XX Not applicable.

As published in the "Crushed Stone and Sand and Gravel in the First Quarter of 1993," Mineral Industry Survey, based on estimated 1991 totals.

²Most of the 1992 data have been revised owing to adjustments of quarterly data to agree with 1992 totals.

Data may not add to totals shown because of independent rounding and differences between projected totals by States and by regions.

⁴Number of companies reporting for the quarterly survey.

⁵Does not include Alaska and Hawaii.

⁶Includes Alaska and Hawaii.

One metric ton is equal to 1,000 kilograms or 2,204.62 pounds. To convert short tons to metric tons, multiply short tons by 0.907185.

⁹Total quantity and total value in thousand metric tons and thousand dollars.

TABLE 6
CONSTRUCTION SAND AND GRAVEL SOLD OR USED IN THE UNITED STATES IN 1992, BY MAJOR USE

Use	Quantity (thousand short tons)	Value (thousands)	Value per ton
Concrete aggregates (including concrete sand)	265,930	\$1,083,966	\$4.08
Plaster and gunite sands	9,662	51,411	5.32
Concrete products (blocks, bricks, pipe, decorative, etc.)	12,040	49,532	4.11
Asphaltic concrete aggregates and other bituminous mixtures	96,702	419,732	4.34
Road base and coverings	189,216	587,399	3.10
Road stabilization (cement)	3,380	11,774	3.48
Road stabilization (lime)	1,466	5,146	3.51
Fill	88,722	191,726	2.16
Snow and ice control	6,955	23,225	3.34
Railroad ballast	1,002	4,944	4.93
Filtration	2,435	11,777	4.84
Other	6,541	29,794	4.55
Unspecified:1			
Actual	124,656	470,532	3.77
Estimated	110,546	400,324	3.62
Total ²	919,300	3,341,300	3.63
Total ^{3 4}	833,975	3,341,300	4.01

Includes production reported without a breakdown by use and estimates for nonrespondents.

As published in the "Crushed Stone and Sand and Gravel in the First Quarter of 1993," Mineral Industry Survey, based on estimated 1991 totals.

²Most of the 1992 data have been revised owing to adjustments of quarterly data to agree with 1992 totals.

³Data may not add to totals shown because of independent rounding, and differences between projected totals by States.

⁴Number of companies reporting for the quarterly survey.

⁵Due to a low number of reporting companies, no production estimates by quarters were generated.

One metric ton is equal to 1,000 kilograms or 2,204.62 pounds. To convert short tons to metric tons, multiply short tons by 0.907185.

⁷Total quantity and total value in thousand metric tons and thousand dollars.

²Data may not add to totals shown because of independent rounding.

³One metric ton is equal to 1,000 kilograms or 2,204.62 pounds. To convert short tons to metric tons, multiply short tons by 0.907185.

^{*}Total quantity and total value in thousand metric tons and thousand dollars.

PRODUCTION OF CONSTRUCTION SAND AND GRAVEL IN THE UNITED STATES IN 1992, BY GEOGRAPHIC REGION

			·		

INDUSTRIAL SAND AND GRAVEL

By Wallace P. Bolen

Mr. Bolen, a physical scientist, has been the commodity specialist for industrial sand and gravel since October 1988. Domestic survey data were prepared by Dominique Alexis, statistical assistant; and the international production table was prepared by Ronald Hatch, international data assistant.

Probably no other nonmetallic mineral has more diversified uses than silica (industrial) sand, mainly because of its common occurrence around the world and its distinctive physical characteristics, including hardness, resistance to high temperature and chemical action, and relatively low price. Silica sand is the major component of common glasses, foundry molding and cores, abrasive blast sand, and hydraulic fracturing sand. Industrial sand and gravel is also important in ceramics, chemicals, and fillers for rubber and plastics, and also is utilized in golf courses, as a flux in smelting and chemical production, as filter media, and in many other uses.

Complying with the provisions of the Metric Conversion Act of 1975 and the Omnibus Trade and Competitiveness Act of 1988 (Public Law 100-418), beginning with this issue of the Annual Report for Industrial Sand and Gravel, the U.S. Bureau of Mines will publish its statistical information on industrial sand and gravel in U.S. customary units as well as in metric units. Initially, the reporting in dual units will be applied to the totals only, with increased emphasis on metric units in successive years.

DOMESTIC DATA COVERAGE

Production of industrial sand and gravel in 1992 increased to 27 million tons, about 5% more than production in 1991. Production increased in response to improved demand for silica for blasting, chemicals, fiberglass, filtration, flat glass, hydraulic fracturing (frac) sand, nonmetallurgical flux, silicon and

ferrosilicon, and specialty glass.

Exports of silica sand and gravel decreased about 10% in quantity and 15% in value compared with those of 1991. Imports of industrial sand and gravel nearly doubled in quantity and the associated value increased 163%. Domestic apparent consumption of industrial sand and gravel in 1992 was 25.7 million short tons, an increase of about 7% compared to that of 1991.

Domestic production data for industrial sand and gravel were developed by the U.S. Bureau of Mines from voluntary surveys of U.S. producers. Of the 159 industrial sand and gravel operations surveyed, 147 (92%) reported to the U.S. Bureau of Mines. Their combined production represented about 97% of the U.S. total published in table 1. The production of nonrespondents was estimated mostly using employment data. Of the 159 operations, 155 (97%) were active and 4 idle. (See table 1.)

BACKGROUND

One of the first industries to use silica sand was the glass industry. At least 4,000 years ago, long before iron was smelted, glassmaking was already a known craft. Although the place and date of the first manufactured glass are not known, the oldest known specimens of glass are from Babylon (ca. 2600 B.C.) and Egypt (ca. 2500 B.C.), where the industry was well established by about 1500 B.C. Many varieties of glass were known during Roman times. Little is known of the glassmaking methods used in Europe from the fall of Rome until the

10th century, when stained glass was produced in Venice. After this, Venice remained the leader in fine glassware for the next four or five centuries. In the 17th century, a process for casting glass was invented in France, and later, England began to make flint glass, marking the beginning of modern glass technology.

Glassmaking was apparently the first industry to be transplanted from Europe to North America, first to Mexico and later to the British colonies. The first manufacturing establishment in what is now the United States was a glass factory at Jamestown, VA, built in 1608. The 1885 edition of "Mineral Resources of the United States," the predecessor of today's U.S. Bureau of Mines "Annual Reports," reported a total of 317,000 tons of silica sand produced in 1884 in the United States, under "Glass Materials." In 1992. a total of 27 million tons of silica sand was produced in the United States for a variety of uses, of which 11.4 million tons was for glassmaking. Today, glass has become an invaluable product with a multitude of forms and applications.

Metals casting was probably the second industry that used silica sand. Today, the casting industry provides vital components for most modern manufacturing industries. The number of industries using silica sand is growing constantly, as are the products made by using silica sand.

Definitions, Grades, and Specifications

Sand is defined throughout the industry and by the American Society for Testing

and Materials (ASTM) as granular rock particles that pass through a No. 4 mesh (0.187-inch) U.S. standard sieve, are retained on a No. 200 mesh (0.0029-inch) sieve, and are the result of natural disintegration or comminution cemented rock. Industrial sand or silica sand is the term used by the industry for sands that have a very high percentage of silicon dioxide (SiO₂) and are essential materials in glass manufacture, in ferrous and nonferrous foundry operations, in certain chemical and metallurgical processes, for hydraulic fracturing of oil and gas deposits, and in many manufactured products as fillers or extenders.

Most industrial sands have been named for their specific uses, for example, glass, foundry, abrasive, filler, and hydraulic fracturing sands. Almost invariably, these sands, in addition to being high in silica, consist mostly of quartz grains.

Products for Trade and Industry

Silica sand had a wide range of uses in a significant number of industries, the most important being glass and foundry. Other uses were metallurgical and as abrasives, as fillers, for filtration, and for hydraulic fracturing of rock formations to improve recovery in oil wells.

Glass sand was used as a main constituent for manufacturing glass containers, flat glass, safety glass, pressed and blown glass, fiberglass, and a wide variety of specialty glasses such as optical glass and industrial glass.

Glass sand had to meet rigid specifications with respect to purity and silica content, depending on the kind of glass being manufactured. Only a very small amount of iron oxide and chromium compounds could be tolerated, and a high percentage of aluminum, calcium, or magnesium oxides was undesirable. The standards of the American Ceramic Society for glass sand indicated that all grains should pass through a No. 20 mesh screen, between 40% and 60% should be retained on a No. 60 screen, between 10% and 20% on a No. 80 screen, and not more than 5% should pass a No. 100

screen. Sand for first-quality optical glass should contain 99.8% SiO₂ and a maximum of 0.1% aluminum oxide (Al₂O₃) and 0.02% iron oxide (Fe₂O₃). Third-quality flint glass could contain only 95% SiO₂ and as high as 4% Al₂O₃. Only in the low-quality amber glass was the content of Fe₂O₃ permitted to reach 1%.

Most glass manufacturers established their own specifications for the physical size and chemical purity of the raw materials that have to be met by the suppliers of glass sand. Recently, glass manufacturers showed an increased interest in finer glass sands because processing of smaller particles required lower temperatures and, therefore, reduced the consumption of energy.

Foundry sands included molding sand and core sand that were used for casting iron-, aluminum-, and copper-base alloys. Required properties included cohesiveness sufficient to hold together the mold or core when moist, which is achieved by a bonding agent; refractoriness to withstand the high temperature of the molten metal; strength to resist the weight of the metal; permeability to release vapors and gases generated during cooling of the metal; and proper texture and composition to produce a smooth casting that will not react with the metal. Most metals were cast in "green sand," which is a mixture of silica and clay, although to a lesser extent, resins or oils were also used as a bonding agent instead of clays. In the case of naturally bonded foundry sands, the amount of clay minerals present affected their usefulness. Standard tests and specifications for foundry sands were published by the American Foundrymen's Society.1

Refractory sands were used in the manufacture of silica brick and tile, quartzite (gannister) being the commonly used raw material. Required properties were "the capability of maintaining the desired degree of chemical and physical identity at high temperatures" and resistance to abrasion, impact, thermal shock, and high level of load. Refractory silica materials were classified based on their general composition and on their distinctive properties. Standard

classifications and specifications for silica refractory brick were published by the ASTM.²

Quartz sands, on the Knoop scale at 820, are quite hard and are one of the oldest abrasives known. Abrasive sands were quartz sands used in stone sawing, glass grinding, metal polishing, and sand blasting. No rigid specifications existed for these sands, but sound, clean, hard, and closely sized sand grains were required. Purity and grain-shape specifications varied with the type of abrasive action and the requirements of the final product. An angular particle shape with sharp cutting edges was generally required.

Hydraulic fracturing sand was pumped into oil or natural gas wells as a sandliquid mixture to break up petroleumbearing formations and act as a propping agent, allowing oil or gas to move more freely toward the producing wells. Some of the major requirements for fracturing sands were spherical, well-rounded grains of clean, dried, and well-screened quartz sand, free of any materials such as feldspar, calcite, and clay. The most common size was 20/40 mesh; other sizes included 6/12, 8/16, 12/20, 40/70, and 70/140, but these sands represented only about 15% of the total sand used as proppant. "Recommended Practices for Testing Sand Used in Hydraulic Fracturing Operations," published by the American Petroleum Institute, was used as a guide by industry.3

Ground sand or silica flour has found wide industrial application as a filler in paint, plastics, rubber, ceramics, and a variety of other products. Mainly because of the diversity of its uses, no standard specifications exist for the silica flour used in most of these applications except grain size and chemical composition.

Silicon carbide, which was used as an abrasive, for refractory uses, and in specialty ceramics, was produced by the reaction of silica sand (60%) and coke (40%) at elevated temperatures up to 2.400° C.

Metallurgical sand was used as a fluxing agent for basic oxides in various smelting operations and as a source of

silicon in ferrosilicon manufacture. The ferrosilicon was a steel alloying additive. Filter sand was used extensively in filtering water for municipal and industrial use and swimming pools and in sewage-treatment plants. Engine sand was used in locomotive haulage to improve traction. Other sands were used in special cements, in manufacturing silica brick and tiles for furnace linings and beds, for coal washing, and in manufacturing pottery. Industrial sand was also used for chemical production, golf courses (both in traps and in green construction), and in a growing variety of building products. Industrial gravel was used as the source material in the production of silicon and ferrosilicon and as a flux for the production of copper, nickel, and elemental phosphorus. Some gravel was also used as filtration media, mainly in municipal water-treatment facilities.

Industry Structure

In 1992, 88 U.S. companies with 155 active operations produced silica sand and gravel. The individual industrial sand and gravel operations ranged in size from those producing about 1 million tons annually to those reporting less than 10,000 tons per year. Most of the production came from large operations that were mostly owned or operated by a small number of companies. In the past 10 to 15 years, there was a gradual trend toward larger operations, mostly because small plants were becoming less economical. The viability of small operations was dependent on demand in local markets, mining conditions, and the degree of processing required to supply the final product.

Beyond the move toward larger operations, the industry has also developed into two groups: one, the larger national companies that produce many grades of silica, and the other, which consists mainly of smaller and local companies that produce industrial sand and gravel for limited uses and often include construction sand and gravel. Because companies that traditionally produced only construction sand and

gravel may sometimes produce sand for industrial uses, the number of companies could change by upward of 10% annually.

Geology-Resources

U.S. resources of industrial sand and gravel were expected to be sufficient to meet domestic demand in the foreseeable future. although their geographic distribution and quality often did not match market requirements. The availability of these reserves was controlled to a significant degree by land use and/or environmental constraints. Reserves of industrial sand and gravel owned or controlled by domestic producers were estimated to total about 3 to 4 billion tons.

Although silica reserve data for the rest of the world were not available, it could be assumed, on the basis of geologic evidence, that world reserves were sufficient to meet demand, even if not always at the locations where needed.

Industrial sand or silica sand was produced in the United States from a variety of geological formations ranging in age from late Precambrian to mid-Tertiary. About 70 stratigraphic units were known as having an economic potential for this industry. Lithologically, these deposits ranged from quartzites, sandstones with different degrees of cementation, quartz conglomerates, chert deposits, and quartz pegmatites to terrace sands and gravels, and dune sands. Most of the high-quality industrial sand was produced from a few geological formations in the Eastern United States. Oriskany sandstone, or more precisely the Ridgeley formation of Early Devonian age, was one important source of silica sand. It extended from New York State to southern Virginia and eastern Ohio, but was being mined only in central Pennsylvania, northwestern Maryland, and northern West Virginia, where the formation was thick enough to be of commercial value. It was a hard, white orthoguartzite with medium to fine. angular and subangular, and well-sorted The St. Peter sandstone of Middle Ordovician age, extending from

Wisconsin and Minnesota through Iowa, Illinois, and east-central Missouri, was another major source of industrial sand. The best known center of production of silica sand from this formation was the Ottawa district of La Salle County, IL, where it was known as "Ottawa sand," and to a lesser degree in southern Wisconsin and east-central Missouri. It was a soft and poorly cemented high-purity orthoquartzite with coarse, rounded grains. The weak cement holding the silica grains together was mostly a light-colored clay.

In addition to the two formations just mentioned, the most important sources of industrial sand in the United States. numerous other deposits also were being mined for silica sand in different parts of the country. Included are the Jordan sandstone of Upper Cambrian age in Minnesota and Wisconsin, a primary source of hydraulic fracturing sand; the Raritan formation of Upper Cretaceous age in central New Jersey, and the Cohansey sand of probable Miocene age in southern New Jersey; and the Tuscarora quartzite of Lower Silurian age in Pennsylvania and Virginia that is used for the manufacture of refractory bricks. Other deposits are the Sylvania sandstone of Devonian age in the Detroit area; the Oil Creek and McLish formations of Lower Ordovician age in Oklahoma, which are a southwestward extension of the St. Peter sandstone; and the Hickory sandstone of Cambrian age in central Texas that produced mostly hydraulic fracturing sand.

In the West, the most important sources of industrial sand were the Ione formation of Eocene age in northern California, the Silverado (Paleocene) and Tejon (Eocene) formations in southern California, and the Eureka quartzite of Middle Ordovician age in central California.

Approximately two-thirds of the U.S. industrial sand and gravel was produced east of the Mississippi River, especially in the industrialized areas of the East North Central, South Atlantic, and Middle Atlantic regions. Of the top five producing States that accounted for about 42% of 1992 production, three—Illinois,

Michigan, and New Jersey—were in the East and the other two-California and Texas—were in the West. concentration of the industrial sand operations in the Eastern part of the United States resulted from the existence of high-quality geologic deposits close to the major consuming industries, glass and foundry. In the South and West, demand from the oil and gas industry in the Louisiana, Oklahoma, and Texas area has been the largest factor for the sustained growth of industrial sand operations in Texas. California production remained large due to demands from local industry. particularly the glass container industry, of which the wine industry consumes a large portion, and the distance of California from the traditional production areas in the Midwest.

Technology

Exploration.—A large number of geologic formations with economic potential as a source of industrial sand have been mapped and described in literature over many years and were, therefore, well known. Consequently, detailed exploration and development work for new industrial sand operations was expected to occur on some of these The qualities of a silica formations. deposit necessary for a viable operation should include proper particle size, chemical composition, degree of cementation, and deposit uniformity. Also, the nature and amount of waste material and the economic feasibility of its removal and possible use or disposal should be studied. The evaluation of the new deposit should also include an environmental impact study as required by most local or State agencies before authorizing a new mining operation.

If the raw material should prove to meet the requirements and adequate reserves are demonstrated, the development stage of the operation could be started. Economic feasibility and marketing studies should be performed by analyzing all factors important for any such mining operations. Included are the availability of power and water supply, mining and processing costs and

requirements, and the condition of nearby roads and highways. Other factors include the proximity of rail haulage; the cost of compliance with local, State, and Federal regulations; and the proximity and density of local population as well as its attitude toward such a project.

Mining.-Most industrial sand was mined from open quarries, but a few underground operations existed, mostly because of an exceptionally thick overburden or environmental limitations. Surface mining methods and equipment varied with the type of the geologic formation, size and configuration of the deposit, production capacity, estimated life of the operation, and location of the deposit with respect to urban centers. The mining methods depended primarily on the degree of cementation of the rock, although most open pit mining operations included site clearing and removal of the overburden; mining of the silica rock or sand; processing of the material, including crushing, screening, classification; and reclamation of the extraction area. Unconsolidated sands. such as the Cohansey of New Jersey, below the ground water level were dredged. Much of the St. Peter sandstone was first loosened by light blasting and then washed down by hydraulic jets or "monitors" into sumps, from which it was pumped to the processing plants. Harder rock such as the Oriskany sandstone required blasting and primary and secondary crushing before it could be processed.

Processing.—Processing of mined silica sand required specialized operations that varied considerably with the nature of the deposit and the physical and chemical requirements of the desired product. Depending on the degree of cementation, several stages of crushing were necessary to achieve the desired size reduction. Gyratory crushers, jaw crushers, impact mills, or roll crushers were used as primary or secondary crushers, and smooth rolls, media mills, autogenous mills, high-speed hammer mills, or fluid energy jet mills were used

for grinding the product down to 50 Some producers microns and finer. employed flotation cells, with a variety of flocculants, to remove unwanted minerals and fines if they were not easily removed through mechanical scrubbing and separation. which most producers installed. Dry or wet screening was used to separate particles of sizes down to about 150 microns, and wet or air classifiers processed particles from 250 microns into the submicron range. Vibratory screens and gyratory screens, in addition to mechanical, hydraulic, or air classifiers, were used, depending on the size distribution required.

Research for the silica mining industry related not only to new methods that increased output and reduced production costs but also to health and safety problems as well as exploration, land management. and reclamation. Significant technological developments instrumental in maintaining adequate production at relatively stable real costs were mostly in the processing plant technology. The use of computerized systems in plant operation and quality control increased: this, along with improved mining and processing equipment, permitted the recovery of salable fractions that were previously considered uneconomical.

Recycling.—Recycling of silica sands was limited to some foundry sands, particularly those used for making cores and molds with no-bake resin-bonded sands, some abrasive and airblasting sands, and, increasingly, postconsumer glass and scrap glass (cullet) that substitutes for batch mix (including industrial sand). Most glass recycling was restricted to container glass, with green and amber being consumed at a higher rate than flint, which was more difficult to use in the batch mix. As the level of glass used increases, so does the level of quality required. Contamination of cullet by ceramics and nonmagnetic materials was an increasing concern. International trends toward increased recycling of glass and foundry sands and innovative ideas on recycling other materials should influence greater recycling of silica products.

A report was published on the use of cullet in the glass industry. Cullet use reduces the demand for silica in glass production; therefore, cullet use and trends were an important indicator for silica consumption. This report considered various aspects of cullet use and handling and also looked at the savings in energy with cullet use as it varied by percent cullet in the batch mix. The highest savings were reportedly obtained when cullet levels were 80% to 90% of batch.4 Glass recycling was put at 31% in the United States for 1991. This included glass used in glasphalt and those that were refilled and represents an increase from the 1990 rate of 28%.5

Byproducts and Coproducts

Small amounts of gold and silver were recovered occasionally as a byproduct or coproduct from some unconsolidated silica sand deposits. Also, during the processing of some silica resources, other minerals, including clays, feldspars, mica, and quartz crystals, were produced as byproducts and coproducts.

Economic Factors

Silica sand deposits are nonrenewable resources. New mining methods combined with advances in mineral processing that were introduced during the past decade have increased the number of silica deposits that can be commercially developed.

The industrial sand industry was very competitive, largely because silica sand is a relatively abundant mineral, with supply usually exceeding demand. The delivered price of the product, in addition to quality, was a very important element in any major transaction. The producer with an operation closest to the market had a significant advantage over competitors. Combining sophisticated (and therefore expensive) processing equipment backed by technical knowledge and solid sales expertise was important. For this reason, only a small number of large companies were able to compete successfully and succeed in the silica sand business and supply a wide variety of products. Smaller, less efficient operations became uneconomical as operating costs, as well as costs associated with meeting various Federal, State, and local regulations, continued to increase. The only alternatives they had were to either limit the range of products they supplied to close markets or go out of business.

Prices.—As a result of rapidly rising costs of labor, energy, and mining and processing equipment, 1992 constant dollar prices of industrial sand rose steadily between 1973 and 1983. From 1985 to 1992, 1992 constant dollar prices fluctuated in the \$15.75 to \$16.75 range owing to decreased demand and tight competition in some markets. Prices are expected to continue to fluctuate, although they should slowly rise as a result of the cost of compliance with more stringent environmental, land use, and safety regulations.

Costs.—Production costs for silica sand were determined to a large extent by the cost of labor, equipment, energy supply, water availability, and the additional burden of compliance with environmental and safety regulations. Production costs varied widely depending on the nature of the geologic deposit, the geographic location, and the type and number of products produced. Profits were relatively small for most producers, total production costs being close to the f.o.b. selling price per ton.

Tariffs.—There has been no tariff on imported silica sand containing 95% or more SiO₂ and not more than 0.6% iron oxide from most favored nations since January 1, 1987. For all other countries, the tariff for imported silica sand remains \$1.94 per long ton.

Depletion Provisions.—The depletion allowance for industrial sand and gravel was 14%.

Operating Factors

Environmental Requirements.— Major environmental considerations that had to be dealt with in mining and processing industrial sand and gravel were emission of particulate matter into the air. discharge of processing water, and noise abatement. Air pollution constituted a major problem in the processing plants, especially in the drying and packaging stages of finer products such as silica flour, silicosis being the major disease that can be contracted as a result of longterm exposure to silica dust. Because of the high cost of compliance with the environmental regulations designed to reduce this health hazard and possible long-term liabilities associated with it. some companies were no longer producing silica flour or did not plan to produce it in the future. Both wet and dry methods of dust control were used. The most important water pollutant was clay in suspension as a result of washing and screening silica sand. Because of the large quantities of water used to process silica sands and the need of compliance with stringent regulations, the treatment of discharge water by the sand producer was expected to require increasingly sophisticated and expensive processing methods. Significant progress was made in reducing noise pollution, both inside and outside of the operations, including noise and vibration produced by blasting and movement of heavy trucks.

Sand producers had to obtain mining permits from the appropriate governmental agency, which sometimes also required an Environmental Impact Statement (EIS) and a reclamation plan that met its guidelines or regulations. More and more emphasis was being placed by local communities improving the overall appearance of the operating mines as well as on land reclamation after mining was completed. At the same time, industry and the communities had to recognize the time and costs required to protect the environment and the importance of agreeing on fair and realistic environmental standards. Many States, counties, and towns had zoning laws that regulated land use.

Most of the active silica sand quarries as well as the known deposits were on private land, which was either owned or leased on a long-term basis by the producers. These deposits contained high-quality silica sand and were in the best locations with respect to markets. Unlike the construction sand and gravel industry, the industrial sand industry was usually not significantly affected by increasing land values near populated areas.

Transportation.—Transportation costs for silica sand were often equal or considerably greater than the cost of the product at the processing plant. Because of the large variety and number of consumers of silica sand, long-distance haulage was not uncommon. In 1992, the largest tonnage, 56% of all industrial sand, was shipped by truck because most users require a versatile and rapid delivery system. Substantial quantities, 38% of the total, were also shipped by rail, especially when large volumes were sent long distances. The remaining tonnage was shipped by barge or used at the mine.

ANNUAL REVIEW

Legislation and Government Programs

On May 29, 1992, the Occupational Safety and Health Administration (OSHA) issued a final ruling that determined that nonasbestiform varieties of asbestos are far less dangerous than regular asbestos and therefore tremolite, anthophyllite, and actinolite should be exempted from regulation under the asbestos standard. OSHA stated that this will result in \$73.6 million in annual savings and affect 970 ceramic and paint manufacturers and 25,000 aggregate-user operations.

The U.S. Bureau of Mines publication "Crystalline Silica Primer" was released to the general public to help in understanding the crystalline silica issue. This publication explains the nature of crystalline silica, where it is found and used, and how it is qualitatively and quantitatively identified.

Issues

Preliminary findings of a multimillion dollar study, conducted in Switzerland, involving 1,000 laboratory rats, indicate that fiberglass does not cause lung cancer.⁶ An editorial that reviewed four studies on fiberglass and lung cancer also was published on this topic.⁷

Production

The Midwest (East and West North Central regions) continued to lead the Nation in production with about 41% of the 27 million tons produced in the United States, followed by the South (South Atlantic, East and West South Central regions) with about 35%, and the West (Pacific and Mountain regions) with 15%. (See table 2 and figure 1.)

Based on the 1990 census estimations on population, 1992 U.S. per capita industrial sand and gravel production was 0.11 ton. Per capita production by major geographic region was 0.19 ton in the Midwest, 0.11 ton in the South, 0.08 ton in the West, and 0.05 ton in the Northeast.

The five leading States in the production of industrial sand and gravel. in descending order of volume, were Illinois, California, Michigan, New Their combined Jersey, and Texas. production represented 42% of the national total. Significant changes within the five major producing States included Michigan and New Jersey, where production decreased nearly 9% and 7%, respectively, and in Illinois, where production rose 6%. **Production** increased in the majority of States, but several States experienced a decrease in silica production. (See tables 3, 4, and

The U.S. Bureau of Mines canvassed 88 producers of industrial sand and gravel with 155 active operations. About 75% of the industrial sand and gravel was produced by 46 operations, each with an annual production of more than 200,000 tons. The 10 leading producers of industrial sand and gravel were, in descending order of tonnage, Unimin Corp., U.S. Silica Co., Fairmount

Minerals Ltd., The Morie Co. Inc., Oglebay Norton Co., Badger Mining Corp., Construction Aggregates Corp., Simplot Industries Inc., Owens-Illinois Inc., and Manley Brothers of Indiana Inc. Their combined production, from 57 operations, represented 69% of the U.S. total.

Merger and acquisitions activity slowed in 1992 but operations moved in and out of the industrial sand and gravel sector as some companies (re)introduced silica for industrial uses while others removed operations from the industrial sand and gravel sector.

U.S. Silica's San Diego County, CA, operation did not produce or sell any industrial sand and gravel in 1992 after final closure in late 1991.

Fairmount Minerals has acquired 100% of the stock of United Western Supply Co. (Uni-West), one of the leading suppliers of silica sand to the U.S. foundry market with facilities in Denver, Portland, and Seattle.⁸

Little Hill Mines Inc., Pinal County, AZ, changed its name to Silica Mines Inc., in August.

L-Bar Products Inc., King County, WA, changed its name to Reserve Silica Corp.

following producers (re)introduced into the industrial sand and gravel population in 1992: Parr Industries Inc., Mobile County, AL; Savannah Abrasives Inc., Effingham County, GA; Irving Brother's Gravel Co. Inc., Grant County, IN; Northern Gravel Co., Muscatine County, IA; Winter Brothers Materials Co., St. Louis County, MO; Abrasives Inc., Grant County, ND; Schrader Sand and Gravel, Pike County, OH: Humble Sand Co. Inc., Ottawa County, OK; Taggart Sand Products, Providence County, RI; Nicks Silica Co., Madison County, TN; and Faulks Brothers Construction Inc., Waupaca County, WI.

Consumption and Uses

Sand and gravel production reported by producers to the U.S. Bureau of Mines was actually material used by the companies or sold to their customers. Stockpiled material was not reported until consumed or sold.

Of the 27 million tons of industrial sand and gravel sold or used, 42% was consumed as glassmaking sand and 20% as foundry sand. Other important uses were abrasive sand (7%) and frac sand (6%). Because some producers did not report a breakdown by end use, their total production as well as the estimated production for nonrespondents were included in "Other uses, unspecified," which represented about 3% of the U.S. total.

Specialty silicas were usually produced by means of chemical processing of natural silica or as a byproduct of other mineral or chemical processing. Although the U.S. Bureau of Mines did not specifically collect information for specialty silicas, their consumption does affect natural silica sales. Specialty silicas included, but are not limited to, fumed silica, fused silica, precipitated silica, sol-gel silica, and ultrahigh-purity silica. These silicas were used in abrasives, catalyst, electronics, food, health care, optics, paper, plastics, refractories, rubber, specialty coatings, and others. By 1992, specialty silicas sales had increased to more than \$400 million and were expected to grow to \$500 million by 1995.9

On the regional level, more than one-third of the glassmaking sand was produced in the South, followed by the Midwest and the West. Almost three-fourths of the foundry sand was produced in the Midwest. More than three-fourths of the hydraulic fracturing sand was produced in the Midwest, and the majority of the abrasive sand was produced in the South (62%). (See table 6 and figure 2.)

Northeast.—Cumberland County, NJ, continued to be the largest source for the glass and foundry sand markets in the region. Unimin, U.S. Silica, Morie, and WHIBCO Inc., all of which operated plants in the county, were among the largest producers of sand for these markets. U.S. Silica's plant in Huntingdon County, PA, also produced significant amounts of sand for the glass

market. Morie and Ricci Brothers Sand Co. Inc., both in Cumberland County, NJ, produced a major percentage of the abrasive blast sand in the region.

Midwest.—Unimin's plants in La Salle and Ogle Counties, IL; LeSueur and Scott Counties, MN; Jefferson County, MO; and Columbia County, WI, were among the leaders in producing sand for the glass, foundry, and frac sand markets. Fairmount Minerals, with operations in Berrien and Van Buren Counties, MI: Geauga County, OH; and La Salle County, IL, was a major producer of sand for the blast, foundry, frac, and glass sand markets in the region. U.S. Silica's plants in La Salle County, IL, were large producers for the glass, foundry, and frac markets and its St. Louis County, MO, operation was a large producer for the glass market. Construction Aggregates Corp., Ottawa County, MI; Nugent Sand Co. Inc., Muskegon County, MI; and Sargent Sand Co., Wexford County, MI, were all large producers for the foundry industry. Badger Mining, Jackson and Green Lake Counties, WI, was a major producer for the frac and foundry markets. Manley Brothers of Indiana, La Salle County, IL, was also a large producer for the glass and foundry markets. Major producers for the blast sand market included Oglebay Norton Co., Knox and Perry Counties, OH, and All Purpose Sand Co., St. Louis County, MO.

South.—Unimin and U.S. Silica were two of the largest producers of sand for the glass and foundry markets. Unimin's major plants were in Izard County, AR: Richmond County, NC; Pontotoc County, OK; Kershaw County, SC; Johnson County, TX; and Frederick County, VA. U.S. Silica's Bullock County, AL; Johnston County, OK; Lexington County, SC; Limestone County, TX; and Morgan County, WV, operations were the major contributors for these markets. Morie's Tuscaloosa County, AL; Marion County, GA; and Carrol County, TN, plants were large producers of foundry and glass sand. Cobb Industrial Corp., Red River

Parish, LA; Foster-Dixiana Corp... Lexington County, SC; Huey Stockstill Inc., Pearl River County, MS; Mid-State Sand and Gravel Co., Allen Parish, LA; Pioneer Concrete of Texas Inc., Liberty County, TX; and Specialty Sand Co., TX, were large Newton County, producers of blasting sand. W.R. Bonsal and Co. and B.V. Hedrick Gravel and Sand Co., both in Anson County, NC, produced a large percentage of the industrial gravel used in the production of silicon and ferrosilicon. Oglebay Norton's Texas Mining Co. and Vulcan Materials Co., both in McCulloch County, TX, were the largest producers of frac sand in the region. WHIBCO in Kershaw County, SC, was an important producer of foundry sand. APAC Arkansas Inc., Crawford County, AR, and Short Mountain Silica Co., Hawkins County, TN, were important producers of glass sand. Oglebay Norton's Texas Mining Co., McCulloch County, TX, was also an important contributor of blast sand in the region.

West.—Corona Industrial Sand Co., Lane Mountain Silica Co., Owens-Illinois, Simplot Industries, and Unimin were the five largest producers of glass sand in the region, with major operations in Riverside County, CA; Stevens County, WA; Amador County, CA; Clark County, NV; and Contra Costa County, CA, respectively. Lane Mountain Silica, Stevens County, WA; Lone Star Industries Inc., Monterey County, CA; and P.W. Gillibrand Co., Ventura County, CA, were the major suppliers for the sandblasting industry in the region. Simplot Industries, Clark County, NV, also supplied a large portion of the foundry sand consumed. FMC Corp., Power County, ID; Rhone-Poulenc Basic Chemicals Co., Beaverhead County, ID; and Monsanto Industrial Chemicals Co., Caribou County, ID, each produced industrial gravel for phosphate rock processing.

Transportation

Of the total industrial sand and gravel produced, 56% was transported by truck

from the plant to the site of first sale or use, unchanged from 1991; 38% was transported by rail, down from 40% in 1991; 3% by waterway; and 3% was not transported. Because most of the producers did not report shipping distances or cost per ton per mile, no transportation cost data were available.

Prices

Compared with that of 1991, the average value, f.o.b. plant, of U.S. industrial sand and gravel increased 3% to \$15.76 per ton. Average unit values for industrial sand and industrial gravel were \$16.03 and \$11.59 per ton, Nationally, respectively. ground industrial sand used as fillers for rubber, paint, and putty, etc., had the highest value per ton (\$86.81), followed by ground silica for molding and core facings (\$48.32), ground silica sand used in ceramics (\$43.21), ground silica for scouring cleansers (\$39.57), ground sand used for fiberglass (\$29.64), and frac sand (\$25.90).

Industrial sand and gravel prices generally increased as the industry rebounded from the very poor 1991 sales levels. Those end uses that sustained greater prices in 1992, compared to 1991, included blasting, ceramics, container glass, fiberglass, fillers, flat glass, foundry, refractory, scouring cleansers, and traction. Silica for chemicals, frac sand, roofing granules and fillers, silicon carbide, and specialty glass experienced a decrease in unit value.

The average value per ton of industrial sand and gravel was highest in the West (\$17.51), followed by the Northeast (\$16.67), the South (\$16.01), and the Midwest (\$14.72). Prices can vary greatly for similar grades of silica at different locations in the United States. For example, glass sand's average value per ton varied markedly, from \$18.85 in the West to \$10.05 in the Midwest. Tighter supplies and higher production costs in the West increased the cost of sand and gravel in this region.

Foreign Trade

Exports.—Exports of industrial sand, compared with those of 1991, decreased 10% to 1,474,000 tons, and the value decreased 15% to \$90.4 million. Of this, 66% went to Canada, 8% went to Mexico, 5% went to Brazil, 5% went to the Netherlands, 4% went to Japan, and the remainder went to numerous other countries throughout the world.

Imports.—Compared with those of 1991, imports for consumption of industrial sand nearly doubled to 181,000 tons valued at \$2.5 million. Almost 75% of this was lower value silica from Belgium. Nearly 25% of the imports were from Australia. The remainder, sold for very high values per ton, was small amounts of specially prepared silica sand from Canada, France, Germany, Japan, Mexico, the Netherlands, Sweden, the United Kingdom, and Venezuela. (See tables 7 and 8.)

World Review

World production of industrial sand and gravel, based on information usually provided by foreign governments, was estimated to be 117.1 million short tons, a decrease of 5% from that of 1991. The United States was the leading producer followed by, in descending order, the Netherlands, Argentina, Germany, and Italy. Most countries in the world had some production and consumption of industrial sand and gravel because of its basic uses in glass and foundries. However, because of variation in descriptions and usage for silica sand and gravel, reliable information was difficult to obtain. In addition to those countries listed, many other countries were believed to have had some type of silica production and consumption. (See table 9.)

Current Research

Developments and research into new ways to produce specialty silicas and advanced ceramics and glasses, as well as improved technology and new uses of silica-based materials, illuminates areas that have potential to greatly impact consumption trends and amounts.

In previous years, this report has highlighted advanced composites and ceramics, and progress and research has continued in these areas. Glass fiber-reinforced polymer was increasingly being used in the auto industry in semistructural applications, high-gloss outer panels, and under bonnet parts. 10

A new composite that has been developed offers twice the impact resistance of conventional fiber-reinforced plastics. The new material incorporates carbon and glass fibers in a crystallized matrix. If the glass fiber content reached 70%, the material was 20% lighter than nylon 6,6. The material was to be marketed as structural materials for engine rooms, industrial robot arms, and in sporting goods. 11

Silicon carbide filler was introduced into a ceramic/metal composite to improve the wear of liners in slurry operation involved with mining. The new product has shown a tenfold increase over the wear life of current rubber or urethane liners. This development offers two benefits to the silica industry, decreased cost at the mine/mill, and possibly increased sales of silica.¹²

Silicon nitride was being evaluated as a potential material for engine valves. It was hoped that the use of advanced ceramics would lead to improved fuel efficiency and reduction of emissions for future auto engines. Weight savings had been reduced by at least 60% over the use of steel and spring force. Therefore, there were lower friction losses and lower consumption, exhaust, and noise emission.¹³

Owens-Corning Fiberglass was experimenting with glass-reinforced concrete as an alternative to traditional steel-reinforced concrete. It appeared that the glass-reinforced segment was holding up much better than the other test materials. This method of reinforcing could save millions of dollars in bridge repairs annually in the United States.¹⁴

Several advancements were reported on the processing of silica. These

advancements may offer opportunity for greater silica consumption. Geltech Inc. was creating a highly pure, porous silica by means of a sol-gel process. The solgel process produced pure silica by chemically reaching silicon alkoxide with water. This silica reportedly has good structural strength and can withstand high temperature. ¹⁵

An exciting new route to silica compounds has been announced by researchers at the University of Michigan. Starting with ordinary silica sand, they have succeeded in creating a host of silica-based compounds that form the building blocks for a variety of new compounds.¹⁶

The technology and uses of glass and glass fibers continued to be researched and developed on many levels. Corning Inc. has introduced new vitrification technology for making durable, nonhazardous glass from municipal solid waste fly ash contaminated with toxic metals.¹⁷

Scientists at the Hebrew University in Jerusalem have succeeded in embedding virtually any chemical compound in glass. Applications that were considered possible included the use of glass as analyzing sensors for identifying chemicals, contaminants, and pollutants in air and water.18 In a related report, researchers at the University California-Los Angeles have developed a smart glass that changes colors in response to the presence of chemical compounds.19

Boeing Co. research has concluded that using hollow S-2 glass fibers can reduce the weight of composite parts by 15% to 20% over E-glass. Boeing tested the composites with the S-2 glass and those with E-glass and determined that although lighter, the S-2 glass composites retain most of the mechanical properties of E-glass. The fibers are manufactured by Owens-Corning Fiberglass Corp.²⁰

Owens-Corning Corp. reported on a new product concept—fiberglass vacuum insulation. This was designed to meet new Federal requirements that appliances such as refrigerators and freezers be more energy efficient and be free of chlorofluorocarbons. The concept

consisted of a vacuum panel of thermally crafted fiberglass inside a steel foil container. The design reportedly provided a very high performance insulation product with an R value per inch of 50, more than six times that of urethane foam insulations used today.²¹

Pilkington PLC of the United Kingdom has developed a technique for producing high-quality molten glass using an electrically powered furnace. Until now, glass produced using electric furnaces has contained microscopic bubbles. The savings provided by electric furnaces include easy installation, maintainability, and one-half the pollutant emission of a conventional furnace. The largest drawback was that the cost of electricity may be prohibitive.²²

It has long been predicted that superthin glass coatings will eventually supplant traditional barrier materials in flexible packaging. Airco Coating Technologies said it will deliver its first commercial flexible film production system using SiO_x coatings.²³

Semiconductor technology also impacts the silica industry via silicon chip technology and manufacture. Researchers from the Fraunhofer Institute for Solid State Physics, Munich, Germany, have caused chip material to emit light through a silicon-radiance effect. As a result of this work, the scientists are looking at possible subsequent applications for porous silicon in LED's, which would be much cheaper and easier to produce than other semiconducting materials such as gallium arsenide.²⁴

The most promising hope for greater silica consumption remains fiber-optic replacement of copper wire and new installation. In 1992, fiber optics continued to garner much attention as a fast-paced growth market for glassmaking minerals. In 1991, shipments totaled \$981 million and sales were predicted to be about \$2.5 billion by 1996. Silica glass, which represents 95% of the market, will remain the most prevalent material used for optical fiber.25 Another report concluded that fiber-optic undersea systems were showing growth at an average annual rate of 20%, to \$12.5 billion by 1997.26

A pilot plant that would consume silica for the production of silicon metal was dedicated by Dow Corning in East Selkirk, Manitoba, Canada. This plant will apply a never before used technology for making silicon metal, used in the production of silicone products. route uses silicon dioxide as a raw rather than silicon material the tetrachloride traditionally employed. Tests are expected to be finished by the end of 1993.²⁷

OUTLOOK

Demand

The forecast range of total U.S. demand in the year 2000 was expected to be 27 to 37 million short tons for industrial sand and gravel. Probable demand was expected to be about 33 million tons. All forecasts were based on previous performances for this commodity within various end uses and contingency factors considered relevant to the future of the commodity.

Glass Sand

Since 1987, annual demand for glass sand had fluctuated between 11.1 and 12.3 million tons. Sand consumed for container glass has decreased since 1987, mainly because some glass containers were being replaced by aluminum cans and plastic containers and also because the amount of glass being recycled was increasing. Additionally, manufacturers of container glass were using thinner walls in glass containers, and this process had cut down the amount of sand used. Also, a new, thinner, lighter safety glass was used in automobiles, and its use was growing. However, glass fibers and novel uses for glass may offer new avenues for silica sales for glass. For example, a paper was published discussing the use of glass as a host for hazardous waste. This topic has been the subject of ongoing discussion and research for several years and has been followed in this publication in recent years. This latest paper discusses glass as a host for heavy metal

oxides, particularly arsenic, barium, cadmium, chromium, lead, selenium, and silver. Should this use become commonplace, consumption of glass sand may increase. As a result of these contingency factors, demand for glass sand was expected to grow slowly until the year 2000. Probable demand for glass sand for the year 2000 was forecast to be 13 million tons, with a range of 12 to 15 million tons.

Foundry Sand

The use of foundry sand was seen to be dependent mainly on automobile production. Recently, many foreign automakers have opened plants in the United States, and this should support growth in sales of foundry sands as a greater percentage of cars sold in the United States will also be made in this country. Another important factor for the future consumption of virgin foundry sand was the recycling of used foundry sand. The level of recycling was not clear but it is thought to be increasing.

Other materials or minerals compete with silica as foundry sand but these other "sands" usually suffer a price disadvantage. The merits of carbon grain as a foundry sand were described recently by American Colloid Co. Although not a true mineral, this material does compete with silica sand. The carbon sand of possesses a number physical advantages that make it potentially highly suitable for foundry casting. However, this material is more than 10 times the price of silica sand and therefore its use would probably be limited.29 Based on foundry activity, competing materials, and recycling, the probable forecast for foundry sands in the year 2000 was expected to be 7.5 million tons, and the range was expected to be 6 to 9 million

Hydraulic Fracturing Sand

Frac sand was sold in greater volumes in 1992 compared to 1991, even though on June 12, 1992, the Baker-Hughes' rig count hit its lowest level since the tally was begun in the 1940's. Fortunately,

the Baker-Hughes' count did finally sustain a year to year increase for the week ending October 16, 1992, and U.S. drilling permits surged 9.6% on a month to month basis in September 1992. Demand was expected to grow for this end use during the decade, partially due to strong exports of frac sand. Probable demand for hydraulic fracturing sand for the year 2000 was expected to be 2.1 million tons, with a range of 1.6 to 2.4 million tons.

Adequacy of Supply

Domestic production was expected to continue to meet more than 99% of demand through the year 2000. Imports, mostly from Australia, Canada, and Europe, were expected to remain minor.

The United States was the largest producer and consumer of silica sand among the market economy countries and was self-sufficient in this commodity. Most of it was produced in the Eastern part of the United States, where the largest deposits and major markets are. A significant amount of silica sand was also produced in the West and Southwest, mostly in California and Texas.

Because the unit price of silica sand was relatively low, except for a few end uses that required a high degree of processing, the location of silica sand deposits in relation to the market was an important factor that may work for or against a sand producer. Consequently, a significant number of relatively small operations supplied local markets with a limited number of products.

The constant-dollar price of domestic silica sand had fluctuated since 1983 and was expected to continue fluctuating because of strong competition among producers for retention of dwindling markets for traditional uses.

Possible Supply-Demand Changes

Several factors could affect supplydemand relationships for silica sand. Further increases in the development of substitute materials for glass and cast metals could reduce demand for glass sand and foundry sand but would increase demand for silica flour, which is used as a filler in plastics, and for glass fibers, which are used in reinforced plastics. Also, increased efforts to reduce waste and increase recycling could hinder glass sand demand. However, with advances in high-tech materials, silica sand may see increased consumption for ceramics, fiber optics, and other silicon and glass compounds. Although developments could cause demand for silica sand to decrease, the total value of production could increase because of the increased unit value of the new specialized sands.

An increase in the price of oil on the international market would stimulate domestic drilling and extraction from new and old oil deposits. This would increase demand for domestic hydraulic fracturing sand

Concern over the use of silica as an abrasive due to health concerns and the imposition of stricter legislative and regulatory measures concerning silica exposure could decrease demands in many silica markets. Silica sand for use in the abrasive blast industry was being attacked as a health hazard as marketers of competing materials, including garnet, slags, and olivine, pushed the use of their "safer" abrasive medium.

Development of more efficient mining and processing methods is expected to continue. This will enhance development of lower grade silica sand deposits closer to markets but not presently mined. Such developments are expected to increase silica sand reserves.

SILICON

By Larry D. Cunningham

Mr. Cunningham, a physical scientist with 13 years of U.S. Bureau of Mines experience, has served as the commodity specialist for silicon since February 1992. Domestic survey data and trade data were prepared by Ms. Lisa Harley, statistical assistant.

Silicon (Si) is a light chemical element with both metallic and nonmetallic characteristics. In nature, silicon combines with oxygen and other elements to form silicates. Silicon in the form of silicates constitutes more than 25% of the Earth's crust. Silica is a silicate consisting entirely of silicon and oxygen. Silica (SiO₂) as quartz or quartzite is used to produce silicon-base products for the iron, steel, aluminum, and chemical industries.

The average annual dealer import price for silicon metal and ferrosilicon declined from that of the previous year. Based on contained silicon, overall domestic production increased to about 370,000 metric tons, and consumption of silicon increased to about 535,000 tons.

Overall U.S. trade volume of silicon exports was up by 10%, while overall trade volume of silicon imports increased by 26%. Domestic ferrosilicon producers filed a number of cases against importing nations alleging injury to the domestic industry.

DOMESTIC DATA COVERAGE

Domestic production data for the silicon commodity are developed by the U.S. Bureau of Mines by means of monthly and annual voluntary surveys. The "Silicon Alloys" survey canvasses the operations listed in table 2. The figures in table 1 represent 100% of the production and shipments from these operations.

BACKGROUND

Definitions, Grades, and Specifications

Silicon metal and ferrosilicon are referred to by the approximate percentage of silicon contained in the material and by the maximum amount of trace impurities present. There are two standard grades of ferrosilicon. with one grade approximately 50% silicon and the other 75% silicon by weight. In addition to the standard grades of ferrosilicon, there are miscellaneous silicon alloys that contain silicon and other elements. The most common of these allovs are magnesium ferrosilicon and calcium silicon. However, other elemental additions include barium, boron, manganese, strontium, and titanium.

Metallurgical-grade and polycrystalline silicon metal are referred to by their minimum silicon content and maximum impurity level. Typical impurities cited for metallurgical silicon metal are aluminum, calcium, and iron. Typical polysilicon impurities include carbon, boron, and phosphorus and are commonly measured at the parts per million and parts per billion levels.

The American Society for Testing and Materials (ASTM) publishes standards for ferrosilicon and silicon metal. ASTM Specification A100 covers seven regular grades of ferrosilicon for steelmaking and foundry uses designated A, B, C, D, E, F, and G and subgrades designated as low-aluminum, boron-bearing, and calcium-bearing. ASTM Specifications A518 and A861 cover high-silicon cast iron castings and high-silicon iron pipe and pipe fittings for corrosion-resistant

uses. ASTM recommends that the producer furnish with each shipment an analysis showing the silicon content and, on request, also include aluminum, carbon, manganese, phosphorus, and sulfur contents. Semiconductor Equipment and Materials International (SEMI) has published standards for both polycrystalline and single crystal grades of silicon.

Products for Trade and Industry

Several grades of ferrosilicon are produced and sold in the United States. However, most of the ferrosilicon consumed domestically in 1992 was either 50%- or 75%-grade material, the majority being 50%-grade. The domestic silicon industry in 1992 supplied about 60% of all ferrosilicon products. Of the miscellaneous silicon alloys consumed in the United States, magnesium ferrosilicon is the most significant. Almost all ferrosilicon products are consumed by the iron and steel industry.

Metallurgical-grade silicon metal is used by the primary aluminum, secondary aluminum, and chemical industries. The products sold to these industries vary considerably in their specifications. The and primary aluminum chemical industries generally require more stringent specifications than those of the secondary aluminum industry. addition, the chemical industry requires that the metal be ground into a fine powder rather than the lump form used by the aluminum industry.

The first crystalline silicon was made in 1854. Comprehensive investigations of the effects of silicon in steel stimulated a great demand for silicon in the steel industry in the 1880's, and with the development of the electric furnace in the late 1800's came expanded production of ferrosilicon. By 1949, the first silicon pure enough for use in transistors and other semiconductor devices Beginning produced. in 1951. commercial production of high-purity silicon gave impetus to the rapidly expanding electronics industry.

Polycrystalline silicon (ultrapure, 99.9%) was a product largely confined to research until 1956, when its use in manufacturing components for commercial applications was estimated to have exceeded that used for research. By 1958, an estimated 20,412 kilograms of high-purity silicon valued at \$16 million was consumed by the electronics industry for the manufacture of diodes, rectifiers, and transistors.

Geology-Resources

The United States has an abundance of silica deposits for the production of ferrosilicon and silicon metal. For the production of these materials, 98% to 99% purity is preferred. However, trace amounts of aluminum and iron are also acceptable. Physically, the material should not contain fines and should not crumble easily.

Technology

Silicon metal and ferrosilicon are produced by the reduction of silica (SiO₂) to silicon (Si) in a submerged arc electric furnace. A typical charge consists of silica as beneficiated quartz or quartzite; coal, coke, or charcoal as a reductant; wood chips for porosity; and, when producing ferrosilicon, iron in the form of steel scrap or iron ore. During the furnace operation, raw materials are periodically charged into the top of the furnace, and the molten metal or alloy is periodically tapped at the bottom of the furnace and cast into chills or ingots. The material is then crushed to specific size requirements starting at about 20 centimeters down to 200 mesh.

Metallurgical-grade silicon metal is the

starting material for high-purity silicon consumed by the electronics industry. First, silicon metal is used to produce an intermediate product such as silicon trichlorosilane (TCS). A vapor deposition process is then used to form a rod or boule of high-purity polycrystalline silicon (polysilicon) from the TCS. A single crystal boule is made from polysilicon by two methods. The Czochralski (CZ) method uses a seed crystal to grow a rod of single crystal silicon from a molten crucible of polysilicon. The Float Zone (FZ) method uses an induction coil to produce a molten zone within a rod of polysilicon. The coil starts at one end of the boule where a seed crystal starts the crystal growth. The coil moves slowly down the boule, allowing a single crystal to be formed. After being sliced into wafers, the silicon is used by the electronics industry to produce integrated circuits.

Recovery of silicon from secondary sources is not normally practiced. The only secondary possibility is recovery from scrap metal. However, any value of contained silicon would be incidental to the value of the primary metal. In 1992, the average price for ferrosilicon was about \$0.36 per pound and the average price for silicon metal was about \$0.60 per pound. For the future, recycling of silicon in the form of ferrosilicon and silicon metal is expected to be insignificant.

Byproducts and Coproducts

Silicon metal and ferrosilicon furnaces produce a material that is referred to as silica fume, silica dust, or microsilica. Originally, this material was considered of little or no value. However, microsilica is now used as an additive in a number of different products, including high-strength concrete.

Economic Factors

Production of silicon metal and silicon alloys is extremely power intensive, requiring a power input of approximately 8,000 to 12,000 kilowatt-hours per ton of silicon content.

The location of ferrosilicon and silicon metal smelters is normally determined by balancing marketing costs against processing costs. Consequently, on a worldwide basis, smelting plants are near iron and steel industries or trade routes serving them, where cheap fossil fuel or electric energy is available or where a combination of these factors exists. The availability of hydroelectric power in large quantities at competitive prices, the lack of a sizable steel industry, and the presence of deep natural and ice-free harbors contributed to Norway becoming the largest exporter of ferrosilicon in the world. The high cost of electric power, proximity to world trade routes, and the demands of an established iron and steel industry have made Germany, Japan, and the United Kingdom three of the world's largest importers of silicon metal and ferrosilicon. During the 1980's, Brazil established itself as a major producer of silicon ferroalloys and silicon metal, joining countries such as Canada, Iceland, and Norway that have low power costs. In contrast, high power costs have forced Japanese ferroalloy producers to cease production of silicon metal and drastically curtail silicon ferroalloy production.

By 1960, consumption of high-purity silicon by the electronics industry was more than 31,751 kilograms. However, the market was becoming saturated with material resulting from increased output by new plants and the expanded production from older ones. Prices were in the range of \$150 to \$330 per pound compared with an average price of \$330 per pound for metal consumed in 1958. By the mid-1960's, improvements in silicon devices and the increased use of integrated circuits in the computer and aerospace industries had contributed to an accelerated consumption of high-purity silicon.

Demand for metallurgical-grade silicon alloys and metal is determined by the level of activity in the steel, ferrous foundry, aluminum, and chemical industries and is little affected in the short term by prices for these materials. As a result, prices tend to vary widely with changes in demand and supply.

From the period 1955 to 1969, the

price of silicon alloys and metallurgicalgrade metal remained stable. During this 15-year period, the domestic producer price fluctuated between \$0.12 and \$0.145 per pound for the 50%-grade ferrosilicon and between \$0.181 and \$0.219 per pound for metal.

Prices began to rise in the early 1970's owing to higher costs of scrap iron, metallurgical-grade coal, electric power, and the cost of newly installed pollution control devices to comply with local and Federal Government standards, which became effective in 1975. Responding to increased demand, rising inflation, and higher energy costs, prices rose steadily from 1977-81.

By the end of 1988, domestic producers reportedly were operating at close to capacity. However, the recordhigh prices of 1988 had declined significantly by yearend 1990. sudden decline in prices was mainly caused by the oversupply of material resulting from the reactivation of idle capacity; the development of new capacity in South America; and the escalation of low-cost imports from China, South America, and the U.S.S.R. Consequently, production cutbacks were scheduled by several domestic producers as global production outpaced demand, resulting in a continued soft world market.

Principal elements in the cost of silicon and ferrosilicon production are (1) delivered costs of the ore; (2) energy cost; (3) cost of reductant coke or low ash coal; (4) cost of iron in the form of steel scrap, if required; and (5) labor. The cost of all these elements, and particularly the cost of energy, has increased rapidly since 1970. In addition, new capital costs for pollution control equipment were added.

ANNUAL REVIEW

Legislative and Government Programs

The U.S. International Trade Commission (ITC) in late June announced that it had made affirmative determinations in the preliminary countervailing duty investigation on

imports of ferrosilicon from Venezuela and in the preliminary antidumping investigations on imports of ferrosilicon from Argentina, China, Kazakhstan, the Russia Federation. Ukraine. Venezuela. The ITC found a reasonable indication that a U.S. industry is either materially injured or threatened with material injury because of imports of ferrosilicon from Venezuela that are allegedly subsidized. Similar findings were made on imports of ferrosilicon from Argentina, China, Kazakhstan, Russia, Ukraine, and Venezuela that are allegedly sold in the United States at less than fair value.

The investigations were instituted in response to petitions filed on May 22, 1992, by domestic producers AIMCOR, American Alloys Inc., and Globe Metallurgical Inc.; former producers Alabama Silicon Inc. and Silicon Metaltech Inc.; and union locals of the United Autoworkers of America, the United Steelworkers of America, and the Oil, Chemical and Atomic Workers.

The Department of Commerce (DOC), which conducts its own investigations, subsequently began its preliminary countervailing duty and antidumping investigations in these cases. The DOC in mid-August announced that it had affirmative made a preliminary countervailing duty determination on ferrosilicon from Venezuela. Department made a preliminary finding that benefits, which constitute bounties or grants, are being provided to Venezuelan manufacturers, producers, or exporters of the subject merchandise. DOC directed the U.S. Customs Service to suspend liquidation (defer final import processing) of all entries of ferrosilicon from Venezuela, entered or withdrawn from warehouse, for consumption effective August 25, 1992. Customs required a cash deposit or bond at 4.97% ad valorem for entries of the merchandise.

The DOC in late October announced that it had preliminarily determined that ferrosilicon from China is being, or is likely to be, sold in the United States at less than fair value. The DOC directed Customs to suspend liquidation of all entries of ferrosilicon from China, that

are entered or withdrawn from warehouse, for consumption effective November 5, 1992. Customs required a cash deposit or bond equal to the estimated margin amount, 137.73% (all manufacturers/producers/exporters), by which the foreign market value of the product exceeds the U.S. price.

the DOC in late Additionally, December announced that it had preliminarily determined that ferrosilicon from Kazakhstan, Russia, Ukraine, and Venezuela is being, or is likely to be, dumped in the United States. The DOC directed Customs to defer final import processing of all entries of ferrosilicon from Kazakhstan, Russia, and Ukraine for consumption effective September 30, 1992. Customs required a cash deposit or bond equal to the estimated margin amount of 104.18%. Suspension of liquidation of all entries of ferrosilicon from Venezuela was effective December 29, 1992. The estimated margin amount for Venezuela was 1.49%. At the same time, the DOC announced that it had preliminarily determined that ferrosilicon from Argentina is not being, nor is likely to be, sold in the United States at less than fair value.

The DOC and ITC will continue to conduct countervailing duty and antidumping investigations in these cases.

The DOC in October initiated a formal scope inquiry into the outstanding antidumping duty orders on silicon metal from Argentina, Brazil, and China, which have identical scopes, or specified ranges of silicon content of material covered under the rulings. In 1991, the DOC and ITC had determined that imports of silicon metal, containing between 96% and 99.99% silicon by weight, from these countries were sold at less than fair value in the United States and caused material harm to the domestic industry. The DOC assessed the dumping duty for China at 139.49% and that for Argentina at 8.65%. The duty for Brazil was assessed against individual producers over a range of 87.79% to 93.2%. The inquiry was in response to a request in March by petitioners in the original investigation that DOC determine that material containing a lower silicon content, between 89% and 96% silicon by weight, having a relatively high aluminum content, is covered by the antidumping duty order in effect for silicon metal imports from China.

In Proclamation 6465 of August 25, 1992, the President proclaimed that it is appropriate to designate as preferred trading partners each of the former republics of Yugoslavia, other than Serbia and Montenegro, under the General System of Preferences.

During the year, the United States officially entered into agreements on trade relations with 5 of the 12 independent states that succeeded the former U.S.S.R. Most-favored-nation (MFN) status was extended to the Republic of Armenia, April 7; the Russian Federation, June 17; Ukraine, June 23; the Republic of Moldova, July 2: and the Republic of Kyrgyzstan. August 21. In addition, the United States officially extended nondiscriminatory treatment to products of the Republic of Albania effective November 2. MFN status means significantly lower U.S. import duties for silicon products from these states. MFN tariffs for silicon products range from duty free to 9% ad valorem, whereas non-MFN tariffs for silicon products range from \$0.044 per kilogram of contained silicon to 45% ad valorem.

Silicon metal is a raw material for the production of many silicone-base products. including silicone breast implants. Congress granted the FDA regulatory authority for implant devices in 1976. However, on January 6, 1992, the Food and Drug Administration (FDA) placed a 45-day moratorium on the sale of silicone gel-filled breast implants. The FDA asked producers and medical practitioners to halt the sale and use of silicone gel-filled breast implants pending the review of the safety and effectiveness of such devices. The FDA moratorium was prompted by safety and health concerns surrounding leaky and/or ruptured implants allegedly causing autoimmune diseases. Subsequently, an FDA advisory panel of medical and other experts convened in February. The panel's job was to review safety issues and make recommendations on continued use of silicone gel-filled breast implants.

In mid-April, the FDA announced that, in keeping with the recommendations of the advisory panel, it would allow silicone gel-filled breast implants to be available only under special conditions. Women with an urgent need for reconstruction with implants would be allowed access to them. Manufacturers. with FDA approval, would set up studies that would enroll any woman who needs the implants for breast reconstruction. The FDA would require carefully controlled research studies for each model of implant that manufacturers wish to continue marketing. In addition, women would have to sign a special form certifying that they had been told about the risks of the implants and agree to enroll in a registry so that they could be notified about information on the implants in the future.

Production

Overall gross production of silicon products increased 2% compared with that of 1991. Production of silicon metal rose by 10%, while production of ferrosilicon and miscellaneous alloys declined slightly. There was a small increase in overall shipments of siliconcontaining products. Producer stocks of silicon-containing materials decreased by 5% overall. Ferrous scrap used in the production of these products was estimated to be more than 170,000 tons.

Dow Corning Corp., Midland, MI, a joint venture between Dow Chemical Co. and Corning Inc., announced in March that the company would be permanently quitting the manufacturing of silicone gelfilled breast implants. Additionally, Dow would pay up to \$1,200 per patient toward the cost of removing the company's implants from women who cannot afford the operation and whose doctors say the operation is medically necessary. Dow would also set up a \$10 million fund for implant research. The company reportedly will cease providing silicone gel for other implantmakers. except where it is bound to do so under existing contracts. Dow pioneered the

product in the early 1960's, and estimates put the company's total sale of implants since that time at about 600,000. The company, with a reported 30% share of the national implant market, decided to stop making and selling the implant devices after the FDA's January 6 moratorium on the sale of silicone gelfilled implants. Estimates indicate that up to 1 million women in the United States have silicone gel-filled breast implants. Also, Dow reportedly disclosed in December that it would no longer produce five implant grades of silicone for sale effective March 31, 1993. However, the company would continue to manufacture 45 other medical grades of silicone materials.

Additionally, Dow Corning Corp. in December commissioned a \$25 million 6-megawatt silicon metal pilot plant in East Selkirk, Manitoba. The new process is said to be more energy efficient and environmentally cleaner than conventional methods. Construction of the plant began in late 1990. Funding for the project was provided by Dow Corning, the U.S. Department of Energy, the Canadian Government, and the Province of Manitoba. Dow planned to operate the plant through 1993 and then make a decision regarding the construction of a commercial-size facility.

Hemlock Semiconductor Corp., Hemlock, MI, a joint venture between Dow Corning Corp., Shin-Etsu Handotai Co., and Mitsubishi Materials Corp., reportedly was embarking on a \$65 million expansion of its polycrystalline silicon capacity. The expansion was intended to meet the growing demand for ultrapure semiconductor-grade silicon in terms of both quality and volume. The expansion is expected to be completed in 1994, with an increase in production capacity of about 75% anticipated. Hemlock supplies an estimated 20% of all polycrystalline silicon used worldwide.²

In October, Columbia Aluminum Corp., Goldendale, WA, reportedly reached a tentative agreement to purchase the silicon metal producer Silicon Metaltech Inc., Wenatchee, WA. Silicon Metaltech has operated since June 1990 under the protection of chapter 11 of the

U.S. Bankruptcy Code. The sale process is expected to take up to 6 months to finalize.³

In October, it was reported that Degussa Corp., the U.S. subsidiary of Germany's Degussa AG, had commissioned a new hydrophobic fumed silica plant in Waterford, NY. The \$40 million facility reportedly is the first of its kind in the United States and will serve the growing domestic market for fumed silica used in silicone sealants, coatings, and printing inks. In addition to the general market, the new plant reportedly will supply the fumed silica requirements of an adjacent silicone manufacturing facility owned by the General Electric Co.⁴

Union Carbide Corp., Danbury, CT, disclosed that a number of companies were exploring the possibility of buying its OrganoSilicon Products, Systems, and Services group. The company intends to sell the group as part of a plan to sell \$500 million in nonstrategic company assets during the next 2 years. Group worldwide sales in 1992 reportedly were more than \$300 million.

Globe Metallurgical Inc., Cleveland, OH, a major U.S. silicon metal producer, was reported to be considering the acquisition of Dow Corning's 12,000-metric-ton-per-year (mt/yr) silicon metal facility in Springfield, OR. Production from the plant is currently used for Dow's internal silicon metal applications.⁶

In late July, it was reported that Elkem Metals Co. would be shutting down a 45-megawatt furnace at its ferrosilicon plant in Ashtabula, OH. The furnace would be down for up to 8 weeks for scheduled maintenance and upgrading. The furnace upgrade was said to include modifications to improve operating and casting performance. A standby 45-megawatt furnace was to be restarted and operated during the maintenance period, and no loss of production was anticipated.⁷

Consumption and Uses

The aluminum industry used silicon metal in the production of wrought and cast products, while ferrosilicon was used primarily as a deoxidizing and alloying agent in the production of iron and steel products. Metallurgical-grade silicon metal was also used as the basic raw material in the manufacturing of many chemical products and intermediates such as silicones and silanes. Overall reported consumption of silicon alloys and metal for most major end uses was up in 1992. (See table 3.)

Apparent consumption of silicon metal and silicon-containing ferroalloys was estimated to be about 535,000 tons of contained silicon. Consumption of silicon metal was estimated at 195,000 tons, while consumption of ferrosilicon and miscellaneous silicon alloys was estimated to be about 340,000 tons. Compared with that of 1991, consumption of silicon metal increased by more than 10%, and consumption of ferrosilicon and other alloys increased 5%. Ferrosilicon and miscellaneous silicon alloys accounted for more than 60% of all the silicon materials consumed, based on silicon content.

Markets and Prices

Table 4 shows the average annual import price for 50%- and 75%-grade ferrosilicon as well as silicon metal. Prices are posted in cents per pound of contained silicon. Overall ferrosilicon prices continued to decline, with the 50%- and 75%-grade material following similar price change patterns. The import price for 50%-grade ferrosilicon started the year at \$0.35 to \$0.355 per pound, reached a high in July of \$0.388 to \$0.393, then fell to \$0.35 to \$0.36 by yearend. The import price for 75%grade ferrosilicon started the year at \$0.315 to \$0.32 per pound, peaked in July at \$0.375 to \$0.38, then fell to \$0.355 to \$0.363 by yearend.

The import price for silicon metal started the year at \$0.585 to \$0.595 per pound, fell to a low of \$0.548 to \$0.555 in April, then increased steadily to a high of \$0.663 to \$0.668 by yearend. During the year, domestic producers instituted a round of price increases that raised the price of silicon metal from a range of \$0.56 to \$0.60 per pound of contained silicon early in the year to \$0.685 by yearend for some producers. The price

increases reportedly were attributed to reduced producer inventories and increased demand by the aluminum and chemical industries.

Foreign Trade

U.S. exports of ferrosilicon increased 11% compared with those of 1991, based on gross weight. (See table 6.) Total value of ferrosilicon exports increased by more than 6%. Nearly 70% of the exported material was shipped to Canada and Mexico. Silicon metal exports were up by 3% based on gross weight, while the total value of the exports decreased by 16%. Canada, Japan, and the Republic of Korea were major recipients of the materials.

U.S. imports of silicon-containing alloys increased significantly compared with those in 1991. (See table 7.) Imports of ferrosilicon categorized as "55% to 80% silicon, other" increased by more than 30% based on gross weight, with the total value for this category increasing by nearly 30%. A substantial increase also occurred in ferrosilicon categorized as "Other," which included all ferrosilicon of less than 55% silicon content. Imports of "Other" ferrosilicon increased 70% based on gross weight and 60% by total value. Brazil and the former U.S.S.R. accounted for about 28% and 26%, respectively, of total imports. The schedule of tariffs that applied during 1992 to U.S. imports of selected silicon materials is given in table

Overall imports of silicon metal products decreased 25% based on gross weight and 8% by total value. Imports of silicon metal categorized as "99.00 to 99.99% silicon" decreased by more than 36% based on gross weight and almost 30% by total value. Imports from Argentina, Brazil, and China for this category were down substantially, owing in part to dumping tariffs levied against the three countries in 1991.

The U.S. net import reliance for ferrosilicon and silicon metal products were estimated to be 38% and 17%, respectively, compared with 33% and 17% the previous year. The overall

import reliance for silicon products was estimated to be 31%.

World Review

Brazil.—Eletrovale SA Indústria e Comércio, a joint venture between State-owned Cia. Vale do Rio Doce (41%), Kawasaki Steel Corp. (20%), Mitsubishi Corp. (20%), and Metalur Mecanica (19%), reportedly completed the \$30 million installation of a 30-megavolt-ampere (M•VA) furnace at its Nova Era Works, Minas Gerais State. The new furnace reportedly will double the company's annual ferrosilicon production capacity to about 44,000 tons.⁸

Ligas de Aluminio SA (Liasa), Brazil's largest silicon metal producer, in May sought protection from creditors under the Brazilian bankruptcy law, citing debts of about \$56 million. In the late 1980's, Liasa boosted silicon metal production capacity at its Pirapora Works in Minas Gerais State from 20,000 mt/yr to about 48,000 mt/yr.

Eletrometalurgia Rima SA, a ferrosilicon and silicon metal producer, was reported to have made its final payment in November as part of the company's restructuring under credit protection. The company went into receivership in late 1990 owing to cashflow problems resulting in part to high interest rates and electricity charges. Rima reportedly has the capacity to produce about 24,000 mt/yr of silicon metal, 12,000 mt/yr of ferrosilicon, and 9,000 mt/yr of calcium-silicon. In late December, the Rima facility was reported to be operating at full capacity. Most of the company's production is destined for export.9

Silex Trading SA, a Brazilian trading and finance company, purchased 80% of the shares of Eletroila SA, a silicon metal producer, in September from Norway's Ila og Lilleby Smelteverker for an undisclosed sum. The company's name was to have been changed to Eletrosilex with Ila og Lilleby retaining a 20% share in the operation. The company, located at Capitao Eneas in Minas Gerias State, has a reported silicon metal production capacity of about 22,000 mt/yr.¹⁰

Canada.—An explosion at Elkem Metal Co.'s Chicoutimi ferrosilicon plant in Quebec, Canada, on August 7, reportedly resulted in one fatality and caused considerable damage to the one-furnace facility. Production at the 30,000-mt/yr ferrosilicon plant was suspended until December owing to an investigation into the cause of the explosion, and until required repair to the facility was completed. Customer needs reportedly were met from Elkem's worldwide ferrosilicon stocks.

China.—According to The TEX Report, Chinese exports of ferrosilicon totaled 280,000 tons valued at \$130.72 million, compared with 319,900 tons valued at \$164.03 million in 1991. The decline in ferrosilicon exports was influenced by a rise in the domestic sales price for the material owing to an increase in demand from the iron and steel industry.

European Community (EC).—The European Commission imposed a 32% antidumping duty on imports of ferrosilicon from Egypt and Poland. The decision followed an investigation of a dumping complaint petitioned by the EC ferroalloy producer association in late 1990. The low price level of the imported material was claimed to be forcing EC producers to sell comparative material at prices that often did not cover production costs.

The Commission announced in July that it had initiated a preliminary investigation into imports of ferrosilicon from China and the Republic of South Africa. EC producers reportedly had claimed that substantial dumping of material was eroding EC market prices. A decision on the investigation is not expected until sometime in 1993.

In mid-August, the Commission announced that it had imposed permanent antidumping duties on silicon metal originating from Brazil. Provisional duties on Brazilian silicon metal imports to EC-member countries were imposed in April 1992. The duties result from a complaint by the EC Liaison Committee of Ferroalloy Industries in July 1990, on

behalf of EC silicon metal producers. The final duties, expressed as a percentage of the net free-at-community border price, were imposed as follows: Rima Electrometalurgia, 34.6%; Electroila, 29.8%; Cia. Ferroligas Minas Gerais, 26.4%; Camargo Correa Metais, 20.4%; and Cia. Brasileira Carbureto de Calcio, 18.3%.

Germany.—Ferrosilicon production in the former east Germany reportedly was halted in February owing to poor economics and environmental conditions. In the late 1980's, ferrosilicon production at the Ferrolegierungswerk Lippendorf plant at Neukieritzsch reportedly was about 26,000 mt/yr.

Iran.—The Iran Ferrosilice reportedly made plans to construct a 25,000-mt/yr ferrosilicon plant to be sited at Semnan, Iran. The company was said to have contracted with the German firm Mannesmann Demag AG for the construction of the plant, which would 75 % - grade ferrosilicon. produce Commissioning of the plant is expected in late 1993 to early 1994. The new plant is expected to be the first ferrosilicon production facility in Iran with most material destined for domestic consumption.12

Japan.—According to The TEX Report, imports of ferrosilicon into Japan totaled 416,000 tons compared with 470,600 tons in 1991. China accounted for about 209,000 tons of ferrosilicon imports. Japanese exports of ferrosilicon totaled about 80,000 tons, with the majority of the material destined for the Republic of Korea and Taiwan. Imports of silicon metal into Japan increased to about 148,000 tons. Silicon metal imports from China and Brazil totaled about 78,000 tons and 41,000 tons, respectively. Consumption of silicon metal by the Japanese aluminum alloy sector was relatively unchanged at about 54,000 tons.

Kazakhstan.—In October, it was reported that ferrosilicon production at

the Yermakovsky Ferroalloy Works had been cut by more than 40% owing to poor market conditions and a deteriorating economy. Ferrosilicon production at the plant in 1991 was reported to be about 525,000 tons. The plant has an estimated annual ferrosilicon production capacity of about 750,000 tons.

Norway.—Ila og Lilleby, part of the Fesil KS group, applied for court protection in July to renegotiate the company's debts regarding ferrosilicon and silicon metal plants at Lilleby Metall. Holla Metall, Hafslund Metall, and Rana Metall. A debt committee composed mainly of Ila Lilleby's creditors was subsequently formed. At a meeting in November, the committee accepted in principle a proposal for refinancing the The refinancing package company. proposed by Lilleby provided for a combination of new share capital, write down of loans, improved loan conditions. and a dividend of 25% to creditors that have no securities or mortgages in any of the company's plants. The proposal was to be presented to Lilleby's creditors in early 1993.

During the year, Elkem E/S undertook a series of measures to improve the company's liquidity and earnings. The company decided to focus resources on its core business areas such as ferroalloys, silicon metal, aluminum. carbon/microsilica and energy, and to curtail or dispose of several less core activities. These restructuring measures resulted in a work force reduction of 679 employees. Additional measures were to be implemented in 1993, which would further reduce the company's work force by approximately 500 employees. 1992, Elkem's ferrosilicon production was reported to be approximately 300,000 tons and its silicon metal production capacity was reported to be approximately 140,000 tons. 13

Russia.—Overall production of ferrosilicon in the Russian Federation in 1991 totaled 538,000 tons compared with 433,000 tons in 1990, according to The TEX Report. In 1991, production at

Russia's two largest ferrosilicon producers, the Chelyabinsky Electrometallurgical Works (240,000-mt/yr reported capacity) and the Kuznetsk Ferroalloy Works (350,000-mt/yr reported capacity) was reported to be about 200,000 tons and 270,000 tons, respectively. Russian exports of ferrosilicon in 1991 were reported to be about 83,000 tons compared with 75,000 tons in 1990.

Saudi Arabia.—The Gulf Ferro-Alloys Co. reportedly will tender a contract in January 1993 for the construction of its planned 75,000mt/yr ferroalloys and silicon metal plant. The four-furnace operation will produce various grades of silicon metal, ferrosilicon, manganese allovs, and silicomanganese. About 7,000 tons of the planned 10,000-ton silicon metal production will go to the Dubal aluminum smelter in the United Arab Emirates. Ferrosilicon production will be for export. Quartz feed material will be produced locally and imported from Iran and Oman. 14

South Africa, Republic of.—Silicon Technology (Pty.) Ltd., Silitech, a subsidiary of Chromecorp Technology Pty Ltd., was reported to have purchased a carbide plant near Newcastle. Two electric furnaces at the facility used for carbide production, a 40-M•VA and a 56-M•VA, will be converted for ferrosilicon production. Annual combined ferrosilicon capacity is planned for about 55,000 tons. Ferrosilicon production at the facility is anticipated in early 1993.

Ukraine.—Ferrosilicon production capacity at the Stakhanovsk Ferroalloy Works in the Ukraine was reported to be about 650,000 mt/yr. In 1991, overall production of ferroalloys in the Ukraine reportedly decreased by 10% compared to those of 1990. For the same period, ferroalloy exports reportedly decreased by more than 30%.

Yugoslavia.—In June, it was reported that ferrosilicon production in

Ruse. Slovenia, and Jegunove. Macedonia, appeared to be normal and largely unharmed by the ongoing civil war in the region. However, ferrosilicon and silicon metal production in Jaice. Bosnia Hercegovina, had shut down as a result of the war.¹⁵ In the late 1980's. ferrosilicon and silicon metal production in the former Yugoslavia was more than 100,000 tons and 25,000 tons, respectively.

OUTLOOK

Demand for silicon metal is driven by consumption in the aluminum and chemical industries. For 1993. industry sources indicate that silicon metal demand in the aluminum industry will increase by less than 3%. The automotive sector will continue to contribute to this growth through increased aluminum content within each vehicle, as automobile producers seek to make vehicles lighter and more fuel efficient. Within the chemical industry, silicon metal is used to produce a wide variety of silicone-base products and intermediates. Industry sources indicate that the domestic silicon compounds industry will grow by more than 5% per year through 1997. Silicon growth in this sector is attributed to silicone elastomers (particularly injection-moldable silicone rubbers), silicon alloys used in superalloy production, and silicones used in household and personal care products, all of which are expected to increase about 7% per year during this period.

Ferrosilicon is consumed primarily by the iron and steel industry. The industry uses ferrosilicon for both deoxidation of molten metal and as an alloying agent. The outlook for steel is discussed in the annual report Iron and Steel. For 1993, no significant increase in Western World steel production is expected. Domestic steel production in 1993 is expected to improve somewhat over that of 1992 with a corresponding improvement in the demand for ferrosilicon. However,

domestic consumption of ferrosilicon is not expected to exceed the 390,000 tons consumed in 1990. Factors that could influence future consumption of ferrosilicon by the steel industry include technological changes and trade agreements. Additionally, the source of domestic ferrosilicon supply could be significantly affected by pending import cases. During the year, some domestic producers filed a number of antidumping and countervailing duty cases against various importing nations alleging injury to the domestic ferrosilicon industry. Preliminary findings by the ITC and the DOC in a number of the cases supported the charges.

SILVER

By Robert G. Reese

Mr. Reese, a physical scientist with the Branch of Metals, has been the commodity specialist for silver for 11 years. Domestic survey data were prepared by Lisa Conley and Kevin Bacon, statistical assistants; and international data tables were prepared by Virginia Woodson, international data coordinator.

Although less volatile than in 1991, the average annual silver price declined for the fifth consecutive year. Analysts attributed the continued decline to weak investor demand combined with stable industrial consumption and abundant supplies. During the year, a number of companies responded to the continued weakness in the silver price by suspending mining operations at several silver-producing mines. As a result. domestic silver production declined for the second consecutive year. However, the drop in production was less than expected. Although mining ceased, many mines processed stockpiled broken ore and continued to produce silver.

DOMESTIC DATA COVERAGE

Domestic mine production data for silver were developed by the U.S. Bureau of Mines from four separate, voluntary surveys of U.S. operations. Typical of these surveys was the lode mine production survey of copper, gold, lead, silver, and zinc. Of the 111 silver-producing lode mines to which a survey form was sent, 109 responded, accounting for an estimated 93% of the total U.S. mine production shown in tables 1, 2, 4, 5, and 6.

BACKGROUND

Silver has played an important role in peoples' lives since ancient times. Early people used silver for ornaments and utensils and as a substance that could be bartered for other goods and services. This concept of the "value" of silver eventually led to its use as the standard in monetary systems, such as that of the Roman Empire, and as a means of paying for international trade. Silver continued to be the standard for most currencies until the discovery of major silver deposits in Mexico and Peru. As more silver deposits were discovered in the 18th and 19th centuries, countries gradually abandoned silver as the standard for their currencies in favor of a gold standard.

Expanding industrial use of silver eventually led to the elimination of silver in U.S. coinage. In the early 1960's, the U.S. Department of the Treasury became a major supplier of silver to industrial consumers. The Treasury, however, had insufficient stocks both to meet industrial demand and to maintain an adequate supply of circulating silver coinage for a prolonged period. When the silver price reached \$1.29 per ounce, the value of the silver in a silver dollar equaled \$1 in currency. At silver prices greater than \$1.29, the silver in a silver dollar would have been worth more than \$1 in currency, and as a result, it could have been advantageous to melt silver dollars their silver content. for decreasing the amount of circulating coinage. Similarly, if the silver price rose above \$1.38 per ounce, the silver in dimes, quarters, and half-dollars would have been worth more than the coins' face value. To avoid a possible meltdown of the circulating coinage, the Treasury attempted to control the silver price through increased silver sales and increased minting operations from 1964 to 1967. A reduced silver content halfdollar, along with silverless dimes and quarters, were introduced in 1965 to help maintain the supply of circulating coinage, and in 1967, the Treasury announced that all silver coins were being withdrawn from circulation.

Silver occurs as native metal, but is usually found combined with sulfur. Until the 16th century, the ratio of silver to gold produced in Europe was about 10:1. Most of the silver was obtained from the lead sulfide ore galena. With the discovery and exploitation in the 16th and 17th centuries of silver deposits in the Americas, silver production shifted away from Europe. As production increased in Bolivia, Mexico, and Peru, the world ratio of silver to gold production increased because silver was relatively more abundant than gold in the New World. Following the 1859 discovery of the Comstock Lode in Nevada, the United States was the world's leading silver producer from 1871 to about 1900. Mexico was the leading producer from 1900 to 1968, yielding to Canada from 1968 to 1976. In 1976, Mexico regained the position of the world's leading silver producer, a position that it held through 1992.

Definitions, Grades, and Specifications

The purity of silver in bullion, coinage, jewelry, or other items is usually expressed by its "fineness," or parts per thousand. Pure, or "fine," silver is 1,000 parts fine or 100.0% silver. Sterling silver is 925 fine, or 925 parts (92.5%) silver and 75 parts (7.5%) copper. Domestic coin silver is an alloy that was

used in minting coinage until 1964 and contained 900 parts silver and 100 parts copper. Commercial silver bullion ranges from 999 to 999.9 fine. For any fineness of silver bullion, the principal impurities are gold or copper. Doré silver is unrefined silver bullion generally containing a variable percentage of gold as an impurity. Silver for the National Defense Stockpile (NDS) is required to be 999 fine; free of slag, dirt, or other foreign material; and in bars weighing approximately 31 kilograms.

Uses and Products for Trade and Industry

The most important use of silver is in photographic materials. Silver is used in the manufacture of film, photographic paper, photocopying paper, X-ray film, photo-offset printing plates, and in some other minor light-sensitive products. Photographic materials are produced by depositing thin layers of silver salts, gelatin, and dyes onto a support material. Silver salts, although not extremely sensitive to light when first exposed to illumination, produce a greatly intensified image when subsequently treated with photographic chemical developers. The developer reduces a portion of each silver salt grain to metallic silver, depending on the intensity of the light to which the grain was exposed. The resulting gray to black metallic silver forms a negative image of the original object.

Silver is used in electrical and electronic products because of its high electrical and thermal conductivity and its resistance to corrosion. Silver has the highest thermal and electrical conductivities of any metal. Silver, in general, can be characterized as strongly resistant to atmospheric and ordinary oxidation and exceptionally resistant to corrosion by weak acids. Although silver commonly reacts with sulfur-containing atmospheric gases to form a sulfide tarnish, the tarnish itself offers little electrical resistance and does not prevent the use of silver as an electrical contact material. Pure silver is generally used in low- and medium-current switching devices. In other applications where the

device requires higher strength, more wear resistance, better resistance to arcing, or lower costs, silver is usually alloyed with another metal such as copper or palladium to produce the desired characteristics.

Batteries constitute another electrical use for silver. Silver batteries produce a high-energy output per unit size and weight, but are generally characterized by a short life and high per unit cost. Primarily because of the short life and high costs, the use of silver batteries has been confined to defense and space applications where battery weight, size, and reliability are major concerns. There is, however, a growing use for small silver-zinc button cells in such commercial applications as calculators and hearing aids.

The use of silver for decorative purposes can be divided into three main applications. Probably the oldest use of silver is its use in jewelry. Silver or a silver alloy, usually silver and copper, is flattened and shaped into objects that can be worn for personal adornment. Sterlingware, the second decorative use, consists of articles such as bowls and flatware that are often functional as well as decorative. Sterling silver is an alloy of silver (92.5%) and copper (7.5%). The third decorative use for silver is electroplated ware. Electroplated ware generally consists of the same types of objects produced as sterlingware, the difference being that electroplated ware is made by depositing a thin silver layer on a base metal object, whereas the sterlingware object is formed entirely of the silver-copper alloy. Because less silver is used in a piece of electroplated ware than is used in a similar piece of sterlingware, the price of the plated piece is less than the price of a corresponding sterlingware piece.

The refrigeration and air-conditioning industry uses silver in the form of brazing alloys because of the ability of silver brazing alloys to wet various base metals at temperatures below their melting points. In general, silver brazing alloys do not dissolve or attack steel in normal usage, are ductile, maintain their strength over a wide range of temperatures, and

will join a variety of materials. Silver is added to some solders to improve their flow properties, corrosion resistance, and wettability.

Silver is also used in mirrors, catalysts, medicinals, dental amalgams, bearings, coins, medallions, and a variety of commemorative objects. Silver is used in mirrors because of its high reflectivity in the visible portion of the spectrum. Silver catalysts are used in oxidation reactions such as the production of formaldehyde from methanol and the conversion of ethylene to ethylene oxide. Medicinal compounds include the soluble salts, such as the nitrates and citrates, and insoluble compounds such as the oxides. halides, and proteinates. In dentistry, silver is an important component of amalgam fillings.

Refined silver is available in the form of bars, grain, sheet, strip and foil, wire, rod and tubing, powder, and flake. Bars produced at refineries generally weigh about 31 kilograms and are about 30.5 centimeters long by 12.7 centimeters wide and 10.2 centimeters thick. Grain silver is produced by pouring molten silver into water, creating irregularly shaped silver particles less than 1.3 centimeters across. Silver sheet and foil are available in widths of up to almost 2.1 meters and as thin as 0.01 millimeter. Generally, the thinner the sheet or foil, the narrower it is in width. Silver rod and wire can range from 5 centimeters in diameter to 0.1 millimeter in diameter. Openings in silver tubing can range from capillary size through 15 centimeters in diameter. Silver powders are generally powder-size (0.5 to 2 micrometers) spherical particles, although coarser-sized particles can be produced.

Geology-Resources

About two-thirds of the world silver reserves and resources is contained in copper, lead, and zinc deposits. Ores in which silver or gold is the main component account for the remaining one-third of total world reserves and resources. U.S. silver resources are estimated to be about 190,000 tons. Total world silver resources are estimated to be

about 780,000 tons.

The chief silver minerals found in U.S. reserves are native silver (Ag), argentite (Ag₂S), cerargyrite (AgC1), polybasite (Ag₁₆Sb₂S₁₁), proustite (Ag₃AsS₃), pyrargyrite (Ag₃SbS₄), and tetrahedrite {Cu₃(Sb, As)S₃}. Other ore minerals of silver are the tellurides, stromeyerite, and pearceite.

U.S. silver reserves are usually found associated with intermediate felsic rocks such as andesites and rhyolites, in veins ranging from a few centimeters to several meters in width. Ores from which silver is produced as a byproduct are usually found in copper porphyries, massive sulfide deposits, or in copper-lead-zinc vein deposits. Historically, most of the U.S. silver production has been from the Rocky Mountain States. It is likely that if major new reserves are discovered, the deposits will be in this region.

Technology

Mining.—Silver is mined using wellestablished open pit and underground methods. Open pit mining consists of removing overburden, drilling and blasting the exposed ore, loading the broken ore, and hauling the ore to the processing plant. Overburden removal is done with draglines or bulldozers. depending on the depth of the ore body. The broken ore is loaded by either power shovels or front-end loaders, and the ore is shipped to the processing plant by truck, train, conveyor belt, or some combination of these transport modes, depending on the distance to the plant.

Underground mining of silver is generally done using one of several stope mining methods. Stope mining consists of the development of a series of horizontal workings, or stopes, into the ore body from a shaft or tunnel. The stopes are above each other and can be vertically separated by as much as 60 meters of ore. The ore between the stopes is removed through the use of explosives.

Beneficiation.—Current treatment of silver-containing base metal ores is almost entirely by a flotation process.

The concentrates contain the silver along with the copper, lead, and zinc. The silver is recovered from intermediate products resulting from smelting the concentrates. In predominantly lead ores. silver is carried down with the lead in smelting and separated from it by the addition of zinc to the molten silver-lead mixture. The mixture is allowed to cool. and the virtually insoluble silver-zinc alloy separates from the molten lead and rises to the surface where it is skimmed. In addition to the silver, this first crust contains some lead and any gold contained in the original ore. The zinc is distilled in a retort for reuse. The retort residue is roasted to recover the gold and silver as doré metal and the lead as litharge.

In predominantly copper ores, the silver is carried down with the copper in smelting. In the electrolytic refining of copper, the silver accumulates in the anode slime, from which it is recovered as silver bullion by smelting.

Gold and silver ores are generally treated by cyanidation. The ores are crushed by grinding in rod or ball mills and then leached with a dilute cyanide solution. Zinc dust is used to precipitate the gold and silver from the cyanide solution. The precipitate is melted in a furnace to produce a doré metal.

Silver bullion is generally refined using an electrolytic process. In the process, electricity is applied to a standard electrolytic cell in which the impure silver bullion is used as the anode, silver nitrate and nitric acid is used as the electrolyte, and either a pure silver strip or graphite is used as the cathode. Passage of an electrical current results in dissolution of silver in the anode and its subsequent deposition as silver crystals on the cathode. The silver crystals are periodically stripped from the cathode and collected, melted, and cast into bullion bars.

Economic Factors

Costs of mining silver ores vary greatly with depth, ground control problems, ventilation, width of vein, continuity of ore bodies, location,

presence of byproduct metals, and the availability of electricity, water, labor, and equipment. Low-grade deposits can usually be mined profitably if sufficient quantities of other metals are contained in the ore. Accurate information on capital costs is difficult to obtain, not only because of variability in the factors enumerated above, but because of differences in accounting methods and definitions used by the mining industry. In general, the cost of mining silver ranges from less than about \$30 per kilogram (\$1 per troy ounce) to more than \$260 per kilogram (\$8 per troy ounce). Underground mining is, in general, more expensive than surface mining.

U.S. tax laws permit silver-producing companies a depletion allowance of 15% for domestic operations and 14% for foreign operations. There are no tariffs on the importation of silver ores, concentrates, doré, scrap, or refined bullion. Tariffs on semimanufactured silver can be as high as 27.5% ad valorem for countries receiving most-favored-nation classification and can be as high as 110% ad valorem for imports from those countries classified as non-most-favored nation, depending on the item.

Operating Factors

Silver mining is, in general, no more hazardous than other mining, but because of the depths reached in the Coeur d'Alene district, rock bursts there are relatively common. Temperatures are uncomfortable at these depths, and air conditioning must be used in ventilation systems. Gains in productivity are difficult to achieve because possibilities for mechanization are limited by the relatively narrow veins mined. In recent years, companies have attempted increase productivity through modification of labor agreements to allow more flexibility in work assignments and compensation and by improved mining plans.

Although in most circumstances silver is not a toxic substance in other than very large doses, a standard has been

established for worker exposure to airborne particulate silver. The Occupational Safety and Health Administration currently requires that the concentration of either silver metal or soluble silver compounds be less than 0.01 milligram per cubic meter of ambient air in workplaces.

Nearly all silver-bearing ores are processed after grinding by flotation or cvanidation. Pollution of downstream waters by fine solids from flotation plants is a problem that requires adequate ponding and retention of tailings. Disposal stabilization of the or accumulated tailings can be a problem at some mines. It can be partially solved in those deep mines where ground support is needed by pumping the tailings back into In cvanidation operations, the mine. extreme care must be exercised to avoid contamination of the ground water, nearby watercourses, or surrounding areas through losses of leach solution. As a result, the solution collection system for returning the leachant to the storage tanks and the system for monitoring water in the surrounding area must be adequate to prevent pollution.

Achieving adequate air pollution (sulfur dioxide) control and disposing of slag and other wastes (iron and silica) are the problems encountered in smelting silver ores. Refining presents little environmental concern because the bulk of noxious impurities are removed during the smelting step; however, spent solutions from electrolytic refining present a disposal problem because of toxic materials in the solutions.

ANNUAL REVIEW

Legislation and Government Programs

Public Law 102-281, enacted May 13, 1992, authorized a number of programs for using silver from the NDS. Title I of the law authorized the production of silver coins to commemorate the 200th anniversary of the White House. Title II authorized the minting of gold, silver, and copper-nickel clad coins to commemorate soccer's "World Cup," to be held in the United States in 1994.

Title III authorized the production of silver medals to commemorate the sacrifices made and services rendered by the United States Armed Forces during the Persian Gulf conflict. Title IV authorized the production of gold, silver, and copper-nickel clad coins to commemorate the quincentenary of Christopher Columbus' discovery of America. Title V authorized the minting of gold, silver, and copper-nickel clad coins to honor James Madison and the Bill of Rights.

the Mint began During 1992, production of the White House and Christopher Columbus Quincentenary Commemorative Coins. Both silver coins had the same specifications. Each coin, manufactured from a 90% silver-10% copper alloy, weighed 26.73 grams. The diameter of each coin was 3.8 centimeters. Inscribed on each coin was its year of issue, "1992"; face value (\$1); and the words "Liberty," "In God We Trust," "United States of America," and "E Pluribus Unum." Both coins were legal tender. The enabling legislation limited the number of coins to be issued to 500,000 for the White House commemorative coin, and 4,000,000 for the Christopher Columbus Quincentenary

Included in the sales price of each coin was its face value and the cost of labor. materials, dies, machinery, and various expenses, including overhead, marketing, and shipping required to design and issue the coins. Also added to the price of each coin was a surcharge. The \$10 per coin surcharges collected from the sale of the White House coins were paid to the White House Endowment Fund. fund was to use the proceeds to assist in its efforts to raise an endowment for support of the White House's collection of fine art and historic furnishings and for maintenance of the historic public rooms of the White House. The Christopher Columbus Fellowship Foundation received the \$7 per coin surcharges collected from the Christopher Columbus Ouincentenary coins. The foundation was authorized to use the collected surcharges along with any other authorized appropriations to provide stipends for fellowships to encourage new discoveries in all fields of endeavor.

Title V authorized the issuance of the Madison-Bill of Rights commemorative coins beginning on January 1, 1993. The enabling legislation contained provisions for two silver coins. One coin was to have a diameter of 3.8 centimeters; weigh 26.73 grams; be composed of a 90% silver-10% copper alloy; and have a \$1 face value. The obverse of this coin was to be emblematic of James Madison, the fourth President of the United States, while the reverse was to emblematic of his home, Montpelier. The law limited the number of dollar coins that could be minted to 900,000. The second silver coin was to have a diameter of nearly 3.1 centimeters; weigh 12.5 grams; be composed of a 90% silver-10% copper alloy, and have a face value of a half dollar. The design of the half dollar coin was to be emblematic of 10 amendments to the the first Constitution, known as the Bill of Rights, and was limited to 1,000,000 coins. Included in the sales prices for the coins were a \$6 per coin surcharge for the dollar coin and a \$3 per coin surcharge for the half dollar coin. Proceeds from the surcharges were to be used by the James Madison Memorial Fellowship Trust Fund to encourage teaching and graduate study of the Constitution of the United States.

The World Cup commemorative coins authorized by Title II were to be available not later than January 3, 1994. The silver coins authorized by the act were to have a \$1 face value, and the number minted was limited to 5,000,000 coins. As with the other dollar silver coins authorized by Public Law 102-281, specifications for the coins were a diameter of 3.8 centimeters, weight of 26.73 grams, and to be struck from a 90% silver-10% copper alloy. To be included in the per coin sales price were costs of design and production and a \$7 per coin surcharge. World Cup USA 1994, Inc., the organizing committee for the event, was authorized to use 90% of the proceeds received from the surcharge for the purposes of organizing and staging the 1994 World Cup. The remaining 10% of the surcharge proceeds were to be distributed to institutions through the United States Soccer Federation Foundation, Inc., in the form of scholastic scholarships to qualified students.

Eligibility for the silver medals authorized by Title III was restricted to those members of the United States Armed Forces, as determined by the Secretary of Defense, who served in a combat zone during the Persian Gulf conflict. The act also authorized the Secretary of the Treasury to mint and sell bronze duplicates of the silver medals. The sales price for the bronze duplicates was to be sufficient to cover the cost of the duplicates and the costs of designing and striking the silver medals. The silver medals authorized by the act were not to be struck or distributed until sales of the bronze duplicates and/or private donations were sufficient so that the medals could be produced at no net cost to the U.S. Government.

Public Law 102-484, the National Defense Authorization Act for Fiscal Year 1993, signed by the President on October 23, 1993, authorized the disposal of 2.611 tons of silver from the NDS. Public Law 102-484 also authorized the disposal of a number of other metals and materials from the NDS. anticipated completion of the disposals within a 5-year period beginning on October 1, 1992, unless it was deterdetermined that completion of the disposals would cause undue disruption of the market. Before carrying out the disposals, however, the law required the President to submit a revised annual materials plan under section 11(b) of the Strategic and Critical Materials Stock Piling Act (50 U.S.C. 98h-2(b)). Contained in Public Law 102-484 were special limitations regarding the silver disposals. The disposal of silver could only be made in the form of coins or as material furnished by the Federal Government to a contractor in the performance of a Federal Government contract.

Production

Silver was produced from preciousmetal ores at 81 lode mines and from base metal ores at 36 lode mines. In 1992, 18 mines each produced more than 30 tons of silver: their aggregated production equaled 79% of total domestic production. Silver was also produced at nine placer operations.

In late July, Homestake Mining Corp. acquired Corona Corp., a Canadian gold company. At the time of its acquisition, Corona had interests in 10 producing mines in Canada, Mexico, and the United States. At the 10 mines acquired with Corona, the principal product is gold, although most of the operations also recover varying amounts of byproduct silver. Company officials viewed the acquisition as an opportunity to acquire low-cost operations and reserves at a time of continuing low precious-metal prices. The acquisition was expected to lower Homestake's overall production costs.

Alaska.—During the year, workers at the Greens Creek Mine mined and processed about 441,200 tons of ore and recovered nearly 218 tons of silver.² During the year, the recovered silver grade increased from 511 grams per ton in 1991 to 587 grams per ton in 1992. The increase in recoverable silver was attributable in part to modifications made to the mill to increase its processing rate, and its metals separation capabilities. At yearend 1992, Greens Creek's estimated proven and probable reserves were about 11,100,000 tons grading 395 grams of silver per ton.

According to company officials, performance at the Red Dog Mine remained unsatisfactory owing to problems in processing some difficult ore types. The operation processed more than 1,435,000 tons of ore in 1992 compared with nearly 1,451,000 tons during the previous year. Average silver content of the ore was 99 grams per ton.³ Several projects were undertaken during 1992 to improve the operation's dust control. Dust control reportedly is a problem in the Artic because the low temperatures make conventional

treatments ineffective. Enclosing outside conveyors and stockpiles and constructing a specialized truck loading station were among the projects completed to improve air quality.

California.—Although mining ceased at Lac Mineral Ltd.'s Colosseum Mine in San Bernardino County during the third quarter, mill operations continued through yearend. The open pit operation recovered gold and byproduct silver using a carbon-in-pulp processing plant. Milling operations at the site were expected to cease near mid-1993.

Following the completion of most construction during the second quarter, the first gold pour at the Hayden Hill Mine occurred near mid-June. The mine, in Lassen County, recovered 896 kilograms of gold and nearly 2.5 tons of silver. Initial production was lower than anticipated owing to startup problems, a lower than anticipated ore grade, and adverse weather during the fourth quarter. Mining occurred at two pits, approximately 300 meters apart. A 3,200-ton-per-day cyanide leach/carbon-in-pulp mill processed the higher grade ore. Lower grade ore was heap leached.

Mining operations were completed at the Shumake Mine in February. The mine, a small open pit operation near Los Angeles, used heap-leach technology to recover gold and silver. During 1992, the mine produced 846 kilograms of gold and 4 tons of silver.⁵ Leaching was expected to continue through mid-1994.

Idaho.—Production began at the Black Pine Mine in Cassia County. The open pit heap-leach operation commenced mining and processing in December 1991, with the first metal pour in January 1992. The mine consisted of three deposits and had an expected life of 4 years. In 1992, the mine produced 1.5 tons of gold and 463 kilograms of silver.⁶

At its DeLamar Mine, NERCO Minerals Co. completed a program to detoxify the mine's tailings pond in response to a bird mortality problem. Included in the program was construction of a cyanide recovery facility to remove

the cyanide from the tailings before its deposition in the pond. The DeLamar Mine produced 1.2 tons of gold and 57 tons of silver in 1992.

In June, Coeur d'Alene Mines Corp. purchased Hecla Mining Corp.'s 12.5% nonoperating interest in the Galena Mine. The acquisition increased Coeur's holding in Galena to 62.5%. Asarco, the mine's operator, owned the remaining 37.5%. In late July, operations at the mine were temporarily suspended. Company officials attributed the decision to continued low silver prices. In 1992, Asarco milled approximately 65,000 tons of ore and recovered 40 tons of silver.8

Hecla Mining Co. obtained all the required environmental and construction permits needed for its Grouse Creek project. During the permitting process, the project's supplemental environmental impact statement was praised by both State and Federal officials. The project addressed all necessary environmental concerns. Reportedly, the project will not impact any salmon habitat and sets a new precedent for the preservation of wet-lands. At yearend 1992, reserves at the Grouse Creek project were about 13.1 million tons grading 1.6 grams per ton gold and 34 grams per ton silver.9

Continued efforts by its workers to reduce costs enabled the Lucky Friday Mine to operate on a break-even basis for most of the year, despite lower silver prices. For the year, the mine produced 63 tons of silver from 159,000 tons of ore.¹⁰

The Sunshine Mine operated at about one-half capacity throughout 1992. Company officials reduced operations at the mine in early June 1991 owing to low silver prices and the need for the company to preserve cash. During 1992, exploration at Sunshine concentrated on locating additional higher-grade ore. According to company officials, early drill results support their theories, and the exploration program was expected to continue in 1993. During 1992, the mine produced 79 tons of silver. 11

Hecla Mining Co. completed leaching at the Yellow Pine Mine in August. The heap-leach operation produced 63 kilograms of gold and 48 kilograms of

silver in 1992.¹² During the year, the mine's electrowinning plant was disassembled and shipped to Hecla's La Choya project in Mexico. Although investigating development of sulfide reserves at Yellow Pine, the company expects reclamation of the site to be completed in 1993. The Yellow Pine Mine, previous winner of several environmental awards, won the Pacific Northwest Pollution Control Association's Industrial Pollution Control Award for its innovative strides toward water quality improvement.

Montana.—Production at the Beal Mountain Mine increased slightly owing in part to the installation of a new crushing plant and to an expansion in process plant capacity. During 1992, Beal Mountain recovered 1,624 kilograms of gold and 249 kilograms of silver, compared with 1,472 kilograms of gold and 243 kilograms of silver in 1991. 13

Canyon Resources Corp. mined approximately 1.4 million tons of ore at its Kendall Mine. The Kendall Mine, an open pit heap-leach operation, produced about 2 tons of gold and 567 kilograms of silver. 14

In its first full year after taking over mining operations, Pegasus set production records at the Montana Tunnels Mine. From startup until mid-June 1991, mining at Montana Tunnels had been performed by a contractor, while Pegasus operated the processing plant. Among the records set were tons of ore mined and production of gold, silver, and zinc. During 1992, Montana Tunnels mined 4.2 million tons of ore and recovered 2 tons of gold, 41 tons of silver, and 17,632 tons of zinc. 15

Production at the Zortman/Landusky Mine declined slightly in 1992. Company officials attributed the drop to the mining of lower grade ore. During the year, the mine produced its 31st ton of gold. For 1992, the Zortman/Landusky Mine recovered 4 tons of gold and 24 tons of silver. 16

Nevada.—At its Battle Mountain Complex, Battle Mountain Gold Co.

recovered approximately 6 tons of gold and 13 tons of silver.¹⁷ In 1991, the company had produced approximately 8 tons of gold and 13 tons of silver at this location. The company processed more than 1.1 million tons of ore through its on-site carbon-in-pulp mill and leached an additional 1.1 million tons. Corporate officials expected the high-grade millable ore in the Fortitude deposit to be depleted during the first quarter of 1993, resulting in a significant decrease in output. Heap leaching of several small nearby deposits will likely account for most of the production in 1993. Exploration and drilling during 1992 resulted in the discovery of additional low-grade mineralization that may be economical.

Although ore at the mine had been depleted in 1991, leaching on a reduced level continued at the Buckhorn Mine through yearend. Reclamation of open pits at the site and access roads were essentially complete. Leaching was expected to continue through 1993, at which time the heap will be decommissioned and the remaining reclamation work completed.

Production at the Bullfrog Mine increased during the year owing in part to the mining of higher grade ore. Surface operations at the mine encountered high-grade ore shoots not previously indicated by drilling. Underground development to access the higher grade North Zone reserves continued, and production from underground mining reached 750 tons per day. During the year, Lac Minerals Ltd. changed mining methods for the underground operation to undercut drift and fill to lower operating costs. In 1992, the mine produced 10 tons each of gold and silver.¹⁸

At the Candelaria Mine, continued leaching of previously mined ore resulted in the production of nearly 33 tons of silver and 62 kilograms of gold.¹⁹ NERCO suspended mining operations at the mine in November 1990, owing in part to low silver prices.

During 1992, operating costs and production improved at the Florida Canyon Mine, although the grade of ore mined declined. Company officials attributed the lower costs and higher

production to the completion of a number of projects in 1992. Among these projects were an upgraded materials handling system, an increase in the mine's Merrill Crow plant capacity, installation of a baghouse in the refinery, and installation of a new mercury retort. In addition to these projects, Pegasus renegotiated its contract with the company performing the mining operations at the site, resulting in lower operating costs. For the year, Pegasus recovered 3 tons of gold and 1 ton of silver from the heap-leach operation.²⁰

Silver production at the McCoy/Cove Mine increased significantly for the second consecutive year. In 1992, the mine produced 246 tons of silver, compared with 175 tons in 1991 and 62 tons in 1990.21 The McCov/Cove Mine consisted of two deposits, about 2 kilometers apart. Production at the Cove deposit occurred from both surface and underground operations. At the McCov deposit, the pit remained closed, and only the underground operation produced ore. Gold production also increased slightly. Company reports attributed the increased production to an increased mining rate resulting from the purchase of six new 172-ton-capacity trucks and a new 17.6cubic-meter wheel loader. The trucks replaced nine 77-ton trucks and enabled Echo Bay to increase the mine's mining rate from a nominal 150,000 tons per day to 168,000 tons per day.

At the Paradise Peak Mine, silver production declined for the second consecutive year, despite increased mill throughput and expanded heap leaching. The continued drop in silver production was expected owing to depletion of the high silver content portion of the ore body. Gold production, however, increased. In 1992, gold production was approximately 8 tons, while silver production was about 60 tons.²² In 1991, the mine had produced 6 tons of gold and 72 tons of silver. The company milled approximately 1,567,000 tons of ore and leached about 4,277,000 tons. previous year, the company milled 1.4 million tons and leached about 2.9 million tons.

The Rawhide Mine, owned and

operated by Kennecott Corp. a wholly owned subsidiary of The RTZ Corp. PLC, produced 3 tons of gold and 25 tons of silver in 1992.²³

Both silver and gold production at the Rochester Mine decreased slightly in 1992. The mine produced about 6,674,000 tons of ore and recovered about 169 tons of silver and 2 tons of gold. In 1991, the mine produced 178 tons of silver and 2 tons of gold.²⁴ Near midyear, the company completed construction of a new 186,000-square-meter leach pad, increasing the available leaching surface at the mine to 836,000 square meters.

Despite record mining and milling rates at the Sleeper Mine, byproduct silver production declined for the second consecutive year. Gold production at the mine also declined. Company officials attributed the drop to the continuing decline in ore grades. To help reduce operating costs, Amax Gold Inc. completed construction of a conveyor system to move ore to the leach pads in early 1992. For the year, the Sleeper Mine milled 814,000 tons of ore, added 7.811.000 tons of ore to its leaching pads, and recovered 8 tons of silver and 4 tons of gold.25

Although mining ceased at the Wind Mountain Mine in January, owing to the depletion of ore reserves, leaching continued throughout the remainder of 1992. During the year, the heap-leach operation produced 9 tons of silver and 2 tons of gold.²⁶ Although site reclamation began immediately, leaching was expected to continue as long as it was economically viable.

Other States.—Cyprus Minerals Co. halted mining operations at Copperstone Mine in December following exhaustion of economically recoverable ore reserves. The open pit mine, in Arizona, produced gold and a small quantity of byproduct silver. Although mining at the site was completed, mill operations were expected to continue through early 1993, during which low-grade ore previously mined would be processed. The company began reclamation of the mine site.

In 1992, the San Luis Mine in Costilla County, CO, produced 2 tons of gold and 871 kilograms of silver.²⁷ Production was lower than expected owing to some startup problems. During the year, the mine was closed temporarily to address elevated levels of cyanide in the tailings Officials attributed the high cyanide levels to two factors. A higher than anticipated copper content in the ore resulted in a higher than expected consumption of cvanide during processing. Additionally, the original detoxification system was unable to sufficiently lower the cyanide content of the mill's discharge. Fortunately, the tailings ponds performed as designed, and no cyanide was released to environment. During the spring and summer, company officials reduced the cyanide levels in the ponds and installed a new detoxification unit.

Production at the Magmont Mine in Missouri declined by more than 40% during the year, and employment fell to 126 from 151. Surface drilling yielded no additional reserves, and it was forecast that the mine would be exhausted and shut down in the next 2 years. In 1992, nearly 873,000 tons of ore was milled compared with more than 1 million tons of ore in 1991.

At its copper refinery in El Paso, TX, Phelps Dodge Corp. recovered 74 tons of byproduct silver. El Paso refinery came primarily from Phelp Dodge's copper mines and smelters in Arizona and New Mexico and the Santa Gertrudis Mine, in Mexico. At the Morenci Mine in Arizona, Phelps Dodge mined about 42,240,000 tons of ore. At its Chino and Tyrone Mines in New Mexico, the company mined about 15,567,000 tons and 1,173,000 tons of ore, respectively.

During May, Amax Gold Inc. exercised its option to acquire a 62.5% interest in the Haile property in Lancaster County, SC, from Piedmont Mining Co. Piedmont had operated a small mine on the property over the past 6 years, but suspended mining in August 1991 following negotiation of the option and earn-in agreement with Amax Gold. Leaching operations at the existing Haile

Mine essentially ended during 1992. The two companies formed a joint venture in July to further explore and develop the property. During the remainder of the year, the joint venture conducted various technical studies to determine the feasibility of developing a large-scale mine on the property. The joint venture planned to conduct additional studies and exploration drilling during 1993.

Lac Minerals halted mining at the Richmond Hill Mine in South Dakota during the third quarter. The open pit heap-leach operation recovered 1 ton each of gold and silver in 1992.²⁹

In Utah, byproduct gold and silver production at the Bingham Canyon Mine increased to 16 tons and 134 tons, respectively.30 In 1991, the mine had produced 14 tons of gold and 112 tons of In January 1992, Kennecott completed the expansion of the mine's grinding and flotation facilities. projects, begun in 1990, increased the mill's capacity by 33% to 117,000 tons of ore per day. In March, Kennecott announced plans to construct a new smelter at the mine and to expand the existing refinery. Completion of these projects is expected during 1995, at which time Kennecott expects to be capable of smelting and refining all of the copper concentrates produced by Bingham Canyon on-site.

Sunshine Mining Co. terminated its lease agreements for the Burgin and Trixie Mines in Utah following its decision to suspend operations at the Trixie Mine. Upon termination, the properties reverted to their lessor companies, Chief Consolidated Mining Co. During the year, Sunshine recovered approximately 5 tons of silver and 187 kilograms of gold from the properties.³¹

Gold and silver production at Hecla Mining Corp.'s Republic Unit declined in 1992 despite setting a production record for the quantity of ore mined. Corporate officials reported that the mine's known high-grade areas were mined out and attributed the mine's lower precious-metal production to the milling of lower graded ore. In 1992, the Republic Unit processed 93,000 tons of ore and

recovered nearly 2 tons of gold and 9 tons of silver. In 1991, 87,600 tons of ore was processed to produce 2 tons and 10 tons of gold and silver, respectively.³²

Consumption and Uses

Apparent U.S. demand for silver in 1992, calculated as refinery production from primary materials and from old scrap plus net imports of refined bullion, was 4,057 tons. Included in the apparent demand calculation was the amount of silver absorbed by investors and the amount of silver required by the domestic fabricating industry. As the U.S. economy recovered from the most recent recession, domestic apparent demand increased for the first time since 1989. The increase, however, was less than 6%, reflecting the sluggishness of the recovery and the continued lack of investor demand.

Near mid-1993, the Silver Institute published estimates of silver consumption in 1992 by end use. CPM Group, a private consultant, developed estimates for the Silver Institute. According to CPM, domestic industrial silver consumption in 1992 of 3,698 tons was essentially unchanged from the previous year.33 Photography remained the largest end use for silver, accounting for an estimated 2,003 tons. electrical contacts and conductors, CPM estimated that domestic industries consumed 569 tons. Among the possible explanations for the stagnant consumption levels were the weak domestic economic recoverv and efforts by manufacturers to reduce operating costs through better inventory management.

Markets and Prices

The daily domestic silver price, as quoted by Handy & Harman, ranged from a low of \$3.63 per troy ounce on December 29 to a high of \$4.32 on January 16. The price began 1992 at \$3.94 per troy ounce rose to its peak near midmonth, and gradually drifted downward for the remainder of the year. The average price for 1992 of \$3.94 marked the fifth consecutive year in

which the average had declined. In 1991, the low price of \$3.58 occurred on February 26, the high price of \$4.53 occurred on June 10 and 11, and the average for the year was \$4.04.

In Europe, the London spot price followed a pattern similar to that of the Handy & Harman price. The U.S. dollar equivalent of the London spot price, as quoted in Metals Week, began 1992 at \$3.87 per troy ounce and ended the year at \$3.66. The low and high prices of \$3.65 and \$4.34 occurred on August 26 and January 21, respectively. The average for 1992 was \$3.95. In 1991, the low, high, and average London spot prices were \$3.55, \$4.57, and \$4.05, respectively.

Many factors contributed to the generally lower silver prices in 1992. Analysts cited sluggish U.S. and world economic growth, which tended to dampen the industrial demand for silver. Also cited were the relatively low inflation rates and the availability of large quantities of silver in both reported and unreported stocks. Low inflation rates discouraged additional purchases by those investors who view silver as a hedge against inflation. The availability of large stocks tended to hold down prices because investors tended to take profits whenever the silver price rose significantly.

The amount of silver represented by the future contracts traded on the Commodity Exchange Inc. (COMEX) decreased to 469,093 tons. In the previous year, futures contracts traded on COMEX represented 646,129 tons of silver. At the Chicago Board of Trade, the quantity of silver corresponding to the futures trading volume decreased from 3,654 tons in 1991 to 1,711 tons in 1992. Mid-America Commodity On the Exchange, the quantity of silver represented by the futures trading volume declined from 408 tons to 276 tons in

Stocks

Total accountable stocks at yearend 1992 decreased by 378 tons over those of yearend 1991. Declines in most

Government-held stocks more than compensated for the continued buildup of stocks held by futures exchanges and increased industry stocks. Analysts cited the lack of investor demand as the primary reason for the continued stock buildup on the commodity exchanges. Regarding the growth in industry-held stocks, analysts cited the low silver price along with increased optimism concerning the U.S. economy.

The total quantity of Government-held silver continued to decline. Department of the Treasury stocks declined by 253 tons to 775 tons by yearend 1992. Similarly, the NDS silver holdings declined from 2,611 tons to 2,255 tons. The U.S. Mint, as authorized by Congress, used NDS silver for various coinage programs. At yearend, the Department of Defense held 29 tons, an increase of 3 tons from the previous year. Since 1985, the total quantity of Government-held silver has declined by more than 2.200 tons. Various Government coinage programs have consumed nearly all the silver represented by this decrease.

Foreign Trade

U.S. silver exports improved in 1992, but remained lower than the totals reported for 1990. The countries receiving the largest increases in U.S. silver exports were Canada and the United Arab Emirates. Shipments to these countries increased about 119 tons and 108 tons, respectively. Increased shipments of refined bullion (45 tons) and waste and scrap material (72 tons) accounted for the increased trade with Canada. For the United Arab Emirates. the increased shipments consisted of refined bullion. The largest drop in U.S. silver exports was that to Japan, which decreased by 118 tons from the previous year. Cumulatively over the past 10 years, the United States has exported about 11,709 tons of silver. Canada (2,585 tons), Japan (2,503 tons), the United Kingdom (2,340 tons), and France (1,298 tons) have received most of the U.S. silver exports.

U.S. silver imports increased in 1992

for the fifth consecutive year, owing primarily to increased imports of impure silver-bearing materials, including waste and scrap, as well as doré and precipitates. The increased imports were due to increased exports by Germany (202 tons), Mexico (172 tons), Canada (140 tons), Peru (123 tons), and France (123 tons).

World Review

World mine production of silver decreased in 1992, despite increased production from countries such as Australia, Chile, and Mexico. For those countries where production increased, analysts attributed the higher production to factors such as capacity expansions and more efficient operations at existing mines, and to the opening of new byproduct mines. In those countries where production dropped, analysts cited factors such as the closure of uneconomic mines and the general economic and political conditions within the country.

CPM Group estimated that world fabrication demand for silver increased nearly 2% in 1992, to 18,360 tons, owing primarily to increased demand in India.³⁴ Demand for silver in industralized countries such as the United States, however, decreased slightly.

Australia.—In 1992, Aberfoyle Ltd. processed a record amount of ore through its mill at the Hellyer Mine. During the year, the mill processed nearly 1.4 million tons of ore with an average grade of 12.5% zinc, 7.1% lead, and 170 grams per ton silver. In 1991, the mill processed more than 1.2 million tons of ore.³⁵

Company officials expected mining to end at the Pajingo Mine in mid-1993 owing to depletion of known reserves. Ore stockpiles, however, should allow the mill to operate through early 1994. In addition to surface mining, Battle Mountain Gold conducted limited underground mining at Pajingo during 1992. For the year, the mine milled 178,000 tons of ore and produced 1 ton of gold and 7 tons of silver.³⁶

Production began at the Peak Mine in

New South Wales. The gold-silver operation began commercial production in July and was officially commissioned in October. Through yearend, the mine had treated 215,911 tons of ore containing 480 kilograms of gold and 114 kilograms of silver.³⁷

At the Red Dome Mine in Queensland, mining ceased near yearend. In 1992, the mine produced about 3 tons of gold and 14 tons of silver, compared with 2 tons and 7 tons of gold and silver, respectively, the year before. 38 In 1993, gold and silver will be recovered from stockpiled ore; however, several studies were being conducted that could result in additional reserves.

Bolivia.—Company officials began testing a new mill at the Kori Kollo Mine in December. The new carbon-in-pulp cyanide leach mill will be used to treat the sulfide portion of the deposit. In 1992, heap leaching at Kori Kollo recovered 2 tons of gold and 11 tons of silver.³⁹

Canada.—Nerco completed construction of a pressure oxidation circuit (autoclave) at its Con Mine. The company planned to use the autoclave to process refractory ores and to treat and stabilize arsenic sludge produced by the mine's former owners as a byproduct of their gold operations. In 1992, the Con Mine recovered 4 tons of gold and 933 kilograms of silver.⁴⁰

Placer Dome Inc. reported the production of 97 tons of silver at the Equity Silver Mine in British Columbia. In 1991, the mine recovered 175 tons of silver. Company reports attributed the decline in production to the mining and processing of lower grade ores. The mine was expected to cease operation in late 1993, following the exhaustion of minable reserves.

At the Heath Steele joint venture, operations exhausted surface minable ore reserves at the Stratmat Boundary Mine early in the year, and production was shifted underground. Production also occurred at the joint venture's B-Mine. Heath Steele was a joint venture of Brunswick Mining and Smelting Corp.,

and Noranda Inc. For the year, the Heath Steele operations produced copper, lead, zinc, and 30 tons of byproduct silver. 42

At its Kidd Creek Div., Falconbridge Ltd. reported the production of 111 tons of silver during 1992.43 Production from the division's No. 1 and No. 2 Mines accounted for nearly all of the byproduct silver production. Development of the No. 3 Mine continued, and initial stoping began. A ramp being driven from the surface reached the 6100 level in December. Work continued on various including reclamation projects. rehabilitation of the complex's tailings As part of its reclamation program, the company purchased three 85-ton trucks to haul waste rock from the surface for use as underground backfill.

Brunswick Mining and Smelting Corp. Ltd. mined and milled a record amount of ore at its No. 12 Mine during the year. In 1992, production averaged about 9,100 tons per day, approximately 7% greater than in 1982, its previous best year. For the year, the mine produced 232 tons of silver by milling 3,874,000 tons of ore. 44 Construction began on an effluent treatment system in 1992. Brunswick's smelter produced more than 90 tons of silver doré.

At the Sullivan Mine, byproduct silver production declined slightly, owing primarily to the processing of lower grade ore. In 1992, Cominco Ltd. milled 1,597,400 tons of ore grading 27 grams of silver per ton, compared with 1,688,300 tons grading 39 grams of silver per ton during the previous year. 45

Highland Valley Copper Co. received the British Columbia Mine Reclamation award during the year. The award recognized the company's commitment to systematic research and development at its Valley Mine. Studies of subjects such acid drainage potential revegetation development were expected to aid in the development of viable land use plans for eventual mine closure. During the year, the mine produced about 32 tons of silver contained in concentrate, compared with about 33 tons the previous vear.46

Chile.—Production at the El Indio Complex increased, owing in part to a corporate decision to concentrate on mining ores with a relatively higher precious-metal content. The El Indio Complex consisted of the El Indio and Tambo Mines. In the third quarter, the company completed a 4-kilometer tunnel. The tunnel provided access to the ore body at depth and was expected to be used for exploration and haulage. During the year, the operation milled about 1,078,000 tons of ore and leached 412,000 tons to recover 7 tons of gold and 47 tons of silver.⁴⁷

In 1992, workers at the Escondida Mine milled 14,070,000 tons of ore to produce 762,800 tons of copper concentrate containing 2 tons of gold and 78 tons of silver. 48 During the year, the mine's partners agreed to expand Escondida's mining and milling capacities. Expected completion for the expansion projects was during the third quarter of 1993, at which time Escondida's nominal capacity would be 400,000 tons of copper in concentrate per year.

The La Coipa Mine produced 502 tons of silver in 1992 compared with 159 tons in 1991. The increased production represented the first full year production of a new 15,000-ton-per-day processing plant that began operating in October 1991. The new plant, a conventional cyanide leaching gold and silver recovery plant, replaced an existing 1,000-ton-per-day mill.

Production at the San Cristobal Mine decreased because of lower than anticipated ore grades. The mine, a typical open pit operation, used heap leaching to recover 2 tons of gold and 6 tons of silver.⁴⁹

Indonesia.—In early 1992, workers at the Grasberg Mine completed various projects designed to increase the operation's mining and milling capacities. During the period 1989-92, mine and mill capacities increased from 20,000 tons per day to approximately 57,000 tons per day. To expand its mining operations, the company developed an access road between the mine and mill, purchased

additional loading equipment. and larger haul trucks. purchased Construction of the access road reduced the company's dependence on an aerial tramway system to transport ore to the mill. At the millsite, the company increased its crushing capacity, expanded the number of primary mills from three to seven, and increased the site's flotation capacity. During the year, the operation milled more than 21 million tons of ore and produced 51 tons of silver, 20 tons of gold, and nearly 281,000 tons of copper. 50 To take advantage of the large reserves at the site, company officials, in August, approved plans to expand the operation's mining and milling capacity to 90,000 tons per day. The new projects were expected to be completed by mid-1996.

The Kelian Mine began operation in early 1992 and reached its operating capacity of 6 million tons of ore during April. For the year, the mine treated 6,197,000 tons of ore and produced doré containing nearly 15 tons each of gold and silver.⁵¹

Mexico.—The Mexican Government introduced a 10-Peso bimetallic circulating coin in late 1992. Each coin contained 5 grams of silver. The Government expected to begin production in 1993 of a 20-Peso bimetallic coin that would contain 8 grams of silver. Together, the 10-Peso and 20-Peso coins were expected to consume 715 tons of silver in 1993. Silver for the coins was to be purchased from new mine production within Mexico.

Copper and byproduct silver production remained essentially unchanged at the Maria Mine in the State of Sonora, despite declining ore grades. Officals attributed the stable output to increased productivity at both the mine and concentrator.

Silver production at the Real de Angeles Mine declined, owing in part to the mining of lower grade ore and lower mill recoveries. In 1992, the Real de Angeles Mine produced 254 tons of silver, compared with 264 tons during the previous year. 52

New Zealand.—Operations at the Waihi Mine produced 2 tons of gold and 12 tons of silver during the year.⁵³ During the year, the company conducted studies aimed at reducing future operating The present plan for the mine requires that both ore and waste be crushed at the mine site and then conveyed to either the mill or the waste As the pit deepens, the ore dump. becomes harder, thereby increasing operating costs. One possible solution being examined consists of driving twin tunnels between the mine and the mill. Construction of the tunnels would allow haulage of the waste material directly to the dump without crushing. alternative was expected to be evaluated during 1993.

Papua New Guinea.—Silver production at the Misima Mine declined in 1992. despite an increase in the quantity of ore mined. During the year the mine produced 6,928,000 tons of ore and recovered 65 tons of silver, compared with 6,169,000 tons of ore and 80 tons of silver in 1991.⁵⁴ To improve its milling operations, the company constructed and incorporated a new secondary crushing plant at the site during 1992.

The Porgera Mine produced gold and byproduct silver-bearing ore from both surface and underground operations. In precious-metal 1992. production increased, owing in part to expansion of both the underground and mill facilities. Additional projects planned for the mill should allow the concentrator to process 8,500 tons of ore per day and allow increased production from the open pit operations.

OUTLOOK

The dominant component of domestic silver supply remains byproduct silver, recovered in the processing of other nonferrous metals such as copper, gold, lead, and zinc. Most nonferrous ores contain some silver. Processing the ores concentrates the silver either in a waste stream or with the principal product.

Once concentrated, the additional cost to recover the silver is minimal. result, the quantity of silver supplied to the market is somewhat independent of the silver price. Another important consideration when forecasting domestic silver supply is the effort made over the past several years to reduce operating costs. Faced with prolonged declining prices, many precious-metal producers have successfully lowered their costs of production. Therefore, despite the recent temporary closure of some large primary silver mines, it is likely that during the period 1993-95, domestic silver mine production will remain between 1,600 and 2,000 tons. Worldwide, mine production of silver should remain near 15,000 tons.

Future industrial demand for silver is harder to forecast owing to its many diverse uses. Over the next few years, the industrial demand for silver will likely follow the general economy, either upward or downward, but remain near 3,700 tons. Worldwide, silver demand will grow slightly with the gradual opening of new markets in less developed countries.

Estimated. Revised.

³Reported figure.

¹Recoverable content of ores and concentrates produced unless otherwise specified. Table includes data available through June 23, 1993.

²In addition to the countries listed, Botswana produces silver (probably 1 kilogram or less per year), Austria, and Thailand may produce silver, but information is inadequate to make reliable estimates of output levels.

Of total production, the following quantities, in kilograms, are identified as placer silver (the balance being silver content of other ores and concentrates): 1988—34,319; 1989—58,000; 1990—52,000; 1991—40,000 (revised); and 1992—40,000 (estimated).

⁵Smelter and/or refinery production.

⁶Less than 1/2 unit.

⁷Formerly part of Yugoslavia; data were not reported separately until 1992.

⁸Includes production from imported ores.

⁹Formerly part of the U.S.S.R.; data were not reported separately until 1992.

¹⁰Dissolved in Dec. 1991; however, information is inadequate to formulate reliable estimates for individual countries other than those listed in this table.

¹¹Year beginning Apr. 1 of that stated.

SLAG—IRON AND STEEL

By Cheryl Solomon

Ms. Solomon, a physical scientist with 7 years of U.S Bureau of Mines experience, has been the commodity specialist for iron and steel slag since 1990. Domestic survey data were prepared by Robin Kaiser, statistical assistant.

Iron and steel slags are byproducts of the iron and steel industry and are used in diverse commercial applications in construction and roadbuilding. Slags are used in road bases, various types of concrete aggregates and products, glass manufacture, mineral wool, railroad ballast, and soil conditioning.

Research during the year emphasized a wide range of uses worldwide for both iron and steel slags, such as blending in cement, agglomerating iron ore fines or steel tailings, or setting in drilling fluids. An international conference on fly ash, silica fume, slag, and natural pozzolans was held in Istanbul, Turkey. (See Research section of this report.)

Domestic consumption of reported iron slag showed a 6% increase when compared with that of 1991, while the consumption of reported steel slag decreased by a little more than 3%.

DOMESTIC DATA COVERAGE

Data for sales, use, and transportation of iron and steel slag are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. processors. Of the 99 operations canvassed, 99 responded, representing 100% of the total sales or use quantity data shown in table 1. Value data had to be estimated for several operations using reports from prior years adjusted by industry trends.

BACKGROUND

Definitions, Grades, and Specifications

Slags are produced in many metallurgical operations, but this

publication deals exclusively with iron slag and steel slag produced during the ironmaking and steelmaking processes.

In the production of iron, the blast furnace is charged with iron ore, flux stone (limestone and/or dolomite), and coke for fuel. Two products are obtained from the furnace: molten iron and slag. The slag consists primarily of the silica and alumina from the original iron ore combined with calcium and magnesium oxides from the flux stone. It comes from the furnace as a liquid at temperatures of about 2,700° F, resembling molten lava.

The blast furnace operation is a continuous process. The raw materials are fed into the top, and the products, molten iron and liquid slag, are drawn off at regular intervals throughout the entire day. Slag is produced at an average worldwide rate of 250 to 350 kilograms of slag per ton of hot metal (kg/thm) or pig iron.² The slag is usually run into iron ladles for conveyance to the cooling pit, or it may run straight into a cooling pit close to the furnace. When the material cools and solidifies, the gases create voids within the structure. These voids impart special engineering properties when the slag is used as an aggregate.3

The density and porosity of the slag are affected by the conditions of cooling as well as by its chemical composition. Depending upon the manner in which the molten slag is cooled and solidified, three distinct types of blast furnace slag can be produced: air-cooled, expanded, and granulated.

Air-cooled slag is allowed to run into a pit adjacent to the furnace or is

transported in large ladles and poured into a pit some distance away. Solidification takes place under the prevailing atmospheric conditions, after which cooling may be accelerated by water sprays on the solidified mass. After a pit has been filled and cooled sufficiently to be handled, the slag is dug, crushed, and screened to desired aggregate sizes.

Expanded slag is formed by controlled processing of molten blast furnace slag with water, or with water and other agents such as steam or compressed air. or both. The formation of gases and steam increases the cellular or vesicular nature of the slag, producing a lightweight product. Several methods of expanding the slag are employed involving the pouring of molten slag in open pits or the use of mechanical devices, one of which produces particles Expanded slag is a in pellet form. strong, lightweight aggregate suitable for making lightweight concrete, either as building blocks or as structural elements for buildings or for bridge decks, for example.

Granulated slag is produced when molten slag is cooled rapidly by means of high-pressure water jets and solidifies into a glassy, granular product. This is the most rapid cooling process, producing little or no crystallization. The granulated slag may be crushed and screened or pulverized for various applications.

The steel industry also produces steel slag during the steelmaking process. The manufacture of steel involves the removal from the iron of excess quantities of carbon and silicon by oxidation. Steel slag is composed of roughly 50% lime. The other two main constituents are silica and iron oxide. The steel slag contains significant iron quantities and few voids, making it a tough, hard, heavier material. Different types of steel slag are generated from the open-hearth, basic oxygen, and electric arc furnaces.

Air-cooled and expanded slag are defined by ASTM Standard C 125-88.⁴ Granulated slag is specified by ASTM C 989-88, "Standard Specification for Ground Iron Blast Furnace Slag for Use in Concrete and Mortars," which was first published in 1982.⁵

The specifications for steel slag aggregate used in asphaltic concrete are covered by ASTM D 5106-91, "Standard Specification for Steel Aggregates for Bituminous Paving Mixtures." 6

Industry Structure

In general, most slag processors operate under contracts of 3 to 10 years with steel companies. The services the slag processors typically offer to the steel mill industry are hauling and transporting the slag away from the mill site, processing the slag, and recovering and distributing metallics and nonmetallics. Because slag hauling and processing facilities are capital intensive, the slag processors usually try to negotiate a longterm initial contract with the steel company recover the capital investment. Subsequent contracts may be

Depending upon the specific situation at the mill site, the slag processor may assume ownership of the slag at the point of discharge or process it for a fee and/or market the finished product and pay royalties to the steel company on sales. Some steel companies may allow the processor to share in royalties on these sales. Although there are many variations in the way a particular slag processor and steel mill will set up their agreement, two possible options are considered here. The slag company may be paid to haul and transport the slag. process it, and market the finished product. The steel company, in turn, receives a royalty on the completed sale and a purchase discount on material | recycled to the mill. Second, in a minority of the contracts, the slag processor takes ownership of the material and pays little or no royalties to the mill. In this situation, the slag processor would 100% of the assuming site development and capital costs, including facilities for screening, metallic separation, and crushing and heavy equipment, such as slag pot haulers, to move the material.

Technology

Slag processing systems include the following.7

Pit Granulation.—Molten slag is poured, either from a slag ladle or directly from the furnace, into a pit filled with water, or is hit with sprays of water to rapidly quench it. The blast furnace slag forms granules that have a glassy or vitrified structure. The slag granules are then separated from the granulation water and transported to the drying and grinding plant.

Gravel Layer Filter Bed System.—Pit granulation is developed further with the gravel layer filter bed system. The slag is granulated at the furnace in a granulation head by high-pressure water sprays. The slag slurry flows down a runner to an agitating tank where water is injected to keep the slag in suspension. The slag is dewatered and then excavated by a computer-controlled bucket crane. The gravel layer filter bed keeps the water in the system in a closed circuit, thus preventing water pollution. Blue Circle Cement Inc. of Sparrows Point, MD, has operated a gravel layer system since 1981.

Filter Hopper System.—Filter hopper systems use large dewatering silos lined with screens to dry the slag. This system extends the filtering system upward to conserve plant space. However, because the filtering is less efficient in the filter hopper system, pumping the slurry is necessary in the filter hopper.

Slag Pelletizer.—The slag pelletizer was developed by National Slag Ltd. in Hamilton, Ontario, as a means of bringing very high hydrogen sulfide gas emission levels typical of the "pit process control.8 under foaming" Pelletized slag is produced by expanding molten blast furnace slag under water sprays and then passing the flow of this pyroplastic material over a spinning drum on which fins are mounted. The fins break up the slag, which then forms into pellets owing to surface tension. Although previous expanding processes have been of the batch type, this is a continuous process so that gaseous emissions are effectively diluted by generation over a long period of time. Because of this rapid cooling, the pelletizer can be thought of as an "air granulator."

The pelletizer has been installed in at least eight countries. Currently in Canada, about 400,000 tons of slag is pelletized annually and separately ground for use as a cementing material by the St. Lawrence Cement Co., Lafarge Canada Inc., and St. Mary's Cement. The pelletizers are installed near Hamilton, Ontario, where the major steel producers are located.

Operating Factors

Environmental Requirements.— Slag processors have had to be aware of environmental considerations, in much the same manner as have other mineral processing or manufacturing industries. During the past decade, concerns about the environment as embodied in the Clean Air Act of 1990 or Solid Waste and Clean Water legislation have grown. Concurrently, recycling and reuse of materials have become firmly established.

In keeping with public and private emphasis on improving the environment and preventing environmental harm, the slag industry has taken an active stance toward environmental responsibility in slag plant operations. Installation of new equipment, incorporation of improved operating procedures, and increased emphasis on such slag processing as slag

granulation and other types of processing have all favorably impacted the slag industry.

At the same time, the emphasis on reuse of materials has meant that slag, which has been used as far back as Roman times, has been given renewed interest as a useful byproduct that serves as a substitute for mined aggregates. In addition, the use of slag as a commercial product is vastly more useful to the environment than it would be if it were landfilled.

Because of the different ways in which iron and steel slags can be utilized and the variety of steel slags available in the market, the slag processor can advise the user of iron and steel slags as to the best possible use for any given slag.

ANNUAL REVIEW

Legislation and Government Programs

Pennsylvania Residual Waste Regulations expanded the category of coproduct to include iron and steel slags after they were processed. Such slags, therefore, would no longer be considered waste products.⁹

Production

Many of the projects involving slag in 1992 were related to highway and road construction. The building market was still depressed; however, it had somewhat improved from that in 1991.

Heckett Co. closed its Mississippi Steel plant in Jackson, MS and Bethlehem Steel plant in Johnstown, PA. Heckett started up a plant in Hickman, AR; however, no outside sales were expected until the Nucor Steel mill built the roadways.

The Levy Co. of Portage, IN, supplied blast furnace slag chip to resurface the Indianapolis Speedway acceleration and deceleration lanes. The project followed the prior resurfacing of the entire track with slag. Levy also resurfaced Highway I-55 Burr Ridge, IL, with steel slag chips. In addition, the Levy Co. reconstructed the parking area, running track, and tennis courts of Merrillville

Indiana High School with blast furnace slag ballast and slag dense-graded base.

Standard Lafarge's Eastern Region, headquartered in Coraopolis, PA, completed shipments of more than 450,000 tons of blast furnace slag coarse aggregate for portland cement concrete used in the construction of the new Greater Pittsburgh International Airport terminal facility in 1992. (See cover photo.)

Consumption and Uses

Sales of slag products generally reflected demand from the construction industry. The Department of Commerce reported that value of new construction in 1992, \$426.7 billion, increased by 6% compared with that of 1991. The value of highway and street construction, \$32.8 billion, was estimated to have increased by approximately 9% from that of 1991.

Blast furnace slag was used as a ground product to replace portland cement in concrete, as a special lightweight aggregate in blocks and highrise buildings, as a concrete aggregate replacing common concrete aggregates and sands, as a highly skid-resistant asphalt aggregate, and as a road base where the rough, interlocking surface and shape and cementitious properties enhance its load-bearing values.

Air-cooled blast furnace slag was the predominant form of iron slag processed in the United States, accounting for 90% of blast furnace slag sales in 1992. The most significant end use in 1992 for air-cooled slag was as a road base. Air-cooled blast furnace slag also was used as an asphaltic concrete aggregate, other concrete aggregate, fill, mineral wool, glass manufacture, and railroad ballast. (See table 5 for related data.)

Consumption of combined expanded and granulated slag was 1,407,000 tons valued at \$24,925,000. Granulated slag was predominantly used in the manufacture of cement and expanded slag in the manufacture of lightweight concrete blocks.

Steel slag is principally used for highly skid-resistant asphalt road surfaces, road

bases, and asphaltic aggregates.

Reported steel slag consumption decreased slightly compared with that of 1991 (see table 6). Steel slag used in asphaltic concrete and road bases decreased by 24% from that of 1991.

Transportation

Most slag is used within about a 50-kilometer (km) radius of its source. Trucking costs make slag uncompetitive with mined aggregates when transportation distances exceed about 50 km. Some slag may be delivered over greater distances to areas that do not have other aggregates for use in construction and roadbuilding.

Of all the iron and steel slag products sold in 1992, 83% traveled by truck, with an average marketing range of 45 km; 4% traveled by waterway, with an average range of 404 km; and 3% traveled by rail, with an average range of 400 km. The remaining 10% was used at the plant where it was processed. (See table 4.)

Markets and Prices

The average price, f.o.b. plant, for all blast furnace slag was approximately \$7.06 per ton, almost 15% less than that of 1991, but well within the range of the past 5 years (see table 7). The price of air-cooled blast furnace slag decreased from \$6.10 per ton in 1991 to \$5.88 per ton in 1992. However, with the exception of the 1991 data, the upward trend in prices for air-cooled slag begun in the early 1970's continued until the current year. Granulated and expanded slag price information was withheld to avoid disclosing company proprietary data. The unit value for steel slag decreased from \$3.41 per ton in 1991 to \$3.02 per ton.

Foreign Trade

Statistics developed by the U.S. Department of Commerce, Bureau of the Census, indicated that approximately 132,000 tons of granulated blast furnace slag was imported from Canada during

1992. These Canadian imports reportedly entered primarily through Savannah, GA, Cleveland, OH, Buffalo, NY, and Detroit, MI. The Canadian imports may be expanded or pelletized slag.

Exports of granulated slag were 2,060 tons. Most of the slag exports went to Canada; however, 600 tons of granulated slag was exported to Chile, Guatemala, Mexico, and Venezuela.

World Review

In 1992, slag cement plants were set up or expanded in a number of countries to supply cement to those areas in need. New European standards also were anticipated to possibly affect slag sales throughout Europe. In one example, in the United Kingdom, the industry sells the slag to contractors such as ready-mix companies that buy cement and slag. In other European countries such as Belgium, Germany, and the Netherlands, the slag is sold to the cement manufacturer, who would then blend it at the cement plant. The issue is concerned with standardization at the plant level and may become important in North America as well.

Australia.—In 1992, there was reduced demand for slag products and quarry products. 11 Production was about 3 million tons of iron and steel slag. About 375,000 tons of blast furnace slags was used in Australian cements, with another 500,000 tons used in road construction and as an aggregate in concrete. Slag production and consumption centered around the iron and steel slag produced by Broken Hill Proprietary Co. Ltd. (BHP) in two areas in Australia—Port Kembla and Newcastle.

The Port Kembla area of New South Wales had Australian Steel Mill Services, a consortium of Edward C. Levy Co. of Detroit, MI, and Queensland Cement Co., a wholly owned subsidiary of Holderbank Co. Approximately 1.3 million tons of blast furnace slag was processed into 700,000 tons of air-cooled slag and 600,000 tons of granulated slag. Approximately 50% to 60% of both types

was used for road pavements, concrete aggregate, and cement manufacture. The rest was stockpiled. Approximately 500,000 tons of basic oxygen furnace (bof) slag was produced, with 100,000 tons used for road pavements and the rest stockpiled.

In Newcastle, there were three slag contractors, Boral Quarries, of Boral Ltd.; Steel Cement, Ltd. (owned mainly by a consortium of Australian and Japanese companies), and Steelstone The first two Services (Australia). contractors processed approximately 500,000 tons of blast furnace slag; 50% was air-cooled slag used in road pavements and construction and 50% was granulated slag used in cement manufacture and road construction. The latter contractor processed about 200,000 tons of steel slag, of which 50,000 tons was used for road construction and the balance was stockpiled.

In Whyalla, South Australia, 350,000 tons of blast furnace slag and 125,000 tons of steel slag were produced, but the plant was not near a significant market and was therefore not sold. Electric arc furnace slag also was produced in Melbourne, Victoria, and in Newcastle & Sydney, New South Wales.

Blast furnace slag cement marketed in Australia conformed to Australian Standard AS 1317. AS 1317 permitted slag to represent 20% to 65% of the total cementitious content.¹²

Belgium.—All of the production of blast furnace slag, about 2.8 million tons in 1991, was granulated. The production of this slag was insufficient to meet the demand of the cement industry that purchases it. The price of the slag, therefore, has increased to the equivalent of \$9 per ton. Steel slag production was approximately 1 million tons and went principally to fill, forest and farm roads, industrial roads, or parking lots. The steel slag also was used in hydraulic engineering, in the manufacture of Portland cement, in agriculture, and in steelmaking.13

Brazil.—Usinas Siderurgicas de Minas

Gerais SA (Usiminas), Brazil's second largest steel mill, discovered a way to mix its own slag with clay and cement to make what it calls "ecological bricks." Because the heat of the slag cooks the bricks in the open air, no oven-firing process is needed to harden them, as in the case of conventional bricks.

France.—In 1992, 13 million tons of pig iron and 4.7 million tons of blast furnace slag were produced, or 360 kg of slag was produced for every ton of pig iron.¹⁵ Of this slag, approximately 50% was granulated, 40% was air cooled, 10% was pelletized, and a negligible amount was expanded or processed in other ways. Sales of slag, 6.9 million tons, included the slag produced, slag from stocks, and older slag banks. The amount of granulated and pelletized cement sold was 3.5 million tons. Of the granulated and pelletized slag, 2.6 million tons was used in cement, 0.4 million tons was used for coarse slag and slag sand on roadways, 0.3 million tons of lightly crushed slag was used on roadways, and 0.03 million tons was a mixture of granulated slag and crushed air-cooled slag used to make road bases. Sales of crushed air-cooled slag were 2.7 million tons and included slag from stocks and from older slag banks. Fifty-six percent of the air-cooled slag was used on roadways, 30% as coarse slag, 9% for concrete and slag bricks, 2% for ballast, and 3% in other uses.

There were approximately 10 blast furnaces in operation. There were two or three blast furnaces at Sollac at Dunquerque, and two-thirds of the production was granulated. Sollac at Fos-sur Mer had two blast furnaces, one of which was granulating two-thirds of its production and one that was pelletizing two-thirds of the production. Lorfonte at Hayange had two blast furnaces; where one was granulating 100% of the production and one was not granulating at all. Lorfonte at Rombas had two blast furnaces that granulated 100% of the production. Unimetal a Caen had one blast furnace that granulated 100% of production. The production at this blast furnace was expected to stop in July 1993.

Sixty-six percent of the granulated slag was utilized in France, and the remainder was used abroad. Ninety-eight percent of the air-cooled slag was used in France.

Germany.—There was 7.08 million tons of iron slag produced in Germany and 8.25 million tons was sold.16 Some of the blast furnace slag sales were taken from stores of slag produced in prior years. Fifty-seven percent of the slag was air-cooled slag used for road construction, 38% was granulated slag for cement, 3% was granulated slag for road construction, 1% was foamed slag for road construction, and less than 1% was air-cooled slag for fertilizer. There was 4.7 million tons of steel slag produced in Germany, with 82.4% being sold. Fifty percent of the steel slag sold was used as aggregate for roads, 21% was recycled back to the blast furnace. 16% was for landfill, 7% was for fertilizer, and 6% was for other uses.

Slag used in Germany must conform to special requirements for leachability (in addition to conforming to certain technological requirements). The leaching was done according to German Standard DIN 38414. There were no common limits within Germany for the application of byproducts. Therefore the state of Northrhine-Westfalia (Nordrhein-Westfalen) created special limits for each of 11 byproducts. According to the leachability of the slags they could be used as aggregate in various fields of application, e.g. as aggregate in road construction in asphalt or unbound layers; in ground water protection areas as an aggregate under layers impermeable to water (such as asphalt or concrete layers) and in other ways.

India.—Both Champion Cement Industries Ltd. and Shubham Industries were in the process of setting up minicement plants in Orissa. The plants, with capacities of 45,000 tons and 39,600 tons per year, respectively, were to manufacture ordinary portland cement and portland slag cement.¹⁷

Sagar Cements also was setting up a

new slag grinding unit at Visakhapatnam in Andhra Pradesh. The unit was to manufacture portland blast furnace slag cement with slag obtained from the Visakhapatnam steel plant. The plant could supply the deficient cement markets in West Bengal, Orissa, and the north coastal district of Andhra Pradesh. 18

Japan.—The share of electric arc furnace steel in total Japanese raw steel production rose from 24.4% in 1980 to 31.6% in 1990. It slipped to 30.9% in 1991 with the recession, but rebounded to 31.3% in the first 10 months of 1992. There were approximately 100 electric arc furnaces with a capacity of 30 tons or more operating in Japan. The total number of blast furnaces installed at 9 major steelmakers in Japan totaled 47, with 14 of them suspended from operation for repair. 19

These trends should impact the amount and type of slag that Japan has available. Japan already is operating under the Law for the Promotion of the Utilization of Recyclable Resources enacted in 1991. This plan provides for businesses to improve technologies for expanded use of iron and steel slag.²⁰

Korea, Republic of.—Supplies of slag cement were expected to greatly increase following a massive expansion and construction of new plants.²¹ The cementmakers have been attracted to the slag cement due to low production costs. Ssangyong Cement Industrial Co. Ltd. dedicated a 1.2-million-ton slag cement plant in Kwangyang that was expected to produce 100,000 tons of slag cement per month.²²

Also in Kwangyang, combined production of slag cement by Ssangyong, Hankook Slag Cement, Koryo Cement, and Pohang Azu Cement was approximately 1.8 million tons in the second half of 1992.

Tongyong Cement and Halla Cement also were constructing slag cement plants in Kwangyang. The annual output was to range from 1 million to 1.2 million tons. Hankook Slag and Koryo were to have annual production capacities of 1.5

million tons and 1.2 million tons, respectively. The companies chose Kwangyang because there is a huge foundry there run by the Pohang Iron and Steel (POSCO) steel mill.

Slag cement, which is mixed with ordinary cement and slag in a 1:1 ratio, was used mainly for building dams and bridges because of its sustained strength and low creation of heat of hydration. Slag cement was first developed in Korea in 1978 for commercial production.

addition, the Ministry Environment added additional uses for steel slag to increase its practical applications.²³ The new regulations will help industrial circles increase recycling of the slag from revolving and electric arc furnaces, which had previously been considered industrial waste. Steelmakers such as Inchon Iron and Steel, Kangwon Industries, and Dong Kuk Steel Mill, which use electric arc furnaces, planned to install slag recycling facilities to make the former waste a value added material. POSCO was to develop other uses for slag in value added ceramic areas.

South Africa, Republic of.—R. Snowden of Ove Arup, Inc. in the Republic of South Africa presented a paper entitled, "The Specification and Use of Slag in South Africa" at the seminar, "Concrete Performance-The Role of Blended Cements," in October 1992. The following comments were obtained from this paper. Blast furnace slag manufacturing facilities were primarily in the Transvaal and in Natal due to transportation costs. There were three slag processing plants, Vanderbiilpark and Pretoria Witwatersrand and Newcastle in Northern The slag was used in the manufacture of cement, where a 50-50 blend was used most often. Because dolomite is used instead of limestone as a flux in the blast furnace, the slags had a much higher magnesia content than most other slags.

The slag was used in such diverse structures as gravity concrete dam walls, multistory buildings, industrial applications such as chimney stacks, power stations, structures subject to chemical attack, and marine structures such as breakwaters and harbors. The cement industry was privately owned in the Republic of South Africa, and there were no policies or pricing incentives that gave preference to the use of slag in concrete. The current ex-factory price of slag relative to the local cement price was approximately 55%. Therefore, the use of blast furnace slag could result in up to a 25% reduction in the cement cost. The availability of slag in the Transvaal and Natal led to a number of blending plants being installed. In 1991, consumption of slag as cement was 5.8% of the total cement market. Cement that was made of 45% slag comprised 3.5% of the market.24

Taiwan.—Almost 1 million tons of blast furnace slag was expected to be produced in 1993. This slag was to be used to produce slag powder and portland blast furnace slag cement. (See Current Research section of this report.)

United Kingdom.—The amount of blast furnace slag produced in 1992, approximately 3 million tons, did not vary much from that in 1991.25 Building and construction markets remained depressed throughout 1992, and volumes and prices of cementitious materials stayed down. Ravenscraig Steelworks in Scotland closed in June 1992. Remaining in operation were the slag operations of Teesside and Scunthorpe in England and Lllanwern and Port Talbot in Wales. Similar to the slag marketing arrangements in the United States, the ironmaker or steelmaker did not market the slag; instead, there were companies that marketed the slag. There were two slag marketing companies, both owned approximately 50% by British Steel Co. and 50% by an aggregate producer. In England, East Coast Slag, owned by British Steel and Tarmac PLC, marketed the slag produced at Scunthorpe and Teesside. At the latter location, the iron slag was produced at Redcar and the steel slag was produced at Luckenby. Wales, Cambria Stone, owned by British Steel and Wimpey Hobbs of George

Wimpey PLC, marketed the slag produced at Llanwern and Port Talbot.

With respect to the type of processing of the slag, there was one granulator left in operation, at Scunthorpe, and another at Llanwern, which was expected to be commissioned in 1993. Two of the plants in the United Kingdom also used pelletized slag. Steel slag produced at Scunthorpe was the only steel slag sold in other than negligible quantities.

Evered Bardon PLC, the aggregates and quarry group, sold the slag cement division of Civil and Marine for 25 million pounds (approximately \$38 million). ²⁶ Civil and Marine Slag Cement Ltd. bought the slag cement business that has plants near London and in South Wales.

The British Standard (BS) 1047 was used for air-cooled blast furnace slag for aggregates. In addition, the majority of ground granulated blast furnace slag was produced according to BS 6699 for supply directly to the concrete manufacturer, ready-mixed, site-mixed, or precast, for production of portland blast furnace cement concrete.

Current Research

The fourth international conference on "Fly Ash, Silica Fume, Slag, and Natural Pozzolans in Concrete," was held in Istanbul, Turkey, May 3-8, 1992.²⁷ The conference was sponsored by the American Concrete Institute, Detroit, MI; the Canadian Centre for Mineral and Energy Technology of the Energy, Mines and Resources of Canada; and other organizations in Canada and Turkey. More than 25 papers on slag were presented. Topics included permeability, strength, temperature control, elasticity, shrinkage, and resistance to freezing and thawing.

Research studies on iron and steel slag focused on a variety of end uses. Agglomeration of fines, both iron ore fines as well as of steel tailings, were the subject of a couple of research studies. Uses for both iron and steel slag in cement were featured. Many of the studies focused on a number of different types of materials used together in

cement, such as slag, fly ash, silica fume, etc. These studies were addressed in the 1992 Cement Annual Report chapter by this author.

Blast Furnace Slag.—The coldbonded pelletization of iron ore fines using ordinary portland cement binder was emerging as a potential energy saving agglomeration process for proper utilization of Indian iron ore fines. The possibility of substituting ordinary portland cement/clinker by cheaper lowgrade Indian granulated blast furnace slag was investigated by the Regional Research Laboratory in Assam, India.²⁸ One of the conclusions of the study was that 40% to 50% of the ordinary portland cement (opc) requirement in making coldbonded iron ore pellets could be substituted by granulated blast furnace slag.

Ground granulated blast furnace slag (ggbfs) used in cement was the subject of a number of articles.

A study carried out in Canada was designed to formulate the proportioning of concrete mixes made with ggbfs activated with sodium silicate and to determine their properties and durability.²⁹ It was expected that the new information on resistance to freezing and thawing, chloride ion penetration, and sulfate attack would encourage the use of slag concrete in the construction industry.

In another study on ggbfs, concrete made from a 1:1 mixture of ciment fondu high-alumina cement (hac) and ggbfs showed an increasing trend in strength up to 5 years when kept under water.³⁰ In addition, the sulfate resistance of blended hac containing ggbfs was shown to be better than that of the hac by accelerated tests.

The microstructure and microanalysis of hardened cement pastes made from ggbfs and opc were studied at Oxford University.³¹ Although much is known about the hydration chemistry of slag cements, there is relatively little knowledge about their microstructure at the level of resolution achieved with electron microscopy. The paper presented the results of application of this technique to the study of ggbfs/opc blends

combined with electron microprobe analysis.

A new method of obtaining improved zonal isolation using drilling fluid solidification technology was developed by the Shell Development Co.³² Hydraulic blast furnace slag could be activated to set in drilling fluids, which are difficult to convert to cements with other solidification technologies. addition, among other properties, the slag had low impact on rheological and fluid loss properties of drilling fluids and was available in large quantities from multiple sources. Although conversion of drilling fluids or muds into cements suitable for well cement operations has been a subject of interest in the petroleum industry for more than 50 years, improved zonal isolation in the annular space between a casing and borehole has been and continues to be the primary reason for pursuing this technology.

Slag cement showed good binding properties for agglomeration of fine tailings and backfill in a study conducted at Laurentian University in Sudbury. Ontario.33 The Canadian mining industry produces more than 500 million tons of tailings and waste rock annually. The fine tailings cannot be used in backfill materials for surface impoundments. The fines usually end up in tailings ponds, but in many cases the tailings are reactive and degenerate with time, resulting in the seepage of acid and toxic heavy metals into natural drainage systems. This is a major environmental concern to the mining industry. Agglomeration of mill tailings, by using slag cement and lime, could produce a useful aggregate material for use as backfill.

In Taiwan, at the China Steel Co., the 1.1 million tons of blast furnace slag anticipated to be produced in 1993 would be used to produce slag powder and portland blast furnace slag cement. To extend the application range of the blast furnace slag cement, the reactivity of the slag and the methods to increase the activity of the slag were investigated. It was shown that a higher cooling rate could increase the reactivity and activity of this blast furnace slag. Slag powder with the finest granularity had very good

reactivity.

Steel Slag.—The Pennsylvania Department of Transportation evaluated steel slag from open-hearth, basic oxygen, or electric arc steelmaking processes for use as an aggregate for bituminous asphalt mixes. Hituminous asphalt mixes demonstrated several good mix characteristics when steel slag aggregates were used. They were high stability, high skid resistance, longer heat retention after mixing, and ease of compaction.

The removal of phosphorus is essential to recycle the iron, manganese, and lime in steelmaking slags. In a doctoral thesis from the University of Minnesota, the phosphorous mineralogy, its distribution in steelmaking slags, and methods for its removal were detailed.³⁵ Eighty percent of the phosphorus was associated with the locked dicalcium silicate, and a possibility of flotation upgrading was discussed.

Removal of chromate by reduction using slag from a steel plant was studied at the Ravishankar University in Raipur, India.36 It was found that the slag could reduce hexavalent chromium, which is toxic, to trivalent chromium and then to chromium metal. Hexavalent chromium is found in industrial wastes mainly as chromates and dichromate chromium compounds that are added to cooling water to inhibit corrosion. The standard technique for the removal of chromates has been to lower the pH of the waste stream to 3.0 or lower with sulfuric acid. The disadvantages inherent in this reduction treatment are that SO₂ is released into the ambient air, the reduction is not 100% complete, the amount of residual hexavalent chromium depends upon the time allowed for the reaction, the pH of the reaction mixture, and the concentration and type of reducing agent employed, and the method is not cost effective. Slag produced from steel manufacture was seen as widely available and an effective material to convert hexavalent chromium.

A review of the reports concerning steel slag for blended cement (ssbc) manufacture as well as preliminary work utilizing Australian produced steel slag

was conducted at the University of Wollongong.³⁷ The ssbc was investigated with respect to strength, volumetric stability, and grindability with and without incorporation of opc clinker. Steel slag contained a similar mineral composition to that of opc clinker; however, the slag could become unstable due to free calcium oxide. Experiments have proven that the combined use of ssbc and ggbfs and/or opc clinker could balance the composition fluctuations in the steel slag and some CaO in the steel slag could be absorbed by ggbfs, thereby preventing the occurrence of instability of ssbc specimens. Removal of the fine iron particles was absolutely necessary for steel slag to be manufactured into ssbc.

Studies from the University of Wollongong in 1991 showed that instant chilled steel slag had acceptable volume stability and compressive, splitting, and flexure strength for use in concrete.38 A subsequent study considered two additional aspects of instant chilled steel slag aggregate concretes—brittleness and fracture toughness. Considerable benefits could be derived from using instant chilled steel slag as coarse aggregate in concrete, such as increased strength and reduced brittleness compared to limestone.

The state of the art in the utilization of iron and steel plant byproducts was described in a German paper.³⁹ As a result of intensive research, a wide range of applications for all kinds of slags has been found. Depending on cooling rates, blast furnace slag showed different kinds of mineral structures and physical properties. Utilization of byproducts of the steel industry in Germany was detailed.

Two papers were reported on concerning the use of steel slag in China. One paper developed at the Tangshan Iron and Steel Co. covered the possibility of utilizing steel slag generated at every steelworks based on the formation of slag and its physical and chemical properties.⁴⁰

Another paper described the methods of radiation treatment and results of radiation assessment for slag at Baotou Iron and Rare-earth Co.⁴¹ The results showed that the slag could be utilized to

absorb radiation.

OUTLOOK

Production of steel slag was expected to rise owing to an increase in steel production. Because of increasing use of scrap in the steel mill, electric arc furnace slag production also was expected to rise.

Slag used in cement was likely to increase owing to the favorable cost with respect to cement, properties of slag that enhance the cement, and environmental factors.

Slag prices were expected to stay low, owing to increased competition among slag processors.

Consumption of the construction aggregate segment, including iron and steel slag, recycled materials, clays, etc., was forecast to rise by 12% each year to 50 million tons in 1995.⁴² Growth would be greatly attributable to increased use of recycled concrete and asphalt materials, solid wastes, and incinerator ash in construction applications.

SODA ASH

By Dennis S. Kostick

Mr. Kostick, a physical scientist with 14 years of U.S. Bureau of Mines experience, has been the commodity specialist for soda ash since 1979. Domestic survey data were prepared by Maria Arguelles, mineral data assistant; and international data tables were prepared by Ted Spittal, international data coordinator.

DOMESTIC DATA COVERAGE

U.S. soda ash production data are collected by the U.S. Bureau of Mines from monthly, quarterly, and annual voluntary surveys of U.S. operations. Of the six soda ash operations to which a survey request was sent, all responded, representing 100% of the total production data shown in this report.

Data pertaining to soda consumption by end use is collected quarterly from the industry. Trade statistics are obtained from the U.S. Department of Commerce, Bureau of the Census, and analyzed using trade data provided by the Journal of Commerce's Port Import Export Reporting Service (PIERS). The export data collected by the Census Bureau may not correspond to the export data provided by the soda ash producers in the quarterly survey of soda ash sales or the PIERS data. discrepancy between the export data sets is because Census data report the transaction on the date the cargo physically departed from the U.S. port whereas soda ash producers consider a shipment as exported when it leaves the plant. The overland transit time between the plant and port and any carryover export inventory, both in domestic and foreign warehouses or teamtracks, are the major reasons for the difference between the export data.

Most people have never heard of soda ash, yet it is used in many familiar consumer products found in virtually every home—glass, soap and detergents, paper, textiles, and food. Chemically, soda ash is known as sodium carbonate. It is the 11th largest inorganic chemical

in terms of production of all domestic inorganic and organic chemicals. petrochemical excluding feedstocks. Internationally, there are two types of soda ash—natural and synthetic. United States is the world's largest soda ash-producing nation with the world's largest natural deposit of trona, the ore from which soda ash is refined. Because the majority of world output is made synthetically, which usually is more expensive to manufacture, U.S. natural soda ash is extremely competitive in world markets. (See table 1.)

BACKGROUND

Although soda ash represented about 2.6% of the total \$32 billion nonfuel mineral industry that was surveyed by the U.S. Bureau of Mines in 1992, its use in familiar household products consequently contributes substantially to the gross national product of the United States. Soda ash is one of the basic inorganic chemicals produced in the world. Most countries do not have economic deposits of sodium carbonatebearing minerals and must produce soda ash by various manufacturing techniques, which are labor-, capital-, and energyintensive. In addition, the processes generate byproduct sodium chloride and calcium chloride, which are usually discharged as waste effluent that contribute to environmental problems.

Natural soda ash was probably first obtained as evaporite incrustations along the edges of alkaline lakes in Lower Egypt. It was used about 3500 B.C. to make ornamental glassware, as evidenced by many of the early Egyptian glass

artifacts. The Egyptians also mixed lime and soda ash to make caustic soda. The caustic soda was combined with silicate minerals obtained from the Sinai Desert. This made a soluble silica, which was added to aluminum-rich Nile River silt. producing a silica-aluminate cement mortar with superior bonding properties. In the Old Testament, it was referred to as neter but has also been known as natrium, kali, trona, and natron. Until the 18th century, soda ash was obtained mainly by burning seaweeds and marine plants, leaching the soluble material from the ashes, and evaporating the solutions to dryness. About 13 short tons of ash vielded 1 ton of sodium carbonate and 14 kilograms (30 pounds) of iodine as a byproduct. The final material was very impure but could be used in the manufacture of glass and soap and detergents. Pliny, a Roman historian, listed soda ash in the manufacture of glass, as a medicine for colic pains and skin eruptions, and for making bread, in the first century A.D.

In 1791, Nicolas Leblanc, a French chemist, developed a process for making soda ash from "salt cake" (from salt and sulfuric acid), coal, and limestone. The French Revolution interferred with its development, and his patent and factory were confiscated with him receiving only token compensation. Napoleon returned his factory to him but Leblanc was not able to raise enough capital to reopen it, and he committed suicide in 1806. More than 30 years passed before the process first became successful in Liverpool. England. The process was not used successfully in the United States except during a short period from July 1884 to

January 1885 at Laramie, WY.

Ernest and Alfred Solvay developed an improved method for making soda ash from salt, coke, and limestone, with ammonia as a catalyst in the early 1860's. That process was first used in the United States in 1884 at Syracuse, NY, in a plant that continued to produce soda ash until 1986. It was the first of about 10 synthetic Solvay plants that were in operation by 1939 in the United States, and ironically, the last 1 to close. The Solvay process gained in popularity over the years and is now the basic method used throughout the world for making synthetic soda ash. In addition to the were Solvay plants, there three electrolytic process plants in Tyrone, PA, Covington, VA, and Luke, MD, that were operated by West Virginia Pulp and Paper Co. in 1939.

The site of the first commercial production of natural soda ash in the United States was from two deposits known as the Soda Lakes near the present town of Fallon, NV. Asa L. Kenyon acquired title to Little Soda Lake in 1855 and sold it to Higgins and Duffy in 1868, when the first 300 tons of natural soda ash was produced. Production of adjacent Big Soda Lake began in 1875 and reached its peak in 1887. The brines became diluted as the lake levels rose in 1907 because regional dam construction affected the local water table. Searles Lake in California was originally mined for borax as early as 1874. Soda ash production began in 1926 by the West End Chemical Co. American Potash Corp., formerly the American Trona Corp., was the second company to produce soda ash at Searles Lake in 1931.

Definitions, Grades, and Specifications

The following terms are used in the soda ash industry:

Ammonia-Soda Process.—Also known as the Solvay process and lime-soda process.

Dense Soda Ash.—Has a bulk density

of 0.96 to 1.06 grams per cubic centimeter (60 to 66 pounds per cubic foot). It is produced by hydrating light soda ash followed by dehydration through calcination to produce denser crystals. In Eastern Europe, dense ash is made by compressing light ash between rollers to increase the density, followed by screening.

Light Soda Ash.—Has a bulk density of 0.51 to 0.62 grams per cubic centimeter (32 to 39 pounds per cubic foot). It is produced by calcining the sodium sesquicarbonate precipitate recovered from the carbonation towers or vacuum crystallizers.

Natural Soda Ash.—Soda ash produced from trona ore, sodium carbonate-bearing brines, or surface mineralization.

Soda Ash.—Synonymous with sodium carbonate. It is a general term that can apply to soda ash produced from natural sources or from various chemical processes.

Sodium Sesquicarbonate.—Can refer to the name for the chemical composition of trona or the chemical process that produces a light- to intermediate-grade of soda ash having an average bulk density of 0.8 gram per cubic centimeter (50 pounds per cubic foot).

Synthetic Soda Ash.—Term for soda ash produced from one of several chemical processes, such as the Solvay process.

Trona.—The principal ore from which soda ash is made. It is composed of sodium carbonate, sodium bicarbonate, and water. The monoclinic crystals are prismatic to tabular, with colors ranging from translucent (spar variety) to shades of brown, which vary depending on the amounts of contained organic matter. Trona has a specific gravity of 2.17 with a hardness of 2.5 to 3 on the Mohs scale. About 1.8 tons of trona is required to produce 1 ton of soda ash.

The terms "soda ash" and "sodium carbonate" are used interchangeably. The material manufactured from Wyoming trona normally contains more than 99.8% sodium carbonate, and the sodium chloride content ranges between 0.01% to 0.02%. The amount of iron is less than 10 parts per million. Searles Lake brines are processed to yield a product of similar high quality, with salt and sodium sulfate as the principal trace impurities. The average material produced by a Solvay soda ash plant is about equal to the natural product in sodium carbonate content, but often contains a larger quantity of salt. Dense soda ash, because of its greater bulk density, may command a higher price than the light variety and is preferred for glass manufacture because the light soda ash leads to frothing in the glass melt. Light soda ash is preferred by many chemical and detergent industries because it dissolves more readily. Sodium sesquicarbonate has an intermediate bulk density and is used in some detergent and bath salts.

Typical official specifications for soda ash include American National Standard (R1969) "Standard 11-1956 Specifications for Soda Ash," which appears as the American Society for Testing and Materials (ASTM) Designation D458-74 (Reapproved 1979); and British Standard (BS) 3674: 1963 "Specification for Sodium Carbonate The British (Technical Grades)." Standard specifies, among other requirements, not less than 57.25% Na₂O and not more than 0.005% Fe₂O₃; the ASTM, a minimum of 99.16% Na₂CO₃. Both standards specify methods of testing.

Industry Structure

The U.S. soda ash industry is composed of six companies; five in Wyoming and one in California. All produce natural soda ash only either from sodium carbonate-rich brines or from underground mining of trona ore. Foreign investment in U.S. soda ash operations has risen from 10% of capacity in 1981, when Societe Nationale Elf Aquitaine of France bought Texasgulf Chemical Co., to 49% in 1992. Five of

the six U.S. companies have either Australian, Belgian, French, Japanese, or Korean partners. FMC remains the only U.S. producer without any foreign ownership. (See tables 2 and 3.)

Geology-Resources

The definitions of resources, reserves, and reserve base are published in U.S. Geological Survey Circular 831, Principles of a Resource/Reserve Classification for Minerals. Briefly, "resources" describe the quantity of ore present, regardless of grade or ease of The "reserves" are the extraction. portion of the resource that are economic to mine using the current technology and value of the commodity.

There are numerous sodium carbonatebearing mineral occurrences throughout the world; however, only 93 deposits in 23 countries have been geologically evaluated. Although several of these deposits have been quantified, most are economically insignificant or too remote to be commercially developed. largest and the most economically significant deposit is the trona deposit in southwest Wyoming. All soda ash deposits can be classified in one of five modes of occurrences. In decreasing order of economic importance, they are as follows: buried, surface or subsurface brines, crystalline shoreline or bottom crusts, shallow lake bottom crystals, and surface efflorescences.

There are 13 sodium carbonate-bearing minerals that contain varying percentages of sodium carbonate. They are, in descending order of sodium carbonate content (with bicarbonate converted to carbonate), thermonatrite, 85.5%; trona, 70.4%; nahcolite, 63.1%; bradleyite, 47.1%; pirssonite, 43.8%; northupite, 40.6%; tychite, 42.6%; natron, 37.1%; dawsonite, 35.8%; gaylussite, 35.8%; shortite, 34.6%; burkeite, 27.2%; and hanksite, 13.6%;

The trona found in the Green River Formation in southwest Wyoming is an excellent example of a buried trona deposit. The Wilkins Peak Member contains 42 beds of trona, 25 of which have a thickness of 0.91 meters (3 feet)

or more. Eleven of these exceed 1.83 meters (6 feet) in thickness covering an area more than 3,100 square kilometers (1,200 square miles). The trona beds were deposited about 50 million years ago in the early to middle Eocene epoch in an ancient freshwater lake, named "Lake Gosiute" by Clarence King in 1878. The sodium and carbonate constituents of trona owe their respective origins to the leaching of the extensive pyroxeneandesite volcanic ash layers and the seasonal influxes of carbonate-rich sediments into the local depositional basin. In addition, subterranean thermal springs contributed a significant quantity of dissolved alkaline carbonates as well as sodium, calcium, silica, and bicarbonate ions. Trona can precipitate only in the presence of abundant carbon dioxide, which probably was supplied from the atmosphere and/or the biogenic decay of Eocene plant and aquatic remains. For 4 million years. Lake Gosiute went through many stages of filling and evaporation, thereby depositing more than 42 beds of trona on the lake bottom along with repetitive beds of marlstone, limestone, oil shale, and sandstone-mudstone. The decrease of the inflow to the lake was probably in response to climatic changes that resulted in the final evaporation of the waters. The former Lake Gosiute is the present Green River Basin.

Assuming 1.8 tons of trona yields approximately 1 ton of soda ash, about 47 billion tons (52 billion short tons) of identified soda ash resources could be obtained from the 56 billion tons (62 billion short tons) of bedded trona and the 47 billion tons (52 billion short tons) of interbedded or intermixed trona and halite that are in beds greater than 1.22 meters (4 feet) thick. Approximately 34 billion tons (37 billion short tons) of reserve base soda ash could be obtained from the 36 billion tons (40 billion short tons) of halite-free trona and the 25 billion tons (27 billion short tons) of interbedded or intermixed trona and halite in beds more than 1.83 meters (6 feet) thick. Although about 15 million tons (16 million short tons) of trona is presently being mined annually, with these minable reserves Wyoming could supply all domestic

requirements for more than 3,100 years at the 1991 demand level. As technology improves in the future, mining of the subeconomic grades of ore would further extend the life of the trona deposit to more than 5,100 years. With Wyoming reserves estimated at 20 billion tons (22 billion short tons), the United States, through this one deposit, could supply the world all the soda ash to meet the current demand levels for about 630 years.

The U.S. Government established a Known Sodium Leasing Area (KSLA) in Wyoming within the perimeter of the trona depositional basin. The trona within the KSLA is subject to Federal and State leasing regulations and private lease agreements. Although most of the leasable trona averages 93% sodium sesquicarbonate, several areas contain lower grade trona because of local depositional contamination along the lake margins, thereby reducing the reserve estimates of that particular area. A series of Pleistocene playa lakes rich in evaporate minerals found in California comprise the second largest reserves of sodium carbonate in the United States. Subsurface sodium carbonate-bearing brines and crystalline material comprise the resource at Searles Lake, which is a nearly dry playa 15 kilometers (9 miles) long by 11 kilometers (7 miles) wide with an area of about 104 square kilometers (40 square miles). Surface sodiumbearing crystalline minerals predominate at Owens Lake, which was first mined in 1885 by the Invo Development Co. Both deposits have combined reserves of about 817 million tons (900 million short tons).

Two potential sources of soda ash-nahcolite (natural sodium bicarbonate) and dawsonite (sodiumaluminum-carbonate)—are associated with oil shale in the Piceance Creek basin in northwest Colorado. Identified resources of 29 billion tons (32 billion short tons) of nahcolite and 17 billion tons (19 billion short tons) of dawsonite, equivalent to 18 billion tons and 6 billion tons (20 billion short tons and 7 billion short tons), respectively, of sodium carbonate resources, would be available as a byproduct of oil shale processing or as single mineral extraction. These deposits were formed in middle Eccene time with the nahcolite occurring as aggregates (62%), disseminated crystals (24%), and impure beds (14%).

The only other commercial natural soda ash deposit in the Western Hemisphere, excluding those in the United States, occurs at Lake Texcoco, near Mexico City, Mexico. Two caliche layers at a depth of 46 meters (150 feet) act as a filter and reservoir for the sodium carbonate-rich brine resource. With an average concentration of about 7% sodium carbonate, the resource contains about 180 million tons (200 million short tons) of available soda ash.

The Rift Valley of eastern Africa has several alkaline lakes resembling those of California. Only Lake Magadi in Kenya is presently in production. The soda ash reserves of these lakes are renewed annually from natural active volcanic sources. Other African countries that may become future suppliers of soda ash are Chad, Ethiopia, Niger, the Republic of South Africa, Tanzania, and Uganda. Botswana developed its Sua Pan salt and soda ash deposit in 1991. Elsewhere, deposits of natural soda ash occur in Bolivia, Brazil, Canada, India, Pakistan, the Commonwealth of Independent States (C.I.S.—formerly most of the U.S.S.R.), and Venezuela. Plans are under way to develop deposits in China at Xilin Gol and in the Wulan Buh desert area. A trona deposit in Turkey near Beypazari is also under consideration for development.

Technology

Soda ash from Wyoming trona is mined, crushed, dried, dissolved, filtered, recrystallized, and redried. In California, soda ash from sodium carbonate-bearing brines is solution mined, carbonated, filtered, dried, decomposed, bleached, and recrystallized to dense soda ash.

Exploration.—Because of the scarcity of economic soda ash deposits in the world, many nations continue to search for new prospects. Smaller and less well-known deposits are often reevaluated by different groups at different times and with usually the same results. As new

techniques of exploring are developed and used, such as Landsat satellite remote sensing imagery and side-scanning radar, new deposits may be discovered.

In the United States, exploring for soda ash continues. An area near the junction of the Black's Fork and Green River in southwest Wyoming has potential. Some of the ground water near Farson contains dissolved trona and organic matter creating a "black trona BWAB, a Denver-based water." company, planned to develop this area and extract the sodium carbonate from the black water and convert the organic material to fungicides, pesticides, and pigments. In Oregon, a few companies have expressed interest in evaluating the sodium carbonate deposits at Summer Lake and Abert Lake, which are near several pulp and paper manufacturers. These manufacturers have traditionally obtained their soda ash and caustic soda pulp-bleaching chemicals from Wyoming and Washington producers, respectively. As soda ash and caustic soda prices increase and overland transportation costs rise, these Oregon deposits may have commercial significance because their locations are nearer to the pulp markets.

Mining.—Commercial mining of Wyoming trona began in 1948, with the first mining on Federal land commencing in 1950. Between 1950 and 1992, more than 238 million tons (262 million short tons) of trona (equal to about 132 million tons or 146 million short tons of soda ash) has been mined. Only about 0.7% of the 36 million tons (40 million short tons) of halite-free trona reserve base has been used since mining began.

Underground mining of Wyoming trona is similar to coal mining, except that trona is a harder mineral than coal. The five present Wyoming soda ash producers use room-and-pillar, longwall, shortwall, and solution mining techniques individually or in combination. The room-and-pillar method has an ore extraction efficiency rate of about 45% (55% of ore remains as pillars for structural integrity), the longwall and shortwall methods each have efficiency rates of about 75%, and solution mining

has an efficiency rate of about 30%. These rates are important when calculating the amount of reserves that are minable. Based on the types of mining techniques, the author used a 60% average extraction efficiency rate to calculate reserves (remaining 40% stays in-place as pillars for structural integrity and unavailable for present extraction). The ore is undercut, drilled, blasted, mucked, crushed, and transported to the surface by well-established methods and various state-of-the-art mining equipment. The conventional blasting method using prilled ammonium nitrate and fuel oil (ANFO) is a standard and reliable method. Continuous mining uses vehicles equipped with a rotating cylindrical cutter. Continuous miners are used by Tg Soda Ash, Inc., in its shortwall technique. The longwall technique was used by General Chemical Corp. and is now used by FMC Wyoming Corp. Adopted from coal mining use, the longwall method uses a special trackmounted shearer that moves in front of a hydraulic-operated roof support system.

FMC has pioneered the use of solution mining to dissolve and recover deeply buried trona. Using an array of injection and recovery wells, a solvent (dilute sodium hydroxide) is introduced under pressure to dissolve the underlying trona. This technique has had moderate success since its first commercial debut in 1985. Beginning in 1990, FMC used the majority of the output from its solution mining for manufacture of caustic soda, from which some sodium cyanide was produced.

To reduce mining costs and maintain their competitiveness in the world, many Wyoming soda ash companies implemented continuous belt and mobile track conveyor systems to transport trona underground more efficiently. This new haulage system has replaced ore-carrying shuttle cars, reduced the mine work force, and increased the quantity of ore mined per shift. Companies have also been considering eliminating conventional mining but retaining other mining methods sometime in the foreseeable future to further reduce labor, safety, and other operating costs.

Subterranean brines between 15 and 107 meters (50 and 350 feet) below the surface at Searles Lake in California are extracted using an array of injection and recovery well drilled down to specific depths where mineral concentrations favor maximum extraction. The Argus plant of North American Chemical Co. uses sodium carbonate-rich brines found in the Mixed Layer zone 67 meters to 95 meters (220 feet to 310 feet) below the surface. Solar concentration ponds are used to aerate and concentrate the brine to improve processing efficiency.

Processing.—Crushed trona is calcined in a rotary kiln at 163° to 204° C (325° to 400° F) to dissociate the ore by the monohydrate process, which produces only dense soda ash with carbon dioxide and water as byproducts. The calcined material is combined with water to dissolve the soda ash and to allow separating and discarding of the insoluble material such as shale and shortite by settling and/or filtration. The waste material is piped in a slurry to containment basins, also known as tailing The resulting clear liquid is concentrated as necessary by triple-effect evaporators or mechanical vapor recompression crystallizers, and the dissolved soda ash precipitates as crystals of sodium carbonate monohydrate, Na₂CO₃ • H₂O. The crystallization temperature is about 100° C (212° F), which is below the transition temperature of monohydrate to anhydrous soda ash. Other dissolved impurities, such as sodium chloride or sodium sulfate. remain in solution. The crystals and liquor are separated by centrifugation. The sodium carbonate monohydrate crystals are calcined a second time at 300° F to remove water crystallization. The resultant finished product is cooled, screened, and shipped by rail or truck in bags or bulk.

An alternate method of soda ash production from trona is the sesquicarbonate process. Crushed trona is first dissolved and filtered to remove insoluble impurities. The liquor is evaporated in vacuum crystallizers, and the sodium sesquicarbonate precipitate is

cooled to 38° C (100° F) and centrifuged to produce a pure product, which has uses as such. The sesquicarbonate can be further calcined at 204° C (400° F) to produce anhydrous soda ash of light to intermediate density.

The complex brines of the lower level of Searles Lake are first treated with carbon dioxide gas in carbonation towers to convert the sodium carbonate in solution to sodium bicarbonate, which will precipitate under these conditions. The sodium bicarbonate is separated from the remainder of the brine by settling and filtration and is then calcined to convert the product back to soda ash. decarbonated brine is cooled to recover borax and Glauber's salt. A second dissolving, precipitating with carbon dioxide, filtering, and calcining the light soda ash to dense, refines the product to better than 99% sodium carbonate.

At Owens Lake in California, crude soda ash has been mined and processed by Lake Minerals Corp. by simply digging perimeter channels that allow the interstitial fluids to drain. The surface was tilled to promote evaporation to reduce moisture content, followed by harvesting with front-end loaders.

At Lake Magadi, Kenya, crude trona is dredged from surface crusts, crushed, washed, and calcined to convert the sodium sesquicarbonate to soda ash. At Lake Texcoco in Mexico, underground brines are recovered and sent to a surface spiral concentrator to promote the solar concentration of the sodium carbonate in On the Kola Peninsula in Russia, soda ash is recovered from processing nepheline-bearing rocks. Nepheline, a sodium-potassium-aluminum silicate, is calcined in rotary kilns to yield alumina, potash, and soda ash. alumina content of the rocks is about onehalf that of bauxite but the mining and processing produces byproduct soda ash. The Petukhi and Tanatar (Mikhaylovskiy) natural soda ash lakes in Altay Kray of West Siberia provide some source of natural product.

Synthetic soda ash using the Solvay process uses salt and limestone as raw materials. A purified sodium chloride brine is saturated with ammonia and

carbon dioxide gas to produce ammonium bicarbonate, which reacts with the salt to form sodium bicarbonate and ammonium chloride. The sodium bicarbonate is calcined at 177° to 218° C (350° to 425° F) to light soda ash, and the gases produced are recycled back to the liquid phase. The liquid containing ammonium chloride is reacted with milk of lime to recover the ammonia and to produce byproduct calcium chloride. Limestone and coke are required to make the milk of lime. Dense soda ash is produced by hydrating light ash to produce larger sodium carbonate monohydrate crystals. The crystals are dehydrated in dryers to change the bulk density. To produce 1.0 ton of synthetic soda ash requires about 2.8 tons of steam, 1.7 tons of salt, 1.4 tons of limestone, 0.6 ton of coal for the boilers, and about 0.2 ton of coal for the dryers. Disposition of effluent streams containing high concentrations of calcium chloride and sodium chloride is a major problem for all Solvay soda ash plants. The Solvay process discharges about 1.7 tons of waste products that include sodium chloride and calcium chloride.

Other chemical processes can produce synthetic soda ash. The Japanese use an ammonium chloride coproduction process, a variation of the Solvay process, that converts all the sodium content of the salt into soda ash, whereas the Solvay process converts only about 70% of the sodium. The Japanese process also produces byproduct ammonium chloride that can be used as a fertilizer for growing rice in wetlands. The New Asahi process was also developed in Japan and uses less energy than the traditional Solvay process. An electrolysis-free process to produce vinvl chloride monomer with coproduct soda ash was developed in the Netherlands but has not been in commercial operation. The method yields soda ash instead of caustic soda and uses steam and carbon dioxide instead of electricity. The energy consumption is reported to be one-half that of the Solvay process.

Recycling.—There is no recycling of soda ash by producers; however, many glass container manufacturers are using

cullet glass, thereby reducing soda ash consumption.

Byproducts and Coproducts

Borax, potassium chloride, sodium chloride, and sodium sulfate are produced as coproducts with soda ash by North American Chemical in California. Wyoming, only value-added products, such as sodium bicarbonate, sodium hydroxide soda). sodium (caustic sesquicarbonate, and sodium tripolyphosphate, are produced from Soda ash-bearing purge trona ore. liquors and waste streams, normally considered waste byproducts, have been sold to powerplants for flue gas desulfurization because of their sodium carbonate content.

Substitutes

Sodium hydroxide can be substituted for soda ash in some applications, but usually only at a higher cost and when available. About 1.3 tons of soda ash must be used to have the same chemical effect as 1.0 ton of caustic soda. Soda ash is usually shipped in dry, bulk form whereas caustic soda is transported as a liquid in various-sized closed containers.

An alternate source of soda ash is nahcolite, natural-occurring sodium bicarbonate found in a vast deposit in Colorado. The nahcolite could be converted to soda ash by calcination.

Economic Factors

Prices.—The list prices of natural and synthetic soda ash historically were identical until the mid-1970's when higher energy costs and costs to implement the controls imposed by antipollution legislation caused the synthetic soda ash price to increase compared to that of the natural material. New natural soda ash producers came onstream in 1976 and 1982 and contributed to slight changes in price-value trends. Changes in the domestic demand pattern also affected average annual values, especially after 1980, when domestic demand declined.

The list prices quoted in trade journals or by producers differ from the annual average values reported to and by the U.S. Bureau of Mines. The values are the combined total revenue of California and Wyoming natural bulk, dense soda ash sold on an f.o.b. plant basis at list prices, spot prices, discount, long-term contracts, and for export, divided by the quantity of soda ash sold. This value may or may not correspond to the posted list prices.

Tariffs.—The United States imposes a 1.2% ad valorem tariff on imports of soda ash from countries having most-favored nation-(MFN) status. There is a 8.5% ad valorem tariff on imports from non-MFN sources.

Many nations levy import tariffs or antidumping duties of varying percentages on U.S. soda ash. In Western Europe, an antidumping duty of 67.5 European Currency Units (about \$67.13 per ton) had been imposed on U.S. soda ash sold on the continent; however, the duty was rescinded in late 1990. Import tariffs in some other countries in 1992 were as follows: Republic of Korea, 12.5%; Australia, 10%; Mexico, 10%; Taiwan, 10%; Thailand, 10%; Colombia, 5%; Indonesia, 5%; Japan, 3.9%; and Malaysia, 2%. Some of these duties will decline over time.

Taxes.—The total effective tax rate on the Wyoming trona industry is about 12.64% and comes from two major taxes. The trona severance tax of 5.5% is a State excise tax on minerals as they are removed from the ground and is applied as a percentage of assessed valuation. The collected taxes are disbursed to the Permanent Wyoming Mineral Trust Fund (2.0%), the General Fund (2.0%), and the Capital Facilities Revenue Account (1.5%). The property, or ad valorem, tax is about 7.14% of the assessed value of trona produced from the mines. The ad valorem taxes on trona are higher than any other Wyoming minerals, including oil, gas, and coal. Other ad valorem taxes are placed on the assessed value of real property (buildings and equipment)

and State sales and use taxes on equipment and facilities.

Royalties.—Soda ash mined on Federal lands is subject to the Mineral Leasing Act of 1920, which provides royalty payments to the U.S. Government. The Federal royalty is 5% of the quantity or gross value of the output of the product at the point of shipment to market. Each Federal lease also has other costs, such as bonds, acreage rental fees, sodium prospecting permit application fees, and permit bonds.

In Wyoming, the soda ash deposit within the Known Sodium Leasing Area is under the jurisdiction of the U.S. Government (administered by the Bureau of Land Management), the State, and the Union Pacific Railroad, which was given alternate 1-square-mile sections north and south of the railway it constructed in the 1860's. Of the almost 915,000 total acres of sodium mineral estate, the Federal ownership is 55.7%; Union Pacific, 38.1%; and the State, 6.2%. Sixteen lessees hold 53 active and inactive Federal leases having a total of 75,783 acres. To prevent a possible land monopoly, no lessee may hold more than 15.360 acres of Federal land, but may lease more private or State land. The State royalty rate is tied to the Federal rate of 5%; however, the private royalty rate varies. One-half of all Federal royalties collected by the Minerals Management Service is disbursed back to Wyoming for various State and local programs.

In California, the Federal Government maintains 33 sodium mineral leases having 26,799 acres. The major lessee is North American Chemical Co., which produces soda ash, sodium sulfate, and salt on its sodium leases on Searles Lake.

Depletion Provisions.—The mineral depletion allowance granted to the mining industry through legislation passed by the U.S. Government has been an important inducement for companies willing to accept the risk and high cost of mining development. The concept of depletion allowances for minerals is similar to the

depreciation of other assets. Although cost depletion and percentage depletion are two methods used to compute depletion deductions, most companies prefer to use the latter. About 100 mineral categories are entitled to percentage depletion. The rates range between 5% and 22% of the gross income from the mineral property, depending on the mineral and location (foreign or domestic), and are subject to a limitation of 50% of the net income from the property. The significance of percentage depletion is that the deduction is based on the quantity of the first marketable product (soda ash and not trona) and not necessarily on the amount invested. The mineral depletion allowance for soda ash is 14% for U.S. companies mining from domestic or foreign sources.

Operating Factors

Operating factors are different for mining companies than for manufacturing facilities engaged in producing natural soda ash and synthetic soda ash, respectively. The shift in U.S. soda ash production from synthetic to natural has been caused by higher costs attributed to the greater energy and labor requirements of the Solvay process and environmental regulations. Within the natural soda ash industry, the operating factors vary for producing the commodity from brines and from trona ore.

Environmental Requirements.—U.S. natural soda ash facilities do not have difficult problems disposing of effluents. Residual insoluble material is piped to surface tailing ponds and allowed to settle. Some soda ash in solution that is not economically recoverable from processing is discharged and is converted to sodium decahydrate in the ponds and precipitates on the bottom of ponds to become an additional source of soda ash if needed. For example, FMC has been dredging some of its sodium decahydrate that has been accumulating since 1950. Some pond water is recirculated into the mines and used as drilling and cutting coolant. Because of changes in environmental legislation in Wyoming, Solvay Minerals has begun discharging its waste material into abandoned sections of its underground mine, thereby using less area on the surface for tailing ponds. The expense of underground discharge is partially offset with the reduction in costs of constructing and maintaining surface tailing ponds.

The alkaline surface ponds, with a pH up to 10.5, have posed some problems for migratory fowl that land on the ponds. The alkaline solutions strip the insulative natural oils from the feathers, thereby increasing the vulnerability of the birds to death from hypothermia. Also, birds have drowned because of the weight of sodium decahydrate that crystallizes on them when the temperature falls below 4° C (40° F). All trona producers have established a rehabilitation program to recover and release contaminated birds and to minimize the mortality and morbidity rate.

Land surrounding trona operations in Wyoming is relatively undeveloped, and the influx of large numbers of workers has caused great strain on the local facilities for housing, schools, shopping, and entertainment. Soda ash companies have provided financial assistance to aid local government in handling any overloads caused by the migration of their employees and families into community. The companies have given financial aid to employees purchasing homes in the surrounding communities and other fringe benefits such as low-cost transportation to and from work.

Toxicity.—Although soda ash is not considered a highly toxic substance, contact with the eyes may be injurious and prolonged contact with the skin may cause irritation, especially to those who have allergic reactions to alkaline materials. It has also been found to be corrosive to the stomach lining if ingested. It has an acute oral lethal dose (LD50) of 2.8 grams per kilogram (when tested on a rat) and a primary skin irritation index (PSII) of 2.54 (when tested on a rabbit). **Simultaneous** exposure to soda ash and lime dusts should be minimized because in the presence of moisture, as from perspiration, the two materials combine to form caustic soda, which is very harmful. Soda ash is not flammable, and the dust is not explosive.

Employment.—According to a survey conducted by the U.S. Bureau of Mines, the Wyoming soda ash industry employed 1,212 people in the 5 trona mines and 1,678 people in the soda ash refineries in 1992. The total quantity of trona mined by the Wyoming soda ash industry was 14,885,012 tons in 1992.

Energy Requirements.—Natural soda ash plants consume considerably less energy per unit of product produced than do synthetic soda ash facilities. As the cost of energy has increased since the 1973 energy crisis, the differential in production costs between natural and synthetic soda ash has become greater. This is one of the major reasons why U.S. natural soda ash has maintained its competitiveness in the world market.

An early U.S. Bureau of Mines energy study using 1973 data indicated that 15.8 million British thermal units (Btu's) was required to produce 1 ton of synthetic soda ash, whereas the energy requirement to produce the same quantity from trona was 7.2 million Btu. The domestic soda ash industry has reduced its energy requirements significantly since 1973 by replacing gas-fired dryers with steam-tube units and installing mechanical vapor recompression units to replace tripleeffect evaporators. The industry has also converted to coal exclusively or combined with other fuel sources. Plants operated by Tg and Solvay Minerals and the Argus plant operated by North American Chemical Co. use coal only. As a result of these energy-saving measures, the Wyoming soda ash industry lowered its energy requirement to a range of 4.5 to 6 million Btu, depending on the individual producer. An estimated one-half of the energy consumed in natural soda ash refining using triple-effect evaporators is evaporating, one-third is calcining, and the remainder, for drying.

These energy requirements exclude the

amount of energy needed to ship soda ash to foreign markets. Although it has been estimated that it would take about 2.9 million Btu of additional energy to transport soda ash by rail and by ship to Western Europe, nevertheless natural soda ash production requires less energy than the Solvay process or any other synthetic technique.

Transportation.—The western geographic locations of the domestic natural soda ash industry often pose problems because of the great shipping distance to most foreign customers. Even within the United States, the majority of domestic consumption is in the Midwest and east of the Mississippi River. Overland and ocean transportation rates become important factors in the delivered price of soda ash and must be considered seriously in negotiations with foreign consumers who often have alternate supply sources. Bulk freight rates can usually be reduced by shipping in larger volumes, such as in 7,500-ton unit trains.

The railroad is the dominant mode of transportation for the shipment of soda ash. In Wyoming, the Union Pacific Railroad provides the main service to the industry. All bulk soda ash that is railed is carried in covered hopper cars, each handling about 98 tons. Although the railroad companies make their cars available, most soda ash companies have their own sizable fleet.

Beginning in 1985, soda ash was shipped in large quantities by truck. Bonneville Transloaders, Inc. trucked soda ash from Green River to the Burlington Northern Railroad's line at Shoshoni, WY. Of the almost 8.4 million tons (9.2 million short tons) of soda ash produced in Wyoming, Bonneville trucks about 770,000 tons (850,000 short tons) out of Green River. Other trucking companies have started similar operations with the Southern Pacific (shipping more than 227,000 tons or 250,000 short tons per year) and Denver Rio Grande Railroads to compete with Union Pacific.

The railroads have been involved in establishing soda ash bulk loading terminals at ports to handle large volumes

of material for export. Kansas City Southern Railroad's terminal at Port Arthur, TX, has a railcar unloading capacity of about 1,000 tons per hour. Material is conveyed to a ship loader spout for transfer to bulk cargo ocean vessels. Port Arthur was the third largest port of the 24 ports that shipped soda ash in 1992, most of which was shipped to South America. The Columbia-Snake customs district in the Pacific Northwest has a bulk loading terminal that transferred the most soda ash, 60%, in 1992.

ANNUAL REVIEW

Issues

The dissolving of the U.S.S.R. in December 1991 and of Yugoslavia in April 1992 had an adverse affect on soda ash production in those nations. It is doubtful that their domestic soda ash industry will thrive until economic and political stability are achieved. Elsewhere in the world, acquisitions and expansions of several operations were among the major highlights that occurred in 1992. In addition, U.S. soda ash exports to Europe increased substantially as a result of the removal of the antidumping tariff in 1990 into the European Community (EC).

Production

U.S. production of natural soda ash from California and Wyoming increased 4% to 9.379 million tons. A total of 137,433 tons of soda ash equivalent from soda liquors and mine waters was included in the total and used primarily for neutralizing powerplant process water. The liquors represent a growing market for soda ash producers and provide additional revenue. In addition, 151,127 tons of soda ash equivalent was used to manufacture chemical caustic soda by FMC, Solvay Minerals, and Tg Soda Ash.

Solvay S.A. of Belgium, the world's largest synthetic soda ash producer, acquired in May through its U.S. subsidiary Solvay America, Inc., the 80%

share of Tenneco Mineral Co.'s natural soda ash facility in Green River, WY, for \$500 million; \$200 million from internal funds and \$300 million long-term debt arranged through Solvay America using U.S. financial sources.¹ Solvay also acquired the 68,000-ton-per-year chemical caustic soda unit, the 51,000-ton-per-year sodium sulfite unit, and the 54,000-tonper-year ground trona unit. transaction provided Solvay with access to several markets in the Western Hemisphere previously economically inaccessible from its plants in Europe. The transaction provided Tenneco Inc. the needed capital to pay down debt in its \$3 billion restructuring action. Asahi Glass of Japan continued to hold its 20% ownership in the remainder of the operation. Tenneco Minerals in April had completed installing 635,000 tons (700,000 short tons) of new capacity, raising total production nameplate capacity to 1.81 million tons (2 million short tons) annually. The expansion exceeded the original design capacity, which was supposed to be 545,000 tons (600,000 short tons).

This was not the first time that Solvay of Belgium had been involved in the U.S. soda ash industry. The first synthetic soda ash plant constructed in the United States was in 1881 at Syracuse, NY, by the Solvay Process Co. whose employees were trained in operating the plant at Solvay's plant in Dombasle, France. When the Germans quit supplying the United States with potash in 1914, Solvay built and briefly operated a potash facility in 1916 at Searles Lake, CA, and constructed a town named Borosolvay. In addition, Solvay used solar evaporation to recover potash at Salduro in western Utah beginning in 1917. Solvay also constructed and operated synthetic soda ash plants at Detroit, MI, (1898 to 1969) and Hutchinson, KS (1908-18).

FMC Wyoming Corp. announced plans in December to add an additional 545,000 tons (600,000 short tons) of annual production capacity to its existing operation.² The \$125 million expansion, if approved by corporate headquarters, would raise overall capacity 22%, or from 2.8 million short tons to 3.4 million

short tons. The project would add about 40 to 50 new jobs to FMC's present work force of 1,180 people.

On June 30, TOSOH Corp. of Japan formed TOSOH Wyoming Inc., a wholly owned subsidiary of TOSOH America Inc., through the purchase of a 24% partnership from BTR Nylex's U.S. subsidiary The Andover Group Inc. Andover owned Australian Consolidated Industries, which held 49% of the joint venture with General Chemical (Soda Ash) Partners in Wyoming. TOSOH paid \$82 million for its 24% share of the operation that has a capacity of 2.2 million short tons per year. The Japanese company produces synthetic soda ash in Japan where it has a 240,000-ton-per-year facility.3

Vulcan Chemical Co. and Cominco American formed a joint venture in April to produce soda ash at Owens Lake, near Lone Pine, CA.⁴ The planned facility will have an annual capacity of 545,000 tons (600,000 short tons), and is estimated to cost \$100 million, not including transportation arrangements.

North American Chemical Co. in April announced that it planned to install an additional 545,000 tons (600,000 short tons) of capacity to its Argus facility at Searles Lake in California.⁵ The project is scheduled to be on-stream in 1994 and is expected to cost \$50 million. When completed, the total annual capacity of the facility will be 1.8 million short tons. The company will use new solution mining techniques and will enlarge the plant's soda ash drying facilities. North American also entered into a 50% joint venture in March with NaTec Resources Inc. that was producing bicarbonate from nahcolite (natural sodium bicarbonate) in the Piceance Creek basin of northwest Colorado.6 NaTec's facility has an annual capacity of 113,000 tons (125,000 short tons) of high-purity nahcolite. The partnership, named White River Nahcolite Minerals Ltd. Liability Co. (a newly created NaTec subsidiary), was finalized in June with NaTec receiving \$10 million in cash payable over 4 years with no interest. In November, the company was renamed White River Nahcolite Minerals. North American ceased producing sodium bicarbonate at its Searles Lake operation, which had an annual capacity of about 20,000 tons.

Consumption and Uses

U.S. apparent consumption in 1992 decreased slightly compared with that of the previous year whereas reported consumption was virtually identical. The discrepancy between the two forms of consumption was attributed disagreement between the sources of export data used to derive consumption statistics. The two sources were the Bureau of the Census, which reports exports upon departure from the U.S. port, and the soda ash producers, which consider a shipment as exported when their export association (ANSAC) takes charge at California or Wyoming plant sites. Transit times between the plant and port, which can take about 2 to 3 weeks before the cargo is actually exported, and carryover export inventories contribute to the discrepancy between reported and apparent consumption as well.

The recovery of the domestic economy in 1992 continued to have a negative effect on the domestic glass container industry; however, soda ash sales to the flat glass sector increased, indicating favorable economic conditions for the domestic construction and automobile manufacturing industries. The industrial building construction industry consumes about 57% of all flat glass made, whereas the automotive glass sector used 25%. Based on reported industry sales, the manufacture of glass products increased Glass manufacture represented about 49% of domestic soda ash consumption, with the container sector comprising 59% of this end use: flat. 27%; and fiber and specialty, 7% each. The other end uses include chemicals (primarily sodium bicarbonate, sodium chromates, sodium phosphates, sodium silicates), 24%; soap detergents, 12%; distributors, 6%; flue gas desulfurization, 2%; and pulp and paper, water-treatment, and miscellaneous, 2% each.

U.S. reported consumption of soda ash | U.S. soda ash.

decreased in the chemical, soap and detergent, water-treatment, and flue gas desulfurization sectors in 1992. The change in demand was because of the general economic conditions of the major soda ash-consuming market. (See table 4.)

Detergents is the third largest use of soda ash. Soda ash is used as a builder to emulsify oil stains, reduce the redeposition of dirt during washing and rinsing, provide alkalinity for cleaning, and soften laundry water. In addition, soda ash is a component of sodium tripolyphosphate (STPP), another major builder in detergent formulations, but soda ash consumption has been decreasing because phosphatic detergents can contribute to the environmental problems of eutrophication. Many regions of the Nation have adopted phosphate limitations or bans. These areas represent about 40% of the U.S. population. In response to environmental issue, detergent manufacturers began reformulating their detergents to make compact and superconcentrated products. These reformulations require sodium silicates and synthetic zeolites, which are made from soda ash. Liquid detergents, which do not contain any soda ash, compete with powdered detergents and command 40% of the household laundry detergent market, up from only 15% in 1978.

Stocks

Yearend stocks of dense soda ash in domestic plant silos, warehouses, terminals, and on teamtracks amounted to 371,424 tons. Producers indicate that a potential supply problem could exist when inventories fall below 180,000 tons. Most consumers of soda ash do not have storage facilities to accommodate large quantities of soda ash and must rely on suppliers to provide the material on a timely basis. The majority of the U.S. soda ash producers that have been exporting to Europe have several foreign warehouses for product storage. These warehouses serve the needs of most foreign soda ash consumers that purchase

Markets and Prices

Domestic and export sales are essentially the two markets for soda ash. In the domestic market, the large volume buyers of soda ash are primarily the major glass container manufacturers, whose purchases are seasonal (more beverage containers made in second and third quarters for summertime beverage consumption). Soda ash sales to the flat glass sector are usually dependent on the state of the economy because the largest use of flat glass is in automobile manufacture and residential housing and commercial building construction. These two major industrial sectors are especially sensitive to changing economic conditions. If construction starts and automobile sales are up, soda ash sales will proportionally follow.

Beginning September 1, General Chemical Corp. announced it intended to increase its off-list prices by \$5 per short ton, not to exceed the \$98 list price. Increased export demand, the recovering U.S. economy, and emerging caustic soda replacement markets were cited as the justification for the price hike. Rhône Poulenc also announced a \$5 off-list price increase to offset the high operating costs and continued investment in plant facilities. Most contracts are written with any new terms for the following year. By yearend, it did not appear that the price movement held.

The average annual value for dense natural soda ash, f.o.b. Green River, WY, and Searles Valley, CA, was \$89.21 per ton (\$80.93 per short ton), which was an increase of 1.6% over that of the previous year. The value is not a "price;" it is the value of the combined revenue of California and Wyoming bulk dense soda ash sold on an f.o.b. plant basis at list prices, spot prices, discount, long-term contracts, and for export, divided by the quantity of soda ash sold. The list price for Wyoming bulk, dense soda ash remained at \$98 per short ton while the California price for the comparable product held at \$123 per short ton. (See table 5 and figure 1.)

Foreign Trade

U.S. soda ash exports rose 8% in 1992 to reach a record high of 3.0 million tons. U.S. exports to 51 countries, on a regional basis, were as follows: Asia, 42%; Europe, 23%; South America, 17%; North America, 10%; Africa, 3%; Oceania, 2%; Central America and the Middle East, 1% each; and the Caribbean, less than 1%.

The U.S. soda ash industry has waited since the early 1980's for the trade barriers with the EC of Western Europe to end. With the removal of the antidumping tariffs on U.S. soda ash in late 1990, export sales to Europe began to rise. By yearend 1992, domestic soda ash exports to the EC were about 582,000 tons; a 1,323% increase from that of 1980. Total exports to Europe, including Sweden and Yugoslavia (exports actually went to Hungarian glass plants through a Yugoslavian port), were 695,000 tons in 1992. Figure 2 shows the level of exports to Europe relative to the U.S. total from 1980 through 1992. The graph shows the effect on U.S. soda ash exports from the implementation of antidumping duty by the EC Commission after 1982 and the elimination of that duty in 1990. Figure 3 shows the level of exports to Europe among the six U.S. companies in 1991 and 1992 that are reflected in the increases for those years shown in figure 2.

Although export sales to Western Europe were strong during the past 2 years, three important issues began in about the third quarter of 1992. They were the rise in the strength of the U.S. dollar relative to European currency, the stagnation of European demand, and the reduction by Solvay S.A. of Belgium of its price of synthetic soda ash by 10% to 15% in certain countries. (See tables 6, 7, and 8 and figures 2 and 3.)

World Review

Industry Structure.—The developed nations are generally the largest consumers of soda ash. Although the production and consumption quantities vary among the countries, the end-use

patterns are basically the same (e.g., glass, chemicals, and detergents are the major sectors). Although the United States is the largest soda ash-producing country in the world, foreign ownership in the U.S. soda ash industry is presently 49% of nameplate capacity.

Eleven countries have the capability to produce more than 1 million tons annually. The major ones include, in descending order, the United States, the C.I.S., China, Germany, India, Japan, France, and Bulgaria. Most of these countries have large populations that require consumer products made with soda ash. The lesser developed nations tend to have greater soda ash demand and higher rates of growth as soda ash-consuming industries are developed. (See table 9.)

Capacity.—World soda ash production capacity is about 35 million tons divided among 36 countries. Approximately 70% of world capacity is synthetic soda ash and 30% is natural. The United States represents 30% of world capacity and 95% of the total natural capacity.

The largest soda ash company in the world, excluding state-owned facilities, is Solvay S.A. of Belgium. With its acquisition of Tenneco Minerals' natural facility in Wyoming in 1992, it operates 10 plants in 8 countries and has a combined annual capacity of about 6.07 million tons. FMC Wyoming Corp. of the United States is the second largest, with 2.59 million tons (2.85 million short tons) of capacity.

Australia.—Penrice Soda Products of Australia announced plans to expand and modernize its Osborne facility by 25% to 500,000 tons. The project will cost \$20 million to \$30 million over the next 4 years. The company plans to export 40% of its soda ash to various Asian countries by 1998.

China.—A decrease in Chinese domestic consumption caused soda ash inventories to increase. As a result, production limits were implaced that caused utilization rates to fall to

approximately 70%.8 Output was estimated at 4 million tons, of which about 200,000 tons was exported to several Asian nations. In 1985, it was forecasted that China would begin to become an active exporter.9 The decline in consumption and production caused the price of Chinese soda ash to fall to 900 Renminbi Yuan (\$164 per metric ton).

Ethiopia.—A natural soda ash project with an annual capacity of 200,000 tons on Lake Abijata was under consideration. Although the planned project is estimated to generate \$4 million to \$5 million in annual operating revenue, a large quantity of bird species represents an environmental problem. A feasibility study was delayed because of the prolonged civil war in northern Ethiopia.10

Germany.—The 300,000-ton expansion at the Bernburg synthetic soda ash plant that Solvay S.A. of Belgium regained control of in 1991 in the former German Democratic Republic was completed in July 1992. Although the expansion was for dense soda ash, the older facility also has a unit that has an annual capacity of 240,000 tons of light soda ash. The majority of the output of the complex is for consumers in Czechoslovakia and some C.I.S. Republics. Part of the modernization program will improve product quality such as reducing sodium chloride content in the soda ash to less than 0.15%. Solvay has already achieved this goal at its plants in Austria, Belgium, and western Germany.11

Jamaica.—The Government-owned Jamaican Bauxite Institute initiated a feasibility study to produce caustic soda using local limestone and imported U.S. soda ash from ANSAC. The country uses about 300,000 tons of caustic soda annually to treat bauxite ore. About 190,000 tons of limestone and 200,000 tons of soda ash would be required to produce 300,000 tons of 50%-strength caustic soda. A small 60,000-ton-peryear facility is under consideration with construction costs estimated at \$20

million. The results of the feasibility study, which was funded by the European Investment Bank of Luxembourg, may allow for a larger-sized plant. The study began in November and is slated to take 6 or 7 months to finish.¹²

Pakistan.—ICI Pakistan, of which ICI PLC owns 61%, announced plans to expand its synthetic soda ash plant at Khewra, Punjab Province. Capacity will be raised from 146,000 tons per year to 196,000 tons per year. The expansion is needed to meet the growing domestic demand that has been 6% to 7% annually. The project is scheduled for completion in December 1994 at a cost of \$32 million. 13

Poland.—The two State-owned synthetic soda ash plants at Janikowo and Inowroclaw, with a combined capacity of 850,000 tons per year, were offered for sale at yearend as the country began to privatize certain industries. A foreign partner may acquire up to 80% of the operations that are anticipated to be sold together. Solvay of Belgium, Rhône-Poulenc of France, and Brunner Mond of England have indicated their interest in the joint venture but formal bids were not to be submitted until early 1993.14 Improvements in soda ash handling were completed at the Port of Szczecin on the Baltic Sea in Poland by Fast Shipping Ltd. to accommodate shipments within and out of the country. New silos, warehouses, and handling equipment were installed to improve the quality control of soda ash distribution. Daltrade Ltd. of the United Kingdom serves as the import agent for Polish soda ash. Improvements have been made at the Ports of Howden Dyke, Humberside, and Perth in Scotland. 15

United Kingdom.—Brunner Mond, which operates two synthetic soda ash plants at Lostock and Winnington, continued to restructure its business by eliminating 400 jobs over the next 2 years. The company formed five business units to streamline plant operations and administrative functions. ¹⁶

OUTLOOK

The political changes that have occurred in the past 2 years in the former U.S.S.R. and in other Eastern European nations have begun to cause an economic impact in those countries. Some of the state-owned soda ash plants, such as those in Poland previously discussed, are being partially sold to private companies to generate needed revenue and to reduce operating and maintenance previously incurred by the Governments. Less economic, older soda ash plants, like that of Czechoslovakia that closed in 1991, will be targeted for possible closure in the next few years, thereby reducing world soda ash production capacity. This could represent a favorable opportunity for the U.S. soda ash industry to export product to these areas. It is very likely that some of the newer and more efficient plants will be modernized and equipped with pollution abatement technology to reduce atmospheric emissions and wastewater discharges in response to the growing international environmental movement. World soda ash demand continues to increase, which will provide the stimulus for foreign companies to continue considering investing in natural soda ash ventures in Wyoming and California to guarantee long-term and inexpensive supplies of soda ash. (See figure 4.)

Exports

The outlook for U.S. soda ash exports remains optimistic. The two largest exporting organizations in the world are Solvay and the American Natural Soda Ash Corp. (ANSAC). Although ANSAC is prohibited from exporting to EC nations, the six individual U.S. soda ash producers will continue to strive to increase exports to that region. Stagnant market conditions in Europe, the strength of the U.S. dollar relative to European currency, and the decrease in the European soda ash sales price will probably lessen U.S. soda ash export sales for the short term. Because of the higher cost structure of manufacturing

synthetic soda ash, it is doubtful that the European sales price can remain low for very long before it has an adverse economic affect on the producers. Export opportunities to the Middle East and South America are very favorable. It also is likely that some South American production capacity could be reduced as certain countries examine the economic status of some facilities.

Glass

Domestic consumption of soda ash in the glass container sector declined for the fifth consecutive year because of (1) the increasing use of cullet, (2) the national interest in recycling, and (3) the continuing competition with polyethylene terephthalate (PET) plastic containers.

The public's perception that glass is more completely recyclable compared to plastics will raise the quantity of cullet now being consumed. Aside from the problems with plastics' recyclability, the public also is concerned about the dioxin emissions from incineration of polyvinyl chloride (PVC) bottles.

Municipal landfills are a growing national problem. Glass reportedly accounts for 8.4% of disposable household waste. The U.S. Environmental Protection Agency has a goal of reducing the Nation's waste by 25% by 1992. It is probable that new taxes will be placed on items manufactured at the source of production to encourage greater use of recycled products. Rebates would be given for every ton of recycled material utilized.

Chemicals

The international chloralkali supply and demand situation in 1992 was not a major problem as was forecast previously. Although a few chloralkali plants shut down during the year, they were basically the unprofitable ones. Chemical caustic soda produced by the lime-soda process will satisfy part of the projected caustic soda shortages. A potential 545,000 tons (600,000 short tons) of caustic soda could be made available from Dow Chemical, pending

its decision to produce propylene oxide by a different alternative method. By the end of 1992, the domestic chlorine market rebounded and caustic soda became available at less expensive prices, which lessened the demand for chemical caustic soda from trona.

Soap and Detergents

About 10 million tons of laundry detergents is consumed annually in the world. Most detergents are composed of many active and inert chemical ingredients. Household liquid detergents phosphate-free detergents and considered environmentally safe products. More soda ash has been added as a phosphate-replacement builder in various detergent formulations to meet regional phosphate discharge requirements.

The environmental movement in Europe has also prompted foreign detergent manufacturers to consider changing formulations to reduce phosphate content. In Germany, consumption of phosphates in detergents dropped from 276,000 tons in 1975 to 80,000 tons in 1987. The quantity of packaging waste discarded to landfills prompted detergent manufacturers to testmarket compact and superconcentrated products in different regions. Whatever amount of soda ash lost due to reformulation could be partially offset from the use of soda ash in synthetic zeolites and sodium silicates in the new formulations.

In Europe, superconcentrated liquid detergents were introduced recently that use polyethylene glycol rather than water as the carrying agent. These newer detergents reportedly contained smallersized water softening particles, which increased the quantity of particles per wash and allowed them to disperse quicker, thereby enabling the cleaning agents to work faster.¹⁷ In the United States, about 50% of all detergents contain enzymes that are effective at stain and environmentally removal are Approximately 40% of acceptable. powdered detergents and 60% of liquid detergents contain at least one enzyme.¹⁸

Consumer preferences also usually

help determine the preferred detergent and format (i.e., liquid versus powdered, unit dose packets versus bulk). Depending on the choice, the growth of future soda ash sales for detergents is optimistic.

Pulp and Paper

Although the U.S. pulp industry is growing at about 2.75% per year, changes are taking place to alter the pulpmaking and papermaking processes. Pulp mills are striving to address the environmental issues regarding dioxins and furans, improve productivity, reduce costs, and improve paper quality. One solution is alkaline paper-sizing, which produces alkaline-based paper rather than acid-based. The conversion is not being implemented as fast as the environmental issue is mounting. Other alternatives include substituting certain pulping chemicals.

chlorine Dioxins. created from molecules introduced in the paper bleaching process, have been detected in bleached paper products as reported in a study of the 104 kraft-pulp mills in the United States. To avert the public's reaction to the issue, the industry began investigating substituting chlorine-base chemicals for nonchlorine pulping and bleaching agents, such as oxygen and hydrogen peroxide. About 1.8 million tons of chlorine is used in pulp bleaching annually. Industry sources estimate a 25% to 30% reduction in chlorine consumption by 1995. If this forecast is accurate, coproduct caustic soda, which is used to delignify wood pulp, could be in short supply. This situation could result in additional quantities of soda ash being used instead of caustic soda, although it would take 1.3 tons of soda ash to have the same chemical effect of 1.0 ton of caustic soda. FMC Wyoming Corp., Solvay Minerals Inc., and Tg Soda Ash, Inc., have begun to produce caustic soda from their Wyoming soda ash operations. Although the majority of the output is for captive needs, the opportunity will demonstrate the economic feasibility of producing caustic soda from nonsalt feedstocks. Soda ash consumption in the pulp and paper sector could increase during the next few years depending on the strength of chlorine demand, which is influenced by the strength of polyvinyl chloride and ethylene dichloride sales.

Flue Gas Desulfurization

The Clean Air Act, as amended by Public Law 101-549, will require the Nation's powerplants to reduce emissions of sulfur and nitrogen compounds produced from burning fossil fuels. Although most high-sulfur coal is used in eastern powerplants where inexpensive calcium-base compounds are located, sodium-base sulfur dioxide removal agents, such as trona and nahcolite, have opportunities for commercial development in the west.

In 1992, about 144,000 tons of soda ash was used for reducing stackgas emissions in the West and Midwest. Transportation costs will reduce the competitiveness of sodium minerals in the East in the future; however, the concern regarding water quality and quantity will be major issues in the Western United States in the 1990's. Several wetscrubbing utility plants, which use tremendous amounts of water, are evaluating the economics of replacing traditional wet-scrubbing systems using lime with dry-injection technologies using calcium- and sodium-base agents. The addition of some sodium minerals removes additional sulfur and a nitrogen substantial amount of the materials. Eastern powerplants will probably use low-sulfur coal rather than use trona or nahcolite resources found in the West. As Western powerplants retrofit older facilities with dry-injection scrubbing equipment to conserve water, demand for soda ash will increase.

Although the outlook for the U.S. soda ash industry is very good, the structure of the industry continues to change as foreign participation increases. The United States will remain an important supply source of inexpensive natural soda ash for international consumption. However, a growing percentage will be shipped by the foreign partners of the U.S. resource—primarily Australia,

Belgium, France, Japan, and the Republic of Korea. More shares of the U.S. soda ash industry are available for joint venture at the present time.

Total	11.81		
Total metric tons	10.71		

¹A joint venture between General Chemical Corp. (51%), Australian Consolidated Industries International (ACI-25%), and TOSOH Wyoming Inc. of Japan (24%), which purchased part of ACI's share June 1992.

Includes natural and synthetic. Natural only, and soda liquors and mine water converted to soda ash equivalent in 1988 and thereafter; 73,365 tons in 1988, 95,027 tons in 1989, 111,894 tons in 1990, 117,289 tons in 1991, and 120,608 in 1992.

²Export data for 1988 were adjusted by the U.S. Bureau of Mines to reconcile data discrepancies among the Bureau of the Census, the American Natural Soda Ash Corp, and Statistics Canada.

²Acquired Dec. 1, 1990, from Kerr-McGee Chemical Corp., with Oriental Chemical Industries of Korea as partner (27%).

³Joint venture between Rhône-Poulenc Basic Chemicals Co. of France (51%) and Union Pacific Resources Co. (49%).

⁴Acquired mid-1992 from Tenneco Minerals Co. Operation is a joint venture with Solvay S.A. of Belgium (80%) and Asahi Glass Co. of Japan (20%), which became a partner in Feb. 1990. A 600,000-ton expansion was completed June 1992.

⁵Owned by Texasgulf Inc., subsidiary of Societe Nationale Elf Aquitaine of France (100%).

[&]quot;Estimated. "Revised. NA Not available; included in "Other."

Source: U.S. Bureau of Mines.

¹Natural and synthetic except where noted.

²Natural soda ash only for 1987 and thereafter; natural and synthetic from yearend 1982-86.

Also known as apparent consumption (production plus imports minus exports plus or minus stock changes) and is equal to "Total U.S. primary demand."

Estimated consumption for 1982-86 was based on industry sources; reported consumption 1987 and thereafter were from quantitative and qualitative quarterly surveys of producers' sales. Other end-use categories were incorporated in the survey.

Includes soda ash used in petroleum and metal refining, leather tanning, enamels, etc. Also includes data in categories indicated by "NA."

Because end-use data prior to 1987 were estimated, industrial demand and U.S. primary demand calculations (both based on production, trade, and inventory data) were assumed to be equal to total U.S. consumption. Beginning with 1987, reported consumption data by end use often disagreed with derived apparent consumption calculations that necessitated, including an "Undistributed" category to account for the discrepancies. These discrepancies are because of the fluctuating balance of inventory in transit from plants to domestic or export destinations, and unsold foreign inventories of U.S. producers.

Values are the combined total revenue of California and Wyoming natural, bulk, dense soda ash sold on an f.o.b. plant basis, at list prices, spot prices, discount, long-terms contracts, and for export, divided by the quantity of soda ash sold. This value may or not be synonymous with the posted list prices of the commodity. Gross domestic product used to derive constant 1992 dollars; 1987=100.

Light 58%, 100-pounds, paper bags, carlot same basis	do.	150.00	151.00
Bulk, carlot, same basis tons	do.	123.00	103.00

Sources: Chemical Marketing Reporter. Current Prices of Chemicals and Related Materials. V. 238, No. 27, Dec. 31, 1991, p. 31; and v. 242., No. 26, Dec. 25, 1992, p. 29.

Includes soda ash equivalent from soda liquors, purge liquors, and mine water sold to powerplants or water treatment: 73,365 tons in 1988, 95,027 tons in 1989, 111,894 tons in 1990, 117,289 tons in 1991, and 137,433 in 1992.

²Data are from the Bureau of the Census and may vary from the quantity reported by the producer and/or importer. Actual imports are proprietary data but have been distributed into appropriate end-use categories and included in "Total domestic reported consumption."

Reported consumption data do not agree with apparent consumption data shown in tables 1 and 3 because of dissimilar sources of export data. The data vary because of different reporting periods, overland transit times between plant and port, and carryover export inventory.

As reported by producers. Includes Canada. Data may not necessarily agree with that reported by the Bureau of the Census for the same periods.

⁵Revised from monthly Mineral Industry Surveys data because of 181 metric tons (200 short tons) of misreported export data in first quarter 1989.

⁶Represents soda ash from domestic origin (production and inventory changes) and imports, and for exports.

⁷An extra 23,548 metric tons (25,957 short tons) of coproducer sales is included in total, but specific end-use breakout is unknown.

TABLE 8
U.S. IMPORTS FOR
CONSUMPTION OF SODA ASH

	Disodium carbonate ¹				
Year	Quantity (metric tons)	Value ² (thousands)			
1988³	120,609	\$15,999			
1989³	128,790	17,396			
1990	145,534	20,495			
1991	134,312	21,299			
1992	71,663	12,772			

Beginning in 1989, import data were reclassified under the Harmonized Commodity Description and Coding System (HS Code No. 2836200000). Prior years were classified under the Tariff Schedule of the United States, Annotated, TSUSA No. 4208400 (calcined) and No. 4208600 (hydrated and sesquicarbonate).

²C.i.f. value at U.S. ports.

³Also contains sodium carbonate, hydrated and sesquicarbonate.

Source: Bureau of the Census.

²Adjusted using PIERS data to include 12,257 tons exported in Mar. and Sept. through Los Angeles, CA, customs district.

In July, 33,069 tons was shipped to China, but credited to Bulgaria, by the United States to fulfill Bulgarian export commitment. Data included with China.

⁴Data representing imports from the United States as reported by Statistics Canada, International Trade Div. The Bureau of Census export statistics indicated only 123,254 tons in 1988.

⁵Includes 33,069 tons shipped by the United States but credited to Bulgaria.

⁶Formerly part of Yugoslavia.

⁷Adjusted using PIERS data to include 43 tons in July through Tampa, FL, customs district.

⁹The majority was bagged and transshipped to China.

⁹Formerly part of the U.S.S.R.

¹⁰Erroneous notation of shipment of 1,193 tons (\$190,800), to Russia through Houston customs district in May. The error is not included in total.

¹¹Adjusted to include 4,410 tons shipped in September and December.

¹²Dissolved in Apr. 1992.

¹³Data may not add to totals shown because of independent rounding.

SODIUM SULFATE

By Dennis S. Kostick

Mr. Kostick, a physical scientist with 14 years of U.S. Bureau of Mines experience, has been the commodity specialist for sodium sulfate since 1979. Domestic survey data were prepared by Maria Arguelles, mineral data assistant; and international data tables were prepared by Doug Rhoten, international data coordinator.

Sodium sulfate is produced from natural sources and as a byproduct from different chemical processes. Natural sodium sulfate is produced from naturally occurring brines and crystalline deposits found in California and Texas. It also is found as a constituent of saline lakes, such as the Great Salt Lake in Utah. Synthetic sodium sulfate is recovered as a byproduct from various manufacturing processes. Both types of sodium sulfate have several important and useful applications in various consumer products.

DOMESTIC DATA COVERAGE

Domestic production and inventory data for natural sodium sulfate are developed by the U.S. Bureau of Mines from monthly and annual surveys of U.S. operations. Of the three natural sodium sulfate operations to which a survey request was sent, all responded, representing 100% of the natural sodium sulfate data used in this report.

Synthetic sodium sulfate data were collected by the U.S. Department of Commerce, Bureau of the Census, from quarterly and annual surveys (aggregate data published in Current Industrial Reports, Inorganic Chemicals, MQ28A and MA28A) of companies engaged in recovering and selling byproduct sodium sulfate. Any revised Census Bureau data have been included using most recent Census Bureau statistics. These data are aggregated with U.S. Bureau of Mines natural sodium sulfate data and included in several tables. (See table 1.)

BACKGROUND

Natural sodium sulfate was known to have been used as a medicine as early as the 16th century. It was first accurately described in 1658 by Johann Rudolf Glauber, a German chemist whose name is still associated with the hydrated crystal, Glauber's salt (Na₂SO₄ • 10H₂O), and the anhydrous mixed sulfate, Glauberite (Na₂SO₄ • CaSO₄).

Glauber and other researchers prepared sodium sulfate by reacting common salt with sulfuric acid. The invention of the Kraft process for making pulp and paper in 1880 provided the first major industrial market for sodium sulfate.

Definitions, Grades, and Specifications

The following terms are used in the sodium sulfate industry:

Anhydrous Sodium Sulfate.—Refined sodium sulfate or the mineral thenardite (Na₂SO₄). Named for the French chemist, Louis Jacques Thenard, thenardite is a colorless to white mineral with a specific gravity of 2.67 and a hardness of 2.5 to 3. Because of its whiteness and purity, it is used in detergents, pharmaceuticals, dyestuffs, glass, and ceramic glazes. Commercial-grade material has a bulk density of about 1.23 grams per cubic centimeter (77 pounds per cubic foot).

Byproduct Sodium Sulfate.— Synonymous with synthetic sodium sulfate. It is recovered as a byproduct from various chemical and textile manufacturing processes.

Glauber's Salt.—Same as the mineral mirabilite (Latin "sal mirabile" or "wonderful salt"), sodium sulfate decahydrate (Na₂SO₄ • 10H₂O). The mineral contains 55.9% water of crystallization and forms opaque to colorless needlelike crystals.

High Purity.—Refers to anhydrous sodium sulfate with a purity of 99% or greater. Usually sold to detergent, glass, and textile industries.

Low Purity.—Some processes occasionally produce sodium sulfate that does not meet certain physical or color specifications required by certain consumers despite being a chemically pure product. This grade of sodium sulfate is generally sold to sectors that are not as concerned about whiteness or particle size, such as the pulp and paper industry, at reduced prices.

Natural Sodium Sulfate.—Sodium sulfate obtained from mining crystalline sodium sulfate-bearing minerals or from sodium sulfate-bearing brines.

Salt Cake.—Normally refers to impure sodium sulfate containing 90% to 99% Na₂SO₄. Because of its impurity or possible discoloration, it usually is sold only to the pulp and paper industry.

Synthetic Sodium Sulfate.—Same as byproduct sodium sulfate.

Sodium sulfate made from natural brine usually contains less than 0.5% total impurities, but that produced as a

byproduct of other manufacturing may contain much larger quantities. material meeting U.S. Pharmacopeia (U.S.P.) specifications and that intended for glassmaking must contain at least 99% sodium sulfate. In addition. glassmakers' grade must be low in iron and heavy metals. Technical grades of sodium sulfate may have from 2% to 6% impurities. Purchases of detergent or rayon-grade sodium sulfate are based Its sodium primarily on whiteness. chloride content may be between 1.5% and 2.0% and its iron content between 60 and 100 parts per million.

Industry Structure

Three companies produced natural sodium sulfate from a total of three plants in California, Texas, and Utah. domestic natural sodium sulfate industry supplied about one-half of the total output of U.S. sodium sulfate. Because of the location of these plants, most natural sodium sulfate is marketed in the West and southern gulf areas. **Byproduct** material was supplied by 13 companies operating 14 plants primarily in the Midwest and Mid-Atlantic regions. Total rated production capacity in 1992 was 776,000 tons, and the industry operated at 78% of this capacity. (See table 2.)

Geology-Resources

Sodium is the sixth most abundant element in the Earth's crust. Sodium sulfate-bearing mineral deposits are geologically young, mainly of postglacial age. Sodium sulfate is widespread in occurrence and is a common component of seawater and many saline or alkaline Economic reserves of natural sodium sulfate are estimated at 3.3 billion tons worldwide. With world production of natural sodium sulfate averaging about 2.2 million tons per year, supplies are sufficient to meet anticipated demand for several centuries. The quantity of synthetic sodium sulfate is dependent on the longevity of the manufacturing firms recovering byproduct sulfate.

Surface depressions or lakes that have no outlets and are fed by spring waters

flowing over volcanic rocks containing sulfide minerals often yield soluble sulfide salts that are oxidized by contact with the air to produce sulfates. Some minerals over which the spring water may flow contain the sulfates directly, such as bentonite or gypsum. When an inland lake of this type evaporates and becomes highly concentrated in salts, one of the first salts to precipitate would be mirabilite, also known as Glauber's salt, which has very poor solubility at low During seasonal temperatures. temperature variations, the sulfate will precipitate preferentially to the lake bottom.

Thenardite and mirabilite are the only sulfate minerals that are sodium commercially important. Many economic deposits of sodium sulfate are in the form of crystalline beds of mirabilite such as those found in Canada and the former U.S.S.R., which has the world's largest sodium sulfate resource in the Kara-Because mirabilite Bogaz-Gol Gulf. converts to thenardite when exposed to air, its outer surface may develop a Some buried thenardite crust. sedimentary formations contain very large deposits of thenardite and glauberite, such as the deposit in Villarrubia de Santiago in Spain.

Sodium sulfate is also found dissolved in underground brines in California, Texas, and other parts of the world. The sulfate is usually converted to mirabilite when extracted from the brine by mechanical refrigeration techniques. (See table 3.)

Technology

The technology to mine and process natural sodium sulfate involves mechanical refrigeration or natural chilling to induce crystallization followed by dissolution, filtration, evaporation, and drying. Recovery of byproduct sodium sulfate from chemical processes involves various techniques.

Mining.—Sodium sulfate is extracted from the upper level of the Searles Lake brine in California and is treated separately from the carbonate-rich lower

level and mixed layer brines. The sodium sulfate-bearing subterranean brines in western Texas are the simplest deposits. the domestic brine Mechanical refrigeration is used to extract Glauber's salt crystals from the brine. The Great Salt Lake in Utah also contains valuable quantities of sodium sulfate. Brine from the most concentrated northwest segment of the lake is pumped into solar evaporation ponds on the eastern shore of the lake where sodium chloride first precipitates as the water Sodium sulfate crystals evaporates. precipitate in a fairly pure state when winter weather cools the brine to -1° to 4° C (30° to 40° F). The crystals are picked up by large earth-moving machinery and stored outdoors until further processing to anhydrous sodium sulfate can take place.

Processing.—At Searles Lake, the brine is first cooled at about 16° C (60° F) to precipitate borax crystals, which are removed from the system for subsequent further processing and sale. A second cooling to about 4° C (40° F) precipitates the sodium sulfate in the form of These crystals are Glauber's salt. separated from the brine on a rotating drum filter. They are then redissolved in fresh water in a vacuum crystallizer. After the second separation and drying. the crystals are about 98.2% sodium sulfate. Additional treatment can obtain a 99.3% purity. Major impurities remaining are sodium chloride, sodium carbonate, and boron.

In Texas, after the crystals are processed in rotary drum vacuum filters and washed, they are melted and dehydrated using mechanical vapor recompression evaporators, which are more energy efficient than triple effect evaporators or submerged gas burners. Final classifying, centrifuging, drying in rotary kilns, and screening converts the Glauber's salt to marketable anhydrous sodium sulfate of 99.7% purity.

Purification and dehydration procedures at the facility on the Great Salt Lake are similar to those of other sodium sulfate plants. The final product results in a purity between 99.5% and

99.7%.

Sodium sulfate is also produced as a byproduct of the production of ascorbic acid, boric acid, cellulose, chromium chemicals, lithium carbonate, rayon, resorcinol, and silica pigments. It is also recovered from certain flue gas desulfurization operations. The Mannheim and Hargreaves furnace processes also produce byproduct sodium sulfate. In the Mannheim furnace, salt and sulfuric acid are reacted to form hydrogen chloride (HCl) and sodium sulfate. The Hargreaves furnace produces HCl and sodium sulfate by the reaction of sulfur dioxide, sodium chloride, air, and water. The Mannheim process is the major method used in Europe, but its use in the United States has decreased considerably since less expensive methods to produce HCl became available.

Recycling.—Because of environmental concerns regarding sulfur emissions from pulp and paper mills, many Kraft pulpers were installing pollution abatement equipment to reduce sulfur losses in the pulping process. This will result in more sodium sulfate being recycled and less used in batch makeup solutions.

Byproducts and Coproducts

The brines of Searles Lake in California contain sodium sulfate as well as coproduct borax, potassium chloride, sodium chloride, and soda ash. The Great Salt Lake in Utah is a source of magnesium compounds, potassium sulfate, sodium chloride, as well as sodium sulfate. The brines in Texas do not yield any secondary products.

Some manufacturers of ascorbic acid, boric acid, cellulose, chromium chemicals, lithium carbonate, rayon, resorcinol, and silica pigments produce sodium sulfate as a byproduct of the process. The sodium sulfate is considered a waste product but has marketability.

Economic Factors

Prices.—Producers of natural sodium sulfate tend to market and sell most of their own product, but most synthetic producers use major chemical distributors or chemical supply companies as sales agents. The principal product made and sold by the synthetic sodium sulfate producer is the primary economic factor. Because sodium sulfate is considered a waste product, it will be sold at a price that ensures prompt sales. This practice tends to set the rates at which the natural product can be sold.

The list prices quoted in trade journals or by producers of all grades of sodium sulfate differ from the annual average values reported by the U.S. Bureau of Mines. The value represents the combined amount of total revenue of domestic natural sodium sulfate sold at list prices, spot prices, long-term contracts, discounts, and export divided by the aggregated quantity of sodium sulfate sold. The published value does not necessarily correspond to the posted list price. (See table 4.)

Tariffs.—Import tariffs serve to protect the interests of domestic producers for particular products. For sodium sulfate, a 32.5-cents-per-ton tariff is imposed on imported anhydrous sodium sulfate from countries having most-favored-nation (MFN) status and \$2.95 per ton from those with non-MFN status. There are no import tariffs on imported salt cake, regardless of the country of origin.

Royalties.—Sodium sulfate mined on Federal lands is subject to the Mineral Leasing Act of 1920, which provides for royalty payments to the U.S. Government. The royalty is 5% of the quantity or gross value of the output of the product at the point of shipment to market. Each Federal lease also has other costs, such as bonds, acreage rental fees, sodium prospecting permit application fees, and permit bonds. The Searles Lake sodium sulfate deposit is the only resource with active operations that

has any Federal leases. Because of the variety of the brine constituents, the operator has a commingling agreement with the U.S. Government to compute royalties.

Depletion Provisions.—Legislation passed by the U.S. Government provides an allowance for the depletion of natural resources, notably timber and minerals. The depletion allowance is an important inducement for companies willing to accept the risk and high cost of mining development. The concept of depletion allowances for minerals is similar to the depreciation of other assets. Although cost depletion and percentage depletion are two methods used to compute depletion deductions, most companies prefer to use the latter. About 100 mineral categories are entitled to percentage depletion. The rates range between 5% and 22% of the gross income from the mineral property, depending on the mineral and location (foreign or domestic), and are subject to a limitation of 50% of the net income of the property. The mineral depletion allowance for natural sodium sulfate is 14% for U.S. companies mining from domestic or foreign sources.

Operating Factors

Operating factors are different for mining companies producing natural sodium sulfate compared with manufacturing facilities recovering byproduct sodium sulfate. The quantity of synthetic sodium sulfate recovered is directly associated with the production capabilities of the primary industry (e.g., rayon, lithium carbonate, etc.) and the sulfate recovery rates.

Environmental Requirements.—Land usage may become a problem when sodium sulfate is obtained by solar evaporation, as in the case of the Great Salt Lake brines. Large areas of relatively flat land are required to allow for adequate concentration and evaporation. When land values are high, the capital required for land acquisition

may increase operating costs. Disposal of the waste liquors from which sodium sulfate was extracted may develop into a major ground water discharge problem in some areas. Reinjection of spent solutions into underground source strata is expensive but often is the only acceptable method of disposal.

Because sodium sulfate is water-soluble, most releases of sodium sulfate to the environment affect water quality rather than air or land quality. These releases are mainly from Kraft pulp mills, which typically discharge between 5 and 15 million kilograms (11 to 33 million pounds) of sodium sulfate per year per site. The resulting drinking water concentrations have been estimated as high as 38.8 milligrams per liter, which is significantly below the maximum concentration level of 250 milligrams per liter set by the National Secondary Drinking Water Standard.

Problems associated with chemical effluents discharged from manufacturing plants that recover sodium sulfate have also caused environmental concerns not attributed to sodium sulfate. The second largest byproduct sodium sulfate facility in the United States at Front Royal, VA, owned by Avtex Fibers Inc., was closed in late 1989 by Federal and State regulatory agencies because contaminated water discharges containing carbon disulfide and polychlorinated These toxic biphenyls (PCB's). chemicals were produced from rayon manufacture, not sodium sulfate recovery.

Toxicity.—Sodium sulfate was deleted in early 1989 from the list of toxic chemicals under section 313 of Title III of the Superfund Amendments and Reauthorization Act of 1986. The U.S. Environmental Protection Agency (EPA) determined that there was no evidence that sodium sulfate caused, or could reasonably be anticipated to cause, adverse human health or environmental effects as specified in the act.

Employment.—According to the Bureau of Labor Statistics and industry

sources, approximately 300 persons are employed in mining and processing natural sodium sulfate in the United States. No data are available on the number of personnel employed in recovering byproduct sodium sulfate.

Energy Requirements.—The energy requirements to mine natural sodium sulfate are minimal compared with the amount of energy required to process it. An early U.S. Bureau of Mines energy survey reported that 4.5 million British thermal units (Btu's) was required to produce 1 ton of natural sodium sulfate. With the interest in conserving energy, some technical improvements, such as the installation of mechanical vapor recompression crystallizers, have reduced the overall energy requirement to slightly less than 2 million Btu's per ton of sulfate produced.

Transportation.-All natural sodium sulfate is shipped in bulk or in bags by either rail or truck. The mode of transportation depends on the location of the customer, quantity purchased, and difference in freight rates. Because of the location of the natural producers in the West and Southwest, very little natural sodium sulfate is shipped to the East because transportation rates reduce its competitiveness with synthetic sodium sulfate. Consumers in the Midwest and East tend to rely on synthetic sodium sulfate produced in various Midwest and Southern locations.

ANNUAL REVIEW

Total U.S. sodium sulfate production decreased more than 15% in 1992 according to preliminary statistics from the Bureau of the Census. U.S. apparent consumption declined 23%. Most of the decline in output was from byproduct sources that decreased 25% compared with that of the previous year. Production of natural sodium sulfate declined only about 5%. The downturn in production was attributed to the stagnant national economic conditions that

affected some of the industries that recover byproduct sodium sulfate. Although the United States is one of the largest producers in the world of natural and synthetic sodium sulfate, its share has decreased from 23% of world production total in 1980 to 14% in 1992. Figure 1 graphically shows the trend of U.S. production since 1970. Total production has declined 51% since 1970. (See figure 1.)

Issues

The environmental movement in North America continued to adversely affect the North American sodium sulfate industry. Changes toward oxygen-based bleaching chemicals by the pulp and paper industry have reduced the sales by several sodium sulfate suppliers. Some of the chemicals can be produced on-site at various pulp mills. One of the chosen bleaching chemicals, chlorine dioxide, produces sodium sulfate as a byproduct that can be used and partially recycled by the pulp mills. By producing their own sodium sulfate, certain pulp mills would not have to purchase any sodium sulfate.

Sodium sulfate consumption by the soap and detergent industry, which has been the largest consumer of sodium sulfate, remained stagnant because of product reformulations. In addition, the national environmental growing awareness regarding the volume of packaging material discarded to landfills prompted certain detergent manufacturers to begin making superconcentrated or compact products that are packaged in smaller containers. This reduction in package size minimizes the amount of landfill waste but also reduces the quantity of sodium sulfate used in powdered detergents. Sodium sulfate is used as a filler in powdered home laundry detergents.

Production

Domestic sodium sulfate production decreased 15% in 1992 primarily because of reduced demand for saltcake by the pulp and paper industry and declining use of high-purity material in powdered detergents. Formosa Chemicals and Fibres Corp. USA decided not to construct a \$700 million viscose rayon plant near Wallace, LA. Aside from generating 215 tons of sodium sulfate daily, the facility was to process 8,350 tons of hardwood pulp to make 300 tons of rayon fiber each day. The decision to not build the plant was because of long delays in the permitting process and the difficulty of operating the plant under the restrictions imposed by the EPA.¹

The rayon staple fiber plant at Lowland, TN, was purchased in July by Lenzing A.G. of Austria from BASF Corp. The facility has a synthetic sodium sulfate production capacity of 34,000 tons annually. The transaction makes Lenzing the second largest domestic rayon manufacturer; Courtaulds Fibers is the largest.²

A battery recycling center is under construction in Waynesboro, GA, that is scheduled to recover about 27,000 tons of sodium sulfate annually. The facility, which is planned to be on-stream in early 1994, is owned by GNB Inc.³

The United States and Spain were the largest producers of total sodium sulfate, representing 14% each of the world total. Mexico produced 12%, followed by Canada, 7%; Japan and the former U.S.S.R., 6% each; and Germany, 5%. These seven countries accounted for approximately 63% of the world's output of total sodium sulfate, based on obtainable production data. (See tables 5 and 6.)

Consumption and Uses

Domestic sodium sulfate apparent consumption decreased 23% from that of the previous year. Most of the same conditions that affected demand in 1990 still remained in 1992. Concern for the environment was the paramount reason behind the stagnant supply and demand situation. Imports for consumption of sodium sulfate, primarily from Canada, were less than the historical average because of the depressed U.S. markets in which sodium sulfate is consumed.

An estimated 44% of the total sodium sulfate consumed in the United States is

for use as a filler in powdered laundry detergents. Many areas in the country have adopted phosphate bans or limitations because phosphatic detergents contribute to the environmental problems of eutrophication. The affected areas represent about 33% of the U.S. population. In response to this environmental issue, detergent manufacturers have reformulated many of their detergents by switching from sodium tripolyphosphate (STPP) to tetrasodium pyrophosphate, which has the same building power as STPP but requires less to be used, thereby reducing the amount phosphate released into environment. These reformulations used more sodium sulfate as filler, which was beneficial to the sodium sulfate industry.

Sodium sulfate consumption decreased in the Kraft pulping industry because of the economic recession affecting the paper industry and the recycling of paper products. Kraft pulping represented about 83% of the domestic pulp market in 1992. Public awareness about the environmental issue of nondegradable plastic packaging made many people prefer brown paper grocery bags (produced by the Kraft process), which degrade in landfills much more readily than plastic bags. Kraft pulping represents about 24% of the total demand for sodium sulfate.

The use of sodium sulfate in textiles apparently is increasing, according to industry sources. Salt traditionally has been used in the dyeing process to separate organic contaminants, promote "salting out" of dyestuff precipitates, and to blend with dyes to standardize concentrated dyes. The equipment used in this process used stainless steel, which was susceptible to corrosion because of the salt. The textile industry began substituting the salt with sodium sulfate. which is not corrosive to manufacturing equipment. More than 100,000 tons of sodium sulfate was consumed by the textile industry in 1992, according to reliable industry estimates. (See figure 2.)

Stocks

Yearend inventories of natural sodium sulfate stored by the three producers were 47,006 tons, which was a 33% increase over that of the previous year. The material stockpiled was anhydrous sodium sulfate. Synthetic sodium sulfate was marketed mainly through major chemical distributors, which have separate storage facilities from the producers.

Markets and Prices

The average value declined from \$87.34 per metric ton (\$79.23 per short ton) in 1991 to \$77.97 per metric ton (\$70.73 per short ton) in 1992 for bulk sodium sulfate, f.o.b. mine or plant.

In May, Elf Atochem North America announced that it was raising its price of natural sodium sulfate by \$5 immediately at its bagging facility in Charlotte, NC.⁴ Prior Chemical Corp. announced an increase in its price of bagged anhydrous sodium sulfate from Mobile, AL, by \$5 per ton effective August 1. The company also indicated that it would raise its offlist price of bagged and bulk material at different supply locations by \$5 as of July 15.⁵ North American Chemical Co. raised its off-list price of sodium sulfate by \$5 effective August 1.⁶ (See table 7.)

Foreign Trade

Canada represented virtually all of the total U.S. imports of sodium sulfate. Some imports were received from Germany, Japan, Mexico, and the United Kingdom. Total imports amounted to more than 158,000 tons in 1992, an increase of almost 1% compared with those of the previous year.

U.S. exports of 155,000 tons were 50% higher in 1992 when compared with those of the previous year. Approximately 46% of the total quantity was shipped to Australia, mainly for consumption by the detergent industry. Sodium sulfate also was exported to Chile, 13%; Colombia, 11%; New Zealand, 9%; and the Republic of Korea, 7%. The majority of exports were in the form of low-purity salt cake. (See tables

8 and 9 and figure 3.)

World Review

Industry Structure.—About 51% of the world sodium sulfate production in 1992 was from natural sources; the balance was represented by synthetic sodium sulfate recovered from various chemical and manufacturing processes. Although the U.S. Bureau of Mines collects or estimates data from 30 sodium sulfate-producing countries. countries are known or assumed to have produced synthetic sodium sulfate, but production statistics are not reported, and available information is inadequate to make reliable estimates of output. (See table 10.)

Capacity.—The data in table 2 are rated capacities for domestic natural operations and byproduct recovering facilities in 1992. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable longterm operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Mine capacity for natural sodium sulfate is derived from available company data on ore throughput to the refinery. The ore refers to mined crystalline sodium sulfate, harvested precipitate, or sodium sulfate-bearing brines. Refinery capacity for natural sodium sulfate pertains to the total amount of anhydrous sodium sulfate that the plant is capable of processing from the ore. Synthetic sodium sulfate-refining capacity is dependent on the production capabilities of the primary industry and the sodium sulfate recovery rates.

Canada.—Salt of the Earth Co. was

formed by members of the former Agassiz Resources Co., which closed in July 1991. The new company acquired Agassiz's plant at Saskatchewan and began producing natural sodium sulfate for sale to the Canadian detergent industry.⁷

Finland.—Kemira Fibres of Valkeakoski constructed a new sodium sulfate plant that increased the company's production capacity by 30,000 tons annually. The new plant, which cost FM30 million (\$6.9 million), replaces the company's existing facility. The material will be sold primarily to various international textile manufacturers.⁸

OUTLOOK

Natural and synthetic sodium sulfate production and consumption decreased 36% and 46%, respectively, from those of 1980 to 1992. The decreases were because of changes in the recovery operations of consuming industries mandated by environmental legislation requiring reductions in sulfate emissions and declining use of sodium sulfate in powdered laundry detergents. Although production has been relatively flat since about 1982, domestic consumption of sodium sulfate has fluctuated primarily due to detergent reformulations that contain reduced quantities of sodium sulfate. U.S. consumption is expected to decline further, or least optimistically remain flat, in the next few years.

The United States has been a very important market for Canadian sodium sulfate. In 1992, 56% of Canadian output was exported to the United States. If domestic markets continue to decline, Canadian producers would continue to encounter financial hardships and would be forced to look for more distant export opportunities or consider possibly mothballing or closing some production capacity until market conditions improve. Sodium sulfate imports from Mexico were relatively minor in 1992 compared with those of the previous years.

Production

The changes in the domestic demand situation have prompted several byproduct sodium sulfate producers to consider changing their process technology that would alter the composition of byproduct wastes. For example, hydrochloric acid plants could use potash, rather than salt, to recover potassium sulfate instead of sodium sulfate. Potassium sulfate is a fertilizer used for tobacco, fruits, nuts, and other crops.

Detergents

The use of sodium sulfate as a filler appears to have peaked in 1989. 1992, sodium sulfate consumption in detergents reportedly was higher than that reported in 1991; however, the quantity of sodium sulfate available for consumption based on preliminary data reported by the Bureau of the Census indicates an opposite viewpoint. According to industry sources, the major detergent manufacturers switched back to making more traditional large boxes of powdered detergent. The changeover is unpredictable and varies depending on the economy, environmental considerations, Sodium sulfate-based detergents compete with some of the popular sodium sulfate-free liquids and superconcentrates, which were first manufactured in Japan in 1987. Since their introduction into the United States in 1989, superconcentrates comprise 29% of the domestic detergent market.

Pulp and Paper

Environmental concerns regarding sulfur emissions prompted many Kraft pulpers to install pollution control equipment to reduce sulfur losses in the pulping process. Furthermore, many Kraft pulpers are changing their bleaching chemicals to abide by the new environmental regulations. Production of sodium chlorate, which is used to make chloride dioxide, will continue to increase as the demand for oxygen-based bleaching chemicals rises. The process will produce sodium sulfate as a

byproduct, thereby reducing the demand for saltcake. Recycling of brown paper bags made by the Kraft process will also reduce sodium sulfate consumption in the future.

Estimated. Revised.

¹Includes natural and synthetic. Total production data for synthetic sodium sulfate, obtained from the Bureau of the Census, were revised in Dec. 1990 M28A Inorganic Chemicals, Current Industrial Report.

²The value for synthetic sodium sulfate is based upon the average value for natural sodium sulfate.

²Chemical Week. Lenzing Expansion Reflects Sunny Outlook in Rayon. V. 151, No. 6, p. 8.

TABLE 2 U.S. PRODUCERS OF NATURAL AND SYNTHETIC SULFATE IN 1992

Product and company	Plant nameplate capacity (thousand metric tons)	Plant location	Source
Sodium sulfate, natural:			
Great Salt Lake Minerals & Chemicals Corp.	45	Ogden, UT	Salt lake brine.
North American Chemical Co., Westend plant	218	Trona, CA	Dry lake brine.
Ozark-Mahoning Co.1	141	Seagraves, TX	Do.
Total	404		
Sodium sulfate, synthetic:			
Lenzing A.G. ²	34	Lowland, TN	Rayon manufacture.
Courtaulds North America Inc.	45	La Moyne, AL	Do.
Cyprus Minerals Co. ³	16	Kings Mountain, NC	Lithium carbonate.
Flour Corp., Doe Run Co.	9	Boss, MO	Battery recycling.
W. R. Grace & Co.	8	Nashua, NH	Chelating agents.
J. M. Huber Corp.	32	Etowah, TN	Silica pigment.
Do.	14	Havre de Grace, MD	Do.
INDSPEC Chemical Corp.	35	Petrolia, PA	Resorcinol manufacture.
North American Rayon Corp.	14	Elizabethton, TN	Rayon manufacture.
Occidental Chemical Corp.	109	Castle Hayne, NC	Sodium dichromate manufacture.
Public Service Co. of New Mexico	6	Waterflow, NM	Flue gas desulfurization.
Teepak, Inc.	6	Danville, IL	Cellulose manufacture.
Star Enterprise ⁴	3	Delaware City, DE	Flue gas desulfurization.
Total	372		
Grand total	776		

Ozark's Brownfield plant, owned by Atochem North America (formerly Pennwalt), was placed on standby in Sept. 1987; 64,000 tons of capacity is not included in total industry capacity.

²Acquired from BASF July 1992.

³Facility idle since 1986.

Owned by Saudi Refining Inc. (50%) and Texaco Inc. (50%).

TABLE 3 WORLD NATURAL SODIUM SULFATE RESERVES AND RESERVE BASE

(Million metric tons)

	Reserves	Reserve base ¹	
North America:			
Canada	84	272	
Mexico	165	227	
United States	857	1,361	
Total	1,106	1,860	
Europe:			
Spain	180	272	
U.S.S.R. ²	1,814	2,268	
Total	1,994	2,540	
Africa:			
Botswana	188	227	
World total ³	3,300	4,600	

¹The reserve base includes demonstrated resources that are currently economic (reserves), marginally economic (marginal reserves), and some of those that are currently subeconomic (subeconomic resources). These definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals."

²Dissolved in Dec. 1991.

³Rounded.

NOTE: Resources of sodium sulfate are known to also exist in Antarctica, Argentina, Chile, India, Iran, Italy, Mongolia, Romania, the Republic of South Africa, and Turkey. Production of synthetic sodium sulfate is dependent on the supply and demand of the primary product.

Estimated. Revised.

¹Natural and synthetic except where noted. Synthetic sodium sulfate data obtained from the Bureau of the Census are revised periodically and may differ from previous published reports by the U.S. Bureau of Mines. World production data also are periodically revised on receipt of updated information.

²Natural sodium sulfate only.

³Estimated using data from "Chemical Profile" issues on sodium sulfate by Chemical Marketing Reporter for 1983, 1986, and 1989.

[&]quot;Included with "Other" prior to 1992.

Includes ceramics, chemicals (potassium sulfate, sodium hyposulfite, sodium sulfide, sodium silicate, and sodium aluminum sulfate), feed supplements, printing inks, sulfonated oils, textile dyeing, veterinary medicines, and viscose sponges.

⁶Dollars per ton for natural sodium sulfate, f.o.b. mine or plant.

Although data from 1990 and thereafter will be published in metric units, historical values based on short tons will continue to be published for reference.

CRUSHED STONE

By Valentin V. Tepordei

Mr. Tepordei, a geological engineer with more than 20 years of industry experience, has been the crushed stone commodity specialist with the U.S. Bureau of Mines since 1981. Domestic survey data were prepared by the crushed and broken stone survey staff of the Branch of Data Collection and Coordination.

Crushed stone is one of the most accessible natural resources and a major basic raw material used by a wide range of industries from construction to agriculture, chemicals, and complex industrial processes. Despite the relative low value of its basic products, the crushed stone industry is a major contributor to and an indicator of the economic well-being of the Nation.

Complying with the provisions of the Metric Conversion Act of 1975 and the Omnibus Trade and Competitiveness Act of 1988 (Public Law 100-418), beginning with this issue of the Annual Report for Crushed Stone, the U.S. Bureau of Mines will publish its statistical information on crushed stone in U.S. customary units as well as metric units. Initially, the reporting in dual units will be applied to the totals only, with increased emphasis on metric units in successive years.

A total of 1.16 billion short tons (1.05 billion metric tons) of crushed stone was produced for consumption in the United States in 1992, a 5.3% increase compared with that of 1991. This tonnage represents the second consecutive year of crushed stone production of more than 1.1 billion tons, approaching the 1987 through 1990 levels of production. (See table 1.)

About three-quarters of the crushed stone production continued to be limestone and dolomite, followed by granite, traprock, sandstone and quartzite, miscellaneous stone, calcareous marl, shell, marble, volcanic cinder and scoria, and slate, in order of volume. (See table 2.)

Foreign trade of crushed stone remained relatively minor again in 1992. Exports increased 66.9% to 4 million tons (3.7 million metric tons) while value

increased 31.5% to \$43 million compared with that of 1991. Imports of crushed stone, including calcium carbonate, also increased 35.1% to 7.7 million tons (7 million metric tons) while the value increased 57.3% to \$60.7 million. Domestic apparent consumption of crushed stone was 1.16 billion tons. (See tables 8 and 9.)

The major issues of concern to the crushed stone industry are: the implementation of the Clean Air Act Amendments of 1990 and its complex legal and technical provisions; the amended Federal Water Pollution Control Act of 1977, the Clean Water Act, section 404, dealing with "wetlands" and the associated "no net loss of wetlands" policy; the Storm Water Pollution Prevention Program; the Occupational Safety and Health Administration's (OSHA) Hazard Communication Standards regulating the use of products containing more than 0.1% crystalline silica; and the provisions of the Federal Endangered Species Act.

The removal of nonasbestiform Anthophyllite, Tremolite, and Actinolite (AT&A) from the scope of the present Occupational Safety Health Advisors standards for regulating occupational exposure to asbestos in 1992 eliminated one of the major area of concern of the construction aggregates industries.

DOMESTIC DATA COVERAGE

Domestic production data for crushed stone are developed by the U.S. Bureau of Mines from voluntary surveys of U.S. producers. Full surveys of crushed stone producers are conducted for odd-numbered years only. For even-numbered years, only annual estimates

for each State are generated based on information provided by the quarterly sample survey of crushed stone and sand and gravel producers. This survey, implemented by the U.S. Bureau of Mines in 1989, provides production estimates by quarters for each State and the nine geographic regions. The sample surveys canvass most of the large companies in each State, accounting for most of each State's production. The results of this survey are published each quarter in the Quarterly Mineral Industry Survey of Crushed Stone and Sand and Gravel Producers.

BACKGROUND

Crushed stone is a term applied to rock that has been broken and/or crushed after quarrying. It is a low-value product characterized by its "place value," a term that describes the importance of the location of the geologic deposit in reference to the market. Stone in its multitude of forms represents a very significant part of the Earth's crust. As one of the most accessible natural resources, it has been used since the earliest days of our civilization. First used as a tool or weapon, it was then used as a construction material, and later. in its crushed form, as one of the basic raw materials for a wide variety of uses, ranging from agriculture and chemicals to complex industrial processes.

The beginnings of the crushed stone industry are difficult to trace, but it is known that the Greeks, and later the Romans, the first great road builders, used limestone and lime extensively. In the 19th century, the mining of crushed stone was labor intensive. Men with sledge hammers and shovels used their

muscles to work the quarries and produce crushed stone that was used mostly for road and railroad construction.² The modern crushed stone industry began in England in about 1815 and expanded rapidly after the invention of the mechanical rock crusher in 1858.³ Today's crushed stone industry is vastly different. It evolved from a laborintensive to a capital-intensive industry where the work force mostly directs and controls sophisticated and powerful equipment operating in the quarries.

In the United States, railroad ballast was the principal market for the crushed stone industry during the last half of the 19th century. Passage of the Federal Aid Highway Act in 1916 acknowledged the national importance of highways, and subsequent highway construction created a new and significantly larger market. The crushed stone industry grew tremendously, especially in the second half of this century. Production increased from 130 million tons in 1928 to a high of 1.25 billion tons in 1988, mainly owing to rapidly increasing demand for highway, railroad, and other construction work. Today the volume of crushed and broken stone produced is greater than that of any other mineral mined in the United States. The United States is, in general, self-sufficient in crushed stone, producing enough to meet most of the domestic needs. Small quantities of crushed stone, used mostly as construction aggregates, are being imported by water from the Bahamas, Canada, Mexico, and to a smaller extent Scotland and the United Kingdom.

Most of crushed stone is used for construction purposes, mainly as aggregate with or without a binder. Road base or road surfacing material, macadam, riprap, and railroad ballast are the major uses without a binder. Aggregate for cement and bituminous concrete in highway and road construction and repair and in residential and nonresidential construction are the major uses for aggregates with a binder. Other uses include cement and lime manufacture, agriculture, metallurgical flux, and fillers and extenders.

Although crushed stone resources are

widespread and in adequate supply in most parts of the United States, local shortages exist. Land use conflicts and environmental problems associated with rapid urban expansion are major factors contributing to these shortages. Demand pressures, land use regulations, and the cost of meeting environmental and reclamation requirements are factors that will cause a rising price trend. Larger operations with more efficient equipment, more automation, and better planning and design will be the trend of the industry in the future.

Definitions, Grades, and Specifications

Crushed and broken stone is a term applied to rock that has been broken and/or crushed into smaller, irregular fragments or ground to specified particle sizes. Crushed stone is also classified by kind of stone, including limestone, dolomite, marble, shell, granite, traprock, sandstone, quartzite, slate, volcanic cinder and scoria, and miscellaneous The terminology used by the stone. crushed stone industry is not always consistent with mineralogical definitions. Limestone and dolomite are rocks composed, respectively, of the minerals calcite, CaCO₃, and dolomite, CaMg (CO₃)₂; however, they are usually called limestone by the industry, and intermediate varieties are seldom Some deposits of distinguished. limestone consist chiefly of the mineral which has the aragonite. composition as calcite, but has a different crystal structure. Marble may include any calcareous rock that will accept a polish. Marl is calcitic and contains varying amounts of shale or clay. Granite includes the coarser grained igneous rocks such as true granite and syenite. Gneisses, although metamorphic rocks, are usually included with granite. Quartzite is a well cemented sandstone that is indurated to the extent that, when fractured, it breaks across the grain. Traprock includes all dense, dark, and fine-grained igneous rocks such as basalt, diabase, and gabbro.

Crushed stone in its different rock types and particle sizes is used in a wide

variety of applications in many industries, including construction, chemical, metallurgical, and agriculture. For the purpose of collecting and disseminating production information, the U.S. Bureau of Mines generally accepts the rock type classification and the principal end uses and their definitions as reported by the crushed stone producers.

Specifications for crushed stone are numerous because of the large number and the variety of uses, the diversity of stone types, and the variations in physical and chemical requirements for different uses. Various national specifications and tests exist for crushed stone products, but the most active organizations in preparing and reviewing them are the American Society for Testing and Materials (ASTM)⁴ and American Association of State Highway and Transportation Officials (AASTO). For construction aggregates, these are regarded by industry as guide or reference specifications. State specifications are often much more stringent and vary from The most common State to State. specifications and tests relate primarily to gradation, but soundness, shape, abrasion resistance, porosity, chemical compatibility, and content of soft particles are also important.⁵ Specifications for construction aggregates are written by commercial users; government agencies, including Federal, State, county, and city construction and highway departments; and the ASTM. Problems arise for the producers of construction aggregates when their product is sold or used in several different cities, counties, or States, many of which may have different specifications. Some progress is being made toward the standardization of aggregate sizes for similar requirements. A need exists for a more active interchange of data and experience among aggregate consumers and producers.

Specifications for limestone used in portland cement manufacture require a content of more than 75% calcium carbonate (CaCO₃) and less than 3% magnesium carbonate (MgCO₃). For white portland cement, the iron content of the raw materials should be very low, less than 0.01%. Because raw materials

are finely ground for processing, chert nodules or coarse quartz grains are Limestone for lime undesirable. manufacture should contain more than 90% calcium carbonate, often more than 97% or 98%, less than 5% magnesium carbonate, and less than 3% of other impurities. For lime produced in vertical kilns, 5- to 8-inch stone is recommended. while in rotary kilns 3/8- to 2 1/2-inch stone may be used. Limestone and dolomite should be sufficiently hard so as not to decrepitate when heated. Highmagnesium lime made from dolomite than should contain more 40% magnesium carbonate.

Specifications for the use of limestone or dolomite as fluxstone vary with the pyrometallurgical process, the kind of ore processed, and the final use of the slag: silica content should not exceed 2% to 5%, magnesia content should be less than 4% to 15%, and sulfur less than 0.1%. Size specifications also vary and include ranges from 1 to 4 inches, 2 to 4 inches, and 3 to 6 inches. The limestone or dolomite used for glassmaking should contain at least 98% CaCO₃ or MgCO₃, respectively, and less than 0.05% to 0.02% iron oxide. Size specifications vary with the manufacturer and the kind of glass being produced, but uniformity is a major requirement; usually 100% of the material should pass a No. 10 sieve (2 millimeters) and 96% to 100% should be retained on a No. 100 sieve (0.15 millimeters).

Requirements for agricultural limestone are not very rigid and depend on the specific use: as direct application to soil, as filler and conditioner for fertilizers, in animal mineral feeds, or as poultry grit. In all of these applications, CaCO₃ or MgCO₃ equivalent or content is of major significance. Many individualized specifications exist for a wide variety of industrial applications, mostly pulverized limestone for rock dusting, or as asphalt, plastic, rubber, paper, or paint fillers or extenders.⁶

Products for Trade and Industry

The ultimate use of crushed stone determines the specification for particle

size and gradation, shape, rock type, and chemical composition. Crushed stone can be used without any binder, for a variety of construction or industrial applications, or it may be mixed with a matrix binding material such as bituminous or portland The most common use of crushed stone for construction purposes is as aggregate without a binder, including road base or road surfacing material, macadam, riprap, railroad ballast, filter stone, etc. The second largest use of crushed stone is as aggregate for cement and bituminous concrete in a variety of forms and applications in residential and nonresidential construction, highway and road construction and repair, airports, dams, sewers, and foundations. Sized crushed stone is used to make asphaltic concrete aggregate and road bases. Broken surfaces adhere to the hot asphaltic mixture better than rounded surfaces do and provide interlocking surfaces that tend to strengthen the asphaltic concrete. Broken particles pack better and tend to move less under load than rounded particles do and, therefore, make better road bases for highway and road construction. This is essential because bases and asphaltic concrete tend to flow when placed under great or long duration stresses. Other uses include limestone for cement and lime manufacturing and as agricultural limestone used as direct application to soil, as filler and conditioner for fertilizers, in animal mineral feeds, or as poultry grit. Smaller amounts of crushed stone are used for a wide variety of applications ranging from metallurgical fluxing of antimony, copper, iron, lead, and zinc to the manufacture of glass, ceramic pottery, paper, and as fillers and extenders in asphalt, paint, rubber, and plastics.

A growing amount of limestone is being used in the removal of sulfur oxides from stack gases, primarily from coal burning electric generating stations, and for mine dusting to enhance mine safety by reducing the explosion risk of highly combustible coal dust.

Industry Structure

Because of the low unit value, crushed stone is usually produced near the point of use; therefore, the industry is concentrated mostly in or nearby large, rapidly expanding urban areas. Crushed stone is produced in every State except Delaware, with more than 75% of the national total coming from two major geographic regions, the South and Midwest. The largest quarries tend to be concentrated in the States with the largest populations and largest productions of crushed stone.⁷

Although limestone is produced in all States except Alaska, Delaware, Louisiana, New Hampshire, and North Dakota, the major producing States are east of the Rockies. Crushed marble is produced mostly in the eastern part of the United States in Alabama, Georgia, and Pennsylvania. Crushed granite is produced primarily in Appalachia, with Georgia, North Carolina, South Carolina, and Virginia being the largest producing States. Crushed traprock is produced mainly in the northeast and the Pacific Coast States. with California, Connecticut, Massachusetts, New Jersey, Oregon, and Washington the largest producing States. Crushed sandstone and quartzite are produced in 27 States led by Arkansas, California, and Pennsylvania. Most crushed slate is produced in the Eastern part of the United States, mainly in Arkansas, Georgia, and Virginia. Shell, primarily oyster residue, is produced by dredging along the Gulf Coast. Volcanic cinder is produced in the West, mainly in Arizona, California, and New Mexico.

On the basis of tonnage, the crushed stone industry is the largest nonfuel mineral industry in the United States. The industry is widespread and has a large variation in operation size, kind of stone, and size of material produced. The individual companies range in size from small, independent producers with 1 quarry to large, diversified corporations with 50 or more crushed stone operations.

In 1991, the last year when a complete survey of the crushed stone producers

was conducted. 1,597 companies produced crushed stone from 3,287 operations with 4,011 active quarries. Individual crushed stone quarries range in size from those producing between 1 and 11 million tons annually to those reporting less than 50,000 tons per year. However, most of the tonnage comes from large operations. In 1991, for example, 53 operations each reporting production of more than 2 million tons per year represented only 1.7% of the total number of operations, but accounted for 17.4% of total crushed stone The large operations are production. owned or operated by a small number of companies. In 1991, the combined production of the top 10 producers operating 507 quarries accounted for 30% of the total output of crushed stone in the United States.

The 10 leading producers were Vulcan Materials Co.; Beazer USA Inc./Hanson PLC; Martin Marietta Aggregates; Lafarge Construction Materials; Dravo Basic Materials Co.; CSR America, Inc.; Material Services Corp.; Florida Rock Industries Inc.; Rogers Group Inc.; and Lone Star Industries Inc.

In the past several years, significant changes in the structure of the crushed stone industry have occurred, caused primarily by mergers and acquisitions. An established and well managed company with significant reserves in the ground becomes a potential target of larger companies trying to lock up sufficient reserves or expand into the aggregate business. Some of the recent acquisitions were made by foreign companies or were associated with the influx of foreign capital. Two of the top five crushed stone-producing companies in 1991 are subsidiaries of foreign companies.

The United States is the largest producer of crushed and broken stone among the market economy countries. Other major producing countries are Australia, Canada, France, Germany, Japan, and the United Kingdom. Some information about the production of crushed stone in foreign countries may be found in the U.S. Bureau of Mines Minerals Yearbook Volume III, Area

Reports: International. For nonreporting countries, estimates of crushed stone outputs can be based on indirect sources such as the level of cement consumption.

Geology-Resources

Bedrock deposits are classified on the basis of their origin into sedimentary, igneous, and metamorphic Sedimentary rocks were produced from the consolidation of loose sediments through chemical or mechanical sedimentation. Limestone, which is primarily calcium carbonate (CaCO₃), and dolomite, which is calcium-magnesium carbonate [CaMg(CO₃)₂], are the most common sedimentary rocks produced through chemical or biochemical sedimentation. Limestone and dolomite formations are widespread in the United States, with most of the deposits being of Paleozoic age, with a few of Mesozoic and Tertiary age. Most States have adequate reserves for use in construction and other applications that do not require chemically pure stone.8 High-calcium limestone and high-purity dolomite make up only a small fraction of all limestone and dolomite formations, and occur in restricted areas, mostly in the eastern part of the United States, with some formations in the Western States as well.9 High-purity dolomite deposits are more limited in occurrence than the highcalcium limestone. Of the clastic sedimentary rocks that are produced through mechanical sedimentation, only sandstones, rocks consisting predominantly of cemented sand-size particles, are, to a limited extent, used as crushed stone.

Igneous rocks, rocks that solidify from molten volcanic magma, are classified as intrusive and extrusive rocks. Intrusive or plutonic rocks are those that were formed deep beneath the ground surface, are coarse grained, and include granite, diorite, and gabbro as rock types. Extrusive or volcanic rocks are igneous rocks that were formed from molten volcanic magma at the Earth's surface, are fine grained, and include andesite, rhyolite, and basalt. Plutonic and volcanic rocks are further subdivided on

the basis of mineralogy in light-colored igneous rocks with high-silica content that includes granite, diorite, rhyolite, and andesite, and dark-colored igneous rocks low in silica content that include gabbro, diabase, and basalt, commonly called traprock. Granite and traprock are the most common igneous rock-types used as crushed stone. Granite occurs primarily in the eastern part of the United States from Maine to Georgia, along the Appalachian Range where major producing States are located. It also occurs in Arkansas, Minnesota, Missouri, Oklahoma, Texas, and Wisconsin, and in all Western States except Utah. Most of the traprock occurs in California, Hawaii, Idaho, Oregon, and Washington in the West: in Connecticut, Maryland, Massachusetts, New Jersey, New York, North Carolina, Pennsylvania, and Virginia in the East: and to a smaller extent in Minnesota and Texas.

Metamorphic rocks are formed from preexisting rocks through mineralogical, chemical, and structural changes produced by high heat and pressure. The metamorphic rocks include gneisses, marbles, quartzite, slates, and schists. Marble, quartzite, and slate are the major types of metamorphic rocks used to some extent as crushed stone. Marble occurs primarily in Alabama, Georgia, New York, Vermont, and Virginia in the East, and in California and Texas in the West.

A comprehensive report showing geologic occurrences of potential sources of crushed stone and sand and gravel of the conterminous United States for use as natural aggregates was published by the U.S. Geological Survey.¹⁰

On the basis of geologic evidence, stone resources of the United States and the world are sufficient to meet demands, although not always precisely at the locations where needed. Reserves, which are measurable amounts of crushed stone that can be produced profitably with current technology under existing economic and political conditions, are controlled mostly by land use and/or environmental constraints. The actual volume of stone available is so vast as to preclude the necessity of measurement on a large scale. The local shortages that occasionally exist are caused less by a lack of stone than by urban encroachment or zoning regulations that force closure of operating quarries or prevent the development of new ones.

Technology

Major technological developments have been instrumental in maintaining adequate production at relatively stable real costs in the crushed stone industry. Equipment manufacturers usually conduct most of the research related to improvements in the mining and processing of crushed stone operations. Larger, more efficient equipment is being developed and improved constantly. The use of computerized control systems in plant operation and quality control has increased significantly in recent years. Automatic controls. along with monitoring by closed-circuit television coordinated with automated counting and recording and radio communications systems, have been installed in many of the larger and newer operations. Automated plants have significantly improved operating efficiency and produce the optimal product mixture to fit market requirements at lower cost.

As part of the national drive to reduce air pollution, significant progress is being made toward the desulfurization of stack gases resulting from coal burning electric generating stations and some industrial installations.¹¹ Limestone and lime are used as chemically reactive agents in most of the dry or wet scrubbing processes as well as in the treatment of acidified waters, specifically lakes and streams.

Exploration.—A large number of geologic formations that have economic potential as a source of crushed stone have been mapped and described in literature over the years. Consequently, detailed exploration and development work for any new crushed stone operation will most probably be done on one of these formations. However, in the event that a new stone deposit is discovered, more exploration and evaluation work would be required before development.

Preliminary examination can establish the extent and nature of the deposit. This is followed by a detailed exploration program aimed at obtaining reasonably accurate information about the quality of the available material, including the kind of stone, its chemical composition and degree of cementation, and the degree of uniformity throughout the deposit. Also, the nature and the amount of waste material and the economic feasibility of its removal, processing, and marketing must be studied. In most cases, an environmental impact study is required by local or State agencies.

If the raw material cost and quality are proven to be adequate and sufficient reserves are demonstrated, development stage of the operation can be started. Economic feasibility and marketing studies include: analysis of the availability of power and water supply; mining and processing costs and requirements; the condition of nearby roads and highways and the proximity of rail haulage; the cost of compliance with local, State, and Federal regulations; and the proximity and density of local population, as well as its attitude toward such a project.

Mining.—Most crushed and broken stone is mined from open quarries; however, in many areas, factors favoring large-scale production by underground mining are becoming more frequent and more prominent.

Surface mining equipment varies with the kind of stone mined, the production capacity needed, the size and shape of the deposit, estimated life of the operation, location of the deposit with respect to urban centers, and other important factors. Ordinarily, drilling is done with tricone rotary drills, long-hole percussion drills, and churn drills. Blasting in smaller operations may still be done with dynamite, but in most medium- to large-size operations ammonium nitrate-fuel oil mixtures (AN-FO), which are much lower in cost, are used.

Underground operations are becoming more common, especially for limestone mining in the central and eastern parts of the United States, as the advantages of

such operations are increasingly recognized by the producers. operating underground, a variety of problems usually connected with surface mining, such as environmental impacts and community acceptance, significantly reduced. Underground room-and-pillar mines can be operated on a year-round basis, do not require extensive removal of overburden, and produce a minimum of environmental disturbance. The need for less surface space is also an important factor in areas of high land costs. Subsidence has not been a problem in areas mined, and the conventional practice has been to leave 12% to 15% of pillar areas and 6 to 8 feet of stone in the mined roof. specific advantage of underground quarries is the creation of valuable storage facilities. In many cases, the value of the sale or rental of the storage space may exceed the value of the stone mine. Thus, the incentives for producing stone from underground mines can be enhanced by the economic advantages of subsequent use of the excavated areas.

Loading and hauling equipment has grown larger as increased demand for stone has made higher production capacities necessary. Track-mounted equipment is still used extensively, but hydraulic, tire-mounted hauling equipment is predominant.

Processing.—Processing plants have become larger and more efficient, in part because of an increase in the use of computerized systems. control controllers and/or Programmable computers are viewed today as valuable tools that improve operating efficiency and product quality. Primary crushing is often done at or near the pit, usually by jaw or gyratory crushers, but impact and other special types of crushers are also used for nonabrasive stone or stone that tends to clog conventional crushers. The cost effectiveness of permanent crushing installations can be limited because the raw material moves away from the primary stage. It becomes increasingly expensive to haul material from the production face to the crushing plant. Improved crusher technology

increased capacity toward equipment mobility are accelerating the use of in-pit movable primary crushers. There is an increased interest in the use of portable crushers ranging in size from 500 tons per hour up to 5,000 tons per hour. For secondary crushing, a variety of comminution equipment is used, depending on plant size, rock type, and kind of material being produced. Cone crushers and gyratory crushers are the most common types used, but impact crushers, including hammer mills, and roll crushers are often used. conveyors are being used extensively to haul material within the quarry because they provide continuous operation, low maintenance costs, low work force requirements, and reduced noise levels. Conveying systems are often associated with in-pit crushers and consist of several portable units and a stationary field conveyor. The portable conveyors, usually in 100- to 200-foot lengths, make the connection between the portable crusher and the field conveyor and provide a good range of motion. The increased use of conveyors reduces significantly the use of haul trucks in quarries.

Screening is the single most important part of the processing cycle of crushed stone particles. A wide variety of screen types exists, and their selection is a function of the material processed as well as the final product required. Inclined vibratory screens are most commonly used in stationary installations, while horizontal screens are used extensively in portable plants. For screening large sizes of crushed stone, grizzly bars, rod decks, and heavy punched steel or plastic plates are used; for smaller sizes, woven wire, welded wire cloth, rubber, or plastic screens are used.

Processed crushed stone is usually stored in open areas except for relatively small quantities that go to the loadout bins. In the more efficient plants, the crushed stone is transported from the storage piles on belt conveyors through tunnels installed under the piles, thus facilitating the blending of any desired mixture of sizes from different piles.

Recycling.—As the Nation moves into an age of increased environmental consciousness, recycling of old concrete and asphalt, used mostly in pavements, is increasing. Local scarcity or high cost of construction aggregates in some areas as well as waste disposal problems are recycling more making attractive economically. In most States, limited recycling, especially in road construction, is either encouraged or required by law. The best utilization for recycled cement concrete is as road base material, because the matrix of concrete cannot be converted back to cement, and also because of the lower strength of concrete compared with that of natural aggregates. Sound crushed concrete can make good coarse aggregate, but the fines produced in crushing the concrete have a higher absorption, are more friable, and will require a higher amount of asphalt in asphaltic concrete and a higher amount of mixing water in portland cement.¹²

The amount of asphalt roads recycled is significantly larger than that of concrete roads, mainly because asphalt can be rejuvenated with oil additives and used in pavements, significantly reducing the cost of the finished road. Experience has shown that about 35% of crushed asphalt pavement can be recycled into new asphalt mixtures. Proper testing under engineering supervision in all construction projects using recycled materials as aggregates should be performed to ensure that the technical specifications are met.

Byproducts and Coproducts

Clay of good quality is sometimes encountered in limestone overburden and is mined as a coproduct. Gypsum is commonly encountered beneath beds of limestone and is mined as a coproduct. Amphibolite rock commonly occurs as formations paralleling spodumene-bearing pegmatitic dikes and is mined concurrently with these, notably in North Carolina. This coproduct of lithium mining is marketed primarily as roadstone. Stone is also mined in conjunction with many metallic ores and nonmetallic minerals, but seldom does a market exist for it.

Economic Factors

Crushed stone is a high-volume, low value commodity. The industry is highly competitive and is characterized by thousands of operations serving local or regional markets, largely because stone is an abundant mineral. Production costs are determined mainly by the cost of labor, equipment, energy, and water, in addition to the costs of compliance with environmental and safety regulations. These costs varv depending geographic location, the nature of the deposit, and the number and types of products produced. Despite having one of the lowest average per ton values of all mineral commodities, the constant dollar price of crushed stone has changed relatively little over the past 20 years. As a result of rising costs of labor, energy, and mining and processing equipment, the average unit price of crushed stone increased from \$1.58 per ton, f.o.b. plant, in 1970 to \$4.70 in However, the unit price in 1991. constant 1987 dollars fluctuated between \$3.37 and \$3.90 per ton, while the unit price in constant 1970 dollars fluctuated between \$1.41 and \$1.63 per ton for the same period. Increased productivity achieved through increased use of automation and more efficient equipment was mainly responsible for maintaining the prices at this level.

The delivered price of the product, in addition to quality, is a particularly important element in any major transaction because of the low unit value of crushed stone, and therefore, producers that are closest to markets have a significant advantage. Sophisticated equipment backed by technical knowledge combined with solid sales expertise are becoming very important. For this reason, large companies are better able to compete in the crushed stone business, especially when there is a need for a wide variety of products. Smaller, less efficient operations become less economical as operating costs, as well as costs associated with meeting various Federal, State, and local regulations, continue to increase. The only alternatives these producers have are to

CRUSHED STONE—1992

supply local markets with a limited number of products. The gradual trend toward larger operations has continued, mostly because the stone industry is capital intensive, and it is becoming less economical to operate small quarries. The viability of small operations is dependent on the demand in the local markets, mining costs, and the degree of processing required to supply the final product.

A 5% depletion allowance based on gross income is allowed for crushed stone used in construction, including aggregates. The depletion allowance for chemical and metallurgical crushed stone is 14%.

Operating Factors

Many States, counties, and cities in the United States have zoning laws, and land within each governmental unit is usually zoned to indicate acceptable land uses. If mining is permitted in a zone and a crushed stone company owns or leases land within that zone, the company may apply for a use permit or its equivalent to begin an operation. If the parcels to be quarried are on lands under both city and county jurisdiction, permits usually must be obtained from each. An acceptable reclamation plan that meets the guidelines regulations of the appropriate governmental agency must also be approved. Environmental concerns such as noise, dust, beautification, and storage of wastes must be accounted for in a manner satisfactory to the governmental entity involved. Wastewater discharge requirements must be planned for and met. If the deposit to be worked is on land controlled by a State or Federal agency, that agency's requirements must also be satisfied.

In most States, permits for crushed stone operations require an Environmental Impact Report (EIR) or Environment Impact Statement (EIS). A reclamation plan and a use permit application may also be required, with considerable overlap of subject matter with the EIS. A complete EIS may cover all the problem areas at once and facilitate acceptance.

Environmental Issues.—Many of the environmental problems facing crushed stone producers arise because a great number of stone quarries and processing plants are in suburban areas near the major crushed stone markets. environmental considerations that must be dealt with in mining and processing of crushed stone are emission of particulate matter into the air, discharge of processing water, noise abatement, and employee and public health and safety. Air pollution constitutes a major problem in processing plants, especially in the drying and packaging stages of fine particle products such as limestone used as fillers or extenders. Both wet and dry methods of dust control are used. The most important water pollutant is clay in suspension that results from washing and screening crushed stone. Because of the large quantities of water used to process stone and the need for compliance with often stringent regulations, the treatment of discharge water by crushed stone producers is becoming a necessity that may require sophisticated and expensive processing methods. Significant progress has been made in reducing noise pollution both inside and outside of the quarries, including noise and vibration produced by blasting and movement of heavy trucks. Therefore. the industry must be concerned first about any practices that can affect the community environment. An effective effort must be made to reduce noise, air, and water pollution and to improve the overall appearance of the operating mine, processing plant, and transportation facilities. Second, the industry and community must recognize the time and costs required to protect the environment and the importance of agreeing on fair and realistic environmental standards. Because crushed stone is a local industry, the effect of supply deficiencies and cost of material will affect the local community first. Undue delay and unreasonably high cost can strongly affect the movement of crushed stone into the marketplace. Also, stringent controls by the local governments that prevent permits being issued to operators can have adverse economic effects on the communities around them. These conditions can make it difficult to assess the timing and even the possibility of plants going on-stream and can therefore affect the supply of crushed stone into the marketplace.

Although much progress is being made through premining planning, the crushed stone industry continues to have problems with environmental controls, land use conflicts, and reclamation practices. Many of these problems are acute because extraction areas and plants must be reasonably near consumers who are largely in metropolitan areas.

Transportation.—Transportation is a major factor in the delivered price of crushed stone. The cost of moving crushed stone from the plant to the market often equals or exceeds the sales price of the product at the plant. Because of the high cost of transportation and the large quantities of bulk material that have to be shipped, crushed stone is usually marketed locally. The high cost of transportation is responsible for the wide dispersion of quarries around the country, usually near highly populated areas.

However, increasing land values combined with local environmental concerns are moving crushed stone quarries farther from the end-use locations, increasing the price of delivered material. Economies of scale, which might be realized if fewer, larger operations served larger marketing areas, would probably not offset the increased transportation costs.

Truck haulage is the main form of transportation used in the crushed stone industry, despite the fact that it is the most expensive mode of transportation on a cost-per-ton/per-mile basis. producers have their own truck fleet and deliver their own raw materials and products. A significant and increasing amount of crushed stone, however, is being hauled by independent truckers because of the cost of maintaining a truck fleet, particularly when the market is highly variable. Rail and water transportation combined account for about 8% of total crushed stone shipments. In recent years, an increased amount of crushed stone is being shipped into the

CRUSHED STONE—1992 1285

United States by water from Bermuda, Canada, Mexico, and the United Kingdom, using large oceangoing vessels. Some of these are self-unloading vessels.

ANNUAL REVIEW

A total of 1.16 billion short tons (1.05 billion metric tons) of crushed stone was produced for consumption in the United States in 1992, a 5.3% increase compared with that of 1991. This tonnage represents the second consecutive year of crushed stone production of more than 1.1 billion tons, approaching the 1987-90 levels of production. (See table 1.)

Legislation

On June 8, 1992, OSHA announced that it was amending its standards governing the "Occupational Exposure to Asbestos, Tremolite, Anthophyllite, and Actinolite (AT&A)"13 by removing nonasbestiform AT&T from the scope of the present standards affecting the general industries, including the construction industries. OSHA has determined that substantial evidence is lacking to conclude that AT&T present the same type or magnitude of health effect as asbestos or that employees would be at significant risk because nonasbestiform AT&T were not regulated in the asbestos standards. The nonasbestiform varieties will be regulated according to limits set for "particulates not otherwise regulated." The latest administrative stay enforcement of the revised standards was also removed by OSHA effective May 29, 1992.

The U.S. Environmental Protection Agency (EPA) issued final general stormwater permits to regulate discharges resulting from industrial and construction activities that disturb 5 or more acres. Facilities that must be covered by a stormwater permit include many mining operations where water comes into contact with raw materials or wastes. All facilities covered by a general permit must prepare and implement a site-specific stormwater pollution-prevention plan. To assist industry in complying with the stormwater requirements, the

EPA has developed guidance manuals on sampling and on pollution prevention management practices.

The removal of nonasbestiform AT&T from the scope of the present OSHA standards for regulating occupational exposure to asbestos in general industries, including the construction industries, eliminates a major area of concern for the construction aggregates industries.

Issues

The new complex legal and technical provisions of the comprehensive amendments of 1990 to the Clean Air Act and the implementing regulations for these provisions constitute a major area of concern to the crushed stone industry. One major emphasis of the amendments is expanded authority given to EPA and the States to enforce the new law and asses increased penalties. EPA is now authorized to issue administrative orders with penalties of up to \$200,000 for noncompliance, and its field inspectors can issue citations for minor violations with penalties of up to \$5,000 per day for each violation. The law also includes provisions for new Federal permits to be issued by the State agencies that include source specific emission limitations and related monitoring, recordkeeping, and reporting requirements. Complying with the new provisions of the Clean Air Act Amendments will constitute a major challenge to all crushed stone producers.

The implementation of the provisions of the amended Federal Water Pollution Control Act of 1977, the Clean Water Act, section 404, dealing with "wetlands" and the establishment of a "no net loss of wetlands" policy constitutes one of the major areas of concern to the crushed stone industry. There is a significant amount of uncertainty regarding the process of designating some lands as wetlands and whether the current exemptions to the Clean Water Act, section 404, permit program will be maintained in the future. Several bills were reintroduced in the 103d U.S. Congress to replace the current section 404 of the Federal Water Pollution Control Act. The new proposed bills plan to provide a concise and structured program for the delineation of wetlands based on their functions and values and will balance the need for effective protection of the Nation's important wetlands with the need for essential community growth and the constitutional rights of landowners.

Another issue of concern to the construction aggregates industries is the classification of crystalline silica as a probable human carcinogen by the International Agency for Research on Cancer, an agency of the World Health Organization. OSHA-regulated sites that receive and/or use products containing more than 0.1% crystalline silica must with OSHA's Hazard comply Both the Communication Standard. classification of crystalline silica as a probable human carcinogen and the requirement to quantitatively analyze for crystalline silica at the 0.1% level are controversial.

Production

A total of 1.16 billion short tons (1.05 billion metric tons) of crushed stone was produced for consumption in the United States in 1992, a 5.3% increase compared with that of 1991. (See table 1.) Based on prior year data, it is estimated that about three-quarters of the crushed stone production continued to be limestone and dolomite, followed by granite, traprock, sandstone and quartzite, miscellaneous stone, marble, shell, calcareous marl, volcanic cinder and scoria, and slate, in order of volume. Production information by kind of stone is available only for oddnumbered years when full surveys of crushed stone producers are conducted by the U.S. Bureau of Mines.

The production estimates indicate that in 1992, compared with the reported 1991 data, the output of crushed stone increased in all geographic regions except the Pacific. The largest increases were recorded in New England, 19.3%; the East South Central, 14.7%; and the West North Central, 12.4%. The only region showing a decrease in the production of crushed stone was the Pacific with -10.6%.

The South Atlantic region continued to lead the Nation in the production of crushed stone with an estimated 252 million tons or 21.7% of the U.S. total, followed by the East North Central region with 228 million tons or 19.7%, and the East South Central region with 137 million tons or 11.8%. (See table 3.) Crushed stone was produced in every State except Delaware.

The 10 leading States in the production of crushed stone, in order of volume, were Illinois, Pennsylvania, Texas, Florida, Kentucky, Missouri, North Carolina, Ohio, Virginia, and Tennessee. Their combined production represented 49.7% of the national total.

Significantly less changes in ownership, acquisitions, and mergers occurred in the crushed stone industry in 1992 compared with prior years. Martin Marietta Aggregates of Raleigh, NC, acquired in the first half of 1992 a 50% interest in Kaser Corp. of Des Moines, IA. Kaser operates 10 quarries in Iowa and 3 quarries in Missouri.

Granite Construction Co. of Watsonville, CA, acquired from Tarmac America of Herndon, VA, 13 crushed stone and sand and gravel operations in southern California. The transaction also included 10 ready-mixed concrete plants and 5 asphalt operations.

Consumption and Uses

Crushed stone production reported to the U.S. Bureau of Mines is actually material that was either sold or used by producers. Stockpiled production is not reported. Therefore, the "sold or used" tonnage represents the amount of production released for domestic consumption or export in a given year. Because some of the crushed stone producers reported only their total production and no breakdown by end uses, their production is included in "Unspecified, actual" totals. estimated production of nonrespondents is reported under "Unspecified, estimated." (See table 7.) Production information by uses of stone is available only for oddnumbered years when full surveys of crushed stone producers are conducted by the U.S. Bureau of Mines.

Prices

Compared with the actual prices of 1991, the 1992 estimated average unit price for all crushed stone increased 2.6% to \$4.82. Over a 21-year period, the average unit price of crushed stone increased from \$1.72 per ton, f.o.b. plant, in 1972, to \$4.82 in 1992. However, the unit price in constant 1987 dollars fluctuated between a low \$3.37 per ton in 1991 and a high of \$3.90 in 1971. Price information by kind of stone and uses is available only for odd-numbered years when full surveys of crushed stone producers are conducted by the U.S. Bureau of Mines.

Foreign Trade

The widespread distribution of domestic crushed stone deposits and the high cost of transportation limits foreign trade mostly to local transactions across international boundaries. U.S. imports and exports are small, representing less than 0.5% of the domestic consumption. However, shipments of crushed stone by water from Canada and Mexico are increasing.

Exports.—Exports increased 66.9% to 4 million tons (3.7 million metric tons) while value increased 31.5% to \$43 million compared with that of 1991. About 95% of the exported crushed stone was limestone. Canada remains the major destination for the exported crushed stone with 88.3% of the total exports. (See table 8.)

Imports.—Imports of crushed stone, including calcium carbonate, also increased 35.1% to 7.7 million tons (7 million metric tons) while the value increased 57.3% to \$60.7 million.

About 92% of the imported crushed stone was limestone, 47% of which came from Mexico, 31% from Canada, and 12% from the Bahamas. (See table 9.)

Imports of natural calcium carbonate fines decreased slightly to 2,300 short

tons. About 65% of processed calcium carbonate was imported from France.

Shipments of crushed stone from the Bahamas, Canada, and Mexico into the United States continued in 1992. The imported crushed stone, used mostly as construction aggregates or for cement manufacturing, was distributed in Alabama, Florida, Georgia, Louisiana, Michigan, New York, Ohio, Pennsylvania, Texas, and Washington. This trend is expected to continue, and the volume of imports, especially from Mexico, to increase.

World Review

Canada.—The 1991 production of stone in Canada was 88 million metric tons, a decrease of 21% from the revised final 1990 total of 111 million tons. valued at \$663 million. The Province of Ontario continued to be the largest producer of stone, with 38.7 million tons valued at \$238 million, followed by Quebec with 34.8 million tons valued at \$209 million. The two Provinces accounted for 83.7% of the total stone production. Preliminary estimates for 1992 stone production indicate a decrease of 7% to 81.6 million tons valued at \$508 million. The Provinces of Ontario and Quebec continued to be the largest producers of stone with about 83% of the total output. The above totals do not include the crushed stone used in the Canadian cement and lime industries.

United Kingdom.—The 1991 production of crushed stone in Great Britain (Northern Ireland not included) was 184.9 million tons, a decline of 7% compared with the 1990 total, as reported by the British Geological Survey. Of this total, 148 million tons was used for construction purposes. About 62% of the total output of crushed stone was limestone and dolomite. **Preliminary** estimates indicate that the 1992 production of crushed stone remained at about the same level with the prior year at 185 million tons.

Current Research

Recognizing the need for research into properties and adequate use aggregates, crushed stone, and sand and gravel, as well as the need for reliable technical information in this area, the National Aggregates Association and the National Stone Association established in 1990 the Aggregates Foundation for Technology, Research, and Education (AFTRE.) The main purpose of the foundation was to establish and provide the funding for a new Aggregates Research Center (CAR). On August 25, 1992, the formal ceremonies establishing CAR took place at the University of Texas at Austin. The center will be operated jointly by the University of Texas at Austin and Texas A&M University and financed by the AFTRE. The center's mission is to conduct scientific and technical research related to aggregates; coordinate technology transfer activities: establish a central information clearinghouse on aggregates technology; and develop undergraduate and graduate engineering courses and continuing education programs related to aggregates research.

A technical advisory committee overviewing the center's activity identified six priority areas of research that include: fine aggregates properties and their influence on end products; uses for fines resulting from the processing of aggregates; performance-related tests for aggregates; proper use of aggregates in asphaltic concrete to minimize rutting; prevention of alkali-silica and alkalicarbonate reactivity of aggregates in portland cement concrete; and nature and effects of coatings on aggregates.

Nineteen ninety-two was the last year of the 5-year Strategic Highway Research Program (SHRP) created by the U.S. Congress through the Surface Transportation and Uniform Relocation Assistance Act of 1987. SHRP's mission was to produce usable research results targeted toward technical areas where there is potential for improvement of our highways and the materials used to build them, research that could also yield significant cost savings. SHRP's

research activities account today for more than one-quarter of all highway research conducted in the United States by Federal agencies, States, and the private industry.

SHRP's four areas of research are asphalt, concrete and structures, highway operations, and long-term pavement To improve the performance. performance of asphalt concrete mixtures. a new set of specifications called Superpave is being finalized by SHRP. Superpave specifications use performance-based criteria and take into account environmental factors and traffic volumes and loads, a dramatic departure from earlier mixture specifications.14 SHRP also continues to refine and improve its asphalt binder specifications that will produce a superior quality asphalt and address the rutting, lowtemperature cracking, fatigue cracking, aging, and loss of adhesion problems.

SHRP's concrete program is in the final stage of developing new engineering guidelines, materials tests, and specifications that will produce consistently a more durable concrete for use in highway construction work. SHRP's program identified materials and the processes needed to produce a very early, high strength concrete that requires only 4 hours of curing time, therefore speeding up the construction process and reducing interruptions of the traffic flow.

Alkali-Silica Reactivity (ASR) of concrete is a major cause of deterioration in highway structures and pavements. SHRP's research found that lithium hydroxide introduced into concrete can prevent or inhibit ASR. Laboratory evaluations also showed that lithium hydroxide alone, or in combination with class-F fly ash, is very effective in inhibiting expansion even in concrete made with highly reactive aggregates.

SHRP's structure program is developing guidelines for evaluation, protection, and rehabilitation of structures. The presence of chloride in concrete is the number-one cause of distress in highway structures. Unprotected reinforcing steel used in concrete structures is highly susceptible to chloride-induced corrosion. Several of SHRP's research projects are exploring

new ways of evaluating structures and preventing corrosion.

As the U.S. highway system ages and traffic volumes and weights continue to increase, roadway maintenance expenditures have become the fastest growing portion of highway budgets. The performance of materials, methods, and equipment used in highway maintenance and repair continued to be investigated by SHRP's highway Field tests to operation program. evaluate materials and procedures for pavement repair are being conducted by cooperative States under different climatic and installation conditions. Twenty-two such test sites have been built. The performance of the test sites will be monitored by the Federal Highway Administration (FHWA).

SHRP's Long-Term Pavement Performance (LTPP) program addresses the issue of how best to use and protect the very large investment made every year in building and maintaining highway pavements. SHRP's LTPP program, the largest and most comprehensive pavement performance test in history, is collecting data on pavement conditions, climate, traffic, and load conditions over a 20-year period. Eight hundred of the LTPP test sections contain common types of pavement in use throughout the United States, general pavement studies, and 340 other sites have been specially constructed to study certain engineering factors in pavement design. The collected data will vitally needed provide technical information regarding improved design techniques to highway agencies and pavement design organizations. Since its inception, the LTPP program has been international in scope. Fifteen countries are participating in the program, conducting research, and forwarding data to SHRP.

In July 1992, responsibility for the ongoing LTPP research and data collection effort was assumed by the FHWA, while the Transportation Research Board has assumed responsibility for maintaining the LTPP data base.

A low-cost dewatering technique for fine-grained slurries usually produced in

1288 CRUSHED STONE—1992

the processing of crushed stone has been developed by the U.S. Bureau of Mines. The technique consists of injecting a polymer into the line carrying the slurry and dewatering the resulting flocs on a static, hydrosieve screen. The key to successful dewatering is the formation of strong flocs that will not break apart as the floc moves down the screen. To produce strong flocs, the mixing time and the turbulent conditions in the flow line to the screens must be optimized. This is accomplished by varying the feed rate and the length of pipe carrying the slurry and the polymer mixture to the screens.¹⁵ The initial field tests were conducted at a Birmingham, AL, limestone quarry. The waste slurry consisted of fine-grained calcium-magnesium carbonate. testing program included an evaluation of the parameters for polymer concentration, mixing time, and effect of turbulence during the mixing. Field test results showed that 50% solids were produced using 1.4 pounds of polymer per ton of solids treated, at a cost of \$0.50 per pound of polymer.

Just a few years ago, plant automation was considered to be something that can be implemented only in large crushed stone and sand and gravel operations. Today, plant automation has become a necessity essentially for operations of any size. The principal advantages of plant automation are improved product quality. lower unit cost for the final product, reduced plant wear, and improvements in health and safety of the operators. The current requirements to limit dust and noise exposure for example can, in many cases, be best handled by automating high-exposure tasks and removing workers from potentially high-exposure areas. These factors also apply to retrofitted plants.16

Variations in ore reserves can require careful mixing and blending of stone from different parts of the deposit to meet market requirements. The use of mine planning software presents a series of significant advantages: produces detailed production scheduling; provides significant cost savings, especially by reducing labor costs; provides rapid response in mine planning; and provides

advanced quarry optimization.

Looking at plant automation and the future, two emerging technologies will have a significant impact on this industry: "smart sensors" and "expert systems." Smart sensors will play an important role efficient. more more automation processes while expert systems will be used for diagnosis of plant problems and early prediction of impending failures. Some basic research in the areas of adaptive learning networks (ALN's), fuzzy logic, and neural networks, the underlying technologies for smart sensors, as well as research in the development of expert system to diagnose equipment failures is being conducted by the Bureau.

Technology

The Metric Conversion Act of 1975 declared a national policy of coordinating the increasing use of the metric system in the United States and provided for the establishment of a U.S. Metric Board to coordinate the voluntary conversion to the metric system. It was followed by the Omnibus Trade and Competitiveness Act of 1988 (Public Law 100-418), which declared the metric system measurement "the preferred system of weights and measures for United States trade and commerce." The Act provides that each Agency of the Federal Government, by a date prior to the end of fiscal year 1992, will use the metric system of measurements in procurements, grants, and other businessrelated activities. The only allowed exceptions are for circumstance that will demonstrate that the use of the metric system is impractical or is likely to cause significant inefficiencies or loss of markets to U.S. firms.¹⁷

Mine Safety and Health Administration (MSHA) and FHWA, two Federal Government agencies working closely with the crushed stone and sand and gravel industries, developed plans and schedules for their conversion to the metric system that were published for public comments during 1991. Although the MSHA metrication plan is scheduled to be completed in 18 months and in

place by July 1993, the FHWA metrication schedule expands over a longer period of time and is scheduled to be completed by September 30, 1996.

The U.S. Bureau of Mines is also in the process of completing the conversion to the metric system in all its publications. Beginning with this issue of the Annual Report for Crushed Stone, the statistical information on crushed stone will be published in U.S. customary as well as metric units. Initially, the reporting in dual units will be applied to the totals only, with increased emphasis on metric units in successive years.

The participants of the 1992 European Concrete Study Tour sponsored by the American Association of State Highway and Transportation Officials, FHWA, and American Concrete Pavement Associations observed highways and met with experts in Austria, Belgium, France, Germany, and the Netherlands. also attended presentations made by experts from Italy, Portugal, Spain, and Switzerland concerning portland cement concrete pavements in their countries. The group of 21 American highway and payement experts concluded that "the new and recently built portland cement concrete highways observed were built with a common philosophy—worry more about design, materials, and construction excellence, and less about cost. The European highways featured wellconceived, durable concrete slabs placed on thick, well-drained bases, resulting in superior pavement structures. The pavements were built with the best technology available, much of which has been developed in the United States. The European nations are building their portland cement concrete highways for the future with 30- to 40-year designed service life, compared to our 20 years. The European highways carry a large volume of trucks, with allowable axle weight substantially above those in the U.S. "18

Jointed plain concrete pavements (JPCP) are constructed most often in Europe, and their design has been improved over time through effective research. Continuous reinforced concrete pavements (CRCP) have been built in

CRUSHED STONE—1992 1289

several countries, most commonly Belgium and France. The new and rehabilitation designers in most countries are developed by teams of experts and placed in "pavement design catalogs" for use by design engineers. Emphasis is on the design of total pavement system, not just the thickness of the concrete slab.

Warranties for pavement construction work are used in Europe. For concrete pavements, warranties range from 4 to 9 years. Two-layer slab construction is common in some countries for safety, noise, and economic reasons. A hard high-quality aggregate is used in the upper 4 to 7 cm (1.6 to 2.8 in) of the slab. Two-layer paving equipment is available to place this pavement in one pass.

Rehabilitation of pavements is performed at a higher level of condition than in the United States. Designer CRCP and JPCP overlays are common on old concrete pavements that are often cracked and seated or picked up and crushed and used as base. Jointed, steel-fiber-reinforced concrete and asphaltic concrete pavements have been used successfully in Belgium.

Recycling of pavements is on the rise in Europe, with total recycling of concrete and other construction materials required by law in Austria. Recycled concrete that includes up to 10% recycled asphalt concrete materials is used routinely in Austria. Concrete durability problems do not exist in Europe because high-strength concrete is used. Reduction of pavement-tire noise levels is an important environmental issue in Europe.

Recycling of construction materials, especially concrete and asphalt pavements as well as construction debris, is increasing throughout the United States as well as most industrialized countries. Construction and demolition debris (C&D) are bulky, difficult to handle, and expensive to move and dispose of materials. C&D represent 5% to 15% by weight of the waste stream and, for economic as well as environmental reasons, are becoming a subject of increased interest for expanded recycling programs. The reuse and recycling of C&D can make a significant contribution

to aggregates conservation and reduced landfill requirements. The European Demolition Association, which represents more than 1,000 European demolition and recycling companies in Western Europe. recently conducted a survey of its members. The purpose of the survey was to determine the present status and practices in recycling and the future requirements of its members related to the expected growth of this industry. The review of the information provided by the survey indicated that: recycled material produced from concrete or mixed debris can be used as aggregates in new concrete; there is a need to create a larger market for recycled material by establishing national or preferably European specifications; and despite significant differences between the European Community countries, the volume of recycled C&D is expected to grow faster than in the past. 19 A similar report reviewing the status of recycling of construction materials in Canada was published by the Ontario Ministry of Natural Resources.20

More and more specialized software programs that increase efficiency and productivity of crushed stone and sand and gravel operations are now available. These software programs cover operations from mine planning to drilling and blasting, conveying, dispatching, and equipment management. Many of these software systems can be combined for overall computer management of aggregates operations. The programs can assist quarry and plant operators in increasing output by providing accurate, up-to-the-minute information, some of it not even available in the past. ²¹

OUTLOOK

The demand for crushed stone in 1993 is expected to be about 1.2 billion tons, a 4% increase compared with that of 1992. Gradual increases in demand for construction aggregates are anticipated after 1993 as well, based on increased volume of work on the infrastructure that is being financed by the Intermodal Surface Transportation and Infrastructure Act of 1991 and the recovery of the U.S.

economy. It is estimated that the demand for crushed stone will reach 1.4 billion tons in 1995. The projected increases will be influenced by construction activity primarily in the public construction sector.

Crushed stone f.o.b. prices are not expected to increase significantly, even if the demand for construction aggregates will rise over the forecasts. However, the delivered prices of crushed stone are expected to increase, especially in and near metropolitan areas, mainly because more aggregates are transported from distant sources.

PRODUCTION OF CRUSHED STONE IN THE UNITED STATES IN 1992,
BY GEOGRAPHIC REGION

-				

DIMENSION STONE

By Harold A. Taylor, Jr.

Mr. Taylor, a physical scientist with 27 years of industry, Federal Government, and U.S. Bureau of Mines experience, has been the commodity specialist for dimension stone since 1981. Domestic survey data were prepared by Robin Richardson, statistical assistant.

Production of dimension stone decreased 15% to 1.09 million short tons valued at \$183 million. More than one-half of the dimension stone produced was granite. Limestone, marble, sandstone, and slate were also produced.

Exports of dimension stone decreased 15% in value to \$55 million. The value of dimension stone imports for consumption decreased 15% to \$404 million, equivalent to 221% of the value of domestic production.

DOMESTIC DATA COVERAGE

Domestic production data dimension stone are developed by the U.S. Bureau of Mines from voluntary surveys of U.S. producers of rough and finished dimension stone. The survey of dimension stone producers was not conducted in 1992. A sample survey based on the first 9 months of data was used to generate State annual preliminary estimates. Of the 296 dimension stone operations surveyed for 1991 and 1990, including those that were idle, 256, or 86%, responded, representing 94% of the estimated value shown in table 1. The final 1990 data are based on data from the 1991 survey, and updated 1990 preliminary data for nonrespondents were estimated using preliminary production reports, adjusted prior-year production levels, and employment data. (See table

BACKGROUND

Definitions, Grades, and Specifications

Dimension stone is a natural rock material that has been selected, trimmed,

or cut to specified or indicated shapes or sizes, with or without one or more mechanically dressed surfaces. This includes rough stone, rubble, ashlar, blocks, panel, and curvilinear shapes. Finished surface requirements may vary from a controlled fractured surface to The most ground and polished. prominent required qualities of dimension stone are strength, toughness, hardness, resistance to environmmental damage. Color and grain structure contribute largely to price and marketability. The principal types of dimension stone used in construction are granite, marble, limestone, sandstone, and slate.

Stone classification by type in the dimension stone industry is somewhat ambiguous and does not correspond in some respects with the same terms used in mineralological rock descriptions. The U.S. Bureau of Mines generally accepts the classification reported by producers. Granite includes all feldspathic crystalline rocks of predominantly interlocking texture with mineral grains visible to the naked eye; these include igneous and metamorphic rocks, including quartz diorites, syenites, quartz porphyries, gabbros, anorthosites, and gneisses. White, gray, black, pink, and red are the common colors for granite, but greens, browns, and other shades are produced in some localities.

Limestone includes dolomitic types as well as calcitic. The latter contain less than 5% magnesium carbonate (MgCO₃). Dolomitic limestone contains 5% to 40% MgCO₃. Marble is a recrystallized (metamorphosed) limestone containing grains of calcite or dolomite or both. In commercial usage, it is any calcareous

crystalline rock or serpentine, a hydrous magnesium silicate, capable of taking a polish. Travertine is a type of marble similar to onyx except that it is precipitated from warm or hot water; it has a banded cellular structure and contains cavities up to one-half inch in width that are lined with microstalactites. Dark green serpentines are classified as marble in the industry because they are often crisscrossed with marblelike veinlets of lighter materials, chiefly calcity or dolomite, and because of their ability to take a high polish.

Commercial sandstone is a sedimentary rock consisting mostly of quartz, sometimes with feldspar, or rock fragments of clastic texture bonded by silica, clay, calcite, or iron oxide. Bluestone is a dense, hard, fine-grained feldspathic sandstone that splits easily along a plane into thin, smooth slabs. It is commonly dark or slate gray in color, and its name no longer has color significance. Brownstone is a feldspathic sandstone of brown reddish-brown color caused by abundant interstitial iron oxide. Flagstone may be either a sandstone or a slate that splits into large, thin slabs.

Quartzite is a metamorphic equivalent of sandstone that has been firmly cemented by secondary silica or by recrystallization so that it is essentially homogeneous and fractures through rather than around the original sand grains.

Slate is a fine-grained metamorphic rock derived from shale, siltstone, or claystone. It has prominent cleavage that is oriented independently from the original sedimentary bedding. Mineral constituents are quartz, mica, sericite, or chlorite with assorted minor accessories. Shale is composed mostly of original clay

minerals, and cleavage is parallel to the bedding.

Traprock is a commercial term for all dark, igneous rocks too fine in grain size to be called black granite. In addition to extrusive flow rocks such as basalt, andesite, or dacite, traprock includes intrusive igneous rocks such as diabase, diorites, gabbros, pyroxenites, amphibolites, and peridotites.

Miscellaneous stones used for dimension purposes include schist, scoria, soapstone, wollastonite, argillite, and many others.

Geology-Resources

Domestic resources of most types of dimension stone used in construction are practically unlimited. There considerable interstate transportation of certain types of stone such as Indiana limestone, Georgia marble and granite, and Vermont granite, marble, and slate. A lack of deposits of certain specific varieties of dimension stone especially noted for their esthetic qualities in architecture and artifact manufacture is an important cause of importation of these varieties, for example, brightly colored marbles from Italy.

Technology

Mining.—Present mining methods range from antiquated and very inefficient to modern and technically superior. Quarrying methods include use of various combinations of diamond saws, wire saws, diamond wire saws, chain saws, channeling machines, drilling machines, wedges, and broaching tools. The choice of equipment depends on the type of dimension stone, size and shape of deposit, production capacity, labor costs, economics, and management investment attitudes.

Little blasting is done in the mining of dimension stone. Blocks cut from the face are sawed or split into smaller or thinner blocks for ease in transportation and handling and taken to processing plants, often at the quarry site, for final cutting and finishing operations.

Processing.—Stone-sawing equipment includes large circular saws 10 feet or more in diameter, some with diamond inserts and some using other abrasives; diamond circular saws of smaller size; and reciprocating diamond-bladed or loose-abrasive gang saws for multiple cuts. Various types of diamond and other equipment are used for smoothing, polishing, edging, and decorating the finished stone products. (See table 2.)

Economic Factors

The depletion allowance for dimension stone is 14%. Dimension stone quarries are generally in mountainous or hilly areas remote from areas of dense population. Because land use for other purposes is limited, the cost of land is reasonable.

Transportation costs for dimension stone are high because of its weight and because special handling methods are required to prevent damage to the finished stone. A single stone panel broken in transit not only results in the loss of the many employee-hours of skilled labor required to produce it, but also can cause construction delays that are even more costly. Nevertheless, dimension stone is routinely shipped long distances by motor and rail freight, and special domestic varieties are shipped by ocean freight to foreign countries.

Operating Factors

The dimension stone industry faced several environmentally related issues this year, primarily noise and crystalline silica. The most universal was noise pollution from the handheld burners used in many granite quarries. The operators of these burners, in particular, can be affected by the high noise level. This burner is now used only where the alternate methods using the automatic self-propelled burner, the diamond wire saw, or drill and blast with Primacord cannot be used.

Stone primary and waste products are not toxic, nor are the supplies utilized in their production. However, sufficient exposure to crystalline silica-rich stone

dust can cause silicosis. The firms are required to saw with water and have employee face masks to protect against silica-containing stone dust. Water and air filtration systems specifically designed for dimension stone operations are beginning to be installed in the industry.

Although these issues were primarily or exclusively Federal in origin, other environmental requirements do vary from State to State and are often a cause of conflict between State or local governments and the quarry operators.

The dimension stone-consuming industry does recycle some postconsumer waste, and the producing industry in Vermont is trying to reduce energy and water consumption. A high proportion of granite curbing, about 80%, is recovered and reused again as curbing. Monuments, mausoleums, and tombstones stay in place for centuries, unless disturbed. However, building products usually end up in a landfill. The graniteproducing industry in Vermont is conserving energy by installing more efficient lighting and motors and insulating its plants more. It is also conserving water and eliminating stream pollution by reusing clean water from its recently installed settling ponds.

The approximate number of employees in the dimension stone industry by stone kind are granite, 9,600; limestone, 1,100; marble, 1,500; slate, 950; and sandstone and other dimension stone, 850. Of the total 14,000, about 3,100 are employed in quarrying and approximately 10,900 in finishing operations. Major States for employment were Georgia with 2,100 employees, Vermont with 1,700, Minnesota with 1,250, North Carolina with 850, Texas with 700, and Indiana with 650.

Fuel is used to power quarrying equipment, and electricity is used for sawing and finishing. Water is used in some quarries to cool equipment such as chain saws and in sawing and finishing plants to cool the equipment; water consumption is relatively minimal in all instances.

ANNUAL REVIEW

Production

Dimension stone was produced by 176 companies at 288 quarries in 34 States. Leading States, in order of tonnage, were Indiana, Georgia, and Vermont, together producing 44% of the Nation's total. Of the total production, 50% was granite, 29% was limestone, 12% was sandstone. 3% was slate, 3% was marble, and the remaining 3% was miscellaneous stone. Miscellaneous stone included quartzite argillite, schist, soapstone, and traprock (basalt). Leading producing companies in terms of tonnage were Cold Spring Granite Co., principally in California, Minnesota, South Dakota, and Texas; Rock of Ages Corp. in New Hampshire and Vermont; and Fletcher Granite Co. Inc. in Massachusetts and New Hampshire (1990-91).

Granite.—Dimension granite includes all coarse-grained igneous rocks. Production decreased 4% to 615,000 tons and decreased slightly in value to \$108.8 million in 1992. Granite was produced by 75 companies at 110 quarries in 19 States. Georgia continued to be the leading State, producing 26% of the U.S. total, followed by Vermont and These three States Massachusetts. together produced about 48% of the U.S. total. Cold Spring Granite, Rock of Ages, and Fletcher Granite Co. were the leading producers and accounted for 48% of U.S. production.

Swenson Granite Co. bought the quarries of Coggins Granite Inc. of Elberton, GA, on January 29, 1992. Swenson Granite of Concord, NH, also owns Rock of Ages Corp. of Barre, VT, the major quarrier in Vermont and the owner in turn of an operation in Quebec, Rock of Ages Canada Ltd. In early 1992, Rock of Ages Canada Ltd. In early 1992, Rock of Ages Canada Ltd. purchased 49.9% of Carrieres Norgranit, Inc. and a minority interest in Groupe Polycor, both Quebec granite quarriers. Rock of Ages Corp. sold its 50% interest in Whetstone Granite Co., a granite quarrier in South Dakota and Minnesota,

to co-owner Dakota Granite Co., while retaining some interest in quarry properties.

Coggins also sold its Chapel Rose Quarry in Oklahoma and its Radiant Red Quarry in South Carolina to Swenson Granite Co. The Georgia quarries sold include the Royalty Blue, the Berkeley Blue, and the Millstone, plus nine idle quarries and 2,800 acres of land in three Georgia counties. A few of the idle quarries may be reopened, but a finishing plant is not planned. Swenson has placed these assets with a subsidiary, Royalty Granite Corp.

Keystone Granite Co. and Childs & Childs Granite Co. Inc. formed a joint venture to buy out Matthews International's quarry division, including its North Carolina plant and quarry and two South Carolina quarries. The new venture is called Carolina Quarries Inc. and will emphasize exporting rough blocks.

Two Pacific Coast quarries were announced. One was a white granite quarry south of San Diego, CA, owned by M. W. Mihelich & Associates. The other was a black granite (gneiss) quarry in northeastern Washington owned by Black Star Stone Co. Associated finishing facilities were said to allow or shortly will allow the firms to sell polished or finished products.

Fletcher Granite Corp. tested a prototype water-jet technology for cutting stone at a quarry near Chelmsford, MA.

Limestone.—Dimension limestone includes bituminous, dolomitic, and siliceous limestones. Indiana, the leading State, produced 190,000 tons in 1992 compared with 189,010 tons in 1991 and 198,242 tons in 1990. Wisconsin. usually the second or third largest producer, produced 56,612 tons (revised) valued at \$3,560,400 (revised) in 1991 and 53,500 tons valued at \$4,402,000 in Kansas produced 30,807 tons (revised) valued at \$3,128,000 (revised) in 1991 and 30,315 tons valued at \$3,142,000 in 1990. Alabama Limestone Co. was purchased by Cathedral Stoneworks, Ltd. of New York City from bankruptcy. The new owner planned to modernize the operation.

Marble.—Omya, Inc. began to dissolve its Vermont Marble Co. dimension marble operations late in the year. It hoped to lease its Danby White Quarry and sell its other dimension stone quarries.

Sandstone.—Dimension sandstone includes calcareoussiliceousand cemented sandstones or conglomerates. Ouartzite may be described as any siliceous-cemented sandstone. Ohio produced 47,031 tons (revised) of sandstone valued at \$2,443,000 (revised) in 1991 and 33,976 tons valued at \$2,201,625 in 1990. In 1991, Pennsylvania produced 14,542 tons of sandstone valued at \$1,599,000 (revised) and Utah and Arizona combined totaled 19,630 tons valued at \$902,000.

In addition to the quantities shown in table 7, dimension quartzite totaled 35,877 tons (revised) worth \$2,946,000 (revised) in 1991. Utah and Idaho combined totaled 13,206 tons valued at \$1,127,000 in 1991.

Waller Bros. Stone Co. of Scioto County, OH, bought Briar Hill Stone Co. also of Ohio, from the United Bank of Canton, OH. The company is now back in production at a significant level.

A group of Canadian investors bought Cleveland Quarries Co. of Amherst, OH. It is also producing at a significant level. The investors are planning a new \$5 million finishing plant that will use waterjet cutting technology. (See tables 3 and 4.)

Consumption and Uses

Dimension stone was marketed over wide areas. Industry stockpiles were not monitored, and production during the year was assumed to equal consumption.

Consumption of domestic dimension stone decreased 15% to 1.09 million tons valued at \$182.8 million in 1992 compared with 1.28 million tons valued at \$211.5 million (revised) in 1991 and 1.23 million tons valued at \$232.1 million in 1990.

Consumption of domestic granite decreased to 615,000 tons valued at \$108.8 million in 1992 compared with 632,100 tons valued at \$105.3 million in 1991 and 628,400 tons valued at \$120.8 million in 1990.

Domestic limestone consumption was 368,000 tons valued at \$40.0 million in 1992 compared with 367,100 tons valued at \$49.5 million (revised) in 1991 and 360,600 tons valued at \$51.0 million in 1990.

Domestic marble consumption, including travertine, totaled 43,000 tons valued at \$26.0 million in 1992 compared with 42,980 tons valued at \$26.1 million in 1991 and 29,203 tons valued at \$24.3 million in 1990.

Consumption of domestic slate totaled 32,800 tons valued at \$17.5 million in 1992 compared with 32,800 tons valued at \$17.5 million in 1991 and 35,980 tons valued at \$17.5 million in 1990. (See tables 5, 6, 7, 8, 9, and 10.)

Prices

The average price for dimension stone increased to \$168 per ton, up slightly from \$166 in 1991.

Foreign Trade

Exports.—Exports of dimension stone, about 50% of which was granite, decreased 15% in value.

Imports.—Imports for consumption of dimension stone decreased 15% in value to \$404 million, mostly because of decreases in imports of all major categories of dimension stone. On a value basis, marble accounted for 54% of imports, followed by granite, 29%. (See tables 11, 12, 13, 14, and 15.)

World Review

Some production of dimension stone occurred in most countries of the world. As usual, Italy produced about one-half of the world's total. Other significant producers were Brazil, China, Finland, India, Norway, Portugal, Spain, Sweden,

Turkey, and the United States.

A major dimension stone outlook article was published by an Italian dimension stone specialist. In general, this is a time of weak economies and many uncertainties. World dimension stone production has probably topped out for a while; even hitherto fast-growing Spain had a 5% decrease in production. World dimension stone trade fell even It is predicted that it will get more. worse: dimension stone use in construction lags behind the economy. Conditions in the major markets can be summarized as follows: the Middle Eastern market has been improving along with rebuilding from the Gulf War. The American market was in the worst shape. The European market experienced moderate but slowing growth, ranging from mild negative growth for the United Kingdom to solid positive growth for Germany; Italy had no growth. Japan and the rest of the Far East had extremely strong markets.1

Australia.—Although the industry dates back into the 19th century, it only became sizable in the 1980's. The most important stone is granite, the quarry production of which averages 350,000 cubic feet. Next in importance is sandstone; marble, limestone, and slate are minor. A total of 24 exporters of dimension stone are individually listed.²

Brazil.—The Brazilian Government published its 1991 production statistics; production of rough dimension stone in 1991 (preliminary) totaled 1.65 million tons (77% granite and 23% marble), compared with 1.42 million tons in 1990 and 1.65 million tons in 1989.

Canada.—Newfoundland Slate Inc. completed its facility at Bourgoynes Cove and began limited production this year. The plant and quarry cost about \$6 million and has a capacity of 5,500 tons per year of roofing slate product. Technology for the plant and European marketing was the responsibility of Ardoisieres d'Angers SA, France's leading slate producer. The product will

also be marketed in North America and Japan. The firm is one-half owned by McAsphalt Industries Ltd. of Ontario and one-half owned by a private party.

Italy.—A battle has been raging between the marble quarriers and finishers of Carrara and the local council (government) supported by the Tuscan regional administration. The government wants to develop a park in the higher elevations of the Apuan Alps behind Carrara, above approximately 4,000 feet. Ouarrying is banned inside the park boundaries, and three quarries already have had to close. The marble industry is the direct and indirect source of employment for most of the local inhabitants. The council felt that the park and concurrent stronger enforcement of environmental regulations were long overdue.

Japan.—The nation's largest marble deposit has been discovered in Nyukawa. Gifu Prefecture, when it had been thought that all marble deposits were exhausted. Resources total 53.5 million tons over an area of 0.8 square mile, probably enough for 300 years of domestic consumption. The marble ranges from red to gold and is so hard that it will probably be mostly used in flooring. Quarry production is scheduled to begin in 1995 with an initial product capacity of 1,320 tons per year. Although total domestic demand is expected to grow rapidly, some displacement of European imports is

The U.S. Bureau of Mines dimension stone specialist wrote an experience-based article on the huge Japanese market for granite.³ Although the huge market for monumental granite reportedly has almost no growth, the smaller market for building granite has grown rapidly enough to catch up. Domestic production goes almost entirely to the monumental market, while rough granite imports go to both markets. Imports have been mostly rough granite, but imports of finished granite are rapidly closing the gap. Although Japanese buyers are reportedly very demanding, the expected growth

makes the market very attractive to granite producers.

Spain.—A comprehensive recent article covered the fast-growing Spanish dimension stone industry.4 Spain has very large granite and marble industries and is the world's largest exporter of slate roofing. Production in 1990 totaled 3.41 million tons, of which 1.86 million tons as block was marble, 1.09 million tons as block was granite, and 0.46 million tons was roofing slate. addition, 1.28 million tons of other stone products was produced, almost one-half of it marble. Domestic consumption was apparently about 87% of production; by end use, 36% was consumed as paving and 22% as outdoor building cladding.

A slowdown in domestic construction began in the second half of 1991 as preparations for the Seville World's Fair and the Olympic Games were completed. The largest producers continue to be the Ingemar Group (granite and marble) and the Cupire-Padesa Group (slate). outlook for the Spanish dimension stone industry is for much slower growth. Spain, as part of the European Committee for Standardization, is helping to prepare Europewide dimension stone standards, terminology, and test methods.

United Kingdom.—A recent article on the slate industry indicated that demand for slate in 1991 dropped drastically owing to a recession-triggered slump in construction. Domestic slate production dropped 24% while imports were halved. Penrhyn Quarries Ltd., a subsidiary of Alfred Mc Alpine PLC in Wales, remains the largest producer and, in turn, has U.S. and Irish subsidiaries. Burlington Slate Ltd. is the largest producer in the English Lake District.⁵ Later in the year, both Penrhyn Quarries and Burlington Slate laid off 20% of their employees because of the worsening recession in building.

Current Research

Several helpful publications were released last year. In particular, the Marble Institute of America published The Dimension Stones of the World, Volume I. It lists the physical and chemical properties and has a colored photograph of each of many major U.S. and world stones. This volume will be of great assistance to those interested in individual stones and those in charge of selecting stones.6

Another publication is a bibliographic guide to the literature on dimension stone. It lists more than 270 publications on stone use in buildings, monuments, and art, plus geology, technology, history, trade names, and markets. The publications often cover only one State or quarrying area.7

An article describing stone selection and specification was published. describes how to prepare a successful bid for a job, the adequate preparation leading up to it, and the painstaking followthrough that has to occur.8

An article pointed out that installation of thin stone veneer on buildings was not associated with an increased knowledge of stone properties. It therefore requires careful engineering and testing throughout the design and construction phase. The testing should cover strength, durability, permability, and other factors, including environmental.9

An innovative tile product sold by Granite & Marble World Trade (GMWT) uses water-jet cutting technology to help create inlay patterns and textured surfaces on stone tiles. Creative Edge of Fairfield, IA, GMWT's joint venturer, makes the tile and is presently cutting a 15-foot by 30-foot granite mural of the Chicago skyline for GMWT. Inlay work has traditionally been done entirely by hand.

OUTLOOK

Projected demand for dimension granite totaled 1.5 million tons for 1995 and 2.2 million tons for the year 2000. Demand for dimension marble totaled 400,000 tons for 1995 and 600,000 tons for the year 2000. Demand for dimension limestone totaled 350,000 tons for 1995 and 390,000 tons for the year 2000, while demand for slate should be

35,000 tons in 1995 and 37,000 tons in the year 2000. This relatively slow rate reflects a major drop in the market for building stone in 1989-91 and a welcomed major recovery later in the 1990's. Certain segments will continue to grow rapidly, such as uses in kitchens and bathrooms. The supply will be adequate and is likely to shift in favor of domestic producers.

DIMENSION STONE—1992 1313

¹Includes California, Colorado, Connecticut, Maine, Minnesota, Missouri, New York, Texas, and Virginia.

²Missouri includes a small amount of other dimension stone for 1992.

³Data may not add to totals shown because of independent rounding.

One metric ton is equal to 1,000 kilograms or 2,204.62 pounds. To convert short tons to metric tons, multiply short tons by 0.907185.

⁵Total quantity and total value in metric tons and thousand dollars.

¹Includes Puerto Rico.

²Includes rubble.

³Includes rough stone used for flagging and unspecified uses.

Includes a minor amount of slate used for billiard tabletops, blackboard, bulletin boards, and school slates, and unspecifed uses.

⁵Data may not add to totals shown because of independent rounding.

One metric ton is equal to 1,000 kilograms or 2,204.62 pounds. To convert short tons to metric tons, multiply short tons by 0.907185.

⁷Total quantity and total value in metric tons and thousand dollars.

DIMENSION STONE—1992 1321

STRONTIUM

By Joyce A. Ober

Mrs. Ober, a physical scientist with 15 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for strontium since 1986. Domestic survey data were prepared by Linder Roberts, statistical assistant, and the world production table was prepared by Virginia A. Woodson, international data coordinator.

production of celestite. strontium ore, has grown significantly over the past several years in response to increased demand for strontium carbonate, the most important strontium compound derived from celestite. Trade statistics from the U.S. Bureau of the Census show large increases in imports of both celestite and strontium compounds in These figures, along with decreased exports of strontium compounds, indicate that domestic consumption of strontium remains strong. Although quantities may fluctuate from year to year, the general consumption trends continue to increase.

Chemical Products Corp. (CPC) of Cartersville, GA, was the only U.S. producer of strontium compounds from celestite. CPC produced strontium carbonate from imported ore because there were no active celestite mines in the United States.

Strontium occurs commonly in nature, averaging 0.034% of all igneous rock; however, only two minerals, celestite and contain strontium in strontianite. sufficient quantities to make its recovery practical. Of the two, only celestite has been found to occur in deposits of sufficient size to make development of mining facilities currently attractive. Celestite, the most common strontium mineral, consists primarily of strontium sulfate. Strontianite, the second most common mineral, consists primarily of strontium carbonate. Strontianite would be the more useful of the two common minerals because strontium is used most commonly in the carbonate form, but few deposits have been discovered that are suitable for development.

DOMESTIC DATA COVERAGE

The sole U.S. strontium carbonate producer voluntarily provided domestic production and sales data to the U.S. Bureau of Mines. Production and stock data, however, were withheld from publication to avoid disclosing company proprietary data.

The Bureau also estimated the distribution of strontium compounds by end use. Of the 11 operations to which a survey request was sent, all responded. The information collected from this survey and the information provided by the U.S. Bureau of the Census on strontium trade were the basis for the end use estimates shown in table 2. (See table 1.)

ANNUAL REVIEW

Production

Although there have been no active celestite mines in the United States since 1959, celestite deposits have been identified nationwide. During World War II, domestic mining of celestite resources was conducted in Texas and California. U.S. celestite mines had at that time been inactive since World War I, and strontium minerals were imported to satisfy domestic demand.

Strontium carbonate, the most important strontium compound by far, was produced in 1992 by one company in the United States. CPC was the only domestic company that produced strontium chemicals from celestite. All the celestite CPC used was imported from Mexico. CPC utilizes the black ash method of strontium carbonate production

at its facility. The black ash method and the soda ash method are the two most common recovery techniques. The black ash method, known alternatively as the calcining method, produces chemical-grade strontium carbonate, which contains at least 98% strontium carbonate. The soda ash or direct conversion method produces technical-grade strontium carbonate, containing at least 97% strontium carbonate.

The black ash method received its name because the first step in the procedure involves mixing the crushed and screened celestite with powdered coal, making a black mixture. The mixture is then heated to about 1,100° C, expelling oxygen in the form of carbon dioxide from the insoluble strontium sulfate to form water-soluble strontium sulfide.

Strontium sulfide is dissolved in water and the resulting solution filtered. Carbon dioxide then passes through the solution or soda ash is added. Either compound provides the necessary carbon and oxygen for strontium carbonate to form and precipitate from the solution. The precipitated strontium carbonate is then removed from the solution by filtering and is dried, ground, and packaged. The sulfur released in the process is either recovered as elemental sulfur or as other byproduct sulfur compounds.

In the soda ash method, ground celestite is washed and most of the water removed. The thickened mixture is then mixed with soda ash and treated with steam for 1 to 3 hours. During this time, celestite and soda ash react to form strontium carbonate and sodium sulfate. Sodium sulfate is water soluble, making

it possible to separate the insoluble strontium carbonate by centrifuging. Although the soda ash method is a simpler process, the lower grade of the product causes it to be the less preferred method of recovery. The black ash method is the most common method of strontium carbonate production, and new production facilities usually use black ash technology.

CPC purchased the strontium nitrate production facilities from FMC Corp. in Modesto, CA, when that company discontinued production of carbonate and nitrate in 1984. The company moved the equipment to Cartersville and now is also the sole U.S. producer of strontium nitrate.

Several U.S. companies produced strontium metal and compounds from strontium carbonate. Calstron Corp. of Memphis, TN, produced strontium metal, Mallinkrodt Inc. of St. Louis, MO, produced strontium chloride, and Mineral Pigments Corp. of Beltsville, MD, produced strontium chromate. A few other companies produced downstream strontium compounds, but on a very small scale.

Domestic strontium deposits were operated in 1944 near Blanket, in Brown County, TX; in Nolan County, TX; in the Fish Mountains in Imperial County, CA; and near Ludlow, CA.1 At that time, the major use for strontium chemicals was for pyrotechnic applications such as signal flares and tracer bullets required for military Immediately following applications. World War II, this demand decreased markedly, causing domestic production of celestite to decrease quickly and eventually disappear.

Resources in the United States have been estimated at 3.2 million metric tons, with an identified reserve base of 1.4 million tons. The reserve figure includes material containing no more than 60% strontium sulfate, which is much too low grade to meet today's rigid specifications. In addition to deposits operated in the early 1940's, celestite has been discovered in Arizona, Arkansas, Kentucky, Michigan, Missouri, New York, Ohio, Pennsylvania, Tennessee,

Utah, and Washington.²

Consumption and Uses

Approximately 80% of all strontium was consumed in ceramics and glass manufacture, primarily in television faceplate glass and ceramic ferrite magnets, and in smaller amounts in other ceramic and glass applications. Over the past 20 years, color television production has become the major consumer of strontium. Because strontium compounds possess unique properties, technologies have been developed that take advantage those properties for specific applications. All color televisions and other devices containing color cathode-ray tubes sold in the United States are required by law to contain strontium in the faceplate glass of the picture tube. Strontium blocks X-rays better than barium, which was previously used, and although lead is a better X-ray barrier than strontium, it causes a browning of the glass, which makes its use undesirable. Major manufacturers of television picture tube glass incorporate about 8%, by weight, strontium oxide in their glass faceplate material. strontium is added to the glass melt in the form of strontium carbonate, and during processing, it is converted to strontium oxide. In addition to blocking X-rays, the strontium improves the appearance of the glass, increasing the brilliance and improving the quality of the picture.

Trends in television production show a shift to larger, flatter tubes that require thicker glass, and therefore, more strontium. Although the television industry in the United States is considered mature, there is a continuing demand for replacement televisions as well as additional sets in large numbers of households. The trend to personal computers and sophisticated, computerized instrumentation increased the demand for strontium in color monitors for these devices.

Permanent ceramic magnets were another large end use for strontium compounds, in the form of strontium ferrite. When these magnets were first developed, they were used primarily as magnetic closures for refrigerator doors. Applications have expanded to include extensive use in small direct current (dc) motors, especially for automotive applications such as windshield-wiper motors, as well as loudspeakers, other electronic equipment, toys, and magnetically attached decorative items.

Strontium ferrites are used in permanent ceramic magnets because they have high coercive force, high thermal and electrical resistivity, and are chemically inert. They retain their magnetism well, are not adversely affected by electrical currents or high temperatures, and do not react with most chemical solvents. Other properties that make the strontium magnets more attractive for specific applications are their resistance to demagnetization and lower density, making them more desirable in applications where weight is a factor.

Barium or lead can replace the strontium in ferrite magnets, but strontium ferrites have been found to possess the best combination of properties necessary for superior magnets.

One of the most consistent and continuing applications for strontium has been in pyrotechnic devices. Strontium burns with a brilliant red flame, and no other material has been found to be better in this application.

The strontium compound used most frequently in pyrotechnic devices was strontium nitrate. Some strontium compounds are slightly hygroscopic, but strontium nitrate takes on very little water and imparts the desired brilliant red. Strontium carbonate, strontium oxalate, strontium sulfate, and strontium chlorate can be used in pyrotechnic applications, but strontium nitrate was used in significantly larger quantities than any of these.

Pyrotechnic devices were used in military and nonmilitary applications. Military pyrotechnic applications that contained strontium included tracer ammunition, military flares, and marine distress signals. Nonmilitary applications included warning devices and fireworks.

Zinc used in diecasting alloys is required to contain less than 0.003%

lead. Strontium was used to remove lead impurities during the electrolytic production of zinc. The addition of strontium carbonate in sulfuric acid to the electrolyte reduced the lead content of the electrolyte and of the zinc that is deposited on the cathode.

The addition of strontium chromate to paint creates a coating that is resistant to corrosion. It is an effective coating for aluminum, most notably on aircraft fuselages and ships. These paints are used to some degree on aluminum packaging to prevent package corrosion. The nitrate and chloride contents of strontium chromate paint pigment are very strictly controlled to prevent corrosion.

Consumption of metallic strontium was still a very limited factor in total strontium consumption. Small amounts of strontium are added to molten aluminum to improve the castability of the metal, making it more suitable for casting items that have been traditionally made from steel. The addition of strontium to the melt improves the machinability of the casting. The use of cast aluminum parts is currently gaining popularity in the automotive industry. Aluminum parts were impractical before modification techniques were developed. The reduction in the weight of the automobile by using cast aluminum parts instead of steel helps to improve energy efficiency of the cars incorporating these parts.

At the present time other end uses consume only small amounts of strontium and strontium compounds. As mentioned previously, the presence of strontium in glass applications improves the brilliance of the glass. It also improves the quality of certain ceramic glazes as well as eliminating the toxicity that may be present in glazes containing lead or barium. One high-tech strontium ceramic is strontium titanate, which is sometimes used as substrate material for semiconductors and also in some optical and piezoelectric applications.

Strontium chloride was used in toothpaste for sensitive teeth. For this application, impurities must be strictly controlled, with limits for some of them

in the parts per million range.

Strontium phosphate was used in the manufacture of fluorescent lights, and the entire range of strontium chemicals was used in analytical chemistry laboratories. (See table 2.)

Prices

The average customs value for celestite imported from Mexico was about \$68 per ton (\$61 per short ton), 12% less than the average value in 1991. Mexico was the source of nearly 100% of celestite imports in 1991. Imports of very small quantities of high-valued celestite were reported from Denmark, France, and Madagascar. The exceptionally high unit value and small shipment sizes indicated that these imports were for mineral specimens, not for conversion to strontium carbonate.

The average unit customs value of imported strontium carbonate was \$0.59 per kilogram and the average value for strontium nitrate was \$0.97 per kilogram; the values for both compounds were slightly lower than the average values reported for 1991.

Foreign Trade

According to reports from the U.S. Bureau of the Census, exports of strontium compounds decreased 34% from the levels reported in 1991. Imports of celestite increased 35% from the levels reported in 1991.

Mexico was once again the most important source for imported strontium compounds; Germany was second. Imports of strontium carbonate in 1992 were 39% higher than those in 1991, with imports from Mexico comprising 82% of total carbonate imports. Imports of strontium nitrate were about the same as those in 1991. (See tables 3, 4, and 5.)

World Review

In almost all instances, celestite deposits occur in remote, undeveloped locations far from population centers in areas where inexpensive labor is available for mining. Huge deposits of high-grade

celestite have been discovered throughout the world. Strontium commonly occurs along with barium and calcium, two elements with chemical properties very similar to strontium, thus making separation difficult. Because removing many impurities from celestite is difficult and energy intensive, current strontium chemical producers require material to contain at least 90% strontium sulfate. Most of the currently operating celestite facilities can produce sufficient supplies with only minimal processing necessary to achieve acceptable specifications. Hand sorting and some washing are all that are necessary at many strontium mines; a few operations use froth flotation or gravity separation to beneficiate ore.

Detailed information on most world resources is not readily available. Many of the large deposits are in remote, sparsely inhabited areas, and very little formal exploration has been done. Other deposits may be well identified but are located in countries from which specific mineral information is not easily obtained.

Capacity.—Two types of strontium capacity exist, ore production capacity and compound production capacity. Strontium compound capacity is deemed a better indicator of the status of the strontium industry for several reasons. Essentially all strontium is consumed in compound form, primarily as the carbonate and to a lesser extent as the nitrate. Strontium carbonate is also the intermediate product in production of downstream compounds. At least 10 countries mined celestite in 1992. Virtually all of the celestite mined annually is consumed in the production of strontium carbonate and other strontium compounds. Very little strontium was consumed directly in the mineral form.

Listing both ore and compound production capacity could be misleading, possibly resulting in double-counting of strontium capacity. Because most ore is produced for market by means of very simple sorting and beneficiation techniques, capacity can easily be raised to meet increased demand. Strontium

carbonate production capacity is the limiting factor in strontium production, requiring more complicated sophisticated processing facilities. strontium carbonate Therefore. production capacity, reported in terms of contained strontium, is usually selected for tabulation. Strontium carbonate capacity has increased because of the continued growth in international sales of color television sets.

Capacity information, compiled from published reports, establishes worldwide strontium carbonate production capacity at about 245,000 tons per year, but estimates place the capacity utilization at between 70% and 75% due to a current overcapacity situation. It is likely that some of the existing capacity will be shut down in the near future, bringing supply capabilities more in line with demand requirements.

Algeria.—Celestite was mined in Algeria from a surface deposit near Beni Mansour. Estimated reserves were more than 1 million tons. The deposit was mined by Enterprise des Produits Nonferreux et des Substances Utilès (ENOF) and was controlled by L'Enterprise Nationale de Developpement Minière (Edemines), a division of Société Nationale, de Recherches et d'Exploitations Minières (SONAREM). No strontium has been exported in recent years, but in the past, up to 3,600 tons per year has been exported to nations in Eastern Europe and Germany. Although the celestite was relatively low grade, only about 70% strontium sulfate, it contained low concentrations of barite. gypsum, iron, and silica, making it possible to concentrate the ore to acceptable levels using only gravity separation.3

Argentina.—Celestite mining was controlled by the Argentine Mining Union at the San Juan Mine in the Province of Mendoza. Celestite has been identified at several other small mines, the Maria Del Carmen and Don Luis Mines also in Mendoza Province and the Rayoso, Julio, Carro Partido, and Llao Llao Mines in

the Province of Neuquen. It is unlikely that any production was carried out on a regular basis at these mines. Most Argentine production was exported to Brazil.⁴

Canada.—Canada has produced celestite ore in the past from the McRae deposit, also known as the old Kaiser Celestite Mining Ltd. mine. It is located at Lake Enon, Cape Breton County, Nova Scotia. Mineral rights were acquired by Timminco Metals, a division of Timminco Ltd. of Toronto, in 1985. Exploration identified reserves of more than 1 million tons of celestite, with grades ranging from 60% to 65% strontium sulfate. Reopening the mine has been considered, but the low grade of the ore makes economic feasibility questionable. Other strontium deposits have been identified in British Columbia. Newfoundland, and Ontario, 5 but none as significant as the deposit in Nova Scotia.

Timminco Metals was the largest producer of strontium metal in the world. The company operated a processing facility in Westmeath, Ontario. The strontium production facilities in Westmeath and facilities in Haley, Ontario, produce strontium metal by the aluminothermic reduction of strontium oxide.

China.—Celestite was mined in China almost exclusively for consumption. An ore-dressing facility at the Nanjing Mine in Jiang Su Province has a capacity of 10,000 tons per year. The Nanjing deposit is reported to be of high grade and close enough to the surface for open pit mining.⁶ Import data indicate that strontium chemical plants must exist, but no specific details were available. Strontium carbonate from China has been reported in the United States, and reports also indicated that Japan imports strontium carbonate from China.

Germany.—Kali-Chemie AG of Hannover, a subsidiary of Belgium's Solvay SA, produced strontium carbonate from imported celestite at its plant in Bad Hoenningen. The company, with its joint venture and partial interests in other countries, is the largest strontium carbonate producer in the world, and this plant is the single largest strontium operation in the world. The production facility uses the black ash method and was renovated in 1991 to increase the strontium carbonate production capacity from 15,000 to about 70,000 tons per year. 7 Kali-Chemie imported most of its celestite from Spain and Turkey; it exported nearly all the production, most of which goes to the United States and the Republic of Korea. Kali-Chemie also produced strontium hydroxide and strontium nitrate. The nitrate was produced by its Italian subsidiary, Societa Bario e Derivati SpA in Massa.8

Iran.—One of the world's largest celestite deposits is in the northwestern part of the Dasht-e-Kavir salt desert. The deposit was mined by Iran Strontium Co., a subsidiary of Cherkate Sahami Va Maadani Irani (Simiran). Average strontium sulfate values for the deposit were reported at more than 91%, but there were unfavorably high levels of barium sulfate and calcium sulfate. Proven reserves total 1.8 million tons of celestite, 430,000 tons of which has no Most of the celestite overburden.9 produced from this deposit was exported to the former U.S.S.R., but the economic and political situation in that part of the world has limited markets for the Iranian celestite. The company is trying to establish new markets for its celestite throughout the world.

Italy.—Mining has been done by Minera Chimica Farnesiana SpA in Tarquinia, near Rome. Most production of this 75% strontium sulfate and 5% barium sulfate product was sold domestically. Annual production capacity at the mine was 7,300 tons per year, but production ceased in 1988. Some of the processed ore has been exported to the U.S.S.R. in the past. Other deposits are known to exist in the interior of Sicily, although none have recently been mined. 10 Societa Bario e Derivati, a

1326 STRONTIUM—1992

subsidiary of Kali-Chemie AG, produced strontium nitrate at Massa. Production and capacity figures were not available; most of the production is exported to the United States. The plant was closed in 1992 because the cost was too high to meet new environmental requirements.¹¹

Japan.—Although celestite was not mined in Japan, it has been the largest consumer of strontium carbonate in the world, mostly due to its large television and electronics industry. Four companies produced strontium carbonate from imported celestite. Honjo Chemical Corp. operated a production facility for 11,000 tons per year of carbonate at Neyagawa in Osaka and another of the same capacity at Okayama in Okayama using celestite from Spain and China. There have been strong indications that Honjo may close at least one or both of these operations owing to less expensive imports and the shift of television tube production to other countries. 12

Sakai Chemical Industries Co. also produced strontium carbonate, by the black ash method, in Osaka at a 12,000-ton-per-year plant using Chinese, Mexican, and Spanish celestite. Japan Special Chemicals (Nihon Tokushu Kasei) and Dowa Chemicals also produced strontium carbonate, but on a much smaller scale. The total capacity for both companies was only about 1,100 tons per year. These two companies used celestite from Spain. ¹³

Korea. Republic of.—Although celestite deposits have not been identified in Korea, its growing electronics and television industry prompted a European company to form a joint venture with a Korean firm. Kali-Chemie and Samsung Corning Ltd., Korea, formed Daehan Specialty Chemicals Co. Ltd. to build a strontium carbonate and barium carbonate plant at Onsan. The plant began operation in 1990 with combined production capacity of 40,000 tons per year of strontium carbonate and barium carbonate. The production was marketed to the growing television industry in that country. The black ash method was

used.14

Mexico.—Mexico has become a major supplier of both celestite and strontium carbonate. Vast celestite deposits provide abundant raw material for the strontium carbonate producers in Mexico and throughout the world. Since Mexican strontium carbonate production began in 1987, capacity has expanded tremendously, making the country the largest producer worldwide with nearly 40% of the world's total production capacity.

Cia. Minera La Valenciana SA (CMV) bought the strontium carbonate processing equipment when a major U.S. strontium carbonate and strontium nitrate producer (FMC Corp.) closed its California plant in 1984. The plant, which utilized the soda ash method of carbonate production and was converted to the black ash method, was relocated to Torreón in Coahuila State, near a company-operated mine where production began in 1987. The plant capacity has been upgraded to 50,000 tons per year.

CPC operated a strontium carbonate plant in Reinosa, Tamaulipas, close to the U.S. border, which began production at the end of 1991. Capacity was reported at about 22,000 tons per year. Sales y Oxidos (SYOSA), 86% owned by Kali-Chemie, operated a black ash strontium carbonate plant near Monterrey with the capacity of 15,000 tons per year.15 Quimica Dinamica SA de CV operates an 8,000-ton-per-year strontium carbonate and strontium nitrate plant in Monterrev. Planning to install a larger black ash plant in the future, the company used the soda ash process for strontium carbonate production. The company had announced plans to increase capacity to more than 50,000 tons, but that development will depend on the continued strength of strontium demand. Quimica Dinamica is currently a major force in the strontium nitrate market.16

Mexico was the world's largest producer of celestite in 1992. The most recent Directory of Mexican Non-Metallic Minerals Trust lists 11 companies currently mining celestite. The newest mine, operated by Minera La Roja SA,

began production in 1990 from the La Ilusion Mine in Coahuila. Proven reserves are 500,000 tons with total reserves of almost 3 million tons. The ore is upgraded through flotation to a minimum 95% strontium sulfate.¹⁷

CMV mined celestite from the San Augustín deposit near Torreón, and Compañía Minera Ocampo SA mined a deposit near Saltillo in Nuevo Leon State. as well as some small production in Hidalgo, Aguascalientes, and Chihuahua States. Reserves of the San Augustín Mine have been estimated at more than 725,000 tons. SYOSA and Quimica Dinamica operated mines in Coahuila. Other small operations occur in Aguascalientes, Chihuahua, and Nuevo Leon. In most cases, Mexican celestite is very high grade, and only hand sorting is required to achieve at least 92% strontium sulfate with low barium content. Abandoned mines and easily identified deposits that have not yet been developed are common throughout a large area in northern Mexico. Reserves are believed to be vast, but these deposits have not been extensively explored. 18

Morocco.—A joint venture between CPC and Kali-Chemie has established Mobar SA, a project to mine celestite in northern Morocco at Ksar El Kebir. Heavy-media separation is necessary to produce 94% strontium sulfate. The operation was in the startup phase. ¹⁹

Pakistan.—All strontium mines in Pakistan are the property of Provincial governments and are operated by private companies for the governments. Recent celestite production figures have been reported for two active mines, one near Dawood Khail and one near Karachi.²⁰ Tawakkal Mineral Exports recovered celestite from these mines in the Dadu District of Sind Province. No beneficiation was necessary to produce 94% strontium sulfate. Reserves of celestite have not been quantified at this location.²¹ Other deposits with 500,000 tons of reported reserves have been identified in the Punjab Province.22

Spain.—Spain traditionally has been one of the largest celestite producers worldwide. Celestite was produced from the Montevive deposit, which was operated by Herederos de Aurelio Vilches, with sales and Farjardo Bruno marketing handled by SA. Selective mining and hand sorting was all that was necessary to produce ore grades of more than 92% strontium sulfate, although a concentration plant has been constructed. Reserves are believed to be at least 2 million tons. Most production from Montevive is exported to Japan, some remains in Spain, and the rest is exported to Germany.23 Another deposit at Escúzar near Montevive is operated by The ore is Kali-Chemie Iberia SA. upgraded to 95% strontium sulfate by heavy-media preconcentration flotation. Production from this site is shipped to other Kali-Chemie operations in Germany and Korea.24

Promotora de Industria del Sur (Proinsur SA) produced strontium carbonate and strontium nitrate at a combined facility near Granada until the end of 1991 when market conditions prompted its closure. The plant had a design capacity of 8,000 tons per year of carbonate but never reached capacity. Strontium carbonate was produced by the soda ash method. The plant also had a production capacity of about 3,000 tons per year of nitrate, which was not fully utilized.²⁵ Plans to improve Proinsur's process have been developed, but have been shelved until market conditions improve.

Turkey.—Turkey competes with Iran, Mexico, and Spain in claiming the world's largest strontium reserves. Barit Maden Turk AS produced celestite from a mine near Sivas. Run-of-mine ore was gravity separated to produce a concentrate with a minimum of 95% strontium sulfate. Because of the harsh climate in the region, the mine was operated on a seasonal basis, usually from May to Another mine near Sivas October. formerly was operated by Bilfer Madencilik AS, which reestablished concessions for future mining. Identified reserves have been placed at 550,000 tons, and further reserve potential is estimated to be greater than 2 million tons. Turkish celestite was primarily exported to Korea and Germany.²⁶

Former U.S.S.R.—Very little is known about production of strontium minerals in this area. Deposits are known in the Karakum Desert, Zaunguz Plateau; Permian deposits near Bashkir; caprocks of the Romy and Isachkov salt domes: Pinega area, Archangel Province; Yakutsk, eastern Siberia; and in Turkestan from eastern Fergana to the shores of the Caspian Sea, and from southeastern Bucharia to the shores of the Sea of Aral. Reserves are believed to be very large, but the ore grade is probably not high.²⁷ No details are available concerning the production of strontium carbonate in the former U.S.S.R. except that there has been production in the past, probably from domestic celestite as well as from imports from Iran and Turkey. Recent changes in the political and economic situation in this region may have caused disruptions in production as indicated by attempts by traditional celestite suppliers to establish new markets, but as with many former Soviet industries, details remain a mystery.

United Kingdom.-Until World War II. virtually all celestite processed in the United States was imported from the United Kingdom. When the war interfered with transportation of the ore, other sources were developed, and U.K. celestite never regained its prominence. Celestite deposits, occurring in the Bristol area, were mined by Bristol Minerals Co. Ltd. This was one of the few sites in the world where celestite deposits are not in remote locations. The ore was crushed, washed, and graded to achieve a product with 95% strontium sulfate.28 The Bristol deposits were finally exhausted in 1992, and mining was curtailed. The company developed a spiraling and flotation process for handling mine tailings and keep the operation going until the tailings have been reprocessed.²⁹ (See table 6.)

OUTLOOK

The strontium carbonate capacity situation has clouded the picture for the future of the industry, but for the most part, the future continues to look bright for the near term. Changes have occurred regarding leading celestite and strontium carbonate producers, but production and consumption continue to expand.

Continued growth is expected in the color television industry, and larger screens are expected to increase in Demand for strontium popularity. carbonate for television application should expand. Other markets will probably continue at their current, slower rate. Development of a technology to produce an affordable flat television display could severely reduce the demand for strontium carbonate, but this is not expected in the near future. Although a high-quality, large, flat screen is not yet available, small models are, and research continued to improve the technology. The question remains whether a new display system can be developed that will be economically attractive to the general public. Initial devices are expected to find application in military hardware and other sophisticated medical and scientific instrumentation. Flat screen display systems may eventually replace cathoderay tubes, and, at that point, strontium producers may experience a serious setback.

SULFUR

By Joyce A. Ober

Mrs. Ober, a physical scientist with 15 years of industry and U.S. Bureau of Mines experience, has been a commodity specialist since 1986. Domestic survey data were prepared by Pamela G. Shorter, statistical assistant; and the international production table was prepared by Doug Rhoten, International Data Section.

Although both production and consumption decreased for the third consecutive year, the United States retained its position as the world's leading producer and consumer of sulfur and sulfuric acid. The quantity of sulfur was recovered during the refining of petroleum, and the processing of natural gas was greater than any time since the U.S. Bureau of Mines began reporting statistics for this type sulfur. production of sulfur through the Frasch process, however, was lower than it had been for more than 50 years. Frasch production was a result of production cutbacks of one of the three mines that operated throughout 1992 and the slower-than-expected startup at a new mine that began operation during the year. Total production and shipments of sulfur from all sources were slightly lower than they had been in 1991.

Sulfur production from a major salt dome on Federal lease block Main Pass 299 in the Gulf of Mexico began at the end of April. Rights to develop this deposit were acquired from the U.S. Department of the Interior in 1988. Main Pass 299 was the first new domestic Frasch mine to be built in more than 20 years.

Shipments of recovered elemental sulfur were nearly three times higher than Frasch shipments, and total shipments were slightly lower than those in 1991. Recovered sulfur exports, primarily from California where sulfur supplies exceeded local demands, were higher than Frasch sulfur exports.

Byproduct sulfuric acid from the Nation's nonferrous smelters and roasters, essentially mandated by laws concerning sulfur dioxide emissions, supplied a significant quantity of sulfuric acid to the domestic merchant acid market. Marketing continued to be difficult for some producers because smelters were near western copper mines and far from major sulfuric acid markets.

Worldwide, sulfur production decreased about 5% compared to that in 1991, with a 19% decrease in Frasch production and a slight increase in the amount recovered from petroleum and natural gas processing. Frasch production was lower because only three mines operated in the United States for the full year, Mexican and Polish mines operated at low rates, Iraq had not resumed full production following the war in the Persian Gulf, and political and economic problems continued in Eastern Europe and the former U.S.S.R. Recovered elemental production increased in Asia, the Middle East, North America, and Western Europe; decreased in Eastern Europe and the former U.S.S.R.: and remained about the same in the rest of the world. About two-thirds of the world's elemental sulfur production came from recovered sources; the quantity of sulfur supplied from these sources was dependent on the world demand for fuels and petroleum products, not on the demand for sulfur.

World sulfur consumption decreased an estimated 7%. Consumption in fertilizer production decreased and consumption for a myriad of industrial uses continued to be pressured by environmental constraints placed on the products produced or effluents from the chemical processes utilizing sulfur or its major derivative, sulfuric acid.

World trade of elemental sulfur decreased by an estimated 1.2 million metric tons, about 8% below levels recorded in 1991. Although U.S. sulfur inventories decreased about 32% from yearend 1991, worldwide producers' stocks of elemental sulfur increased nearly 5%. (See table 1 and figure 1.)

DOMESTIC DATA COVERAGE

Domestic production data for sulfur are developed by the U.S. Bureau of Mines from four separate, voluntary surveys of U.S. operations. Typical of these surveys is the "Elemental Sulfur" survey. Of the 177 operations to which a survey request was sent, 173 responded, representing 98% of the total production shown in table 1. Production data for the nonrespondents were estimated using prior-year reported production.

BACKGROUND

Sulfur, through its major derivative sulfuric acid, ranks as one of the more important elements utilized by humanity as an industrial raw material. It is of prime importance to every sector of the world's industrial and fertilizer complexes. Sulfuric acid consumption has been regarded as one of the best indexes of a nation's industrial development.

Also known as brimstone, "the stone that burns," sulfur was used in small quantities for thousands of years. Ancient people were probably first drawn to native sulfur by its bright yellow color and pungent odor. Early humanity used

sulfur as a colorant for cave drawings, as a fumigant, for medicinal purposes, and as incense. As early as 2000 B.C., the Egyptians used sulfur in the bleaching of linen textiles. In the Odyssey, Homer refers to its use as a fumigant. During the Peloponnesian War, fifth century B.C., the Greeks burned a sulfur-pitch mixture to generate suffocating gases. The Romans combined brimstone with tar, pitch, and other combustible materials to produce the first incendiary weapons. Muslims during the "Golden Age of Arabic Science," from about A.D. 700, developed alchemy and were probably the first producers of sulfuric acid. Sulfur is a necessary ingredient in gunpowder, which was developed as a pyrotechnic in China by the 10th century. Gunpowder's introduction into Europe led to its use in warfare in the 14th century and made sulfur an important mineral commodity for the first time.

However, it was not until the birth of the science of chemistry in the 1700's and the growth of chemical industries in the 1800's that sulfur became of major importance to the world outside of its use in warfare. Early chemists soon recognized the importance of sulfuric acid as the cheapest and most versatile of the mineral acids, and it rapidly became and remains the most commonly used acid in the chemical industry.

Sulfur is one of the few elements that occurs in the native, or elemental, state. It also occurs combined with iron and base metals as sulfide minerals, and with the alkali metals and alkali earths as sulfate minerals. In petroleum, sulfur is found in a variety of complex organic compounds, and in natural gas as hydrogen sulfide (H₂S) gas. In coal, sulfur occurs in complex organic compounds and as "coal brasses" (pyrites-marcasite). Commercial production of sulfur in the United States is accomplished by a variety of methods dictated by the source of sulfur.

Definitions, Grades, and Specifications

Bright Sulfur.—Crude sulfur free of discoloring impurities and bright yellow in color.

Brimstone.—Synonymous with crude sulfur.

Broken Sulfur.—Solid crude sulfur crushed to minus 20-centimeter size.

Crude Sulfur.—Commercial nomenclature for elemental sulfur.

Dark Sulfur.—Crude sulfur discolored by minor quantities of hydrocarbons ranging up to 0.3% carbon content.

Elemental Sulfur.—Processed sulfur in the elemental form produced from native sulfur or combined sulfur sources, generally with a minimum sulfur content of 99.5%.

Frasch Sulfur.—Elemental sulfur produced from native sulfur sources by the Frasch mining process.

Native Sulfur.—Sulfur occurring in nature in the elemental form.

Prilled Sulfur.—Solid crude sulfur in the form of pellets produced by cooling molten sulfur with air or water.

Pyrites.—Iron sulfide minerals that include pyrite, marcasite, and pyrrhotite.

Recovered Sulfur.—Elemental sulfur produced from combined sulfur sources by whatever method.

Slated Sulfur.—Solid crude sulfur in the form of slatelike lumps produced by allowing molten sulfur to solidify on a water-cooled, moving belt.

Sulfur Ore.—Unprocessed ore containing native sulfur.

Sulfuric Acid.—Sulfuric acid of commerce produced from all sources of sulfur, generally reported in terms of 100% H₂SO₄ with a 32.69% sulfur content.

Products for Trade and Industry

Elemental sulfur of commerce, sometimes called crude sulfur or

brimstone, may be marketed in either the liquid or the solid phase, generally with a minimum sulfur content of 99.5%. Most elemental sulfur marketed in North America is sold as liquid sulfur. In worldwide commerce, sulfur is shipped either as broken sulfur or formed sulfur. sulfur—prills. slates. pastilles—is generally preferred to broken sulfur because it is less prone to dusting and the release of fugitive dust at terminals where sulfur is stored and transferred from one transportation mode to another. Sulfuric acid may be sold at various strengths, usually depending on the requirements of the consumer. The acid is generally marketed on a 100% basis, but is normally shipped at 66° Baume (93% H₂SO₄), as 98% acid, or as 20% to 22% fuming oleum, which is sulfur trioxide dissolved in sulfuric acid.

Industry Structure

Over the centuries, many fundamental changes have occurred in the sources of sulfur supply. Early civilizations obtained their meager requirements from native sulfur deposits in or around volcanoes. The increase in demand for sulfur in the late 1700's and early 1800's was largely satisfied from extensive deposits in Sicily. native sulfur Monopolistic practices by the owners of sulfur mining facilities in Sicily led to exorbitant sulfur prices, causing consumers to adopt iron pyrites as the second major sulfur source during the mid- to late-19th century. development in 1895 of the Frasch process for mining the large native deposits associated with salt domes in Louisiana and Texas brought a new and important source of sulfur to the United States and world markets. Frasch sulfur and pyrites maintained their joint predominance as world sulfur sources through the mid-1970's.

With small beginnings in the 1930's and increasing significantly from the 1950's onward, environmentally mandated or involuntary sulfur recovered during natural gas processing and petroleum refining grew to surpass Frasch sulfur and pyrites as the world's major source

of sulfur. In addition, increasing quantities of byproduct sulfuric acid from smelting operations have been produced to comply with pollution control laws and environmental regulations worldwide.

Sulfur in its various forms is produced worldwide, with no single nation predominating as a producer or supplier to world markets. In 1992, world sulfur production and consumption amounted to 52.4 million and 53.1 million metric tons, respectively. The United States was the world's largest producer and consumer; however, the United States was a net importer of sulfur. Canada and the former U.S.S.R. produced nearly equal quantities of sulfur in 1992, but the former U.S.S.R. was a net importer. while Canada was the world's largest exporter of elemental sulfur. Poland, the fifth largest producer, ranked second among exporting nations. China, the world's fourth largest producer and largest pyrites producer, was the third largest sulfur consumer; China, however, satisfied most of its sulfur requirements from internal sources.

Geology-Resources

Sulfur is widely distributed in nature, constituting 0.060% of the Earth's crust. Sulfur combines with most other elements, except the inert gases and nitrogen. Practically all plant and animal life on Earth contains some sulfur. Only a very small portion of the world's sulfur resources occurs in sufficiently concentrated quantities to justify commercial extraction by mining or other recovery methods. Sulfur is one of the few substances found in nature in the elemental form: it also occurs combined with other elements as sulfides, sulfates, or organic compounds in sedimentary, metamorphic, and igneous rocks, as well as in all fossil fuels. By type, sulfur deposits are classified as follows:

Native (Elemental) Sulfur Deposits.—These include deposits (1) in anhydrite-limestone cap-rock on the top and flanks of salt domes, (2) in bedded anhydrite-gypsum evaporite basin formations, and (3) in unconsolidated

volcanic deposits. In salt done cap-rock and evaporite beds, the sulfur is believed to have been formed by hydrocarbon reduction of anhydrite, assisted by bacterial action. Volcanic sulfur was produced by the reaction between escaping hydrogen sulfide and sulfur dioxide.

Large deposits over salt domes are mined in the gulf coast regions of the United States and Mexico. Extensive deposits in evaporites are mined in west Texas, Iraq, Poland, and the former U.S.S.R. Together, these deposits are by far the principal source of mined elemental sulfur, generally extracted by the Frasch hot-water process. Most volcanic sulfur occurrences are in the circum-Pacific belt. Volcanic sulfur deposits are locally important, but furnish only a minor portion of the world's sulfur supply.

Sulfide Deposits.—These deposits of (1) ferrous sulfides (pyrite, marcasite, and pyrrhotite) that, while they quantities of may contain minor nonferrous metals, are generally mined and processed for their sulfur content and (2) nonferrous metal sulfides, which are mined for their metal content and in the processing produce sulfur in the form of sulfuric acid. In order of importance from the quantity of acid produced, sulfide minerals of copper, lead, zinc, molybdenum, nickel, mercury, arsenic, antimony, and silver are the most noted in the nonferrous sulfide group.

Sulfate Deposits.—These include bedded deposits of anhydrite and gypsum. Although they are mined on a large scale worldwide for their mineral content, they represent one of the world's largest, yet virtually untapped sulfur resources. Existing technology can recover elemental sulfur from these sources, but the economics are presently unfavorable.

Natural Gas.—Hydrogen sulfide occurs as a component of natural gas in many parts of the world. To market this "sour" natural gas, the hydrogen sulfide must be removed and, consequently, as additional sour natural gas fields have been brought into production, elemental

sulfur recovered from these fields has become a major source of the world sulfur supply. Major deposits of sour natural gas occur in western Canada, the Near East, and the former U.S.S.R.; substantial deposits occur in the mountain and gulf coast regions of the United States and in Germany, France, Mexico, and Venezuela.

Petroleum and Tar Sands.—Complex organic sulfur compounds occur as a component of petroleum and tar sands in a wide range of concentrations. In the refining of petroleum or bitumen from tar sands, a portion of the sulfur is removed and recovered in the elemental form. Changing environmental regulations have required larger proportions of contained sulfur to be removed annually. The vast petroleum reserves of the Near East contain high percentages of sulfur, as do many of the recent discoveries in Mexico and off U.S. the west coast. Canadian tar Additionally, sands constitute a major sulfur resource.

Coal and Oil Shale.—Sulfur occurs as pyrites or complex organosulfur compounds in varying concentrations in both coal and oil shales. Although little sulfur is produced from these vast resources at present, the potential for large-scale output exists in the United States and in the rest of the world.

Economic Factors

During the past 20 years, world sulfur price leadership has shifted from dominance by the U.S. Frasch producers to the Canadian exporters. The transfer was aided in the 1980's by Canada's ability to export most of its production from the Port of Vancouver and by its willingness to ship large volumes of sulfur from vatted stocks. maturation of Sultran Ltd., dealing almost exclusively with sulfur destined for the offshore market, into a well-organized and skilled transportation arm of the Canadian sulfur industry aided immeasurably in Canada's ascension to world price leadership. However, the steep price reductions in the past 2 years have confused the issue of price leadership. Canada's role is still very important, but the oversupply of sulfur in Europe, Poland, and Saudi Arabia also has had an effect on prices.

In the United States, the quoted liquid Frasch sulfur price, f.o.b. terminal Tampa, FL, has traditionally been the benchmark price. Toward the end of 1992, the industry seemed to be abandoning this practice. Although a Tampa Frasch price was published weekly in trade publications, reports in those publications indicated that contract prices were becoming less dependent on these posted prices, and in fact only one Frasch producer was posting its prices weekly. Recovered sulfur producers, in many cases, consider the economic desirability of producing sulfur subordinate to the necessity of producing As a result, domestic recovered elemental sulfur producers normally offer sulfur at a price at least \$5 to \$15 per ton below the Tampa quote to ensure prompt sale and reduce storage costs. This marketing strategy has resulted in restricting Frasch sulfur sales from many market areas that they formerly served.

During the 1980's, the sulfur price showed a significant degree of volatility compared with its prior history, and the early years of the 1990's continued that trend. The worldwide recession of 1982 and the U.S. Department of Agriculture Payment In Kind program in 1983 reduced world sulfur production and demand. (See figure 2.)

Operating Factors

Increasing environmental concerns have had an impact on the sulfur industry, as they have had on most other industries. The effects on the sulfur industry can be interpreted as both positive and negative as far as sulfur is concerned, but certainly positive in terms of decreasing pollution.

Even before the Clean Air Act became law in 1977, oil refineries and natural gas processors realized the necessity of removing sulfur from their products and offgases. The U.S. Bureau of Mines began collecting data on recovered sulfur in 1939, and references were made to this

type of sulfur prior to that, but with no official data to quantify the recovery. At first, recovered sulfur was considered a waste material, not a commercial byproduct. As time went on, the importance of recovered sulfur increased as sulfur demand increased faster than the supply of Frasch and other native sulfur. Recovered sulfur became the primary domestic source of elemental sulfur in 1982.

The Clean Air Act set limits on the quantity of pollutants that could be released into the atmosphere. dioxide was identified as one of the most common pollutants and one of the major contributors of acid rain, known to damage both natural and artificial environments. New gas-cleaning apparatus removed as much sulfur dioxide as was technologically possible from offgases. Petroleum refiners and gas processors were able to recover a greater percentage of sulfur from the gas stream as elemental sulfur, metal smelters (especially nonferrous metals) recovered byproduct sulfuric acid, and coal and oil burning electric powerplants recovered byproduct gypsum (calcium sulfate), cutting emissions dramatically. The type of byproduct recovered was determined by the sulfur content of the gas stream: elemental sulfur was recovered when the sulfur dioxide content was relatively high.

Amendments to the Clean Air Act of 1990 required a 50% reduction of sulfur dioxide emissions by the year 2000, and electric power stations are believed to be the source of 70% of all sulfur dioxide emissions. For this reason the 1990 amendments will concentrate on the further reduction of emissions from electric utilities. Existing technology to recover elemental sulfur from powerplant offgases has a cost estimated to be 50% higher than the cost of recovering byproduct gypsum. Although some byproduct gypsum is consumed in the same end uses as natural gypsum, much of it is disposed as waste. Although no utilities currently are recovering commercial quantities of elemental sulfur in the United States, as landfill costs become higher elemental sulfur recovery becomes a more attractive alternative to byproduct gypsum production.

Over the years, larger quantities of sulfur have been recovered for a number of reasons, including increased petroleum refining and natural gas processing, more stringent limitations on sulfur dioxide emissions, and higher sulfur contents of the crude oil refined. Other contributing factors are lower sulfur content limits set on petroleum-based fuels. As a result, recovered sulfur production increased about 6% in 1992, although refinery production grew only about 1% in 1992.

As sulfur supplies, either as elemental sulfur or byproduct sulfuric acid, have grown due to increased environmental awareness, the demand for sulfur has decreased in some consuming industries for the same reason. Some industries (i.e., uranium processing) have contracted or completely disappeared owing to concerns regarding environmental damage caused by their processes. industries, such as titanium dioxide production, have converted to more environmentally "friendly" processes that do not use sulfuric acid. In addition, many consumers who continue to use sulfuric acid are putting new emphasis on regenerating or recycling spent acid.

Another area where improved air quality has had an impact on sulfur use is in agriculture. As reduced sulfur dioxide emissions decreased acid rain, sulfur content of soils also has decreased. Sulfur is now recognized as an important plant nutrient, necessary for the most efficient use of other nutrients and optimum plant growth. Because many soils are now deficient in sulfur, a demand for sulfur-containing fertilizers has been created, and farmers must now buy a nutrient that previously had been available at no cost.

Increased environmental awareness has created a dilemma for sulfur producers. While pollution reduction requirements have created increased supplies of sulfur and sulfur products, similar requirements have caused a decrease in demand. This situation will persist and the imbalance between supply and demand could increase. Disposing of excess sulfur, recovered while cleaning the air to protect the environment, may create

another environmental problem.

ANNUAL REVIEW

Legislation and Government Programs

The 1990 amendments to the Clean Air Act required a 50% reduction from 1980 levels of sulfur dioxide emission nationwide by the year 2000. The 1990 Act contains an innovative measure to control emissions through market-based incentives rather than more traditional, strict, inflexible rules. The Emission Allowance Market (EAM) will make it possible for companies that have been able to reduce emissions at their operations to sell unneeded allowances to companies that have not been able to meet pollution reduction requirements.

Other types of pollutants will eventually be controlled by this process, but sulfur dioxide will be managed first. Because electric powerplants are believed to be the source of about 70% of all sulfur dioxide emissions in the United States, the EAM will concentrate on that industry. The Environmental Protection Agency has chosen the Chicago Board of Trade (CBoT) to administer allowance sales.

Utilities will be assigned emission allowances based on historic fuel consumption and sulfur dioxide emission These assigned allowances will decrease over time to meet the goal of 50% reduction. Additional allowances will be available for purchase on the open Each utility must buy its assigned allowances directly from the Government at a predetermined price. If a specific power station finds it cannot meet its pollution requirements, it must buy additional allowances on the open market or from another utility that has reduced its emissions and thus possesses emission allowances that are in excess of its needs. Additional allowances may be purchased directly from companies offering them for sale or through auctions at the CBoT. All of the Government's unassigned allowances will be sold through CBoT.

Phase 1 of the EAM program will affect the 10 largest power stations in 21

Eastern and Midwestern States. Compliance will be required by January 1, 1995, with sales of future emission allowances beginning at the CBoT in March 1993. Phase 2 will encompass approximately 700 remaining smaller utilities with compliance required by January 1, 2000. As time passes, all emission allowances will be purchased through auction or on the open market, with none through direct sale from the Government.

Production

Frasch.—Native sulfur associated with the cap rock of salt domes and in sedimentary deposits is mined by the Frasch hot-water method, in which the native sulfur is melted underground and brought to the surface by compressed air. In January 1992, the United States had three Frasch mines operating in Louisiana and Texas; another mine in Louisiana began operating during the year. Mines in Texas were Pennzoil Sulphur Co., at Culberson, and Texasgulf Inc. (TG), at Boling Dome in Wharton County. Freeport Sulphur Co. owned and operated two mines in Louisiana. The Caminada Pass mine 14 kilometers offshore in the Gulf of Mexico operated throughout the year, and Main Pass, 27 kilometers offshore, began operating in April.

In December 1988, Freeport McMoRan Resource Partners, operator for a consortium that included the IMC Fertilizer Group Inc. and Felmont Oil Co., reported a geologic reserve of about 50 million tons of sulfur on its Federal lease block, Main Pass 299, which is offshore in the Gulf of Mexico, 27 kilometers from the mouth of the Mississippi River. The announcement was based on the results of five exploratory holes. Additional drilling in 1989 delineated the size of the salt dome deposit and established the total reserve at 67 million tons, which made Main Pass 299 the second largest domestic sulfur deposit yet discovered. McMoRan began construction on the offshore platform for the mine in 1990, and production of natural gas, oil, and sulfur began in 1992. The company

expects to reach full capacity of about 2 million tons per year sometime in 1994. The estimated cost of the project was more than \$750 million. The startup at Main Pass was somewhat slower than expected owing to some technical problems as well as low sulfur prices. The company chose to concentrate on oil and gas production until sulfur prices improved.

Frasch sulfur output decreased 550,000 tons from the quantity produced in 1991 and was only about one-third of what it was in 1981. Shipments to domestic and overseas consumers were 17% lower in 1992 than they were in 1991. Frasch sulfur accounted for 22% of domestic production in 1992. Approximately 86% of Frasch sulfur shipments was for domestic consumption; the remainder, for export. The total value of Frasch sulfur shipments decreased by more than \$120 million.

Recovered.—Recovered elemental sulfur, a nondiscretionary byproduct from petroleum refining, natural processing, and coking plants, was produced primarily to comply with environmental regulations that were applicable directly to emissions from the processing facility or indirectly by restricting the sulfur content of the fuels sold or used by the facility. processing plants accounted for two-thirds of the total domestic output of sulfur in all forms compared with 66% in 1991. Production and shipments of recovered sulfur were 6% higher, reaching alltime high levels owing to record production from the Nation's petroleum refineries. Production and shipments from petroleum refineries were 7% and 6% higher. respectively, and from natural gas processing plants, about 5% and 6% higher, respectively, than those in 1991. Recovered elemental sulfur was produced by 58 companies at 151 plants in 26 States, 1 plant in Puerto Rico, and 1 plant in the U.S. Virgin Islands. Most of these plants were of relatively small size, with only 22 reporting an annual production exceeding 100,000 tons. By source, 52% was produced at 3 coking plants and 85 refineries or satellite plants treating refinery gases. The remainder was produced by 27 companies at 60 natural gas treatment plants. The five largest recovered-sulfur producers in 1992 were Exxon Co. U.S.A., Standard Oil Co. (California), Standard Oil Co. (Indiana), Shell Oil Co., and Mobil Oil Corp. The 52 plants owned by these companies accounted for 55% of recovered elemental sulfur output during the year. (See tables 2, 3, and 4.)

Byproduct Sulfuric Acid.—Byproduct sulfuric acid at copper, molybdenum, and zinc roasters and smelters amounted to 12% of the total domestic production of sulfur in all forms. Eight acid plants operated in conjunction with copper smelters, and lead, eight were accessories to molybdenum, and zinc smelting and roasting operations. The five largest acid plants (all at copper mines) accounted for 78% of the output. The five largest producers of byproduct sulfuric acid were Phelps Dodge Corp., Magma Copper Co., ASARCO Incorporated, Kennecott Corp., and Cyprus Miami Mining Corp. Their eight plants produced 85% of the 1992 total. (See table 5.)

Pyrites, Hydrogen Sulfide, and Sulfur Dioxide.—The total sulfur contained in these products did not constitute a significant portion of total domestic sulfur production. (See figure 3.)

Consumption and Uses

Domestic consumption of sulfur in all forms was slightly lower in 1992 than it was in 1991. In 1992, 79% of the sulfur consumed was obtained from domestic sources compared with 77% in 1991 and 80% in 1990. The sources of supply were domestic recovered elemental sulfur, 51%; domestic Frasch sulfur, 18%; and combined domestic byproduct sulfuric acid, pyrites, hydrogen sulfide, and sulfur dioxide, 10%. The remaining 21% was supplied by imports of Frasch and recovered elemental sulfur.

The U.S. Bureau of Mines collected end-use data on sulfur and sulfuric acid according to the Standard Industrial Classification of industrial activities. Shipments by end use of elemental sulfur were reported by 59 companies, and shipments of sulfuric acid were reported by 50 companies. Shipments of both elemental sulfur and sulfuric acid were reported by seven companies.

Sulfur differs from most other major mineral commodities in that its primary use is as a chemical reagent rather than a component of a finished product. predominant use as a chemical reagent generally required that it first be converted to an intermediate chemical product prior to its initial use by industry. The largest sulfur end use, sulfuric acid, represented 86% of reported consumption. Some identified sulfur end uses were tabulated in the "Unidentified" category because these data proprietary. Data collected from companies that did not identify shipment by end use were also tabulated as "Unidentified." Although there are no supporting data, it could be reasonably assumed that a significant portion of the sulfur in the "unidentified" category was shipped to sulfuric acid producers or was exported.

Sulfuric acid, because of its desirable properties, retained its position, both domestically and worldwide, as the most universally used mineral acid and the largest volume inorganic chemical in terms of the quantity produced and consumed. U.S. consumption of sulfur in sulfuric acid (100% basis) decreased by about 4% in 1992 owing to decreases in demand for sulfuric acid in industrial uses. Demand for sulfuric acid for the production of phosphoric acid, the largest single end use, was virtually unchanged from that of 1991. Sulfuric acid demand for copper ore leaching, the second largest end use, decreased about 6% as reported by sulfuric acid producers. Reported shipments of sulfuric acid for petroleum refining and other petroleum and coal products were not significantly different from those of 1991, but reported consumption of elemental sulfur in those end uses was nearly double.

According to the 1992 canvass reports, company receipt of spent or contaminated sulfuric acid for reclaiming totaled 2.7 million tons. The largest source of this

spent acid continued to be the petroleum refining industry, which accounted for 49% of the total returned. About 1.2 million tons of spent acid was reclaimed from chemical producers. The remaining reclaimed acid was from manufacturers of ferrous and nonferrous metals, paper, storage batteries, and some unidentified sources.

The largest use of sulfur in all forms, for agricultural purposes, increased from 9.0 million tons in 1991 to about 9.3 million tons. The estimated quantity of sulfur needed to manufacture exported agricultural chemicals decreased by about 550,000 tons to 4.1 million tons, indicating that sulfur consumption for fertilizers intended for domestic consumption increased more than 500,000 tons. Although consumption of sulfur for fertilizer production phosphatic experienced little change in 1992 and exports of fertilizer decreased, domestic consumption of fertilizer was relatively stable. Low export demand resulted in increased producers' stocks of phosphatic fertilizers. (See tables 6, 7, and 8 and figure 4.)

Stocks

Yearend inventories held by Frasch and recovered elemental sulfur producers decreased 32% from those of 1991, which would normally indicate a tightness of supply, but this was not the case in 1992. Because of low world demand and increased competition for domestic markets, at least one Frasch producer chose to cut production and ship from inventory to reduce expenses. Combined vearend stocks amounted approximately a 23-day supply compared with a 34-day supply in 1991, a 40-day supply in 1990, a 37-day supply in 1989, and a 32-day supply in 1988 based on apparent consumption of all forms of sulfur. (See table 9.)

Markets and Prices

The posted price for liquid sulfur exterminal Tampa, FL, began the year at \$98 and dropped to \$88 per ton in October. On the basis of total shipments

and value reported to the U.S. Bureau of Mines, the average value of shipments of Frasch sulfur, f.o.b. mine, for domestic consumption and exports combined decreased from \$87.05 to \$58.15 per ton. The average value, f.o.b. plant, for shipments of recovered elemental sulfur varied widely by geographic region; the national average value for the year was \$45.20 per ton, almost \$20 per ton less than the average for 1991. The average value for all elemental sulfur was \$49.17 per ton in 1992, 31% lower than that in 1991. (See table 10.)

Foreign Trade

Exports of elemental sulfur from the United States, including the U.S. Virgin Islands, decreased 19% in quantity and 42% in value. According to the Bureau of the Census, exports from the west coast were 568,000 tons or 77% of total U.S. exports.

The United States continued to be a net importer of sulfur; imports exceeded exports by about 1.8 million tons in 1992. Frasch sulfur from Mexico and recovered elemental sulfur from Canada. both delivered to U.S. terminals and consumers in the liquid phase, furnished 99% of all U.S. sulfur import requirements. Total elemental sulfur imports decreased 10% in quantity; imports by rail from Canada increased 11%, while waterborne shipments from Mexico were 33% lower than those in 1991. Imports from other sources, very small compared to those from Canada and Mexico, decreased 77%.

The United States also had significant trade in sulfuric acid. Sulfuric acid exports decreased about 6% from those of 1991. Imports, which were significantly greater than exports, were mostly by rail from Canada. The tonnage increased 8% from the quantity reported in 1991; the value of imported sulfuric acid increased Approximately 456,000 tons of acid was imported into the Tampa, FL, area, about 18% less than the Tampa acid imports of the previous year. Two sulfuric acid terminals had been established there in 1989. (See tables 11, 12, 13, and 14.)

World Review

With production, consumption, and prices down for the second consecutive year, 1992 was a disappointing year for the global sulfur industry. Frasch producers experienced production cutbacks, and as consumption decreased, international competition for available markets became more intense.

Industry Structure.—In 1992, the sulfur industry remained divided into two sectors, discretionary and nondiscretionary. In one, the mining of sulfur or pyrites was the sole objective; this voluntary production of native sulfur or pyrites was based on the orderly mining of discrete deposits, with the objective of obtaining as nearly a complete recovery of the resource as economic conditions permit. In the other, sulfur or sulfuric acid was recovered as an involuntary byproduct. the quantity of output subject to demand for the primary product irrespective of sulfur demand. In 1992, involuntary sources represented almost 64% of the elemental sulfur produced worldwide.

Large quantities of Frasch sulfur were produced from mines in only five countries: Iraq, Mexico, Poland, the former U.S.S.R, and the United States. Poland and the former U.S.S.R. also produced significant quantities of native sulfur using conventional mining techniques; small quantities of native sulfur were produced in Asia, Europe, and South America. Pyrites were the prime sulfur source in southern Africa, China, much of Eastern Europe, Finland, and Spain and were an important source in Scandinavia and the former U.S.S.R.

Recovered elemental sulfur was the predominant sulfur source in Canada, France, Germany, Saudi Arabia, and the United States. Additionally, recovered elemental sulfur was an important source in Iran, Japan, and the former U.S.S.R. Sulfur production in Iraq and Kuwait was beginning to recover from the effects of the Gulf War, but was significantly lower than that in previous years. Production levels in Iraq will affect world markets minimally until economic sanctions are lifted by the United Nations.

International sulfur trade was dominated by a limited number of exporting countries; exports from Canada, Poland, Saudi Arabia, the United States, Mexico, and Germany, in descending order of the quantity shipped, accounted for 86% of sulfur trade in 1992. Major sulfur importers in 1992 were the United States, Morocco, India, Tunisia, Brazil, the Republic of Korea, and the United Kingdom, in descending order of importance, all with imports of more than 500,000 tons.

Capacity.—The data in table 15 are rated capacity for Frasch mines, elemental sulfur mining facilities and attendant beneficiation plants, pyrites mines and plants, sulfur and/or sulfuric acid recovery units associated with petroleum refineries, natural gas processing plants, metal smelting operations, electric powerplants, and coke ovens as of December 31, 1992. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the facility, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with a minimum of capital expenditure. Rated capacity is not equivalent to engineering (design) capacity of installed equipment.

Frasch mines operate continuously, and capacity is related to the quantity of superheated water that can be injected into the associated sulfur deposit. The nature of Frasch mining makes capacity quite variable over time and depends on the number of "steaming wells," water injection rates, water losses from the formation, location of wells within the deposit, and length of time that the deposit has been worked. The rated capacity or realizable capacity of a Frasch mine generally decreases as the deposit becomes depleted.

Petroleum refineries—large, very

costly, and complex processing facilities designed to produce a spectrum of fuels and petrochemical products—operate continuously. Sulfur recovery units make up only a small segment of these facilities; because sulfur recovery is environmental mandated by the installed sulfur considerations. recovery capacity at petroleum refineries generally exceeds the expected sulfur production. To ensure that the loss of a sulfur recovery unit does not require the shutdown of the entire refinery, multiple sulfur recovery units, each capable of servicing the petroleum refinery, are The quantity of sulfur installed. petroleum recovered bv domestic refineries in the United States during 1991 was equal to slightly more than 50% of the installed engineering capacity. Rated capacity for petroleum refineries is assumed to be 50% of installed engineering capacity.

Natural gas processing plants may be installed to service gasfields and/or oilfields that contain significant quantities Gas plants are of associated gas. designed to accommodate the natural gas from a specific field that may contain, in addition to methane, which is sold as pipeline gas, varying amounts of dioxide, nitrogen. carbon helium, condensable hydrocarbon liquids, and poisonous hydrogen sulfide. The poisonous nature of hydrogen sulfide makes its removal from pipeline gas imperative. Sulfur removal and recovery plants in natural gas facilities vary in size from small units rated at 5 to 10 tons per day to multiple-train plants capable of recovering thousands of tons per day. In general, sulfur recovery rates from gasfields approximate installed engineering capacity, based on a 340- to 345-day-per-year operation of all units, in the first 7 years of operation. succeeding years, sulfur recovery declines steadily because the gas apparently becomes "sweeter" over time and because gas flow rates drop as the field is depleted. Rated capacity for gas processing plants is based on the age of the plant and its recent production history.

Rated capacity for plants operating in

conjunction with metal smelters, powerplants, and coking operations is assumed to approximate engineering capacity. Where information on design capacity is unknown, rated capacity was estimated to be equal to the greatest output recorded by a plant or country in the past 5 years. World rated sulfur annual production capacity is significantly lower than the installed world engineering capacity of approximately 91 million tons. (See table 15.)

Canada.—Production in Canada was 6.35 million tons, slightly higher than that of the previous year. Canada was the world's largest sulfur exporter, with nearly 90% of production exported. Sulfur recovered from natural gas processing represented 76.8% of total Canadian production, with 7.6% from oil sand and 3.7% from oil refining.

The majority of Canadian sulfur is produced in Alberta and British Columbia. With the completion of Shell Canada's Caroline natural gas recovery project in Alberta, an additional 1.5 million annual tons of sulfur capacity should be operational by early 1993; full production capacity is expected to be reached by the end of that year. An estimated 25 million tons of sulfur is contained in this deposit, which has an average hydrogen sulfide content of 35.3%.

Shell completed a pilot-scale project to determine the feasibility of producing sulfur from a deposit containing more than 90% hydrogen sulfide as well as elemental sulfur. The Bearberry sulfur resources were estimated at 40 million tons, and because of the corrosiveness of the material, presented significant challenges to designing a successful Suitable materials recovery process. were developed, and the pilot project proved successful. However, because the cost of construction of a full-scale plant would be prohibitive, especially with sulfur prices at current lows, the operation was shut down after proving its success.

China.—The third largest sulfur consumer and fourth largest sulfur

producer was nearly self-sufficient in sulfur. China is the largest pyrites producer, representing more than one-half of all pyrites production and large pyrites reserves. This was the only country in which pyrites production is growing; this trend is expected to continue.

Former U.S.S.R.—Production of sulfur in all forms decreased substantially for the fifth consecutive year. The majority of sulfur in the former U.S.S.R. was produced in Kazakhstan, Russia, Turkmenistan, and the Ukraine. Three Frasch mines were operated in the Ukraine and one in Turkmenistan. Technical and economic problems with the Frasch operations suggested that production will continue at reduced levels in the immediate future.

Considered the world's last oil and gas frontier, many oil companies were interested in forming joint ventures in the former U.S.S.R. The potential exists for large sulfur recovery capacity when new oil and gas operations are commissioned.

Sulfur production began at the Tengiz oil and gas condensate field in the Republic of Kazakhstan in 1991. Since that time, Chevron reached an agreement with the Government of Kazakhstan for a 50% interest in the further development of the Tengiz and Korolov oilfields and gasfields. Tengiz was believed to have huge oil reserves and associated sour gas. Korolov was much smaller, but with a higher sulfur content.

Originally, four production phases were planned for Tengiz, but for the time being, only Tengiz I and Tengiz II are expected to be completed. Tengiz II was expected to come on-stream in 1992, but experienced delays. If all phases of the project are completed, sulfur recovery capacity could be more than 3 million tons per year when oil production reaches its peak in the year 2010.

Negotiations were proceeding with the Government of Kazakhstan and a British and Italian joint venture to develop the Karachaganak oil and sour gas condensate field. This field also has a large sulfur-producing potential due to its 22% hydrogen sulfide content.

The Astrakhan sour gas field in the

Russian Republic began producing in 1987, but serious environmental problems forced its shutdown in 1989 for repairs and improvements. It was restarted in 1992 and gradually approached its capacity to recover 1.8 million tons of sulfur per year. The second phase of production, Astrakhan II, was expected by the end of 1993.

Iraq.—Iraq's Frasch sulfur operation suffered no damage during the war in the Persian Gulf, but sulfur production and exports were believed to be low due to the United Nation's trade embargo that remained in effect. Reports from Iraq stated that production at Mishraq had reached 2 million tons per year. It was doubtful that output was that high, but Iraq represents a significant additional source of supply when sanctions are lifted.

Kuwait.—Oil production resumed at the end of 1991 after oil well fires were extinguished and some refineries repaired following the Gulf War. Refinery repairs were slower than expected, and sulfur recovery was possible at only one refinery before the end of 1992. Sulfur recovery was expected at the other refineries in Kuwait by the end of 1993.

Mexico.—Frasch sulfur production decreased for the fourth consecutive year to about 820,000 tons. Four mines were operating at the beginning of the year, but Azufrera Panamericana S.A. (APSA), operator of the Coachapa/Otopan and Jaltipan Mines, was declared bankrupt and the mines were closed in November. The remaining mine, Texistepec, owned by Compania Exploradora del Istmo S.A. and Texasgulf, was expected to close in 1993, reducing the number of major Frasch-producing countries to four.

Morocco.—Morocco was a major world importer of elemental sulfur because of consumption at its phosphate fertilizer facilities at Safi and Jorf Lasfar. Imports were about 2.5 million tons in 1992, a 20% increase from approximately 2.1 million tons imported in 1992.

Poland.—Frasch production was 33% lower than it was in 1991 and 44% lower than the annual average for the 1980's. Economic problems in Eastern Europe and the former U.S.S.R. took their toll on the Polish sulfur industry. In the past, the majority of Polish sulfur exports was to this region, but Polish exports in 1992 were about 2.5 million tons, 14% less than those in 1991. Africa was Poland's largest customer, receiving 42% of exports, followed by Eastern Europe and the former U.S.S.R., taking 21%.

Poland was the largest world producer of native sulfur, with major mines at Jeziorko, Grzybow, and Machow. Due to high production costs, Machow closed during the year. The construction of the new Osiek Mine was beset by financial problems, and startup, which had been expected in 1992, was delayed until 1993. (See table 16.)

OUTLOOK

The future of the sulfur industry seems clearer than it has for the past few years. Unfortunately, the outlook is not very positive. Sulfur production and consumption will continue a general upward trend, but growth of consumption will lag behind production increases. Production will decrease from Frasch deposits, but growth of recovered production will more than compensate for any increased demand. As a result, stocks will build.

World sulfur demand, from 1993 to 1997, is forecast to increase at an annual rate of about 1% per year. From 1997 to the year 2002, growth is expected to be higher, at almost 2%. World demand is projected to attain 55.9 million tons in 1997 and increase to about 61 million tons in the year 2002. In the short term, U.S. sulfur demand is forecast to increase from 12.7 million tons consumed in 1992 to 13.5 million tons in 1997 and 14.0 million tons in the year 2002.

Almost two-thirds of sulfur consumption in the United States is for agricultural uses. More than 90% of U.S. agricultural sulfur demand and almost 80% of world agricultural sulfur consumption was for the manufacture of

phosphoric acid in 1992. World demand for phosphate fertilizers is forecast to increase at an annual rate of about 2% for the next 10 years. It is assumed that 90% of the growth will be for the production of phosphoric acid to produce high-analysis fertilizers, which will directly affect world sulfur demand. Consumption of sulfur for phosphate fertilizer manufacture in the United States is divided into two main components: (1) for phosphate fertilizers demand consumed by domestic farmers and (2) demand for exported phosphate fertilizers.

In 1992, an estimated 4.1 million tons of sulfur was required to manufacture the phosphatic fertilizers exported from the United States compared with 4.2 million tons of sulfur for domestic phosphoric fertilizer use. However, this may be misleading. Domestic fertilizer consumption appears to have grown significantly in 1992, but in reality, producers built up their own stocks because exports were depressed and production continued at capacity. Domestic phosphate production will probably decrease in 1993 owing to large producers' inventories; sulfur demand will decrease accordingly. Sulfur demand for domestically consumed phosphates is forecast to increase slightly through 1997 and remain relatively stable thereafter.

The broad spectrum industrial or nonagricultural sulfur use category accounted for almost 33% of U.S. sulfur consumption and about 42% of world sulfur demand. Although significant variations in demand for the diverse elements within this broad category are expected in the United States and other geographic areas, world industrial demand is expected to average less than a 1% increase annually over the next 10 years, reaching 23 million tons in the year 2002.

The necessity for the removal of sulfur from solid, liquid, and gaseous effluents for environmental protection has caused the production of sulfur and sulfur compounds from these sources to exceed production from primary sources of supply. The long-term prospect is that 85% or more of the world sulfur supply

will come from environmentally regulated sources and that output from these sources will be produced regardless of world sulfur demand. As a result, it is probable that after the turn of the century, no new operation that produces sulfur as its primary product will be developed, except where it may be deemed necessary for political or social reasons. In 1980, voluntary sources of production, Frasch, native sulfur, and pyrites accounted for 50% of world output, about 55 million tons. In 1992, these same sources supplied only 36% of world production, 52.4 million tons.

It is anticipated that in the short term. owing to decreased production at Frasch operations, world sulfur supply and demand will be closely balanced. However, a number of new production facilities that will be completed soon, are under development, or are in the planning stage will create tremendous new supply sources. The completion of the Caroline Gasfield should increase Canadian capacity by 1.2 million tons in 1993. The completion of a new mine in Poland and new associated gas processing facilities in the former U.S.S.R. are currently behind schedule, but upon completion could add an additional 5.3 million tons of annual production capacity. Freeport McMoRan's new Main Pass 299 Mine came on-stream in 1992 and could be producing at a rate of more than 2 million tons per year sometime in 1994, increasing U.S. Frasch capability by almost 1 million tons compared with that of 1990 and 2 million tons more than that in 1991. additions to world production from expansions and new facilities at oil refineries and gas processing plants should amount to several hundred thousand tons. A worldwide sulfur surplus will probably develop in 1993, a surplus that could persist through the year 2002, keeping prices low. World sulfur production may attain a level of 60 million tons in 1997 and exceed 62 million tons in the year 2002.

[&]quot;Estimated. Revised. W Withheld to avoid disclosing company proprietary data; included with "Byproduct: Unspecified sources."

In addition to the countries listed, a number of nations may produce limited quantities of either elemental sulfur or compounds (chiefly H_2S or SO_2) as a byproduct of petroleum, natural gas, and/or metallurgical operations, but output, if any, is not quantitatively reported, and no basis is available for the formulation of reliable estimates of output. Countries not listed in this table that may recover byproduct sulfur from oil refining include Albania, Bangladesh, Brunei, Burma, Costa Rica, Guatemala, Honduras, Jamaica, Malaysia, Nicaragua, Paraguay, and the Republic of Yemen. Albania and Burma also may produce byproduct sulfur from crude oil and natural gas extraction. No complete listing of other nations that may produce byproduct sulfur from metallurgical operations (including processing of coal for metallurgical use) can be compiled, but the total of such output is considered as small. Nations listed in the table that may have production from sources other than those listed are identified by individual footnotes.

The term "source" reflects both the means of collecting sulfur and the type of raw material. Sources listed include the following: (1) Frasch recovery; (2) native, comprising all production of elemental sulfur by traditional mining methods (thereby excluding Frasch); (3) pyrites (whether or not the sulfur is recovered in the elemental form or as acid); (4) byproduct recovery, either as elemental sulfur or as sulfur compounds from coal gasification, metallurgical operations including associated coal processing, crude oil and natural gas extraction, petroleum refining, tar sand cleaning, and processing of spent oxide from stack-gas scrubbers; and (5) recovery from the processing of mined gypsum. Recovery of sulfur in the form of sulfuric acid from artificial gypsum produced as a byproduct of phosphatic fertilizer production is excluded because to include it would result in double counting. It should be noted that production of Frasch sulfur, other native sulfur, pyrites-derived sulfur, mined gypsum-derived sulfur, byproduct sulfur from extraction of crude oil and natural gas, and recovery from the sulfur is extracted as a credited to the nation where the recovery takes place, which in some instances is not the original source country of the crude product from which the sulfur is extracted.

¹Table includes data available through July 26, 1993.

⁴Formerly part of Yugoslavia; data were not reported separately until 1992.

⁵Reported figure.

⁶Less than 1/2 unit.

In addition, may produce limited quantities of byproduct sulfur from oil refining.

^{*}Includes only the elemental sulfur equivalent of sulfuric acid produced as a byproduct from metallurgical furnaces; additional output may be included under "Byproduct: Unspecified sources."

Official Polish sources report total Frasch and native mined elemental sulfur output annually, undifferentiated; this figure has been divided between Frasch and other native sulfur on the basis of information obtained from supplementary sources.

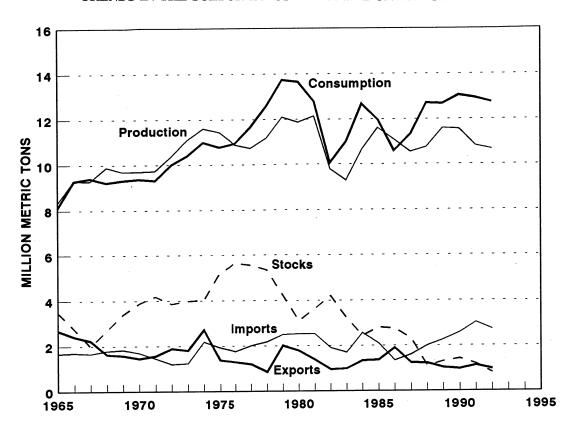

¹⁰Estimates for 1988-92 include byproduct production from synthetic fuels.

¹¹Detail may not add to totals shown because of independent rounding.

¹²Dissolved in Dec. 1991. This commodity is believed to be produced in Azerbaijan, Belarus, Estonia, Kazakhstan, Russia, Turkmenistan, Ukraine, and Uzbekistan; however, information is inadequate to formulate reliable estimates of individual country production.

¹⁵Dissolved in Apr. 1992.

FIGURE 1
TRENDS IN THE SULFUR INDUSTRY IN THE UNITED STATES

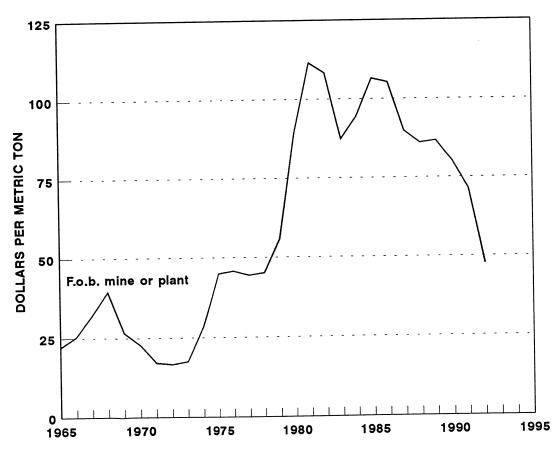

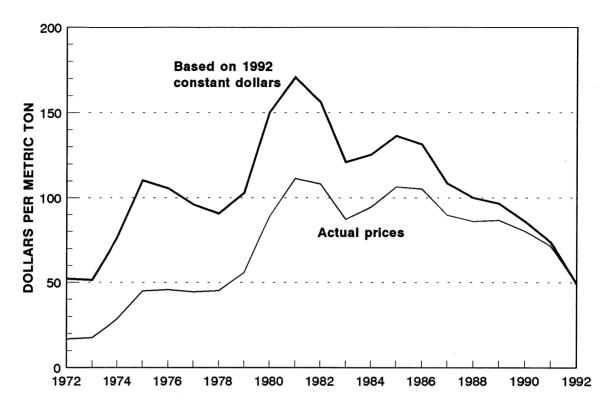

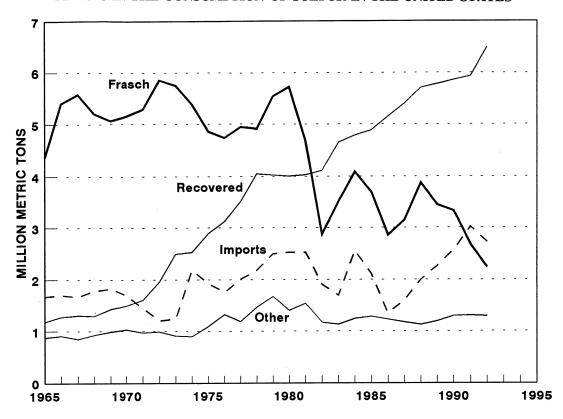

FIGURE 2
TIME-PRICE RELATIONSHIPS FOR SULFUR

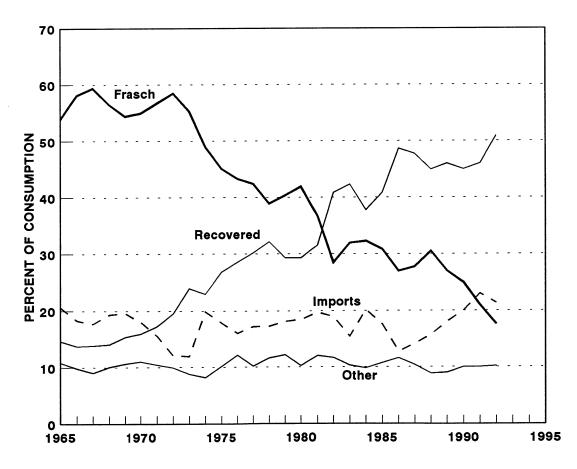

Based on the average reported prices for elemental sulfur (Frasch and recovered), f.o.b. mine and/or plant, these prices reflect approximately 90% of the shipments of sulfur in all forms during 1973-92.

FIGURE 4
TRENDS IN THE CONSUMPTION OF SULFUR IN THE UNITED STATES

TALC AND PYROPHYLLITE

By Robert L. Virta

Mr. Virta, a physical scientist with 17 years of U.S. Bureau of Mines experience, has been the commodity specialist for talc and pyrophyllite since 1986. Domestic survey data were prepared by Linder Roberts, statistical assistant; and international data tables were prepared by Jeremy Tidwell, international data assistant.

Domestic production of talc decreased 4% from 1,037,000 metrics in 1991 to 997,000 tons in 1992. The value of crude ore decreased 2% in value from \$32 million to \$31 million. Sales of crude and processed talc decreased 5% in tonnage from 864,000 tons to 817,000 tons and increased 15% in value from \$83 million to \$95 million. Imports for consumption increased 19% in tonnage to 80,000 tons and 4% in value to \$12 Exports decreased 2% in million. tonnage to 175,000 tons and increased slightly in value. The major domestic use for talc was in ceramics, which accounted for 35% of the domestic consumption, followed by paper, 20%; paint, 18%; roofing, 9%; plastics, 5%; and cosmetics, 5%. Other applications accounted for 8% of consumption. Production and sales of pyrophyllite were unchanged from those of 1991. The major uses for pyrophyllite were in ceramics, refractories, insecticides, paint, plastics, paper, and rubber, in decreasing order of consumption.

DOMESTIC DATA COVERAGE

Domestic production and sales data for talc and pyrophyllite are developed by the U.S Bureau of Mines from a voluntary survey of U.S. mines and mills. Survey forms were sent to 17 companies that operated 45 mines and mills. Twelve companies that account for approximately 90% of the domestic production responded to the survey. Production data for the nonrespondents were estimated from reported prior-year production levels adjusted by trends in employment and other guidelines. (See table 1.)

ANNUAL REVIEW

Legislation and Government Programs

The Occupational Safety and Health Administration (OSHA) issued a final rule on June 8, 1992, removing the nonasbestiform varieties of actinolite, anthophyllite, and tremolite from the scope of its asbestos standard. The nonasbestiform varieties will be regulated according to limits set for "particulates not otherwise regulated."

The Mine Safety and Health Administration (MSHA) continued to review its proposed revisions to its air quality, chemical substances, respiratory protection standards. The proposed permissible 8-hour timeweighted average exposure limit is 2.5 milligrams per cubic meter (mg/m³) of air for talc (containing no asbestos), 3 mg/m³ for respirable soapstone, and 6 mg/m³ for total soapstone dust. The nonasbestiform varieties of tremolite, anthophyllite, and actinolite would be covered under the proposed respirable mine dust standard.²

MSHA continued reviewing its proposed rule that would create a hazard communication standard. Mine operators would be required to provide information to their employees through labeling, material safety data sheets, and employee training if hazardous chemicals were produced or used on the premises.

Issues

One issue that continues to attract attention is the classification of crystalline silica as a probable human carcinogen by the International Agency for Research on Cancer, an agency of the World Health Organization and OSHA. Under OSHA's Hazard Communication Standard, products containing more than 0.1% crystalline silica must be labeled. Additionally, OSHA-regulated sites that receive and/or use these products must comply with OSHA's Hazard Communication Standard.

Production

Talc.—Twelve companies operating 17 mines in 7 States produced talc, soapstone, and steatite. These companies generally were structured to cover all aspects of talc mining, from mining to processing. Only a few companies hired custom grinders to mill the ore. The largest of the domestic producers were Luzenac America Inc., Dal Minerals, Gouverneur Talc Co., Montana Talc Co., and Pfizer (Minerals Technologies Corp.). The major producing deposits were in Montana, New York, Texas, and Vermont.

Commercial talc production was from deposits that were formed through hydrothermal alteration of ultrabasic rocks and low-grade metamorphism of siliceous dolomites. They generally occur as lenses or pods in the country rock. Magnesite, quartz, chlorite, magnetite, serpentine, anthophyllite, tremolite, dolomite, and actinolite may be present as accessory minerals.

Most of the domestic talc production was from open pit mining operations. Underground mining was used only when a large waste-rock-to-ore ratio made open pit mining uneconomical. Typically, overburden was removed and blasting was used to fracture the ore. The companies then used selective mining and

manual or automated sorting to produce a high-grade feed for the mill. Jaw crushers were used to reduce the size of the mill feed, and ball mills or roller mills were used to produce the final product. Fluid-energy mills or pulverizing mills were used for ultrafine grinding of the talc ore. In a few instances, the ore was calcined prior to milling to increase its whiteness.

Flotation processes were used when the desired product purity was not obtained by using conventional processing. The milled ore was chemically treated, passed through rougher and cleaner cells to separate the talc from the gangue material, dried in a flash dryer, and ground in a pulverizer. Ore composition, reagent type, pulp density, pH of the flotation system, and residence time in the flotation circuits determined flotation efficiency.

Pfizer Inc. reorganized its minerals operations under a subsidiary company called Minerals Technologies Corp. The subsidiary will control the precipitated calcium carbonate, limestone, talc, and refractory operations.³

The sale of Cyprus Minerals Co.'s talc mines and mills to RTZ Corp. PLC was completed. The mines and mills will operate under the name Luzenac America Inc.

U.S. mine production of crude talc decreased 4% in tonnage to 997,000 tons and decreased 2% in value to \$31 million. (See table 1.) This is the lowest production level since 1984, following several years of growth. Producers in Montana, New York, and Texas reported increases in production, corresponding with increased sales to the ceramics, paint, and paper industries. production in California, Oregon, and Virginia was unchanged while that of Vermont decreased. Mines that operated in Montana, New York, Texas, and Vermont accounted for 98% of domestic talc production. Montana led all States in the tonnage and value of talc produced. (See table 2.)

Pyrophyllite.—Pyrophyllite was mined by two companies operating three mines in North Carolina and one company

operating one mine in California. Production was from hydrothermally altered volcanic deposits of acidic composition. The deposits consisted of pyrophyllite with sericite, andalusite, and/or quartz as accessory minerals. After removing the overburden, the ore was either stripped using dozers and scrapers or extracted using conventional open pit mining techniques. The ore was dried, and then jaw crushers and gyratory crushers were used to reduce the size of the mill feed. Ball, pebble, or roller mills were used to produce the final product. U.S. mine production of crude pyrophyllite was unchanged from that of 1991.

Consumption and Uses

Talc.—Talc was used in a wide variety of products because of its softness (1 on the Mohs scale), purity, fragrance retention, whiteness, luster, moisture content, oil and grease adsorption, electrical chemical inertness, low conductivity, high dielectric strength, and high thermal conductivity. properties were not universal to all talcose materials because of differences in their mineralogical composition and particle shape. Mineral content was extremely important because determined the end use for the material. Generally, only two or three of these properties were critical for any one application.

Domestic producers reported that overall sales (including exports by producers) declined 5% in tonnage to 817,000 tons and increased 15% in value to \$95 million in 1991. (See table 1.) The major consumer of talc was the construction industry, where it is used in ceramic tile and sanitaryware, joint compounds, paint, and roofing. The enduse distribution was ceramics, 35%; paper, 20%; paint, 18%; roofing, 9%; cosmetics, 5%; plastics, 5%; and insecticides, refractories, rubber, and other, 8%. (See table 3.)

Sales to the ceramics, cosmetics, paint, and rubber industries increased slightly. Sales to the paper industry increased 14%

despite a poor year for the paper industry in 1992. The largest decreases in reported sales were in plastics and roofing. Reported sales to the plastics industry decreased 28%, contrary to current trends in plastics manufacturing. Some talc classified as "Other" in table 3 and imported talcs undoubtedly were used by the plastics industry. It is likely that domestic consumption of talc in plastics actually increased slightly in 1992 rather than decreased. Consumption of talc by the roofing industry decreased from 88,000 tons to 70,000 tons. As with plastics, some of the sales to the roofing industry may have been classified as "Other" in table 3. A modest decrease in consumption of talc for roofing was expected based on the state of the construction industry.

Approximately 76% of the data presented in table 3 was reported by the companies; the remainder was estimated from reported prior-year data adjusted by trends in employment and other guidelines. Approximately 80,000 tons of imported talc was not included in this end-use breakdown. The imported talc was purchased primarily by mineral brokers who do not participate in the U.S. Bureau of Mines survey. Imports represent slightly less than 10% of the total reported domestic sales by U.S. talc producers.

Pyrophyllite.—Pyrophyllite, being different in composition from talc, did not have the same applications as talc. Properties such as softness (1 to 2 on the Mohs scale), whiteness, chemical inertness, high melting point, low electrical conductivity, and high dielectric strength made pyrophyllitic materials useful for ceramics and refractories.

Domestic consumption of pyrophyllite was unchanged from that of 1991. The largest portion of domestically produced ground pyrophyllite was used in ceramics, followed by refractories, insecticides, paint, plastics, paper, and rubber.

Markets and Prices

Talc prices varied depending on the

quality and the degree and method of processing. The unit value of crude talc based on data reported by producers was \$31 per ton. The average reported unit value of processed talc was \$116 per ton. The average unit value of crude and processed pyrophyllite was less than that of 1991. Unit values for imported crude and ground talc ranged from \$35 per ton to \$584 per ton for shipments exceeding 100 tons. Unit values for cut or sawed talc ranged from \$467 per ton to \$1,273 per ton for shipments exceeding 100 tons. The average unit value for all imported talc was \$156 per ton. Unit values for exported crude and ground talc ranged from \$38 per ton to \$557 per ton for shipments exceeding 100 tons and averaged \$172 per ton for all exports.

Prices, quoted by the American Paint & Coatings Journal, December 28, 1992, in U.S. dollars per metric ton for paint-grade talc in carload lots ranged from \$99 to \$220. Approximate equivalents, in dollars per metric ton, of price ranges quoted in Industrial Minerals (London), December 1992, for talc, c.i.f. main European ports, ranged from \$112 to \$352. (See table 4.)

Foreign Trade

Talc exports decreased 2% in tonnage to 175,253 and increased slightly in value to \$30,069,590. Canada was the largest importer of talc, followed by Belgium-Luxembourg, Taiwan (9,451 tons), Germany (8,582 tons), and Japan. (See table 5.) Talc imports increased 19% in tonnage to 79,560 tons and 4% in value to \$12,408,496. Canada and China supplied 76% of all talc imports. (See table 6.)

World Review

China is the world's largest producer of talc. The United States remained the largest market economy talc producer and Japan remained the largest pyrophyllite producer. China, Japan, and the United States accounted for 52% of the world's talc and pyrophyllite production. (See table 7.)

Austria.—One open pit mine and three underground talc mines operated in Styria. The open pit mine produced about 100,000 tons per year or about 75% of the country's production. Owing to difficulties in mining underground in altered rock, one of the underground mines switched from top slicing to underhand cut-and-fill mining. This method, which uses a cement and gravel or waste rock backfill, successfully rock resolved several mechanics problems. Tests also were being conducted to determine the practicality of using mechanical cutting equipment to replace drilling and blasting.4

China.—A new pyrophyllite deposit was discovered through a joint United Nations and Chinese mineral exploration project. The deposit, which is in the Fujian Province, is the largest discovered in China. The deposit contains approximately 16 million tons of pyrophyllite.⁵

Italy.—Construction began on Talco Sardinia's talc processing facility near Orani. The company is building a new 40,000-ton-per-year mill. The company will supply talc for the Italian talc market and for export to European countries.⁶

Netherlands.—Westmin Talc BV acquired complete ownership of the talc mill operated by Jan de Poorter BV in Amsterdam, Netherlands. The plant has a milling capacity of 40,000 tons per year. Westmin Talc will use the plant to supply the European talc market.⁷

Current Research

The U.S. Bureau of Mines conducted a study of an underground talc mine in which rock falls, pillar sloughing, and other ground control problems were observed. The principal ground control problem and the greatest hazard was pillar instability. This was attributed to the steeply dipping orientation of the foliation in the talc ore body. Artificial support and more uniform pillar design would have minimized pillar sloughing.

A boundary element model showed that uneven loads on the irregularly shaped pillars could have been reduced by better pillar design. Measurement of roof convergence and pillar loading failed to detect significant changes during mining. This suggested that the hanging wall could support large spans between pillars and permit high extraction ratios.⁸

OUTLOOK

The past 15 years has been a period of change for the talc and pyrophyllite industries. Several mines were closed in response to environmental issues, many small mines closed for economic reasons, and several large mining operations were sold as major corporations changed their business strategies. Twenty-eight companies mined talc and pyrophyllite in 13 States in 1978. By 1992, these numbers had dropped to 15 and 8, respectively.

Domestic consumption of talc and pyrophyllite during this period has ranged from a low of 744,000 tons in 1982 to a high of 1,054,000 tons in 1988 and 1990. Consumption declined during the recession of the early 1980's and increased again through 1990. The economic downturn of the late 1980's did not affect the talc and pyrophyllite industries until 1991, when consumption dropped below 1 million tons.

Despite these changes, demand for talc and pyrophyllite should remain strong. Domestic consumption can be expected to range from 900,000 tons to 1,000,000 tons per year in the near future. Ceramics will continue to be the major domestic end use for talc, followed by consumption in paper, paint, roofing, plastics, and cosmetics, in descending order. For pyrophyllite, the major domestic end uses will continue to be in ceramics and refractories.

Estimated. Revised. W Withheld to avoid disclosing company proprietary data; not included in "Total."

¹Table includes data available through May 18, 1993.

In addition to the countries listed, Czechoslovakia produces talc, but information is inadequate to make reliable estimates of output levels.

³Reported figure.

⁴Total of beneficiated production, salable direct shipping production, and that consumed by producers.

⁵Data based on Iranian fiscal year beginning Mar. 21 of year stated.

⁶Formerly part of Yugoslavia.

⁷All production in Yugoslavia from 1988-91 came from Macedonia.

⁸Data based on Nepalese fiscal year beginning mid-July of year stated.

⁹Dissolved in Dec. 1991; however, information is inadequate to formulate reliable estimates for individual countries.

¹⁰Dissolved in Apr. 1992.

TIN

By James F. Carlin, Jr.

Mr. Carlin, a physical scientist with the Branch of Metals, has been the commodity specialist for tin for 13 years. Domestic survey data were prepared by Elsie Isaac, statistical assistant; and international data tables were prepared by Ivette Torres, Chief, Section of International Data.

Tin was one of the earliest metals known to humankind. Tin occurs in nature mostly as the oxide mineral cassiterite. Tin metal is commonly used as a protective coating or as an alloy with other metals. It finds applications in products and processes as diverse as tin cans. solder for electronics, chemicals, bronze fittings, and flat-glass production. Its strategic importance is exemplified by the fact that it generally has been the largest dollar-volume holding of all metals in the National Defense Stockpile (NDS) since the establishment of the stockpile in the 1940's.

In 1992, for the 11th consecutive year, there was an excess of tin on the world market. Excess stocks were believed to be about 40,000 metric tons of tin at yearend.

The price of tin remained in a fairly narrow band throughout the year and at a level that was low by historical standards. World tin mine output declined as producers reduced output in view of continued low tin prices. In the United States, there was continued interest in the recycling of used tin cans largely due to the rising costs and limited space of landfills.

DOMESTIC DATA COVERAGE

Domestic consumption data for tin are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. tin users. All of the 290 consumers to which a survey request was sent responded. (See table 1.)

BACKGROUND

Definitions, Grades, and Specifications

Primary or virgin tin metal is cast and sold as bars, ingots, pigs, and slabs in weights of 50 kilograms or less. Most of the tin metal imported into the United States is in the form of 45-kilogram pigs. During 1982-84, the American Society of Testing and Materials (ASTM) Pig Tin Task Group developed a new specification for grade-A tin, calling for 99.98% minimum tin content and 0.030% maximum bismuth content. This specification bore the code B-336-90. In 1990, the American Tin Traders Association modified the silver content of tin to be 0.01% maximum. This action was taken to limit some tin metal that was being imported into the United States with high silver content, which was thought to be detrimental to the electronic soldering industry.

Products for Trade and Industry

Tin is rarely used in its pure form, but is usually alloyed with other metals. Bronze, developed in the fourth millennium B.C., traditionally was a copper-base alloy containing about 10% to 15% tin to harden the copper. Today, the term "bronze" is seldom used without a modifier because it is applied also to some copper-base alloys containing no tin. The most important tin bronzes are the phosphor bronzes, containing up to 12% tin with small additions of phosphorus, and the gun metals, which are tin-bronze casting alloys containing from 1% to 6% zinc. Brass, another old

and important alloy, is primarily an alloy of copper and zinc, but often tin is a component.

There are numerous solder compositions, typical of which are tinsilver solder (95% tin, 5% silver), antimony-tin solder (95% tin, 5% antimony), and soft solders (ranging from 1% to 70% tin, with the remainder essentially lead).

Tin-base babbitt is an alloy containing antimony and copper, used for lining bearings. Lead-base babbitt metal contains 1% to 10% tin.

Compositions for tin foil and "white metal" vary with the producer. Most foil now is a tin-lead alloy. Some foil is made from relatively pure tin or tin containing small amounts of copper or antimony hardener. White metals, such as britannia metal, jewelers metal, and pewter, are tin alloys, normally hardened with antimony. Pewter may have a wide range of composition, but high-grade pewter contains 90% to 95% tin, with 1% to 2% copper and the remainder antimony. Copper and antimony serve as hardeners.

Tinplate is a thin-gauge steel sheet product that has a very thin tin coating on both surfaces; the steel thickness and the weight of surface tin coating vary according to end-use requirements. Terneplate is sheet steel coated on both surfaces with a tin-lead alloy.

Tinplate is commonly shipped as coil, solder as ingot, bronze as strip or plate, and brass as any of these forms. Each of these semifinished products is then used to fabricate a wide variety of end-use items. Brass and bronze are also produced in cast forms. Tin usually

becomes a very small, but essential, part of the end-use item's weight or cost.

Industry Structure

At least 35 countries mine or smelt tin. Virtually every continent has an important tin-mining country. Most operations are privately owned, but many are publicly owned. A similar situation exists in the tin-smelting industry.

In major Southeast Asian tin-producing countries, small, labor-intensive, highunit-cost mines, such as gravel-pump mines, produce a significant proportion of total output. In these same countries, massive, expensive dredges also are used. Large, privately owned mining enterprises operate in Southeast Asia. but many of the operations are also Government-owned. The four largest tinmining companies in the market economy countries are Paranapanema in Brazil, P.T. Timah in Indonesia, the Malaysia Mining Corp., and Corporación Minera de Bolivia (COMIBOL).

agreement establishing the An Association of Tin Producing Countries (ATPC) came into force on August 16, 1983. The five charter members were Bolivia, Indonesia, Malaysia, Thailand, and Zaire. Australia and Nigeria joined later. The stated objectives of the ATPC were to obtain fair returns for tin producers and adequate and stable supplies at reasonable price for tin consumers, to facilitate cooperation in the marketing of tin, and to enhance the growth of tin use. Members stated that they viewed the ATPC as complementary and supportive of the activities of the International Tin Council. The Tin Council was an association of leading world tin producer and user countries that attempted to stabilize tin prices and supply-demand from 1956 until its demise in 1989. In recent years, the most visible activity of the ATPC has been to attempt to reduce the world oversupply of tin through a series of supply rationalization schemes. These programs have essentially featured export-control limits placed on the seven member countries. Although these programs have succeeded in drastically reducing the huge tin

oversupply, they have not eliminated it largely because major producers such as Brazil and China were not bound by the guidelines of the programs.

U.S. mine production of tin has been negligible for many decades. Small quantities of tin concentrates are produced from placer deposits in Alaska, and small quantities were once produced in several Western States.

In recent decades, the only tin smelter in the United States was the Texas City, TX, facility of TexTin Corp. In recent years, this smelter treated tin concentrates imported from Bolivia and Peru as well as some domestic tin concentrates and some accumulated secondary residues. In 1989, owing to continued low tin prices and difficulties in obtaining feedstocks, TexTin ceased tin production and converted its equipment to process secondary copper.

The tinplate-producing industry is quite concentrated, comprising only seven major steel firms. The solder-producing industry is considerably more dispersed, but most of the tonnage is accounted for by a relatively few soldermaking firms. During the past decade, both the tinplate and the solder industries have undergone considerable consolidation. Although there are a number of companies in the tin chemical field, one firm dominates.

The other domestic tin-using industries are diverse, such as the brass, bronze, and flat-glass industries, and are represented by hundreds of firms and plants; most are in the East and Midwest.

Geology-Resources

Tin is a relatively scarce element; its average abundance in the Earth's crust is about 2 parts per million (ppm), compared with 94 ppm for zinc, 63 ppm for copper, and 12 ppm for lead. Tin is preferentially concentrated by magmatic differentiation processes and shows a worldwide affinity for granitic rocks or their extrusive equivalents. The principal deposits are scattered irregularly along a belt surrounding the Pacific Ocean. Most of the world's tin is produced from placer deposits; about one-half of placer tin comes from Southeast Asia.¹

The only mineral of commercial importance as a source of tin is cassiterite (SnO₂), although small quantities of tin are recovered from the complex sulfides stannite, cylindrite, franckeite, canfieldite, and teallite. Cassiterite has a high specific gravity (6.8 to 7.1), a Mohs scale hardness of 6 to 7, and is usually a dark-brown or black color with an adamantine luster.

Because cassiterite is both heavy and chemically inactive, it is concentrated in residual (eluvial) placers that form over or adjacent to bedrock source areas where weathering and erosional processes remove lighter rock materials and gravity assists in downslope movement of heavy minerals released by weathering. richest placers are stream deposits (alluvial placers) found where flowing water has concentrated heavy minerals generally derived from residual placers. Ocean beach sands also may contain placer accumulations of tin; such placers are mined offshore in Indonesia and No extensive tin placer Thailand. deposits have been found in the conterminous United States.

Technology

Exploration.—Historically, prospecting for tin has been carried out by the time-honored methods of panning, drilling, and pitting. As rich deposits were exhausted and the costs of exploration rose, the search for tin required more sophisticated methods. Geophysical and geochemical analyses have been employed to cover large areas more rapidly, isolating areas of possible tin deposits so that drilling can be more effective and less costly.

Mining.—Principal methods for mining placer deposits are bucketline dredging and gravel-pump operations, although hydraulicking and various open pit methods are also used. The bucketline dredges used are floating dredges similar to those used to mine other placer deposits. The ore is excavated and transported by buckets to the interior of the dredges, washed on screens, and concentrated in jigs and on shaking tables. Tailings are discharged at

the rear of the dredges to fill in the mined pond, and the crude tin concentrate is sent to the dressing shed for final concentration.

Although gravel-pump and hydraulic mining both use water jets to break up the tin-bearing material, the methods of conveying the material to the launders differ. In gravel-pump mining, a pump is used, whereas hydraulicking employs the pressure developed by a natural head of water. In each method, the material is washed through a riffled launder, called a palong in Malaysia, where cassiterite is collected by the riffles and the waste is washed away.

In open pit operations, the material is excavated by power shovels and transported on a conveyor belt to the washing plant for treatment.

Vein tin deposits are mined by methods similar to those used in the hard-rock mining of other nonferrous ores. Access to the ore bodies is by adits and shafts. The ore is broken by conventional drilling and blasting and transported from the mine to a concentrator for treatment.

Processing.—The crude tin concentrate from placer mining is further upgraded by washing, tabling, and magnetic or electrostatic separation. The final product is virtually pure cassiterite.

Tin ore from lode deposits is reduced to the necessary size by conventional crushing and grinding. The ore is concentrated by gravity methods involving screening, classification, jigging, and tabling. The gravity concentrate is usually of lower grade than placer concentrate owing to associated sulfide minerals. The sulfide minerals are removed by flotation or magnetic separation, with or without roasting, to produce a second-stage concentrate.

Cassiterite in placer deposits is fairly coarse grained, and recoveries range from 90% for gravel-pump mines to 95% for dredging operations. However, the cassiterite in vein deposits is very fine grained and is difficult to recover by gravity concentration. Cassiterite ore at mines in Australia, Bolivia, the Republic of South Africa, and the United Kingdom

are floated, but recoveries are seldom more than 70%. Recovery of the tin content in Bolivia is reportedly as low as 50%.

Cassiterite is reduced to tin by heating with carbon at 1,200°C to 1,300°C. The almost pure cassiterite concentrate from placer deposits is smelted directly. Other concentrates, particularly from Bolivia, contain impurities that must be removed before smelting. This is usually done by roasting the tin concentrates with or without fluxes, followed by acid leaching. During roasting, most of the sulfur and arsenic are removed as oxides. Bismuth, copper, iron, and zinc oxides are leaching the removed by roasted concentrate with sodium carbonate or sulfate and leaching with water. Antimony, bismuth, lead, and silver may be removed by a chloridizing roast, followed by an acid leach.

In modern tin-smelting plants, reverberatory furnaces are used to smelt primary tin concentrate and to resmelt the slag for additional tin recovery. Although blast and electric furnaces are also used to smelt tin concentrate, reverberatories are often preferred because of better control, cleaner slags, and superior efficiency in smelting finely divided materials. Electric furnaces are often favored for energy-saving reasons, especially for smaller smelters.

Tin smelting is a batch operation. A typical charge consists of cassiterite concentrate, a carbon reducing agent, and limestone and silica fluxes. From 10 to 12 hours is required to smelt a charge. When smelting is complete, the molten batch is tapped into a settler, from which the slag overflows into cast-iron pots. The molten tin from the bottom of the settler is cast into slabs or pigs for refining.²

The slag, containing 10% to 25% tin, is resmelted to yield a slag containing less than 1% tin.

Heat treatment is the most widely used refining method and consists of heating the tin from smelters on a inclined hearth to a temperature slightly above the melting point of pure tin, but below the melting points of the impurities. Thus, the comparatively pure tin melts and

flows into a kettle, leaving impurities such as iron and copper in a dross residue that is retreated to recover the contained tin.

The molten tin is then stirred with green wood, which produces a strong boiling action. During the stirring, the metal impurities and part of the tin are oxidized and form an oxide dross that is skimmed off. Sometimes tossing is used instead of stirring. In this operation, hand ladles of molten tin are dipped from and poured back into the kettles, exposing the tin to the oxidizing action of the air. After refining has been completed, the tin is cast into pigs for marketing.

Recycling.—The only form of tin recycling in which free tin is produced is In recent decades most detinning. detinning has been conducted on new, flat tinplate scrap, mostly from tin mills or canmaking plants. In the detinning of flat tinplate, generally the tinplate scrap is treated with a hot solution of caustic soda in the presence of an oxidizing agent to dissolve the tin as sodium stannate. The base steel is then washed and compacted into bales for shipment. The tin may be recovered from the stannate solution as metal, sodium stannate crystals, or tin Because of advantages processing costs and production of a highpurity metal, the common practice is electrolysis of the stannate solution to yield metallic tin. The refined tin averages as high as 99.99% purity, with antimony, iron, and lead as common impurities.

Until recent years, the detinning of used tin cans was not performed on an economic, high-volume basis because cans were often in a crushed condition and had enamel coatings and food particles attached that made effective detinning impossible. However, in the late 1980's, techniques were developed to detin these used tin cans. The most common method is to shred the cans into small popcorn-sized pieces and then proceed with the caustic soda treatment.

Most scrap tin is alloyed tin (such as solder, brass-bronze, or babbitt) that is recycled in its own alloy industry. These producers refine undesired elements from

the scrap charge or may use additions to build up desired elements.

Byproducts and Coproducts

In some tin placer deposits, large amounts of columbium, tantalum, and rare-earth minerals are associated with the cassiterite. Some lode tin deposits contain numerous other materials such as copper, lead, silver, and zinc, usually in the form of sulfides.

Tin has been recovered as a coproduct of molybdenum mining at the Climax lode mine in Colorado. Small quantities have been produced as a coproduct of placer gold mining or tailings-cleanup operations in Alaska or South Dakota. It has been produced as a byproduct of lead-zinc mining in Ontario and British Columbia, Canada.

In some major tin-producing countries, such as Malaysia and Thailand, tantalum contained in tin smelter slags is a major source of tantalum supply.

Substitutes

Alternative materials, often less costly, have been a significant factor in the downward trend in domestic consumption over the past two decades. Aluminum and chromium-coated tin-free steel were two materials used to replace tinplate in beverage cans over the past two decades. Other substitutes for tinplate include enameled steel, glass, paper, and plastics. Nonmetallic materials, aluminum, copper, galvanized steel have largely replaced terneplate for roofing and both tinplate and terneplate for other construction. In general, no satisfactory substitutes have been found for tin in solder, although lowering the tin content of the solder may be possible in some applications. Aluminum alloys, other copper-base alloys, and plastic could be substituted for some bronzes. Low-tin aluminumcopper, or lead-base- bearing alloys and roller or ball bearings, may be substituted for babbitt metal. Other chemicals may replace some tin chemical compounds for use as fungicides, biocides, marine antifouling paints, or polyvinyl chloride stabilizers.

ANNUAL REVIEW

Legislation and Government Programs

The NDS continued in its fourth year of being managed by the Department of Defense, with day-to-day operations guided by the Defense Logistics Agency (DLA).

The DLA sold 8,815 tons of tin from the stockpile in 1992. DLA continued its tin swap program with the ferroalloy upgraders through their broker-agents and also continued its direct cash sales to industrial users. The direct sales were held each day, with orders for lots of 5 tons or more being accepted daily between 1:30 p.m. and 3:30 p.m. at the price set by the DLA for that day. Pickup points for the stockpile tin were increased by seven compared with the four locations used in 1991. The pickup points were: Point Pleasant, WV; Curtis Bay, MD; Hammond, IN; Stockton, CA; Sommerville, NJ; New Haven, IN; Gulfport, MS; Baton Rouge, LA; Anniston, AL; Granite City, IN; and Warren, OH. This year as an innovation, DLA tin customers were allowed to select their tin by brand. Brands such as Banka, Longhorn, and Pass were available.

The DLA had authority from Congress to dispose of 12,000 tons of tin in fiscal 1992. At yearend 1992, the NDS inventory was 153,896 tons of tin and the stockpile goal was 42,674 tons. DLA also announced it had awarded its fiscal 1993 ferroalloy upgrading contracts to Elkem and Macalloy. Payment for each contract would be 25% tin, 35% payment in kind, and 40% other commodities.

Throughout the year, no substantive action was taken on the bill (S. 391) calling for either a ban or reduction in the use of lead in certain products, but the bill did remain active. Certain features of the bill calling for drastic lowering of lead content could be of special importance for tin because tin is often a coalloy of lead.

Strategic Considerations

Tin's strategic importance is indicated by its major position in the NDS. Tin is used in such defense-related products as solder for printed circuit boards used in aircraft and night-vision weaponry, and bronze fittings for naval gear. Tin in the NDS is stored in warehouses around the country, often close to plants that would use the tin during wartime.

It is considered unlikely that domestic tin deposits will yield significant amounts of tin in the next 10 years; therefore, the Nation's strategic needs must be met by imports, the NDS, and recycling.

Issues

Throughout the year major tinproducing countries and some tin traders voiced their displeasure with the increased pace of NDS tin disposals (compared to recent years) and the prospect of the same or even faster paced sales in future years. They argued that the disposals made in these higher annual quantities disrupted the tin market and depressed the price of tin.

In January, hearings were held for two at the International Trade Commission in Washington, DC, at which interested tin industry officials were invited to express their concerns over proposed U.S. Government action that would raise sharply the tariffs on tin. bauxite, some steel items, and a variety of nonmineral goods imported from China. The punitive tariffs were to be in retaliation for violation of U.S. intellectual property rights. Shortly after these January 6-7 hearings, the Office of the U.S. Trade Representative announced that an accord had been reached with China on the matter and that the tariffs would not be imposed.

The chairman of the Pig Tin Task Group for the ASTM announced an initiative to institute a new low-lead Grade A specification for tin metal used for tinplate. The revised specification called for a maximum lead content of 0.020%, compared with 0.050% in the current Grade A specification. The ASTM B-2 Committee accepted the

proposed new specifications. By yearend, the ASTM membership had not yet voted on the issue.

Production

The Lost River Mining Corp., in Alaska, operated the only mine in the United States to produce any amount of tin concentrates. It produced a very small amount. This mine has operated intermittently as a tin producer for many decades. The tin output from the mine amounted to only a small fraction of domestic tin requirements.

Alco-Met Corp., Boston, MA, reportedly was satisfactorily completing its first full year of producing high-grade tin at its Boston plant. The firm intended to fill part of the gap left by the closure of the Capper Pass tin smelter in the United Kingdom. The plant's initial capacity was 100 tons annually of 99.9999%-pure tin. Such purities were favored for certain electronic applications.

MIDCO Inc., St. Louis, MO, announced the startup of its new tin smelter designed to produce Grade A tin from secondary sources. The tin was to be sold in ingot form, with expected production at the rate of 3,000 tons annually. The MIDCO brand of tin was sanctioned by the London Metal Exchange. Before this year, MIDCO had been producing a tin-lead solder at this facility.

Consumption and Uses

Primary tin consumption decreased slightly in 1992. The major consumption category of tinplate registered a fairly significant decline, which was partly offset by a modest increase in the solder category.

Tinplated steel and tin-free steel accounted for 27% of the 131 billion cans shipped domestically; aluminum accounted for 73%. This compared to 1991 figures showing steel accounting for 27% of the 129 billion cans shipped domestically and aluminum accounting for 73%. Aluminum held an overwhelming advantage in the beverage

can market, while steel predominated in the food can and the general-line markets.³

Weirton Steel Corp., Weirton, WV, announced it had joined a collaborative effort with Nippon Steel Corp., Japan, and the Sollac Div. of Usinor, France, to work together to develop a lighter weight steel can to increase the competitiveness of the two-piece steel beer and soft drink can. All three firms rank among the world leaders in tinplate production.

The Ball Corp. agreed to purchase Heekin Can Co. for \$90 million. Ball was based in Indiana, and Heekin was based in Ohio. Ball had been strongest in using aluminum for beverage cans, while Heekin's strength had been in tinplate for food cans.

During the year, reports from the domestic automotive industry indicated an accelerated conversion from copper-brass radiators to aluminum radiators. Ford led the trend, with 90% of its cars and trucks now fitted with aluminum radiators. General Motors now had about 60% of its cars and trucks fitted with aluminum radiators. Until 1991, Chrysler reportedly used only copper-brass, but started to use aluminum radiators for its new Dodge Caravan and Plymouth Voyager minivans and the new LHplatform Chrysler Concorde, Eagle Vision, and Dodge Intrepid models. Reportedly, most European carmakers were also moving rapidly to aluminum radiators. This is in sharp contrast to Japan's carmakers, who have remained with copper-brass in all their cars made in Japan as well as in their American factories. One of the main driving forces toward aluminum radiators has been the desire and need by carmakers to improve fuel efficiency, and one of the ways to achieve that is to favor lighter weight components such as aluminum radiators. Solder is used to seal copper-brass radiators, so these trends have negative implications for tin usage. (See tables 2, 3. and 4.)

Markets and Prices

Marketing of tin metal in the United States was performed mostly through

trading firms, which imported the tin from a variety of countries and warehoused the tin in this country until they sold it to customers. Foreign-owned trading firms seemed to dominate the field. Most tin dealers were based in or near New York, NY. Some tin was also marketed directly in the United States by large foreign producers who maintained sales offices here and sold their tin metal, usually on a 1-year contract basis, only to the largest users. Foremost among these direct-sale operations was Indo-Metal Corp., which served as the exclusive North American sales outlet for tin metal produced by Indonesia's Governmentowned tin production organization. The year was one of continued consolidation following a few years of significant shakeouts in the tin trading community.

The price of tin metal, as published in Metals Week, remained in a fairly narrow band all year, although it experienced a brief spurt in the May through August period. The LME remained the primary trading focus for tin. The Kuala Lumpur Commodities Exchange in Malaysia continued as an active tin trading forum.

Following the startup of the new LME warehouse in Baltimore, MD, the LME announced its approval of three more warehouses in the United States. The new warehouses were in Toledo, OH; St. Louis, MO; and Long Beach, CA; and were expected to accept delivery of aluminum, nickel, tin, and zinc.

Foreign Trade

Brazil supplanted Bolivia as the major source of U.S. tin metal imports. China ranked second, followed by Bolivia, Indonesia, and Malaysia.

Imports declined somewhat, although a part of the slack was absorbed by increased Government stockpile disposals.

Imports of tin in all forms (ore and concentrate, metal, and waste and scrap) remained free of U.S. duty. (See tables 5, 6, and 7.)

World Review

The seven ATPC member countries, which accounted for about 60% of world

tin output, agreed to export limits of 87,000 tons in 1992, down from 95,000 tons in 1991. Brazil and China, not members of ATPC, also agreed to restrict exports. The ATPC announced that, in view of the current tin overhang depletion rate, it could continue its export quota program only until 1994. In March, the ATPC estimated world tin stocks to be 37,000 tons (in the 1981-85 period world tin stocks were believed to be as high as 100,000 to 125,000 tons), and they felt a normal stock level of 20,000 tons could be achieved by 1993.

Australia.—The Renison Bell Mine in Tasmania, owned by Renison Consolidated Goldfields Ltd., remained the largest tin mine, accounting for more than 90% of Australia's total mine output. It was the world's largest hardrock underground tin mine and a relatively low-cost producer with substantial high-grade reserves.

Rebounding from a lengthy period of inactivity in 1991 owing to labor strife, Renison continued mining throughout the year but with a scaled-back work force. Most of Renison's mine output was shipped to either the Datuk Keramat Smelter Co. or Malaysia Smelting Co. tin smelters in Malaysia for refining. The Renison material was an important feedstock for both Malaysian smelters because domestic Malaysian mine output has declined in recent years.

Greenbushes Ltd. continued to mine tin and tantalum near Perth, in Western Australia. This operation produced about 200 to 300 tons of tin-in-concentrate annually in recent years.

Bolivia.—Tin production continued at the higher levels characteristic of the pattern established in recent years. However, Bolivia lost its position as the dominant source of tin for the United States and ranked third in that category.

Corporación Minera de Bolivia (COMIBOL), the Government-owned mining organization, was reportedly expanding its rationalization scheme in response to urging from the World Bank. In recent years, COMIBOL had reduced its work force from 30,000 to about

6,000 people. Reportedly, plans were to change COMIBOL into a mostly administrative function, overseeing the mining contracts of various private firms. Traditionally, the Huanuni tin mine, in the Department of Oruro, has been the richest underground tin mine in Bolivia. The capacity of the mine is 3,600 tons of tin in concentrate annually, with the output going to the Vinto metallurgical complex of COMIBOL. Another important operation was the Catavi-Siglo tin mine in the Department of Potosí, with reported reserves of 3,900 tons.

The large Brazilian tin-mining company Paranapanema started work on recovering the tin values from the tin tailings and dumpings at the Catavi-Siglo Mine. In 1991, Paranapanema won the bidding for the tin tailings and dumpings at that site. Paranapanema expected to invest \$8 million in the recovery at Catavi-Siglo, which had an estimated 21 million tons of dumpings. Catavi-Siglo had been the world's largest underground tin mine before it was closed in 1986.

Compania Minera del Sur (COMSUR) started construction on a 1,000-ton-perday milling plant at the Bolivar tin-silverzinc-lead operation. COMSUR was onethird owned by RTZ Ltd. Bolivar was estimated to have 856,000 tons of reserves (1.26% tin) and more than 350,000 tons of tailings (0.76% tin).

Empresa Nacional de Fundiciones (ENAF), the Government-owned smelting organization, announced the signing of long-term contracts to supply two tin trading houses: Toyota Tsusho and Leopold Lazarus. The material involved was reportedly 99.90% tin with low-lead content; low-lead metal was increasingly welcomed in the marketplace. ENAF also signed a contract to toll smelt up to 5,000 tons of tin concentrates from Minsur's tin mine in San Rafael, Peru. This was believed to be ENAF's first contract for toll smelting. Minsur's tin concentrates had been toll smelted in Brazil, Malaysia, and Mexico. addition, ENAF completed the conversion of its tin smelter from heavy fuel to natural gas. The reduction in operating costs expected to result from the switch from oil to gas would allow ENAF to

further reduce its treatment charges.

Landlocked Bolivia was granted access to the Pacific Ocean in a historic bilateral agreement between the Governments of Bolivia and Peru. In the past, the main mining areas of Bolivia had been obliged to transport their exported mineral output to the ports of Arica or Antofagasta in northern Chile. The port of Arica is very small, and shipments to Antofagasta, which is further south, were costly and time consuming. It was believed that access to the Peruvian port of Ilo would result in quicker and cheaper exports of Bolivian tin and concentrates. Ilo was a deep natural port, but expansion was needed and planned. The development of Ilo was to be funded by InterAmerican Development Bank and would include the construction of a road from LaPaz to Ilo.

Brazil.—Brazil continued its 3-year string of tin mine production at rates considerably below those established in prior years and ranked second in world tin mine output. It ranked third in world tin smelter production. Tin mines and smelters were mostly privately owned, sometimes by foreign firms. Tin was mined from both alluvial and lode deposits. Brazilian mines were generally considered the lowest cost to operate in the world. Brazil was not a member of ATPC, but generally agreed to cooperate with the spirit of its guidelines and restrict its tin exports.

The Paranapenema Group was the largest private tin producer in the world, owning and operating six tin mines. The mines were Capipore in the State of Amapa, Massangana (also known as C-75, Ariquemes, and Serrinha) in the State of Rondônia, São Francisco in the State of Mato Grosso, São Raimundo in the State of Pará, and Iarape Preto and Pitinga, both in the State of Amazonas.

Pitinga used four Elliot bucket wheel dredges and mined to a depth of 6 to 8 meters. The mine site employed nine floating wash plants and seven gravel-pump plants. The dredging capacity was about 13 million cubic meters annually. Management was in the process of developing mining of a soft weathered tin

ore, separate from the alluvium, and was reportedly considering constructing a tin smelter. Total investment at Pitinga was about \$115 million.

There were a series of alternating legal decisions about the continued operation of the Bom Futuro Mine near Ariquemes in Rondônia State. During 1991, the Government closed tin-mining operations by independent miners (garimpeiros) on the site. This year, various tribunals issued decrees alternately favoring the garimpeiros and occasionally the Ebesa tin-mining consortium of companies. During the year, tin-mining activity at Bom Futuro was nil except for some possible tin smuggling.

Burma.—Mining Corp. Two, based in Rangoon, was responsible for the country's entire production of tin, as well as antimony, tungsten, and other metals. The organization totaled about 1,000 persons who operated various underground, opencast, gravel-pump, and dredge tin operations, as well as a tin concentrator at Tavoy. The country's tin ore was smelted at the Syriam smelter, with a capacity of 1,000 tons annually.

Canada.—Rio Algom Ltd. closed its East Kemptville, Nova Scotia, tin mine early in the year owing to continued low tin prices. Discovered as a tin property in 1979, the mine started production in 1985 and had a series of owners. Rio had provisions of \$20 million to cover closing costs. Rio was 53% owned by RTZ Ltd., and the demise of this mine represented the end of RTZ's involvement in tin mining; since 1991, RTZ's other tin holdings (all based in the United Kingdom) ceased operations.

China.—For the third consecutive year, China led the world in tin mine output. Yunnan Tin Corp., a subsidiary of China National Nonferrous Metals Industry Corp. (CNNC), Gejiu City, Yunnan Province, was the largest tin producer. It operated 5 underground mines, 7 open pit mines, 10 mineral dressing plants, and 1 smelter, giving it an annual mine production capacity of 7.5 million tons of tin ore, while the smelter

capacity was 40,000 tons of refined tin yearly. Both surface alluvial deposits and underground lode deposits were worked. After 100 years of exploitation, the high-grade alluvial deposits were virtually depleted. Low-grade alluvial tin ores of fine particle size, tailings, and underground lodes were the main sources.

Yunnan used reverberatory smelting of tin concentrate, pyrometallurgical refining of tin metal, electrolytic separation of tinlead alloy, and tin slag fuming. It used a continuous electrothermal crystallizer for removal of lead and bismuth using the different melting points and specific gravities of tin and lead-tin alloy. Several other tin smelters around the world utilized Yunnan's crystallizer technology.

The Dachang Mining Administration (a subsidiary of CNNC) in Dachang, Nandan Xian, Guangxi, Zhuangzu Zizhiqu, continued its expansion program that was expected to eventually make it China's largest tin mine.

The Gejiu tin smelter, owned by Yunnan Tin Corp., announced that the London Metal Exchange approved the YT brand as good for delivery. This smelter had an annual output of 12,000 tons. It treated concentrates with a grade of about 40% to 60% tin and produced 99.0% and 99.9% tin purity with a maximum lead content of 0.03%.

France.—CMB Packaging launched a new three-piece tinplate can. The can had a lithographed tinplate body and a full aperture easy-open end. It also had symmetrical vertical flutes that provided stiffening and allowed a down-gauging of the tinplate used from about 0.21 mm to 0.17 mm, providing a weight savings of 20%. A new production plant at CMB's factory in Cambridgeshire, United Kingdom, was to produce the item.

Germany.—Consolidated Tin Smelters, the subsidiary of Amalgamated Metal Corp. (AMC), announced plans to sell its 50.5% ownership in Malaysia's Datuk Keramat Holdings (DKH) owing to Keramat's intention to diversify into banking. AMC would retain its interest in DKH's subsidiary, Datuk Keramat

Smelting (DKS). A group of Malaysian businesses were reportedly interested in buying AMC's stake in DKH. DKS had been producing about 20,000 tons of refined tin in recent years. The smelter had an installed capacity of 60,000 tons of concentrates, but effective capacity was considerably lower and still dropping because of the lower quality foreign concentrates DKS blends with the higher quality domestic concentrates. Effective capacity was reported to be about 30,000 tons annually.

Hong Kong.—The Mainland Tin Smelting Co., which owned and operated a 7,200-ton-per-year tin smelter, announced it may add a third furnace to the plant. A Far Eastern firm purchased a 20% stake in Mainland Metals Holdings Ltd., which controls Mainland Tin Smelting, Mainland Alloys, and Mainland Metals. Mainland Tin Smelting had an application before the London Metal Exchange for registration of its tin.

India.—Reports indicated that erratic supplies of tinplate and sharply increasing tinplate prices combined to create turmoil in the country's metal packaging industry. In India, some of the functional advantages of tinplate over other packaging materials were even more pronounced than in other countries owing to the diverse climatic conditions in various parts of the country and some rough transit handling facilities. Based on these considerations, tinplate could be expected to have won market share at the expense of competitive materials: however, the problems of prices and supplies tended to force canmakers from Total installed capacity for tinplate. tinplate production was 300,000 tons, but even though demand was about 435,000 tons annually, production never exceeded 180,000 tons. The main reason for the production has been Government's import policy toward tin mill blackplate. In the late 1970's and early 1980's, the cost of imported blackplate was lower than prices charged by Indian producers, and because of the large outflow of foreign exchange, the Government then tried to discourage

imports through import licensing and customs levies. However, domestic capacity remained underutilized, and the domestic producers did not modernize or expand their plants. Adverse exchange rate fluctuations and the high rate of customs duty increased the cost of tinplate to the users, and food packers have been switching to other materials. One of India's three tinplate producers, KR Steelunion, closed its 60,000-ton-peryear plant at Bombay. The two other producers were Steel Authority of India and Tinplate Co. of India. On the positive side, the Government was promoting exports of foodstuffs and accorded priority status to the food processing industry. The ministry of food processing tried to win a further cut in the excise duty on packaging materials and the customs duty on imported materials. These moves could revive India's demand for timplate.

Indonesia.—This country ranked as the world's third leading tin mine producer and as the world's fourth leading tin smelter producer.

Tin mining was performed mostly offshore, usually by means of large-scale dredging. P.T. Tambang Timah (P.T. Timah), the Government-owned mining firm, ranked as one of the world's largest tin-mining organizations and accounted for about 80% of Indonesia's output. In recent years, P.T. Timah's three primary tin production complexes were on the islands of Bangka, Belitung, and Singkep, with the Bangka Island facilities accounting for 70% of P.T. Timah's tin production. In the past 2 years, P.T. Timah embarked on and generally completed a stringent restructuring program designed to bring its costs in line with the depressed tin price. closed its operations on Belitung and Singkep Islands and consolidated all its tin production on Bangka Island. It also moved its headquarters from Jakarta to Bangka Island. This year was one of consolidation for P.T. Timah.

P.T. Timah announced it had begun producing low-lead tin after acquiring a crystallizer from China for its tin smelter. This low-lead tin was intended mostly for

users in Japan and the United States. Its major application was for tinplate.

P.T. Timah sold its tin output in the United States exclusively through its subsidiary, Indo-Metal Corp., in New York, NY.

Japan.—Two firms announced the start of mass production of plastic food cans to compete with the steel can. Mitsubishi Kasei Corp. and Mitsubishi Plastics Industries Ltd. launched the joint project after 4 years of testing and evaluation. This newly developed can was molded of multilayered plastics by a process licensed by Hitek Ltd., of Richmond, Victoria, Australia. The can was to be marketed under the name "KP-CAN"; it consisted of two layers of recycled polypropylene and composite layers of gas-sealing ethylene-vinyl alcohol copolymers and a bonding resin. all of which were sandwiched between two polypropylene layers. This plastic can was said to be 40% lighter than the comparable steel can, suitable for use in microwave ovens, and could be made transparent. The cost of the plastic can was said to be about 10% higher than the cost of the comparable steel can. Initial deliveries were made to the Hoko Fishing Co. (Japan). Current production was 18 million plastic cans per year, but Mitsubishi announced plans that could lead to production of 120 million cans annually.

Korea, Republic of.—Lucky Metals Ltd. announced the possibility of closing its Changhang tin smelter this year owing to low tin prices and lack of a steady source of tin concentrates. Changhang tin smelter, with production of about 1,000 tons annually, depended mostly on tin concentrates from China. But in 1992, that source of concentrates had declined sharply owing to China's preference to export tin metal rather than tin concentrates and to keep its own tin smelters operating at a high rate. The startup in recent years of Mainland Metal's tin smelter in Hong Kong also aggravated tin concentrate sourcing problems for Changhang.

Pohang Iron & Steel Co., one of the

world's largest tinplate producers, announced it had reached an agreement with Shanghai No. 10 Iron and Steel Co. (China) to construct a 120,000-ton-per-year electrolytic tinning line. The line was to be constructed at Shanghai's Pudong Industrial Complex. Construction was expected to start in 1993, subject to approval by the Government of China, with a 1995 startup. The line's cost was estimated at \$97 million.

Malaysia.—This country ranked only sixth in world tin mine production after leading the world for most of the past century. The country continued to lead the world in tin smelter production.

At midyear, the President of the Malaysian Chamber of Mines decried the sad state of its tin industry. He observed that after 100 years of exploitation, the industry was suffering decline because of very low ore grades. The situation was aggravated by rising costs. Labor costs were cited as a special problem, rising sharply as the tin industry encountered harsh competition for workers from other sectors of a robust economy, such as tourism and construction. Production from the gravel pump sector accounted for 45 of the 49 mines closed this year. The total number of tin mines still operating fell to 92, the lowest number since the 1950's.

Malaysia Mining Corp. (MMC) remained the largest tin producer in the country, but continued low tin prices depressed its operations. MMC continued its movement away from tin, and for the third year continued the expansion of its exploration program in other base metals and gold in several countries, including Brazil, Burma, China, Laos, and Vietnam. MMC already had been active in engineering and construction and was preparing to enter the manufacturing field too.

The Sunjei Lembing tin mine was reopened. The mine has had a series of closings and reopenings since the 1940's and was last closed in 1987. Now, a Chinese Malaysian partnership has reopened parts of the mine, with plans to bring the whole complex back into operation.

Malaysia's two large tin smelters raised their tin concentrate treatment charges and were reportedly operating near full capacity. The two smelters, operated respectively by Datuk Keramat Holdings Bhd. and Malaysia Smelting Corp. Bhd., were supplementing declining demand for the refining of local concentrates by absorbing additional foreign tin concentrates. **Smelting** charges, which had declined sharply in 1991, rose to about \$290 per metric ton of contained tin for concentrates grading 70% tin. Datuk refined about 35,000 tons of tin annually, about 85% of which was foreign. Malaysia Smelting refined about 30,000 tons annually, about 60% of which was foreign. The two smelters, both in Penang State, together accounted for about 20% of world tin-smelting capacity. It was believed that Malaysia's importance in tin smelting would increase in future years as depressed tin prices and environmental problems make it more difficult for tin smelters in other countries to compete with Malaysian smelters.

Mexico.—Tin mining was focused in the north-central region adjoining the States of Durango, Zacatecas, and San Luis Potosí. The country's main tin mine, the El Perro Mine, was owned by Cia Mineral Pizzuto.

Estaño Electro S.A. de C.V. operated a tin smelter at Tlalnepantla, near Mexico City. Fundidora de Estaño S.A. operated a tin smelter at San Luis Potosí. Metales Potosí S.A. had a smelter in San Luis Potosí, as did Minera de Rio S.A. Most of the tin concentrates processed by the four smelters were imported.

Metales Potosí announced it was operating at full capacity, 4,800 tons per year, for the first time since the international "tin crisis" of late 1985. Potosí toll processed tin concentrates from Australia, Bolivia, Peru, Portugal, and Zaire. In the late 1980's, operating levels had been as low as 40% to 50%, but improved as more tin concentrates became available as a result of tin-smelter shutdowns around the world. Potosí's treatment charges reportedly rebounded to a more normal and profitable level of about \$600 to \$700 per ton. This year,

with sales of \$18 million, the smelting operation was unprofitable, but sales were expected to reach \$30 million in 1993, signaling a return to profitability. Onehalf of the tin Potosí produced was used to make the firm's solder, and the remainder was exported to the United States. However, to reduce its dependence on one commodity, the firm began constructing a facility to recover metals from low-grade copper scrap. By yearend 1993, this plant was expected to start treating 10,000 tons of copper scrap annually, producing blister copper, zinc oxide, tin, and lead.

Netherlands.—The large steel producer, Hoogovens, which had acquired a 40% stake in the Norwegian tinplate producer Norsk Blikkvalseverk (NB) in January 1990, agreed to acquire the remaining 60% of the firm. Hoogovens has long been a major tinplate producer. The acquisition added 130,000 tons annually to Hoogoven's yearly production of 670,000 tons of timplate. Hoogovens now controlled about 20% of the European tinplate market.

Nigeria.—Tin was mined from alluvial deposits by two major companies: Consolidated Tin Mines Ltd. and Nigerian Tin and Allied Minerals Products Ltd. Cassiterite was mined in association with columbite, tantalite, and tungsten minerals. All tin concentrates were shipped to the sole tin smelter, the Government-owned Makeri Smelting Co., in Jos, Plateau State. Makeri continued to operate well below capacity.

Substantial amounts of tin concentrates were reportedly smuggled out of the country. The Government officially permitted only refined tin to be exported, on which a 15% royalty per ton was charged. These exports were then marketed by London-based Decacia International Ltd.

Peru.—Minsur negotiated a contract with Bolivia's state-owned smelting organization, ENAF, for the toll treatment of 3,600 tons of tin concentrates. ENAF had excess capacity. Minsur produced about 13,000 tons

annually of tin concentrate, grading about 50% tin. Minsur previously had similar deals with Capper Pass (United Kingdom) and Potosí (Mexico) and still had similar contracts with Cesbra (Brazil) and the two Malaysian tin smelters.

Portugal.—Europe's largest tin mine, Somincor's Neves Corvo copper-tin mine in southern Portugal, announced good progress with its tin production. Neves Corvo had total output of 9,000 tons of tin concentrates to yield 6,500 tons of tin. In 1991, grades of the flotation concentrates (which amount to about 25 % of total tin production in terms of metal content) ran about 30% tin: after some operating capital improvements, average grades in 1992 ran 45% tin or better. This emphasis on improving concentrate grades was associated with Somincor's agreement on a long-term contract this year with the Zamora tin smelter in Spain. Zamora has traditionally been a processor of high-grade tin concentrates.

Russia.—Tin mining was conducted mostly in the far eastern regions of the country. The country's major tin smelter, the Novosibirsk Integrated Tin Works, actively sought business ties with Western firms. The 35,000-ton-per-year tin smelter sought foreign tin concentrates for smelting and refining because the facility found itself operating below capacity owing to a shortage of feed. The smelter used a variety of feed ranging from 15% to 70% tin, although the average grade tended toward the low side, at 25% to 30% tin. Also, the smelter could handle low-grade residues down to about 1% to 2% tin, although as environmental restrictions are increasing, treatment of low-grade feed may continue only for another few years. The smelter was still owned by the Russian Government, but under an agreement signed 3 years ago, the plant was leased to the operators for 11 years. smelter, which employed about 2,000 people, produced mostly 99.92% tin but also had a small production of higher purities. The company also produced tin solder and solder paste. Novosibirsk planned to commence production of organic tin chemicals in 1993 using a process developed in-house. Most of the smelter's tin output was consumed in Russia, but some went to Byelarus, Kazakhstan, and the Ukraine.

Reportedly, tin consumption in Russia was about 38% in solder, 24% in tinplate, 12% in tinning, and the rest in a variety of applications.

Hyundai Resources Development Co. (Republic of Korea) announced plans to start mine development work on the Prayouny tin deposit near the far east city of Khabarovsk. Estimates made by geologists had set reserves at Pravouny at 50 million tons of ore. Mine output would be 1 million tons of tin ore annually or about 5,000 tons of tin-inconcentrate annually. The tin grade was believed to be 0.5%, and some copper was present. Hyundai formed a 50-50 joint-venture with a Khabarovsk firm called Dalgeologia to develop the mine. It was reported the tin concentrates would be shipped to the Solnechny copper smelter near Komsomolsk. Hyundai's involvement, much of the concentrate could be exported to the Republic of Korea and other countries in Southeast Asia, although some also could be shipped across Siberia to the tin smelter at Novosibirsk in south-central Russia. Hyundai believed that, if its own studies support the earlier Soviet numbers, mine development could commence by yearend. The Hyundai group companies have been among the most aggressive foreign firms in trying to develop natural and mineral resources (including coal and timber) in the former Soviet Far East. Hyundai, which was the first foreign trading firm to establish an office in the port city of Nahodka, this year relocated its base to Vladivostok with the lifting of restrictions on foreign access to the former Soviet naval port.

South Africa, Republic of.—Rooiberg Tin Ltd. announced plans to close part of its tin-mining operations and to focus mining activities on high-grade tin ore reserves. The decision to high grade was motivated by low rand-denominated tin prices that have put the mine under pressure to reduce costs or shut down. Ore production would be cut from the 12,000-ton-per-month level to 6,000 tons. The firm had enough high-grade reserves to last 1 year. Rooiberg's tin smelter, which secured all its feed from the Rooiberg tin mine, produced less than 1,000 tons of tin metal in 1992.

Thailand.—Once the country's largest revenue producer among metals, tin mine and smelter production remained steady this year, but at a much lower level than prevailed a decade ago. Now Thailand ranks only fifth among the world's tin mine producers. Other industries such as tourism, real estate, rubber, palm oil, and shrimp farming continued to draw investment away from tin mining in the south, where most tin reserves were located.

The Thai Pioneer Enterprise tin smelter announced plans to boost annual production at its Pathum Thani plant by 6,000 tons, to 12,000 tons. To cover the cost of raising its output, Thai Pioneer planned to double its capital. Thai Pioneer was owned 60% by Van Waaden and Associates of the Netherlands; the remaining shares were held by local Thai business groups, including Universal Mining.

Thaisarco, the country's major tin smelter, announced the start of a 2-year, \$1.2 million exploration program over a large site in the Andaman Sea. Also, Thaisarco announced current discussions with the Offshore Mining Organization (OMO), the Government tin-mining agency, about the possibility of mining for tin in OMO's concession near the site of Thaisarco's own exploration program. The firm's renewed interest in tin mining was attributed to its difficulties in sourcing enough feed. The smelter was running trial lots of tin concentrate from Laos as part of its attempt to make up for the decline in Thailand's mined tin The smelter's production of 11,000 tons of tin metal this year was considerably less than its capacity of 38,000 tons.

Turkey.—Although the country has not been a major tin producer in modern times, archaeologists and scientists

working on bronze artifacts in Turkey announced evidence that sheds light on obtained tin. how early humans Throughout the Near East, bronze articles from 5,000 years ago attest to the importance of this copper and tin alloy to early cultures. In the past, archaeologists had unearthed many copper mines nearby but had no idea where the tin originated. Some evidence had pointed to mountains in Afghanistan as the nearest possible source, and there had been clues that tin was an active trading item. But recently, tin ore was found at Goltepe, in the mountains near Ankara, Turkey. Radiocarbon dating techniques showed that tin was extracted there about 2500 B.C. It was hypothesized that these ancient people extracted tin using a multistep, low-temperature technique. The findings added evidence to a growing perception that ancient cultures may have depended on small, local mineral deposits more than previously believed.

United Kingdom.—Carnon Consolidated Ltd. announced plans to develop two new levels at its South Crofty tin mine in Cornwall. A decline to service these levels was already in place and was equipped with a conveyance suitable for ore removal and human transport. Carnon planned to invest about \$7 million over the next 5 years.

Vietnam.—A joint-venture announced by Japanese, Taiwanese, and local interests that would establish a new plant for the manufacturing of tin cans in Vietnam by 1994. The joint-venture would be capitalized at \$2.5 million and would be 29% owned by the Japanese trading firm of Tomen Corp., 51% by Taiwan's Ton Yi Industrial Corp., and remainder by а Vietnamese Government-owned corporation. plant would be in Ho Chi Minh City and would be capable of producing about 70 million tin cans annually. It was expected that Ton Yi would supply the tinplate, and that the cans produced would be intended for pineapples and other fruits, vegetables, and marine products. Exports of canned products would be handled by Tomen with most shipments to be made to Japan, Russia, and Western Europe. Vietnam promoted the export of its agricultural and fishery products to the West to earn foreign exchange. In recent years, its export sales to these markets were slow because of quality problems with tin cans. Vietnam produced about 30 million tin cans annually. With the additional announced can capacity, the country was expected to meet the entire demand for cans for canned exports.

Current Research

In the United States, 3M Corp.'s Electrical Specialties Div. in Austin, TX, announced development of a new Underwriter's Laboratory Recognized Scotch Foil Shielding Tape #1183 that employs a tin-alloy coating on smooth copper foil to enhance a durable electromagnetic field. This tape was a tin-alloy coated version of the 3M #1181 tape and provided shielding when wrapped around flat and round cable, and cable connectors. The electrically conductive adhesive enabled #1183 tape to make electrical connection across seams and between mating sections of electronic enclosures ranging from small equipment housings to large shielded rooms. The tape also could suppress the energy radiating from seams between the sectors of dish antennas. The tin-alloy coating on both sides of the foil reportedly provided two significant benefits: environmental stability and corrosion resistance, and exceptional solderability for applications such as sealing the seams when the tape was used as a shield around cable connectors.

In France, CMB Packaging announced development of a new three-piece tinplate can. The can had a lithographed tinplate body and a full-aperture, easy-open end. It also had symmetrical vertical flutes that provided stiffening and allowed a downgauging of the tinplate used from about 0.21 mm to 0.17 mm, providing a weight savings of 20%. A new production plant was being built at CMB's factory in Cambridgeshire, United Kingdom, to make the new item.

In Japan, Sumitomo Metal Mining Co.

announced that it had developed, in conjunction with Tohoku Chemical Co., a new type of highly transparent indiumtin oxide film that could be printed like ink onto flat-panel video displays. Currently, forms of indium-tin oxide, a key component of liquid-crystal or electroluminescent displays used on a wide variety of electronic devices, must be sputtered onto the panel, baked, and then etched via standard lithographic methods. The new material offered the potential to produce larger displays while significantly reducing costs.

the United In Kingdom, the International Tin Research Institute (ITRI), based in Uxbridge, announced a widening of the scope of its tin research activity. Since its 1932 founding, the ITRI had limited its research activities for, and funding sources to, its tin producer sponsors. This year, the ITRI established a new limited liability company called ITRA. The facilities of ITRA would be open to commercial firms and to trade or research associations worldwide. Organizations subscribing to ITRA would have the opportunity to participate in cooperative research projects that were of mutual interest to a particular industrial sector or to place specific research contracts with ITRA, with exclusive access to the results. Although ITRA will be a separate organization, with its own subscribers and clients, it would be fully supported by all the facilities of ITRI, including technical expertise and support staff.

The ITRI also announced success in its 2-year effort to develop a cyanide-free plating system for tin-zinc coatings. The new plating electrolyte was claimed to be less corrosive and easier to control and operate than the original plating process, which used hydrofluoric acid. The ITRI said that a patent was being sought and that a number of industrial firms were trying the new plating process. They felt that a new market for tin of at least 1,000 tons yearly worldwide would result from this new development. The next stage would be to adapt the process to continuous strip plating, which would tap the large galvanized steel and automotive markets.

Also in the United Kingdom, two subsidiaries of the Cookson Group, Fry's Metals and Electrovert, announced an Anglo-Canadian partnership for the worldwide manufacture and marketing of fusible alloy core technology. The process was originally developed by Fry and the product made in its Clydebank, Scotland, plant. The process was ordinarily used for making plastic components in the automotive and aerospace industries and allowed components with complicated internal structures to be produced in a single hollow piece. Castings were made using tin-bismuth or tin-lead-antimony alloy molds, which form the internal structure of the plastic form. The low-melting point alloy was carefully melted away to leave a precisely formed casting. This property allowed lightweight, smooth forms to be made from high melting point plastics with good insulating properties that were suitable for auto engine components such as inlet manifolds. water pumps, and thermostat housings. An additional benefit was reportedly the recycling of the tin alloys used in casting. Each casting machine was estimated to use 3 to 5 tons of tin alloy at any one time, of which Fry's estimated less than 1% was lost annually in the process. Fry forecasted a probable market of at least 400 machines of this type.

CMB Closures Ltd., United Kingdom, announced the development of a new microwaveable tinplate cap. The plastic-lined tinplate closure, with a tamper-evident "pop-up" button, was sealed to a specially developed glass bowl-shaped container. CMB started to conduct trials with the new cap in the United States and felt the item could be commercially available by 1993.

British Steel Corp., a major tinplate producer, announced development of a competitive material that does <u>not</u> use tin. Its trade name was Hi-Top, and it was somewhat akin to tin-free steel (TFS, developed 25 years ago) with an electrolytic chromium-chromium oxide coating. The coating on Hi-Top was a duplex structure; 80% of its thickness consisted of chromium metal adjacent to the steel substrate and 20% hydrated

chromic oxide-hydroxide in a layer above the metal. The precise composition was controlled by the processing conditions.

British Steel also brought to market another competitive packaging product called Ferrolite. The product was developed by **CMB Packaging** Technology PLC, and British Steel became the sole licensee for production of Ferrolite in the United Kingdom for sale worldwide. The product featured a polymer coating on one or both sides of a steel strip. The firm claimed Ferrolite was applicable to most tin mill product applications, including aerosol can components, full aperture easy-open ends, and draw/redraw cans; but technology for welding was not yet commercially available. The firm indicated that a particularly interesting market Ferrolite was in the production of shallow drawn trays for pet food and ready-meal markets, and claimed testing had shown that Ferrolite trays could be safely used in microwave ovens and provided even heating of the contained food.

OUTLOOK

Supply

The supply of tin for the United States was expected to continue to originate primarily in Asia and South America and to enter the country in the form of refined tin metal. Although some promising tin deposits existed in the United States, primarily in Alaska, these were not expected to become major production sites during the next 10 years, especially if tin prices remain low. The NDS is expected to continue to be an important and probably increasing source of tin supply because the stockpile goal is substantially lower than the current inventory. Increased scrap recovery, both through alloy recycling and detinning, is a possibility, and that could help ameliorate the Nation's dependence on imported tin.

Worldwide, the oversupply of tin that has existed since the early 1980's appears likely to persist for at least a few more years. The advent of several new tin mines in countries such as Brazil and

China appears likely.

Demand

The demand for primary tin in the United States was forecast to be static in the next few years. There appears to be some chance that tinplate may regain a small portion of the beverage can market in the next few years, especially if tin can recycling increases and if tinplate can maintain or widen its cost advantage over aluminum.

Among the major metals, tin has had a relatively good record with regard to toxicity and the environment, and this aspect may help tin gain market share at the expense of more troublesome metals. In particular, if regulations continue to negatively impact the use of lead in applications such as solder, the demand for tin as the complimentary alloy component may increase.

Worldwide, new tinplating lines are being built in developing countries, and tinplate traditionally is a stronger competitor than aluminum in canmaking markets outside the United States. Therefore, the outlook for overall tin demand is for modest growth of about 1% annually in the next few years.

Numerous research efforts in recent years have resulted in new applications for tin that could result in small-scale increases in tin consumption in future years, but there have recently been no major new applications.

⁶Estimated. Revised. W Withheld to avoid disclosing company proprietary data; not included in "Total."

¹Contained tin basis. Data derived in part from the Monthly Statistical Bulletin of the International Tin Council, London. Table includes data available through July 26, 1993. ²Reported figure.

³Concentrates gross weight reported, estimated 47% Sn content.

⁴Formerly part of the U.S.S.R; data were not reported separately until 1992.

⁵Concentrates gross weight reported, estimated 70% Sn content.

⁶Dissolved in Dec. 1991.

⁷Nonduplicated total of content of concentrates plus smelter production.

Estimated. Revised. W Withheld to avoid disclosing company proprietary data; not included in "Grand total."

Data for 1988-90 is derived in part from UNCTAD. Wherever possible, total smelter output has been separated into primary (from ores and concentrates) and secondary (tin metal recovered from old scrap). This table reflects metal production at the first measurable stage of metal output. Table includes data available through July 9, 1993. ²May include some secondary metal.

³Reported figure.

⁴Formerly part of the U.S.S.R..

⁵All production in the U.S.S.R. from 1988-91 came from Russia.

⁶Dissolved in Dec. 1991.

TITANIUM

By Joseph Gambogi

Mr. Gambogi, a physical scientist with 10 years of Government and industry experience, has been a commodity specialist since 1988. Domestic survey data were prepared by Giovanni C. Jacarepaqua, statistical assistant; and international data tables were prepared by Amy Buck, Section of International Data.

Titanium (Ti) is a lightweight metal well known for corrosion resistance and high strength-to-weight ratio. Titanium comprises about 0.62% of the Earth's crust and occurs primarily in the minerals anatase, brookite, ilmenite, leucoxene, perovskite, rutile, and sphene. Although titanium is best known for its use as a metal alloy, titanium is primarily used in the form of titanium dioxide (TiO₂). Titanium dioxide is used widely as a white pigment in paints, paper, and plastics. Other minor uses of titanium minerals include ceramics, chemicals, welding rod coatings, heavy aggregate, and steel furnace flux.

World production of titanium concentrates was estimated to be 1,637,000 metric tons. Owing to increased demand by the titanium pigment industry, domestic consumption of TiO₂ in concentrates increased 22% from the 1991 level. The pigments industry accounted for about 97% of TiO, consumption in concentrates. Apparent domestic consumption of TiO, pigments was about 1,000,000 tons. The paint, paper, and plastics industries were the largest consumers of pigment. In 1992, domestic production capacity of pigment increased to 1,197,000 tons.

World production capacity of titanium sponge was estimated to be 111,000 tons. Domestic consumption of titanium metal in 1992 increased slightly, and domestic shipments of mill products increased by about 3%. One of the titanium sponge producers closed its 10,900-metric-ton-per-year production facility. Consequently, domestic capacity of titanium sponge fell to 19,500 tons.

DOMESTIC DATA COVERAGE

Consumption data for titanium raw materials are developed by the U.S. Bureau of Mines (USBM) from one voluntary survey of domestic operations. Of the 30 operations canvassed, 26 responded, representing 99.5% of the data in table 7. Data for nonrespondents were estimated based on prior-year consumption levels.

BACKGROUND

Definitions, Grades, and Specifications

Ilmenite is the most abundant titanium mineral, with the chemical formula FeTiO₃ and theoretical composition of 52.7% TiO₂ and 47.3% FeO. However, the term "ilmenite" is also used to include material that has been oxidized and leached during weathering, containing up to 70% TiO₂, about 25% to 30% iron oxides, and about 5% of oxides of other elements. When the alteration is extreme, the residual material is essentially amorphous to finely crystalline TiO₂ and is called leucoxene.

Rutile is essentially crystalline TiO₂, and commercial concentrates usually contain about 95 % TiO₂. Synthetic rutile or rutile substitutes are derived from ilmenite by processes involving oxidation and reduction treatments followed by leaching of iron. Synthetic rutile concentrates approach rutile in chemical composition but, being residual leached grains, are porous and composed of very fine crystallites, while natural rutile grains are usually single crystals.

Anatase also is crystalline TiO₂, but has a different crystal structure than rutile. Anatase is not yet available

commercially, but large deposits of anatase-bearing ore in Brazil are being developed.

Commercially available titaniferous slags made by electric furnace smelting of ilmenite with carbon contain 70% to 85% TiO₂. Slags being produced at the end of 1992 were 80% TiO₂ slag from Sorel, Quebec; 85% TiO₂ slag from Richards Bay, Republic of South Africa; and 75% TiO₂ slag from Tyssedahl, Norway.

Titanium tetrachloride (TiCl₄), the intermediate compound from which titanium metal and chloride-process TiO₂ are manufactured, is a colorless to pale yellow liquid at room temperature, with a boiling point of 136° C.

Titanium sponge metal is the primary metal form obtained by vapor phase reduction of TiCl₄ with magnesium or sodium metal. It is called sponge because of its appearance and high porosity. Titanium ingot for forging into billet and mill products is obtained by melting sponge in a vacuum-arc furnace, with or without scrap titanium or alloying additions.

Titanium dioxide pigment is characterized by its purity, refractive index, particle size, and surface properties. The particle size is critical and must be closely controlled within the range of about 0.2 to 0.4 micron to develop optimum pigment properties. The superiority of TiO₂ as a white pigment is due mainly to its high refractive index and resulting light-scattering ability, which impart excellent hiding power and brightness. Titanium dioxide pigments are produced as two major types: rutile and anatase. Rutile-type pigment, less reactive with paint vehicles in sunlight than is the anatase type, is preferred for use in

outdoor paints. Anatase pigment has a bluer tone than the rutile type, is somewhat softer, and is used mainly in indoor paints and in paper manufacturing.

There are no rigid specifications for raw materials to be used as feed for making TiCl₄ for metals or pigment manufacture, or for ilmenite or slag to be used in the sulfate pigment process. However, certain impurities such as chromium, columbium, manganese, phosphorus, and vanadium can seriously impair pigment properties, so these impurities are an important consideration in the selection of concentrates for pigment production. Concentrates to be used for making TiCl4 should be low in calcium and magnesium, which form high-boiling-point chlorides that cause trouble in fluid-bed chlorinators.

Industry Structure

About 40% of the world's titanium feedstocks are supplied by three titanium slag producers: Richards Bay Minerals, the Republic of South Africa; OIT Fer et Titane Inc. (QIT), Canada; and Titania A/S, Norway. The remaining 60% of demand is supplied by producers of ilmenite and rutile concentrates (both natural and synthetic). Most of the production facilities for these concentrates are found in Australia, India, Malaysia, Norway, Sierra Leone, and the Republic of South Africa. Some of the largest producers of these feedstocks are: Cable Sands Ltd., Consolidated Rutile Ltd. (CRL), Indian Rare Earths Ltd. (IREL), Renison Goldfields Consolidated Ltd. (RGC), Sierra Rutile Ltd., the TiWest joint venture, and Westralian Sands Ltd.

World TiO₂ pigment output in 1992 came from about 60 separate facilities ranging in annual capacity from a few thousand tons to nearly 300,000 tons. The world's four largest TiO₂ pigment producers are E.I. du Pont de Nemours & Co. Inc. (Du Pont), SCM Chemicals Inc., Tioxide Group PLC, and Kronos Inc. These four companies own or control about 60% of world capacity. Another 20% of world capacity is divided between Bayer AG, Ishihara Sangyo Kaisha, Kemira Oy, Kerr-McGee

Chemical Corp., Sachtleben Chemie GmbH, and Thann et Mullhouse. The remaining 20% of world capacity was divided between about 20 other producers. An estimated 40% of the world's capacity is in North America while about 39% is in Europe (Eastern and Western).

There are 10 major producers of titanium sponge in the world. In Japan there are three producers: Titanium Co. Ltd., Showa Titanium Co. Ltd., and Toho Titanium Co. Ltd. In the United States there are two producers. Oregon Metallurgical Corp. (Oremet) and Titanium Metals Corp. of America (Timet). In the former U.S.S.R., there are producers at Berezniki, Russian Federation; Ust Kamenogorsk, Republic of Kazakhstan; and Zaporozhye, Ukraine. The United Kingdom's one sponge producer is Deeside Titanium Co. China has one known producer in Shanghi. The United States accounts for about 18% of the world's sponge production capacity.

The titanium industry is moderately integrated from raw materials to semifinished products. Du Pont, the world's largest pigment producer, obtains ilmenite, rutile, and leucoxene from its own mines in Florida and from various suppliers in other countries. In addition to various pigment-related holdings, Tioxide Group owns a 36% share of Westralian Sands Ltd. in Australia. Tioxide is owned by the world's largest paint producer ICI PLC. Kronos. formerly NL Industries Inc., supplies ilmenite to its European pigment plants from its mine at Tellnes, Norway. Titania, a subsidiary of Kronos, operates a smelting plant at Tyssedahl, Norway, that processes part of the Tellnes ilmenite to produce titanium slag for the same market. Hanson Industries PLC, United Kingdom, owner of SCM Chemicals, has a 49% interest in RGC, the major producer of titanium minerals in Australia. Kerr-McGee Chemicals is a joint-venture partner in the Australian minerals sands producer TiWest and holds 25% interest in the new Saudi Arabian pigment producer Cristal Pigment Co. Nearly all of the remaining TiO₂ pigment manufacturers buy their raw materials from independent producers of titanium concentrates.

Outside China and the former U.S.S.R., sponge metal producers do not own their own titanium mine. One U.S. sponge producer purchases rutile and manufactures TiCl₄, the intermediate compound used for commercial production of titanium metal. The other U.S. producer purchases TiCl₄.

Technology

Exploration.—Hard-rock ilmenite deposits, because of their inherent magnetic properties, are readily amenable to the application of aero- and ground-magnetic geophysical surveys. These deposits generally respond to such surveys by reflecting abnormally positive magnetic intensities, although in some cases negative magnetic anomalies may result. Once such anomalies are mapped. further exploration may take place in the form of detailed geological observations and ultimately drilling to test the anomalies and delineate the associated ilmenite deposit.

If initial diamond drilling indicates an economic deposit, development drilling proceeds on a set grid pattern of about 70 or 100 meters. Intermediate holes are drilled to fill in major gaps in information on geologic structure or ore continuations. Drill cores are visually logged and split for chemical assay to determine TiO₂ and iron content.

Sand deposits of titanium minerals are mostly near continental margins where erosion of regional granitic and metamorphic rocks containing ilmenite and rutile has led to accumulation of these minerals in coastal plain sediments. Working and reworking of these sediments by ocean waves on beaches and in streams resulted in various degrees of sand sorting and concentration by particle size, density, and resistance to abrasion. Well-sorted sands are much more likely hosts for ilmenite, rutile, and other heavy minerals than are unsorted sands.

Titanium minerals are dark in color, and their concentration in predominantly quartz sands is often readily visible. Initial discovery has therefore often been made through surface observation. In exploration, hand panning of samples has been a very useful exploration tool.

Some titanium mineral ore bodies are detectable by ground or airborne magnetometer surveys or, if monazite or zircon is present, by low-level radiometric surveys.

Drilling to determine the extent of sand deposits in the first phase of development should be done to a depth of at least 15 meters and preferably 30 meters. The type of drill needed will depend on the nature of the ground, including the presence of clay, hardpan, roots, stumps, and other organic material, as well as the depth of the water table.

Approximate minimum requirements for an economic sand deposit of titanium minerals include reserves of 300,000 to 1 million tons of TiO₂ content in rutile or ilmenite and heavy-mineral content in the ore of 1% to 5%, depending on the mix of ilmenite, rutile, and other valuable minerals.

Mining and Concentration.—For mining sand deposits of titanium minerals, a dredge is usually used. This may be bucket-ladder type but is more likely to be suction type. The dredge floats in its own pond, digging forward and stacking tailings aft. concentration, the separation of heavy minerals from the lighter quartz-feldsparmica fraction, is usually accomplished by wet-gravity methods. The Humphreys spiral has been standard for this separation since its introduction about 1940, but pinched-sluice separators of various designs also have been used. In Australia, the Reichert cone concentrator, which operates on the pinched-sluice principle, has been successful for large-tonnage operations. Flotation also has been used to some degree. For separating the minerals from stream-type deposits, jigs are usually chosen because they are the concentrating device least sensitive to extreme grain size variation.

The final wet-mill concentrate is dried, usually in a rotary kiln, before further treatment. The subsequent flowsheet depends on the mineral assemblage to be treated. Ilmenite and rutile are usually

removed together by electrostatic separation. The ilmenite-rutile conductor fraction of dried wet-mill concentrate is then subjected to high-intensity magnetic separation, yielding a final ilmenite product. The rutile fraction is further cleaned by screening and additional electrostatic separation. Zircon and monazite products are recovered from the nonconductor fraction of the wet-mill concentrate by a combination of gravity, electrostatic, and high-intensity magnetic separation.

Ilmenite is also mined from two hard-rock deposits, one in Canada and one in Norway. The ore bodies are massive, and open pit mining is practiced.

At Tellnes, Norway, the ore is crushed, ground, and subjected to wet-magnetic separation to recover magnetite. An ilmenite concentrate containing about 44.5 % TiO₂ is recovered by flotation of the nonmagnetic portion, as was formerly done at the MacIntyre Development, Tahawus, NY, where ilmenite mining ceased in 1982.

At Allard Lake, Quebec, ore at 32% to 36% TiO₂ is shipped from the mine to the beneficiation plant at Sorel, Quebec; some of the ore is shipped to steel companies as a substitute for fluorspar flux. For upgrading to slag, the ore is crushed and ground, concentrated by gravity methods, roasted to remove sulfur, mixed with a reducing agent, and smelted in an electric arc furnace. high-purity pig iron is produced. The titanium is concentrated in the slag. known as Sorelslag, which contains 80% TiO₂. Because the iron content of the slag is low, its use reduces the quantity of iron sulfate in the liquid effluent of sulfate process pigment plants. Because of its relatively high content of magnesium and calcium, which cause operating problems during chlorination, Sorelslag is not used to make TiCl..

At Richards Bay, Republic of South Africa, both rutile and ilmenite are produced from heavy-mineral sand deposits. The ilmenite, containing about 50% TiO₂, is relatively low in magnesium and calcium and is smelted with carbon in an electric furnace to

produce an 85% TiO₂ slag. Because of its low content of impurities, the Richards Bay slag is acceptable for manufacturing TiCl₄ and is also a feed material for the sulfate pigment process.

Materials made from ilmenite that have a TiO₂ content approaching that of natural rutile are known as synthetic rutile or beneficiated ilmenite. Processes to produce rutile substitutes from ilmenite fall into three general classes: those in which the iron is completely reduced to metal and separated from the reaction mass either physically or chemically, those in which iron is reduced to the ferrous state and chemically leached away from the titanium, and those in which the ilmenite is selectively chlorinated to remove iron and other impurities. Richards Bay slag also may be regarded as a rutile substitute because of its high grade (85% TiO₂) and suitability for the manufacture of TiCl₄.

Pigment Production.—Titanium dioxide pigment is produced commercially by two methods that require different raw materials. In the sulfate process, ilmenite or titanium slag is reacted with sulfuric acid, a portion of the iron sulfate formed may be crystallized and removed, and titanium hydroxide is precipitated by hydrolysis, filtered, and calcined. In the chloride process, rutile is converted to TiCl, by chlorination at 850° to 950° C in the presence of petroleum coke. All U.S. commercial chloride-process plants use fluid-bed chlorinators, although static-bed systems can be used for this purpose.

Titanium tetrachloride so prepared may be used either in making pigment, or with additional purification, for reduction to metal. In making pigment, the TiCl₄ is oxidized with air or oxygen at about 1,000° C, and the resulting fine-size TiO₂ is calcined at 500° to 600° C to remove residual chlorine and any hydrochloric acid that may have formed in the reaction. Aluminum chloride is added to the TiCl₄ to ensure that virtually all of the titanium is oxidized in the rutile crystalline form.

Recoveries of TiO₂ in pigment are approximately 90% and 80% to 85% for

chloride-process and sulfate-process plants, respectively.

Metal Production.—Feed materials needed for metal production are the same as those for chloride-process pigment because formation of TiCl₄ is required in both cases. Rutile and rutile substitutes are the only titanium raw materials used for metal production in the market economy countries.

Titanium sponge is produced by reducing TiCl₄ with sodium or magnesium under an inert atmosphere at temperatures up to 1,040° C. Residual chlorides are removed by vacuum distillation, inert gas sweep, or after cooling and crushing, by leaching in very dilute acid. The sponge is compacted, usually with some scrap and alloying additions, and made into ingot by two or more successive vacuum-arc melting operations.

Recycling.—Scrap titanium generally accounts for 40% to 50% of ingot production. Scrap is generated by producers of ingot and mill products and by consumers of mill products in fabricating finished products or components. It is estimated that up to 75% of titanium ingot metal becomes scrap during processing to finished parts.

Clean and well-segregated scrap, processed to remove impurities, is blended with sponge metal and alloying constituents and remelted to ingot. Remelting is mainly by vacuum-arc consumable-electrode processing. Cold-hearth melting (electron-beam and plasma-arc) is also used, especially for chips and turnings. Cold-hearth melting is very effective in ensuring removal of high-density inclusions, such as tungsten carbide tool particles, which settle out in the hearth area during melting. substantial quantity of titanium scrap, particularly unprocessed turnings, is consumed directly or in making ferrotitanium for use in steel and other alloys.

Economic Factors

Costs.—Construction cost of a 110,000-ton-per-year synthetic rutile plant completed in 1977 at Mobile, AL, was reportedly \$53 million, or about \$480 per annual ton of product.

The cost of constructing a new 82,000-ton-per-year chloride-process pigment plant is about \$2,500 per ton of annual capacity. Sulfate-process plants, including neutralization facilities, were said to cost considerably more. operating costs for chloride plants, which may be operated continuously and are more easily automated, reportedly were as much as 30% lower than those for sulfate plants. The cost of finishing titanium pigment for marketing is about the same for both processes and composes a significant portion of the total costs. Mineral raw material costs in the sulfate process are appreciably lower than those in chloride-process plants that use rutile as feed material.

Plant costs for producing titanium sponge are very high. The estimated cost per annual ton of capacity is about \$12,000 to \$15,000. Raw material costs for producing titanium sponge are about the same, whether reduction is with sodium or magnesium, and the selection of one reductant over the other depends upon local market economics.

Tariffs.—The duties shown in table 1 reflect results of the Tokyo Round of Multilateral Trade Negotiations completed in 1979 under which tariffs on many items were reduced in several stages over the period January 1, 1980, to January 1, 1987. (See table 1.)

Depletion Provisions.—The depletion allowance for ilmenite and rutile is 22% when mined from domestic deposits and 14% from foreign deposits.

Operating Factors

Environmental Requirements.— Heavy-mineral sand mining presents few serious environmental hazards. The land is restored by returning the bulk of the sand after removal of the ore minerals and may even be improved in low, flat areas. Dune areas can be left in nearly their original form, and the sand can be stabilized by seeding and replanting.

The major environmental problem in the titanium industry is the disposal of wastes from pigment-producing processes that use ilmenite, generating up to 3.5 tons of waste per ton of product. Solutions to this problem required the development of methods to neutralize and control the effluent now produced by the sulfate pigment process, mainly a solution of waste sulfuric acid and ferrous sulfate heptahydrate. Deep well disposal has been used for waste ferric chloride produced when ilmenite is used to make TiCl₄. In processes for making synthetic rutile, the effluent solutions are treated to regenerate the original leaching agent, such as hydrochloric acid, which is recycled, and to form useful byproducts such as sodium sulfate, ammonium sulfate, and iron oxide. sulfate-process technology, there is a strong trend away from disposal of waste materials in streams or in the ocean. Both U.S. sulfate-process producers now are using waste treatment plants that neutralize acid effluent with limestone and lime and produce gypsum and iron oxide byproducts.

Toxicity.—Titanium is a nontoxic material, as demonstrated by the use of TiO₂ in cosmetics and the use of titanium for making pacemakers and other implant devices for humans. However, some titanium compounds can be hazardous; for example, TiCl₄, which reacts violently with water or moisture in the air, forming TiO₂ and hydrochloric acid.

Energy Requirements.—According to a 1975 study for the USBM, energy requirements for alluvial mine production are about 5.1 million British thermal units (Btu) per ton of TiO₂ in concentrate. Production of pigment requires about 75 to 112 million Btu per ton of TiO₂, depending on the process and feed material used. Titanium sponge production uses from 408 to 466 million

Btu per ton of metal, of which about 248 to 270 million Btu is required to regenerate the reductant and chlorine. The conversion of sponge metal to titanium ingot requires an additional 46 million to 57 million Btu per ton of titanium ingot.¹

ANNUAL REVIEW

Strategic Considerations

Security of Supply.—Import reliance, defined as imports less exports plus adjustments for inventory changes, may be used as a measure of dependence on foreign sources of supply. Expressed as a percentage of consumption, import reliance for ilmenite, including high TiO, slag made from ilmenite, was 35% in 1980 but increased to about 80% in the 1982-84 period because of cessation of production at two U.S. ilmenite mines. Ilmenite import reliance through 1992 generally has been in the 70% to 80% range. Import reliance for rutile declined from about 90% in 1980 to about 60% in 1983, and in later years it has remained in the 60% to 70% range because of increased production of synthetic rutile. However, this decline was at the expense of increased import reliance for ilmenite, because the domestic synthetic rutile was made from imported ilmenite.

Dependence on foreign rutile sources for the production of titanium metal could be eased or eliminated in an emergency in two ways, using current commercial processing methods: (1) Synthetic rutile could be made from domestic ilmenite now being mined in Florida, or ilmenite that could be mined from other deposits, such as the Tennessee ilmenite sand deposits: (2) Titanium tetrachloride for metal production could be made directly from ilmenite, as is done by Du Pont for TiO, pigment manufacture. Another possible solution to this problem is the development of new processes that utilize domestic ilmenite and perovskite that contain too much calcium and magnesium to be used directly for making TiCl₄. Availability of such processes would encourage production of domestic ilmenite, which fell from about 450,000 tons of contained TiO₂ in 1975 to about 165,000 tons of TiO₂ in 1982. In 1992, ilmenite mine production capacity was about 200,000 tons per year of contained TiO₂.

Import reliance for titanium sponge as a percentage of consumption has ranged from 0% to 16% between 1980 and 1991, and the United States was a net exporter in 1990. In 1992, import reliance was withheld to avoid disclosing company proprietary data. Titanium concentrates currently used to make TiCl₄ for metal production are mostly imported rutile and synthetic rutile, but domestic concentrates could be used for this purpose in an emergency, possibly at higher cost.

Stockpile.—The Defense Logistics Agency began a modernization program in 1992 to dispose of obsolete and excess materials contained in the National Defense Stockpile (NDS). Although titanium sponge metal remained on the list of strategic and critical materials for stockpiling purposes, the Government's NDS goal was lowered from 176,901 tons to 48,367 tons. The NDS inventory in December contained 23,555 tons of specification metal and 9,857 tons of nonspecification material. Rutile was removed from the list of strategic and critical materials.² (See table 2.)

Issues

Although the United States has large reserves of titanium in the form of ilmenite, nearly all of U.S. titanium sponge production has been derived from imported rutile and synthetic rutile. This heavy reliance on foreign concentrates has developed because most producers of TiCl₄, the intermediate compound used to make titanium and a large part of the world's TiO₂ pigment, prefer rutile or synthetic rutile over ilmenite as plant feed material.

Production

Concentrates.—U.S. producers of ilmenite in 1992 were RGC (USA) Mineral Sands, Inc. [formerly Associated

Minerals (USA) Ltd. Inc.] at Green Cove Springs, FL; Du Pont at Starke and Highland, FL, both from mineral sands deposits; P. W. Gillibrand Co., Simi Valley, CA, as a coproduct of its rock, sand, and gravel operations; and Nord Ilmenite Corp., Jackson, NJ, from a previously mined mineral sands deposit. RGC was the only U.S. producer of natural rutile. Kerr-McGee was the sole domestic producer of synthetic rutile, at Mobile, AL.

Du Pont's new dredging operation at its Maxville site was under construction in 1992 and was scheduled to be commissioned in the first half of 1993. The opening of the Maxville site is expected to coincide with the partial closing of Du Pont's nearby Highland operation. Du Pont also purchased land in Georgia as a potential expansion of its titanium mineral operations.

Ferrotitanium.—Ferrotitanium was produced by Galt Alloys Inc., Canton, OH, and Shieldalloy Metallurgical Corp., Newfield, NJ. Two grades were produced—a 40%- and a 70%-titanium grade.

Metal.-In February, RMI Titanium Co. closed its metal reduction facility and supporting sodium production facility at Ashtabula, OH. The closure left Oremet and Timet as the two remaining producers of titanium sponge in the RMI had no plans to United States. reopen the 10,900-ton-per-year sponge operation, but planned to continue to produce mill products, hot-formed parts, superplastically formed parts, and titanium powder. Later in the year, RMI Titanium and Precision Tube Technology formed a joint venture to manufacture and sell titanium welded coiled tubing. The venture company, called Titanium Tube Technology, targeted its products for offshore petroleum drilling operations. Specific uses were subsea umbilicals that carry injection and control lines for offshore drilling operations.

Timet neared completion of a 10,000-ton-per-year titanium sponge facility.

The facility's vacuum-distillation process was based on technology developed in Japan. The newer technology was expected to produce a much higher quality sponge with fewer impurities and lower production costs. Union Titanium Sponge Corp., a consortium of Japanese companies, contributed to the financing for the facility and had the option of converting the debt to equity interest in Timet.

Timet and Axel Johnson Metals Corp. formed a joint venture called Titanium Hearth Technologies. The joint venture operated an electron-beam hearth furnace at a Morgantown, PA, facility. The cold-hearth furnace was built by Axel Johnson with a melt capacity of 5,400 tons per year of titanium ingot and slab.

Owing to poor market conditions, several companies closed their facilities. International Light Metals (ILM) Corp., a subsidiary of Martin Marietta Corp., permanently shut down its fabricating plant in Torrance, CA. ILM had been a major supplier of titanium extrusions and forgings for the aerospace industry.

Howmet Corp. temporarily shut down its titanium ingot facility at Reno, NV. The Ladish Co. permanently closed its west coast forging facility at Vernon, CA, and consolidated its forging operations into its Cudahy, WI, facility. (See tables 3 and 4.)

Titanium Dioxide Pigments.—Du Pont began operating what the company called a market development unit (MDU) at its Johnsonville, TN, TiO₂ facility. The MDU unit simulated plant conditions such that experimental lots of TiO₂ pigments could be produced without interrupting output from the facility's normal production.

Kronos commissioned a new chlorideroute titanium dioxide plant at Lake Charles, LA. The facility had two pigment lines with a total capacity of 80,000 tons per year.

Kemira Inc. announced plans to construct a new research and development center at its Savannah, GA, facility. Construction of the center was expected to be completed in 1993.

SCM Chemicals completed the final

stage of its environmental improvement program to comply with the Environmental Protection Agency's regulations introduced by the Bevill Amendment to the Resource Conservation and Recovery Act. (See table 5 and 6.)

Consumption and Uses

Concentrates.—Total U.S. reported consumption of TiO₂ in concentrates increased 22% from the 1991 level. This increase was partially attributed to increased production of titanium pigments. Although ilmenite consumption decreased by 11%, slag consumption increased 66%, and rutile consumption increased 31%. The pigments end use accounted for 97% of total consumption. (See table 7.)

Ferrotitanium.—Reported consumption of titanium in the form of ferrotitanium and scrap in steel and other alloys was nearly unchanged from the revised 1991 level.

Metal.—Net shipments of mill products increased by about 3%, and sponge production was withheld to avoid disclosing company proprietary data. Consumption of scrap for remelting increased by about 30% and supplied a calculated 51% of ingot feedstock. Casting shipments decreased by about 16%. Estimated U.S. mill product usage application was as follows: commercial aerospace, 49%; military aerospace, 24%; and nonaerospace uses, 27%. Nonaerospace uses include those in the specialty chemical, pulp and paper, oil and gas, marine, and medical industries.

Pigment.—Apparent domestic consumption of TiO₂ pigments was about 1,000,000 tons, about 7% more than that in 1991. The paint, paper, and plastics industries were the largest consumers of pigment. (See tables 8 and 9.)

Stocks

The TiO₂ content of inventories of

ilmenite and rutile decreased 3% and 29%, respectively. Overall TiO₂ content of concentrate stock decreased by about 2%. Stocks of TiO₂ pigments increased to 108,000 tons, a 50% increase from that of 1991. Pigment stocks held by producers would satisfy about 40 days of supply. (See table 10.)

Markets and Prices

Published prices of titanium metal, and pigments concentrates, decreased in 1992. Ilmenite and rutile concentrates fell. The average prices for rutile and ilmenite concentrates fell about 17% and 33%, respectively. reported price range for titanium sponge was 16% lower than that in the previous Although the yearend price for anatase pigment was unchanged, the price for rutile pigment decreased by 6%. (See table 11.)

Foreign Trade

The Department of Commerce (DOC) determined not to revoke the antidumping findings on titanium sponge from the Baltic States and Republics of the former U.S.S.R. The DOC also has separated the 83.96% antidumping order from the former U.S.S.R. into 15 separate orders. (See tables 12, 13, 14, and 15.)

World Review

Capacity.—The capacity data in this report are for mines and benefication plants, sponge metal facilities, and TiO₂ pigment plants as of December 31, 1992. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time at a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and temporarily closed facilities that, in the opinion of the author, can be brought into production within a short period of time and with minimum capital

expenditure.

Mine and mill capacity for the production of titanium concentrates, metal production plant capacity, and TiO₂ pigment plant capacity are generally based on close to 365 days per year operation, 3 shifts per day. Capacity figures are based on information obtained from the producing companies, from news items, and from USBM estimates.

Reserves.-U.S. reserves of ilmenite and rutile occur mainly in ancient beach sand deposits in Florida. Ilmenite concentrates from the U.S. sand deposits contain about 60% to 65% TiO2, while those from rock deposits contain 45% to 50% TiO2. The U.S. reserve base of 34.7 million tons of TiO₂ occurs as 23.5 million tons in ilmenite, 9.8 million tons in perovskite (CaTiO₃), and 1.4 million Other U.S. resources tons in rutile. include additional rock deposits of ilmenite in California, Minnesota, New York, and Wyoming, and sand deposits of ilmenite and/or rutile in Georgia, Idaho, New Jersey, North Carolina, Oregon, and South Carolina, as well as large quantities of accessory rutile in porphyry copper ores and mill tailings.

compiled a USBM has The computerized file of worldwide mineral the Minerals deposit data called Availability System (MAS). The MAS Advanced Deposit Information Tracking System contains location and descriptive information on mineral occurrences, mines, and mineral processing operations Most of the reserve and worldwide. resource data found in this report were derived from MAS reports. A public access version containing nonproprietary information contained in the MAS data base is available on request.

Major titanium reserves in the United States are owned by Du Pont and RGC in Florida. Reserves in Australia are held mainly by RGC, Consolidated Rutile; Westralian Sands, and Cable Sands. Reserves at Allard Lake, Quebec, Canada, are held by QIT, a subsidiary of RTZ Corp. PLC. QIT also has a 50% interest in Richards Bay mineral sands deposits in the Republic of South Africa. Major deposits in Brazil, India, and Sri

Lanka are held by the respective Governments. Kronos controls Titania, wner of the large hard-rock deposit at Tellnes, Norway. (See tables 16, 17, and

Australia.—RGC Mineral Sands Pty. Ltd. received approval from Australia's Northern Territory Minister of Energy and Mines to conduct exploration for mineral sands on the islands of Melville and Bathhurst, northern Australia. Two exploration licenses were granted for two separate areas measuring approximately 1,600 square kilometers each. exploration was expected to begin within Although RGC was 3 to 6 years. designated as the mine operator, the project was to be a joint venture among the Tiwi Land Council, Tiwi Resources Pty. Ltd., and RGC.3

CRA Ltd.'s wholly owned subsidiary Wimmera Industrial Minerals (WIM) curtailed its exploration efforts of the WIM 150 deposit near Horsham, Victoria. Although promising mineral recoveries had been achieved at the pilot plant level, the company concluded the project was not economically viable. The WIM deposit was reported to have a measured resource of 25 million tons of minerals 10 to 15 meters thick covering an area of 40 square kilometers under 4 to 5 meters of overburden. The company planned to continue technical development of processing alternatives.4

Woodburn Mineral Sands, formerly closed Holdings, Australmin operations at Newrybar, Australia. The company had an estimated production capacity of 12,000 tons per year for rutile and 10,000 tons per year for zircon.5

RGC reopened its Eneabba North Mine and temporarily closed its Eneabba South and West operations in Western Australia, north of Perth. The Eneabba North Mine was reported to be more cost efficient to operate and contain a higher ilmenite grade.6

Cable Sands Pty. Ltd. announced plans to proceed with its Jangardup mineral sands project in Western Australia. The new deposit was expected to produce 200,000 tons per year of ilmenite suitable for use by chloride pigment producers.

Construction at the site was expected to begin in early 1993, and production was expected to commence in mid-1994.7

Canada.-New Pascalis Mines Ltd. and Tiomin Resources Inc. announced plans to merge the two companies under a new company called Tiomin Resources Inc. Tiomin held mineral exploration rights to a 208-square-kilometer heavymineral sands deposit at Natashquan, Quebec, and planned to conduct a feasibility study to determine if the deposit is economically viable.8

Czechoslovakia.—As part of a privatization effort by the Czechoslovakian Government, the majority interest in titanium pigment producer Precheza a.s. Formerly was scheduled to be sold. known as Prerovske Chemicke Zavody, Precheza produced pigment using sulfatebase technology and had an estimated capacity of 25,000 tons per year.9

India.—IREL proposed a joint venture with the Government of Kerala, India, to mine heavy minerals at Neendakara. The proposed area for development was a 4by 22-kilometer strip near Kollam on the Arabian Sea and was reported to contain ilmenite, monazite, rutile, zircon, and sillimanite.10

In Kerala, Cochin Minerals and Rutile Ltd. were constructing a synthetic rutile facility. The facility was scheduled to be commissioned in mid-1993 and was expected to produce up to 10,000 tons of synthetic rutile annually. completed, the plant would produce a ferric chloride byproduct and about 1,000 tons of titanium dioxide suitable for pigment applications.11

Italy.—Tioxide Specialties Ltd. opened a 360-ton-per-year finishing plant at its Scarlino, Italy, facility. The new facility was designed to produce surface treated ultrafine titanium dioxide. particle size of about 60 nanometers, the ultrafine TiO2 particles were transparent to visible light but blocked ultraviolet Output from the plant was radiation. expected to be used in a variety of sunscreen applications. 12

Malaysia.—Tioxide Group Ltd. commissioned a 50,000-ton-per-year sulfate-base TiO₂ pigment plant at Telok Kalong, Malaysia. The new facility was part of Tioxide's global strategy to support both chloride-base and sulfate-base technology.¹³

Mozambique.—Kenmare Resources was in the process of developing a heavy-mineral deposit in Mozambique. The ore body had been estimated by the company to be 167 million tons with a heavy-mineral content of 3.25%.¹⁴

Sierra Leone.—In the Bonthe District, Sierra Rutile shifted its rutile mining operations from its Pejabu deposit to its Lanti deposit. The Lanti deposit was reported to be a deeper and higher grade deposit than Pejabu. Sierra Rutile also was reported to have signed a loan agreement with the Commonwealth Development Corp. for improvements in equipment and infrastructure. If completed, these improvements would lead to enhanced mine capacity. 15

South Africa, Republic of.—The Anglo American Corp. announced plans to proceed with the development of its Namakwa mineral sands deposit in the northwestern cape region of the Republic of South Africa. The project included the extraction of an ilmenite concentrate followed by smelting to produce high TiO₂ slag. The design of the smelting furnace was based on a plasma-arc technology. When completed, the furnace was expected to produce up to 195,000 tons per year of high TiO₂ slag and 120,000 tons of pig iron. In addition to ilmenite used for smelting, the deposit was expected to yield up to 140,000 tons of zircon and 38,000 tons of rutile. Production was anticipated to begin in 1994, and total ore reserves reported to be 500 million tons. 16

Spain.—Hitox Corp., Corpus Christi, TX, acquired a 96.6% interest in Fluid Minerals Espanola SA. Fluid Minerals

operated a 2,500-ton-per-year pigment facility at Bunuel, Spain. The acquisition was expected to allow Hitox better access to European markets.¹⁷

United Kingdom.—SCM Chemicals completed construction of a hydrochloric acid recovery plant at its chloride-base TiO₂ pigment plant at its Stallingborough facility in the United Kingdom. The recovery process was designed to reduce the amount of metal oxide waste generated by the chloride process. The process used metal oxides to produce hydrochloric acid suitable for use by the steel pickling industry. In a separate project, SCM planned to develop and install equipment to recycle sulfuric acid on its sulfate-base TiO₂ plant at the Stallingborough facility. ¹⁸ (See table 19.)

Current Research

The USBM is active in several programs to lower the cost of producing titanium alloys. The current research is focused on developing a continuous process to produce titanium powder or granules suitable for powder metallurgy applications. Work also is being conducted to improve the existing technologies for batch-type reduction, arc melting, and fabrication of titanium alloys.

OUTLOOK

Demand for titanium feedstocks is anticipated to grow in line with demand for TiO₂ pigments. However, because of recent increases in global capacity, a surplus of available supply also is expected for the next few years. Increased environmental concerns by the titanium industry are expected to cause tighter specifications for titanium concentrates and a higher reliance on titanium slags and synthetic rutile.

As it has in the past, demand for TiO₂ pigments should follow economic growth. The current overcapacity in the pigment also may continue for the coming 2 to 3 years. A competitive market and increased environmental pressures are likely to force the closure of less

profitable producers. Within 5 to 10 years, increased demand is expected to drive the need for new capacity expansions. Growth in global demand over the next 5 years is anticipated to be about 3% per year.

Reduced demand for titanium alloys by the commercial and military aerospace industry is likely to continue, although a turnaround in the world economy could help improve market conditions. No new titanium sponge capacity is expected for several years, and demand will probably remain near current levels for the next 2 years. The tremendous metal capacity of the former U.S.S.R. is becoming an influential factor in world markets. However, the long-term outlook for the titanium metal industry is largely dependent on the industry's ability is expand into nonaerospace markets.

Total	7,800	300	8,100	33,300	1,400	34,700		

¹The reserve base includes demonstrated resources that are currently economic (reserves), marginally economic (marginal reserves) and some of those that are currently subeconomic (subeconomic resources).

¹Dissolved in Dec. 1991; however, information is inadequate to formulate reliable estimates for individual countries.

²Data may not add to totals shown because of independent rounding.

³Formerly part of the U.S.S.R.; data were not reported separately until 1992.

Includes blooms, sheet, bars, slabs, and other unwrought.

⁵Includes bars, castings, foil, pipes, plates, profiles, rods, sheet, strip, tubes, wire, and other.

²Ilmenite except for the 9.8 million tons in Colorado perovskite.

³Rutile except for the 200,000 tons in Arkansas anatase.

Estimated. Revised. W Withheld to avoid disclosing company proprietary data; not included in "Total."

¹Table includes data available through July 22, 1993.

 $^{^2\}mathrm{Excludes}$ production of unbeneficiated anatase ore.

^{&#}x27;Ilmenite is also produced in Canada and in the Republic of South Africa, but this output is not included here because an estimated 90% of it is duplicative of output reported under "Titaniferous slag," and the rest is used for purposes other than production of titanium commodities, principally as steel furnace flux and heavy aggregate.

⁴Reported figure.

⁵Dissolved in Dec. 1991. All production in the U.S.S.R. came from Russia and Ukraine; however, information is inadequate to formulate reliable estimates for individual countries.

⁶Slag is also produced in Norway but is not included under "Titaniferous slag" to avoid duplicative reporting. Beginning in 1988, about 25% of Norway's ilmenite production was used to produce slag containing 75% TiO₂.

⁷Contains 80% TiO₂.

Contains 85% TiO₂.

TUNGSTEN

By Gerald R. Smith

Mr. Smith, a physical scientist with 29 years of research and commodity experience with the U.S. Bureau of Mines, has been the commodity specialist for tungsten since 1986. Domestic survey data were prepared by Cheryl Mack, statistical assistant; the world production table was prepared by Ronald Hatch, international data coordinator.

The unique high-temperature properties of tungsten and its alloys can be utilized advantageously in the production of numerous end-use items. The high melting point, high density, good corrosion resistance, and good thermal and electrical conductivity properties of tungsten and its alloys and the excellent cutting and wear-resistant properties of its carbide continue to provide important items for consumption in both the domestic and military sectors.

Total reported domestic consumption of tungsten in primary end-use categories decreased by about 13% in 1992 compared with that of 1991. Demand generally declined in the cemented carbide end-use sectors that included the combined cutting tool, mining tool, oil drilling equipment, and wear-resistant component industries. Demand for mill products made from metal powder also declined in 1992. Counter to these declines was an increase in the use of ferrotungsten in steels, particularly in the tool steel sector.

The average price for wolframite concentrates (January-March 1992) and the average combined price for wolframite and scheelite concentrates (April-December 1992) remained essentially unchanged compared with the average price for wolframite concentrates in 1991, according to quotations published in Metal Bulletin. However, the average price for these concentrates progressively decreased during the year, declining by nearly 27% in December 1992 compared with that of January 1992. **Prices** for ammonium paratungstate (APT) on the world market decreased steadily during 1992, consistent with the declining prices for concentrates. The already low tungsten mining activity in the United States further declined in 1992, as the continuing low prices for concentrate and the growing use of intermediate tungsten materials made mining uneconomical and impractical. This condition continued in spite of the imposition of the 151% antidumping tariff on imports of ore concentrates from China that began in July 1991 and continued through all of 1992. Although the tariff provided protection from imports of concentrate, constraints were instituted during 1992 on imports of downstream tungsten products from China, following the expiration of the Orderly Marketing Agreement, in late 1991, that had limited imports of APT and tungstic acid.

A summary of the important U.S. and international statistics for 1992 and the previous 4 years are shown in table 1. (See table 1.)

DOMESTIC DATA COVERAGE

Domestic production data for tungsten are developed by the U.S. Bureau of Mines by means of two separate, voluntary surveys. These surveys are "Tungsten Ore and Concentrate" and "Tungsten Concentrate and Tungsten Products." Of the 24 mining and 16 processing operations to which survey requests were sent, response was received from 63% and 100%, respectively, of those operations surveyed, represented in the production and stock totals shown in table 1.

BACKGROUND

Definitions

Tungsten, a silvery gray metal, has an atomic number of 74 and an atomic weight of 183.92. Its most outstanding physical property is its high melting point of 3,410° C, the highest of all metals. Tungsten is one of the heaviest elements, with a density of 19.3 grams per cubic centimeter at 20° C. It has good corrosion resistance, good thermal and electrical conductivity, and a low coefficient of expansion. At temperatures above 1,650° C, tungsten has the highest tensile strength of all metals.

Tungsten concentrate is sold in units of tungsten trioxide (WO₃). In the United States, sales are based on the short ton unit of WO₃. This is equivalent to 1% of a short ton, or 20 pounds of WO₃, and contains 7.19 kilograms (15.86 pounds) of tungsten. In most other countries, tungsten is sold in the metric ton unit (mtu) and contains 7.93 kilograms (17.48 pounds) of tungsten.

Natural or synthetic scheelite concentrate, in nodular form, is ideal for direct addition to steel melts because the calcium is removed as slag. Fine material in either synthetic or natural scheelite is not desirable because of high dust losses. Wolframite concentrate is not satisfactory for steelmaking because of the manganese and tin content.

Tungsten ores and concentrates are converted into the following intermediate products: APT, tungstic acid, sodium tungstate, tungsten metal powder, and tungsten carbide powder. Most of the

APT is reduced to tungsten metal powder, which then is processed into tungsten carbide powder.

Tungsten alloys and tungsten mill products such as rod, wire, and sheet are produced from hydrogen-reduced tungsten metal powder. The tungsten carbide produced from powder is cemented, usually with cobalt, to form various cutting and wear-resistant tools and parts.

Tungsten chemicals (APT, tungstic acid, and sodium tungstate) are produced as coproducts at some tungsten processing plants and as primary products at others. When not processed further into metal powder, they generally are used in the chemical industry.

Products for Trade and Industry

Tungsten materials can be divided into four major classes, depending on use: (1) a carbide in cutting and wear-resistant materials, and welding and hard-facing rods; (2) mill products made from essentially pure metal; (3) an alloy constituent in high-speed and tool and die steels, superalloys, and nonferrous alloys; and (4) various chemicals and compounds for nonmetallurgical applications.

The extreme hardness of tungsten carbide at temperatures exceeding 1,000° C makes it a preferred metalworking material for cutting edges of machine tools subject to intense wear or abrasion and for metal surfaces in forming and shaping dies. The mining and petroleum industries use tungsten carbide in drill bits, in the cutting edges of earth-moving equipment, and in crushing machinery. Tungsten carbide is used widely in wear parts of transportation and electrical equipment.

In most applications, tungsten carbide generally is cemented with a powdered cobalt metal binder by compaction and sintering. The cobalt content can range from about 3 to 25 weight percent, with the higher content providing greater shock resistance at a sacrifice in hardness. Tantalum and/or titanium carbides are used in conjunction with tungsten carbide in certain cutting and chipping tools. Also, coatings such as titanium carbide, titanium nitride, and

aluminum oxide on tungsten carbide are used extensively to increase the life of inserts for machining applications.

Mill products made from pure or substantially pure tungsten metal powder are used in significant quantities by the electrical and electronic industries. Tungsten wire is used as the filament in electric lamps and as cathodes for electronic tubes. Disks produced from tungsten rods or sheet are used in automotive distributor points, although this end use is declining as the number of automobiles with electronic ignition systems increases. They also are used as contact points in numerous manufactured products. Tungsten metal is employed as heat and radiation shielding, as electrodes for inert-gas welding, as components of X-ray and cathode-ray tubes, and as heating elements in high-temperature resistance furnaces. Tungsten metal is used by the aerospace industry because it retains its strength at elevated temperature in reducing or inert atmospheres. The use of tungsten as a heavy metal for counterweights and balances, especially by the aircraft industry, has been replaced, to a significant extent, by depleted uranium, which approaches the density of tungsten.

Cast tungsten carbide is used principally as a hard-facing material. In this application, carbide particles are applied by a welding process to provide an abrasion-resisting surface layer on the surface to be coated. The carbide may be initially in the form of rod or loose grains in a tube.

As an alloy constituent, tungsten is used primarily in the production of high-speed steels and tool and die steels. Hardness and oxidation resistance at elevated temperatures are the most important properties possessed by these steels, which are used for machinery and equipment in the metalworking, construction, and mining industries. Certain grades of stainless and other alloy steels contain tungsten to improve wear and abrasion resistance, shock resistance, corrosion resistance, and/or strength at high temperatures.

Tungsten is an important constituent in a wide variety of superalloys and

nonferrous alloys. Tungsten-containing superalloys are being utilized increasingly in high-temperature applications for their high-temperature strength and oxidation resistance. Tungsten alloyed with copper or silver is used for electrical contacts to provide wear resistance with adequate electrical conductivity.

Nonmetallurgical applications tungsten include chemicals used in textile dyes, paints, enamels, toners, and coloring glass. Certain tungsten compounds are luminescent and used as phosphors in pigments, X-ray screens, television picture tubes, and fluorescent lighting. Sodium tungstate is employed as a corrosion inhibitor and a fireproofing agent in textiles. APT is used in making catalysts for the refining of petroleum. Among other chemical applications, tungsten compounds are used in chemicalvapor deposition, as catalysts in other chemical processing, and as laboratory reagents.

The chief nonindustrial use of tungsten is in armor-piercing ordnance, but this has been replaced, in part, by depleted uranium.

ANNUAL REVIEW

Legislation and Government Programs

In early March 1992, the U.S. Department of Defense (DOD) submitted an Annual Materials Plan to the U.S. Congress that included recommendations for significant changes in the National Defense Stockpile (NDS) goals for tungsten. Under a newly recommended 3-month war scenario with a 1-year mobilization period, the DOD had proposed that a goal of 6,285 metric tons of contained tungsten be established for the tungsten materials in the stockpile. As an alternative, the DOD also proposed that the tungsten goal be decreased to 14,050 tons from the existing level of 37,336 tons, should the current 3-year war scenario continue to be the preferred approach for determining the stockpile To begin accomplishing the goals. proposed reduction in the tungsten goal, an initial 5-year disposal plan was recommended, during which 9,979 tons of stockpile-grade tungsten was to be sold. About 93% of the tungsten held in the stockpile is in the form of ore concentrates.

Although the initial fiscal year 1993 Defense Authorization Bill prepared by the U.S. Senate contained language consistent with DOD's recommendation to reduce the tungsten in the stockpile according to the 3-month war scenario. the final bill contained no such language. In the final Senate bill, passed on September 18, 1992, tungsten, along with five other materials, was removed from the Senate's disposal list following results of a Government Accounting Office review placing these materials in a "highrisk" category because of the uncertainty of their supply from other countries. As a result of the Senate's action, no further disposals of tungsten from the NDS were authorized in the final fiscal year 1993 Defense Authorization Bill passed by the U.S. Congress and signed by the President in October 1992. According to a DOD spokesperson, however, although no tungsten was authorized for sale in fiscal year 1992 and none was included for disposal in the fiscal year 1993 authorization bill, the matter of future tungsten disposals would undergo further review as part of DOD's preparation of subsequent Defense Stockpile Annual Materials Plans.

Strategic Considerations

Tungsten is an important strategic material necessary for defense purposes. including the industrial base. Currently, the heavy-metal alloys of tungsten, containing 3% to 10% nickel and small quantities of iron or copper, are used in several of the smaller diameter projectiles for penetrating armorplate. Cemented tungsten carbide parts, which exhibit excellent cutting and wear-resistant properties, are vital to the U.S. metalworking, machining, construction, transportation, mining, and oil and gas drilling industries. Tungsten mill products and powders are essential to the lamp and lighting industry as filaments

and electrodes; to the electrical and electronic industries as wear-resistant, electrically conductive contact surfaces; and to the superalloy and steel industries as alloying components. The DOD relies heavily on the maintenance of a broad domestic production base to cover mobilization contingencies. The entire tungsten industry, from mined ore to manufactured products, thus represents an important component of the U.S. defense policy. The DOD continually assesses the U.S. ability to produce tungsten to ensure that this and other sources of supply are sufficient to meet current and projected levels of demand necessary to preserve the national defense. A proposal by the DOD in 1992 contained a recommendation that the quantity of tungsten in the NDS be gradually reduced to about 38% of its present level. DOD's efforts to generally reduce the levels of many metals and materials in the stockpile, in part, reflected a revised assessment of the U.S. defense needs in the world's changing political and military structure. The proposed new levels were intended to prepare the United States in the event of a relatively short, small-scale war rather than a longer term global war.

Issues

During 1992, China continued to be the principal supplier of tungsten products to the world market. Declining prices for concentrates and intermediate materials continued to make it increasingly more difficult for the market economy producers to operate economically. Although efforts were introduced by China to place more adequate controls on its production, distribution, and pricing procedures, there was no evidence of any positive effects on the market by yearend 1992, as a result of these efforts. Most tungsten mines in the United States remained closed or were operated at reduced capacity during the year, in spite of the imposition of a 151% tariff on imports of ore concentrates from China that began in July 1991 and continued through all of 1992. Although the 151% tariff provided significant protection from

imports of concentrate, no protection existed against imports of downstream tungsten products, as a result of the expiration of the Orderly Marketing Agreement in October 1991, limiting imports of APT and tungstic acid, and the failure to institute any new constraints on imports of downstream tungsten products from China during 1992. Discussions continued between U.S. Government and industry officials throughout regarding the possibility of instituting trade restrictions on all downstream products through tungsten carbide powder imported from China, but little progress was made toward implementing any such measures.

As a result of the 151% antidumping tariff on ore concentrates, the shift to importing the downstream intermediate materials, including APT, tungsten oxide, and sodium tungstate, from China continued throughout 1992. Declining prices for these intermediate materials relative to the price for ore concentrate effectively decreased the demand for the ore concentrates provided to the world market by other producers. This additional factor further contributed to the increasing inability of these producers to remain in business during 1992.

Production

The already low tungsten mining activity in the United States further declined in 1992 as the continuing low prices for concentrate and the growing use of intermediate tungsten materials uneconomical and mining impractical. Recent statistical trends in domestic mine shipments and their corresponding values are shown in figures 1 and 2, respectively. Actual mine shipment data have been withheld since 1986 to avoid disclosing the company proprietary data for the one or two mines that were in operation since that time. Producers of tungsten concentrate in 1992 were Curtis Tungsten Inc. at its Andrew Mine, Upland, CA, and U.S. Tungsten Corp., a division of Strategic Minerals Corp., at its Pine Creek Mine, Bishop, Major processors of tungsten materials in 1992 were Buffalo Tungsten Inc., Depew, NY; General Electric Co., Euclid, OH; GTE Products Corp., Towanda, PA; Kennametal Inc., Latrobe, PA, and Fallon, NV; Teledyne Firth Sterling, LaVergne, TN; and Teledyne Wah Chang Huntsville, Huntsville, AL. Net production statistics for tungsten metal powders, carbides, and chemicals are shown in table 2. (See table 2 and figures 1 and 2.)

Curtis Tungsten Inc. operated its Andrew Tungsten Mine near Los Angeles, CA, intermittently during 1992. Adverse weather conditions again affected production at the mine. The mine was closed for nearly a quarter of the year because of heavy rains and flooding, just as it had been closed for nearly 5 months in 1991 because of a severe drought.

U.S. Tungsten Corp., Bishop, CA, continued as the only other company producing tungsten concentrate. As with its mine production, operations at its APT conversion facility were limited because of the low prices existing in the tungsten market.

GTE Corp., Stamford, CT, reported in August 1992 that it had reached an agreement to sell part of its lamp and lighting business to Osram, a Siemans AG company based in Munich, Germany, part to Sylvania Lighting International B.V., an international consortium. Osram will purchase GTE's North American lighting business while the consortium will acquire GTE's international lighting business. Affected by the sale will be all of GTE's electrical products group, including GTE Products Corp., Towanda, PA, a tungsten processor and producer of a variety of tungsten materials and end-use items. The transaction, which needed approval from the European Merger Commission, the U.S. Federal Trade Commission, and the U.S. Department of Justice, was expected to be completed in According to a GTE early 1993. spokesperson, it was anticipated that no jobs would be lost as a result of this transaction.

GTE Corp. further announced in late December 1992 that it had reached a definitive agreement on the sale of its GTE Valenite cemented carbide division, Troy, MI, to Cincinnati Milacron Inc., Cincinnati, OH. The Valenite sale also was expected to be completed in early 1993. When completed, Valenite will become a wholly owned subsidiary of Cincinnati Milacron, with Valenite employees expected to remain as employees of the subsidiary. According to a Milacron spokesperson, Valenite's cemented carbide cutting and wearresistant components business offered an excellent fit with Milacron's precision grinding wheel and metalworking fluids production business. It also would complement Milacron's machine tool equipment operations and products.

Consumption and Uses

Total reported domestic consumption of tungsten in primary end-use categories (table 3) decreased by about 13% in 1992 compared with that of 1991. Demand generally declined in the cemented carbide end-use sectors that included the combined cutting tool, mining tool, oil drilling equipment, and wear-resistant component industries. Demand for mill products made from metal powder also declined in 1992. Counter to these declines was an increase in the use of ferrotungsten in steels, particularly in the tool steel sector. (See table 3.)

Overall weakness in the U.S. economy continued to be the single most important factor influencing the decline in demand for tungsten products during 1992. Weaknesses remained in the major industrial sectors of auto, aerospace, construction, and mining where a significant quantity of tungsten is consumed as cemented carbide components. An increase was observed in the demand for cemented carbide components in the oil drilling industry during the last half of 1992. After the steady decline in the number of oil drilling rigs in the United States, from 1,179 following the war in the Persian Gulf to a low of 596 in mid-June 1992, the number of rigs gradually increased to a high of 935 by yearend 1992, according to figures reported by the International Association of Drilling Contractors and Baker Hughes Inc.

Markets and Prices

Effective April 1, 1992, Metal Bulletin (London) combined the scheelite and wolframite quotations to represent one tungsten ore concentrate price spread. This change was prompted by decreased trading significantly scheelite. The higher scheelite quotation traditionally representative transactions in artificial, low-molybdenum scheelite produced at the King Island Mine in Australia, and the lower quotation was based upon sales of gravity-separated scheelite. With the closure of the King Island Mine in late 1990, there was an eventual near exhaustion of the artificial-type scheelite on the world market. Coupled with the nominal trading in other forms of scheelite in recent years, the new tungsten ore concentrate price spread, accordingly, was more representative of the wolframite sales transactions than of the scheelite transactions.

The average price for wolframite concentrates (January-March 1992) and the new average combined price for wolframite and scheelite concentrates (April-December 1992) (table 4) remained essentially unchanged compared with the average price for wolframite concentrates in 1991, according to quotations published in Metal Bulletin. However, the average price for these concentrates progressively decreased during the year, declining by nearly 27% in December 1992 compared with that of January 1992. (See table 4.)

Prices for APT on the world market decreased steadily during 1992, consistent with the declining prices for concentrates. According to quotations in Metals Week, the average price for APT on the U.S. market, duty-paid and delivered to processing plants, decreased by 20% from an average of \$73.30 per metric ton unit (mtu) tungsten oxide in January to an average of \$58.42 per mtu by yearend. Similarly, the price of APT on the European market, duty-free and including the cost of insurance and freight delivered to Rotterdam, decreased by 25%, from \$62.50 per mtu to \$47 per mtu. Quotations for Chinese No. 1 Grade APT

in Hong Kong declined by 40% during the year from an average price of \$66 per mtu to an average of \$39.50 per mtu.

The price of tungsten metal powder decreased by about 2% in 1992 to \$21.87 per kilogram of contained tungsten compared with \$22.30 per kilogram in 1991, based upon the average value of imported powder reported by the Bureau of the Census. On this basis, the price of tungsten carbide powder increased by about 5% in 1992 to \$24.81 per kilogram of contained tungsten compared with \$23.61 per kilogram in 1991.

Foreign Trade

Comprehensive lists of U.S. export and import trade statistics by material quantity and value and by country of destination and origin are shown in tables 5 through 13. Import tariff rates for the various materials are shown in table 14. (See tables 5 through 14.)

Total U.S. imports of tungsten materials decreased by 57% in 1992 compared with those of 1991. China continued to be the dominant supplier, providing about 28% of all imported tungsten materials. China's share of the total quantity of tungsten materials imported by the United States was down about 18 percentage points compared with that of 1991. The total quantity of tungsten materials imported from China decreased from 7,103 metric tons of contained tungsten in 1991 to 1.829 metric tons in 1992. Of the total tungsten imports from China, the percentages imported as the concentrate and as the intermediate products (APT, tungsten oxide, and sodium tungstate) were 1% and 74%, respectively, 1992, in compared with 45% and 44%. respectively, in 1991. The virtual elimination of imports of concentrates from China in 1992 resulted from the continued imposition of the 151% antidumping tariff on Chinese concentrates that began in July 1991. Major suppliers of concentrates to the United States in 1992 included Bolivia (27%), Peru (25%), Portugal (23%), and Burma (9%).

World Review

Capacity.—Rated capacity for mines and mills as of December 31, 1992, was approximately 48,000 tons of contained tungsten. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Mine capacity for tungsten is based on published reports, maximum production statistics, and estimates. The latter is utilized particularly for certain countries where capacity information is either incomplete or unavailable. Estimated annual mine production capacity declined by about 9% in 1992 compared with that of 1991. Most of this decline was attributed to lower capacity in China, resulting from the apparent closure of several smaller. inefficient following the discontinuation Government subsidies to tungsten mines during the last quarter of 1992.

Austria.—At yearend 1992, Wolfram Bergbau and Huttengesellschaft, operator of the Mittersill Tungsten Mine, Mittersill, Austria, reported plans to place the mine on care-and-maintenance status in early 1993. The concentrate production portion of the company's integrated operation for making tungsten powder was said to have become uneconomical in light of the existence of low-priced tungsten intermediate materials on the world market. The company did not reveal how it planned to acquire material to continue its metal powder production operation once the mine was closed. Average annual production of concentrate at the Mittersill Mine since 1987 was about 1,300 tons of contained tungsten.

Annual concentrate production and

consumption statistics for the world are shown in tables 15 and 16, respectively. (See tables 15 and 16.)

Bolivia.—Representatives from the Bolivian mining industry reported in September 1992 that they would be forced to close many of their remaining tungsten mines unless the world market for concentrates improved significantly or additional financing was obtained. primary reason given for the possible closures was the declining demand for concentrates resulting from the increased use of alternate, low-priced intermediate tungsten materials from China. Affected by the closures would be the medium and small miners and the cooperatives. Corporación Minera de Bolivia, the state mining corporation, ceased production of tungsten concentrates in 1986. Bolivian production of concentrates was about 1,100 tons of contained tungsten in 1992, representing about 3.5% of the estimated world production.

Canada.—In November 1992, Canada Tungsten Mining Corp. Ltd., Vancouver, British Columbia, took an almost complete writedown of the company's leasing interest in the APT production facility in Fort Madison, IA. This cost reduction move also included the sale of the remaining nominal interest in the facility to a subsidiary of AMAX, Inc., Greenwich, CT, which owns a 57% share in Canada Tungsten. In the event that tungsten market factors improve, such that the Fort Madison plant can be reopened, Canada Tungsten will have the option of repurchasing the leasing interest for a nominal amount over an extended period of time. Production of APT was suspended at the Fort Madison plant in March 1990 in what was described at that time as an inventory control measure. Subsequently, the company continued to supply its customers with APT and other upgraded products from its inventories until early 1992.

China.—Representatives of China National Nonferrous Metals Import and Export Corp. (CNIEC) revealed in late 1992 that Government subsidies to tungsten mines officially had been discontinued. This action, part of the market-oriented reforms urged by the State Council, was expected to force the closure of some of the less efficient operations unable to compete as selfdependent, individual enterprises. The move by the State Council appeared to be a continuation of the policy that began in early 1991. In that policy, the Council announced plans to significantly reduce concentrate production as well as to limit the number of ammonium paratungstate and tungsten oxide production facilities. The opinion of some industry observers was that this new Chinese policy and related actions was prompted by the realization that they were not receiving an appropriate economic return for the large quantities of tungsten material being Although the preceding exported. Chinese actions were considered as positive signs toward eventually achieving a more balanced supply-demand condition in the tungsten market, significant additional time obviously was necessary to assess their affect on the market.

In early 1992, CNIEC and China National Minerals and Metals Import and Export Corp. (Minmetals) initiated plans to form a joint venture to control the exports of tungsten materials. Beijing-based company was positioned to fall under the supervision of the Ministry of Foreign Economics and Trade (MOFERT) and was designed to help control tungsten supplies through elimination of the competition for sales between Minmetals and CNIEC. yearend, the joint venture reportedly received the additional support of the State Council, in a further step toward implementation. Although the joint venture appeared to be in direct contrast to the decentralization process and market-oriented reforms that were being carried out by the State Council, it, nevertheless, seemed to gain acceptance as a meaningful measure toward exercising control over China's tungsten products. It was anticipated that, when the venture was implemented, it would include export controls over not only downstream concentrates but also materials.

European Community (EC).—Imports of tungsten concentrate, tungstic acid and oxide, and tungsten carbide powder and fused tungsten carbide from China remained subject to significant duties during 1992. Alternative minimum price standards also were continued for the CNIEC specific exporters, Minmetals. Although there were reports that the present import control measures were ineffective, prompting special discussions with Chinese trade officials, there were no indications, by yearend, that EC officials planned further review of the existing legislation controlling imports of Chinese tungsten materials.

International Tungsten Industry Association (ITIA).—In conjunction with the International Molvbdenum Association, the ITIA held a conference entitled "Alloy Steels and Specialty Alloys 1992." The November meeting, held in Dusseldorf, Germany, included papers detailing developments in the use of tungsten in high-performance nickel alloys, specialty steels for the chemical processing industry, ordnance, tool steels, and high-speed steels. Another paper presented information on tungsten supply, demand, application, and outlook. The outlook portion of this discussion emphasized present complexities and uncertainties with respect to producer stock levels, governmental restructuring in consuming countries, and economic recovery rates in market economy countries. These conditions effectively clouded the forecasts for the market. As a result, both pessimistic and optimistic scenarios were presented that had tungsten concentrate prices ranging from a low of \$60 per mtu to a high of \$100 per mtu by the year 2002.

In early 1992, the ITIA announced plans for its next international symposium. Responding to a proposal by the CNIEC, the site selected for the 6th International Tungsten Symposium was Guangzhou, China, from November 2-4, 1993. The ITIA planned to organize the symposium in conjunction with the Nonferrous Metals Society of China and

the China Tungsten Industry Association, acting as cosponsors.

Korea, Republic of.—Korea Tungsten Mining Co. Ltd. (KTMC) discontinued concentrate production at its Sangdong Mine in Kwang-Do Province, Republic of Korea, at the end of May 1992. According to comments from a company spokesperson, the operation reportedly was closed because of significant competition from China, as well as lower demand and depressed prices for concentrates on the world market. KTMC planned to continue to process concentrates supplied from imports and inventories to meet existing demand for its tungsten products. The Sangdong remain on care-and-Mine will maintenance status while the negative market factors exist. KTMC had been progressively reducing its production of concentrates since 1984, eventually halting sales to the open market in 1988. Production in 1991 was only about onethird that of the previous peak production levels of approximately 2,700 tons of contained tungsten.

Russia.—Effective June 17, 1992, the Russian Federation (Russia) officially received most-favored-nation status in its trade relations with the United States. As a result, the U.S. import tariffs on tungsten materials from Russia were decreased by 66% for ore concentrates and an average of 80% for other tungsten materials. Throughout the year, increasing interest in such imports was shown by both traders and consumers. The materials of interest included ore concentrate, metal powder, ferrotungsten, APT, oxide, and unwrought bar and rod.

United Kingdom.—Murex Ltd., Rainham, United Kingdom, closed its Sheffield, United Kingdom, APT plant at the beginning of 1992 after a compulsory purchase of the facility was made by the Sheffield Development Corp. to acquire land needed for road construction purposes. Even before this forced closure, however, Murex had decreased its APT production to well below plant capacity and was relying mostly on the

free market as its source of APT. According to a company representative, there was no commercial benefit for it in purchasing concentrate and converting it in-house to APT. Using the purchased APT as its starting material, Murex continued to produce various sizes of tungsten metal powder and tungsten carbide powder, as well as grade cemented carbide powders and cast tungsten carbide at its Rainham, United Kingdom, facility. By yearend, however, there were reports that Murex would cease production at its Rainham facility as a result of the adverse business climate.

United Nations Conference on Trade and Development (UNCTAD).—Through its standing committee on commodities. UNCTAD officially approved a new tungsten committee at a meeting held in October 1992. The newly formed tungsten committee, entitled Intergovernmental Group of Experts on Tungsten (IGE), replaced the Committee on Tungsten (COT), which had acted as the intergovernmental tungsten discussion and working group under UNCTAD from December 1964 through February 1992. The IGE planned to continue the efforts of the COT. Under the terms of reference for the COT, opportunities were provided for international consultations regarding trade in tungsten, for promotion of improvements in statistics, for a study of developments in the tungsten industry, and for access to the account for funding developmental activities within the Common Fund under UNCTAD.

The IGE convened its first session in Geneva, Switzerland, on December 7-11. 1992. During the discussions of the Sessional Working Group, a presentation by a representative from the UNCTAD Secretariat's office provided an overview of the status of the world tungsten industry. A pessimistic picture of the current situation and short-term outlook for the tungsten market was presented. Weak demand, caused by a slow growth in the world economy, an abundant oversupply of stocks, and correspondingly lower prices, generally described the present tungsten market. Certain

structural changes occurring in the market also were contributing to its present profile. The changes included an increasing use of obsolete scrap to meet existing demand, continuing governmental restructuring in Eastern Europe and the Commonwealth of Independent States (CIS), and a growing reliance on the use of intermediate tungsten products in favor of the traditional ore concentrates.

The need to improve transparency in the UNCTAD statistics was again expressed during this meeting. After a review of and correction of the country statistics provided to UNCTAD by the various delegations, the representatives of these delegations generally stressed the fact that the continuing absence of significant country data was preventing any appreciable advances in achieving data transparency. The delegates again sought data withheld by China, but none of these data were supplied. Verification of the accuracy of the Chinese data now being carried as estimates by UNCTAD also was unattainable, although an extended intragroup debate was conducted on this subject. Delegates also sought additional data from the Russian Federation and further suggested that data from the individual members of the CIS would be extremely useful. As had been stated in the 1991 meeting of the COT, the delegates from the Russian Federation expressed the hope that, in the future, it would be possible to gather such data and present it for inclusion in the UNCTAD statistics.

The issue of the need for greater cooperation toward achieving market stabilization was revived as the Chinese delegation expressed its support for further discussion on this subject. Most other delegations asserted that the idea of market stabilization had been determined to be outmoded. Furthermore, according to most delegates, pursuit of market stabilization was inconsistent with what they deemed should be the principal focus of the group. According to the work program of the Committee on Commodities, emphasis should be placed means to improve market transparency, including the accumulation. dissemination, and analysis of statistics,

and market intervention should not be a goal of the group.

For consideration by the IGE at its first meeting were four project proposals submitted for funding under UNCTAD's Common Fund for Commodities. The fund supports developmental activities within the individual commodities embraced by UNCTAD. Three of the proposals had been submitted by the Chinese delegation and one by the Secretary General of the ITIA. representing ITIA's members. After considering the report of the committee that had reviewed these proposals, the IGE decided to request the Secretary General of UNCTAD to submit for funding, on its behalf, one of the Chinese proposals, as well as the ITIA proposal. The proposals were entitled "Development of the Rare Earth Doped Cemented Carbide and its Mechanism Research" and "Health and Environmental Effects Testing of Tungsten Materials," respectively. The IGE's recommendation for financing of these proposals was approved on a technical and market basis, provided that no written statement to the contrary, with explanation, was received from any member of the IGE by the Secretary General of UNCTAD by February 11,

A provisional agenda for the second session of the IGE was adopted. Essentially, the IGE agreed in the agenda that its future activities should include enhancing market transparency; improving the collection dissemination of statistics; reviewing the current market situation, short-term outlook, and medium- to long-term perspectives; and considering project proposals for sponsoring under UNCTAD's Common Fund Commodities. In addition, the discussion of cooperation toward achieving market stabilization will remain as an agenda item. It further was agreed that the participation of industry advisors in the meetings should be encouraged and that the duration of the next meeting be shortened to 3 days from the current 5 days.

Current Research

Scientists from Rutgers University and Procedyne Corp., New Brunswick, NJ, reported the scale-up of a new process for preparing ultrafine-grained tungsten carbide powders at their Nanodyne Inc. facility in New Brunswick. The process, which utilizes a series of proven scalable technologies, is capable of producing particles that are orders of magnitude smaller than the approximately 1micrometer size currently achievable using mechanical milling processes. The demand for submicrometer tungsten carbide powder continues to increase in response to the need for cutting and wear-resistant cemented carbide components with superior toughness, as measured by hardness, strength, and impact resistance.1

A new catalytic electrode containing tungsten carbide powder was shown to be an effective device for recombining hydrogen and oxygen gas released during operation of a lead-acid battery. According to the Bulgarian Academy of Science researchers who developed and patented the electrode, it provides a more economical means of rendering such batteries suitable for sealing, that is, requiring no maintenance, than existing methods.² In another research effort offering promise for expanded use of tungsten, certain tungsten and tungstencopper alloys have been included among select materials of construction able to meet the stringent thermal, electrochemical, and wear-resistance requirements in the channel portion of a coal-fired magnetohydrodynamics (MHD) electric power generation system. In this MHD process, an extreme environment is created as an electrically conductive plasma is accelerated through the channel at supersonic velocity and under hightemperature and high-pressure conditions. Laboratory tests, at the present time, have yielded sufficient advancements in the MHD technology so that these materials can be evaluated in large-scale components prototypical of coal-fired powerplant hardware. Adoption of the MHD method by the electric utility industry is still contingent upon the longterm durability of these materials in the MHD channel.³

Results of additional studies on the recycling of tungsten were reported in 1992. In one of these research efforts, heavy-metal alloy machine turnings containing 90% tungsten were converted to a directly reusable heavy-metal alloy powder.4 The process utilized physical pulverizing and sieving techniques combined with air oxidation and hydrogen reduction steps. In another recycling study, an electrolytic method was described for recovering cemented tungsten carbide scrap.⁵ It was shown that the cobalt binder in the cemented carbide could be selectively dissolved anodically at high efficiency, leaving an uncontaminated tungsten carbide product.

The proceedings of an international conference, held in Arlington, VA, in November 1992, reported up-to-date research and development information on tungsten and tungsten alloys.⁶ conference, sponsored by the Metal Powder Industries Federation, Princeton, NJ, included approximately 70 oral and poster presentations outlining the most recent advances in the processing and application of tungsten, its alloys, and its A number of papers composites. revealed potential new methods and offered clearer understandings improving the ballistic behavior of tungsten heavy-metal alloys.

Details on the development of a tungsten-free, energy-saving light bulb were revealed in mid-1992 by two California research groups. The bulb, known as the E-Lamp, was reported to consume about one-fourth of the electrical energy of a conventional incandescent bulb and to last up to 25 times longer. A magnetic coil in the bulb emits a high-frequency radio signal that excites mercury vapor, which, in turn, strikes a phosphorescent coating on the inside of the bulb, emitting visible light.

Several advancements in thermal spray tungsten carbide-cobalt coatings technology were presented in the proceedings of an international conference, sponsored by the American Society for Materials-International.⁸ Spray techniques discussed in the various

papers on carbide coatings included plasma and vacuum plasma, highvelocity-oxy-fuel, and detonation gun. Properties such as microstructure, phase structure, porosity, microstructure, abrasion wear resistance, wear rate, homogeneity, hardness, and bonding strength of the coatings were evaluated. Spraying variables considered included spraying power and distance; coating composition and cooling rate: rate of powder injection in the plasma system; and gas and powder temperature. velocity, and pressure in the high-velocity Coatings were formed on system. substrates such as unalloved steels. stainless steels, rolling mill rolls, and mandrels for precision forging machines.

OUTLOOK

Based upon apparent consumption data accumulated during the first quarter of 1993, the total annual demand for tungsten materials in the United States in 1993 was estimated to be about 7,000 tons of contained tungsten. This would a decline in represent apparent consumption of approximately 5% compared with that of the revised figure of 7,420 tons for 1992. The economic recovery rate is expected to be slow in 1993, continuing to suppress the demand for cutting and wear-resistant components integrally associated with metalworking, machining, construction, transportation, mining, and oil and gas drilling industries. According to industry reports, although the short-term outlook for metal cutting tools, wear parts, and drilling components is not particularly bright, a low growth rate is, nonetheless, expected through the remainder of this Demand in the lighting, decade. electrical, and electronic sectors is expected to continue, although there could be some erosion of this demand in view of recent breakthroughs in development of tungsten-free light bulbs. In addition to the effect of economic factors, any growth in tungsten demand will continue to be dampened by the effects of substitution in the cutting and wear-resistant component industries as well as by technological improvements within the industry that result in a more efficient use of tungsten.

Supplies of tungsten concentrate and intermediate materials for consumption are expected to be sufficient for the remainder of the decade, in spite of the fact that production of concentrates at most domestic tungsten mines continues to be uneconomical. However, in as much as the present production, pricing, and distribution policies of the major supplier, China, appear to be in a state of flux, future supplies from this source are uncertain. Any future curtailment of the flow of tungsten materials from China would likely be accompanied by the entrance of more producers into the market, many of whom have been forced to close or reduce production as a result of the poor world economic conditions. In addition, there is an ever increasing availability of tungsten materials on the market from the CIS.

Low and high prices are reported semiweekly. Monthly averages are arithmetic averages of semiweekly low and high prices. The average price per metric ton unit of WO₃, which is an average of all semiweekly low and high prices, was \$63.00 for 1992. The average equivalent price per short ton unit of WO₃ was \$57.15 for 1992; combined with wolframite quotation beginning Apr. 1992, because of significant decline in trading of scheelite ore concentrates.

²Low and high prices are reported semiweekly. Monthly averages are arithmetic averages of semiweekly low and high prices. The average price per metric ton unit of WO₃, which is an average of all semiweekly low and high prices, was \$56.81 for 1992. The average equivalent price per short ton unit of WO₃ was \$51.54 for 1992.

³Low and high prices are reported weekly. Monthly averages are arithmetic averages of weekly low and high prices. The average price per short ton unit of WO₃, which is an average of all weekly low and high prices, excluding duty, was \$50.91 for 1992. The average equivalent price per metric ton unit of WO₃ was \$56.11 for 1992.

VANADIUM

By Henry E. Hilliard

Mr. Hilliard, a physical scientist with more than 20 years of U.S. Bureau of Mines experience, has been the commodity specialist for vanadium since 1986. Domestic survey data were prepared by Alex Charleston, Statistical Assistant; and international data tables were prepared by Ronald L. Hatch, International Data Specialist.

The principal use of vanadium is as an alloying element in steel. The addition of small amounts of vanadium, often less than 1%, to an ordinary carbon steel can significantly increase its strength and improve both its toughness and ductility. Such high-strength low-alloy (HSLA) steels are attractive in the construction of highrise buildings, bridges, diameter pipelines, and automobiles because of the weight savings obtained. Vanadium-aluminum alloys of titanium are widely used in the aerospace industry. Oxides and chlorides of vanadium play important roles as catalysts in the production of sulfuric acid and other key organic chemicals.

The U.S. Bureau of Mines began reporting statistical data on vanadium in the metric system of units in the 1990 Annual Report. Throughout this report, data will be reported in kilograms (kg) and metric tons (tons) unless otherwise stated.

In 1992, steelmaking continued to account for more than 80% of domestic vanadium demand. Consumption showed a modest increase, from 3,300 tons in 1991 to 4,032 tons in 1992. Although overall imports of vanadium raw materials decreased when compared with 1991, imports of ash, residues, and spent catalysts increased. Total U.S. exports of vanadium materials increased from 1,560 tons in 1991 to about 1,700 tons in 1992.

The oversupply of vanadium that began in late 1989 persisted throughout 1992 despite reduced production by the world's largest producer, Highveld Steel & Vanadium Corp. of the Republic of

South Africa. A result of the oversupply was continuously lower prices in 1992. Highveld's prices [lbs/vanadium pentoxide (V₂O₅)] were as follows: first quarter, \$2.60; second quarter, \$2.45; third quarter, \$2.20; fourth quarter, \$2.10; and 1st quarter 1993, \$1.95. Spot or free market prices averaged 30 cents less than Highveld's price. The price of ferrovanadium (FeV) in Europe and Japan declined nearly 12% during 1992 to about \$11 per kilogram. Low demand and depressed prices caused German FeV producer Gesellschaft Electrometallurge GmbH (GfE) to halt production of V₂O₅ for conversion to FeV at its Nuremberg plant. Austrian producer Treibacher reduced FeV capacity by 30% in 1991, with the intention of returning to full production in January 1992 when market conditions were expected to improve. When market conditions did not improve, Treibacher decided to delay indefinitely the return to full production. Like some other metals, the international FeV market was under pressure from low-cost producers from former Eastern bloc countries, especially Czechoslovakia. Czech producer Mnišek Ferozliatinárske Zavody, Š. P., owns a V₂O₅ plant that supplies feed for its FeV Mnišek, a state-run operations. enterprise, was able to produce FeV at competitive prices by using in-house secondary aluminum in its aluminothermic reduction process. Its conversion costs were about 10% less than its Western competitors. U.S. FeV producers fared a little better than their European and Japanese counterparts.

Prices were reasonably stable, and the U.S. Bureau of Mines reported a modest increase in demand.

The pattern of vanadium use in the United States is not expected to change significantly in the near future, but the level of consumption will be subject to fluctuations in domestic and global steel production.

DOMESTIC DATA COVERAGE

Domestic consumption data vanadium are developed by the U.S. Bureau of Mines from a voluntary survey of all known domestic consumers. In 1992, there were 83 responses to the consumption survey, representing 81% of total canvassed. These 83 respondents are estimated to have accounted for 95% of total domestic consumption, or about 3,800 tons. The estimated consumption of nonrespondents, derived using their past consumption relationships, trends, and data from nonsurvey sources, was about 200 tons. The consumption quantity of 4,073 tons shown in table 1 is the U.S. Bureau of Mines' estimate of total U.S. (reported) vanadium consumption.

BACKGROUND

Definitions, Grades, and Specifications

The term ferrovanadium as used by the U.S. Bureau of Mines includes vanadium-carbon-iron-nitrogen proprietary alloys as well as the conventional forms of ferrovanadium. Some of the more common commercial products are listed

in table 2. A standard specification for ferrovanadium has been developed by the American Society for Testing Materials (ASTM).1

Aluminum-vanadium master alloys contain fixed ratios of vanadium to aluminum and are used in the manufacture of titanium alloys. Amounts of vanadium up to 1 weight-percent improve the strength of titanium-base alloys and promote their thermal stability in the presence of moderate amounts of aluminum. When amounts greater than 4 weight-percent are added, the titaniumbase alloy can be significantly strengthened by heat treatment. three most important commercial titanium alloys containing vanadium are Ti-6Al-4V, Ti-6Al-4V-2Sn, and Ti-8Al-1Mo-1V. The Ti-6Al-4V alloy presently accounts for more than 50% of the titanium-base alloy market.

Products for Trade and Industry

Vanadium is usually traded on the international market in the form of technical grade V₂O₅ and 50% to 80% FeV. Most world exports of vanadium raw material are in the form of vanadium-bearing iron slag from China and the Republic of South Africa, while U.S. and Western European converters are the major importers of these materials. U.S. and Western European converters are the major exporters of downstream vanadium products such as vanadium oxides and FeV to the many small consuming countries. converters also compete for the major markets for pentoxide and FeV exported to Japan and the Republic of Korea. Trade in ferrovanadium is dominated by the major European and U.S. converters. A large part of this trade is within Europe, but exports are also made to other consuming countries. particularly by the Federal Republic of Germany.

Industry Structure

The vanadium industry has a five-

continents. As expected, mines and oilfields form the base of the structure (figure 1). Since 1979, an estimated 83% of world production has come from vanadiferous magnetite (Fe₂O₄). principal sources of the magnetite ore were China, the Republic of South Africa, and the former U.S.S.R. World vanadium production for 1988-92 is shown in table 14. The other 17% of the vanadium was recovered from other pertroliferous materials and spent catalysts.

The second tier is a set of economically unrelated facilities that include (1) pig iron plants with slag recovery units, (2) elemental phosphorus smelters, and (3) generators of petroleum residues, fly ash, and spent catalysts that contain vanadium either as the active material or as a contaminant.

The third tier consists of (1) acidleaching plants with solvent extraction circuits and (2) salt roasting operations. Technical-grade V₂O₅ and NH₄VO₃ are the principal products at this level.

To have an easily marketable product, it is customary at this point to either convert the oxides into an alloy or upgrade their purity to greater than 98.5 weight-percent. The two traditional alloy products have been the 80 weight-percent ferrovanadium and 35 weight-percent aluminum-vanadium master alloy. Variations of five different reduction processes are currently in use throughout the world, with aluminum, carbon, or silicon serving as the reductant. These conversion and upgrading plants, which form the fourth tier of the structure, may be a considerable distance from the mills and slag plants and frequently blend feed materials to improve recovery.

Of the more than 30 privately owned vanadium companies, only 1, the Republic of South Africa's Highveld, operates facilities at all 4 lower levels and can be considered totally integrated. Highveld has plants that process vanadiferous magnetite ores from the Bushveld Igneous Complex. Two other producers. Shieldalloy Metallurgical Corp. and Stratcor, have extensive operations on the second, third, and tiered structure with facilities on six | fourth tiers. Shieldalloy traditionally

used Highveld slag as its starting material low vanadium grades of ferrovanadium.

The fifth tier is composed of producers of vanadium specialty alloys, high-purity vanadium metal, primary vanadium chemicals, and vanadium catalysts. Reading Alloys Inc., Akzo Chemical, and Teledyne Wah Chang Albany illustrate the diversity of operations at this level.

The Republic of South Africa is the world's largest producer of vanadium, usually as a vanadium-bearing slag. Its annual production of about 15,000 tons is approached only by production in Russia, formerly a part of the U.S.S.R. The bulk of Russian production was consumed internally or by other Eastern European countries. Other major producers include China and the United States. Canada, Japan, and Western Europe are heavily dependent on imports of vanadium slag and pentoxide from the Republic of South Africa. Any disruption of South African supplies could seriously upset the balance between vanadium supply and demand.

Geology-Resources

Vanadium is found in many parts of the world, usually in association with other minerals. There are few ores from which vanadium can be economically extracted as a single product. It is, therefore, often extracted as a byproduct or coproduct in the production of other elements, such as iron, phosphorus, or uranium. Increasing amounts are being recovered from petroleum residues and spent catalysts. The world also has extensive subeconomic resources vanadium contained in oil sands, carbonaceous shale, and bauxite.

The crustal abundance of vanadium is estimated to be 100 to 150 parts per million (ppm), about twice that of copper, 10 times that of lead, and almost 100 times that of molybdenum.² As a result, trace vanadium mineralization occurs in a wide range of geologic provinces and environments. At the same time, ore deposits of vanadium are rare because much of the vanadium in igneous rocks occurs dispersed in the relatively insoluble trivalent state and is substituting

for ferric iron in ferromagnesian silicates, magnetite, ilmenite, and chromite. Because of the substitutional phenomenon at the atomic level, vanadium is more abundant in mafic (those high in magnesium and iron) than silicic rocks. Gabbros and norites typically contain 200 to 300 ppm vanadium compared with 5 to 80 ppm for granites. When mafic rocks weather in a humid climate, the vanadium remains in the trivalent state or is weakly oxidized to the relatively insoluble tetravalent state. In either case, the vanadium is captured along with aluminum in the residual clays. Subsequent leaching of the clays can produce bauxite and lateritic iron ores that contain 400 to 500 ppm vanadium. When mafic rocks are intensely oxidized in an arid climate, some of the vanadium is converted to the pentavalent state. The pentavalent cation is considerably more soluble than the trivalent cation, is readily dissolved by ground water, and can be transported over long distances. transport phenomenon can be observed in arid parts of Western Australia where carnotite precipitates from ground water in calcreted drainage systems.3 Yeelirrie, for example, thin films of carnotite were formed in the voids and cavities of river fill when ground water percolated through a tertiary river channel.

Organic materials frequently play a key role in the depositional process by helping to create a reducing environment. At many locations on the Colorado Plateau, carnotite, tyuyamunite, and other secondary uranium-vanadium minerals replace fossil logs and other carbonized plant debris. Some of the best examples of this phenomenon can be seen in the Monument Valley and White Canyon districts where uranium-vanadium ores have been deposited in paleochannels of the Shinarump Member of the Upper Triassic Chinle Formation. Fossils in the Shinarump indicate that the stream channels were cut into the underlying Moenkopi mudstones and then filled with sands, pebbles, and plant debris before the end of the Triassic Period 195 million years ago. Although the uraniumvanadium ores are associated with plant remains, the two elements were precipitated from aqueous solutions percolating through the stream channels long after the host sandstones and conglomerates had formed. The genesis and age of the mineralization remain controversial.

The role of vanadium during the formation of fossil fuels is obscure. There appears to be a relationship between the relatively high concentration of vanadium in coal and petroleum and the burial and subsequent degradation processes that apparently formed the fuels from organisms. The structures of the vanadyl porphyrins found in crude oil are approximately identical to the structures of chlorophyll (magnesium-centered porphyrins present in green plants) and hemoglobin (iron-centered porphyrins present in the red corpuscles of blood). The ratio of vanadium to nickel in crude oil is a function of the oxidation-reduction potential (Eh), the hydrogen ion activity (pH), and the sulfide activity of the environment in which the oil source rocks were deposited. The two metals both form stable metallo-organic complexes in the high molecular weight fractions of crude oil.4 Cleavage of these vanadium and nickel bonds will not occur unless the crude oil is subjected to a temperature greater than 300° C. As a result, the vanadium-to-nickel ratio remains constant for a specific reservoir even when the lower molecular weight components The ratio is therefore migrate away. useful in identifying unmetamorphosed crude oil from different depositional facies of the same source rock.

Technology

Mining.—In the United States, vanadium is recovered as a principal mine product, as a coproduct from carnotite ores, and from ferrophosphorus slag as a byproduct in the production of elemental phosphorus. Increasingly, it is also being recovered from petroleum refinery residues, fly ash, and spent catalysts. In China and the Republic of South Africa, vanadium is recovered as a byproduct of pig iron production from titaniferous magnetite.

Processing.—The steel industry accounts for more than 80% of the world's consumption of vanadium as an additive to steel. It is added to the steelmaking process as a ferrovanadium alloy, which is produced commercially by the reduction of vanadium pentoxide or vanadium-bearing slag with aluminum, carbon, or ferrosilicon.

The first stage in the processing of vanadium-bearing ore is the production of an oxide concentrate. The ore is crushed, ground, screened, and mixed with a sodium salt. This mixture is roasted at about 850° C to convert the oxides to water-soluble sodium metavanadate. The vanadium is extracted by leaching with water and precipitated at pH 3 as sodium hexavanadate (red cake) by the addition of sulfuric acid. The red cake is fused at 700° C to yield a dense, black product that is sold as technicalgrade vanadium pentoxide. Technicalgrade vanadium pentoxide contains a minimum of 86 weight-percent pentoxide and a maximum of 8 weight-percent sodium oxide. The red cake may be further purified by dissolving it in an aqueous solution of sodium carbonate. Aluminum, iron, and silicate impurities precipitate from solution upon pH adjustment. Ammonium metavanadate is then precipitated by the addition of ammonium chloride. The precipitate is calcined to give a vanadium pentoxide product of greater than 99.8% purity.

Vanadium is extracted as a coproduct with uranium from carnotite by direct leaching of the ore with sulfuric acid. An alternative method is roasting the ore followed by countercurrent leaching with dilute sulfuric acid. In some cases, the first leach may be with a sodium carbonate solution. The uranium and vanadium are then separated from the pregnant liquor by liquid-liquid extraction techniques.

More recently spent catalysts have become a major source of vanadium. The catalyst may be either oxidation catalyst used in the production of sulfuric acid and maleic anhydride or hydroprocessing catalyst used in petroleum refining. Vanadium is recovered by first roasting the material in

a controlled atmosphere to solubilize the vanadium and other trace metals, for example, molvbdenum and nickel. It is then milled, leached, and filtered to enable the separation of solids from the solution containing vanadium. solutions go through various precipitation steps before the precipitation of vanadium as ammonium metavanadate, which is then decomposed and fused to form V₂O₅ or used directly to make other vanadium AMAX Metals Recovery chemicals. Inc., Braithwaite, LA, uses a somewhat different process to recover cobalt, molybdenum, nickel, and vanadium from alumina-base spent catalysts. process developed by AMAX in the early 1980's uses a two-stage caustic-leach process, one to solubilize vanadium and molybdenum, and the other to solubilize alumina. The AMAX process separates the spent catalysts into four products: molybdenum trisulfide, vanadium pentoxide, alumina trihydrate, and a nickel-cobalt concentrate.

In China and the Republic of South Africa, vanadium is concentrated in slag resulting from the production of pig iron from magnetite ore. The ore, containing 1.5% to 2.5% vanadium pentoxide, is partially reduced with coal in rotary The ore is then melted in an enclosed furnace that produces a slag containing most of the titanium and pig iron containing most of the vanadium. After the titanium-bearing slag is removed, the molten pig iron is blown with oxygen to form a slag containing 12 to 24 weight-percent vanadium pentoxide. The slag is separated from the molten metal and may then be used as a highgrade vanadium raw material in the usual roast-leach process.

In the aluminothermic process for preparing ferrovanadium, a mixture of technical-grade pentoxide, aluminum, iron scrap, and a flux are charged into an electric furnace, and the reaction between aluminum and pentoxide is initiated. The reaction is highly exothermic, producing very high temperatures. The temperature can be controlled by adjusting the particle size of the reactants and the feed rate of the charge and by using partially reduced pentoxide or by replacing some of the

aluminum with a milder reducing agent. Ferrovanadium containing up to 80 weight-percent vanadium can be produced by this method.

Ferrovanadium can also be prepared by the thermit reaction, in which vanadium and iron oxides are coreduced by aluminum granules in a magnesia-lined steel vessel or in a water-cooled crucible. The reaction is initiated by a barium peroxide-aluminum ignition charge. This method is also used to prepare vanadium-aluminum master alloys for the titanium industry.

The production of ferrovanadium by the reduction of vanadium concentrates with silicon involves a two-stage process which technical-grade vanadium ferrosilicon, pentoxide, lime, fluorspar are heated in an electric furnace. An iron alloy containing about 30% vanadium but undesirable amounts of silicon is produced. The silicon content of the alloy can be reduced by adding more pentoxide and lime to effect the extraction of most of the silicon into the slag phase. An alternative process involves the formation of a vanadiumsilicon alloy by the reaction of vanadium pentoxide, silica, and coke in the presence of a flux in an arc furnace. The molten metal reacts with vanadium pentoxide yielding ferrovanadium. The silicon reduction method has not been used extensively.

A process developed by Foot Mineral Co., Cambridge, OH, (now Shieldalloy Metallurgical Corp.), has been used to produce tonnage quantities of ferrovanadium. This process involves the reaction of vanadium-bearing iron slag with silica, flux, and a carbon reductant followed by refinement by vanadium pentoxide. The reaction takes place in a submerged electric arc furnace yielding a ferrovanadium alloy containing about 40 weight-percent vanadium, 3.5 weight-percent silicon, 3.8 weight-percent manganese, 0.1 weight-percent carbon, and the remainder iron.

Substitutes

Various metals, such as columbium, manganese, molybdenum, titanium, and

are, to some degree, tungsten, interchangeable with vanadium. So far there are no substitutes for vanadium in the all-important aerospace titanium alloys, which were used in jet engine mountings and wing structures. Highpurity vanadium compounds were used as catalysts in the production of sulfuric acid, maleic anhydride, and in pollution control technology where it was required to remove hydrogen sulfide gas from flue gases (Stretford Process). In only a few chemical applications could platinum and nickel replace vanadium catalyst.

Economic Factors

Prices.—The price of FeV declined by more than 12% over the previous 12 months and at the end of April FeV sold for about \$11.70 per kilogram of The \$11.70 price vanadium content. level equated to about \$1.80 per pound for V_2O_5 , but, with V_2O_5 selling for \$2.10 or more, the \$11.70 price represented a loss for most Western converters. Vanadium remained in oversupply, and demand has been in decline for almost 2 years. Sharply lower orders for vanadium alloy steels by the construction and automotive sectors was the driving force behind decreased demand. The depressed market caused some European converters, e.g., Treibacher of Austria and GfE of Germany, to shut down some FeV Treibacher reduced FeV capacity. capacity by 30% in October 1991 with the intention of returning to production in January 1992 when market conditions were expected to improve. The expected improvement in prices did not occur, and the shutdown was extended into the second quarter. GfE halted production of V₂O₅ for FeV at its plant in Nuremberg because the company could not make a satisfactory profit under current market conditions. The company planned to continue FeV production at a reduced rate contingent upon the purchase of V₂O₅ at a favorable price from an outside source. Meanwhile, modest increases in demand were reported in January through April. However, reported consumption in two of the largest steel end-use categories (HSLA and tool steel) remained flat during that period. The outlook for domestic steel production in the third and fourth quarters includes a modest improvement over that of 1991, and a modest increase in demand for vanadium can be anticipated.

Tariffs.—U.S. import duties on selected vanadium items as of January 1, 1992, are listed in table 3. The tariff listing includes rates for both most-favored-nation (MFN) and non-MFN status.

Operating Factors

Environmental Issues.—Because some segments of the geochemical cycle of uranium and thorium coincide with the vanadium cycle, the environmental considerations of vanadium mining are frequently linked to the management of radioactive mine wastes. In addition to careful placement and containment of tailings ponds, special attention must be given to preventing or limiting radioactive contamination of ground water aquifers and to the impoundment and long-term storage of mill tailings and mine waste to control radon daughter exhalation.

In 1982, the Environmental Protection Agency (EPA) published a regulation dealing specifically with the mining of both vanadium ores and uranium-radiumvanadium ores.⁵ Under these rules, the concentration of uranium in mine drainage must be less than 4 milligrams per liter per day for 30 consecutive days. In addition, the U.S. Nuclear Regulatory Commission has issued two regulatory guides dealing with personnel monitoring at uranium mills and processing facilities. The two guides delineate techniques for performing a bioassay on workers routinely exposed to airborne yellowcake (U₃O₈) or airborne uranium ore dust.⁶

In October 1983, EPA published rules dealing with the stabilization and long-term control of mill tailings at inactive uranium-vanadium processing sites.⁷ These rules, which took effect on December 6, 1983, required uranium-vanadium mill operators to install plastic

liners or other protective barriers under their tailings piles to prevent uranium, its radioactive daughter products, and nonradioactive toxic substances such as selenium from contaminating ground waters. Each tailings pond was required to have an earthen cover to minimize emissions and prevent erosion of the sandy surface by wind and rain. The rules also limited radon release from the surface of the pile to 20 picocuries per square meter per second.

Vanadium compounds are irritants chiefly to the conjunctiva and respiratory tract. Prolonged exposure may lead to respiratory irritations with discharge and lower respiratory tract irritation with bronchitis and chest pains.8 Other noted effects of vanadium and its compounds have included dermatitis, conjunctivitis, discoloration of the tongue. Vanadium in high concentrations may alter metabolic processes in animals and humans. The reported toxic effects of exposure to vanadium compounds have been acute, never chronic. Toxic effects vary with the compound involved; for example, vanadium oxytrichloride (VOCl₃) liberates hydrogen chloride gas, and the oral lethal dose (LD₅₀) for V₂O₅ dust in rats is 23 milligrams per kg of body weight.9 The lethal dose value is used to express the toxicity of many compounds and is determined by experiment. As used here, it is milligrams of V₂O₅ per kg of body weight that is lethal to 50% of the experimental animals.

Vanadium metal and its alloys pose no particular health or safety hazard, but they do react violently with certain materials, including bromine trifluoride (BrF₃), chlorine, and some strong acids. The toxicity of vanadium alloys depends on other components in the alloy.

The adopted threshold limit value for time-weighted averages for airborne vanadium, including oxide and metal dusts of vanadium, is 0.5 milligram per cubic meter; the value for fumes of vanadium compounds is 0.05 milligram per cubic meter. These limits are for normal 8-hour workday and 40-hour workweek exposures. The short-term exposure limit is 1.5 milligrams per cubic

meter for dust.¹⁰ The ammonium salts of vanadic acid and vanadium pentoxide have been listed as toxic constituents in solid wastes under the Resource Conservation and Recovery Act.¹¹

ANNUAL REVIEW

Legislation and Government Programs

The Russian Federation was awarded MFN status on June 17, 1992. Vanadium products affected are as follows: V₂O₅, 16% ad valorem MFN vs. 40% ad valorem non-MFN; vanadates, 11.2% MFN vs. 40% non-MFN; FeV, 4.2% MFN vs. 25% non-MFN; and aluminum-vanadium master alloys, free MFN vs. 10.4% non-MFN.

The depressed uranium-vanadium milling industry received more bad news in August when it was announced that the United States had agreed to buy bombgrade uranium from Russia's dismantled nuclear warheads and convert it into fuel for commercial nuclear powerplants. Under a contract to be negotiated over the next year, Russia would sell U.S. companies 500 tons of highly enriched bomb-grade uranium from its nuclear weapons stockpile. The companies would dilute the enriched uranium commercial-grade, then deliver it to customers who now buy from the U.S. Energy Department, which runs its own enrichment plants.

There was already a glut of uranium fuel in the commercial market, much of it attributed to the Russians, who have been exporting commercial-grade uranium for several years. At least in part because of Russian inroads, U.S. U₂O₂ production declined from about 17,000 tons in 1980 to less than 4,000 tons in 1990. At the same time, coproduction of V₂O₅ from uranium-vanadium ores declined from 5,000 tons to 1,200 tons. Meanwhile, imports from Russia and other Republics of the former U.S.S.R. rose from near zero to more than 2,700 tons per year. The Commerce Department made a preliminary finding that Russia was "dumping" uranium in the United States at unfairly low prices. That ruling did not apply to highly enriched bomb-grade uranium because no such material had been sold commercially. A final ruling, due this autumn, could be amended to apply duties to bomb-grade material if it is intended for commercial use.

Russia and five other former Soviet Republics accepted strict quotas imposed by the U.S. Commerce Department that essentially excluded them from the U.S. market unless the price of uranium rises \$3 or more above \$10 per pound. At the end of 1991, when U.S. producers decided to take action, uranium imports from the former U.S.S.R. were about three million pounds per year. Under the new agreement, Russia, Kazakhstan, Ukraine, and Uzbekistan will be excluded from the U.S. market until the price of uranium rises to \$13. At \$13, they can ship 2.9 million pounds per year. The quota rises with price. At \$21, the quotas are lifted. The quota does not apply to the 10 tons of weapons-grade uranium that Russia has agreed to sell to the Department of Energy.

Strategic Considerations

Vanadium is classified as a strategic and critical material because of the significant import dependence of the United States for its vanadium supply and because of the essential use of vanadium in equipment for defense, energy, and transportation.

Steel producers in the market economy countries (MEC) of the United States, Japan, and Western Europe shared a concern about lack common economically viable domestic vanadium raw materials. Also, MEC vanadium supply was from only a few sources, chiefly China and the Republic of South Africa and from just three or four suppliers in these countries. China was expected to soon become a net importer of vanadium, leaving only South Africa and perhaps Russia as the major sources. Japan and Western Europe are more heavily dependent on imports than the United States.

The status of goals and inventories of vanadium materials in the National Defense Stockpile remained unchanged at the end of 1992.

Issues

Prior to about 1984-85, more than one-half of the vanadium mined in the United States was recovered as a coproduct with uranium from sandstone mined on the Colorado Plateau. Companies recovering vanadium from uranium ores were hurt by the downturn in nuclear powerplant construction in the aftermath of the Three Mile Island accident and nuclear reactor subsequent reduced demand for enriched Worldwide recession, high uranium. interest rates, and the cancellation of powerplant construction in the United States caused the Nuclear Exchange Corp. (Nuexco) exchange value of U₃O₈ to decline from \$40.75 per pound in early 1980 to less than \$10 per pound in 1991. The exchange value is Nuexco's judgment of the price at which transactions for significant quantities of uranium concentrates could be concluded on a specified date. Value is based on bids to buy and offers to sell, as well as recently completed and pending transactions.

A direct result of the price decrease was mill closing and decommissioning, personnel cutbacks, and canceled development and expansion plans. This unstable situation had the potential for creating a much higher degree of dependence by the United States on South African and Chinese imports. However, some of the slack was taken up by increased recovery of vanadium from petroleum residues, including spent petroleum catalysts. Recovery of vanadium from this source began during the 1973 and 1978 Arab oil embargoes. After being cut off from light crude from the Middle East, refiners were forced to process crude oils with high-sulfur and high-metal content. The trend toward heavier, sour crude and a tightening of sulfur restrictions on fuel products led to the development of the Flexicoking process, which concentrated 99% of the metals in the feed in a 2% solid purge This material has from the system. become an important source of vanadium and, in some instances, molybdenum and nickel. At the same time, the combustion of increasingly metalliferous fuel oils at powerplants created a second source of feed materials in the form of fly ash and boiler scale. More V_2O_5 produced in the United States is now being recovered from refinery residues, fly ash, boiler scale, and spent catalysts than ever before. U.S. vanadium producers recovered 1,400 tons of vanadium oxides from petroleum residues in 1992.

Production

Vanadium is often considered to be an uncommon element, but actually its abundance in the Earth's crust is comparable to or greater than that of copper, nickel, and zinc. Although there is a plentiful supply of vanadium, it is one of the most expensive elements to In most cases, whether recover. vanadium occurs as a primary ore, a coproduct, or in petroleum, the vanadium content of the material usually runs 1.5% V_2O_5 or less. V_2O_5 is the principal starting material for the production of all vanadium compounds. Therefore, when one speaks of vanadium production or the supply side of the industry, only those involved in the production of V₂O₅ should be included.

At yearend, there were five companies producing V_2O_5 in the United States. Of these, one was a totally integrated company that produced V_2O_5 , vanadium chemicals, FeV, and other vanadium alloys. The others produced mainly V_2O_5 from a variety of raw materials.

Consumption, Uses, and Stocks

Vanadium has been used as an alloying element in steel since 1902, when it was first added to tool steels used for high-speed machining operations. It was found that vanadium prevented grain growth in tungsten-bearing steels and enabled the steels to maintain their hardness at the high temperatures generated in tool steels during high-speed machining. Vanadium is also widely used in high-temperature steels used in steam powerplants. Chromium-vanadium steels are used for steel pipes and

headers, and molybdenum-vanadium steels are used for rotors because of the high creep resistance produced by vanadium carbides.

Metallurgical applications accounted for more than 95% of vanadium consumption, with about 83% for steelmaking. Relatively small quantities of vanadium were used for alloying with nonferrous metals, mostly aluminum. Nonmetallurgical applications included catalysts, ceramics, and vanadium chemicals. The dominant nonmetallurgical use was in catalyst. Much less was consumed in ceramics and electronics (batteries).

Based on published U.S. Bureau of Mines statistics, consumption in 1992 increased by more than 20% over consumption in 1991. However, the actual increase was probably closer to 3% for this period. The apparent large increase was due to temporary data processing problems in compiling 1991 data, resulting in unusually low reporting of consumption in 1991.

Reported consumers' and producers' stocks of vanadium oxides, metal, alloys, and chemicals at yearend totaled 1,084 tons of contained vanadium; at yearend 1991, the number was 935 tons.

Foreign Trade

Overall U.S. export of vanadium products was up by about 16% in 1992. Canada and Mexico were the leading importers of U.S. materials. Most countries imported almost exclusively V₂O₅. Canada, the Republic of Korea, and Venezuela also imported substantial quantities of FeV. Exports of V₂O₅ totaled only 46 tons gross weight, less than one-third of 1991 exports. Exports of FeV totaled 326 tons gross weight, up from 178 tons in 1991.

Imports for consumption of downstream vanadium compounds increased slightly in 1992; imports of raw materials, slag, ash, etc., were up by about 5%. FeV imports totaled 767 tons gross weight, up from 524 tons in 1991. The imported FeV averaged 81% vanadium, with a mean customs value of \$11.88/kg of contained vanadium, down

from \$12.79 in 1991. Canada was the leading source of FeV, with shipments of 365 tons, followed by Austria, 135 tons, and Belgium, 47 tons. Vanadium pentoxide imports totaled 207 tons of contained vanadium, up from 133 tons in 1991; the average declared value was \$3.07 per pound of contained vanadium, down from \$3.22 in 1991. Imports for consumption of vanadium-bearing slag totaled only about 143 tons of contained vanadium, all from the Republic of South An assortment of petroleum Africa. residues, spent catalyst, and fly ash totaling about 1,200 tons of V₂O₅ was imported from a variety of countries.

World Review

Industry Structure.—Vanadium was traded on the world market in vanadiumpetroleum residues, bearing slag, technical-grade V₂O₅, and FeV. Republic of South Africa was the largest producer with more than 60% of the MEC market. Most of the Republic of South Africa's exports of vanadium were in the form of vanadium-bearing iron slag. Japan and Western Europe were the chief importers of this material. The United States imported slag from the Republic of South Africa, and fly ash, petroleum residues, and spent catalyst from many other sources. The large importers of vanadium raw materials, for example, slag, were the chief exporters of V_2O_5 , FeV, and other downstream vanadium products. This trade was dominated by a few large West European converters who competed not only within Europe but also exported to many large and small consumers outside of Europe. Reliable statistics from Russia were not available, but it is believed to be second only to the Republic of South Africa in vanadium production. Most Soviet trade was thought to be with other East European countries. However, significant quantities of Russian and Czech material began to find their way into the world market.

Capacity.—The data in table 12 are rated capacity for mills producing vanadium oxides as of December 31. 1992. Included in this data is capacity to produce vanadium-bearing slag and petroleum coke. Rated capacity is defined as the maximum quantity of product that can be produced on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor. energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought back into production within a short period with minimum capital expenditure.

Australia.—Western Australia has large deposits of magnetite ores containing vanadium and titanium. The deposits consist of a large magnetite-rich intrusive rock. A chemical analysis of the material, undertaken more than 20 years ago, found about 0.32% V₂O₅. This deposit was ignored for many years because of the low price of vanadium. As the price of vanadium climbed from 1987 through 1989, Precious Metals Australia (PMA) reevaluated the deposit at its wholly owned Wagoo Hills Project in the Murchison District of Western Australia. This time, the titanium and vanadium mineralization was found to grade up to 0.93% V_2O_5 and 12%titanium dioxide (TiO₂). The deposit lies within a distinct and reasonably welldefined geologic structure known as Shepard's Discordant Zone (SDZ), which extends along a 10-mile strike within PMA's property. The latest sampling was carried out across the SDZ in areas of abundant titano-magnetite surface rock with samples collected at 2- and 6-yard intervals. Analysis of the samples indicated that the region was likely to contain up to 40 million tons of high-iron magnetite ore containing an average of 0.75% V_2O_5 and as much as 12%titanium. 12

Preliminary metallurgical work suggested that a magnetite concentrate could be produced from grinding and magnetic separation. A \$70 million mine development and processing plant was planned to produce about 2,100 tons of V_2O_5 per year. PMA was determined to continue the development of this project despite low vanadium prices in 1991 and even lower prices in 1992. PMA officials believed Australian mining and materials handling technology to be more efficient than methods used in the Republic of South Africa. They also believed that the Australian ore would be easier to process. PMA has the disadvantage of higher energy costs.

Czechoslovakia.—U.S. imports of ferrovanadium from Czechoslovakia were first reported by the Bureau of the Census in February 1992. Imports for that year totaled only 35 tons vanadium content with a customs value of \$409,000. The material was produced by Mnišek Ferozliatinárske Zavody, Š. P., near Prague. Mnišek owns a V₂O₅ plant that supplied feed for its FeV operations. Vanadium-bearing iron slag feed for the V₂O₅ plant was imported from Russia. Vanadium pentoxide capacity was estimated at about 3.6 million pounds per year with the possibility of expansion if market conditions improve. Ferrovanadium capacity has been estimated at 1,500 tons per year and could be easily increased to 2,000 tons per year if market conditions should warrant higher production. Mnišek, a state-run enterprise, was able to produce FeV at competitive prices by using inhouse secondary aluminum in its aluminothermic reduction process. conversion rate was 10% less than its Approximately Western competitors. 80% of its output was exported, with the remainder consumed by the domestic steel industry. In July the company appointed the Japanese trading house Nissho Iwai as the sole sales for its vanadium exports. During the second half of 1992 Nissho Iwai was expected to sell about 80% of Mnišek's ferrovanadium production to Western Europe, Japan, Southeast Asian countries, and the United States. The company also produced silicon metal at the Mnišek plant.

Netherlands.—Metrex was operating a plant in Heerlen, the Netherlands, that breaks down catalysts into their component parts, recovers the metals and alumina, and sells them to companies that can use them. Company officials stated that it was the only facility of its kind anywhere. However, the plant appeared to be very similar to the one operated by the Metals Recovery Corp. (AMAX-Cri-Met) in Braithwaite, LA, which has been in operation for more than 10 years.

The \$15 million Metrex facility is located in the southeast corner of the Netherlands close to Belgium and German borders. It can process up to 7,000 tons per year of spent hydrodesulfurization catalysts, and capacity can be doubled without much difficulty if demand Cobalt, molybdenum, and requires. nickel contained in the original catalyst formulation, along with vanadium adsorbed during processing of the oil fractions, were recovered. products stemming from the operation were aluminum oxide, which goes to make ceramic and refractory bricks, and gypsum, from the flue gas.

The metal content of hydrodesulfurization catalysts in their original formulation typically is 2% to 3% by weight cobalt, about 4% nickel, and up to 8% molybdenum. About half the weight of the spent catalysts consists The combined carbon, of alumina. hydrocarbons, and sulfur account for about 35%. The remaining 15% represents cobalt, molybdenum, nickel, and vanadium sulfides. According to plant officials, the Metrex process results in a metals recovery efficiency that exceeds 90%.13

Venezuela.—Flexicoke is a byproduct petroleum residue from the noncatalytic thermal conversion process called flexicoking. The huge Lagoven refinery in Venezuela is perhaps the world's largest producer of flexicoke, producing about 300 tons per day. The material from Venezuela may contain as much as 16% V₂O₅ and has been imported by U.S. Vanadium Co. and others as a vanadium raw material. Researchers in

Venezuela (INTEVEP S.A., Simon Bolivar University) recently reported new metallurgical applications of flexicoke. In one application, mixtures of iron ore and flexicoke were agglomerated in pellet form to study the reducibility of iron oxide by using flexicoke as a solid reducing agent and to evaluate the manufacture of self-reducing iron ore pellets as raw material for producing steels in induction furnaces of 5-kg capacity. It was determined that the selfreduced pellets could be used as raw material for manufacturing HSLA steels and steels of medium to high carbon content.14 Another report evaluated flexicoke as a pyroconsolidating agent. For the evaluations, 3 tons of flexicoke per heat of liquid steel was cycled in electric arc furnaces of 150- to 200-ton capacity. The results indicated that the flexicoke can be used as a foaming slag promoter, but its high sulfur content (approx. 2.6%) restricted its use to those steels where maximum sulfur content is 0.015%.¹⁵ For both applications flexicoke is a substitute for metallurgical coke.

OUTLOOK

Like many of its counterparts throughout the metals industry, the vanadium industry was struggling to recover from a recession that caused sales to fall and profits to plummet. And like so many of its counterparts, the industry was finding recovery a painfully slow process. Some traders were optimistic about 1993. They believed that the fundamentals for an economic recovery in the United States were in place. As a result, volume and prices for vanadium products should slowly strengthen in late 1993. There were, indeed, signs that the country was inching toward recovery. Employment was up in the manufacturing sector, productivity was improving, GDP was gaining, and interest rates moved noticeably lower.

Any upturn in the economy will help the vanadium industry, but it is not likely to see the growth rate prevalent in the late 1980's, and the vanadium industry will probably lag the general economy in

1454 VANADIUM—1992

turning around. Working against rapid turnaround are a number of factors, including low demand for vanadium in still weak, major end-use markets. Chief among these is the steel industry (construction and automobiles). Commercial construction is very weak and will continue to be so for some time as vacancy rates in office buildings remain high across the country. There are some hopeful signs in the residential market. The auto industry, on the other hand, seems unable to fully rebound. Throughout the year, sales of domestically produced automobiles were weak, down 20% from the same period in 1991. The constraints on demand have had a number of deleterious effects on the vanadium industry, including lower capacity utilization and prices. new vanadium capacity, the PMA project for example, still was expected to come on-stream in the near future, thus almost guaranteeing that capacity use is not going to rebound as the industry would like.

World demand is forecast to increase by an average of 2% per year, with total world demand reaching 45,000 tons by the year 2000. World production in 1992 was estimated to have been more than 21,000 tons, including about 1,400 tons produced in the United States from petroleum residues and spent catalysts. U.S. production from domestic ores and concentrates was not reported.

Long-term prospects for this highly cyclical industry depend on a number of factors. Producers will certainly be adversely affected by any future economic downturn. Because of restructuring and downsizing occurred in the industry during the last recession, the industry will be better able to cope with a recession than it was in the early 1980's. Traditional forces, such as the demand for motor vehicles and machinery, the level of economic activity, and the use of substitute materials, will continue to be of central importance. The strength of the U.S. dollar and its trade effects will also influence the industry's long-term future.

More than 85% of the demand for vanadium is driven by steel and

nonferrous metallurgical applications. This dependence of the vanadium industry on the demand for steel products is not likely to change in the near future. The remaining demand is driven by chemicals applications. The reader is referred to the outlook section of the Iron and Steel Annual Report for more information on the long-term outlook for the steel industry. An excellent analysis of the chemical industry is published each year in the June issue of Chemical & Engineering News.

Estimated. W Withheld to avoid disclosing company proprietary data; not included in "Total."

In addition to the countries listed, vanadium is also recovered from petroleum residues in Germany, and several other European countries, but available information is insufficient to make reliable estimates. Table includes data available through May 21, 1993.

²Production in this section is credited to the country that was the origin of the vanadiferous raw material.

³Formerly part of the U.S.S.R.

⁴All production in the U.S.S.R. from 1988-91 came from Russia.

⁵Includes production for Bophuthatswana.

⁶Data on vanadium content of vanadium slag are estimated on the basis of a reported tonnage of vanadium-bearing slag (gross weight) multiplied by an assumed grade of 14.1% vanadium.

⁷Data may not add to reported totals shown because of independent rounding of estimated detail.

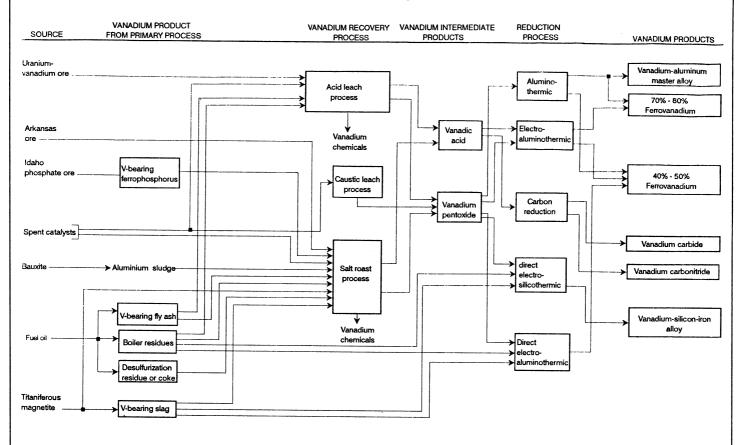

⁸Dissolved in Dec. 1991.

⁹Excludes U.S. production.

¹⁰Production in this section credited to the country where the vanadiferous product is extracted; available information is inadequate to permit crediting this output back to the country of origin of the vanadiferous raw material.

¹¹Reported figure.

FIGURE 1 GENERALIZED FLOWSHEET FOR THE PROCESSING OF VANDIFEROUS RAW MATERIALS

ZINC

By James H. Jolly

Mr. Jolly is a physical scientist (geologist) with more than 35 years of mining experience, including positions with Hecla Mining Co., Roan Selection Trust, and the U.S. Geological Survey. He has been a mineral commodity specialist for the U.S. Bureau of Mines for 20 years and the zinc specialist for the past 11 years. Domestic survey data were prepared by Gloria A. Peebles, statistical assistant. International production tables were prepared in collaboration with country specialists in the Bureau's Division of International Minerals.

Zinc is an essential element for human health and for the development and maintenance of modern society. It has been used by humankind in compounds, alloys, and metal for more than 2,000 years and is surpassed only by aluminum, copper, and iron in historical quantity used. Zinc uses range from medicines and rubber to metal products. Its main use has been to provide corrosion protection for iron and steel. Since 1982, more than one-quarter million tons of zinc had been used to manufacture U.S. pennies.

The domestic zinc industry continued to show improvement as the Nation slowly climbed out of recession. Mine and smelter output increased slightly whereas metal consumption was up 11% and was the highest since 1989. Mine production rose despite fewer operating mines in 1992. Smelter output was similarly up as smelters operated at relatively high-capacity utilization rates, owing largely to higher zinc prices during the year and increased domestic consumption. The value of unmanufactured zinc exports and scrap was about \$283 million, down from \$370 million in 1991. Imports of unmanufactured zinc and scrap totaled about \$918 million, up about \$130 million from that of 1991. The rise in value was attributed largely to increased imports of slab zinc, which accounted for 85% of the import value.

World zinc mine and smelter production declined in 1992. World stocks of both zinc concentrate and zinc metal increased sharply as the year progressed, and by yearend greatly exceeded the levels typical of most other Despite an increasingly large oversupply in 1992, zinc prices rose in the early months of the year counter to market conditions and remained at higher than expected levels through early October. Thereafter, the price fell sharply, reflecting a more realistic measure of market conditions. Higher zinc prices in 1992 were attributed in the press mainly to a rolling options-related squeeze at the London Metal Exchange (LME) believed to have been carried out by a small number of metal traders and zinc producers.

World zinc mine production was about 7 million metric tons for the third straight year while smelter output was below 7 million tons for the first time since 1986. The United States accounted for 7.7% of world mine production in 1992 and 5.8% of world smelter production. The United States was the world's largest zinc consumer and was one of the few countries to show a substantial increase in zinc consumption in 1992. U.S. consumption accounted for about 14.8% of world zinc metal consumption, up from the 13.5% of 1991.

DOMESTIC DATA COVERAGE

Domestic data for zinc were developed by the U.S. Bureau of Mines (USBM) from five separate, voluntary surveys of U.S. operations. Typical of these was the "Slab Zinc" consumption survey sent out monthly or annually, depending on consumption quantities; small consumers are canvassed annually. Of the 288 operations to which the survey was sent, 282 responded, representing an estimated 98% of the total reported slab zinc consumption shown for 1992 in tables 1 and 8. Consumption by nonrespondents was estimated using prior-year consumption adjusted for industry trends.

Reported consumption of slab zinc, however, accounted for only 79% of apparent metal consumption. The difference between reported and apparent consumption is mainly a reflection of the current response rate for the USBM's voluntary industry surveys.

ANNUAL REVIEW

Strategic Considerations

Supply.—U.S. mine and smelter production and capacity can supply only about one-half of domestic zinc requirements in either normal or emergency periods. The domestic ore reserve base is large but could not be tapped adequately until after the first year or so in an emergency situation. Domestic smelter capacity is inadequate and would limit refined zinc output. It would also severely limit the Nation's ability to produce strategic and critical zinc byproduct elements such as cadmium, germanium, and indium.

Zinc mine production in Alaska accounts for about one-half of domestic output; however, all of the Alaskan output is exported. Even if Alaskan zinc concentrates were redirected for U.S. consumption only, little domestic smelting capacity is available to process the material. U.S. mine output greatly exceeds smelter capacity, and in 1992,

resulted in the net export of about 300,000 tons of zinc in concentrate. An additional strategic factor related to Alaskan output is that more than 80% of the State's production is inaccessible for 9 months of the year because of sea ice.

Although imports constitute a large part of U.S. zinc supply, about 60% of the zinc metal, concentrate, and compound imports comes from Canada and Mexico, and, therefore, the risk of supply disruption is low. Other traditional sources of zinc supply depend on sea transport, and the risk of supply disruption is considerably higher.

Stockpile.—A stockpile of zinc for national defense purposes has been maintained by the Government for more than 50 years. In 1992, the President signed Public Law 102-484, which authorized the disposal of the entire inventory of zinc in the National Defense Stockpile (NDS). An annual disposal rate of 68,000 tons was proposed to sell off the 343,000 tons of zinc in the NDS; however, the disposal rate was subject to adjustments based on recommendations of a broad-based market impact committee. Because large stockpile disposals of zinc have occurred in the past, the following historical review of stockpile actions may provide a perspective on future disposals and their impact on defense planning.

The need for a stockpile of critical raw materials for national defense purposes became apparent during World War I (WWI) when shortages of materials upset production schedules, delayed development programs, and slowed exports of vital materials to U.S. allies. When the war broke out in Europe in 1914, the United States was the world's single largest zinc producer, accounting for about 35% of world output, and was self-sufficient in zinc. European countries produced most of the remaining world output, but with the outbreak of war, their zinc production was severely curtailed. Battlefields were near major smelting districts, and naval action disrupted concentrate imports. result, the British and French sought zinc supplies from the United States. Demand and prices soared, leading to rapid

expansion of the U.S. zinc industry. When the United States entered the war in 1917, the industry's capacity to produce zinc exceeded U.S. and export requirements to such an extent that the zinc industry began to worry about industry retrenchment after the war ended. At the end of the war, various Government programs had accumulated in excess of 10,000 short tons¹ of zinc metal and concentrate at domestic smelters; this material was disposed of in 1919 and 1920.

Although zinc was not in short supply in the United States during WWI, it was nonetheless a critical material, in use as brass in artillery and cartridge shell casings, metal liners in ammunition and explosive boxes and magazines, coatings on barbed wire entanglements and sheet metal, a component of naval and battlefield smoke, medical tape and rubber tires, and a substitute for other critical metals, including aluminum, copper, lead, and tin. In the latter part of the war, for example, lead became very scarce, resulting in its substitution by rolled zinc in coffins.

Based on the WWI experience, the U.S. Army developed a list of 42 essential materials required for military operations in 1921, but there was little interest in creating a strategic materials reserve at that time. Materials stockpiling regained impetus in the 1930's owing to deteriorating conditions in Asia and Europe. The Naval Appropriations Act of 1937 authorized the purchase of \$3.5 million of critical materials, and in 1939, the Critical Materials Stockpiling Act of 1939 (Public Law 76-117) authorized \$100 million for stockpiling of designated items, including basic industrial raw materials. outbreak of World War II (WWII) in 1939, however, prevented establishment of the stockpile because the materials to be stockpiled were needed for immediate industrial expansion and military production. The Government, through various agencies, mainly the Reconstruction Finance Corp. and its subsidiary, Metals Reserve Co., controlled the production, price, and distribution of zinc during WWII. Again,

at the start of the war, the United States was self-sufficient in zinc production. As the war expanded, the demand on the domestic industry increased. smelting sector expanded rapidly; the mining sector did not. Mine production rose in 1941 and 1942, but declined thereafter, despite efforts to stimulate output with bonuses and the release of almost 1,100 men from the Army, specifically assigned to work in domestic zinc mines. As a result of deficient domestic zinc mine output, dependence on imported foreign ores and concentrates increased as the war progressed and reached 537,000 short tons (zinc content) in 1943. That year imported ores and concentrates accounted for almost onehalf of U.S. smelter feed requirements as compared with only 5% in 1939. Thereafter through the 1960's decade, imported ores and concentrates continued to account for a substantial portion of U.S. zinc needs.

In 1940, the shortage of zinc became acute, and by the end of the year a voluntary system of supply allocation was initiated by the industry. In March 1941, zinc was declared critical, and in June, came under full allocation control of the War Production Board. Stockpiling during WWII was initially based on a 3-year war scenario, but in August 1943 the war outlook had improved to the point where objectives were reduced to a 1-year supply and in June 1945, to a 3-month's supply.

As WWII was winding down, sentiment for a national stockpile after the end of hostilities increased. The military wanted a stockpile to avoid critical materials shortages in the future, whereas materials producers anticipated adverse affects from the dumping of the Government's materials stocks, including an estimated 400,000 short tons of zinc metal and zinc concentrate, in the postwar Legislative pressure to assist domestic basic industries in adjusting to a peacetime economy aided passage of the Strategic and Critical Stock Piling Act of 1946 (Public Law 79-520) in July 1946. Wartime zinc stocks that had not been sold to domestic industries to assist conversion and reconstruction efforts were transferred or eventually smelted to metal for addition to the National Strategic Stockpile. The zinc industry in the 1946-48 period was able to maintain relatively high production rates owing to purchases for the stockpile and to the smelting of Government concentrates.

The advent of the Korean War (1950-53) resulted in continued zinc purchases for the stockpile. Zinc prices and imports increased, but even though Government allocation limits were in place, there were no serious shortages of zinc during the war. In the period 1954-60, the Government continued to accumulate zinc for the stockpile via direct purchases under the Defense Production Act (DPA) of 1950 (Public Law 81-744) and through barter agreements. Zinc additions from the DPA programs were small, but zinc metal obtained through barter of perishable surplus agricultural products totaled 324,000 short tons from 1954 through 1960. Zinc was removed from the barter list in 1960. Stockpile materials obtained under the barter programs were not placed in the national stockpile but were placed in "supplemental" stockpile and could be released only by the Congress.

The year 1960 marked the end of significant acquisitions for Government's zinc stockpiles. Thereafter, almost all zinc stockpile transactions involved sales in excess of goals. Stockpile goals or objectives often were reviewed and modified on the basis of assumptions governing military and industrial preparedness and length of a potential U.S. war emergency. Stockpile goals were generally based on 5-year and 3-year wars, but in the late 1950's, the war period was reduced to 1 year, based on the assumption that nuclear war would be short and decisive and would eliminate protracted conventional conflict. 1958, the stockpile goal for zinc was reduced from 1,250,000 short tons to 178,000 short tons and in 1963, to zero. The assessment that no stockpile of zinc was required was in part based on the assumption that North American sources supply the necessary requirements in the event of a nuclear or

conventional war. The reduction in goals essentially made 1.5 million short tons of zinc in the Nation's stockpiles available for reentry into the U.S. and world economies. In July 1964, Public Law 88-374 authorized the release of 67,500 short tons of zinc to domestic primary producers and 7,500 short tons to independent zinc-base alloyers. In April 1965, Public Law 89-9 authorized the release of 150,000 short tons of zinc to industry and 50,000 short tons for use by the Government, including the Agency for International Development, the U.S. Mint, and the Department of Defense: another 200,000 short tons of zinc was authorized for release in November 1965 (Public Law 89-322). Sales from the aforementioned public laws continued through 1971.

A new zinc stockpile goal, 560,000 short tons, was established in 1969; but despite earlier disposals, large stocks of excess zinc remained. In April 1972, Public Law 92-283 authorized the disposal of 515,000 short tons of zinc from the national stockpile for domestic consumption only. A total of 440,000 short tons was to be released through domestic primary producers and 75,000 short tons was for off-the-shelf sale. In April 1973, the zinc stockpile goal was reduced to 202,700 short tons, making available more excess zinc. In December 1973, Public Law 93-212 authorized the release of an additional 357,300 short tons of zinc, with 150,000 short tons to be sold directly to consumers and the remaining 207,300 short tons to go through participating primary producers.

All zinc sales ceased in June 1976 when a new stockpile goal, incorporating the stocks of the previous goal and unsold excess stocks, was established. In October 1976 the new stockpile goal, 1,313,000 short tons of zinc, was approved. In 1979, the Strategic and Critical Stockpile Revision Act of 1979 (Public Law 96-41) created the National Defense Stockpile (NDS) by combining the national and supplemental stockpiles. It limited the use of Stockpile materials to the national defense and prohibited Stockpile sales for economic purposes.

The last mentioned provision was added to ensure that the Stockpile could not be used as a means of controlling commodity prices as an anti-inflation mechanism or producing revenue for budgetary purposes, as both were perceived to have been important underlying factors in previous stockpile disposal legislation. In May 1980, the Stockpile contained 383,000 short tons of zinc and a new Stockpile goal of 1,425,000 short tons was established for zinc. Other than a small drop in the zinc inventory, the zinc stockpile situation of 1980 was unchanged until passage of the 1992 legislation.

During the period of Stockpile sales, the Government attempted to aid zinc producers by price stabilization payments, import quotas, tariffs, and marketing of stockpiled metal through primary producers. The Lead-Zinc Small Producers Stabilization Act of 1961 (Public Law 87-347) encouraged zinc production by authorizing prorated payments for small mine producers for the difference between 14.5 cents per pound and the monthly average price of zinc metal, if less than 14.5 cents. This program expired in 1969. Import quotas were imposed on imported concentrates and metal from 1958 through 1965. Imports were restricted to 80% of the average 1953-57 import level. Tariffs on zinc concentrates and metal operated throughout the sales period; however, the President's when economic stabilization program, effective August 1971, froze the price of zinc, additional tariffs in the form of surtaxes on imported zinc products were temporarily imposed. The surcharge was dropped in December.

Conversely, Government stockpile sales and price controls were, to some extent, viewed as detrimental to the health of the domestic zinc-producing sector. Domestic zinc smelting companies maintained their market shares during the stockpile disposal period; however, the sales and prospects of future sales discouraged domestic investments in new technology and facilities. The sales also tended to hold down zinc prices, thereby limiting industry profit that might have encouraged additional investment in the industry. Price controls held U.S. zinc prices well below world prices from August 1971 through the end of 1973; as a result. domestic smelters were adversely affected because they could not effectively compete for foreign concentrates on world markets. U.S. zinc metal production declined after 1969, even though U.S. zinc metal consumption was the highest ever in the early 1970's. In the 1971-75 period, seven smelters permanently closed for a number of reasons, including high costs. obsolescence, and environmental restrictions; however, price controls and stockpile sales undoubtedly contributed to their demise. The Government also was adversely affected by price controls and the price-depressing effect of sales in that it received less value for its metal. This was especially true during the second half of 1973 when the average LME zinc price was more than twice the U.S. controlled price and the world price about 50% higher.

In summary, during WWI the United was self-sufficient in zinc production and capable of supplying its allies with needed refined zinc products. At the start of WWII, the United States again self-sufficient in zinc production, but beginning in 1940 through the end of the war, the U.S. mining sector was not capable of supplying the greatly expanded refining sector with sufficient zinc feed material. As a consequence, the United States became 30% dependent on imported zinc concentrates during WWII, but remained essentially self-sufficient in refined zinc production.

During the Korean and Vietnam Wars, a somewhat similar situation prevailed as that in WWII in regard to zinc production but in these later wars, U.S. stockpiles contained large quantities of zinc that were available if needed. In the 1940-74 period, the U.S. zinc smelting sector, though dependent on imports for almost 40% of its concentrate supply, provided about 90% of U.S. requirements for refined zinc products.

The peak year for domestic slab zinc production was 1969; thereafter, production declined owing to the

permanent closure of 11 of 14 smelters that had operated in the United States in 1968. Two of the remaining three closed for a period of time but reopened after extensive modification. One new "greenfields" smelter opened in 1978, resulting in the four operating primary smelters at the present time. U.S. primary zinc smelter capacity dropped from 1,318,000 short tons in 1968 to 330,000 short tons in 1986, but via expansions, was up to 420,000 short tons in 1992.

Mine production followed a similar but less dramatic decline, although in the past few years the development of a large zinc mine in Alaska reversed the trend and restored U.S. mine output to 1960's levels (about 600,000 short tons per year). Unfortunately, the Alaskan mine, which accounts for about one-half of U.S. zinc mine output, presents problems from a strategic point of view. The mine is isolated, depends on sea transport for supplies and shipments, and has port facilities that are ice-bound for 9 months Presently all concentrate per vear. shipments are exported, but even if they were redirected to the United States. there is no excess domestic smelter capacity to process Alaskan material. In addition, the largest domestic primary smelters processes large amounts of secondary materials, which effectively lowers the primary processing capacity of the United States to about 330,000 short tons, about the same as the mine production of the "lower 48 States."

As a result of the decline in U.S. zinc smelter capacity, a major shift in the zinc import pattern occurred in the early 1970's. Concentrate imports fell sharply, whereas slab zinc imports rose dramatically. U.S. net import reliance on refined zinc products currently averages about 60%, the same as that of the past two decades.

The U.S. zinc industry has been in decline over the past two decades, and the Nation is more than ever dependent on foreign sources for its refined zinc supplies. It is doubtful that any new zinc smelters will be built in the United States in the next decade, owing to the difficulty of obtaining construction permits and the

long-term threat of Superfund liability. Until the early 1970's, the capacities of domestic smelters were adequate to supply most of the Nation's needs, and because there were numerous smelters. rapid expansion was possible. Present capacity is one-third the former level and is less capable of rapid expansion. Since as early as 1940, domestic mine production, though it could be expanded to a considerable extent, has been inadequate. Although domestic output has improved in the past few years, much of this new production is essentially seasonal and unavailable to domestic markets for reasons stated earlier.

Production

Mine Production.—U.S. zinc mine output was up slightly in 1992. Two closed mines reopened in 1992, whereas another that produced zinc in 1991, the Silver Butte copper-zinc-silver mine in Oregon, operated all year but produced no zinc.

The 20 leading U.S. zinc-producing mines accounted for more than 98% of production, with the 5 leading mines accounting for 66%. Alaska, for the second straight year, was the principal zinc-producing State, followed by, in order of output, Tennessee, New York, Missouri, Colorado, and Montana. The leading domestic zinc mine producers were ASARCO Incorporated, Cominco Alaska Inc., Union Zinc Co., and Zinc Corp. of America (ZCA).

The Red Dog Mine in northwestern Alaska and the Greens Creek Mine on Admiralty Island accounted for all of Alaska's zinc production in 1992. The Red Dog Mine, which began operations in late 1989, was owned by NANA Regional Corp. Inc. and leased to Cominco Alaska Inc., a subsidiary of Cominco Ltd., which owns and operates the mining and processing facilities. NANA is paid a royalty that was scheduled to increase after the capital investment plus interest was recovered by the operating company.

Despite significant improvement in zinc recovery from ore, zinc output was marginally less at the Red Dog Mine owing to the milling of slightly fewer tons of ore containing, on average, less zinc. According to the Cominco annual report, zinc recovery in 1992 was 76%, up 8% from last year, but milled ore was only 1,435,000 tons, 15,000 tons less than that in 1991. The ore grade averaged only 19.9% zinc, versus 22.5% in 1991. A total of 218,400 tons of zinc in zinc concentrate and bulk lead-zinc concentrate was produced in 1992, compared with 222,900 tons produced in the previous year. Ore reserves at yearend were 58.2 million tons averaging 18.4% zinc, 5.5% lead, and 103 grams of silver per ton. An additional 14.2 million tons of lower grade ore was classed as inferred reserves.

The Greens Creek Joint Venture, a consortium 53% owned by RTZ Ltd. through its Kennecott subsidiary, Greens Creek Mining Co., and 47% owned by minority partners Hecla Mining Co., Exalas Resources Corp., and CSX Alaska Mining Inc., milled about 400,000 tons, or 3% more ore in 1992. Although the milled ore averaged 10.8% zinc, about 9% higher in grade than that of 1991, zinc production was only 36,900 tons, or 4% less than the previous year, owing mainly to poorer zinc recovery. Three types of concentrates—zinc, lead, and bulk zinc-lead-were produced; all were exported to foreign smelters. At yearend, ore reserves were about 11.1 million tons averaging 13.2% zinc, 4.0% lead, 480 grams of silver per ton, and 4.8 grams of gold per ton.

In Tennessee, zinc was produced at seven underground mines, four by Asarco in east Tennessee and three by Union Zinc. Asarco's production at four mines was 67,900 tons of zinc in concentrate, up 900 tons from that of 1991. At yearend, ore reserves at the four mines were 5.0 million tons averaging about 3.2% zinc, down slightly from the tonnage and grade reported at the end of 1991.

Union Zinc brought its Idol Mine in east Tennessee on-stream in April at an annual production rate of about 12,000 tons of zinc in concentrate. All of the zinc concentrate was expected to be processed at the Jersey Miniere Zinc Co.

(JMZ) plant in Clarksville, TN. The mine, purchased from Kinghill Mines Inc. in December 1989, was last operated by the New Jersey Zinc Co. in 1981. Ore reserves were estimated to be about 5.5 million tons averaging about 3% zinc.

In Missouri, zinc was produced as a coproduct of lead at nine underground lead mines along the Viburnum Trend by three companies, Asarco, The Doe Run Co., and Cominco American Inc., a subsidiary of Cominco Ltd. According to Asarco's annual reports, zinc output in concentrate at the company's West Fork and Sweetwater Mines was 13,900 tons, down 300 tons from that of 1991. At yearend, ore reserves at the two mines totaled 25.6 million tons averaging 0.83 % zinc. Zinc output at the Magmont Mine, a joint venture of Cominco American and Dresser Industries Inc., fell sharply in December when the company instituted planned reductions in labor production owing to ore depletion. Surface drilling yielded no new ore extensions, and as a result, the company continued to plan for eventual ore exhaustion and shutdown in 2 or 3 years. According to the Cominco annual report, the Magmont mill processed about 0.87 million tons of ore grading 1.0% zinc, yielding 7,400 tons of zinc in 12,800 tons of concentrate in 1992. In 1991, zinc production was 1,000 tons higher. At yearend, ore reserves totaled 2.6 million tons and averaged 8.5% lead, 1.3% zinc, and 0.4% copper.

The Doe Run Co., a subsidiary of Fluor Corp., produced about 25,000 tons of zinc in about 45,000 tons of concentrate at its six lead mines and four mills in Missouri in 1992. In November, Fluor announced its decision to exit the lead business and classified Doe Run as a discontinued operation. Fluor planned to divest itself of Doe Run by the end of 1993.

In Idaho, zinc was produced at only one mine, the Lucky Friday silver-lead-zinc mine owned by Hecla Mining Co. Hecla milled 159,000 tons of ore grading 2.7% zinc during the year and produced 3,820 tons of zinc in concentrates, one-third more than that in 1991. Toward the end of the year, declining metal prices

resulted in below break-even operations; however, Hecla kept the mine in production because it was less expensive to keep it operating than to shut it down. Ore reserves fell slightly and at yearend were 405,000 tons, grading 12.8% lead, 2.8% zinc, and 514 grams of silver per ton

In Colorado, zinc was only produced as a coproduct of gold-silver operations at the Leadville Unit, managed by Asarco but jointly owned with the Resurrection Mining Co. Asarco increased zinc output in concentrate to 14,800 tons, up 1,400 up tons from that of 1991. Lead and silver output declined but gold production was up. For 1992 they totaled about 5,530 tons, 9,487 kilograms (kg) (305,000 troy ounces), and 426 kg (13,700 ounces), respectively, compared with 5,800 tons, 9,953 kg (320,000 ounces), and 414 kg (13,300 ounces) produced in 1991. At yearend, ore reserves were 640,000 tons (down 40,000 tons from yearend 1991) grading 8.10% zinc, 3.78% lead, 58 grams of silver per ton, and 2.7 grams of gold per ton.

In Montana, the Montana Tunnels Mining Co., a subsidiary of Pegasus Gold Inc., mined and milled a record 4.15 million tons of ore at its Montana Tunnels Mine in 1992; concentrates containing 17,600 tons of zinc, 6,500 tons of lead, 41,368 kg (1.33 million ounces) of silver, and 2,323 kg (74,700 ounces) of gold were produced. Zinc recovery was 90% in 1992. At yearend, proven and probable reserves were up 7.2 million tons to 34.7 tons grading 0.62% zinc, 0.22% lead, 10.6 grams of silver, and 0.7 gram of gold per ton. The new reserves delineated in 1992 extended the expected mining life of Montana Tunnels to 8.4 years, up from 7 years projected 1 year earlier.

In September, Equinox Resources Ltd. reopened its Van Stone zinc-lead mine in Washington. The mine had been placed on care and maintenance in November 1991 after having only opened in April of that same year. At capacity, the operation was expected to produce 15,000 tons of zinc and 2,000 tons of lead in concentrate annually. Remaining ore reserves were estimated to total 2.5

million tons grading 5.7% zinc and 1.1% lead.

Minnova Inc. completed an underground exploration program at the Pend Oreille lead-zinc mine near Metaline Falls, WA, that resulted in identifying 3.4 million tons of geologic ore reserves grading 10.7% zinc and 1.8% lead. Minnova exercised an option to purchase a substantial interest in the mine's owner, Resource Finance Co., before the end of the year and planned a final feasibility study that could lead to a mine startup date before the end of 1994. The Pend Oreille Mine last operated in 1977.

Permitting difficulties caused Noranda Ltd. to abandon all activities at the Lynne zinc-copper deposit in Wisconsin. Wetlands and bogs over parts of the deposit were classified by the State as lakes, under which State law forbids mining. The Lynne deposit reportedly contained 6 million tons of ore averaging 8.5% zinc, 1.3% lead, and 0.6% copper and had been expected to yield 50,000 tons of zinc annually.

Exxon Minerals Co. and Phelps Dodge Mining Co. reached an agreement to conduct a joint evaluation of the Crandon zinc-copper-lead deposit in Wisconsin. Exxon had previously identified 66 million tons of ore averaging 5.6% zinc, 0.5% lead, and 1.1% copper in the deposit before suspending both permitting and development activities in 1986 based mainly on unfavorable economic forecasts for zinc and copper. A decision by the two companies as to whether or not to proceed with joint-venture development of the property was expected in early 1993.

Smelter and Refinery Production.—
Refined metal production was up slightly from that of 1991 and was the highest since 1981. Three companies, ZCA, JMZ, and Big River Zinc Co., operated four primary zinc refineries in 1992. Secondary zinc metal was produced at 12 secondary plants from waste and scrap materials; however, the largest producer of secondary zinc metal was ZCA at its primary electrothermic smelter at Monaca, PA. A substantial part of the

plant's secondary feed was crude zinc calcine recovered from steelmaking electric arc furnace (EAF) dust mainly by a sister company, Horsehead Resource Development Co. (HRD). The largest producers of zinc metal at secondary plants were Huron Valley Steel Corp., Interamerican Zinc Co., and Gulf Metals Corp.

ZCA continued to upgrade the zinc production capacity of its Monaca, PA, smelter. Since 1988, about 45,000 tons had been added, raising plant capacity to about 146,000 tons in 1992. Most of the added capacity, however, was dedicated to the processing of EAF zinc calcine. The capacities of the other primaries were unchanged, as were the capacities of the secondaries with metalmaking facilities.

ZCA and Mitsui Mining and Smelting Co. formed a joint company, Mitsui/ZCA Zinc Powders Co., to produce high-quality zinc powder for use in mercury-free, alkaline batteries. The joint company was building a \$3 million, 2,700-ton-per-year plant at ZCA's Monaca smelter. Production was scheduled to start in mid-1993.

Zinc Oxide.—Domestic Americanand French-process zinc oxide was produced entirely from zinc metal and scrap by eight companies in 1992. All but one company, Eagle Zinc Co. of Hillsboro, IL, produced French-process zinc oxide. Some impure oxide produced at secondary plants was sold directly for agricultural purposes. The principal zinc oxide producers in 1991 were Asarco, Eagle Zinc, North American Oxide Inc., and ZCA.

ZCA closed its 40,000-ton-per-year, zinc-oxide-producing facilities at Palmerton, PA, in late 1992, but, as the year progressed, increased zinc oxide production capacity by 27,000 tons at its Monaca plant to maintain company production levels.

In June, Midwest Zinc Corp., Chicago, IL, purchased the closed Memphis, TN, zinc oxide plant of PASCO Zinc products for \$1.2 million. PASCO, a subsidiary of Pigment and Chemical Inc., had permanently closed the 18,000-ton-per-year, French-process

zinc oxide plant in July 1991 owing to weak markets and financial difficulties. Midwest rehabilitated the facilities, and, in September, restarted the plant at a reduced rate.

Byproduct Sulfur.—Production of sulfur in byproduct sulfuric acid at primary zinc plants was 148,400 tons, about 12,000 tons higher than production in 1991. Acid production at zinc plants in 1992 was valued at \$15.1 million.

Consumption and Uses

Zinc is found in a great many manufactured products, but its role is not obvious to the public because it tends to lose its identity in the products. Zinccontaining products were used extensively in 1992 for construction, transportation, electrical, machinery, and chemical purposes. Zinc-coated steel sheet, structural shapes, fencing, storage tanks, fasteners, nails, and wire rope were widely used in all types of construction, including transmission and radar towers, industrial plants, culverts, roads, bridges. and airfields. Zinc sacrificial anodes were used to protect ship hulls, offshore drilling rigs, and submerged and buried steelwork, tanks, and pipes. Brass was used as shell casings in ammunition and in tubes, valves, motors, refrigeration equipment, heat exchangers. communication units, and electronic devices. Zinc die-cast parts, such as handles, grilles, bezels, brackets, locks, hinges, gauges, pumps, mounts, and housings, were used extensively in vehicles, machinery, business machines, appliances, household hardware, scientific equipment, and electronic equipment. Zinc dust was used in primers and paints; in alkaline dry cell batteries; in the sherardizing process to protectively coat nuts, bolts, and small parts; for the precipitation of noble metals from solution; and in the zinc industry for the removal of impurities, such as copper, cadmium, and lead, before electrolysis. The metal casings of zinc-carbon dry cell batteries were zinc. In 1992, about 22,000 tons of Special High Grade (SHG) zinc was used by the U.S. Mint to produce 9.1 billion pennies. Zinc compounds were used in corrosion-inhibiting paint primers, chemical catalysts, welding and soldering fluxes, fungicides and pharmaceuticals, paints, rubber, phosphors for cathode tubes and radar scopes, ceramics, and additives to lubricating oils and greases. Zinc ferrites were used in electrical devices in transformers, coils, amplifiers, motors, and tuners, and in electronic devices in radio, television, and computers.

Domestic consumption of slab zinc rose about 100,000 tons to slightly more than 1.03 million tons in 1992. Galvanizing and electrogalvanizing, mainly for sheet and strip, continued to be the principal use of zinc metal, consuming an estimated 50%, followed by zinc-base die-cast alloys, 21%; brass alloys, 14%; and other uses, 15%. SHG accounted for about 55% of the reported slab zinc consumed, followed by Prime Western (PW), 25%; High-Grade (HG), 12%; and other grades, 8%.

Overall, the construction sector of the economy was the largest consumer of zinc, accounting for an estimated 43%, followed by transportation, 20%; machinery, 12%; electrical, 12%; and other, 13%. Zinc metal accounted for about three-fourths of the total zinc in end-use products and zinc chemicals about one-fourth in 1992.

According to the American Iron and Steel Institute, reported shipments of domestically produced galvanized sheet and strip totaled 9.6 million tons, up 1.4 million tons from shipments in 1991. Trends in monthly shipments tended to follow the general trends in the economy, down in the first and fourth quarters of the year and generally up in the second and third quarters. Of the total shipments, electrogalvanized accounted for 22% of the tonnage compared with 23% in 1991. distribution of total shipments by industry sector in 1992 was as follows: automotive, 40%; service centers, 26%; contractors and construction, 20%; and other, including exports, 14%. Exports of galvanized sheet and strip totaled 275,000 tons versus imports of 1.38 million tons.

According to the Bureau of Census, zinc-base alloy die and foundry casting shipments totaled about 173,000 tons, up from 172,000 tons reported in 1991. Zinc die-cast shipments by weight were estimated to have been distributed equally between automotive, hardware, and other uses.

Zinc consumption in the production of copper-base alloy of brass mills, ingotmakers, and foundries was up about 30,000 tons from that of 1991, according to the Copper Development Association Inc. (CDA). The brass and bronze industries were estimated to have consumed about 306,000 tons of zinc, of which about one-half was refined zinc metal and one-half was contained in brass and bronze scrap metal. According to CDA data, brass mills accounted for 85% of the total zinc consumed as metal and scrap in making copper-base alloys.

The zinc content in typical U.S. manufactured automobiles was estimated to average about 17.2 kg in 1992, down about 0.9 kg from that in 1991. Diecastings accounted for about 7.7 kg corrosion protection via galvanizing and coatings, 8.2 kg and other, including rubber, brass, and zinc solder, 1.4 kg.

The apparent domestic consumption of zinc oxide was about 165,000 tons, up from 150,000 tons in 1991, but about the same as that of 1990. Domestic production was up, whereas exports were down. Nonetheless, U.S. producers have increased their share of the U.S. zinc oxide market over the past 4 years, mainly at the expense of imports. Because the USBM information on zinc oxide consumption by industry sector reflects only shipments as reported by the domestic producers, the consumption data listed in table 11 account for only about 80% of the apparent market. Of the reported amounts, the rubber and chemical industries continued to be the principal consumers.

A historical study of zinc production and consumption in the United States for the period 1850-1990 was published in April.² The study showed that the United States was the world's leading producer and consumer of zinc during the 1850-1990 period. During that period an

estimated 41 million tons of recoverable zinc came from U.S. ores, 59 million tons of refined zinc was produced at U.S. zinc plants, and about 73 million tons of zinc entered the U.S. economy in the form of end products. Potential losses of zinc into the environment from U.S. mining, processing, consumption, use, and disposal were estimated to total 63 million tons. About 23 million tons or about 8.5% of total zinc placed in use in the world since 1800 was still in use in the United States at the end of 1990.

Stocks

Metal stocks held by domestic producers, consumers, and merchants continued to decline in 1992 and were at their lowest levels since the early years of WW II. In recent years, these domestic stock levels have tended to be in the 4- to 6-week consumption range but fell into the 3-week range in 1992, reflecting the continuing general trend by consumers and merchants toward lower inventories and just-in-time delivery. Metal stocks in Western countries (exclusive of Eastern countries defined as all countries in the Communist bloc or still former Communist countries) rose sharply as the According to the year progressed. International Lead and Zinc Study Group (ILZSG), stocks in Western countries were 1,129,000 tons at the end of 1992, up 350,000 tons from those at the end of Virtually all of the additional stocks were placed in LME warehouses, as industrial stocks tended to remain at 1991 levels. ILZSG data indicated that 80% of metal stock rise was attributable to increased imports from Eastern countries. Inventories of zinc in concentrate at domestic primary smelters totaled 41,500 tons at yearend compared with only 29,000 tons at the end of 1991, according to the American Bureau of Metal Statistics Inc.

Markets and Prices

In 1991, all U.S. zinc producers switched to an LME price basis. For domestic metal, sellers generally charged a premium of 2 to 5 cents per pound over

ZINC-1992 1473

the LME spot price, or some average of LME prices, to take into account delivery and/or importing costs such as tariff, shipping, and insurance. In this report, the domestic zinc price in 1992 is that published by Metals Week (MW), which based its price on the daily LME spot price for SHG plus a premium that reflected market conditions.

In 1992, the LME established six new warehouse locations in the United States where various LME registered metals, including zinc, could be delivered or picked up. Together, with the Baltimore facility that was established in 1991, the new warehouses at Chicago, IL; Detroit, MI; Long Beach, CA; Louisville, KY; New Haven, CT; and Toledo, OH, were the seven originally planned for establishment in the United States.

The domestic zinc metal price began the year in a declining trend, which reached a daily low of about 49 cents per pound in mid-January. February was lackluster with prices not responding to some industry cutbacks. The daily price per pound at the end of February fell below 48 cents. Prices rose in March despite increases in world and LME zinc metal stocks. In April, prices continued to rise amid stock increases and complaints that the LME zinc cash to 3month contract was being manipulated by a small number of traders and producers who had secured large options positions. In effect, this created supply tightness by withholding metal from the market. By rolling over the options when they expired, prices were kept at artificially high levels (62 to 65 cents per pound) until early October when, in the face of weak world demand and a continuous and relentless rise in world stocks, options support collapsed. Prices fell rapidly from about 65 cents to the 50 cent level in November and December.

An updated version of the USBM historical price series for metals, including zinc, was published.³ Interestingly, the estimated average price of zinc for 1992 in 1987 constant dollars, about 52 cents per pound, was virtually the same as the historic average constant dollar price, 52.16 cents, for the 1920-89 period. A similar comparison showed the

yearend constant dollar price for zinc to be well below the historic average.

Foreign Trade

The value of U.S. exports of basic zinc materials, including waste and scrap, was about \$292 million, down from \$316 million in 1991 despite significantly higher zinc prices in 1992. Export tonnages and value of zinc concentrate and zinc scrap were down in 1992. They accounted for 73% and 16%, respectively, of the total export value for the year.

General imports of zinc concentrate relative to imports for consumption continued to be high. The large disparity was due almost entirely to shipments of Canadian concentrate through Skagway, AK, to world markets. Imports of slab zinc were up about 100,000 tons to meet the increased domestic industrial requirements of 1992. The value of basic zinc imports was about \$922 million, up from \$741 million in 1991. Slab zinc accounted for 85% of the total value of imports.

Three categories of zinc metal were included in the draft proposal for tariff elimination in the North American Free Trade Agreement between Canada, Mexico, and the United States. Tariffs on slab zinc and zinc alloys containing greater than 99.99% zinc would be completely eliminated in Canada and the United States in 1994 and in Mexico in 1999. Tariffs on metal containing less than 99.99% zinc would be phased out by the year 2004 in the United States and by 1999 in Mexico; Canada had no tariff in this category.

In August, the U.S. Senate ratified the Basel Convention, which places restrictions on the movements of hazardous waste between countries and forbids the movements of hazardous waste between countries that have and countries that have not ratified the convention. However, before the United States can officially initiate treaty requirements, the U.S. Congress must pass implementing legislation, which as of yearend, was not in place.

Although the Basel Convention became

a reality for signatory countries in May. the United States and most other members of the Organization of Economic Cooperation and Development (OECD) did not become signatories in 1992. However, the OECD members agreed to abide by a set of controls governing the transboundary movement of recyclable wastes until Basel approval was finalized by its members. OECD wastes were classified into three tiers—green for no restrictions other than acceptable practice, amber predesignation of responsibility and proper legal documentation, and red for no relief from Basel restrictions. Most zinc wastes and scrap were classified in the green tier; these include galvanizer's top and bottom dross, zinc skimmings, die-cast dross, and zinc waste and scrap metal and allovs. The amber tier included zinc ash and residues and zinc slags containing up to 18% zinc. No specific zinc wastes or scrap were included in the red tier. Recyclable waste "contaminated" by material from a more hazardous tier may have to be documented and handled as though it were classed in the tier of the contaminant.

World Review

Despite a general slowing in the world economy, both mine and smelter production in the Western countries rose to record levels. Consumption in Western countries, on the other hand, was only 5.35 million tons, 50,000 tons less than in 1991, according to ILZSG. In Eastern countries, mine output, smelter output, and consumption all declined; however, consumption fell at a faster rate, resulting in huge surpluses in metal output. Net exports of zinc metal to the West from Eastern countries totaled about 280,000 tons, resulting in a huge buildup in Western countries' stocks. Western stocks totaled about 1 million tons at yearend, up about 360,000 tons from the end of 1991; virtually all of the increase was added to LME stocks. Despite poor market fundamentals, zinc prices were considerably higher than expected for most of the year, owing to options-related manipulation of the LME zinc contract. Only in the last quarter of the year did prices fall in reaction to market realities.

Higher mine output, principally in Brazil, Canada, India, and Mexico, offset substantially lower output in Germany, Peru, Spain, Yugoslavia, and several Eastern countries. Germany, Saudi Arabia, and the United Kingdom were nonproducers in 1992.

World metal production was less than that in 1991 but production in Western countries rose slightly to a record 5.62 million tons. Countries with significant production increases, all related to new smelter capacity, were Brazil, Germany, India, Mexico, and Spain. Significant declines in output occurred in Austria because the Gailitz zinc plant closed, Belgium because of the Overpelt smelter closure, Mexico because of technical problems, and Yugoslavia because of the country's civil turomil. Metal production in countries of the former U.S.S.R. declined below 1991 levels despite the importation of concentrate from Western countries. According to ILZSG, these countries imported about 110,000 tons of zinc in concentrate in 1992; some was imported under tolling arrangements.

According to ILZSG, zinc metal consumption in the Western countries was down from the record high of 1991, but nonetheless was the second highest ever. Consumption in Eastern countries was estimated to have fallen for the fourth straight year. The United States recorded only significant increase consumption worldwide, but this was not enough to offset declines in France, Japan, and minor decreases in many other countries. The world's leading metalconsuming nations, in order of estimated consumption, were the United Sates, Japan, Russia, and Germany. Based on ILZSG data, the principal uses of zinc metal in 1992 in the major Western economies were estimated to be as follows: galvanizing, 49%; brass and bronze, 19%; zinc-based alloys, 14%; chemicals, 7%; zinc semimanufactures, 7%; and other, 4%.

On a geographic basis, the Americas accounted for about 44% of world mine output. Europe, including several

countries of the former U.S.S.R., accounted for 16%; Asia and Australia accounted for 23% and 14%, respectively. Canada remained the world's largest producer. Australia, Canada, China, Peru, and the United States together accounted for 58% of the world's zinc mine production; 47 other countries accounted for the remaining 42%.

World exports of zinc concentrates totaled about 3.3 million tons, of which an estimated 90% was from the Western countries. Australia, Canada, Peru, and the United States accounted for 75% of the Western concentrate exports. Canada, Japan, the Republic of Korea, and the Western European countries were the largest importers.

World zinc mine capacity, based on the capacities of operating mines and temporarily closed mines expected to reopen, was about 8.5 million tons at the end of 1992, up about 150,000 tons from 1 year earlier. Seven mines closed, eight mines opened, and seven mines increased capacity in 1992.

The Bismark Mine in Mexico and the Hajar Mine in Morocco, each with zinc production capacities exceeding 50,000 tons, were the largest new mines to open. Two German mines, Hilfe Gottes and Meggan, with a combined capacity of 64,000 tons, were the largest in capacity terms to close permanently.

World smelter capacity totaled about 8.4 million tons at yearend, about the same as last year. Four smelters completed expansions in 1992, adding about 120,000 tons of new zinc capacity. This gain was negated by the closure of the 120,000-ton-per-year Overpelt smelter in Belgium.

OUTLOOK

U.S. demand for zinc is forecast to rise slowly, increasing from slightly more than 1.03 million tons in 1992 to about 1.2 million tons by the year 2000. No major shifts in domestic zinc use are foreseen, although some present uses may yield further to substitution. Near the end of the decade, zinc-air and other zinc battery systems may become important

for electric vehicle propulsion or for load-leveling and power backup systems.

Although the United States has an adequate zinc resource base, imports are expected to continue to account for more than one-half of U.S. zinc supply in the next decade. Mine output is anticipated to remain at historic high levels in the 1990's, but smelter capacity is expected to rise only modestly. No new primary zinc smelters are likely to be built in the United States during the 1990's owing to delavs and economic permitting indecision caused by environmental regulations and the long-term liability threat posed by Superfund legislation. The United States is expected to continue to be a major world exporter of zinc concentrates, and, at the same time, to remain the world's largest importer of refined zinc metal.

Secondary zinc recovery from waste and scrap is anticipated to be a strong growth sector for the zinc industry. Domestic secondary zinc production could increase substantially in the next decade and constitute the source of 35% to 40% of total U.S. zinc metal and compounds consumed annually by the year 2000. Increased secondary recovery is expected to be driven by public policies related to waste and scrap recycling, environment, and public health. Extensive use of zinc in electric vehicle batteries could increase the percentage secondary zinc used annually to more than 50% after the year 2000.

ZIRCONIUM AND HAFNIUM

By Joseph M. Gambogi

Mr. Gambogi, a physical scientist with 10 years of Government and industry experience, has been a commodity specialist since 1988. Domestic survey data were prepared by the Section of Nonferrous Metals Data. World production data are provided by country specialists in the Division of International Minerals.

Zirconium and hafnium are relatively abundant in the Earth's crust; however, zircon (zirconium silicate) is the only naturally occurring mineral of commercial significance. Zircon is a byproduct of the mining and processing of heavy mineral sands for the titanium minerals rutile and ilmenite. The major end uses of zircon are refractories, foundry sands (including investment casting), and ceramic opacification. Zirconium and hafnium metal are both contained in zircon at a ratio of about 50:1. Zirconium-clad fuel rods and hafnium control rods make up the core of Commercial-grade nuclear reactors. zirconium, unlike nuclear grade, contains hafnium and is used in the chemical process industries because of its excellent corrosion resistance.

DOMESTIC DATA COVERAGE

Data in this report are collected from various sources. U.S. mine production of zircon sand is obtained by directly surveying the three producing operations, all of which responded. By collecting zircon consumption data from specific industries that consume it, information regarding the production of downstream products can be obtained. Examples include oxide. metal, chemicals, refractories, abrasives, flour, and frits. However, owing to a lack of participation from larger industries (e.g., refractories), it is difficult to publish reliable consumption figures, thus an estimate is used instead. In smaller industries where there may be only a small set of companies within the survey population representing an entire end use (e.g., abrasives, metal, chemicals), the data are not available for company proprietary reasons. It is for these reasons that only estimated consumption numbers can be used for industry groupings. (See table 2.)

BACKGROUND

Definition, Grades, and Specifications

Zirconium and hafnium are chemically similar elements with atomic numbers 40 and 72, respectively. Both elements are classified in the periodic table as members of Group 4b and have only one oxidation state, +4, and have similar ionic radii. Owing to these similar properties, zirconium and hafnium are usually found together in nature.

Zircon purity is commonly measured by the combined zirconium dioxide (zirconia)-hafnium dioxide (hafnia) content. Hafnium occurs in zircon in a typical ratio of 1 part hafnium to 50 parts zirconium. Commercially available zircon typically grades 64.5% to 66% combined zirconia-hafnia. Zircon grades are similar on a worldwide basis, but no standard requirement exists. Standardgrade zircon has a typical analysis of 65% minimum zirconium dioxidehafnium dioxide, 0.25% maximum titanium dioxide, and 0.12% maximum iron oxide. Intermediate-grade zircon has a typical analysis of 65.5% zirconium dioxide-hafnium dioxide. 0.03% maximum titanium dioxide, and 0.1% maximum iron oxide. Premium-grade zircon has a typical analysis of 66% minimum zirconium dioxide-hafnium dioxide. 0.1% maximum titanium dioxide, and 0.05% maximum iron oxide.

Zirconium metal for the chemical process industry is available in three American Society for Testing and Materials (ASTM)-approved grades: R60702 for unalloyed zirconium, R60704 for the tin-iron alloy, and R60705 for the niobium alloy. Zirconium alloys for the nuclear industry, the compositions of which are specified, are designated as Zircaloy-2, Zircaloy-4, or Zr-2.5 Cb.

Hafnium metal as produced by the Kroll process is called hafnium sponge or "Kroll-process" sponge or metal. After refining by the iodide process, the metal is called crystal bar.

Industry Structure

Zirconium ore minerals are sold by mine producers directly to processors, consumers, and commodity brokers. Primary ore concentrate of zircon and baddeleyite may be used in certain industrial uses with little or no processing, but most applications require additional processing. Processors grind the concentrates to specification for certain applications or convert zircon and baddeleyite to refined products such as zirconium metal, hafnium metal, alloys, high-purity zirconia, and other compounds. Extensive processing is required to produce ultrapurity powders and nuclear-grade metals. Processors producing oxide and metal are often partially integrated. Fabricated and semifabricated products are marketed directly to manufacturers.

Geology-Resources

Zircon is a common accessory mineral in igneous rocks. It is frequently found associated with silicic rocks, including granite, granodiorite, syenite, monzonite, and nepheline syenite. Zircon is also found in pegmatites, crystalline limestone, and the metamorphic rocks gneiss and schist. From an economic viewpoint, sedimentary placer deposits are the most significant.

Placer deposits originate when chemical and mechanical weathering liberates minerals from the source rock. This is followed by transport of the minerals to the sea by water, wind, and gravity. Upon reaching the sea, deposits of economic value form primarily by hydraulic sorting. Heavy minerals, including zircon, are concentrated by traine currents and wave action. Mechanical sorting by the sea and wind further sorts the grains to produce well-sorted beach deposits.

Technology

Economic concentrations of zircon are found in association with other heavy minerals such as ilmenite, rutile, and monazite. Heavy mineral sand deposits are usually mined by floating cutterhead or bucketwheel dredges that handle up to 2,800 mt/h of sand. Sand recovered by these techniques is sent to a wet mill and treated by wet-gravity methods, using spirals, cones, sluices, or jigs to produce a mixed heavy mineral concentrate containing zircon. The mixed concentrate typically contains other economic minerals such as the titanium minerals. ilmenite, rutile, and leucoxene, and often smaller amounts of the rare-earth mineral monazite.

The mixed heavy mineral concentrate is scrubbed, dried, and screened, and the individual heavy minerals are separated by electrostatic, electromagnetic, magnetic, and gravity processes. Zircon, in contrast to ilmenite, rutile, and many other heavy minerals, is nonconductive and can be separated along with monazite by electrostatic methods. Monazite, which is slightly magnetic and may be slightly higher in specific gravity, can be separated from zircon by electromagnets or by additional gravity methods.

To obtain premium-grade zircon, the zircon concentrate from the electrostatic-electromagnetic circuit is again subjected to gravity concentration to reduce the content of aluminum- and titanium-

bearing minerals. Certain zircon products are leached in an acidic solution to remove iron oxide and other grain coatings.

Zircon used in foundry and certain refractory applications is graded and sized and, in many cases, ground or milled to produce zircon flour. Foundry applications generally use zircon sand and flour mixtures, which may be treated with resin coatings and binders.

Zirconia is produced directly from zircon by either plasma fusion or electric arc techniques. The plasma method for zirconia production employs heating a finely divided zircon above its dissociation temperature to form small zirconia crystallites and glassy amorphous silica. The hot zirconia and silica particles are rapidly quenched, and the silica is removed by leaching with sodium hydroxide, leaving insoluble zirconia crystallites.

In electric arc production, zircon is heated to temperatures of approximately 2,500° C, producing dissociation. The silicon component is vaporized and recovered as fumed silica, leaving a residual melt that is air quenched to form zirconia. A more complex electric arc method melts a mixture of limestone and zircon to form calcium zirconate and tricalcium silicate clinker. Cooling of the mixture disintegrates it into a very fine powder composed of tricalcium silicate and lime and a coarser fraction of calcium zirconate crystals. The calcium zirconate is separated from the other constituents by either air classification or The acid-soluble calcium zirconate crystals are treated with acids or other reagents, forming zirconia or zirconium salts.

Other compounds of zirconium, such as the hydrous or carbonated oxide, acetate, sulfate, fluoride, chloride, and organic complexes, are usually prepared from zirconia or its salts by chemical reactions.

The deBoer-van Arkel iodide process, first described in 1925, is essentially a refining process and was commercially adopted in 1945 as the first practical method for producing ductile zirconium metal. Zirconium metal is reacted with

iodine vapor at 200° C to form zirconium tetraiodide, leaving most impurities except hafnium in a solid state. The gaseous halide diffuses to a heated filament where, at 1,300° C, the reaction is reversed, depositing very high-purity elemental zirconium on the filament and regenerating iodine vapor for reuse. The process yields high-purity metal but is expensive to operate. Industrial-scale plants for producing zirconium metal are based on the Kroll process in which zirconium tetrachloride is reduced with molten magnesium in an inert The resulting mixture of atmosphere. zirconium metal sponge and magnesium chloride is vacuum-distilled to remove the magnesium chloride. The zirconium is crushed, sized, and compacted to form a consumable electrode. The electrode is arc melted in an inert atmosphere to give a first-melt ingot. The first-melt ingot is then used as a consumable electrode to produce a metallurgically homogeneous second-melt ingot, which is machined to give a clean surface and readied for fabrication.

Zirconium tetrachloride is produced by chlorinating zircon sand in a fluidized bed containing carbon at a temperature of about 1,150° C.

Byproducts and Coproducts

Zircon is mined from deposits with a heavy mineral grade between 2% and 20%. The associated economic heavy minerals are ilmenite, leucoxene, rutile, monazite, and the tin minerals cassiterite and stannite. Its classification as a byproduct or a coproduct depends on the fraction of zircon in relation to the other If zircon and the titanium minerals are expected to account for the majority of the revenue, it is considered a coproduct. If minerals other than zircon provide the carrying costs of the operation, then zircon is considered a byproduct. Small quantities of baddelevite are recovered as a byproduct of copper, phosphate, and vermiculite mining in the Republic of South Africa.

ANNUAL REVIEW

Issues

Processing of some mineral sands by certain methods results the concentration of radioactive elements in the waste or byproduct streams. Monazite and xenotime, both rare-earth, thorium phosphates, are usually the minerals of consequence because 100% separation of a heavy minerals deposit is impossible to obtain within economic considerations. Monazite inclusions within the zircon grains and/or ionic substitution of uranium, thorium, radium, and/or actinium for the zirconium and/or hafnium within the mineral lattice result in some radioactive contamination. Monazite processing to obtain rare-earth elements results in relatively large production of a byproduct, thorium nitrate. Because demand for thorium is greater than that for rare earths, excess thorium has been placed in low-level storage sites such as those in Barnwell, SC, and Hanford, WA. Processing of zircon and the titanium minerals is much less of a problem because of lower concentrations in the bulk product. However, some concentration does occur in the zirconium chemical and metal industries. These industries have been adhering to Federal code in the handling, storage, and disposal of the byproduct "source material." Generally, if the combined weight of uranium and thorium exceeds 0.05%, the materials are considered to be sources for these radioactive elements. **Domestic** requirements for licensing material, definitions, exemptions, and other pertinent information is found in the Code of Federal Regulations, Energy, 10, Part 40 (10CFR40).

Japan enacted strict importation and industrial guidelines on June 6, 1991, as a result of the July 1990 finding of radiation levels originating from titanium dioxide pigment plant wastes dumped in the Okayama Prefecture. Basically the policy addresses the following key areas: protection of residential areas near plants and dump sites, air quality, strict containment of ore and processing

wastes, and limits on the allowable dose rates exhibited by ores.

Corrective measures to clean up two areas where the zirconium industry was born, in Albany, OR, have been completed after several years of debate at local, State, and Federal levels. The Bureau of Mines' original Northwest Electrodevelopment Laboratory (now the Albany Research Center), where the Kroll Process to produce zirconium sponge was invented, and Teledyne Wah Chang Albany have both completed their individual efforts.

Production

Domestic production and consumption of zircon concentrates increased moderately in 1992 but were significantly lower than levels achieved in the late 1980's. Milled zircon production increased 2% over that of 1992 while zirconium oxide production decreased 11%

U.S. mine producers of zircon in 1992 were RGC (USA) Mineral Sands, Inc. and E.I. du Pont de Nemours & Co. Both producers mined heavy mineral sands deposits in Florida. Nord Ilmenite produced zircon concentrate from a previously mined mineral sands deposit in New Jersey.

Countless other end products also were produced from zircon. High-volume production included refractory bricks and alumina-zirconia abrasives, foundry sands and investment castings, milled and micronized zircon, zirconium chemicals, and zirconia. Zirconium chemicals and zirconia are further processed to produce many other products used in a wide range of applications. Examples of high-value production are cubic zirconia. technical zirconia ceramics, superalloy castings, zirconia textile refractories, and specialty chemicals.

Markets and Prices

In 1992, demand for zircon products increased moderately and reductions in stock levels over the previous 2 years assisted in improving market conditions

for zircon producers. Apparent consumption of zircon concentrates increased 8% compared with that of 1991. Published prices for zircon and zircon oxide-related products varied considerably by product type.

Published prices for zirconium and hafnium products were unchanged while the domestic list price for standard and premium-grade zircon decreased 20% compared with that of 1991. Prices for domestic zircon and aluminum silicates increased 32%, and imported grades of zircon sand increased in the range of 42% to 72%. The published price for imported baddeleyite concentrate increased in the range of 13% to 19% over that of 1992. The changes in prices for zircon oxides were mixed. Prices for commercial-grade powder increased 7% while electronic-grade prices were unchanged. Meanwhile, insulating grades of zirconium oxides decreased 10% to 20%.

World Review

Australia.—Production of zircon by Australian producers was estimated to have increased 20% compared with that of 1991. However, production was significantly less than the record level achieved during 1989. Inventory levels also were also reported to have declined.

Cable Sands (WA) Pty. Ltd. announced plans to proceed with its Jangardup mineral sands project in Western Australia. When completed, the project was expected to produce 200,000 tons per year of ilmenite, 8,000 tons per year of leucoxene, and 8,000 tons per year of zircon. Construction was set to begin in the first quarter of 1993, and initial production was scheduled for April 1994.

ISK Mineral Pty. Ltd. exhausted its Waroona deposit and closed its mining operations south of Perth, Western Australia. After postponing plans to develop its Dardanup mineral sands deposit, ISK scheduled to close its Picton separation plant in 1993. Before the closure, Waroona's capacity was estimated to be 105,000 tons per year of ilmenite, 6,500 tons per year of zircon,

and 2,000 tons per year of leucoxene.1

Owing to poor market conditions, ICI Australia Ltd. closed its zirconia ceramic facility at Rockingham, Western Australia. Although the facility was opened in 1987 to produce electronic-grade zirconia powders, it was reported to be operating at only 25% of its 400-ton-per-year capacity. ICI continued to operate production facilities in North America.²

CRA Ltd.'s plans for the development of the Wimmera (WIM) mineral sands project near Horsham, Victoria, were significantly curtailed. Although promising mineral recoveries had been achieved during a pilot plant investigation, CRA concluded the project was not economically viable. The WIM deposit was reported to have a measured resource of 25 million tons, and the project was expected to annually produce 290,000 tons of heavy mineral concentrates, including 130,00 tons of zircon. The company planned to continue technical development of processing alternatives.

Newcrest Mining Ltd. closed its Woodburn mineral sands mining and processing operations in New South Wales. Although the operation was capable of processing about 24,000 tons per year of concentrate, actual production rates were reported to be significantly less.³

Canada.—In 1992, Tiomin Resources Inc. was in the process of evaluating the development of a deposit reported to have resources exceeding 96 million tons of heavy minerals. Tiomin Resources Inc. held mineral exploration rights to the 208-square-meter property at Natashquan, Ouebec.

South Africa, Republic of.—The Anglo American Corp. announced plans to proceed with the development of its Namakwa heavy mineral sands project located in the northwestern cape region of South Africa. When completed, the project is expected to initially produce 195,000 tons annually of high TiO₂ slag. In addition to the recovery of ilmenite used for smelting to high TiO₂ slag, the

project is expected to recover an estimated 140,000 tons of zircon and 38,000 tons of rutile. Reserves are reported to be 500 million tons, and production is scheduled to begin in 1994.⁴

Richards Bay Minerals sought approval of its St. Lucia mineral sands project in South Africa. Reserves at St. Lucia are estimated at 9.74 million tons of ilmenite, 0.94 million tons of rutile, and 1.66 million tons of zircon.⁵

Vietnam.—Westralian Sand Ltd. was reported to be investing in the modernization and possible expansion of a heavy mineral operation in Ha Tinh, Vietnam. Westralian Sand's investment represented a 60% interest in the operation. The remaining interest was held by the Provincial government and the Vietnamese Ministry of Heavy Industry.

Current Research

Sierra Rutile Ltd. (SRL) developed a froth flotation process to separate fine size zircon, rutile, and ilmenite from heavy mineral dry mill tailings. The froth flotation process was developed to reprocess dry mill tailings that have been stockpiled for many years at SRL's rutile operations. Previously at SRL, ilmenite was recovered as a byproduct but no attempt was made to separate zircon. The new process produces a zircon-rich concentrate and a rutile/ilmenite tailing that can be processed by conventional means to produce salable rutile and ilmenite concentrates. Sierra Rutile was granted a U.S. patent for the zirconrutile-ilmenite process.⁶

OUTLOOK

Zircon is a byproduct of heavy mineral operations whose primary products are titanium-bearing ores and concentrates. Almost all titanium ores are consumed for producing titanium dioxide, the predominant white pigment used in most industries. Therefore, zircon supply is largely driven by demand for titanium dioxide pigments. Because global demand in the titanium pigment industry

is expected to increase moderately over the next few years, the available supply of zircon is also expected to increase moderately.

The outlook for demand of zircon materials is determined by the major consuming industries, including the steel, glass, refactories, and ceramics markets. During the late 1980's, a temporary shortage of material caused prices for zircon products to soar. In reaction to soaring prices and the material shortage, consuming industries developed substitutions and process changes that have eroded zircon demand over the past few years. However, zircon producers have lower price levels and ensure a stable supply of material. If the global economic conditions permit, zircon demand is expected increase to moderately over the next few years.

TABLE 2
ESTIMATED CONSUMPTION OF ZIRCON, BY END USE, BASED ON TOTAL APPARENT CONSUMPTION

(Metric tons)

End use	1991	1992
Zircon refractories¹	18,000	21,000
AZS refractories ²	9,000	9,000
Zirconia and AZ abrasives ³	w	w
Alloys4	w	w
Foundry applications	32,000	35,000
Other ⁵	38,000	40,000
Total	112,000	120,000

W Withheld to avoid disclosing company proprietary data; included in "Total."

1491

¹Includes insignificant amounts of baddeleyite.

²Excludes foundries.

⁵Excludes intermediate oxide associated with metal production.

¹Dense and pressed zircon brick and shapes.

²Fused cast and bonded alumina-zirconia-silica-base refractories.

⁵Alumina-zirconia-base abrasives.

⁴Excludes alloys more than 90% zirconium.

⁵Includes chemicals, zirconium metal, welding rods, sandblasting, and other miscellaneous uses.

TABLE 3 PUBLISHED YEAREND PRICES OF ZIRCONIUM AND HAFNIUM MATERIALS

Specification of material	1991	1992
Zircon:		
Domestic, standard-grade, f.o.b. Starke, FL, bulk, per short ton ¹	\$331.00	\$265.00
Domestic, 75% minimum quantity zircon and aluminum silicates, Starke, FL, bulk, per short ton ¹	184.00	242.00
Domestic, premium-grade zircon, Starke, FL, bulk, per short ton ¹	368.00	294.00
Imported sand, minimum 65% ZrO ₂ , f.o.b., bulk, per metric tor ²	228.00-266.00	309.00-386.00
Imported sand, minimum 65.5% to 66% ZrO ₂ , f.o.b., bulk, per metric ton ²	228.00-266.00	348.00-425.00
Imported sand, minimum 66% ZrO ₂ , f.o.b., bulk, per metric ton ²	228.00-266.00	386.00-464.00
Domestic, granular, bags, bulk rail, from works, per short ton ³	300.00-600.00	300.00-600.00
Domestic, milled, 200- and 325-mesh, rail, from works, bags, per short ton ³	350.00-800.00	340.00-600.00
Baddeleyite, imported concentrate.4		
96% to 98% ZrO ₂ , minus 100-mesh, c.i.f. Atlantic ports, per pound	.4560	.5075
99% + ZrO ₂ , minus 325-mesh, c.i.f. Atlantic ports, per pound	1.07- 1.20	1.16- 1.40
Zirconium oxide: ³		
Powder, commercial grade, drums, 2,000-pound minimum, per pound	2.00- 7.00	3.00- 6.60
Electronic, same basis, per pound	3.50- 8.00	3.50- 8.00
Insulating, stabilized, 325° F, same basis, per pound	4.50	3.35- 4.00
Insulating, unstabilized, 325° F, same basis, per pound	5.00	3.35- 4.00
Dense, stabilized, 300° F, same basis, per pound	3.00	3.60
Zirconium oxychloride: Crystal, cartons, 5-ton lots, from works, per pound ³	.91- 1.04	.91- 1.04
Zirconium acetate solution: ³		
25 % ZrO ₂ , drums, carlots, 15-ton minimum, from works, per pound	.97	.97
22% ZrO ₂ , same basis, per pound	.78	.78
Zirconium hydride: Electronic-grade, powder, drums, 100-pound lots, from works, per pound ³	.3175	.3175
Zirconium:5		
Powder, per pound	75.00-150.00	75.00-150.00
Sponge, per pound	9.00- 12.00	9.00- 12.00
Sheets, strip, bars, per pound	20.00- 50.00	20.00- 50.00
Hafnium: Sponge, per pound ⁵	75.00- 95.00	75.00- 95.00

Estimated. Revised.

¹Includes data available through June 3, 1993.

²Includes production of zircon and caldasite.

³Reported figure.

⁴Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁵Includes production of zircon and baddeleyite.

⁶Dissolved in Dec. 1991.
