SMALL AREA POPULATION PROJECTIONS FOR WISCONSIN

Technical Bulletin No. 59
DEPARTMENT OF NATURAL RESOURCES
Madison, Wisconsin

1972

ABSTRACT

Projections of population and growth rates for Wisconsin communities over the next 20-year period are estimated for use by planners, engineers, public officials and other interested groups.

PREFACE

The population projections in this study were developed by the Department of Natural Resources as required by the Water Quality Management Planning Guidelines of the U.S. Environmental Protection Agency. The projections are not the official state projections. The publication of official state projections is the responsibility of the U.S. Bureau of Census and the Wisconsin Department of Administration, Bureau of State Planning. Where there are differences between the county projections made by the Bureau of State Planning and the county totals in this report, the projections of the Bureau of State Planning should be used.

INTRODUCTION

Population projections are among the more fundamental types of information used in planning. With respect to small area projections, however, neither the federal government nor the State of Wisconsin make population projections below the county level. This report provides population projections for all census tabulated entities including towns, cities, villages and unincorporated places over 1,000, so that intelligent decisions involving the provision of services can be made at all levels of government. Tentative growth rates and sizes of Wisconsin communities for the next 20 years are estimated for use by planners, engineers, public officials and other interested public and private groups.

The projections in this report are based upon predictive equations incorporating the influence of community size, location, proximity to growing urban areas and past growth trends from 1940 to 1970. It is important that the user be aware of five significant limitations of the method. First, it cannot be assumed that either the methodology or the projections developed here are appropriate for all applications. There is no assurance that past trends will continue into the future, although the underlying assumption of these projections is that they will. Even if it were possible to guarantee that past trends could predict future trends, this would be no reason to develop plans to accommodate the trends. While plans can be developed to accommodate projected population or economic growth, plans can also be developed to curtail such growth, thereby invalidating the assumptions upon which the projections were based. For example, simply because urban growth is projected, plans need not be developed to accommodate it. An alternative is to plan to change the circumstances which bring it about. Similarly, because population growth is projected, plans to increase water supply and the capacity

of waste treatment facilities need not necessarily be developed. Rather, alternatives such as controlled development plans or programs to decrease the demand for water and the generation of wastes may be considered.

Second, we assumed that the best predictive equations can be selected by examining a combination of statistics derived from a multiple regression analysis. The statistics examined were the standard deviation, the multiple correlation coefficient, and the Durbin-Watson statistic for autocorrelation.

Third, the predictive model used to project future population for this study incorporates multiple regression analysis. One of the problems associated with this type of projection method is that there is no meaningful upper limit. Oftentimes, land use control policies effectively place a limit upon population growth. For example, there is some upper limit to the population of an area set by zoning, subdivision control, soil characteristics and septic system requirements. Unfortunately, sufficient data were not available to incorporate these limiting factors into the projection model.

Fourth, the reliability of population projections tends to decrease with longer projection periods, rapid population changes and smaller geographies of analysis. The projections for most of the entities exhibit at least two and sometimes all three of these characteristics.

Finally, many demographers compute a range of estimates. A high projection is often used where the costs of underestimating are greater than the costs of overestimating. And a low projection is often used where the converse is true. Although it is possible to calculate the standard deviation for any particular entity, this has not been done. While the standard deviation would be an indication of the high and low projections, they would still have to be modified by local considerations.

DEVELOPMENT OF THE MODEL

Population projection techniques generally correlate population with other variables or conditions. These include mortality, fertility, migration, land use patterns and controls, community size and growth rate, regional characteristics, the legal-political controls governing municipal annexation, incorporation and consolidation, and the spatial distribution of commuting patterns and commercial activity.

The approach that was followed here was to incorporate several standard statistical techniques that have been used in the past by demographers in such a way that they would lend themselves to analysis by multiple regression. For most of these techniques, several alterations in the

original methodologies have been made to allow their incorporation into the methodology developed here.

Initially, an application of the cohort-survival approach to population projection was attempted. The cohort-survival technique is a projection method which adjusts data from the last census forward by age and sex groupings (cohorts) with separate adjustments made for mortality, fertility and migration. Because such adjustments vary depending upon the locality, they are extremely difficult to make. Moreover, reliable small area data series for these variables are not available in Wisconsin. Even if they were, they could not be used without adaptation to a particular set of local assumptions. Thus, the cohort

survival technique was dismissed as a reasonable method for small area population projection in Wisconsin.

As a means of discovering any relationship between community size and growth rate in Wisconsin, a random sample of 83 cities and villages was selected from a list of all cities and villages in the state, arranged by population size. The original list was divided into seven classes of entities according to their size as follows:

1. greater than 20,000
2. 10,000–20,000
3. 5,000–9,999
4. 3,000–4,999
5. 2,000–2,999
6. 1,000–1,999
7. less than 1,000

The only criterion used in the selection of the sample was that the distribution of entities by size class in the sample had to be representative of the distribution of entities by size class in the state. Following the selection of the 83 entities, a multiple linear regression analysis was performed on the sample. The regression equation used was the following:

$$s(t,p) = a_0 + a_1 t + a_2 p$$

where:

a_0, a_1, a_2 = constants determined by the multiple regression

$$t = \text{time} = [t_1, t_2, t_3] = [1945, 1955, 1965]$$

$$s = \text{growth rate} = [s_1, s_2, s_3] = [(P_{50} - P_{40})/p_1, (P_{60} - P_{50})/p_2, (P_{70} - P_{60})/p_3]$$

$$p = \text{population} = [p_1, p_2, p_3] = [(P_{40} + P_{50})/2, (P_{50} + P_{60})/2, (P_{60} + P_{70})/2]$$

$P_{40}, P_{50}, P_{60}, P_{70}$ = census populations in the years 1940, 1950, 1960, 1970

For any entity there were three equations:

$$s_1 = a_0 + a_1 t_1 + a_2 p_1$$

$$s_2 = a_0 + a_2 t_2 + a_2 p_2$$

$$s_3 = a_0 + a_3 t_3 + a_3 p_3$$

For the entire sample there were $83 \times 3 = 249$ equations.

Very poor correlations were found:

r_x = correlations of s with respect to variable x .

$$r_t = 0.013$$

$$r_p = 0.052$$

$$r_{t,p} = 0.053 \text{ (multiple correlation)}$$

FIGURE 1. Department of Resource Development Regions

The principle causes of these poor correlations were the large fluctuations in growth rate experienced particularly by smaller communities over time, and the diverse economic and social characteristics of the state. Consequently, we concluded that on a statewide basis there was little correlation between growth rate and community size.

Because of this poor correlation, the entities in the sample were allocated to geographic areas (referred to as regions) which were identical to those developed by the Wisconsin Department of Resource Development (Fig. 1). These groups were further divided into two categories: those entities having an overall increasing rate (based upon the changes experienced from 1940 to 1960) and those entities having an overall decreasing rate.

As Table 1 illustrates, the addition of these two procedures improved the correlations by a factor of from 2 to 10 times. The delineation of the state into regions which have a more homogeneous social and economic structure and the utilization of these regions as a variable in developing population projections increased the accuracy of the projections.

At this point in the study, a decision was made to use all cities, villages and towns in the state rather than relying upon a set of 83 data points. This was necessary because the number of entities within each group was approaching the point where the analysis would not be statistically significant.

We hypothesized that variations in population growth rate could be explained by the proximity of a growing urban area to the entities for which projections were made. To test this hypothesis for Wisconsin, two variables were introduced. These were the distance from the projected entity to the nearest growing urban area, and a dummy

TABLE 1. Correlation Coefficients for Regions and Growth Rate Groups

Region	Positive Growth Rate			Negative Growth Rate		
	r _t	r _p	r _{t,p}	r _t	r _p	r _{t,p}
1	-.03	-.11	.12	.41	-.21	.43
2	.26	-.07	.28	--	--	--
3	.03	.07	.08	--	--	--
4	-.13	-.16	.21	-.37	.06	.37
5	.01	.09	.09	-.08	.21	.22
6	-.66	.20	.70	.14	.31	.37
7	-.01	-.28	.28	-.21	-.24	.34

variable indicating whether at least 50 percent of the projected entity's area fell within a circle having a radius of 25 miles and an origin at the center of the growing urban area (termed a unit circle).

The 25-mile radius was determined by drawing circles in 5-mile increments and examining the growth rates of the entities that fell within each circle. Beyond a 25-mile radius, growth rates were not significantly correlated with the growth rate of the urban area. For the purpose of this study, a growing urban area was defined as a city or village whose 1970 population was greater than 10,000 and was growing with respect to the 1960 population. Thus, only cities of the first, second and third class were given consideration as growing urban areas.* If at least 50 percent of the entity's area was within the 25-mile radius, the unit circle dummy variable (uc) was assigned a value of +1. If outside the 25-mile radius, the dummy variable was assigned a value of 0.

A multiple linear regression was performed incorporating the distance and unit circle variables. The unit circle variable was found to be 1.5 times more significant than the distance variable. Consequently, the latter was eliminated from the regression equation.

To overcome the persistent problem of fluctuation in the growth rate variable, the 1970 population was substituted as the dependent variable. This significantly increased the coefficients of correlation. The regression equation used was the following (at this point the concepts of regions and growth rate groups had been temporarily eliminated so that the effect of the unit circle could be examined):

$$y = P_{70} = a_0 + a_1P_{40} + a_2P_{50} + a_3P_{60} + a_4 uc (P_{40} \cdot P_{50} \cdot P_{60})$$

where:

$$a_0, a_1, a_2, a_3, a_4 = \text{constants determined by the}$$

*Wisconsin Statutes 62.05 defines these classes as cities of at least 10,000 in population. Some cities have not gone through the formal legal process of reclassification to third class status even though their populations have increased above the class limit. These cities were included in the definition of growing urban areas.

multiple regression analysis (not the same as determined in the first equation)

uc = the unit circle dummy variable; +1 if the entity is inside the unit circle, and 0 if the entity is outside of the unit circle.

The correlations were:

$$r_{P40} = 0.947$$

$$r_{P50} = 0.950$$

$$r_{P60} = 0.990$$

$$r_{uc (P_{40} \cdot P_{50} \cdot P_{60})} = 0.837$$

$$\text{multiple correlation} = 0.998$$

$$\text{standard deviation} = 947$$

Adding the unit circle variable to the regression analysis decreased the standard deviation by 31 percent. Because the variable was also highly correlated with population, the unit circle variable was used in the final model.

In the final analysis, values of (+1) when the entity was within the unit circle and (-0.1) when the entity was outside the unit circle were used, since they produced the highest correlations.

TABLE 2. Standard Deviation for Three Population Groupings

Population Size	Standard Deviations
Greater than 5,000	3,307
1,000 - 5,000	260
Less than 1,000	66

As a method of improving the standard deviation, all entities in the state were divided into the following size categories:

1. less than 1,000
2. 1,000 to 5,000
3. greater than 5,000

These categories were chosen to take account of the number of entities available for each group, the similarity of growth rates and the magnitude of growth rate fluctuations. After the groups were incorporated into the multiple regression analysis, the standard deviation was markedly reduced. This was particularly true in the case of communities less than 1,000 in population. The standard deviation for each class is shown in Table 2. Grouping by community size was important in reducing the standard deviation for small communities, especially when the communities were all within the same region.

To determine the growth rate group (plus or minus) into which an entity fell the following technique was used. Using the population in 1950 and 1960, a linear extrapolation was performed to find the 1970 population (Fig. 2). If, as in the uppermost straight line of Figure 2 the population was increasing and the actual population was greater than the projected value, the entity was given a plus rating. If the population was increasing and the actual population was less than the projected value, the entity was given a minus rating. On the other hand, if the population was decreasing, as in the lower straight line of Figure 2, the opposite groupings were used. The lower two curvilinear equations are the mirror images of the upper two, so that by changing the sign of the variables in the regression equation, the opposite effect is realized. After the projection to 1980 was made, this same procedure was performed again, except that the 1980 population was used instead of 1970, and the 1950 population was dropped.

Grouping the data sets increased the multiple correlation of the predictive equation and lowered the standard deviation, as demonstrated previously. The degree of improvement varied depending upon the region involved and the size of the community.

While cities, villages and towns could be analyzed separately, it became obvious that the large fluctuations in populations due to annexations would seriously limit the accuracy of the model. To eliminate this problem, the concept of clustering was incorporated in the model. A cluster consists of contiguous cities, villages and towns which have gained or lost area to each other through

FIGURE 2. Division of Entities Into Plus and Minus Groups

annexation between the 1950 and 1970 censuses. Consequently, the geographic boundary of a cluster remained constant over the period of its projection. In some cases, a city, village or town was spatially within the outer boundary of a cluster. However, the entity was not included in the cluster if it had not been involved in an annexation with any of the entities making up the cluster.

Prior to the employment of the cluster concept, an attempt was made to correct the 1950, 1960 and 1970 census population figures for the effects of annexation. However, neither the Wisconsin Department of Administration nor the Office of the Secretary of State maintained adequate annexation records in a form which made their use feasible.

With clusters identified throughout the state, entities were grouped into three categories:

1. clustered municipalities and towns
2. towns not in a cluster
3. municipalities not in a cluster

Increased correlations resulted when the data set was separated into these three classes. Again, the degree of improvement varied depending upon the region involved and the size of the community. Because the correlations were significantly improved, the technique was incorporated into the model.

At the inception of this research, a linear predictive equation was used to calculate correlations between variables. Since there was no reason to assume that this was the best form to use, several additional forms of predictive equations, incorporating nonlinear functions, were also utilized in the testing of these relationships. Sixteen forms of predictive equations were used in the final model:

1. $y = a_0 + a_1 \times uc \times m + a_2 \times v + a_3 \times s \times 10.0 \times 1n(r)$
2. $y = b_0 + b_1 \times uc \times m + b_2 \times v + b_3 \times s \times r$
3. $y = c_0 + c_1 \times uc \times m + c_2 \times v + c_3 \times s \times 0.10 \times r^{1.3}$
4. $y = d_0 + d_1 \times uc \times m + d_2 \times v$
5. $y = e_0 + e_1 \times v + e_2 \times s \times 10.0 \times 1n(r)$
6. $y = f_0 + f_1 \times v + f_2 \times s \times r$
7. $y = g_0 + g_1 \times v + g_2 \times s \times 0.10 \times r^{1.3}$
8. $y = h_0 + h_1 \times v$
9. $y = i_0 + i_1 \times uc \times m + i_2 \times s \times 10.0 \times 1n(r)$
10. $y = j_0 + j_1 \times uc \times m + j_2 \times s \times r$
11. $y = k_0 + k_1 \times uc \times m + k_2 \times s \times 0.10 \times r^{1.3}$
12. $y = l_0 + l_1 \times uc \times m + l_2 \times s \times 0.10 \times r^{1.5}$
13. $y = m_0 + m_1 \times s \times 10.0 \times 1n(r)$
14. $y = n_0 + n_1 \times s \times r$
15. $y = p_0 + p_1 \times s \times 0.10 \times r^{1.3}$
16. $y = q_0 + q_1 \times s \times 0.10 \times r^{1.5}$

In the regression analysis:

$$P_{i+1} = P_{70}, P_i = P_{60}, P_{i-1} = P_{50}, P_{i-2} = P_{40}$$

In the projection for 1980:

$$P_{i+1} = P_{80}, P_i = P_{70}, P_{i-1} = P_{60}, P_{i-2} = P_{50}$$

In the projection for 1990:

$$P_{i+1} = P_{90}, P_i = P_{80}, P_{i-1} = P_{70}, P_{i-2} = P_{60}$$

where:

$$y = P_{i+1} - P_i$$

$$m = (P_i + P_{i-1})/2$$

$$s = \frac{P_i - P_{i-1}}{|P_i - P_{i-1}|}$$

$$r = |P_i - P_{i-1}|$$

$$v = (P_i - P_{i-2})/2$$

$$uc = -0.1 \text{ or } 1.0$$

a through q = regression constants.

Because no particular equation would best fit all the data sets, all sixteen forms were fit to each data set (i.e., each population grouping for each region and for each growth rate group). Then the best fit equation, based upon the multiple correlation coefficient, the standard deviation, and the Durbin-Watson statistic was chosen. This technique allowed for varying growth trends and increased the accuracy of the predictive equations.

FINAL PROJECTION MODEL

All cities, villages and towns in the state were first separated into the regions depicted in Figure 3. These regions were delineated on the basis of past growth trends. Unit circles were used to control for the effects of proximity to growing urban areas. Urban clusters were used to control for the effects of annexation. The clusters were assigned to one of the following categories: (1) those less than 5,000 people, and (2) those greater than 5,000 people. The remaining unclustered municipalities and towns were allocated to four mutually exclusive categories: (1) municipalities greater than 5,000 people, (2) municipalities less than 5,000 people, (3) towns greater than 5,000 people and (4) towns less than 5,000 people.

The entities within each category were then classed according to their past growth rate characteristics. This procedure resulted in all of the entities in the state being divided into 70 different data sets. Each entity was then coded according to its location with respect to a unit circle (See map insert). For each data set, a multiple regression was employed to fit the data to the assumed best predictive equation.

A summary of the resulting multiple correlations, standard deviations and Durbin-Watson statistics are given in Table 3. The actual population projections for small areas are listed in the Appendix.

APPENDIX

The entities in the table are arranged alphabetically by county and alphabetically within each county. The first entry is the name of the entity. If an asterisk appears in the name, then the city or village lies within two or more counties.

Unincorporated places follow the town they are contained in. They were included in the regression analysis for cities and villages and were projected to 1980 and 1990. They were not included in the total county population because their populations are included with that of the town. If an unincorporated place falls within a cluster, it is not included in the total cluster population.

FIGURE 3. Study Regions

The second entry is the footnote number. The footnotes are:

0-Normal projection of a single entity

1-No populations were listed for either 1950 or 1960. In this instance, the 1970 population was assumed for 1980 and 1990.

2-No population was listed for 1950. A linear extrapolation was performed to find 1980 and 1990 populations.

3-Indicates a cluster. The sum of the entities in the cluster was used to make the projections.

4-In a few instances where the projection of a cluster population gave extreme values, the sum of the projections of the entities within each cluster were used as the total cluster projection.

MC = multiple correlation coefficient
SD/EQ = standard deviation/equation number used
N/DW = number of elements in sample/Durbin-Watson statistic for auto-correlation

Errata Sheet - Paste over type on p. 7

5-For some towns not in a cluster, the ratio of the 1970 town population to the total 1970 county population was applied to the total 1980 and 1990 county population projections to find the projection for the town.

6-A few cities and villages not in a cluster were projected by a second order difference method.

The third entry is the unit circle variable. A (1) indicates that the entity is within a unit circle while a (0) is used where the opposite is true.

The next six items are the populations for the years 1940, 1950, 1960, 1970 and the projection values for the years 1980 and 1990. The five variables that follow the projections are the percentage growth rates for the decades 1940-1950, 1950-1960, 1960-1970, 1970-1980 and 1980-1990. The percentage changes have been computed using the 1940 population as a common base so that growth rates for all decades can be easily compared. Where no 1940 population was recorded in the census, the 1950 population was used as the base. Similarly, the next decennial population was used where either the 1950 or 1960 population was unrecorded. With respect to the county totals, it is important to point out that these totals may not be equal to the actual census totals. This is due to the effect of clustering, since this involves allocating entities from more than one county to a single county.

Most projected populations of cities, villages and towns are listed separately. In some cases, two or more cities, villages and towns have been combined into a cluster.

An example for Monroe County is shown in Table 4.

The Tomah City Cluster was necessary because parts of Tomah and LaGrange Towns were annexed to Tomah City causing the political boundaries to change. If Tomah City, LaGrange Town and Tomah Town are considered together as a cluster, then the boundary of this cluster remains unchanged even though annexations have taken place within the cluster. This technique increases the accuracy of the prediction. No other interpretation should be made of the cluster.

To apportion the projected cluster population back to the entities making up the cluster, the following procedure is recommended for most cases:

1. Calculate the percentage of population that the entity is of the cluster for 1950, 1960 and 1970.
2. Project (using graph paper or a regression analysis) the percentage for 1980 and 1990.
3. For the projected entity population, multiply the percentage determined in Step 2 by the projected cluster population.

For the Tomah City Cluster the results of this procedure using a linear projection, are shown in Table 5.

In some clusters an entity's percentage of the total cluster may be steadily changing at a changing rate. Under such circumstances other nonlinear methods of apportioning the total cluster population to an individual entity may be more appropriate.

TABLE 4. Example of a Cluster

	1940	1950	1960	1970	1980	1990
Tomah City Cluster	5,412	7,837	8,532	8,840	9,010	9,118
LaGrange Town	850	2,312	2,280	2,224		
Tomah City	3,817	4,760	5,321	5,647		
Tomah Town	745	765	931	969		

TABLE 5. Apportionment of Cluster to Constituent Entities

	1950	1960	1970	1980	1990
Tomah City Cluster	7,837	8,532	8,840	9,010	9,118
LaGrange Town	2,312(29%)	2,280(27%)	2,224(25%)	2,072(23%)	1,915(21%)
Tomah City	4,760(61%)	5,321(62%)	5,647(64%)	5,857(65%)	6,109(67%)
Tomah Town	765(10%)	931(11%)	969(11%)	1,081(12%)	1,094(12%)

ACKNOWLEDGMENTS

The authors wish to express their thanks to the following persons for reviewing this report: John Cain and Donald Thompson, Department of Natural Resources; George Handy, Henry Krebs and Philip Sundall, Department of Health and Social Services; and Douglas Marshall, University of Wisconsin-Madison. Our thanks also to Rahim Oghalai, Department of Natural Resources, for the preparation of the cluster map.

Cover design by Pete Keymack, courtesy of The Print Mint.

The authors are Planning Analysts with the Water Resources Planning Section, Bureau of Water and Shoreland Management.

Edited by Ruth L. Hine
