D. Little Inc., Clemson University, and the Massachusetts Institute of Technology were the other principals involved in the project. Macalloy provided matching funds for phase I. In 1990, a pilot-scale (2,000-kW)

²Imported charge-grade ferrochromium—prices in cents per pound of contained chromium.

³Imported 75%-grade ferrosilicon—prices in cents per pound of contained silicon.

furnace, capable of producing about 1,000 pounds of ferrochromium per hour, was built at Macalloy's smelting facility in Charleston, SC. After successful test firings of the furnace, several production campaigns were run by SCRA and Macalloy. The official results of these test runs are to be reported to DLA in early 1991; sources associated with the project have reported that the initial results were quite favorable. Also in 1991, phase II of the project, which is to involve the planning, development, and construction of a much larger prototype furnace, is to continue under the auspices of DLA. A \$10 million grant was awarded to SCRA for phase II of the project, and as with phase I, matching funds will be provided by Macalloy.

Under contracts awarded in 1989, DLA continued the 7-year-old Ferroalloy Upgrading Program for chromium and manganese materials in the National Defense Stockpile (NDS). Macalloy Corp.'s contract called for the conversion of 126,053 short tons of chromite to highcarbon ferrochromium in 1990 and an additional 126,341 short tons in 1991 at a cost of approximately \$30 million per year. A total of 51,742 short tons of highcarbon ferrochromium was added to the NDS inventory in 1990. The current contract also includes an option for the conversion of a total of 264,791 short tons of chromite in 1992 and 1993. Elkem Metals was under contract to convert 132,861 short tons of manganese ore to highcarbon ferromanganese in 1990 and 132,244 short tons in 1991, at a total cost of approximately \$82 million. A total of 56,383 short tons of high-carbon ferromanganese was added to the NDS inventory in 1990. Elkem's manganese contract also included third- and fourth-year options under which an additional 264,791 short tons of manganese ore would be converted to high-carbon ferromanganese. A third DLA contract, also awarded to Elkem in 1989, calling for the conversion of stockpiled low-carbon ferrochromium to vacuum melting-grade electrolytic chromium metal, was completed. The conversion yielded 1,150 short tons of chromium metal at a cost of \$7.2 million. According to DLA officials, a similar contract was awarded in 1990 for the conversion of stockpiled lowcarbon ferrochromium to 860 short tons of vacuum melting-grade electrolytic chromium metal in 1991 at an approximate cost of \$7 million.

Strategic Considerations

Ferroalloys and silicon metal are essential in the production of iron, steel, aluminum, and silicon-base chemicals, making their continued availability a matter of strategic importance. The domestic ferroalloys industry has been in a state of decline since its peak years in the mid-1970's owing to competition from low-priced imports. Since that time, most of the producers of chromium- and manganese-containing alloys have quit producing those materials or gone out of business altogether.

Issues

The U.S. dependence on foreign sources for most ferroalloy materials has risen steadily over the past two decades. Net import reliance for chromium-, manganese-, and silicon-containing materials was estimated to be 79%, 100%, and 30%, respectively, in 1990. Commercially, the United States is 100% dependent on foreign sources for chromium ore (chromite) and manganese ore used to make ferroallovs containing those elements; however, some of these ores and their respective alloys, along with materials containing columbium and tungsten, are held in the NDS. Supplies of raw materials necessary to produce silicon-containing ferroalloys and metal are readily available domestically, but the capacity to produce these materials has declined in recent years.

In August, a group of domestic silicon producers petitioned the Department of Commerce (DOC) and the International Trade Commission (ITC) for relief from allegedly dumped silicon metal imports from Argentina, Brazil, and China. Brazil also was alleged to have unfairly subsidized its silicon metal industry. The domestic producers involved in the actions taken against Brazil were American Alloys Inc., Globe Metallurgical Inc., Silicon Metaltech Inc. (SMI), and Simetco. These companies, as well as SKW Alloys Inc. and Elkem Metals Co., filed antidumping actions against Argentina and China. In October, the ITC announced their initial findings: that there was reasonable indication of injury caused to the domestic silicon industry by the dumping of imports from the three countries. The DOC later made a preliminary determination that Brazil was not providing countervailable subsidies to its silicon metal industry. The following trade actions were scheduled to be made in 1991: a

final DOC decision in the countervailable subsidy investigation of Brazil; preliminary and final DOC determinations on the alleged dumping of silicon metal by Argentina, Brazil, and China; and final ITC determinations on injury to domestic silicon producers by imports from Argentina, Brazil, and China.

Production

U.S. ferroalloy shipments in 1990 were 860,433 tons valued at \$871 million. The production and shipments of silicon-containing ferroalloys and silicon metal combined comprised the largest portion of the domestic industry based on tonnage and value. These materials were produced by 9 companies at 13 locations. Overall domestic production decreased 4% compared with that of 1989, with major producers cutting back production because of oversupply and low price levels. Applied Industrial Minerals Corp. (AIMCOR), Bridgeport, AL; American Alloys, New Haven, WV; SKW, Calvert City, KY; Elkem Metals, Alloy, WV, and Ashtabula, OH; Globe Metallurgical, Beverly, OH; and Simetco, Montgomery, AL, all idled capacity at some point during the year for major maintenance or because of market conditions.

Elkem Metals, Marietta, OH, was the only producer of ferromanganese and silicomanganese. Macalloy Corp. (Charleston, SC) continued to produce high-carbon ferrochromium. Ferronickel production continued at Glenbrook Nickel Co., Riddle, OR.

The Ferroalloys Association reported that its member companies consumed approximately 4.9 billion kilowatt-hours of electricity in 1990 compared with 5.3 billion kilowatthours the previous year.

Early in the year, Northwest Alloys Inc., a subsidiary of Aluminum Co. of America, closed its 25,000-ton-per-year ferrosilicon operation in Addy, WA. The company, which uses ferrosilicon in the production of magnesium, entered a long-term agreement with Elkem Metals to meet its ferrosilicon needs.

Strategic Minerals Cor. (Stratcor), Danbury, CT, announced plans to acquire Metals and Minerals Inc., a manganese sales subsidiary of Samancor Ltd. (Republic of South Africa), in 1991 to expand its sales line, which had consisted of vanadium-, tungsten-, and chromium-containing materials. With the acquisition, Stratcor plans to market ferromanganese, silicomanganese, and manganese ore.

On June 15, SMI filed for protection under Chapter 11 of the Bankruptcy Law. SMI was reported to have had negative cash flow problems for several months in late 1989 and early 1990, and attributed its problems to a depressed silicon market and unfairly traded silicon metal imports

(see Issues). SMI continued to produce silicon and was hoping to emerge from protection within 6 to 12 months.

AIMCOR completed construction of a new blending facility to produce desulfurizers and slag conditioners for the steel industry. Production commenced in July. The new facility was located next to the company's olivine processing plant in Aurora, IN. AIMCOR's ferrosilicon production facility in Kimball, TN, remained closed.

During the third quarter, Glenbrook Nickel was reported to have reached full

²The same equipment was used at both of these facilities.

³Includes specialty silicon alloys, zirconium alloys, and miscellaneous ferroalloys.

capacity, 1 million pounds of nickel contained in ferronickel per month. The operation reopened in 1989 after it had been closed by a previous owner, M.A. Hanna Co., in 1986. Glenbrook has been using stockpiled ore, which accumulated over 30 years while Hanna operated the smelter, and the company was expected to make a decision whether or not to reopen the Riddle Mine. The stockpiled ore was expected to last only about 3 years at current production levels. Ferrosilicon (50% grade), which is consumed in the ferronickel process, had been produced on-site initially, but Glenbrook stopped production, opting to buy its ferrosilicon on the open market.

In October, Reynolds Metals Co. permanently closed its silicon metal production facility in Sheffield, AL. The 8,500-ton-per-year silicon plant, the production of which was considered captive, was part of one of Reynolds' aluminum reduction facilities that was shut down a few years ago. The parent company reported it would fill its silicon requirements on the open market.

Affiliated Metals and Minerals Inc. emerged from Chapter 11 protection of the Bankruptcy Law and resumed ferroalloy tolling operations under the name Bear Metallurgical Inc. at a new site in Butler, PA. Affiliated had previously conducted ferroalloy tolling at its facility in New Castle, PA. Bear plans initially to toll-convert ferrovanadium and ferromolybdenum with equipment purchased from Affiliated. Bear also plans eventually to produce some of its own alloys and offer value added services such as crushing, briquetting, bagging, and other forms of packaging.

Elkem Metals neared completion of its new research facility in Pittsburgh, PA. The facility was to employ approximately 40 people and was built to replace the company's research center in Niagara Falls, NY. Company officials stated that the emphasis of the new facility and programs was more toward customer applications of ferroalloys rather than ferroalloys processing research.

Molycorp Inc. planned to reopen its Washington, PA, molybdenum roasting facility as a 50-50 joint venture with Kennecott Utah Copper Corp. in early 1991. Roasting of molybdenum concentrates at that site ceased in 1986 when Molycorp closed its molybdenum mining operation in Questa, NM. Under the joint venture, concentrates from Molycorp's Questa

Mine, which reopened in 1989, and Kennecott's Bingham Canyon, UT, mine (about 10 million pounds of contained molybdenum per year each) will be blended as feed in the Washington facility's 20-million-pound-per-year roaster.

Chrome Corp. of America (CCA), a subsidiary of Boulder Gold NL (Australia), continued to study feasibility and to plan the development of a ferrochromium smelting operation in the Stillwater complex near Billings, MT. The new project planned to utilize the Coal Ore Direct Iron Reduction (CODIR) process for chromite developed by Krupp Industrietechnik (Federal Republic of Germany). Smelter feed for the operation initially could come from an existing 600,000-ton chromite stockpile at Columbus, MT; however, continued operation would require the reopening of existing chromite mines, which are estimated to have a life of about 20 years. Startup of the ferrochromium project was scheduled for 1993. At one point during the year, Phelps Dodge Mining Co. entered into a joint-exploration agreement with CCA covering both chromite and platinumgroup metals in the Stillwater complex.

Consumption and Uses

Manganese is required in virtually all steels and most cast irons to counteract the harmful effects of sulfur. It also acts as a mild deoxidizer and is used for strengthening properties in engineering steels. Chromium provides corrosion resistance to stainless steels. Silicon, as ferrosilicon, is the primary deoxidizer used in the production of iron and steel. Silicon metal is used as an alloying agent in aluminum products and as a raw material in the production of silicon-base chemicals.

The iron and steel industry consumes most of the ferroalloys produced; however, other alloy systems, although relatively small in volume, represent substantial and growing markets with respect to value. Some examples are (1) silicon for alloying aluminum, principally the casting varieties; (2) nickel and cobalt-base alloys; and (3) titanium alloys.

Overall domestic usage of ferroalloys and related materials was little changed compared with that of 1989. The steel industry, the major consumer of bulk ferroalloys (i.e., those containing chromium, manganese, or silicon), in general was quite strong, with overall production of raw steel remaining steady throughout most of the year but trending downward at yearend, resulting in a total slightly above that of 1989. Shipments of castings from the ferrous foundry industry, also a large consumer of silicon- and manganese- containing ferroalloys, continued a 2-year decline. Production of stainless steel increased roughly 6% compared with that of the previous year, pushing demand for chromium-containing ferroalloys slightly higher. Aluminum-and silicon-base chemical production totals were slightly higher than those of 1989, increasing overall demand for silicon metal. Demand was mixed for other ferroalloy materials, those containing boron, columbium, molybdenum, nickel, titanium,

price for imported ferromanganese containing 78% manganese ended the year up slightly and was much more stable than the price of most other ferroalloy materials. Yearly average price for imported ferromanganese was roughly 5% higher than that of 1989. The price for imported charge chrome (ferrochromium containing 50% to 55% chromium) fell throughout the year. The yearly average, 47.5 cents per pound of contained chromium, was down about 40% compared with that of the previous year. The yearly average price for imported 75% ferrosilicon, 39.9 cents per pound of contained silicon, was about 20% lower than that of 1989. The price for imported silicon metal ended 2 cents higher than the average for the year, 54.8 cents per pound, which was down 8% compared with that of 1989. Prices for molybdenum- and vanadium-containing ferroallovs were mixed and ended the year on downward trends.

Foreign Trade

The trade deficit for ferroalloys and related metals overall was 884 million, a 10% decrease compared with that of 1989. Exports of ferroalloys and related metals overall decreased 13% compared with that of 1989; however, the associated value of those materials increased 9%. Exports of related metals increased by 49%, which was primarily due to a 78% increase in silicon metal exports.

Imports for consumption of ferroalloys and related metals overall increased 8% compared with those of 1989; however, the value associated with those materials decreased 8%. The Republic of South Africa continued to be the main source of U.S. imports of those materials, accounting for 26% of the total. Of the imported chromium- and manganese-containing materials, the Republic of South Africa supplied 40% and 32% of the respective totals. Other major suppliers of imported chromium-containing materials were Turkey (11%), Yugoslavia (12%), and Zimbabwe (14%). The second leading supplier of manganese-containing materials was France (18%). Imports of ferrosilicon increased 34% compared with those of 1989. The principal sources of ferrosilicon imports were Brazil, 28%; the U.S.S.R., 17%; Canada, 16%; and Venezuela, 14%. Imports of silicon metal overall increased 54%. The principal sources of silicon metal were Brazil, 44%; China, 33%; and Canada, 12%. Complete breakouts by country for U.S. imports and exports of most ferroalloys and related materials can be found in the respective commodity annual reports.

World Review

Capacity.—The data in table 8 are rated capacities as of December 31, 1990, for major countries that produce ferroalloys containing chromium, manganese,

TABLE 7 **FERROALLOY PRICES IN 1990**

and silicon, as well as silicon metal. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Because not all countries or producers make production capacity information available, historical production and trade data have been used to estimate production capacity in some

Albania.—In recent years, the country has encountered difficulties because of water and subsequent electrical power shortages. Lack of rainfall curbed food supplies, while power shortages affected the production of chromite and ferrochromium, the country's most important mineral-metal commodities. Power shortages also delayed the startup of a new ferrochromium smelter at the Elbasan steel and metallurgical complex. Initial plans called for the facility to produce 38,000 tons per year of high-carbon ferrochromium.2

Argentina.—Silarsa, a joint venture between Axel Johnson Metals (30%) and Stein Ferroalloys (70%), started a new 6,500-ton-per-year silicon metal furnace at Mendoza in September. The plant was running at about 85% of capacity and all of the output was expected to be exported to Europe, Japan, and the United States. Construction of a second furnace of equal capacity was planned for 1991.3

Australia.—SIMCOA Pty. deferred indefinitely the expansion of its 30,000-tonper-year silicon metal operation at Kemerton in Western Australia. Initial plans for the operation, which was commissioned by Barrack Mines Ltd. in 1989, included four 18-megawatt electric furnaces. Only two have been built and operated. Output, which had reached full capacity, was being exported to Asia, Europe, and North America.4

Bhutan.—Marubeni Corp. (Japan) announced its plans to form a joint venture with Bhutanese partners, Tashi

²Dollars per long ton.

³Cents per pound of contained element.

⁵Dollars per kilogram of contained element.

⁴Dollars per pound of contained element.

Commercial Corp. and Bhutan's Ministry of Trade and Industry, to build a 15,000-ton-per-year ferrosilicon plant at Pasakha, close to Bhutan's southern border with India. The site was chosen because of its proximity to a new hydroelectric plant. The operation was to be called Bhutan Ferroalloys Ltd. and was scheduled for commissioning at the end of 1992.5

Brazil.—According to Anuario da Industria Brasileira de Ferroligas (ABRAFE), overall ferroalloy production decreased 9% compared with that of 1989 because of a significant decrease. 27%, in the production of steel, the major consumer of ferroalloy materials; continually escalating production costs, primarily

electrical power; and the country's new economic policies. The decrease in production marked the first since the country started its rapid expansion in ferroalloys production and advance into world markets during the 1980's. A number of producers shut down capacity. However, despite the decrease in overall production, a new record level for exports of ferroalloy materials, more than 560,000 tons or 60% of production, was achieved, and some expansion plans continued.

Camargo Correa Metais S/A (CCM) shut down two of its four 18,000-kilovoltampere, 16,000-ton-per-year silicon metal furnaces at its new facility in Tucurui. Para State, because of weak market conditions. The state-of the-art plant, which came on-line with two furnaces in 1988

and two more in 1989, had been producing at full capacity until midyear.6 Other capacity shutdowns included that of one silicon metal furnace at Rima Electrometallurgia in Minas Gerais, Cia. Paulista de Ferroligas' ferrosilicon furnaces in Caxambu, and two of Ferbasa's ferrochromium furnaces in Pojuca.7 Late in the year, Rima Electrometallurgia filed for protection under the country's bankruptcy law.8

Cia. Ferroligas do Amapá commissioned a 12-MVA furnace to produce 22,000-tons-per-year high-carbon ferromanganese at Porto de Santana. The furnace was originally intended for ferrochromium production, but the company felt market conditions favored production of ferromanganese. Most of the furnace's production is expected to be exported to the United States.9

Cia. Brasileira de Metalurgia e Mineracao (CBMM) planned to start construction of a new 23,000-ton-per-year ferrocolumbium production facility at Araxa. The facility was scheduled to begin production in 2 years at which time CBMM would cease production at its existing plant. 10

China.—Annual production of ferroalloys and silicon metal has increased significantly over the past few years, and producers continued to advance their participation in world ferroalloy markets. However, future availability of electrical power for the country's growing industries was questionable, and because world market prices for ferroalloys remained depressed and the Chinese Government placed ferroalloys second in importance to aluminum, it was expected that the country might face ferroalloy and silicon metal production cuts in the future. 11

EC.—In July the EEC imposed a 198-ECU/metric ton tariff on imports of silicon metal from China. The action was taken on complaints from silicon metal producers in the Federal Republic of Germany, France, Italy, and Spain that imports of Chinese silicon metal rose from 0% to 8% of the EC total in 4 years (1985-89).¹²

Late in the year, European silicon metal producers also filed a dumping action against silicon metal producers in Brazil. As with the material from China, silicon metal imports from Brazil into the EC had risen significantly over the past 5 vears. 13

France.—Chromeurope S.A., a subsidiary of Ferroaleaciones Espanolas S.A. of Spain, started its second high-carbon ferrochromium furnace, a 16-MVA unit. The company began produc-

tion at its new Dunkirk facility with a 12-MVA unit in 1988. The combined planned output of the two furnaces was to be 36,000 tons-per-year.¹⁴

Usinor Sacilor planned to build a

100,000-ton-per-year ferromanganesesilicomanganese production facility in Dunkirk. Completion of the project was expected by the end of 1991. Some of the manganese ore was to come from Brazil.

¹Consists of ferroalloys of chromium, manganese, and silicon and silicon metal.

The new plant would supply about onehalf of the company's manganese needs for steelmaking. At yearend, Usinor had received the EC Commission's endorsement of a electricity supply contract with the EDF.¹⁵

Greece.—Hellenic Ferroalloys (HFA) was forced to decrease production of ferrochromium by an estimated 25% because of worker strikes, by both HFA workers and those of the Public Power Cor. (PPC), and an ongoing dispute with the PPC over nonpayment of HFA's bills. Larco, a producer of ferronickel, also lost some production due to the PPC strikes, which reduced electricity to its smelter. 17

India.—Perennial power shortages continued to cause problems for ferroalloy producers, especially in Andhra Pradesh; however, Ferro Alloys Corp. Ltd. (FACOR) helped alleviate this problem with the completion of a 30- megawatt captive powerplant at Garividi to supply its Shreeramnagar ferrochromium works in Barividi. 18

State-owned OMC Alloys Inc. announced that it would suspend charge chrome production at the end of the year owing to rising production costs and poor market conditions.¹⁹

Kolmak Chemicals planned to construct a new 15,000-ton-per-year ferrochromium operation under the name Standard Chrome in Raigarh, Madhya Pradesh. Chrome ore was expected to come from mines in Orissa.²⁰

Netherlands.—Aimcor Formed Products Production Corp., a subsidiary of AIMCOR (United States), started construction of a 200,000-ton-per-year silica briquetting plant in Rotterdam. The operation was to produce a carbon-silica material, trade-named Silgro, to be used as feed in ferrosilicon and silicon metal production in the United States and Europe.²¹

New Caledonia.—Eramet-SLN, a ferronickel producer, was plagued with problems at its Noumea smelter, including a strike, delayed startup of its new oxygen facility, and a transformer fire at the end of the year. The company lost an estimated 4,500 tons of production and twice declared force majeure.²²

Norway.—Elkem A/S purchased the

Norsk Ferrokrom Mo I Rana operation, a joint venture involving Norsk Jern Holding, the FESIL group, and Macalloy Corp. (United States), and formed a new company, Elkem Rana. Norsk Ferrokrom, which had started production in 1989, was Norway's first ferrochromium project and consisted of two furnaces with a total capacity of 100,000-tons-per-year. Only one of the furnaces has been operated, but Elkem had planned to start the second furnace, possibly in 1991.²³

Elkem also purchased the remaining interest in Bjoelvefossen, a four-furnace ferrosilicon operation at Alvik in which Elkem was a 48% owner.²⁴ Later in the year, Elkem announced it would shut one of the furnaces at Alvik as well as one ferrosilicon furnace at both its Bremanger and Thamshavn plants due to market conditions. The shutdowns would amount to about 20,000 tons of material on an annual basis. The company also announced that it would close a second silicon metal furnace at Meraker, leaving only one furnace in operation. Another ferrosilicon producer, FESIL, announced that it would cut production by 20% at its Hafslund, Rana Metall, and Finnfjord facilities.

South Africa, Republic of.—Tubatse Ferrochrome (Pty.) Ltd., a subsidiary of Samancor, commissioned its fifth ferrochromium furnace, making that facility the second largest of its type in the world. The new furnace had an annual production capacity of 60,000 tons, bringing Tubatse's total production capacity to 300,000 tons per year.²⁵

Purity Ferrochrome Pty. commissioned two new 33-MVA, 60,000-ton-peryear ferrochromium furnaces at its smelter near Rustenburg, Transvaal Province. The new operation was later taken over by another of the country's ferrochromium producers, Consolidated Metallurgical Industries (CMI). With the acquisition, CMI increased its total ferrochromium capacity to 325,000 tons per year.²⁶

Middleburg Steel and Alloys (Pty.) Ltd. started a direct-current, transferred-arc plasma furnace for the production of ferrochromium; however, the company was forced to shut the furnace down after experiencing problems with the furnace's refractory lining. The new unit was designed to process chromium ore fines, which are less expensive than lumpy ore and readily available domestically. The furnace should produce up to 120,000

²Excludes silicon materials, which are included with "Other."

³Included with "Other."

⁴Does not include blast furnace capacity.

per year when fully operational and should use only one-quarter of the electrical energy used to produce ferrochromium in a conventional submerged-arc furnace.²⁷

Two new manganese ferroalloy furnaces were commissioned during the year. The first was a 48-MVA silicomanganese unit at the Transallovs Div. of Highveld Steel & Vanadium Corp. Ltd., which raised the company's total manganese ferroalloy capacity to about 200,000 tons per year (175,000 tons per year silicomanganese and 20,000 tons per year medium-/ low-carbon ferromanganese). The second was a 50,000-ton-per-year ferromanganese unit at the Cato Ridge plant of Feralloys Ltd., a subsidiary of AMMOSAL, which raised that company's total ferromanganese capacity to 130,000 tons per vear.28

Saudi Arabia.—United Gulf Industries Corp. planned to build a 25,000-tons-peryear ferrosilicon production facility in Jubail. The company also suggested future interest in building a ferromanganesesilicomanganese smelter if a source of manganese ore could be secured.²⁹ Spain.—Sociedad Espanola de Fundiciones Electricas planned to permanently close its ferroalloy plant near Bilboa and disassemble its two electric furnaces that had been shut down in late 1989 because of high electrical power costs. The company had produced ferromanganese and ferrosilicon for domestic use.³⁰

Sweden.—Ferrochromium producer Swedechrome permanently closed its 80,000-ton-per-year charge chrome production facility at Malmo early in the year. The company stated a number of reasons for the plant's closure, including low ferrochromium prices and an unfavorable cost position due to the country's embargo of South African chrome ore and high electricity prices.

KemaNord permanently closed its 24,000-ton-per-year silicon metal production facility. The company claimed it could not compete with low-cost producers on the world market in times of depressed prices.³¹

Turkey.—Etibank General Management started a fourth high-carbon ferrochromium furnace at its Elazig plant.

The 30-MVA furnace raised total ferrochromium capacity at the Elazig plant to 150,000 tons per year.³²

A consortium of companies from the Republic of Korea, including Sunkyong Ltd., its subsidiary Yukong Ltd., and state-run Korean Mining Promotion Corp. formed a joint venture with Egemetal Medencilik with plans to construct a 40,000-ton-per-year ferrochromium smelter in northwestern Turkey. Completion of the project was scheduled for 1993. The consortium planned to take one-half of the output for use in the Republic of Korea.³³

Yugoslavia.—Ferroalloy producer Dalmacija Dugi Rat placed two of its three furnaces on care and maintenance at the beginning of the fourth quarter owing to weak world market conditions. One of the two furnaces accounted for one-half of the company's 75,000 tons per year ferrochromium capacity, output of which is mostly exported. The second idled furnace, which is capable of producing 25,000-tons-per-year ferromanganese, had been producing ferromanganese and silicomanganese for both domestic use and export.³⁴

OUTLOOK

In recent years, a shift of production from major ferroalloy-consuming countries to countries that possess significant ore reserves and low-cost electric power has occurred. For example, a number of expansions and new operations have been underway in chromite-producing countries (e.g., Finland, the Philippines, Republic of South Africa, Turkey, and Zimbabwe). Some of the projects came online in 1989 and 1990, increasing world ferrochromium capacity by more than 10% to 15%. Further ferrochromium capacity expansion, another 10% to 15%, is expected over the next several years. It is expected that this trend will continue in the future, not only for chromium-containing ferroalloys, but for those of man-

¹Table includes data available through June 21, 1991.

²To the extent possible, ferroalloy production of each country has been separated according to the furnace type from which production is obtained; production derived from metallothermic operations is included with electric furnace production

³To the extent possible, ferroalloy production of each country has been separated so as to show individually the following major types of ferroalloys: Spiegeleisen, ferromanganese, silicomanganese, ferrosilicon, silicon metal, ferrochromium, ferrochromium-silicon, and ferronickel. Ferroalloys other than those listed that have been identified specifically in sources, as well as those ferroalloys not identified specifically but which definitely exclude those listed previously in this footnote have been reported as "Other." For countries for which one or more of the individual ferroalloys listed separately in this footnote have been inseparable from some other ferroalloys owing to the nation's reporting system, such deviations are indicted by individual footnotes. In instances where ferroalloy production has not been subdivided in sources, and where no basis is available for estimation of individual component ferroalloys, the entry has been reported as "Undistributed."

⁵Data for year ending Nov. 30 for 1986; calendar years thereafter.

Although furnace type has not been specified for any ferroalloy production for China, North Korea, and the Republic of South Africa, all electric furnace (and metallothermic) output of these countries has been included under electric furnace (and metallothermic) output except for their production of ferromanganese, which is reported separately below.

⁸Includes ferrochromium-silicon and ferronickel, if any was produced.

⁹Includes silicospiegeleisen.

¹⁰Includes ferrochromium-silicon, if any was produced.

¹¹ Includes ferronickel, if any was produced.

¹² Series excludes calcium silicide.

¹³Includes calcium-silicon, ferrotungsten, ferromolybdenum, ferrovanadium, ferrocolumbium, and other ferroalloys.

¹⁵ Estimated figures based on reported exports and an allowance for domestic use.

¹⁶Ferrovanadium only; other minor ferroalloys may be produced, but no basis is available for estimation.

¹⁷ Soviet production of electric furnace ferralloys is not reported; estimates provided are based on crude source material production and availability for consumption (including estimates) and upon reported ferroalloy trade, including data from trading partner countries.

¹⁸U.S. production of ferronickel cannot be reported separately in order to conceal corporate proprietary information.

¹⁹U.S. output of ferromanganese includes silicomanganese and manganese metal.

²⁰U.S. output of ferrochromium includes ferrochromium-silicon, chromium briquets, exothermic chromium additives, other miscellaneous chromium alloys, and chromium metal.

²¹Includes ferronickel.

²²Spiegeleisen for the Western states of the Federal Republic of Germany is included with blast furnace ferromanganese

²³Includes silicospiegeleisen for France.

²⁴Ferromanganese includes silicomanganese (if any was produced) for countries carrying footnote 6 on "Ferromanganese" data line.

²⁵U.S. production under "Other" for 1988-90.

²⁶ Ferrochromium includes ferrochromium-silicon (if any was produced) for countries carrying footnote 8 on "Ferrochromium" data line.

²⁷Includes ferronickel production for France, Norway, and the United States.

ganese and silicon as well, as more traditional producers of ferroalloys (i.e., countries with well-established steel industries such as the United States and Japan) continue to decrease ferroalloy production capacity.

In most cases, consumption of chromium, columbium, manganese, molybdenum, nickel, silicon, vanadium, and the rare-earths as ferroalloys relates either directly or indirectly to the production of iron and steel. Demand forecasts for steel and the major ferroalloy elements are given in the individual commodity annual reports.

FLUORSPAR

By M. Michael Miller

Mr. Miller, a physical scientist with 13 years of mineral experience with the Department of the Interior, has been the commodity specialist for fluorspar since 1989. Domestic survey data were prepared by Gail D. Mason, mineral data assistant; and international data tables were prepared by Harold Willis, international data assistant.

n the United States, one major producer and two small producers supplied about 11% of the Nation's fluorspar requirements. Supplementing fluorspar as a domestic source of fluorine was byproduct fluosilicic acid production from some phosphoric acid producers. Imports of fluorspar, which continued to supply most of the U.S. requirements, decreased by about 23% compared with those of 1989. Hydrofluoric acid (HF) imports were about 10% lower than reported in the previous year.

DOMESTIC DATA COVERAGE

Domestic production and consumption

data for fluorspar were developed by the U.S. Bureau of Mines from voluntary surveys of U.S. operations. Surveys were conducted to obtain fluorspar mine production and shipments and fluosilicic acid production. Of the five fluorspar mining operations to which a survey request was sent, three responded, representing more than 95% of domestic shipments. Shipments for the two nonrespondents was estimated using data from contacts within the industry. Production statistics in table 1 are withheld to protect company proprietary data. Of the seven fluosilicic acid producers surveyed, seven responded, representing 100% of the quantity reported. The consumption survey was sent to approximately 93 operations quarterly and to 40 additional operations annually. Of the operations surveyed quarterly, 60% responded. Of the operations surveyed on an annual basis, 68% responded. Together, quarterly and annual responses represented 96% of the apparent consumption data shown in table 1.

BACKGROUND

Definitions, Grades, and Specifications

Technically, pure fluorspar, or the mineral fluorite, contains 51.1% calcium and 48.9% fluorine. Natural fluorite is commonly associated with other minerals such as quartz, barite, calcite, galena, siderite, celestite, sphalerite, chalcopyrite, other sulfides, and phosphates. It occurs in well-formed isometric crystals, in massive and earthy forms, and as crusts or globular aggregates with radial fibrous

texture. In crystalline form, it can be colorless or may exhibit a wide range of colors, including yellow, blue, purple, green, rose, red, bluish and purplish black, and brown. It has a hardness of 4 on the Mohs' scale, a specific gravity ranging from 3.01 to 3.60, and a melting point of 1,378° C.

Three principal grades of fluorspar are available commercially: acid, ceramic, and metallurgical. Although the specifications for individual grades are generally well defined, some variation is permitted to satisfy the requirements of individual consumers.

In the United States, acid-grade fluorspar (acidspar) contains at least 97% CaF₂. Some manufacturers of hydrofluoric acid in the United States and Europe can use 96% CaF₂ or slightly lower if the remaining impurities are acceptable. User specifications may impose limits on silica, calcium carbonate, sulfide or free sulfur, calcite, beryllium, arsenic, lead, phosphates, and other constituents. Moisture content of the dried material is preferably 0.1% or less. Particle size and distribution are sometimes specified for proper control of the rate of chemical reaction and stack losses. Very few reserves in the world can be used to produce acid-grade fluorspar without flotation processing.

Ceramic-grade fluorspar is generally marketed as No. 1 ceramic, containing 95% to 96% CaF₂, and No. 2 ceramic, containing 85% to 90% CaF₂. An intermediate grade of about 93% to 94% CaF₂ is also available. Specifications on impurities vary, but may allow a maximum of 2.5% to 3.0% silica, 1.0% to 1.5% calcite, 0.12% ferric oxide, and trace quantities of lead and zinc. Shipments of ceramic-spar are usually tailored to the specific need of individual consumers.

Metallurgical-grade fluorspar (metspar) contains a minimum of 60% effective CaF₂. In the United States, metspar is usually quoted in terms of effective CaF₂ units, obtained by subtracting 2.5 times the silica content of the ore from its total CaF₂ content. The term "metspar" is usually used to refer to material with a maximum CaF₂ content of 85%, but sometimes is used for material as high as 96%, which includes what is technically ceramic grade. Other countries may require a minimum of 80% CaF₂, which allows larger quantities of silica, usually a maximum of 15%, and other contaminants. Metspar is often traded as a lump or gravel that must pass a 25- to 37.5-millimeter screen (1 to 1 1/2 inch) and contain less than 15% of material passing a 1.6-millimeter screen (1/16 inch).

In the domestic steel industry, various shapes and sizes of briquets or pellets are being used. Generally made to consumer specifications, briquets contain varying quantities of fluorspar mixed with binders, fillers, and fluxing agents. Typically made on roll presses and ranging in size from that of a peach seed to a 5-centimeter square, briquets contain 25% to 90% CaF₂ and steel mill waste ingredients, such as mill scale, flue dust, shredded scrap, iron ore fines, and manganese ore fines. The most popular binders are molasses and lime, which do not require baking ovens. Imported briquets are often made from fines accumulated during metspar preparation and from flotation concentrates. Pellets have been made on balling machines using sodium silicate binder.

Geology-Resources¹

Fluorspar occurs in a wide variety of geological environments, which indicates that deposition takes place in a number of different ways. From an economic standpoint, seven of the most important modes of occurrence are as follows:

- 1. Fissure vein deposits commonly occur along faults or shear zones and are the most readily recognized form of fluorspar occurrence in the world. Although the vein structure may be persistent, the fluorspar mineralization commonly occurs as lenses or ore shoots separated by barren zones. Fissure veins occur in igneous, metamorphic, and sedimentary rocks.
- 2. Stratiform, manto, or bedded deposits occur as replacements in carbonate rocks. Some beds are replaced adjacent to structural features such as joints and faults. Frequently, there is a capping of sandstone, shale, or clay.
- 3. Replacement deposits in carbonate rocks along the contact with acidic igneous intrusives are another common type of deposit. Deposits do not have to be the result of contact metamorphism, but may be introduced later, following the contact zone as a conduit and replacing the limestone.
- 4. Stockworks and fillings in shear and breccia zones are another form in which fluorspar occurs. The Buffalo deposit in the Transvaal consists of a network of

fluorspar veinlets in sill-like bodies that are inclusions in the granite of the Bushveld complex.

- 5. Carbonatite and alkalic rock complexes may have fluorspar at their margins. Fluorspar grades are not usually sufficient to be economic, but the Okorusu deposit in Namibia is made up of a number of bodies of fluorspar in limestones, quartzites, and related rocks that have been intruded and metamorphosed by an alkaline igneous rock complex.
- 6. Residual deposits of fluorspar are formed in clayey and sandy residuum that results from surficial weathering of fluorspar veins and replacement deposits. These deposits may be the sources of metallurgical-grade fluorspar. They include detrital deposits blanketing the apex of veins and the upper portions of the veins themselves that have been weathered to depths of 30 meters or more.
- 7. Fluorspar may also occur as a major gangue mineral in lead and zinc vein deposits. Two operations in the Parral area of Mexico have treated the tailings of lead-zinc mines to recover fluorspar from previously discarded gangue minerals.

Identified world fluorspar resources are approximately 365 million metric tons of contained fluorspar. As might be expected, the countries with the highest production have the largest fluorspar reserves, although their production ranking does not necessarily mirror their reserve ranking. World resources of equivalent fluorspar from phosphate rock are approximately 325 million metric tons, which includes about 32 million metric tons from domestic phosphate rock.

Technology

Mining.²—Mining methods vary according to geologic conditions at individual deposits around the world. Deep deposits usually require underground techniques, while wide, shallow deposits employ open pit methods. If the ground is unable to support underground mining, open pit methods may be used even though overburden removal might be substantial. In some cases, open pit methods are used until the mining reaches a practical production limit because of excessive waste removal. Mining then moves underground.

Narrow vein mining is often done by shrinkage stoping and open stoping where strong walls occur, while stratiform or

bedded deposits use room-and-pillar patterns. Replacement and fissure vein deposits are mined with shrinkage stoping or cut and fill methods if they are deep, narrow occurrences. They may also be mined by open pit or strip-mining techniques when they occur near the surface and have competent sidewalls. The replacement and stockwork deposits in the Republic of South Africa, the carbonatite deposit in Namibia, and most of the fissure veins in Thailand are mined with open pit methods. However, replacement deposits in Mexico are extracted by stoping or cut-and-fill methods.

Beneficiation.—Most fluorspar must be upgraded for marketing. Metspar is

often produced by hand sorting of highgrade lump crude ore, followed by crushing and screening to remove most of the fines. In the case of fluorspar ores of lower grade and/or ores with relatively coarse interlocking of minerals, gravity concentration processes are used based on the specific gravity above 3.0 for spar and below 2.8 for most gangue minerals.

Heavy-media cone and drum separators are particularly effective in the 37.5 by 4.75 millimeter (1 1/2 by 3/16 inch) size range, either for producing metallurgical gravel or for preconcentrating crude ore for flotation feed. For the finer sizes, the heavy-media cyclone process is frequently used. The high capacity and low

operating cost of heavy-media methods give very satisfactory results. Ores as low as 14% CaF₂ can be preconcentrated to yield a flotation feed of 40% CaF₂ or more. In the process, lead and zinc sulfides and barite concentrate with the fluorspar, which enriches the flotation feed with these valuable minerals. In some cases, washing plants are also used prior to flotation to remove clay or manganese oxides (wad).

Ceramic and acid grades of fluorspar are produced by multistage froth flotation. Ore from the mine is crushed and ground to proper size; care is taken not to over grind and cause fluorspar to be lost in the slimes. If lead and zinc sulfides are present, they are preferentially floated off with xanthate collector. After this process is completed, all the easy floating fluorspar is removed in a quick pass through a flotation circuit and sent on to the cleaner circuit. The tailings are discarded. The middling product is reground to separate the more finely interlocked grains of fluorspar and gangue and passed through one or more cleaner circuits. The final products generally comprise an acidgrade concentrate and, in some cases, one or more concentrates of lower grade, which are sold as ceramic grade, or pelletized and sold as metallurgical grade. Fatty acids are used as collectors for the fluorspar. Quebracho or tannin is used to depress calcite and dolomite; sodium silicate is used to depress iron oxides and silica; and chromates, starch, and dextrin are used to depress barite. Cyanide is used to depress any remaining sulfides. Lime. caustic, or soda ash can be used for acidity control. Flotation temperatures range from ambient to 80° C.

ANNUAL REVIEW

Legislation and Government Programs

At yearend, the National Defense Stockpile fluorspar inventory was unchanged from yearend 1989. New goals were finalized in 1990 of 900,000 short dry tons (about 816,000 metric tons) for acid grade and 310,000 short dry tons (about 281,000 metric tons) for metallurgical grade.

The Defense Logistics Agency, Defense National Stockpile Center, announced the offering for sale of a portion of the 15,000 short dry tons (13,608 metric tons) of metallurgical-grade fluorspar authorized

¹The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals," which is reprinted in the annual, U.S. Bureau of Mines, Mineral Commodity Summaries.

²Recoverable CaF₂ at the demonstrated level (measured plus indicated).

³The reserve base includes demonstrated resources, reported in terms of 100% CaF₂, that are currently economic (marginal reserves), and some of those that are currently subeconomic (subeconomic resources).

for disposal during fiscal years 1990 and 1991. Sale was authorized of 5,000 short dry tons (4,536 metric tons) for fiscal year 1990 and 10,000 short dry tons (9,072 metric tons) for fiscal year 1991. No bids were received during calendar year 1990. Additional offerings were scheduled for May, July, and September 1991. The material offered is stockpiled near Gallup, NM. It is of nonstockpile grade and has an effective calcium fluoride content of 59%.

Depletion allowances against Federal taxes of 22% and 14%, respectively, remained in effect for domestic and foreign production by U.S. companies.

On November 28, 1990, the Illinois Wilderness Act of 1990 was signed into Federal law. The law designated seven tracts in the Shawnee National Forest in southern Illinois as wilderness and, therefore, components of the National Wilderness Preservation System. The 7 tracts total about 10,630 hectares (26,266 acres). The boundaries of the Shawnee National Forest encompass a substantial portion of the Illinois-Kentucky fluorspar district, including the operations of Ozark-Mahoning Co. The law designated 2 additional tracts totaling about 1,119 hectares (2,764 acres) as special management areas. Within these two areas, prospecting for fluorspar and associated minerals may be allowed for a period of not more than 8 years from the enactment date. If fluorspar and associated minerals are found on these lands, mining may be allowed for a 20-year period from the date of enactment. If no prospecting or mining takes place during the allotted time periods, these special management areas will be designated as wilderness and become components of the National Wilderness Preservation System.³

On November 15, 1990, the Clean Air Act Amendments of 1990 were enacted into law. Title VI covered stratospheric ozone protection. Chemicals damaging to stratospheric ozone were listed as class I and class II substances. Class I substances were separated into five groups, which include the following three groups containing fluorine: group I—chlorofluorocarbons (CFC's) 11, 12, and 113-115; group II—halons 1211, 1301, and 2402; and group III—CFC's 13, 111, 112, and 211-217. Class II substances consisted of hydrochlorofluorocarbons (HCFC's).

Production phaseout schedules were established for all class I substances limiting

TABLE 3
CFC PRODUCTION PHASEOUT

Year	Production limit1
1991	85%
1992	80%
1993	75%
1994	65%
1995	50%
1996	40%
1997	15%
1998	15%
1999	15%
2000	_

¹Percentage of baseline year 1986 or 1989.

production to a percentage of that produced by the individual in the designated baseline year. The baseline year for groups I and II was 1986, and for group III it was 1989. Notwithstanding the scheduled termination of production, limited production and consumption of CFC 114 and the halons may be authorized for national security, aviation safety, fire suppression, and explosion prevention, if it is determined that no safe and effective substitute has been found.

Although a specific phaseout schedule has not been established for class II substances, the law does state that as of January 1, 2015, production of all class II substances are limited to a percentage of that produced by the individual in an as yet to be selected baseline year. Effective January 1, 2030, it shall be unlawful for any person to produce any class II substance. The Environmental Protection Agency has until December 31, 1999, to promulgate regulations phasing out production and restricting the use of class II substances.

The phaseout schedules for both class I and class II substances can be accelerated if new scientific evidence warrants it, the availability of substitutes makes it practical, or the Montreal Protocol on Substances that Deplete the Ozone Layer is modified to include a phaseout schedule more accelerated than the one under this law.⁴

Issues

HF is used as a catalyst to convert low-molecular-weight byproduct hydrocarbons into larger hydrocarbons, such as

2,2,4-trimethylpentane. The resulting compound is called alkylate, and the process is called petroleum alkylation. Alkylate is a prime blending compound for high-octane gasoline.

The use of HF acid for petroleum alkylation and CFC refrigerant production in populated areas has come under intense scrutiny. Accidental releases of HF during transport have heightened the public's awareness of the potential danger from a major accident. The perceived danger from an accidental release of HF acid resulted in an out-of-court settlement between Torrance, CA, and Mobil Oil to end Mobil's use of HF at their refinery in Torrance by 1997. In a similar issue, the Southern Coast Air Quality Management District, the air regulatory panel for the four county Los Angeles area, voted on April 4, 1991, to ban HF use by refiners by the end of 1997 and by refrigerant manufacturers by the end of 1998. Interim controls are scheduled to go into effect January 1, 1992. The ban will take effect unless an additive is developed to prevent the formation of toxic vapor clouds. Four petroleum refineries and one refrigerant plant were impacted by the decision.5

The California bans have impacted primarily the petroleum refining industry. HF is used in about one-half of U.S. refineries. The alternative to HF in the alkylation process is sulfuric acid. The American Petroleum Institute estimated that, based on the average cost of a typical alkylation unit, it would cost about \$4 billion to replace all existing HF alkylation units with sulfuric acid units. Switching from an HF process to a sulfuric acid process would most likely require construction of new alkylation units. Because most of the equipment used in the two processes is not interchangeable, conversion of an existing unit would require shutting down the unit for several months and special chemical cleaning of the few pieces of reusable equipment. Also, the space required for the new equipment would be difficult to find on the existing alkylation unit site. For these reasons, most refiners would decide to construct new alkylation units elsewhere in the refinery rather than convert the existing unit.6

If a ban or severe restrictions on usage were to spread throughout the United States, it would have a major economic impact on other industries that depend on HF as a feedstock or as a necessary

processing chemical. These would include the fluorochemical, aluminum, stainless steel, and uranium chemical industries.

Production

Illinois remained the leading producing State, accounting for about 95% of all U.S. shipments. Data on shipments of fluorspar by State and grade are withheld to avoid disclosing company proprietary data.

Ozark-Mahoning Co., the Nation's largest fluorspar producer and a subsidiary of Atochem North America Inc., operated three mines and a flotation plant in Pope and Hardin Counties, IL. Ozark-Mahoning also dried imported fluorspar to supplement its production. Seaforth Mineral & Ore Co. Inc. dried imported fluorspar at its facilities at Cave-In-Rock. IL, and East Liverpool, OH, for sale primarily to consumers in the ceramic industry. H. & H. Equipment and Engineering Co. produced and shipped metallurgical-grade fluorspar from its mine in Juab County, UT. J. Irving Crowell, Jr., & Son shipped a small amount of metallurgical-grade fluorspar from its Crowell-Daisy Mine in Nye County, NV.

Ozark-Mahoning reestablished production from the former Inverness Mining Co. Minerva #1 Mine. Overall, Ozark-Mahoning's production was evenly divided between the Minerva #1, Annabell Lee, and Denton Mines.

Seven plants processing phosphate rock for the production of phosphoric acid sold a reported 46,754 metric tons of byproduct fluosilicic acid at a value of about \$5,855,000. This was equal to 82,287 metric tons of 92% fluorspar equivalent.

Reported and estimated production of fluorspar briquets for use in steel furnaces totaled about 108,000 metric tons valued at \$10,700,000. Fluorspar briquets were produced by two plants owned by Cametco Inc., one plant owned by National Briquetting Co., one plant owned by Oglebay Norton Co., and one plant owned by Mercier Corp. The Mercier plant went out of business in 1990. Oglebay Norton also dried, packaged, and shipped imported ceramic- and acid-grade fluorspar.

Consumption and Uses

Acid-grade fluorspar, containing greater than 97% calcium fluoride (CaF₂), was used primarily as a feedstock in the

manufacture of HF. Ceramic-grade fluorspar, containing 85% to 95% CaF₂, was used for the production of glass and enamel, to make welding rod coatings, and as a flux in the steel industry. Metallurgical-grade fluorspar, containing 60% to 85% or more CaF₂, was used primarily as a fluxing agent by the steel industry.

Reported domestic consumption by the HF industry decreased by about 18%. Reported consumption by the steel industry increased by about 5%, although the increase may have been simply the result of more accurate reporting. According to the American Iron and Steel Institute, domestic production of raw steel in 1990 remained essentially unchanged from 1989 levels.

In the ceramic industry, fluorspar was used as a flux and as an opacifier in the production of flint glass, white or opal glass, and enamels. Fluorspar was used in the manufacture of glass fibers, aluminum, cement, and brick, and was also used in the melt shop by the foundry industry.

Three companies reported fluorspar consumption for the production of HF. The U.S. Department of Commerce, Bureau of the Census, reported that, based on their monthly survey, anhydrous, technical, and aqueous HF, 100% basis, "produced and withdrawn from the system," was an estimated 136,000 metric tons for 1990 compared with the 1989 quantity of about 177,000 metric tons.

The largest use of HF was for the production of a wide range of fluorocarbon chemicals, including fluoropolymers and CFC's. CFC's were produced by five companies. According to preliminary data from the U.S. International Trade Commission, production of trichlorofluoromethane (CFC-11) decreased by 30% to 61,277 metric tons, dichlorodifluoromethane (CFC-12) decreased by about 47% to 94,586 metric tons, and chlorodifluoromethane (HCFC-22) decreased by about 6% to 138,830 metric tons, compared with 1989 figures.

As a consequence of the passage of the Clean Air Act Amendments, CFC-11 and CFC-12 production will be phased out during the next 10 years and may be phased out even sooner as discussed previously. Because HCFC-22 is not a fully halogenated CFC and has a much lower ozone-depletion potential, it was classified as a class II substance and will be phased out at a later date. The chemical industry

continued to pursue research into replacement compounds for the CFC's and HCFC's that are to be phased out. Construction continued on commercial plants to manufacture some of the most promising replacements. The CFC producers are developing substitutes called hydrochlorofluorocarbons (HCFC's) that have ozone-depletion potentials of about 5% that of CFC-11, CFC-12, and CFC-113, which in total account for more than 90% of CFC consumption. Other substitutes, called hydrofluorocarbons (HFC's), have no ozone-depletion potential because they contain no chlorine atoms. The most likely candidates to replace controlled CFC's are HCFC-22, for use in home air-conditioning and plastic foams; HCFC-123, a potential substitute for CFC-11 in plastic foams and refrigeration; HFC-134a, a potential substitute for CFC-12 in refrigeration and auto air conditioners; and HCFC-141b, a potential substitute for CFC-11 in plastic foams. In addition, some of the replacements will be mixtures of these compounds and other HCFC's and HFC's. Only HCFC-22 is currently in commercial use. Inhalation and toxicity tests continued on the various replacements.

The manufacture of synthetic cryolite and aluminum fluoride for use in aluminum reduction cells was a major use of HF. In the Hall-Héroult process, alumina is dissolved in a bath of molten cryolite, aluminum fluoride, and fluorspar to allow electrolytic recovery of aluminum. An estimated 20 to 30 kilograms of fluorine was consumed for each metric ton of aluminum produced. Aluminum fluoride was used by the ceramic industry for some body and glaze mixtures and in the production of specialty refractory products. It was used in the manufacture of aluminum silicates and in the glass industry as a filler.

HF was consumed in the manufacture of uranium tetrafluoride that was used in the process of concentrating uranium isotope 235 for use as nuclear fuel and in fission explosives. It was also used in stainless steel pickling, petroleum alkylation, glass etching, oil and gas well treatment, and as a cleaner and etcher in the electronics industry. It was used as the feedstock in the manufacture of a host of fluorine chemicals used in dielectrics, metallurgy, wood preservatives, herbicides, mouthwashes, decay-preventing dentifrices, plastics, and water fluoridation.

Fluosilicic acid was used primarily in

water fluoridation, either directly or after processing to sodium silicofluoride, and to make aluminum fluoride for the aluminum industry.

Stocks

Fluorspar consumer stocks decreased substantially from the previous year. Consumer stocks were 54,991 metric tons, down 31% from the level reported in 1989. Government stockpiles of fluorspar remained unchanged and contained a reported 891,957 short dry tons (809,171 metric tons) of acid grade and 294,045 short dry tons (266,753 metric tons) of metallurgical grade. The Government stockpiles also include 899 short dry tons (816 metric tons) of nonstockpile, acidgrade material and 116,777 short dry tons (105,938 metric tons) of nonstockpile, metallurgical-grade material. The Defense Logistics Agency attempted unsuccessfully to sell some of the latter in 1990.

Prices

According to prices published by Industrial Minerals (Metal Bulletin PLC), the price of domestic acid-grade fluorspar increased by about \$5 per metric ton. Published foreign producer prices at yearend were essentially unchanged compared with 1989 prices. Although not published in 1990, prices for Chinese fluorspar were reported to be 20% to 30% below the published prices.

Yearend price quotations from the Chemical Marketing Reporter (CMR) were unchanged at \$0.6875 per pound for anhydrous HF and were unchanged at \$52.00 per 100 pounds for aqueous HF, 70%, in tanks. These quotations were equivalent to about \$1.52 per kilogram for anhydrous HF and \$114.64 per 100 kilograms for aqueous HF, 70%, in tanks. The CMR yearend price quotation for fluosilicic acid, 100% basis, in tanks, was unchanged at \$340 per short ton (about \$375 per metric ton) and for synthetic cryolite was unchanged at \$550 per short ton (about \$606 per metric ton).

Foreign Trade

According to the Bureau of the Census, U.S. exports of fluorspar increased by 191% and had an average value of

\$127 per metric ton. More than 11,000 metric tons were exported to Canada, which received 76% of U.S. fluorspar exports.

Imports for consumption of fluorspar decreased by about 22%, with Mexico remaining the most important supplier, followed by, in descending order of the quantity imported, China, the Republic of South Africa, Canada, Morocco, and Kenya. The average unit value, in dollars per metric ton, was \$135 for acid grade and about \$102 for subacid grade.

U.S. import duties underwent major changes in 1990. Presidential Proclamation 6123 of April 26, 1990, made acidgrade fluorspar from Mexico eligible for preferential tariff treatment under the Generalized System of Preferences, pursuant to Title V of the Trade Act of 1974,

as amended. Effective July 1, 1990, this material was exempted from duty upon entering the United States. The preferential tariff treatment applies as long as Mexico's share of the import market does not exceed 50% or \$89.9 million. Effective on August 20, 1990, the 13.5% ad valorem tariff on imports of all metallurgical-grade fluorspar was suspended through December 31, 1992. The suspension was provided for in Public Law 101-382, Customs and Trade Act of 1990, Title III, Part 1, Section 450F, signed into law August 20, 1990.

Imports for consumption of HF decreased about 11% to a quantity equivalent to approximately 153,000 metric tons of fluorspar. Imports of synthetic and natural cryolite decreased 11% to a quantity equivalent to approximately 8,800 metric tons of fluorspar. Imports of aluminum fluoride decreased about 22% to a quantity equivalent to approximately 54,000 metric tons of fluorspar.

An application was submitted to the Foreign Trade Zones Board, Department of Commerce, requesting a special-purpose subzone status for the alumina and aluminum fluoride manufacturing plant of the Aluminum Co. of America (Alcoa) in Calhoun County, TX, adjacent

to the Point Comfort Customs point of entry. Zone procedures would exempt Alcoa from customs duty payments on foreign material used in its exports. On domestic sales, the company would be able to choose the finished product duty rate that applies to aluminum fluoride (duty free) rather than the rate on fluorspar (\$2.07 per metric ton).⁹

World Review

World fluorspar consumption and production decreased compared with 1989 levels. In order of rank, China, Mongolia,

Mexico, the U.S.S.R., and the Republic of South Africa were the major producers. The international fluorspar industry suffered the initial effects of major changes in traditional markets. Some smaller producers have closed or were in danger of closing because of shrinking markets and price pressures from Chinese suppliers.

Canada.—St. Lawrence Fluorspar Ltd., subsidiary of Minworth Group PLC, London, England, ceased production. Mine production was halted in the third quarter, and the company was put into receivership in January 1991. Pumping stopped in early April 1991, and the mine was allowed to flood. The company had been in production for less than 4 years. Initial production began in 1987 from the Tarefare vein open pit and the Blue Beach North underground mine. The operation produced mainly acidgrade fluorspar, with most being exported to the United States.

China.—Fluorspar exports from China continued at high levels, with reported exports of 1,094,000 metric tons in 1989. Based on reported export data and

estimates of domestic consumption, it is estimated that China produced about 1.5 million metric tons in 1990, U.S. imports from China decreased by about 4% to 153,000 metric tons. China's largest export market remained Japan, although exports to Japan were down by 20% compared with those of 1989. China produces from 15 Provinces, has reserves reportedly in excess of 100 million metric tons, and routinely undercuts all other producers in price. Metallurgical-grade material at 90% CaF₂ was offered in Northern Europe at \$90 per metric ton. c.i.f., and acid-grade material was offered at \$100 to \$105 per metric ton, c.i.f.

Zhejiang Province is one of the major fluorspar-producing Provinces in China. The major fluorspar area is the Wu Yi fluorspar district in central Zhejiang Province. The Dong Feng Fluorite Co., owner and operator of the principal mines and mill, is under the Ministry of Metallurgical Industry. The company operates 14 active mines producing about 600,000 metric tons of ore with an average ore to waste ratio of 1.3:1. They produce on average about 90,000 metric tons of metallurgical grade and 235,000 of acid grade per year.

Denmark.—After more than 130 years, Denmark's production of natural cryolite from the Ivigtut Mine in Greenland has ceased. Mine production ended some years ago, but Kryolitselskabet Oresund A/S, with the Danish State as coshareholder since 1940, continued to process material stockpiled in Greenland and at its Strandboulevarden plant in Copenhagen. In late 1990, the last of the plant stockpile was worked out. Cryolite, sodium aluminum fluoride Na₃AlF₆, is necessary for the electrolytic recovery of aluminum.

Mexico.—Official production figures for Mexico as shown in table 11 were provided by Conseio de Recursos Minerales (the Mexican Council of Mineral Resources). The data tend to be about 10% below industry-supplied figures and do not present the data in a breakdown by grade normally used by the fluorspar industry. The Instituto Mexicano de Zinc, Plomo y Coproductos A.C., collects fluorspar data for the fluorspar industry. According to their numbers, Mexico produced 207,000 metric tons of metallurgical grade and 488,000 metric tons of acid grade in 1990. More than 60% of Mexico's production came from Cía.

²Total includes synthetic cryolite imports; data not available by country.

¹C.i.f. value at U.S. port. Source: Bureau of the Census. Minera Las Cuevas S.A. de C.V. and Fluorita de México S.A. Mexico exported in excess of 300,000 metric tons in 1990, of which more than 60% was shipped to North America.

In May 1990, Industrial Químicas de México S.A. de C.V., a wholly owned subsidiary of Rhne-Poulenc S.A., announced plans for construction of a new HF and xanthate plant in Coahuila, Mexico. The plant was to be completed by the end of 1992 and have a final HF capacity of 60,000 metric tons. Construction plans have now been suspended indefinitely because of changed economic conditions and reduced demand.

Current Research

The U.S. Bureau of Mines, through its basic research program, has investigated column flotation for recovery of highgrade fluorspar concentrate and byproduct

¹Table includes data available through May 24, 1991.
²In addition to the countries listed, Bulgaria is believed to have produced fluorspar in the past, but production is not officially reported, and available information is inadequate for the formulation of reliable

Stimates of output levels.

An effort has been made to subdivide production of all countries by grade (acid, ceramic, and metallurgical). Where this information is not available in official reports of the subject country, the data have been entered without qualifying notes.

Reported figure.

Year beginning Mar. 21 of that stated.

⁶Data for 1986-87 were provided by the Instituto Mexicano de la Fluorita (now disestablished). Data for 1988-89 and total for 1990 are as reported by Consejo de Recursos Minerales.

concentrates from a marginal deposit in Nevada. A sample of about 4,500 kilograms was obtained from the Fish Creek fluorspar deposit in Eureka County, NV, grading about 14% CaF₂. The recovery process consisted of (1) grinding the ore, (2) fluorspar rougher and cleaner flotation, (3) desliming the rougher fluorspar flotation tailings, (4) mica flotation, and (5) silicate rougher flotation. Acid-grade fluorspar, mica, silica sand, and low-grade beryl concentrate were recovered. In addition to technical research, the Bureau conducted a cost evaluation on the use of column flotation to recover fluorspar only from the deposit.¹⁰

OUTLOOK

There are three major sectors of fluorspar demand: metallurgical-grade fluorspar and briquets by the steel industry; acid-grade fluorspar by the aluminum industry, primarily for production of aluminum fluoride; and acid-grade fluorspar by the chemical industry for production of feedstock HF.

Consumption of fluorspar by the steel industry is difficult to quantify. The problem is compounded by the large number of steel mills, the industry's often times indifferent response to consumption surveys, and the lack of accurate data on fluorspar briquets. Consumption of fluorspar by the steel industry has declined dramatically since the introduction of the basic-oxygen furnace and the gradual obsolescence of the open-hearth furnace. Some companies have reported that with certain new furnaces fluorspar use will be unnecessary. Domestically, steel production is expected to be down by 5% to 10% in 1991 owing to the economic recession. A recovery is expected by the end of the year, but many economists are predicting only a weak recovery. As such, it is estimated that overall consumption of metallurgical-grade fluorspar by the steel industry will be flat or continue to decrease during the next 3 to 5 years.

The aluminum industry consumes fluorine from different sources and in different forms. Although some fluorspar is consumed directly, fluorine is also consumed in the form of aluminum fluoride and synthetic or natural cryolite. Aluminum fluoride is manufactured either directly from fluorspar, from HF, or from fluosilicic acid. A small amount of cryolite is imported for consumption, but most is recovered as a byproduct of waste fluorine recovery or, in the case of a new potline, by tapping an operating pot for molten electrolyte. This material, termed "molten crushed bath," is allowed to solidify and is then crushed for use in the startup of a new potline.

The domestic aluminum industry is currently operating at or above rated capacity. No expansion of capacity is anticipated in the next few years, and the consumption of fluorspar and fluorine chemicals by the aluminum industry is expected to remain at current levels during the next 3 to 5 years.

Consumption of acid-grade fluorspar by the chemical industry for the production of HF is the largest market for fluorspar. The largest use of HF is in the manufacture of fluorocarbons (CFC's, HCFC's, and HFC's); the reminder is used in chemical intermediates, glass and metal processing, petroleum alkylation, stainless steel pickling, uranium chemical production, and other small uses. The initial effects of the CFC phaseout are being felt as was demonstrated by the 18% decrease in fluorspar consumption by the HF industry in 1990. It may be too early to judge whether the forecasts for large increases in HF consumption for production of replacement HCFC's and HFC's were far off the mark. Yet, the number and variety of not-in-kind replacements undergoing research or ready for development seem to be growing rapidly. Other forecasts have been more pessimistic from the start and anticipated that any gains in HF consumption for HCFC's and HFC's would be offset by overall decreases in CFC usage. In the short term, fluorspar consumption by the fluorocarbon industry is expected to be at much reduced levels from just a few years ago.

Some areas of HF consumption that are expected to grow are production of fluoropolymers, fluoroelastomers, and new fluorine-containing agricultural and pharmaceutical chemicals. The demand for fluoropolymers and fluoroelastomers could grow by 10% per year in the next 3 to 5 years. Industry estimates project

the combined number of potential fluorine-containing drugs and agrochemicals at more than 500. Unfortunately, these markets only account for a small percentage of HF consumption, and it is highly unlikely these markets will be able to absorb the losses expected in the fluorocarbon sector.

GALLIUM

By Deborah A. Kramer

Ms. Kramer is a physical scientist with the Branch of Industrial Minerals. She has covered gallium for 7 years. Domestic survey data were prepared by Eraina C. Dixon, mineral data assistant.

.S. gallium consumption was slightly higher than that in 1989. Even though demand increased slightly, it has stagnated at about 10,000 kilograms per year for the last 4 years. Most gallium consumption continued to be in the form of gallium arsenide (GaAs) for optoelectronic devices and integrated circuits. As in the past, the United States and Japan accounted for most of the world gallium demand.

Owing to low metal prices and stagnant demand, companies in Australia. Norway, and the United States idled gallium recovery facilities during the year. By yearend, only 50% of the available gallium production capacity was operational. Research on new production technology and development of new devices continued however, as GaAs manufacturers attempted to decrease manufacturing costs and to produce devices that were superior to silicon-base components.

DOMESTIC DATA COVERAGE

Gallium data are collected from two voluntary surveys of U.S. operations. In 1990, there were 31 responses to the "Consumption of Gallium" survey, representing 86% of the total canvassed. Significant quantities of gallium are used by universities and Government research facilities, which are not canvassed by the Bureau's survey; data in tables 1 and 2 representing gallium consumption were adjusted to reflect full industry coverage.

ANNUAL REVIEW

Legislation and Government **Programs**

On September 13, the Deputy Assistant

TABLE 1 SALIENT U.S. GALLIUM STATISTICS

Estimated. W Withheld to avoid disclosing company proprietary data.

Reported figure

Secretary for Export Administration determined that foreign availability existed for certain GaAs to controlled destinations such that current U.S. export controls were ineffective. Consequently, the Department of Commerce planned to publish regulations amending the national security export controls on certain forms of GaAs to controlled destinations. The forms of GaAs covered by the determination include doped, semiinsulating GaAs; conducting GaAs; and undoped, semi-insulating GaAs, except undoped, semi-insulating GaAs having all of the characteristics for use in monolithic microwave integrated circuit applications. 1

Production

Hecla Mining Co. began production of germanium in February at its mine and plant near St. George, UT. After the germanium circuit was operational, the company also planned to begin recovering gallium, but because of declining metal prices, the company closed the operation in August without producing any gallium. At yearend, the plant remained closed, although Hecla hoped to restart the operation if prices improved.

Eagle-Picher Industries Inc. recovered and refined gallium from both imported and domestic sources at its operation in Quapaw, OK. Recapture Metals Inc.. Blanding, UT, recovered gallium from scrap materials.

Consumption and Uses

Domestic consumption of gallium increased slightly from that in 1989, but over the past 4 years, it has stagnated around the 10,000-kilogram-per-year level. Except in military applications, GaAsbase integrated circuits still had limited uses in commercial products. Optoelectronic devices continue to account for much of the U.S. gallium consumption.

In May, Bertram Laboratories, a subsidiary of Chemetall GmbH, announced the purchase of Epitronics Corp., a subsidiary of Alcan Aluminium Ltd. With this purchase, Bertram Laboratories, which manufactures bare GaAs wafers, will extend its capacity to include epitaxial deposition, Epitronics' product specialty. Operations were expected to continue at the companies' plants in Arizona and New Jersev.

Vitesse Semiconductor Corp. reportedly agreed to provide its GaAs manufacturing technology to Thomson CSF of France in exchange for manufacturing capacity. Under the agreement, Thomson will have exclusive distribution rights for Vitesse's digital GaAs components in Western Europe, and Vitesse will have access to Thomson's new manufacturing facility in Grenoble, France.

Vitesse also increased the integration of GaAs digital components by developing a new manufacturing technology. This technology makes possible the production of GaAs gate arrays that have 100,000 gates; the most complex GaAs gate array previously manufactured had 30,000 gates. The company claims that the new GaAs arrays would deliver the same performance as some silicon-base components at comparable prices and with a reduction in power consumption.²

Hewlett-Packard Co. announced the development of a bright yellow lightemitting diode (LED) that has a brightness about 10 times that of existing yellow LED's. The improved performance will enable yellow LED's to be used in applications including sunlightviewable message panels and automotive exterior lighting. Existing applications for vellow LED's will require a lower current, which will reduce heat. Hewlett-Packard expects that the new LED's will be available by yearend 1991.

The Defense Advanced Research Projects Agency (DARPA) invested \$4 million in Gazelle Microcircuits Inc., a maker of digital GaAs components. Unique about this investment was that DARPA would not have to give any return on its investment to the Government's general fund; it would be able to use the return to fund other projects. Another benefit was that DARPA would have greater control over foreign access to Gazelle's GaAs technology.

Markets and Prices

Published vearend prices for gallium and gallium oxide have not changed since 1986. Press reports indicated that the free market price for 99.99999%-pure gallium had dropped to \$150 to \$200 per kilogram by the third quarter. The average value of gallium imports into the United States was \$328 per kilogram, a 13% decrease from that of 1989.

Foreign Trade

Gallium export data were combined with data for other materials by the Bureau of the Census and could not be separately identified. Some data were available on gallium exports through the Journal of Commerce Port Import/Export Reporting Service (PIERS), but this source provided data only on materials that are transported by ship. Gallium oxide, 99.99%-pure	435
Gallium oxide, 99.99%-pure, imported	400- 420

most gallium was shipped by air, it is likely that there were significantly more gallium-containing materials, particularly scrap, that were exported than were reported by PIERS. According to PIERS, 5,751 kilograms (gross weight) of gallium epitaxial material was shipped to France in 1990.

Beginning in 1991, the Bureau of the Census will separate GaAs wafers from silicon wafers under the Harmonized Tariff System. Two new categories will be instituted; one for doped GaAs wafers and one for undoped GaAs wafers.

World Review

Virgin gallium production in 1990 was estimated to be 40,000 kilograms, and Australia, the Federal Republic of Germany, and Japan were the largest producing countries. Lower demand and declining prices for gallium resulted in several companies mothballing gallium recovery circuits during the year.

Although available world gallium capacity data show that significant quantities of gallium can be produced, much of this capacity was not operational at yearend. Because of closures in Australia, Norway, and the United States, only 50% of the total world capacity was operational.

Australia.—Rhône-Poulenc S.A. reportedly stopped producing gallium at its plant in Pinjarra, Western Australia, in the third quarter because of declining demand. With the gallium inventory that built up at the plant, the company could continue supplying its customers' gallium requirements. The 50,000-kilogram-peryear plant had opened in April 1989 and was the largest gallium recovery plant in the world.

Canada.—Johnson Matthey Ltd. announced that it would close its Trail, British Columbia, facility on December 31 as a part of a restructuring of its electronic business. Production and sale of GaAs wafers was expected to undergo retrenchment, but research and development on polished GaAs wafers would be relocated from Trail to Crystar Research in Victoria. In addition, production of other materials, including high-purity cadmium and tellurium, would be relocated to the company's facility in Spokane, WA. Johnson Matthey had purchased the electronic business from Cominco Ltd. in late 1988.

Source: Bureau of the Census.

India.—The Central Engineering and Environment Research Institute (CEERI) reportedly developed a process to recover gallium from alumina wastes. Scientists at CEERI said that the country had a potential to produce 6,000 kilograms of gallium annually by this process. The new process underwent trials at a pilot plant at National Aluminium Co. Ltd.'s alumina plant.

Japan.—In 1989, Japan's demand for high-purity gallium was reported to be 54,000 kilograms. Production was reported to be 6,000 kilograms, imports were slightly higher than 16,000 kilograms, and recovery from scrap was 32,000 kilograms. France, the Federal Republic of Germany, Hungary, and Switzerland were the sources of most of the imports, with lesser quantities supplied by China, Czechoslovakia, and the United States. About 46% of the gallium was used as GaAs and gallium phosphide crystal substrates, and the rest was used in epitaxial production of LED's and laser diodes.3

Dowa Kogyo, a subsidiary of Dowa Mining Co. Ltd., reportedly developed a new use for gallium in ski waxes. By developing a spray version of the new ski wax, the company has increased its market from professional skiers to include the public.

Norway.—Elkem A/S announced that it would mothball its 5,000-kilogram-per-

year gallium recovery circuit at its aluminum plant in Bremanger by yearend. Low gallium prices were cited as the reason for the closure. Elkem's plant, which opened in 1987, produced 99.9%-pure gallium from aluminum smelter flue dusts generated at the company's aluminum plants in Tyssedal and Mosjen.

Current Research

Scientists at the Massachusetts Institute of Technology developed the first laser diode transmitter to pass requirements for intersatellite communications. Designed to send communications over a 23,000-mile distance between satellites, the GaAs laser transmitters were a part of the Laser Intersatellite Transmission Experiment, sponsored by the Air Force Space Technology Center. Increased security of laser transmissions compared to those of radio waves made the lasers attractive for satellite links.

Anadigics Inc. received an \$8 million contract from British Satellite Broadcasting to develop a GaAs monolithic microwave integrated circuit for home television applications.

TRW Inc. announced that it produced a demonstration GaAs integrated circuit that combined both analog and digital function on the same chip. Because the technologies involved in manufacturing analog and digital components differ, previous attempts to combine the two on a single chip resulted in performance

tradeoffs in either one or the other of the components.

American Telegraph & Telephone Co.'s (AT&T) Bell Laboratories announced the development of the first digital optical processor. The experimental device is based on GaAs components called symmetric self electrooptic effect devices (S-SEED) that were developed at AT&T in 1986. In the processor, pairs of S-SEED act like transistors in ordinary computers, except that light is used to communicate between the transistors instead of electricity. Although the experimental device is about 4 square feet in size and operates at slower speeds than most personal computers, it represents a breakthrough in developing optical computers that have processing power potentially 1,000 times greater than existing computers.4

Researchers at the University of California-Santa Barbara developed an indium gallium aluminum arsenide (InGaAlAs) surface-emitting laser that requires about 0.001 ampere to operate, 30% to 40% less than previously reported levels. Lasers such as these could be used in integrated circuits to communicate with light rather than with electricity.⁵

As a first effort in producing laser

diodes that could compete with gas lasers as a source of blue light, scientists at IBM Corp. generated a record 10% efficiency in converting electrical power into blue light by doubling the frequency of a gallium aluminum arsenide (GaAlAs) laser diode. Potential applications include optical storage, displays, undersea optical communications, and photochemistry. The 10% electrical efficiency is several hundred times that of blue gas lasers.⁶

To improve the characteristics of GaAs components produced by metal-organic chemical vapor deposition (MOCVD), two consortia—one in Europe and one in the United States—have been formed. The European Commission provided funding for a 3-year project to allow multiple wafers to be coated uniformly by MOCVD. Using novel equipment developed by one of the consortium members, project members plan to develop GaAs/GaAlAs, gallium indium arsenide (GaInAs), gallium indium aluminum phosphide (GaInAlP), and indium gallium arsenide phosphide (InGaAsP) heterostructures and products for applications such as guided optics, lasers, and microwave electronics for satellite broadcasting equipment. Members of the consortium are Philips BV (the Netherlands), Aixtron GmbH (the Federal Republic of Germany), and Telefonica and Technical University of Madrid (Spain). In the United States, the U.S. Army Electronics Technology and Devices Laboratory (EDTL) formed a cooperative research and development agreement with EMCORE, American Cyanamid Co., and Polytechnic University to investigate aspects of MOCVD technology. EDTL will be responsible for material characterization and device fabrication, EMCORE will perform the MOCVD thin-film growth, and American Cyanamid will provide the chemicals for MOCVD-tertiarybutylarsine and tertiarybutylphosphine. Polytechnic University provided research on the MOCVD process using these liquid replacements for arsine and phosphine, hazardous gases normally used for MOCVD growth.

Other researchers are investigating alternate sources for the arsenic and phosphorous used in MOCVD because of the hazards associated with these gases. At the State University of New York and the University of Illinois, acceptable semiconductor materials were produced at temperatures as low as 100° C using $(C_6F_5)_2$ GaAs $(C_2H)_4$. In this compound,

gallium and arsenic were bonded in a 1:1 ratio. Using a compound in which both the gallium and arsenic are present, rather than using two separate compounds, provided better control over the composition of the epitaxial layer.

Scientists at the National Aeronautics and Space Administration's (NASA) Jet Propulsion Laboratory reported the development of a new technique for epitaxial film deposition to reduce contamination when rectifying contacts are made. Normally, after an epitaxial layer is grown on a GaAs surface under a high vacuum, the gold used as a contact metal interdiffuses with the GaAs and forms an ohmic rather than a rectifying contact. Diffusion can be prevented by exposing the GaAs surface to air, but this may lead to contamination. In NASA's technique, an epitaxial film only two atomic layers thick was deposited on the GaAs surface. The film was thin enough not to constitute an electronic barrier, but thick enough to form a physical barrier to the interdiffusion of gold and GaAs.⁷

At the University of California—Santa Barbara, researchers developed a nonintrusive analytic technique for characterizing the top atomic layers of crystals grown on GaAs by molecular beam epitaxy. The technique, called reflection high-energy electron diffraction (RHEED), involved diffracting electrons of a crystal at an angle and observing the diffraction pattern on a phosphor screen. Diffraction of the electrons is dependent on the type and placement of atoms on the surface. By using RHEED, scientists hoped to reduce manufacturing costs and increase efficiency by optimizing crystal growth.

A new bipolar transistor that was claimed to be the world's fastest ballistic collection transistor was developed by Nippon Telegraph & Telephone Corp. The new transistor, fabricated from layers of GaAs and GaAlAs, was considered as a possible replacement for silicon in the development of high-speed transistors because it operated at five times the speed of a conventional silicon transistor. These GaAs devices could improve the performance of optical and radio communications systems and supercomputers.

By adapting GaAs solar cells, researchers at Varian Associates Inc. developed a component that can convert light from a fiber-optic cable into electrical power. Light transmitted through a fiber-optic cable is directed onto a GaAs solar cell that is divided into six sections. Each section

²All U.S. capacity is standby capacity as of Dec. 31, 1990.

converts the light to electricity at 1 volt, but when connected in series, the sections add up to give 6 volts of electricity, which is enough voltage to power most integrated circuits. Electrical conversion rate of the GaAs solar cells were measured at 45% to 50%, about twice the efficiency of silicon solar cells. A component such as this has applications in the development of fly-by-light aircraft control systems, phased-array radar, bomb detonators in nuclear weapons, and sensors in harsh chemical environments. 8

Continued research efforts led to the development of solar cells with new sunlight-to-electricity conversion efficiencies. Using a three-layer design, with a two-laver GaAlAs-GaAs cell on top of an InGaAs single cell, scientists at Varian Associates reported a 24.9% efficiency in deep-space conditions. This surpassed the previous record of 23.9% efficiency. At the Solar Energy Research Institute, a two-layer cell demonstrated a 31.8% efficiency. The two-layer cell, composed of an upper layer of indium phosphide and a lower layer of InGaAs, was being developed for use on U.S. Navy satellites. Most commercial land-based solar cells have an efficiency rating of about 12% to 16%.

Developments in GaAs production techniques, properties, and integration of

GaAs components into commercial applications were highlighted in several articles in nontechnical journals.⁹

OUTLOOK

At the same time that advances are made in GaAs integrated circuit technology, similar advances are being made in silicon technology, resulting in continuing competition between GaAs and silicon in many applications. Primarily because of its cost, GaAs will continue to be used only in applications where the benefits of its properties outweigh the added cost. In most instances, these types of applications are for defense components, which have limited production.

GaAs components are caught in a vicious cycle. Until costs are reduced, the components will not be used in a significant number of commercial applications that would bring about a substantial increase in demand. But until more applications develop, reducing costs by increasing the scale of production is difficult. Because of costs and competition from other materials, U.S. gallium consumption probably will remain stagnant for the next few years.

GEM STONES

By Gordon T. Austin

Mr. Austin, a physical scientist with more than 30 years industry and Government experience, has been the gem stones commodity specialist since 1986. Mr. William Field, mineral data assistant, prepared the domestic production survey data.

roduction value of natural gem materials in the United States during 1990 was essentially unchanged at \$52.9 million. The materials produced included faceting rough, lapidary rough, carving material, specimen material, natural and cultured freshwater pearls, mother of pearl, agatized coral, and coral.

The reported combined production value of synthetic and simulant materials was \$20.5 million, about a 9% increase over that of 1989. Synthetic gems are laboratory grown and have essentially the same optical, physical, and chemical properties, and the same appearance as the natural gem that they represent. Synthetic gem materials produced in the United States include alexandrite, coral, diamond, emerald, garnet, lapis lazuli, quartz, ruby, sapphire, spinel, and turquoise. Simulants are laboratory grown gem materials that have an appearance similar to that of a natural gem material but have different optical, physical, and chemical properties. The gem simulants produced in the United States include coral, cubic zirconia, lapis lazuli, malachite, and turquoise. Additionally, certain colors of synthetic sapphire and spinel, used to represent other gem stones, would be classed as simulants. Colored and colorless varieties of cubic zirconia are the major simulants produced.

Wholesale and retail outlets, gem and mineral shops, gem and mineral show dealers, cutting factories, and jewelry manufacturers were the major purchasers of domestic gem materials.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines estimates of U.S. production were from the "Natural and Synthetic Gem Material Survey," a

voluntary survey of U.S. operations, and from Bureau estimates of unreported production. Of the approximately 400 operations surveyed, 82% responded, accounting for about 95% of the total production, 92% of the natural production, and 100% of the synthetic and simulant production.

The 400 operations surveyed in 1990 were an increase of about 10% compared with the number of operations surveyed in 1989. The response rate was essentially the same as that of 1989. The Bureau estimated the production by nonresponding operations, by professional collectors, and by amateur or hobbvist collectors. The basis for these estimates were information from published data, conversations with gem and mineral dealers, analyses of gem and mineral shows and sales statistics, and from information informally supplied by collectors. In the formal voluntary survey and the informal surveys, the Bureau is totally dependent upon the cooperation of the producers, brokers, dealers, and collectors. Individuals and companies have been very cooperative and forthcoming with information. The Bureau is very appreciative of this cooperation.

BACKGROUND

The history of production and preparation of gem stones begins with the wearing of items for personal adornment in prehistoric times; this preceded even the wearing of clothes. Amber was mined in the Baltic countries for use as a gem material before 25,000 B.C. Later, the Phoenicians in their writings described their trade routes to the Baltic for amber and to areas in Asia and Africa for other gem materials. The voyages of Columbus brought increased interest in gem deposits, espe-

cially emerald, in South America. The discovery of diamond in Africa in 1859 focused major interest on Africa. More recently, the discovery of diamond in Western Australia in 1967 has resulted in the development of one of the largest deposits in the world.

Commercial mining of gem materials has never been extensive in the United States. Although more than 60 gem minerals and materials have been produced commercially from domestic sources, most of the deposits are relatively small. In many instances, production rests in the hands of the numerous hobbyists and members of mineralogical and lapidary clubs. The Crater of Diamonds State Park near Murfreesboro, AR, is open to the public on a daily fee basis. Many gem-quality stones are found there each year.

Definitions, Grades, and Specifications

Select rocks, certain varieties of mineral specimens, and some organic materials, such as pearl, amber, jet, and coral, are included in gem stones data. Customarily, diamond, ruby, sapphire, and emerald are considered the major gems.

The designation "gem stone" refers to a material appropriate for personal adornment. The most important qualities of gem stones are beauty, durability. uniqueness, and rarity. Beauty, indicated as splendor, purity, or attractiveness, is judged mainly according to the taste of the beholder and includes such appearances as luster, transparency, brilliance. and color. Luster of a mineral or stone is independent of color and is the surface appearance in reflected light. Apart from materials that have a metallic luster, the chief contributors to luster are transparency and refractive index. The perfection of polish enhances the luster of a stone. Visible imperfections impair the luster of transparent stones. However, defects, described as "jardens" or "inclusions,"

may enhance the beauty and value of natural rubies, sapphires, and other gem stones and may be used to identify the country of origin and even the mine. Durability is measured by the resistance of a stone to abrasion, pitting, chipping, or splitting. Resistance to abrasion is correlated with relative hardness, but intrinsic brittleness and toughness indicate resistance to wear in other aspects. Rarity is an essential qualification and is more important for some stones in determining their value than their physical characteristics.

Of the 1,500 mineral species, only about 100 possess all of the attributes required in gems. Silicates furnish the greatest number, including such minerals as beryl, topaz, tourmaline, and feldspar. Oxides such as corundum (ruby and sapphire) and quartz (amethyst, agate, etc.) comprise the second largest group. Sulfides, carbonates, and sulfates are of small importance; the phosphates yield only turquoise and variscite. An exception is pearl, essentially calcium carbonate, which is ranked high as a gem. Diamond, the best known gem stone, is an isometric crystalline form of the element carbon.

In general, gem materials are classified the same as minerals, that is, into group, species, and variety. Group refers to two or more gem materials that are similar in crystal structure and physical properties but have different chemical properties. Each individual member of the group is called a species. Varieties of species have similar crystal structure and chemical characteristics but differ in color. An example of this would be the hessonite variety of the grossular species of the garnet group.

Products for Trade and Industry

Cutting and polishing of gem materials are done to obtain the most effective display of the material. No significant change is made in the fundamental properties, and the preparation is intended to enhance the desirable characteristics that are present initially. Gem materials are cut into gem stones in three main styles; cabochons, baroque, and faceted.

Cabochons are cut in four operations: sawing, grinding, sanding, and polishing. Sawing, the initial step in cutting, is customarily done with a diamond saw to obtain a slab or slice of the desired size and thickness from the rough gem material. The cabochon outline is scribed

onto a flat surface, most often using a template for making a standard size for jewelry mountings. Rough grinding of the stone may be by metal-bond diamond, silicon carbide, or aluminum oxide wheels or coated abrasive disks. In grinding, the hardness of the gem material determines the grit and hardness of the abrasive used. Multiple grinding steps starting with 80- to 100-mesh (grit) through 600-mesh abrasives are normally used. The scratches left by grinding are removed by progressively finer grinding and sanding. Disk or belt sanders use bonded to cloth abrasives, waterproof reinforced paper abrasives, or cloth charged with abrasive pastes. The final polish is obtained by using hard felt, wood, or leather laps, with various polishing agents such as fine diamond compound, tin oxide, tripoli, chromium oxide, cerium oxide, alumina, and rouge.

Polished irregular shapes are called baroque gems. An inexpensive method of polishing baroque gems consists of tumbling them in rubber-lined drums, using a grinding and polishing medium with or without water.

Facet cutting is employed ordinarily on transparent gem stones to increase brilliancy and appearance and is generally confined to the harder materials. Softer materials may be faceted, but extreme care must be exercised in cutting and polishing the stones and in their use in jewelry. The "round brilliant" cut, most commonly used in faceting, has 58 facets, 33 above the circle "girdle" and 25 below it, arranged in eightfold symmetry. The "round brilliant" and some other common cuts are illustrated in figure 1.

Industry Structure

An estimated 80% to 85% of gem and natural industrial diamond is marketed through the Central Selling Organization (CSO) by the Diamond Trading Co. Ltd. and the Industrial Distributors Ltd. The CSO sells uncut gem diamonds on behalf of De Beers and most other major producers at sights (approved bidder viewings) in London, England, in Lucerne, Switzerland, and Kimberley, Republic of South Africa.

The CSO has been extremely successful at maintaining the rough diamond market for about 50 years. In modern times there has never been a decrease in CSO's price of rough diamonds. Table 9 illustrates the timing and the amounts

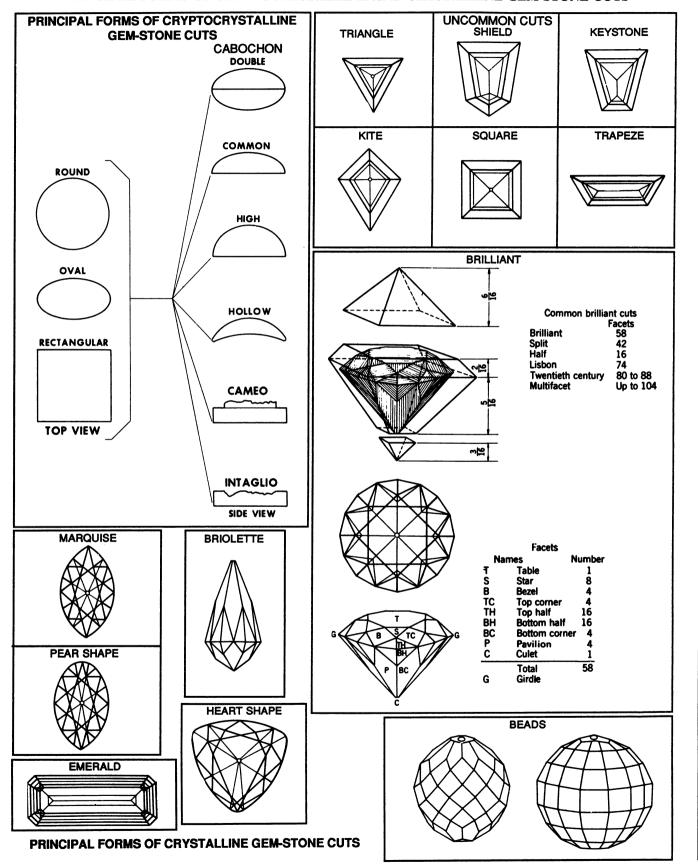

of the average CSO price increases for rough gem diamonds from 1949 until the present. The compounded affect of these increases is a price increase of about 1,800% over the approximately 41.5 years. Thus, a piece of rough that sold for \$100 in August 1949, would sell for about \$1,800 in April 1990.

For more than 30 years, the major diamond cutting and polishing centers of the world were in Belgium and Israel, with a certain amount of the larger stones being cut in the United States. However, in the early 1980's, the development of a large cottage industry in India-today there is estimated to be more than 450,000 cutters -made a major impact on world diamond trade. Indian consumption of most of the world's small-gem, cheapgem, and near-gem rough material in the manufacture of small stones resulted in annual cut-stone exports of almost \$3 billion from April 1, 1988, to March 31, 1989. These small stones averaged less than one-fifth of a carat (0.20 carat). The availability of small inexpensive stones resulted in substantial changes in the design of jewelry. The utilization of small cut diamond stones (usually 0.07 to 0.14 carats each, called melee) to create a pavé effect (set close together to conceal the metal base) is but one example. Cutting and polishing of colored, synthetic, and simulant gem stones is centered in Thailand, India, Hong Kong, and Brazil, where cheap labor and favorable export laws ensure the lowest total costs for finished gems.

Geology-Resources

Gem materials occur in a large variety of igneous, metamorphic, and sedimentary rocks and mineral deposits, usually as a small fraction of the total deposit. The origins are as varied as the occurrences. Principal formation of gem materials is by precipitation from watery solutions, by crystallization from molten rock, and by metamorphic processes. Approximately one-third of gem minerals is composed of silicate minerals, about one-fifth of aluminasilicates, and nearly one-seventh of oxides. The remaining compositional groups include the sulfides, phosphates, borosilicates, carbonates, and, in the single case of diamond, an element. The composition of selected gem materials is included as one of the items

FIGURE 1
PRINCIPAL FORMS OF CRYPTOCRYSTALLINE AND CRYSTALLINE GEM STONE CUTS

in table 2.

The United States has no defined large resources of major gem materials. Emerald deposits are known in North Carolina, as are ruby and sapphire. Historically, sapphires have been mined in Montana, and commercial mining once again is underway. Numerous other domestic deposits of gem minerals are known and have been mined for many years. However, no systematic evaluations of the magnitude of these deposits have been made, and no positive statements can be made about them.

Occasional finds of diamond have been made, but no great diamond pipes or alluvial deposits similar to those of Africa have been reported. Several companies are involved in diamond exploration in the Colorado-Wyoming State line area, in Michigan, Minnesota, Wisconsin, and Arkansas. Diamond-bearing kimberlites have been located, and bulk samples have been processed for diamond recovery. Results have not been made public.

World resources of gem materials are nearly all unevaluated. However, world gem diamond reserve is estimated to be about 300 million carats, including neargem and cheap-gem qualities. Nearly all of the reserves are in Australia, Africa, and the U.S.S.R. (Siberia). The estimates for diamond reserves are of limited value because data needed for reliable estimates are not available from the producers. Reserve data on other gem materials are even less available than for diamond.

Technology

Synthetic Gems.—The first synthetic gem produced was ruby, and later, by various melt techniques, sapphire, spin-

el, rutile, strontium titanate, and cubic zirconia. The Verneuil flame-fusion process, developed in 1902, consists of growing a single crystal in a simple, downward-impinging oxyhydrogen blowpipe flame. In manufacturing synthetic gems, pure oxides of aluminum and titanium, and as needed, moderating and coloring oxides, are charged at the top of a small furnace and melted as they pass through an oxygen-hydrogen flame. The molten material is solidified on a fireclay peg as a carrot-shaped single crystal known as a boule, usually ½ to 1 inch in diameter, 2 to 4 inches long, and weighing 75 to 250 carats. After cooling, the boule is heat treated and tapped at one end to relieve the internal strain that causes the boule to split into two vertical halves. The halves are then cut and polished into gems. Other melt techniques used are the Czochralski pulledgrowth method for ruby, sapphire, spinel, yttrium-aluminum-garnet (YAG), gadolinium-gallium-garnet (GGG), and alexandrite; the Bridgman solidification method for sapphire; and skull melting for cubic zirconia and sapphire.

Solution techniques for manufacturing synthetic gems include flux methods for emerald, ruby, sapphire, spinel, YAG, GGG, and alexandrite; hydrothermal methods for emerald, quartz, and the colored varieties of quartz such as smoky, yellow, citrine, and amethyst; and the high temperature ultra-high-pressure presses used in the manufacture of synthetic diamond in which a molten metal is used as the solvent.

Other techniques involve solid- or liquid-state reactions and phase transformations for jade and lapis lazuli; vapor phase deposition for ruby and sapphire; ceramics for turquoise, lapis lazuli, and coral; and others for opal,

glass, and plastics. However, the Verneuil, Czochralski, and scull melting processes are the melt techniques most often used for gem materials. The various synthetics and the method of production are shown in table 3.

Enhancement of Gem Stones.—Enhancement of all types of gem materials through chemical and physical means has become much more commonplace and in the past few years has included a wider variety of gem materials. Irradiation by electromagnetic spectrum (Xrays, gamma rays, etc.) and by energetic particles (neutrons, electrons, alphas, etc.) is being used to enhance or change the color of diamonds, topaz, tourmaline, quartz, beryl, sapphire, zircon, scapolite, and pearls. Blue topaz is normally irradiated, but this does not imply that all of these gem materials are regularly irradiated.

A number of gem materials can be enhanced by chemical treatment or impregnations. The treatments may alter the bulk of the gem material or only penetrate the surface. This includes bleaching, oiling, waxing, plastic impregnations, color impregnations, and dying. The treatments that alter only the surface of the gem material include surface coatings of various types, interference filters, foil backings, surface decoration, and inscribing. Chemical treatment is more widespread than the common dying of quartz, treatment of turquoise, and oiling of emeralds. Chemical treatment and impregnations have been used to enhance chalcedony, coral, ivory, pearl, tiger's eye, emerald, lapis lazuli, opal, ruby, sapphire, turquoise, beryl, quartz, jade, diamonds, and amber.

The oldest and most common method of gem material enhancement is heat treating. Heat treatment of gem materials was used in Greece and Rome well before the Christian Era. Heat treatment can cause color change, structural change, and improve clarity. In the past, heat treatment was common for quartz and gem corundum. Today, materials that are heat treated to enhance their appearance include sapphire, topaz, beryl, tourmaline, quartz, zircon, amber, diamond, and zoisite.³

Mining.—Gem materials mining operations can range from the most primitive to the most sophisticated. In hard rock, at shallow depths, an operation by one, two, or three persons may be

mined by prybar, pick, shovel, and baskets for carrying material. A larger operation may include drilling, blasting, and minimum timbering. Mechanized hauling and hoisting is done only at the larger mines.

Diamond mining in the kimberlite pipes of Africa and the U.S.S.R. and the lamproite pipes of Australia represent the ultimate in that huge quantities of ore must be mined to extract small quantities of diamond produced at as low a cost as possible.

Placer mining for gem stones ranges from small-scale, simple procedures to huge complicated operations. In some areas, digging is by hand, and sorting and recovery is by panning, screening, or sluicing. Diamond miners in the larger

placer operations use bucket dredges and heavy-duty excavating equipment, as, for example, in Australia, Brazil, the Republic of South Africa, Namibia, and the U.S.S.R.

Processing.—Most gem stone material is broken or crushed where necessary and concentrated by various combinations of hand picking, washing, screening, or jigging. In large-scale operations, mineral benefication methods employ mechanization and the latest technology in all steps from primary crushing and screening to the final recovery processes. Diamond recovery, in particular, makes use of standard gravity methods, grease belts, electrostatic separation, skin-flotation, magnetic separation, separation by X-ray luminescence, and separation by optical sorting.

ANNUAL REVIEW

Production

In 1990, all 50 States produced at least \$1,000 worth of gem materials. Ten States accounted for 95% of the total value of natural gem material produced. The States, in order of declining value of production, were Tennessee, Arkansas, Arizona, Montana, California, Oregon, Alabama, North Carolina, Utah, and Texas. Certain States were known for the production of a single gem material (i.e., Tennessee for freshwater pearls and Arkansas for quartz). Other States produced a variety of gem materials. Arizona produced the greatest variety of gem materials. Production included agate, amethyst, antlerite, azurite, chrysocolla, fire agate, garnets, jade, malachite, obsidian, onyx, peridot, petrified wood, precious opal, shattuchite, smithsonite, and turquoise. California, Idaho, Montana, and North Carolina also produced a variety of gem materials. North Carolina was the only State to have produced all four of the major gems: diamond, emerald, ruby, and sapphire.

The average production value of natural gem materials for the past 10 years was \$20.7 million per year, with a high of \$52.9 million in 1990 and a low of \$7.2 million in 1982. The value of production for the past 10 years must be separated into two trends. The first trend was the period between 1981

through 1985, during which time approximately 24 operations reported production. Production average \$7.4 million per year and was generally level. During the second trend, 1986 to the present, production averaged \$34.0 million and was the result of an increase of 1,567% in the number of producers surveyed.

The reported production value of synthetic and simulant gem materials was \$20.5 million in 1990. The reported value of production increased 9%. The average value of production of synthetic and simulant gem materials for the past 5 years was \$16.2 million, with a high of \$20.5 million in 1990 and a low of \$10.3 million in 1986. Thirteen firms, five in California, four in Arizona, and one each in Massachusetts. Michigan, New Jersey, and Ohio, produced synthetic and simulant gem material. The six States, in order of declining value of production, were Massachusetts, California, New Jersey, Michigan, Ohio, and Arizona.

Arizona is well known for the widest variety of gem materials produced by any State. In 1990, gem material production included agate, amethyst, antlerite, azurite, chrysocolla, fire agate, fluorite, garnet, jade, jasper, malachite, obsidian (Apache tears), onyx, peridot, petrified wood, precious opal, shattuchite, smithsonite, and turquoise. Yet, turquoise, peridot, petrified wood, and azurite/malachite accounted for more than 90% of the total value of gem material produced. Arizona was the largest producer of turquoise, peridot, and petrified wood in terms of dollar value in the United States. It was also the world's largest producer of the first two gem materials. Additionally, there are four manufacturers of synthetic or simulant gem materials in Arizona that produce about \$100,000 worth of material each vear.

Arkansas is famous for the production of quartz crystals. Yet, Arkansas is second in value of production of freshwater pearls and shells and the only State in the United States that has had any sustained diamond production.

For the past 19 years hobbyists have found from 300 to 1,500 diamonds per year at the Crater of Diamonds State Park. Since 1972, about 13,000 diamonds have been recovered; this amount of diamond production is in-

sufficient to classify the United States as a diamond-producing country. Still, the potential to become a diamond producer may be there, and efforts were underway to evaluate this potential more fully. The program to evaluate the diamond deposit was halted by legal actions after completing three exploration drill holes. The program is currently on hold, awaiting the outcome of the litigations.

Gem material production from California includes a variety of materials. California is the leading tourmaline producer in the United States and the only producer of benitoite. Additionally, California produces agate, alabaster, beryl, dumortierite, fire agate, garnet, gem feldspar, jade, jasper, kunzite, lepidolite, obsidian, quartz, rhodonite, topaz, and turquoise. Yet, even with this long list of gem materials, most people think of California in terms of its State gem benitoite, the production of high-quality tourmalines, and its fine orange spessartine garnets.

In May 1989, Pala International reported the discovery of the largest gem tourmaline pocket found in the Himalaya Mine during the past 12 years. The pocket yielded about 500 kilograms of tourmaline; 50% was carving or cabochon grade, less than 1% was faceting grade, and the remainder was specimen grade.

California also has four manufacturers of synthetic or simulant gem materials. The State is the second largest producer of synthetics and simulants in terms of value of total production.

Colorado is not known as a gem material producing State, but it does hold some gem stone honors. For 4 or 5 years prior to 1988, Colorado had the only commercially operated amethyst mine in the United States. It has the only commercially mined deposit of lapis lazuli in the United States and one of the few dig-for-fee topaz deposits currently operating. Additionally, the State was the first to commercially produce turquoise and still has commercially operated turquoise mines. The State also produced the United States' finest gem-quality rhodochrosite and a quantity of highquality rhodonite.

Many different locations in the State produce aquamarine, the Colorado State gem stone. The best known locations and the locations with the longest history of continued production (since about 1884) are Mount Antero and White Mountain in Chaffee County. Mount Antero, at 14,269 feet, may be the highest gem stone location in the United States. White Mountain, separated from Antero by a small saddle, is only slightly lower at 13,900 feet.

Star garnet, the Idaho State gem stone, leads the list of gem materials produced in the State. Idaho is one of two places that produce significant amounts of star garnet; India is the other. These almandite garnets are translucent, purplish-red stones that show four- or six-ray stars when cabochon cut or are transparent deep red stones that can be faceted. The primary sources of Idaho star garnet are the placer deposits on the East Fork of Emerald Creek and its tributary gulches in Benewah County, Additionally, the placers of Purdue Creek in Latah County yield star garnets. Currently, garnets that do not cut stars also are commercially mined from areas in Clearwater County. These garnets range from purplish rose-red to a highly prized "special pink." Gem-quality garnets occur at several other locations in Idaho and are mined periodically by hobbyists or professional collectors for the gem stone market.

Opal is the second largest contributor to the total value of gem material produced in Idaho. The varieties produced include precious, yellow, blue, pink, and common. The Spencer opal mine is the largest producer. At the Spencer Mine, precious opal occurs as one or more thin layers within common onal that have partially filled gas cavities within a rhyolite-obsidian flow. About 10% of the material is thick enough to cut into solid gems; the remainder is suitable for making doublets and triplets. The Spencer Mine is also the source of the pink opal, which occurs as either pink common opal or pink bodied precious opal.

In recent years, an increasing amount of gem material (smokey quartz, aquamarine, topaz, and garnets) has been recovered from the Sawtooth batholith. A significant portion of the batholith lays within the Sawtooth National Recreation Area, administered by the Forest Service, U.S. Department of Agriculture. Herein lies a possible problem. The Forest Service may prohibit the collection of gem and mineral specimens from the National Recreation Area under CFR Title 36, 269.9b, which prohibits the

removal of "natural features of the land." Additionally, all mining is prohibited in a recreation area. It appears that material is still being collected from the area, but this may stop in the future. Hopefully, collectors and the Forest Service can arrive at some mutual understanding where hobbyists can collect material or possibly collect controlled amounts for the commercial market.

In the U.S. gem stone industry, Maine and tourmaline are almost synonymous. In 1822, Maine's Mount Mica was the site of the first gem stone production in the United States. In September 1991, Plumbago Mining Corp. was actively mining the Mount Mica pegmatite for gem material and mineral specimens. Over the years, Mount Mica produced hundreds of pounds of fine-quality gem and mineral specimen tourmaline.

Mount Mica is not the only large producer of high-quality tourmalines. Dunton Mine of Newry Hill is the most prolific gem tourmaline producer in Maine. Since its discovery in 1898, the mine has produced tons of gem- and specimen-grade tourmaline. Other mines and quarries in a three county area produce gem- and mineral specimen-grade tourmalines. These include the Bennett, BB #7, Emmons, Harvard, Tomminen, Waisenen, Black Mountain and Red Hill Quarries, and Nevel Mine in Oxford County. It also includes the Mount Apatite Quarries in Androscoggin County and the Fisher and Porcupine Hill Quarries in Sagadahoc County.

Maine also produces fine-quality beryls—aquamarine, heliodor, and morganite. Pegmatites in Oxford, Androscoggin, and Sagadahoc Counties regularly produce fine-quality blue and bluegreen aquamarine, rich yellow and gold colored heliodor, and rose and peach colored morganite. In 1989, the largest rose colored morganite on record was found at the Bennett Quarry near Buckfield in Oxford County.

In 1989, Plumbago Mining Corp. opened the most significant commercial amethyst mine in the United States near the town of Sweden in Oxford County. Reported production in the first year of operation was about 5,000 pounds of gem-quality and specimengrade amethyst. The gem material has good deep purple color, but is mostly small pieces. An officer of the company did report the cutting of a 12-carat stone from the material and that

some material recovered would yield stones as large as 20 carats.

Montana produces many different gem materials, some suited to faceting, while others are better suited to the cutting of cabochons, carvings, or objects of art. The gem materials that come to mind when Montana is mentioned are sapphires and Montana moss agate, with Dryhead agates a very close third. Yet, amethyst, amazonite, azurite, covellite, cuprite, garnet, onyx, opal, petrified wood, rhodochrosite, rhodonite, smokey quartz, sphalerite, and wonderstone (banded rhyolite) are also produced or have been produced in the State for use as gem material.

Since 1865 Montana has produced sapphires. In recent years, it appears that the Montana sapphire has gained in popularity, and because of the improved popularity, production has increased significantly. Currently, commercial sapphire production is from deposits on the Missouri River in Lewis and Clark County, the Rock Creek area in Granite County, and from the Yogo Gulch area in Judith Basin County. Additionally, there are dig-for-fee sapphire operations on the Missouri River and Rock Creek.

Until 1989, the value of Nevada's gem material production was essentially dependent upon the production of turquoise and opal, and the production of turquoise was, and still is, declining. In 1989, Nevada reported the first major production of nephrite jade.

The Nevada jade is from a deposit near Tonopah. The material varies in color from different shades of green to black, and some is mottled with off-white to tan markings. The reported quality is from fine gem to carving-grade. Mine run jade is available from fist-size pieces to individual boulders that weigh more than 1 ton. The jade is very similar to good to fine Wyoming jade.

Nevada has been a major producer of turquoise since the 1930's, and until the early 1980's, the State was the largest turquoise producer in the United States. Estimates indicate that over the years, 75 to 100 different mines and/or prospects have produced sizable quantities of turquoise. Production varied from a few thousand dollars worth of material at some properties to more than a million dollars at others. Estimates of total production to date

are between \$40 to \$50 million.

Precious opal production from deposits in the Virgin Valley area began in about 1906. The opal from Virgin Valley is comparable to any in the world for its vivid play of color and is unsurpassed in terms of the size of material available. The material varies in color from deep pure black to brown to yellowish-white to white to colorless. The play of color includes all the colors common to precious opal-red, blue, green, yellow, orange, and so on. The opal occurs primarily as replacement of wood, or sometimes, the replacement of cones of conifer trees. The uses of the opal are greatly restricted because of a severe problem with crazing. Currently, two mines in Virgin Valley are open to individuals on a dig-for-fee basis during the summer months. The operators of these mines also mine the deposits for their own inventories.

North Carolina is the only State in the United States where all four major gem materials, diamond, ruby, sapphire and emerald, are found. During 1988 was the last time all four major gem materials were found in the same year. The diamond was found in a gold placer mine, rubies and sapphires were recovered from the Cowee Valley, and emeralds were found near Hiddenite and Little Switzerland.

Production of ruby and sapphire from the Cowee Valley in Macon County began in 1895 when the American Prospecting and Mining Co. systematically mined and washed the gravels of Cowee Creek. Today some dig-for-fee operations are in the Cowee Valley. Many people pay to dig or purchase buckets of gravel to wash to recover gem corundum, garnets, and other gem materials.

Every year there is publicity concerning the discovery of large and valuable rubies and sapphires at one or more of the mines in Cowee Valley. No doubt large corundum crystals and pieces of corundum are found each year. Similarly, valuable rubies and sapphires may be found, but the number of large and valuable gems and the values of these gems often are over-stated. During the period when commercial mines operated in the area, gem material was found that would cut fine-quality 3- to 4-carat stones. Today, the amount of quality gem material has greatly declined. Most of the rubies found are not of top color or clarity and on average are suitable for cutting stones of a carat or less. The sapphires tend to be larger than the rubies and highquality sapphires are more abundant than high-quality rubies.

In 1875, emeralds were discovered near what is now Hiddenite, with the first attempts at commercial mining of emeralds in the Hiddenite area in 1881. Other attempts at mining were made in the 1920's, the 1950's, the 1970's, and the latest ended in 1990. At different times the emerald deposits in the Hiddenite area have produced large emerald crystals, and some significant stones have been cut from Hiddenite material. Yet, to date, it has not been possible to maintain an economically viable mine operation on any of the deposits. This includes the last attempt that would have mass mined the deposit and used a berylometer to sort the emerald from the waste rock. The berylometer worked well, but the amount of emerald present did not support the project.

Historically, Oregon has been known for the production of various picture and scenic jaspers, agates, thundereggs, petrified wood, and to a certain degree, gem labradorite. Oregon's State rock, the "thunderegg," may be the best known gem material from Oregon. Graveyard Point, Priday, and Polka Dot are names that are uniquely associated with beautiful Oregon agates. The same is true for the relationships between the names Biggs, Deschutes, and Sucker Creek and picture or scenic jasper. Yet, gem labradorite, which includes both sunstone and heliolite, is currently the largest single contributor to the value of annual gem material production in Oregon. At least seven firms or individuals currently are producing sunstone and/or heliolite from three different geographic areas.

The other gem material to contribute significantly to the value of Oregon gem material production is opal. During 1988, the first significant commercial mining and marketing of a variety of very fine quality opals from Opal Butte began. The varieties produced include hyalite, rainbow, contra luz, hydrophane, crystal, fire, blue, and dendritic. Exquisite stones as large as 315 carats have been cut from contra luz rough from this deposit.

Tennessee has the largest U.S. production of freshwater pearls and freshwater mussel shells of the 11 producing States. The fishing and marketing of

freshwater pearls and mussel shells are not new in the United States or in Tennessee. There has been an established U.S. freshwater mussel fishing industry since the mid-1850's. The mussels are from the family Unioidae, of which about 20 different species are commercially harvested. During 1990, the value of U.S. mussel shell exports was more than \$50 million.

To date, freshwater pearls from the United States have been a byproduct of the shell industry. Currently, the primary use of the shells is to make the bead nucleus used by the Japanese cultured pearl industry. Additionally, the shells are used in making cameos and as mother-of-pearl. With the coming of the freshwater cultured pearl farms in Tennessee and the increasing popularity of freshwater pearl jewelry with the U.S. consumer, this may change. In 1963, the first experimental U.S. freshwater cultured pearl farm was established. Since the technology for culturing freshwater pearls was proven in the late 1970's, six freshwater pearl farms have been established. These farms are the beginning of the U.S. freshwater cultured pearl industry, and the cultured pearl is the heart and future of the U.S. pearl industry.

The gem material that Utah is best known for, topaz, is not well suited for use as a gem stone, but it does make a fine mineral specimen. Topaz crystals have been collected from certain rhyolite flows in the Thomas Mountains for more than 100 years. Similar crystals also are found in select rhyolites in the Wah Wah Mountains. The crystals from the Thomas Mountains are predominately small. 10 to 20 millimeters long and 4 to 6 millimeters across, and crystals from the Wah Wah Mountains are even smaller. Occasionally, large gem-quality crystals are found. The color of the topaz varies from colorless to light yellow, sherry brown, rose or light pink. Unfortunately, the light yellow to sherry brown color fades to colorless if exposed to sunlight or heat and rose or light pink colored crystals are rare. Because of the size of the crystals and problem with color fading, the material yields only small to very small colorless stones.

Another Utah gem material with nearly a 100-year production history is gem variscite, first produced in about 1893 near Fairfield. The latest recorded commercial production was from near

Lucin during the summer of 1990. Variscite occurs as fracture fillings or as nodules. The nodules may be solid, almost geode in nature, or fractured solid nodules that have undergone alteration. The color of the variscite varies from deposit to deposit and from location to location within the same deposit. It is a shade of light to dark yellow-green, but can occur as a dark, nearly jade green and so pale as to appear almost white. It also can have black and brown spiderwebbing.

Another gem material from Utah is snowflake obsidian. Snowflake obsidian (also known as flower obsidian) earns its name from the bluish-white or grayish-white patterns of cristobalite included into the normally black obsidian. During 1990, two different firms produced this material commercially.

Topaz, variscite, and obsidian from Utah are well known and are nice materials. But, in the author's opinion, the red beryl from the Wah Wah Mountains is the most remarkable and desirable of Utah's gem materials. Bixbite, the variety name for red beryl (called red emerald by some) occurs in rhyolites at several locations in the Thomas and Wah Wah Ranges. The beryl varies in color from a pink to bright red, with the bright red being what could be called strong raspberry-red. The material from most of the locations is not as spectacular, either in crystal size or color, as the crystals from the Violet claims in the Wah Wah's.

The Violet claims in the Wah Wah's are the only known location for commercial production of red beryl. In recent years, the claims have furnished a small but steady supply of materials for both mineral specimens and a few fine-quality cut stones. The crystals average about 10 millimeters in length, and most are flawed. Because of the size of the crystals and flaws, finished stones only average about 0.40 carats with few more than 1 carat. The largest finished stone to date is only 4.46 carats. The material is expensive, but justifiably so, because of its beauty and rarity.

Certain other States produce a single gem material of note; they are Alaska with its two jade mines; Florida's agatized coral; Hawaii's black coral; Minnesota's thomsonite; New York's herkimer quartz; Ohio's flint; and South Dakota's rose quartz.

The value of production by individ-

ual gem material can be reported for those materials that have three of more producers and if one of the three does not account for more than 75% of the total or two of the producers account for 95% or more of the production. Table 4 is a list by commodity in alphabetic order, with values in dollars rounded to the nearest thousand.

Consumption and Uses

Consumption of domestic gem material production was in the commercial and amateur manufacture of jewelry, for exhibit in gem and mineral collections, and for decorative purposes in statuettes, vases, other art objects, and certain industrial applications.

Industrial uses of tourmaline include a simple laboratory instrument to show the polarization of light, as a material to measure the compressibility of fluids, and in gages for measuring high pressures. Mortar and pestle sets, knife edges for balances, textile rollers, and spatulas are some nongem uses of agate. The manufacturing of jewel bearings for timing devices, gages, meters, and many other types of instruments requiring precision elements used natural gem material. These uses are now mostly supplied by artificial and syn-

TABLE 4

VALUE OF 1990 U.S. GEM STONE
PRODUCTION, BY GEM
MATERIALS

Gem materials	Value
Agate	\$250,000
Beryl	105,000
Coral (all types)	60,000
Garnet	78,000
Gem feldspar	500,000
Geode/nodules	240,000
Fire agate	20,000
Jasper	148,000
Obsidian	27,000
Opal	146,000
Peridot	884,000
Petrified wood	633,000
Quartz	1,767,000
Sapphire/ruby	3,727,000
Topaz	26,000
Tourmaline	350,000
Turquoise	1,105,000
Total	10,066,000

thetic crystalline materials.

Some industrial applications requiring clean homogeneous stones used low-quality gem diamond. The quantity of natural and synthetic industrial-grade diamonds used in the United States each year is 12 to 15 times greater than the amount of diamonds consumed by the jewelry industry.

The uses of synthetic and simulant gem crystals include applications in frequency controllers, polarizers, transducers, radiation detectors, infrared optics, bearings, strain gages, amplifiers, lasers, lenses, crucibles, and many more. A recently developed use is as connectors for optical fibers.

The 1990 estimated value of U.S. apparent consumption was \$3,059 million, down about 18% from 1989's record high. The average annual estimated consumption for the past 10 years was \$2,871 million, with a high of \$3,711 in 1989 and a low of \$1,642 in 1982. The trend for estimated consumption for the past 10 years was one of continued growth with about 68% total increase.

In 1990, the value of U.S. estimated apparent consumption of diamonds decreased 18% to \$2.6 billion. The average annual value of apparent consumption of diamonds for the past 10 years was \$2,293 million, with a high of \$3,115 million in 1989 and a low of \$1,642 million in 1982. The trend for the value of apparent consumption for the past 10 years was one of significant increase. The value of apparent consumption of diamonds increased 90% over the period.

The 1990 estimated apparent consumption of colored stones, led by emerald, ruby, and sapphire, was valued at \$397.1 million, a decrease of 3%. The annual average value of consumption of colored stones for the past 9 years was \$325.0 million, with a high of \$406.9 million in 1989 and a low of \$252.4 million in 1982. The trend for apparent consumption of colored stones for the past 9 years was one of fluctuating increases and decreases, but the general tread was one of increased consumption.

The estimated apparent consumption of pearls—natural, cultured, and imitations—was \$16.5 million, a decrease of about 89% from that of 1989. This large decrease makes one wonder if there is not an error in the import

data for pearls. The value was only 17% of the 9-year low reached in 1982.

Estimated apparent consumption of synthetic and imitation gem materials increased about 115% to \$94.1 million. Average apparent consumption of synthetic and imitation gem materials for the past 9 years was \$55.2 million per year, with a high of \$109.1 million in 1987 and a low of \$13.9 million in 1982. The trend for apparent consumption for the past 9 years was one of generally strong growth except for the significant decrease in 1989. Annual apparent consumption increased about 577% over the 9 years.

Prices

Demand, beauty, durability, rarity, freedom from defects, and perfection of cutting determine the value of a gem stone. But the major factor in establishing the price of gem diamond is the control over output and prices as exercised by the CSO Diamond Trading Co. Ltd. The CSO is a subsidiary of De Beers Consolidated Mines Ltd.

The average U.S. wholesale asking price of the top 25 grades (D through H color and IF through VS2 clarity) of a 1-carat diamond fluctuated between \$6,200 and \$7,000 and was \$7,000 at yearend. The average value per carat of all grades, sizes, and types of gemquality diamond imports was \$525, a 29% increase compared with that of 1989. The average value of diamond imports for the past 10 years was \$405 per carat, with a high of \$525 in 1990 and a low of \$353 in 1984. The trend for the average annual value of diamonds imported for the past 10 years was one of general decline, from the 10-year high in 1980 to stable prices in 1986, 1987, and 1988, followed by the 1989 and 1990 increases.

The average yearend wholesale purchase price of a fine-quality 1-carat ruby, paid by retail jewelers on a per stone or memo basis, was \$4,200, an increase of 20% from that of 1989. The average value of ruby imports increased 49% to \$48.71 per carat. The average annual value of ruby imports for the past 9 years was \$37.93 per carat, with a high of \$48.71 in 1990 and a low of \$16.42 in 1984. The trend for the value of ruby imports for the past 9 years was one of rapid decline, 52% for the period from 1982 to 1984. This was followed by a steady, moderate increase.

The average yearend wholesale purchase price of a fine-quality 1-carat sapphire, paid by retail jewelers on a per stone or memo basis, was \$1,600, a 14% increase from that of 1989. The average value of sapphire imports decreased 11% to \$21.57 per carat. The average annual value of sapphire imports for the past 9 years was \$23.22 per carat, with a high of \$27.97 in 1987 and a low of \$18.50 in 1984. The trend for the value of sapphire imports for the past 9 years was one of fluctuating increases and decreases. The 9-year period ended with the 1990 value 12% below the 1982 value.

The average yearend wholesale purchase price of a fine-quality 1-carat emerald, paid by retail jewelers on a per stone or memo basis, was \$2,750, the same as for 1989. The average value of emerald imports decreased 28% to \$43.65 per carat. The average annual value of emerald imports for the past 10 years was \$57.18 per carat, with a high of \$78.79 in 1988 and a low of \$35.06 in 1984. The trend for the value of emerald imports for the past 10 years was one of fluctuating increases and decreases from 1981 through 1984. A steady moderate growth followed until the 2 years of decline in 1989 and 1990, the average value in 1990 being about 76% of the 1981 value.

Foreign Trade

The export value of gem materials increased 33% to \$1,566 million, a record high. The quantity of diamonds exported increased 45% to 1,003,760 carats, and the value of diamond exports increased about 29% to \$1,398.8 million. The average annual quantity of diamonds exported for the past 10 years was 496,477 carats, with a high of 1,003,760 in 1990 and a low of 184,871 in 1982. The trend for the quantity of diamonds exported for the past 10 years was one of moderate decline, 13%, during the first 2 years, followed by significant growth, 443%, from 1983 to 1990. The average annual value of diamond exports for the past 10 years was \$643.6 million, with a high of \$1,398.8 million in 1990 and a low of \$292.8 million in 1982. The trend for the value of diamond exports for the past 10 years was one of decline, 16%, over 3 years, followed by 3 years of moderate growth, 32%, and then 3 years of significant growth, 112%. This

resulting in record-high exports in 1990.

The export of other precious stones, cut but unset and other than diamonds and pearls, increased about 62% to \$70.6 million. The average annual export value for the past 9 years for these natural gem stones was \$42.9 million, with a high of \$70.6 million in 1990 and a low of \$27.7 million in 1984. The 9-year trend for exports value of these types of gem materials was one of fluctuating increases and decreases, but one resulting in a significant total increase, 139% for the period.

Exports of synthetic gem material decreased 8% to \$42.5 million. The average annual value of exports for the past 9 years was \$18.6 million, with a high of \$46.0 million in 1989 and a low of \$6.0 million in 1987 and 1988. The 9-year trend for the value of exports was one of extreme decline, 52%, for

1982-88, followed by steady significant growth, 608%, during the past 2 years.

Exports of natural, cultured, and imitation pearls, not set or strung, decreased about 74% to \$0.9 million.

Reexports of gem material decreased 84% to \$47.3 million.

The value of gem materials imported decreased 10% to \$4,609.3 million from the 1989 record high of \$5,115 million. The value of imported gem diamonds accounted for about 86% of the total. The average annual value of gem material imports for the past 10 years was \$3,839 million, with a high of \$5,115 million in 1989 and a low of \$2,384 million in 1982.

The value of imported gem diamonds decreased about 9% to \$3,955.2 million from the 1989 record high of \$4,358 million. The 10-year trend for the value of diamond imports was one of generally steady continuous growth

with an increase of 80% for the period. During the period, the value of imported uncut diamonds increased 42%, while the value of cut stones imported increased 89%.

The imports of cut diamonds decreased 29% in quantity and 11% in value to 6.3 million carats and \$3,384.4 million, respectively. The average annual quantity of cut diamonds imported was 6.6 million carats, with a high of 8.9 million in 1989 and a low or 1.6 million carats in 1982. The trend for the quantity of cut diamond imports for the past 10 years was one of continued increases until the 1990 decline; the period still ended with imports 80% greater than at the beginning of the period. The average annual value of imported cut diamonds was \$2,762.4 million, with a high of \$3,805.5 in 1989 and a low of \$1.641.0 million in 1982. The trend for the value of imported cut diamonds for the past 10 years was of strong growth and increases. The value at the end of the period was 88% greater than at the beginning.

The value of imports of other gem materials, led by emerald, ruby, and sapphire, was \$558.9 million, an decrease of about 26% compared with that of 1989. Emerald imports decreased about 22% to \$162.4 million. The average annual value of emerald imports for the past 10 years was \$151.9 million, with a high of \$207.5 million in 1989 and a low of \$120.8 million in 1982. The 10-year trend for

the value of emerald imports was one of fluctuating increases and decreases resulting in a 44% increase for the period.

The value of ruby imports increased 18% to \$98.4 million, a record-high value for the past 10 years. The average annual value of imports for the past 10 years was \$77.2 million, with a high of \$98.4 in 1990 and a low of \$58.7 in 1987. The 10-year trend for import values was one of extreme fluctuations. The period ended with values having increased 68% from the 10-year low and establishing a record high for the period.

The value of sapphire imports decreased 18% from the 1989 10-year high to \$81.9 million. The average annual value of sapphire imports for the past 10 years was \$81.8 million, with a high of \$100.0 million in 1989 and a low of \$63.3 million in 1982. The 10year trend for the value of imports was one of extremely fluctuating increases and decreases. The period ended with the value slightly lower than at the beginning of the period.

The value of imported gem materials other than diamond, emerald, ruby, and sapphire decreased 41% to \$216.2 million. The average annual value of imports was \$325.3 million, with a high of \$429.5 in 1988 and a low of \$134.6 in 1981. The 10-year trend for the value of imports was one of fluctuating increases and decreases resulting in the period ending 61% higher than the period started.

World Review

De Beers, Cententary AG's diamond marketing arm, the CSO, reported 1990 sales of rough, uncut diamonds increased 2% over that of 1989 to \$4.17 billion. Sales for the year were up. but sales for the second half of 1990 were 32% less than the sales for the first half of the year. Also, if the sales were adjusted for inflation, which was about 6% in the United States and higher in other leading consumer countries, the value of diamond sales actually decreased. The CSO markets from 80% to 85% of the total world production of natural diamonds. Sales of colored stones remained strong.

Natural diamond production occurs in Africa, Asia, Australia, and South America. The principal producing localities are as follows: in Africa-Angola, Botswana, Namibia, the Republic of South Africa, and Zaire: in Asia-U.S.S.R. (northeastern Siberia and in the Yakut A.S.S.R.); in Australia; and in South America-Venezuela and Brazil.

Foreign countries in which major gem stone deposits (other than diamond) occur are Afghanistan (beryl, kunzite, ruby, tourmaline); Australia (beryl, opal, sapphire); Brazil (agate, amethyst, beryl, kunzite, ruby, sapphire, tourmaline, topaz); Burma (beryl, jade, ruby, sapphire, topaz); Colombia (beryl, sapphire); Kenya (beryl, garnet, sapphire); Madagascar (beryl, rose quartz, sapphire, tourmaline); Mexico (agate, opal, topaz); Sri Lanka (beryl, ruby, sapphire, topaz); Tanzania (tanzanite, garnet, ruby, sapphire, tourmaline); and Zambia (amethyst, beryl).

Angola.—Endiama, the state diamond company, signed a two-part agreement with De Beers' CSO that reestablished a trading relationship that was ended in 1985. The first part of the agreement calls for De Beers to provide a \$50 million loan to Endiama to be used to increase the production from the Cuango area. De Beers will market all of the production from the Cuango area; the area accounts for about 80% of Angola's production.

The second part of the agreement calls for De Beers to spend \$50 million over 5 years on the evaluation of the Camutue kimberlite in northeastern Angola and on the search for additional kimberlite sources of diamonds.

² Jewelers' Circular-Keystone. V. 161, No. 3, Mar. 1990, p. 190. These figures represent a sampling of net prices that wholesale colored stone dealers in various U.S. cities charged their cash customers during the month for fine-quality stones.

Any mines resulting from this agreement will be jointly developed by De Beers and Endiama.

Endiama also signed an agreement with Steinmetz Evens Diamonds for the sale of diamonds produced in the Andrada and Lucapa areas. The alluvial deposits of these areas are about depleted and are of little interest to De Beers.⁴

Australia.—Diamond production in Australia decreased slightly because of a decrease in the production from Argyle. Argyle produced 33.8 million carats compared with 1989 production of 34.4 million, a decrease of about 2%. Estimates of 1990 Bow River production are about 900,000 carats.

In a move to increase the market for diamonds from the Argyle mine, Argyle Diamonds of Australia announced a multimillion dollar advertisement program to promote champagne colored diamonds. The multipart program will be directed primarily at the U.S. market.

More than 90 companies are involved in diamond projects in Australia, with another 23 companies exploring for diamonds on offshore projects. The success of the Argyle mine and reassessment of old information has led to the latest rush concentrated in New South Wales, with some companies in northern New South Wales claiming to have discovered pipes larger than that at Argyle.

Miners in Coober Pedy claimed to have found the world's biggest opal; the uncut opal weighed 5.27 kilograms and has an estimated worth of \$3 million. The stone is 233.37 centimeters long and 12.19 centimeters wide. The opal is milky white in color.

Botswana.—Corona Corp. agreed to acquire control of Repadre Capital Corp. and the new firm will be named Corona Diamonds International Corp. Repadre had agreed to a joint venture with Ampal (Pty.) Ltd. to develop Ampal's diamond licenses in Botswana. Ampal holds multiple prospecting licenses covering about 20,700 square kilometers upon which a number of kimberlites have been identified. Exploration drilling is schedule to start on 30 to 50 of these targets. Corona Diamonds could earn a 40% interest in the properties by spending about \$1.75 million before December 31, 1991. Additional interests can be earned by further expenditures.

The Government of Botswana and Lazare Kaplan International Inc. (LKI) signed a long-term agreement for a diamond cutting and polishing factory in Botswana. The agreement represent a major investment by a U.S. company in Botswana. The factory will be a state-of-the-art plant using automated and manual equipment. LKI will manage the plant and train Botswana workers as operators. It is anticipated that the plant will ultimately employ at least 500 skilled workers.

The Government of Botswana and Mabrodiamn, 85% owner of Diamond Manufacturing Botswana (DMB), signed a contract to expand DMB's 12-year-old cutting factory at Garabone. The agreement was to expand the plant from its current 55 workers to 200 workers. The factory manufactures low-quality 2 grainer sawn rough, but some 10-carat sawn is manufactured also. Cutting factory labor costs in Botswana are lower than in Belgium, but higher than in the Far East.

Canada.—Uranerz Exploration and Mining of Canada reported finding two diamonds, one two millimeters and the other four millimeters, near Melfort in the area of Fort a la Corne. These diamonds are significantly larger than the microdiamonds found in the past. Microdiamonds have been found in the area by other companies, including Claud Resources and Monopros Ltd., a subsidiary of De Beers. None of the companies exploring in the area has yet to discover a commercial deposit of diamonds, but these larger stones do increase the interest of the companies exploring the area. Uranerz plans to spend \$2 million on exploration in the area in the next 2 years.

China.—The Mineral Resources Bureau reports that geologists discovered 13 diamond deposits along the Tanlu Fault Zone that stretches across several Provinces in the eastern part of the country. The Bureau claims to have found more than 100 kimberlites and 4 diamond placers in Shandong Province, while in Liaoning Province it found 3 large primary deposits and 3 smaller placer deposits.

Cook Islands.—The Cook Islands received \$25 million in aid from the U.S. Agency for International Development for the development of a black pearl industry. The pearl industry would be started on the island of Suwarrow and possibly extended to the islands of Pen-

rhyn and Pukapuka.

Guinea.—Currently, at least four companies are either exploring for or mining diamonds in Guinea. Aredor, the company with the longest history in diamond operations in the country, is experiencing a decline in production and in profits. The decline in production is be-

cause of decreasing ore grades. The decreasing profits is because of a combination of lower diamond production and a lower sales price for diamonds. The 1990 average sales price for Aredor's diamonds was down 19% to \$245 per carat.

Star Diamonds has a prospection license area 30 kilometers to the south and east of the Aredor lease. The alluvial

deposits that are of the most interest are those on the flats near Bouro and those at the headwaters of the Bouloumba.

Sidam-Minorex is exploring in an area for diamonds near Forecariah, east of Conakry, and Hydro Mineral Exploration is exploring for diamonds near Bounoudou.

Brigade Aurifere de Guinee has a concession to mine gold in an area north of the Aredor lease in which diamonds may be found also.

Hong Kong.—Less than 50% (42 of 98) of the jadeite jewelry lots were sold at Christie's Swire Ltd.'s auction in October. The 42 lots brought in \$1.4 million. The sale was disappointing according to Christie's, but the jadeite market is and always has been extremely volatile. In November, buyers purchased about 75% (90 of 121 lots) of the jadeite jewelry sold at auction by Sotheby's Hong Kong Ltd. The total purchase price of the jewelry was \$4.02 million. According to a Sotheby's representative, the market for top-quality iade is strong, but the market for decorative materials is very soft.

India.—Imports of rough diamonds fell in 1990 by 16% in value and 37% in volume to \$1.97 billion and 38 million carats, respectively. Total exports of polished stones for the year also declined, caratage decreased 13% to 8.7 million carats, and value fell 9% to \$2.7 billion. The decline in demand of cut goods resulted in the closing down of thousands of production units in the past 12 months and as many as 20,000 workers laid off by yearend. The decreases were blamed on the recession in the United States and the Persian Gulf war. Cut diamonds account for 90% by value of gem and jewelry exports, which in turn account for nearly 20% of the country's total exports.

Indonesia.—Development of the Danau Seran diamond project in South East Kalimantan began in late 1990. Dry mining and a conventional diamond recovery plant will be used in place of a dredge. This approach is cheaper and easier to finance. The Danau Seran contains about 2.9 million cubic meters of diamondiferous gravel with a grade of 0.1 carats per cubic meter. The deposit will be mined over the next 3 years at a production

²Includes some natural advanced diamond.

rate of 72,000 cubic meters per month. The group that put up the \$2 million in financing will control a 25% equity interest. The interests of Indonesian Diamond Corp. (formerly Acorn Securities) and Keymead have been reduced to 44.7% and 10.3%, respectively, with PT Aneka Tambang (Indonesian Government) holding the remainder.⁵

Malaysia.—Boulders of nephrite jade were discovered in Sabah State in the northern part of Borneo. The boulders ranged in size from about 0.5 meters to 1.0 meters. The jade has a flawless area of good color that is suitable for jewelry. The source of the boulders and the commercial viability of the deposit are not known at this time.

Sierra Leone.—The Government of Sierra Leone granted a 20-year concession to Sunshine Mining Co. of the United States to mine and market diamonds from the Kono kimberlite deposit. Exploration and development work to date indicates the deposit contains about 2.4 million carats of recoverable gem-quality diamonds. Sunshine estimated the project capital costs at about \$54 million.

The Government of Sierra Leone granted a lease to Intertarade Prospecting, a Swedish firm, to mine diamonds in an area north of Freetown. The firm announced plans to spend about \$3 million dollars on deposits that are reported to be of marginal viability.

Wildcat Holdings PL, a wholly oned subsidiary of Pioneer Resources, entered into an agreement with Xerxes Ltd. to explore for diamonds in the Baoma district. The area is believed to contain both alluvial and kimberlite diamond deposits.

South Africa, Republic of.—The De Beers Mine, the smallest of the four mines De Beers Consolidated Mines Ltd. operates in Kimberley, is scheduled to close in October 1990. Treatment of surfaces stockpile ore at the mine will continue well into 1991. The mine was discovered in 1871 and operated as an open pit mine until 1885, at which time underground operations were started. The mine closed in 1908 and remained closed until opening once more in 1960 and operated until 1990.

The Kim Diamond Cutting Works, a diamond cutting factory, was constructed in Kimberley. The factory will employ at least 1,280 workers and will process 30,000 carats of local rough per week. The plant will produce from

0.01- to 0.30-carats stones for the export market.

Sri Lanka.—The Government of Sri Lanka changed the regulations on the export of geuda three times during

1990. The first change was made at the end of July when the agreement to sell geuda only to Thailand was ended and the sale of geuda was opened to buyers from all countries. In August, the exports of geuda was restricted to milky corundum; therefore, only firms specializing in the heat treatment of this type of geuda could export materials. In October, the regulations were amended to include silky, yellow silky, ottu, ooral, diesel, and dalan geuda. The Government descriptions used for geuda based on appearance under reflected light include milky (white, blue or yellow with a milky or soapy appearance), silky (white or blue with a shiny effect over the entire stone caused by rutile inclusions), vellow silky (yellow with shiny effect), ottu (blue patches or bi-colored), coral (color concentrated in patches without a definite outline and difficult to locate color source), diesel (brownish with oily appearance similar to diesel), and dalan (loosely sued for two or more of the above varieties in small sizes, also for large stones with many cracks and bubbles). Under the new system the number of carats of geuda exported in-

creased, but the value of geuda exports decreased. 6

Tanzania.—The Government of Tanzania and Tanex Ltd., a company associated with De Beers Centerary AG, concluded an agreement to explore for diamonds over a large area south of Lake Victoria and to the south and west of the Williamson Mine. Exploration in the past has discovered several kimberlites that contained diamonds, but none were economical to mine.

U.S.S.R.—The Soviet Government entered into an agreement with De Beers giving De Beers exclusive marketing right to the U.S.S.R. diamond production for the next 5 years. The agreement was with Glavalmazzoloto, the organization that administers the sale and export of rough diamonds. Under the terms of the contract, a De Beers' subsidiary will provide a \$1 billion advance against future production, but secured by the Soviet stockpile. It is estimated that the contract calls for a purchase of \$1 billion worth of diamonds per year.

It is estimated that the U.S.S.R.'s diamond cutting industry employs about 16,000 workers. The eight Krystall factories at Moscow, Smolensk, Kiev, Barnaul, Vinnitsa, Yerecvan, Kusa, and Gomel employ fewer than 8,000, with the Moscow plant having about 900 workers. The workers at the various factories may be paid by different methods.

The workers at the Moscow plant are paid by the piece according to its size and difficulty of the cut. At Kiev, those workers whose work is not subject to inspection receive a 50% higher salary. Some of the Krystall factories have an incentive program for workers producing stones of 0.3 carats and larger. The incentive is a bonus of 5% of the added value, which is paid to each 20-worker team and is shared by the team.

Annual cut diamond production is a function of the number of workers in the industry and their productivity. If it is assumed that the industry has a production rate of 20 carats of finished goods per month per worker and that polished yields are less than 40%, then the industry's consumptions of rough and yield of finished can be estimated.

It is estimated that during a year the U.S.S.R.'s diamond cutting industry processes about 3.8 million carats of rough that yields about 1.6 million carats of polished goods. The polished goods would be worth between \$500 million and \$550 million on the world market.

Reportedly, the U.S.S.R. is considering a joint venture with unnamed Western concerns to open a new diamond mine and cutting factory. The mine would be on a deposit about 100 kilometers north of Archngel. Reports indicate that the deposit contains 50% gem-quality diamonds.

Vietnam.—A new ruby mine in Hoang Lien Son district of Luc Yen, 270 kilometers west of Hanoi, produced about 1.12 million carats of ruby during 1990. It is estimated by company officials that about 30% of the rough or 336,000 carats is top quality faceting rough; 40%, or 448,000 carats, is medium quality for faceting and cabochons; and 30% is low quality for beads and cabochons. The mine is operated by a Thai-Vietnamese joint venture between B.H. Mining Co. Ltd. and the Vietnamese state gem enterprise, Vinagemco. It is planned for the production to be sold at auction in Hanoi.

Zaire.—It was reported that a 345.7-carat diamond was found in the Sediza Mine. The stone is said to be internally flawless with only a few minor surface blemishes. Early estimates of the stone's value are as high as \$3.8 million.

Zambia.—The Government of Zambia reduced restrictions on the mining and marketing of gem stones. Miners can now retain 50% of foreign exchange earnings instead of 20%. Additionally, a gem stone board, run by miners, and an auction system will be established. The Government estimates that Zambia exported \$200 million worth of gem stones in 1989, although only \$10 million were officially reported.

Zimbabwe.—De Beers was unable to reach agreement with the Government of Zimbabwe on the development of the River Ranch Kimberlite deposit near the southern border at Beitbridge. The deposit was originally discovered in 1975. The Government of Zimbabwe was unwilling to grant De Beers' CSO an

exclusive marketing agreement. The Government wanted to market the production through its Minerals Marketing Corp., which would also retain a portion of the production for domestic processing. The Government has initiated procedures for the forfeiture of the River Ranch claims held by De Beers.

Current Research

An oval jade cabochon in a ring offered to Sotheby's Hong Kong Ltd. for its 1990 jadeite jewelry auction was found to have been treated with a new procedure to improve its appearance. Testing by the Hong Kong Gems Laboratory discovered a coating that is a highly adhesive, colorless organic resin mixed with a chemical compound that makes it resistant to high temperatures. The Gemological Association of All Japan found an oval jade cabochon that had exceptionally good color, luster, and transparency that was poor quality white jadeite treated with a green resinous coating. The coatings can be identified by immersing the piece in methylene iodide and shining a bright light on the stone to display the

thin transparent layer of the coating.⁷

OUTLOOK

World demand for gem diamond can be expected to rise because of increasing effective personal income of the population of the United States and other industrialized countries. Also demand will increase because of highly effective promotional efforts. These promotions are changing social customs in many eastern countries, particularly with the use of diamond engagement rings. The changes are resulting in significant growth in the diamond market. Demand for other precious gems will continue to grow as diamonds become more expensive and the popularity and acceptance of colored stone increases. Demand for synthetic and simulant gem materials for both personal and industrial consumption is expected to increase. The diversity of sizes, types, uses, and values of gem materials precludes any meaningful forecasting of future demand.

^e Estimated. ^p Preliminary. ^r Revised. W Withheld to avoid disclosing company proprietary data.

Table includes data available through May 17, 1991. Total diamond output (gem plus industrial) for each country actually is reported except where indicated by a footnote to be estimated. In contrast, the detailed separate production data for gem diamond and industrial diamond are U.S. Bureau of Mines estimates in the case of every country except Australia (1986-87), Botswana (1987), Brazil (1987), Central African Republic (1986-89), Guinea (1986-89), and Liberia (1986), for which source publications give details on grade as well as totals. The estimated distribution of total output between gem and industrial diamond is conjectural, and for most countries, is based on the best available data at time of publication. Estimated distribution figures have been revised as necessary to correspond to reported total production figures.

² Includes near-gem and cheap-gem qualities.

³ Includes all synthetic diamond production.

⁴ Reported figure.

⁵ Figures are estimates based on reported exports and do not include smuggled diamonds.

⁶Figures do not include smuggled artisanal production.

⁷ Other De Beers' Group output from the Republic of South Africa includes Kimberley Pool, Koffiefontein Mine, Namaqualand Mines, and Venetia Mine.

⁸ Data may not add to totals shown because of independent rounding.
