As a work of the United States government, this material is in the public domain.

For information on re-use see: http://digital.library.wisc.edu/1711.dl/Copyright

The libraries provide public access to a wide range of material, including online exhibits, digitized collections, archival finding aids, our catalog, online articles, and a growing range of materials in many media.

When possible, we provide rights information in catalog records, finding aids, and other metadata that accompanies collections or items. However, it is always the user's obligation to evaluate copyright and rights issues in light of their own use.

MINERALS YEARBOOK

U.S.
DEPARTMENT
OF THE
INTERIOR

BUREAU OF MINES

UNITED STATES DEPARTMENT OF THE INTERIOR ● Bruce Babbitt, Secretary

BUREAU OF MINES

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the sound use of our land and water resources; protecting our fish, wildlife, and biological diversity; preserving the environmental and cultural values of our national parks and historical places; and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people by encouraging stewardship and citizen participation in their care. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

Foreword

This edition of the Minerals Yearbook discusses the performance of the worldwide minerals and materials industry during 1992 and provides background information to assist in interpreting that performance. Content of the individual Yearbook volumes follows:

Volume I, Metals and Minerals, contains chapters on virtually all metallic and industrial mineral commodities important to the U.S. economy. Chapters on advanced materials, nonrenewable organic materials, and nonferrous metals recycling also were added to the Minerals Yearbook series beginning with the 1989, 1990, and 1991 volumes, respectively. A new chapter on materials recycling has been initiated in this 1992 volume. In addition, a chapter on survey methods used in data collection with a statistical summary of nonfuel minerals and a chapter on trends in mining and quarrying in the metals and industrial mineral industries are included.

Volume II, Area Reports: Domestic, contains chapters on the minerals industry of each of the 50 States, Puerto Rico, Northern Marianas, Island Possessions, and Trust Territory. This volume also has a chapter on survey methods used in data collection, including a statistical summary of domestic nonfuel minerals.

Volume III, Minerals Yearbook—International Review, contains the latest available mineral data on more than 150 foreign countries and discusses the importance of minerals to the economies of these nations. Since the 1989 International Review, this volume has been presented as six reports: Mineral Industries of the Middle East, Mineral Industries of Africa, Mineral Industries of Asia and the Pacific, Mineral Industries of Latin America and Canada, Mineral Industries of Europe and Central Eurasia, and Minerals in the World Economy. The reports incorporate location maps, industry structure tables, and an outlook section previously incorporated in our Mineral Perspectives Series quinquennial regional books, which are being discontinued.

The U.S. Bureau of Mines continually strives to improve the value of its publications to users. Therefore, constructive comments and suggestions by readers of the Yearbook will be welcomed.

Acknowledgments

Volume I, Metals and Minerals, of the Minerals Yearbook presents data on more than 60 material commodities that were obtained as a result of the information gathering activities of the U.S. Bureau of Mines.

The collection, compilation, and analysis of domestic minerals industries data were performed by the staffs of the Division of Mineral Commodities and the Division of Statistics and Information Services. Statistical data were compiled from information supplied by mineral producers and consumers in response to canvasses, and their voluntary response is gratefully appreciated. Information obtained from individual firms by means of the U.S. Bureau of Mines canvasses has been grouped to provide statistical aggregates. Data on individual firms are presented only if available from published or other nonproprietary sources or when permission of the respondent has been granted.

The chapter "Survey Methods and Statistical Summay of Nonfuel Minerals" discusses in greater detail procedures for canvassing the minerals industry and this processing and evaluation of these data.

Other information appearing in this volume was obtained from the trade and technical press, industry contacts, and additional sources; this cooperation is gratefully acknowledged.

Statistics on world production were compiled in the Division of Statistics and Information Services and Division of International Minerals from numerous sources, including reports from the U.S. Department of State. U.S. foreign trade data were obtained from reports of the Bureau of the Census, U.S. Department of Commerce. Data on production costs for several commodities were supplied by the U.S. Bureau of Mines, Minerals Availability System.

The U.S. Bureau of Mines has been assisted in collecting mine production data and other supporting information by numerous cooperating State agencies. These organizations are listed in the acknowledgments of Volume II.

Donald G. Rogich

SURVEY METHODS AND STATISTICAL SUMMARY OF NONFUEL MINERALS

By Jacqueline A. McClaskey and Stephen D. Smith

Ms. McClaskey, an operations research analyst with 7 years of Government experience, has been with the U.S. Bureau of Mines Branch of Statistics and Methods Development since 1990.

Mr. Smith, industry data analyst in the Section of Industry Data Analysis and Coordination, was assisted in the preparation of the Statistical Summary by Imogene P. Bynum, Chief, Section of Metals Data; Rosa McGee, Chief, Section of Industrial Minerals Data; Ivette E. Torres, Chief, Section of International Data; and Jim F. Lemons, Jr., Chief, Branch of Materials.

SURVEY METHODS

The U.S. Bureau of Mines (USBM) Information and Analysis Directorate collects worldwide data on virtually every commercially important nonfuel mineral commodity. These data form the base for tracking and assessing the health of the minerals sector of the U.S. economy.

The USBM's data collection activity was instituted by the 47th Congress in an appropriations act of August 7, 1882 (22 Stat. 329), which placed the collection of mineral statistics on an annual basis. The most recent authority for the USBM survey activity is the National Materials and Minerals Policy, Research and Development Act of 1980 (Public Law 96-479, 96th Congress). This strengthens protection for proprietary data provided to the U.S. Department of the Interior by persons or firms engaged in any phase of mineral or mineral-material production or consumption.

Data Collection Surveys

The USBM begins the collection of domestic nonfuel minerals and materials statistics by appraising the information requirements of Government and private organizations of the United States. Requirements that can be met by collecting data from minerals establishments are posed as questions on USBM surveys. Figure 1 shows a typical survey form.

Specific questions about the production, consumption, shipments, etc., of mineral commodities are structured in the survey forms to provide meaningful aggregated data. Thus, the entire mineral economic cycle from production through consumption is covered by 161 monthly, quarterly, semiannual, annual, and biennial surveys.

After the survey form has been designed, a list of the appropriate establishments to be canvassed is developed. Many sources are used to determine which companies, mines, plants, and other operations should be included on the survey mailing list. USBM State Mineral Officers, State geologists, Federal organizations (e.g., Mine Safety and Health Administration), trade associations, industry representatives, and trade publications and directories are some of the sources that are used to develop and update survey listings. With few exceptions, a complete canvass of the list of establishments is employed rather than a sample survey. The iron and steel scrap industry is one of the exceptions where a sample survey is conducted.

The Paperwork Reduction Act requires that any Government agency wishing to collect information from 10 or more individuals or establishments first obtain approval from the Office of Management and Budget (OMB). OMB approves the need to collect the data and protects industry from unwarranted Government paperwork.

Survey Processing

The USBM surveys approximately 25,500 establishments. Each year the USBM mails about 45,000 forms that gather information for 161 different surveys. Each completed survey form returned to the USBM undergoes extensive scrutiny to ensure the highest possible accuracy of the mineral data. The statistical staff monitors all surveys to ensure that errors are not created by reporting in physical units different from the units requested on the form. Relationships between related measures, such as produced crude ore and marketable crude ore, are analyzed for consistency. Engineering relationships, such as recovery factors from ores and concentrates, are also employed. The totals for each form are verified, and currently reported data are checked against prior reports to detect possible errors or omissions.

For the majority of the surveys, which are automated, the forms are reviewed to ensure that data are complete and correct before entering into the computer. The computer is programmed to conduct a series of automated checks to verify mathematical consistency and to identify discrepancies between the data reported and logically acceptable responses.

The USBM is modernizing and automating all of its survey processing and data dissemination functions.

Automated commodity data system functions include computerized preparation of statistical tables; the use of desktop publishing to integrate text and tables; and the implementation of a microcomputer bulletin board, known as MINES-DATA, for electronic dissemination of minerals data. Also, information on minerals and mineral-related publications is now available through an easy-to-use automated facsimile (fax) response system known as MINES FaxBack.

Survey Responses.—To enable the reader to better understand the basis on which the statistics are calculated, each commodity annual report includes a section entitled "Domestic Data Coverage." This section briefly describes the data sources, the number of establishments surveyed, the response percentage, and the method of estimating the production or consumption for nonrespondents.

To produce reliable aggregated data, the USBM employs efficient procedures for handling instances of nonresponse. Failure to return the initial survey form results in a second mailing of the form. If the second form is not returned, telephone calls are made to the The followup calls nonrespondents. provide the necessary data to complete and/or forms verify the survey questionable data entries. Periodic visits to important minerals establishments are also made by USBM commodity specialists or State Mineral Officers to gather missing data and to explain the importance of the establishment's reporting. By describing the use of the published statistics and showing the impact of nonresponse, the USBM strives to encourage respondents to give a complete and accurate reply.

The OMB "Guidelines for Reducing Reporting Burden" stipulates that the minimum acceptable response rate shall be 75% of the panel surveyed. In addition, the USBM strives for a minimum reporting level of 75% of the quantity produced or consumed (depending on the survey) for certain key statistics. Response rates are periodically reviewed.

For those surveys not meeting the minimum reporting level, procedures are developed and implemented to improve response rates.

Estimation for Nonresponse.—When efforts to obtain a response to a survey fail, it becomes necessary to employ estimation or imputation techniques to account for missing data. techniques are most effective when the response rate is relatively high. Some of the estimation methods depend on establishment prior knowledge of reporting, while other techniques rely on external information to estimate the missing data. When survey forms are received after the current publication has been completed, the forms are edited, necessary imputations are made for missing data, and the survey data base is updated. The revised data are reported in later publications.

Protection of Proprietary Data.—The USBM relies on the cooperation of the U.S. minerals industry to provide the mineral data that are presented in this and other USBM publications. Without a strong response to survey requests, the USBM would not be able to present reliable statistics. The USBM in turn respects the proprietary nature of the data received from the individual companies To ensure that and establishments. proprietary rights will not be violated, the USBM analyzes each of the aggregated statistics to determine if the data reported by an individual establishment can be deduced from the aggregated statistics. If, for example, there are only two significant producers of a commodity in a given State, the USBM will not publish the State total because either producer could readily estimate the production of the other. It is this obligation to protect proprietary information that results in the "Withheld" or "W" entries in the published tables. However, if a company gives permission in writing, the USBM will publish the data as long as the data from other respondents are protected from disclosure.

International Data

International data are collected by country specialists in the USBM Division of International Minerals with assistance from the Section of International Data. The data are gathered from various sources, including published reports of foreign Government mineral and statistical agencies, international organizations, the U.S. Department of the United Nations, the State. Organization of Petroleum Exporting Countries, and personal contact by Each specialists traveling abroad. annual "Minerals February an Questionnaire" is sent through the Department of State to more than 130 U.S. Embassies asking them to provide estimates of mineral production for the host country for the preceding year. Missing data are estimated by USBM country specialists based on historical trends and specialists' knowledge of current production capabilities in each country.

Publications

The USBM disseminates current and historical minerals information through a broad range of printed publications.

The Minerals Yearbook summarizes annually, on a calendar-year basis, the significant economic and technical developments in the mineral industries. Three separate volumes are issued each year: Volume I, Metals and Minerals; Volume II, Area Reports, Domestic; and Volume III, Area Reports, International. Chapters in these volumes are issued separately as annual reports before the bound volumes are available. (Volume III country reports appear in bound volume only.)

Volume I of the Minerals Yearbook presents, by mineral commodity, salient statistics on production, trade, consumption, reserves, and other measures of economic activity.

Volume II of the Minerals Yearbook reviews the U.S. minerals industry by State and island possessions.

Volume III of the Minerals Yearbook contains the latest available mineral data

for the year of review on more than 170 foreign countries and discusses the importance of minerals to the economies of these nations. Volume III is presented as five area reports and one world overview: Mineral Industries of Africa, Mineral Industries of Asia and the Pacific, Mineral Industries of Latin America and Canada, Mineral Industries of Europe and Central Eurasia, Mineral Industries of the Middle East, and Minerals in the World Economy.

Mineral Industry Surveys contain timely statistical and economic data on minerals. The surveys are designed to keep Government agencies and the public, particularly the mineral industry and the business community, informed of trends in the production, distribution, inventories, and consumption of minerals. Frequency of issue depends on the demand for current data. Mineral Industry Surveys are released monthly, quarterly, semiannually, or annually.

Mineral Commodity Summaries, an up-to-date summary of about 90 nonfuel mineral commodities, is the earliest Government publication to furnish estimates covering the previous year's nonfuel mineral industry data. It contains information on the domestic industry structure, Government programs, tariffs, 5-year salient statistics, and a summary of international mining news.

State Mineral Summaries provide estimated data and summaries of mineral activities at the State level for the previous year. These summaries have been prepared in cooperation with State geological surveys or related agencies.

Minerals Today, published bimonthly, provides readers with the latest information about developments, trends, and issues concerning the mining, processing, and use of minerals and materials.

Metal Industry Indicators, published monthly, contains indexes that measure the current and future performance of four U.S. minerals industries. For each of the four industries, a composite coincident index and a composite leading index have been developed based on procedures and data similar to those used to construct the U.S. Department of

Commerce's coincident and leading cyclical indicators for the national economy.

Information Circulars are primarily concerned with USBM economic reviews and interpretative analyses. The series also includes surveys of mining and operating activities, guides to marketing of mineral commodities, and compilations of historical information and statistical and economic data on minerals.

Order free copies of the Mineral Industry Surveys or the Metal Industry Indicators from Publication Distribution, U.S. Bureau of Mines, Cochrans Mill Road, P.O. Box 18070, Pittsburgh, PA 15236, (412) 8992-4338.

To purchase Minerals Today, Annual Commodity Reports, Minerals Yearbook, Mineral Commodity Summaries, and State Mineral Summaries, order from the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402, (202) 783-3238.

Information Circulars, Mineral Commodity Summaries, and State Mineral Summaries also may be purchased from the National Technical Information Service, Springfield, VA 22161, 1-800-553 NTIS (in Virginia and foreign countries: 1-703-487-4650).

Electronic Data Dissemination

In addition to the USBM's printed publications, current Mineral Industry Surveys for all commodities and 85 annual reports from the Minerals Yearbook are now available through the USBM's MINES-DATA bulletin board. Using this system, the public may obtain information up to 4 weeks before published copies of the reports would arrive in the mail. The MINES-DATA system may be accessed by calling (202) 501-0373 using a modem set to 1200 or 2400 baud, 8 data bits, no parity, and 1 stop bit. **Further** information on how to use the MINES-DATA system may be obtained from the system operator by calling (202) 501-0406.

Also, current information on minerals and mineral-related publications from the USBM is now available through an easyto-use automated fax response system. The MINES FaxBack service allows callers to retrieve information and order some publications for delivery to their fax machines in minutes, 24 hours per day, 7 days per week. MINES FaxBack makes monthly and quarterly Mineral Industry Surveys publications available to the public at the same time they are forwarded to the printer.

MINES FaxBack works from any Group III-compatible fax machine equipped with a touch-tone telephone (either a built-in handset with touch-tone capability or a separate touch-tone telephone plugged into the fax machine's phone jack). After calling MINES FaxBack, the requestor is guided by a series of voice messages that assist the caller in ordering the desired documents. The caller pays for the phone call that also includes the time needed to deliver the requested document to the caller's fax machine.

To access the MINES FaxBack System, use a touch-tone handset attached to a fax machine or connect a touch-tone telephone to the fax machine's telephone jack and dial (412) 892-4088. Listen to the menu options and select an option using the touch-tone telephone. After completing a selection, press the start button on the fax machine.

STATISTICAL SUMMARY

This annual report summarizes data on crude nonfuel mineral production for the United States, its island possessions, and the Commonwealth of Puerto Rico. Also included are tables that show the principal nonfuel mineral commodities exported from and imported into the United States and that compare world and U.S. mineral production. The detailed data from which these tables were derived are contained in the individual annual reports of Volume I and in the State reports of Volume II of this edition of the Minerals Yearbook.

Although crude mineral production may be measured at any of several stages of extraction and processing, the stage of measurement used in this annual report is what is termed "mine output." It usually refers to minerals or ores in the form in which they are first extracted from the ground, but customarily includes the output from auxiliary processing at or near the mines.

Because of inadequacies in the statistics available, some series deviate from the foregoing definition. For copper, gold, lead, silver, tin, and zinc, the quantities are recorded on a mine basis (as the recoverable content of ore sold or treated). However, the values assigned to these quantities are based on the average selling price of refined metal, not the mine value. Mercury is measured as recovered metal and valued at the average New York price for the metal.

The weight or volume units shown are those customarily used in the particular industries producing the commodities. Values shown are in current dollars, with no adjustments made to compensate for changes in the purchasing power of the dollar.

[&]quot;Estimated. 'Revised. NA Not available. W Withheld to avoid disclosing company proprietary data; value included with "Combined value" data. XX Not applicable.

¹Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

²Recoverable content of ores, etc.

^{*}The Riddle nickel smelter uses lateritic ore mined on Nickel Mountain, lateritic ore imported from New Caledonia, and small tonnages of recycled Ni-bearing catalysts. In 1989, the Glenbrook Nickel Co. purchased the idled mining and smelting complex and restarted the operation. Since then, production of ferronickel on a contained Ni basis has been as follows: 1990—3,701 metric tons (mt) valued at \$32.8 million; 1991—7,065 mt valued at \$57.6 million; and 1992—8,962 mt valued at \$62.7 million.

⁶Grindstones, pulpstones, and sharpening stones; excludes mill liners and grinding pebbles.

⁷Beginning in 1992; aplite is combined with feldspar.

^{*}Excludes abrasive stone and bituminous limestone and sandstone; all included elsewhere in table.

TABLE 2 TOTAL U.S. NONRENEWABLE ORGANIC MATERIALS PRODUCTION, BY QUANTITY AND VALUE¹

(Million metric tons and million dollars)

Preliminary. Revised.

NOTE.— Nonrenewable organic materials represent all nonfuel uses in physical structure applications. The petrochemical industries category includes feedstocks for the production of plastics, synthetic rubber, synthetic fibers, pesticides, coatings, solvents, fertilizers, and other petrochemicals.

¹Quantities valued at the fossil fuel prices given in the Department of Energy, Energy Information Administration, Annual Energy Review 1992, June 1993, p. 71.

²Data do not add to total shown because of independent rounding.

TABLE 3 NONFUEL MINERALS PRODUCED IN THE UNITED STATES AND PRINCIPAL PRODUCING STATES IN 1992

Estimated.					

Estimated

¹Grindstones, pulpstones, and sharpening stones; excludes mill liners and grinding pebbles.

²Content of ores, etc.

³Beginning in 1992; aplite is combined with feldspar.

⁴Principal and other producing States based on value.

⁵No production reported.

⁶Includes byproduct material.

TABLE 4
VALUE OF NONFUEL MINERAL PRODUCTION IN THE UNITED STATES AND PRINCIPAL NONFUEL MINERALS PRODUCED IN 1992

State	Value (thousands)	Rank	Percent of U.S. total	Principal minerals, in order of value
Alabama	\$542,714	19	1.70	Cement (portland), stone (crushed), lime, sand and gravel (construction).
Alaska	526,112	21	1.64	Zinc, gold, lead, sand and gravel (construction).
Arizona	3,165,938	1	9.89	Copper, sand and gravel (construction), gold, cement (portland).
Arkansas	403,822	26	1.26	Bromine, stone (crushed), sand and gravel (construction), cement (portland).
California	2,345,838	3	7.33	Sand and gravel (construction), cement (portland), gold, boron.
Colorado	384,778	29	1.20	Sand and gravel (construction), cement (portland), molybdenum, stone (crushed).
Connecticut	97,192	44	.30	Stone (crushed), sand and gravel (construction), stone (dimension), sand and gravel (industrial).
Delaware ¹	8,575	50	.03	Sand and gravel (construction), magnesium compounds, gemstones.
Florida	1,439,760	5	4.50	Phosphate rock, stone (crushed), cement (portland), sand and gravel (construction).
Georgia	1,346,254	8	4.21	Clays, stone (crushed), cement (portland), sand and gravel (construction).
Hawaii ¹	148,857	39	.47	Stone (crushed), cement (portland), sand and gravel (construction), cement (masonry).
Idaho	306,061	33	.96	Phosphate rock, sand and gravel (construction), gold, silver.
Illinois	733,572	16	2.29	Stone (crushed), sand and gravel (construction), cement (portland), sand and gravel (industrial).
Indiana	476,886	22	1.49	Stone (crushed), cement (portland), sand and gravel (construction), stone (dimension).
Iowa	391,163	28	1.22	Stone (crushed), cement (portland), sand and gravel (construction), gypsum (crude).
Kansas	405,082	25	1.27	Salt, helium (Grade-A), cement (portland), stone (crushed).
Kentucky	400,574	27	1.25	Stone (crushed), lime, cement (portland), sand and gravel (construction).
Louisiana	309,280	32	.97	Salt, sulfur (Frasch), sand and gravel (construction), stone (crushed).
Maine	55,919	46	.17	Sand and gravel (construction), cement (portland), stone (crushed), cement (masonry).
Maryland	339,366	31	1.06	Stone (crushed), cement (portland), sand and gravel (construction), cement (masonry).
Massachusetts	147,401	40	.46	Stone (crushed), sand and gravel (construction), lime, stone (dimension).
Michigan	1,586,977	4	4.96	Iron ore (usable), cement (portland), sand and gravel (construction), stone (crushed).
Minnesota	1,363,939	6	4.26	Iron ore (usable), sand and gravel (construction), stone (crushed), sand and gravel (industrial).
Mississippi	119,964	41	.37	Sand and gravel (construction), clays, cement (portland), stone (crushed).
Missouri	897,189	11	2.80	Lead, cement (portland), stone (crushed), lime.
Montana	539,154	20	1.68	Gold, copper, cement (portland), sand and gravel (construction).
	114,790	42	.36	Cement (portland), sand and gravel (construction), stone (crushed), lime.
Nebraska	•	2	8.09	Gold, sand and gravel (construction), silver, diatomite.
Nevada	2,588,251 42,034	47	.13	Sand and gravel (construction), sinver, diatonine. Sand and gravel (construction), stone (crushed and dimension), clays.
New Hampshire ¹	•	36	.13	Stone (crushed), sand and gravel (construction and industrial), stone (dimension).
New Jersey	240,439

	1990		19	91	1992	
Mineral	Quantity	Value (thousands)	Quantity	Value (thousands)	Quantity	Value (thousands)
		UNDISTRIBUT	TED			
Delaware, Hawaii, New Hampshire, North						
Dakota (1991), Rhode Island, Vermont						
(1991-92), Wisconsin (1991-92), and						
undistributed (1991)	XX	\$5,938	XX	'\$ 13.870	XX	\$25,797

Estimated. Revised. NA Not available. W Withheld to avoid disclosing company proprietary data; value included with "Combined value" figure. XX Not applicable.

¹Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

²Excludes certain clays; kind and value included with "Combined value" figure.

³Excludes certain stones; kind and value included with "Combined value" figure.

⁴Recoverable content of ores, etc.

⁵Grindstones, pulpstones, and sharpening stones; excludes mill liners and grinding pebbles.

⁶Less than 1/2 unit.

⁷Revised data withheld to avoid disclosing company proprietary data; included with "Combined value" data.

^{*}Partial total, excludes values that must be concealed to avoid disclosing company proprietary data. Values excluded from partial total included with "Undistributed States."

⁹Excludes salt in brines; value included with "Combined value" figure.

¹⁰Value excluded to avoid disclosing company proprietary data.

¹¹The Riddle nickel smelter uses lateritic ore mined on Nickel Mountain, lateritic ore imported from New Caledonia, and small tonnages of recycled Ni-bearing catalysts. In 1989, the Glenbrook Nickel Co. purchased the idled mining and smelting complex and restarted the operation. Since then, production of ferronickel on a contained Ni basis has been as follows: 1990—3,701 metric tons (mt) valued at \$32.8 million; 1991—7,065 mt valued at \$57.6 million; and 1992—8,962 mt valued at \$62.7 million.

¹²Excludes traprock.

MINING AND QUARRYING TRENDS IN THE METALS AND INDUSTRIAL MINERALS INDUSTRIES

By Brian T. Brady, Gregory J. Chekan, and Charles V. Jude

Dr. Brady is a physicist who has been with the U.S. Bureau of Mines, Denver Research Center, for more than 25 years. Mr. Chekan is a mining engineer who has been with the U.S. Bureau of Mines, Pittsburgh Research Center, for 14 years and has extensive research experience in coal mine ground control in multiple-seam mining operations. Mr. Jude is a mining engineer at the Denver Research Center who has extensive industrial and research experience in block caving mining operations.

MINING HIGHLIGHTS

Summary

The year 1992 recorded unimpressive economic growth and uncertainties over what changes would occur for the financial market. Falling interest rates in the United States and elsewhere tended to exert a number of positive influences on financial markets and, indirectly, the mining and quarrying industry. interest rate declines during 1992 were no exception. Lower rates prompted many investors to turn their attention to longterm investments such as stocks that offer potentially greater rates of return, causing large cash inflows into the equity market. Lower rates made it easier for businesses to finance growth and for consumers to finance the purchase of products businesses made. Also the rates enabled many companies to increase their health and profitability by refinancing their existing loans at lower rates.

Falling interest rates were not confined to the United States. With Japan and Western Europe in the midst of economic slumps, marketing authorities in many countries overseas lowered rates in an effort to stimulate business activity. True to form, that contributed to stock market rallies abroad. Stabilizing inflation and lower interests stimulated the industry during 1992 and will likely influence favorably the industry for the next few

years.

Worldwide minerals exploration slipped in 1992 from 1991 levels. Although industrial production figures showed the U.S. economy emerging from recession in early 1992, it was not until February 1993 that the lagging indicator of unemployment dropped to 7%. Most other industrialized countries are still in recession.

Preliminary data for 1992 showed industrial production dropping in Japan (5%), Germany (1.4%), the United Kingdom (0.5%), and France (1.48%). The slowdown in industrial production led to reduced mineral demand. This resulted in lean cash-flows from mining operations, which squeezed exploration funding. Although mineral prices were steady during most of 1992, some mineral commodity prices began falling in late 1992 and early 1993.

Exploration 1991-92.—According to Metals Economies Group (MEG), planned 1992 exploration expenditures were down by about 5%. Geographically, the leading exploration target was the United States with 21% of the expenditures, followed by Australia (19%), Canada (18%), Latin America (15%), the Republic of South Africa (9%), and the western Pacific (7.5%). The remaining 10% was split between Europe and Africa.

There were absolute increases in exploration expenditures in the United

States and Latin America. Latin America showed the largest increase. The change in the Mexican mining law allowing foreign ownership of mines should result in the inflow of direct foreign investment in Mexico's mining industry.

Unresolved issues of property rights in Eastern Europe and the former U.S.S.R. are a deterrent to grassroots exploration by western companies in these areas. Projects, such as those of Newmont at Muruntau, Uzbekistan, and by Goldbelt Resources in Kazakhstan, apply new technology to established mining projects in return for a share of production.

The 1992 increase in domestic exploration spending reported by a MEG study is reflected in the increase in new claims on Federal land recorded by the Bureau of Land Management (BLM). Nevada accounted for nearly all of the increase.

During 1992, Congress considered proposals to impose new fees and regulations on exploration and mining on Federal lands. A new BLM claims fee of \$100 for fiscal years 1992 and 1993 was imposed on all claims of record. The intent of the fee was to raise revenue. However, the law's effect also will be to concentrate acreage into fewer independent entities.

The Society of Economic Geologists (SEG) annual survey showed a slight decline in 1991 exploration expenditures by domestic firms in the United States when adjusted for survey coverage. This

survey of U.S. and Canadian firms showed an overall increase for exploration in Latin America from 1990 to 1991.

Respondents were asked to allocate exploration spending by product category. U.S. respondents spent about 71% on gold and 25% on base metals and Canadian respondents spent 27% on gold and 64% on base metals. When exploring in the United States, the Canadian respondents spent about the same percentage of gold as U.S. firms. The increase in base metals exploration relative to gold was reflected by the 1991 increase in the share of core drilling relative to rotary drilling.

In Canada, 1992 exploration expenditures appeared to be down by about 15% from those of 1991. Canada's mining industry is particularly vulnerable to worldwide recession because it is an export-based industry.

The BHP-Dia Met discovery of diamond-bearing kimberlites in the Northwest Territories (NWT) caused a diamond rush that has spilled over to northern Alberta. The massive claimstaking that followed, however, has foreclosed millions of acres to exploration for other minerals.

Gold exploration still accounted for more than one-half of the exploration expenditures in 1992. Newly reported North American gold discoveries included Pipeline (Gold Acres South), NV, by Cortez, and Gold Ridge, NV, by Atlas. New gold zones, ore bodies, and extensions of identified gold properties included the following:

- a new zone at Sunbeam, UT, by Centurion Mines,
- a new zone at Casa Berardi, Quebec, by TYX Gold and Golden Knight,
- a new ore body at Gold Ridge, NV. by Atlas.
- an extension at Jerritt Canyon and Gracie, NV, by Minorco,
- an extension at Amalgamated Kirkland property, Ontario, by Battle Mountain Gold,
- an extension at the New World, MT, by Crown Butte, and
- an extension at the Kendall Mine,

MT, by Canyon Resources.

Other North American discoveries include Pointe Lake (diamonds, NWT) by BHP-Dia Met, Inushshuk (copper-zinc, NWT) by Minnova and Metall Mining, Prairie Creek (lead-zinc-silver, NWT) by San Andreas Resources, and Bell Alard South (copper-zinc-silver, Quebec) by Noranda.

New zones, ore bodies, or extensions were reported at Izok Lake (copper-zinc, NWT) by Minnova and Metall Mining, Gibraltar (copper, British Columbia) by Placer Dome and Newcoast, LaReyna (copper, Mexico) by Aurizon, and Piedras Verdes (copper, Mexico) by Azco.

Outside of North America, gold discoveries include Mount Constantine (Australia) by Hunter Resources and Western Minerals, Nalung (Greenland) by Nunoil, and Big Gossen (Indonesia) by Freeport-McMoRan.

New gold zones and extensions were announced for Macuelaizo (Honduras) by Melinga, El Higo (Dominican Republic) by Canyon Resources and Battle Mountain Gold, Carbine North (Australia) by Samantha Gold, Afema (Ivory Coast) by Eden Roc, Penjom (Malaysia) by Avocet Ventures, Minas de Oro (Honduras) by Kennecott and Fisher-Watt Gold, Kanowna Bell (Australia) by Delta Gold, and Orient Well (Australia) by Melita Mining.

Other reported discoveries include Mount Moss (zinc, Australia), by Jervois, Chacobamba and Ferrobamba (copper, Peru) by Minero, Cannington (polymetallic, Australia) by BHP, Naberru (diamond, Australia) by Great Central Mine, and Bamuigui (diamonds, Central African Republic) by United Reef

Significant extensions were reported at Grasberg (copper-gold, Indonesia) by Freeport-McMoRan, Broken Hill (lead-zinc, Australia) by Pasminco, Golmay (lead-zinc, Ireland) by Arcon, Lisheen (lead-zinc, Ireland) by Ivernia and Chevron, and Cerratappe (copper, Turkey) by Cominco.

The Portugese Directorate of Geology and Mines announced the discovery of base and precious metals in the Iberian

Pyrite Belt in Portugal. Indian and Argentine Atomic Energy Agencies announced uranium discoveries in those countries.

Trends and Outlook.—Forces have already appeared that promise changes for the U.S. mining industry. Proposed revisions to the Mining Law of 1872 would change the current patent system for assignment of minerals rights ownership on Federal lands.

Potential liability under Comprehensive Environmental Response, Compensation and Liability (CERCLA) of 1980 (Superfund legislation) makes it risky to rework domestic mining properties as well as to develop new projects that have any potential of damaging the environment. This law reserves the right to assign liability to firms currently using best management practices for pollution mitigation in the event that emissions standards are tightened in the future. Potentially responsible parties (PRP's) are held joint and severally liable—one PRP could be held totally responsible for a site, even though several parties were involved in ownership and operation.

The emergence of the world economy from recession will fuel base metal demand. For countries seeking loans, the World Bank has been fostering mining laws reform to promote direct foreign investment. Perhaps the mining industry will find those countries making the reforms and having good prospects and stable political regime as attractive areas for future exploration.

In 1992, the U.S. economy grew at a rate of 2%. The gross domestic product rose to \$5,946 billion. With 257 million people—635,000 in mining, including petroleum—the United States has more than 100 million dwelling units and more than 190 million licensed motor vehicles.

New private housing starts rose 11% to 1.2 million units. New car production rose 4% to 5.7 million units. Truck and bus production rose 20% to 4 million units.

The rate of inflation was 3.5%, and the prime rate of interest was 6.25%. The Producer Price Index (1982 = 100)

was relatively unchanged from that of 1991 as follows: fuels and related products and power, 80; metals and metal products, 119; chemicals and allied products, 126; and nonmetallic mineral products, 117.

Energy.—Imports of crude and refined petroleum, costing \$50 billion, rose 3% to 455 million cubic meters (Mm³) [2.9 billion barrels (bbl)]. Domestic petroleum production fell 1% to 582 Mm³ (3.5 billion bbl). Petroleum supplied about 41% of U.S. energy; natural gas, 24%; and coal, 23%.

Coal production, 60% from surface operations, rose 1% to 914 million metric tons (m/t) [1 billion short tons (st)]. About 78% was used to generate electricity and 3% was coked. Exports valued at \$4 billion included 57 Mmt (63 million st) of metallurgical coal and 39 Mmt (43 million st) of steam coal. Uranium mining, including recovery from phosphates, fell 18% to 3 thousand metric tons (kmt) (3,300 st) U₃O₈.

Nonfuel Minerals.—Processed nonfuel mineral materials were valued at \$310 billion. Metals from U.S. ores fell 1% to \$11.1 billion. Industrial minerals rose 6% to \$20.7 billion. Recycled scrap, largely steel and aluminum, fell 30% to \$10 billion.

Imports of nonfuel, mineral-based materials were valued at \$43 billion and exports at \$37 billion. Canada, with which the United States has a free trade agreement and is a partner in the North American Defense Industrial Base, was a major supplier of many minerals. The North American Free Trade Agreement (NAFTA) was signed in October 1993. The United States, Canada, and Mexico are part of the agreement. The treaty, however, still requires ratification by each country's legislature.

Major Metals.—Steel production rose 5% to 84 Mmt (93 million st). Iron ore mining rose 1% to 56 Mmt (62 million st), nearly all pelletized. Net ore imports fell 20% to 7.5 Mmt (8.3 million st). Steel capacity was 103 Mmt (114 million

st). Voluntary agreements limiting imports terminated in March 1992. Net imports of steel totaled 10.5 Mmt (11.6 million st).

There was no domestic mining of chromium, cobalt, or manganese. The Glenbrook Mine, in Riddle, OR, produced 5.5 kmt (6,100 st) of nickel in concentrates and 9.1 kmt (10,000 st) of ferronickel.

Some tungsten and vanadium were mined. Upgrading of Government-stockpiled ores to ferrochromium and ferromanganese continued. This helped maintain some domestic ferroalloy production capacity.

Primary aluminum smelters ran close to capacity, producing 4 Mmt (4.4 million st). Some bauxite was mined but most came from imports of 12 Mmt (13 million st). That was supplemented by net imports of 4 Mmt (4.4 million st) of alumina.

Magnesium production totaled 135 kmt (149,000 st). Titanium mill shipments totaled 16 kmt (18,000 st). Copper production rose 5% to 1.7 Mmt (1.9 million st), and refinery production of 2.1 Mmt (2.3 million st) treated four-fifths primary material and one-fifth scrap.

Lead mining fell 14% to 410 kmt (450,000 st), and zinc mining rose slightly to 520 kmt (570,000 st). Primary refined lead of 300 kmt (330,000 st) was supplemented by 830 kmt (915,000 st) refined from old scrap. About 255 kmt (280,000 st) of primary slab zinc was supplemented by 125 kmt (140,000 st) of secondary plus net imports of 320 kmt (350,000 st).

According to *Metals Week*, yearly lows and highs were as follows:

- copper—98 cents to \$1.21/pound (lb),
- aluminum-51 cents to 65 cents/lb,
- lead—32 cents to 39 cents/lb, and
- zinc—48 cents to 69 cents/lb.

Precious Metals.—In 1992, mines in the United States yielded 320 mt [10.3 million ounces (oz)] of gold and 1.8 kilograms (kg) (58 million oz) of silver. About 10% of the gold and 60% of the silver were a byproduct of base metal mining.

The Stillwater Complex in Montana

produced 1.7 tons (55,000 oz) of platinum and 6.1 tons (195,000 oz) of palladium last year.

Nonmetallics.—Cement production rose 7% to 69 Mmt (76 million st). Four thousand quarries produced 1.1 billion mt (1.2 billion st) of crushed stone, and 4,200 sand and gravel pits produced 750 Mmt (8.30 million st). One thousand clay pits produced 38 Mmt (42 million st), and 61 gypsum mines produced 15 Mmt (16 million st).

About 460 kmt (510,000 st) of magnesium compounds was produced from brines and seawater. An estimated 1.1 Mmt (1.2 million st) of titanium dioxide pigments was produced from domestic and imported minerals.

Sulfur production totaled 10.6 Mmt (11.7 million st), 22% by the Frasch process. Production of other major nonmetallics included 36 Mmt (40 million st) of salt, 16 Mmt (18 million st) of lime, 9.5 Mmt (10.5 million st) of soda ash, and 520 kmt (570,000 st) of B_2O_3 .

Fertilizers.—Mining of fertilizer minerals was essentially unchanged from 1991. Phosphate rock totaled 47 Mmt (52 million st) and potash 1.8 Mmt (2 million st) of K₂O. To that were added 13 Mmt (14 million st) of ammonia. Significant quantities of ammonia and potash are also imported.

Outlook.—The breakup of the U.S.S.R. and the lessening of cold war tensions led to reexaminations of the U.S. strategic posture. This included the roles of the United States-Canada North American Defense Industrial Base and the U.S. stockpile of strategic and critical materials.

The U.S. Department of Defense (DOD) reported to Congress that substantial reduction of stockpile goals and major disposals of stockpile inventories might be possible. In October 1992, Congress authorized the disposal of some stockpiled materials, largely minerals, valued at \$4 billion. To ensure that such disposals (and possibly some acquisitions of new high-technology

materials) did not unduly interfere with the normal markets, Congress specified two major levels of review—one at the DOD level and one at the Presidential level.

In early 1993, the DOD Defense Logistics Agency (DLA) and its Market Impact Committee met frequently. The DLA then held several open meetings with industry to develop acceptable disposal methods.

Meanwhile, economic disorder in the Commonwealth of Independent States (C.I.S.) (the former U.S.S.R.) led to substantial dumping of former Soviet stockpiles of strategic metals, forcing metal prices to soften in a period of general worldwide economic malaise.

Foreign ownership of domestic mines and quarries is increasing, and there is excess world productive capacity for many minerals and metals. Traditional metals and alloys are being replaced by newer engineered materials based on geologically abundant elements, such as carbon, silicon, oxygen, and nitrogen, but costly sophisticated processing For example, the United required. States' production of plastics totaled 30 Mmt (33 million st)—nearly double all metals on a volume basis.

Concerns about global climate change, acid rain, and industrial hazards are leading to more stringent regulations by Federal, State, and local governments. Land use and air and water issues concern the citizens of many lands. The venerable Mining Law of 1872 is scheduled for review and updating by Congress in 1993.

To ameliorate environmental and health and safety problems and to better meet global competitiveness challenges, the U.S. Bureau of Mines (USBM), with its seven Generic Mineral Technology Centers and 30 Mineral Institutes, continues collaborative government-industry-university innovative research in mineral science and technology.

Production Overview

The mineral industry experienced little growth in 1992. The value of processed materials of mineral origin was estimated

at approximately \$310 billion in 1992. The value of U.S. raw nonfuel mineral production in 1992 was estimated at approximately \$32 billion, a 3% increase over that of 1991.

U.S. raw mineral trade declined moderately in 1992. Imports of metal ores and concentrates decreased by almost 5% to \$1.2 billion, while raw industrial mineral imports declined nearly 14% to \$700 million. Similarly, metal ore and concentrate exports fell almost 12% to \$900 million. Raw industrial mineral exports departed from this trend, managing a modest increase of about 1% to \$1.1 billion.

Both metals and industrial mineral mining employment showed modest Together, that decreases in 1992. resulted in a decline of 4.2% for the Considered separately, total employment in industrial mineral mining declined 4.7% to 100,000 workers. Production workers decreased 5.4% to Such declines continued to reflect the weak construction industry leading to relatively flat production of stone, sand, and gravel. Metals mining experienced smaller declines, with total employment falling 3.2% to 54,400, and the number of production workers declining 3.0% to 42,400.

Industrial Minerals

The industrial mineral industry has been slowed in recent years by reduced commercial building construction, which prevailed throughout much of 1992 due to a glut of office buildings, hotels, and other commercial properties. This glut helped dull the performance of crushed stone and sand and gravel industries. Overall, industrial mineral production gained 2% in 1992, and the results were mixed for sand and gravel and crushed stone. The value of production rose about 3% for construction sand and gravel and 4.5% for crushed stone.

U.S. demand for cement (excluding Puerto Rico) increased by 7.6% to 81 Mmt (87 million st). This was the first year cement demand increased since 1987. The cement production increase was due to growth in residential,

nonresidential, and highway construction spending. Plans to stimulate the economy, through Federal, State, and local investments, were under discussion in early 1993.

Agricultural Minerals

Mining of fertilizer minerals was essentially unchanged from 1991. Phosphate rock totaled 47 Mmt (52 million st) and potash 1.8 Mmt (2 million st) K_2O . To that was added 13 Mmt (14 million st) of ammonia. Significant quantities of ammonia and potash also were imported.

The past decade has not been good to the fertilizer industry for many reasons, including plenty of supply coupled with depressed farm prices that stifled demand, closures of mines in Florida, and recent events in Eastern Europe and the C.I.S. In 1992, some activity was noted that may signal the beginning of a slow recovery. Increased demand should gradually occur for sulfates, phosphates, and potash on a worldwide basis, particularly in developing Far East countries where agricultural activity is expected to grow.

Metals

Aluminum.—Throughout 1992, the United States remained almost totally dependent on foreign sources of bauxite for production of primary aluminum metal. U.S. primary aluminum smelters ran close to capacity, producing 4 Mmt (4.4 million st). Some bauxite was mined but most came from imports of 12 Mmt million st) of alumina. Approximately 93% of the domestic and imported bauxite consumed in 1992 was refined into alumina. Primary aluminum smelters received 85% of the alumina supply. Annual alumina capacity was 5 Mmt (5.6 million st), with five Bayer refineries in operation at yearend.

On a global basis, increases in primary aluminum consumption have not kept pace with increases in production capacity. World primary aluminum consumption has stayed relatively constant since 1988. Large inventories of

primary aluminum continue to have a dampening effect on prices, according to the Commerce Department, but producers did not cut back, largely because they have been successful in lowering costs. Commerce estimates the use of aluminum in autos will increase in the next decade as automakers strive to meet future fuel efficiency standards.

Iron and Steel.—In many respects, 1992 was an improvement over the steel industry performance of 1991. Steel production rose 5% to 84 Mmt (93 million st). Iron ore mining rose 1% to 56 Mmt (62 million st), nearly all pelletized. Net ore imports fell 20% to 7.5 Mmt (8.3 million st). Steel capacity was 103 Mmt (114 million st).

Voluntary Restraint Agreements (VRA's) expired in March 1992, and it was hoped they would be replaced with a multilateral steel agreement binding all nations that trade in steel. This agreement had not yet been reached as of early 1993. In mid-1992, about 12 U.S. steel companies filed countervailing duty and antidumping petitions with the Commerce Department of and International Trade Commission. petitions charged 21 foreign countries with market-distorting subsidization and dumping practices. The procedure on these cases continued into 1993.

Copper.—Domestic mine production in 1992 was about 1.5 Mmt (1.7 million st), valued at \$4.1 billion. As in previous copper managed to recessionary conditions. Copper prices, having fallen far less precipitously than those of other base metals in the previous couple of years, dropped no more steeply than the average in 1992. That allowed most producers to continue to record respectable profits. Copper consumption improved in the United States and was estimated to be about 8% higher than that U.S. exports of copper in 1991. materials and semifabricates continued to be high, prompted by the demand from Canada, the Far East, and Mexico.

Lead.—After considerable growth in

refinery production and domestic consumption during 1987-89 and a leveling out in 1990, all sectors in 1992 continued to reflect recessionary conditions. World demand declined for the third year in a row, with supply ahead of demand. An increase in mine output was most noticeable in Canada, while declines were most apparent in the United States and Europe. U.S. lead mining fell 14% to 410 kmt (450,000 st). Primary refined lead of 300 kmt (330,000 st) was supplemented by 830 kmt (915,000 st) refined from old scrap.

Zinc.—Domestic zinc mine production was only marginally higher than in the previous year but, nonetheless, was the highest since 1965. Zinc mining rose slightly to 520 kmt (570,000 st). About 255 kmt (280,000 st) of primary slab zinc was supplemented by 125 kmt (140,000 st) of secondary plus net imports of 320 kmt (350,000 st). Two zinc-producing mines, one in Oregon and the other in Tennessee, opened in 1992. Alaska again accounted for about one-half of the U.S. total output, even though the Red Dog Mine in northwestern Alaska continued to produce below rated capacity.

Galvanizing represents the largest end use of zinc in the United States, and an increase in demand by the two largest users—autos and construction—accounted for a 7.2% increase in consumption in 1992. By 1996, almost all cars and light-duty trucks with steel bodies sold domestically will be made from two-sided galvanized steel.

Precious Metals

Gold.—U.S. gold production yielded 320 tons (10.3 million oz of gold). Despite continuing weak gold prices, the United States maintained its position as the world's second largest gold-producing nation, after the Republic of South Africa. Nevada and California were again the Nation's dominant gold-producing states, together accounting for about 70% of the U.S. total. U.S. gold exploration activity, having peaked about 1988, continued to trend downward.

Estimated uses in 1992 were as follows: jewelry and arts, 70%; industrial (mainly electronic), 23%; and dental, 7%. Environmental pollution abatement continued to be of concern to domestic gold producers, especially in Alaska, where there are many small placer mines.

Silver.—U.S. silver recovery yielded 1.8 kmt (58 million oz) silver. About 60% of the silver was a byproduct of base metal mining. U.S. silver production declined for the second consecutive year. During 1991, operating levels at a number of silver-producing mines were reduced or the mines were temporarily idled. In 1992, operations at these mines generally remined unchanged. The low silver price was cited most often by company officials when announcing mine closures or reduced production rates. Approximately 50% of the refined silver consumed domestically during 1992 was used in the manufacture of photographic products; 21% in electrical electronic products: electroplated ware, sterlingware, and iewelry; and 20% in other uses.

Platinum-Group Metals.-U.S. production of platinum and palladium in 1992 was held at about the same level as that in 1991. Ore containing the platinum-group metals (PGM) was mined, concentrated, and smelted by the Stillwater Mining Co. (SMC), in Nye, The resultant PGM matte was exported to Belgium for refining and separation of the individual PGM. The Stillwater operation produced 1.7 tons (55,000 oz) of platinum and 6.1 tons (195,000 oz) of palladium in 1992. Refined PGM products were distributed among using industries as follows: electrical automative, 38%; electronic, 29%; dental and medical, 9%; chemical, 4%; petroleum refining, 5%; and other, 15%. The automotive, chemical, and petroleum-refining industries used PGM mainly as catalysts. Mine production of PGM was valued at \$38 million in 1992.

Second National Minerals Education

Conference

USBM personnel participated in the second National Minerals Conference, held in Salt Lake City, UT, in June 1993. The National Energy Foundation (NEF) coordinated the conference, with cosponsors including the USBM. American Mining Congress, National Coal Association, and mining associations from Arizona, California, Idaho, Nevada, and Utah. Participating organizations and corporate cosponsors included Caterpillar Inc., Freeport McMoRan, Kennecott Corp., American Coal Foundation, Mineral Information Institute, and the NEF. The NEF conference provided a forum to share ideas, learn what programs are working for others, review educational initiatives underway, and support educational reform.

Incentive Bonus Systems

Mining companies continue to use incentive bonus plans as part of their wage systems in 1992. As an example, after a strike was narrowly averted in 1989, Magma Copper Co. of Arizona realized that its future depended on a major improvement in labor relations. The company began applying innovative human resources programs that directly involved the employee in building a future for the company. The result of 2 1/2 years and 400,000 management and employee hours was a historic 15-year labor agreement and a highly participative work culture.

Instilling this participative culture is ongoing and, in 1992, each of Magma's divisions designed and initiated programs aimed at involving all employees in the running of the operations.

Gainsharing programs were adopted by Magma in 1991. Each division has its own specific gainsharing plan that focuses on performance objectives within the control of employees.

In 1992, Magma and its employees reduced costs by \$0.05 per pound and improved productivity by 12 % over 1991 levels. Employees eligible for gainsharing were paid an average of \$4,750 per person in gainsharing awards.

Mexico Adopts New Mining Law

The Mexican Government published a new Mining Law in July 1992 that regulates Article 27 of the 1917 Mexican Constitution and will be enforced by the Federal Executive Branch through the Secretaria de Energia, Minas e Industria Paraestatal (SEMIP). In terms of the effect on foreign participation in the mining industry, the new Mining Law is much more important than NAFTA, which has little effect on the mining industry.

The new Mining Law allows the private sector to play a much larger role in the mining industry as the Government of Mexico continues to privatize Stateowned companies, divest its mining reserves. encourage and domestic investment and foreign participation in the mining industry. The law allows direct investment, with up to 100% ownership of the capital stock, in exploration works and activities. Through a 30-year trust mechanism, it allows up to 100% of the capital stock that is renewable indefinitely for foreign participation in mining works and activities. The new Mining Law clearly spells out the ores or substances covered by the law and provides greater legal security for holders of exploration and exploitation concessions. The law allows private-sector participation in the exploitation of mineral deposits previously considered as priority and strategic within the domain of Government ownership, such as coal, iron ore, phosphate rock, potassium, and The law extends the term of exploitation concessions from 25 to 50 years, renewable for a similar period, while exploration concessions will be for nonrenewable 6-year periods. Through competitive bidding, it allows exploration and mining for minerals on the continental shelf and underwater shelves of islands, as well as the seabed and the subsoil of the exclusive economic zone. A limiting factor of these concessions is that they are nontransferable.

Some examples of substances not covered by the 1992 Mining Law are as follows:

- petroleum and solid, liquid, or gaseous hydrogen carbides;
- radioactive minerals;
- substances contained in suspension or dissolution by subterranean waters; and
- salt that comes from salt pits formed in basins.

The Mining Law eliminates the need for concessions for ore preparation plants, and the system of substances incorporated in the national mining reserves is eliminated. The individuals engaged in processing minerals subject to this law will be obliged to inform SEMIP when their operations begin, submit the relevant reports, and comply with the general regulations and specific technical standards in the area of environmental balance.

The law brings greater flexibility to the management of mining affairs: eliminates repetitive excessive. obligations and red tape; stimulates smalland medium-scale mining production; and promotes private-sector investment in exploration and mining activities. The beneficial aspects of the 1992 Mining Law, combined with the reduction of corporate income tax to 35% in 1989 and the elimination of the mineral production tax in 1991, have led to an increase in large mining projects being launched with the participation of domestic and international private capital. During 1990 and 1991, almost \$1 billion was invested in the Mexican mining sector, twice the rate of investment in 1989. To date, about 3.9 million hectares of national mining reserves has been divested. In addition, to encourage the exploitation of mineral deposits, the number of mining titles issued has doubled from 2,000 annually to more than 4,200, and the land area covered by concessions has increased from 2.8 million hectares.

LEGISLATION AND GOVERNMENT ACTIONS

Revision of the U.S. Mining Law of 1872

The Mining Law of 1872 established a policy of "self-initiation," whereby a

prospector could file an unpatented mining claim if he made a discovery of a valuable mineral. The filing of a claim establishes a property right to the minerals, subject to annual assessment and work requirements. The claimant can purchase (patent) the surface rights to a valuable mineral deposit after spending at least \$500 in development and paying the appropriate filing fees. A typical claimant may invest \$250,000 in development prior to being issued a patent according to mining industry estimates.

In an effort to restructure the Mining Law of 1872, both Senator Bumpers (S. 433) and Congressmen Rahall (H.R. 918) and Defazio (H.R. 2614) introduced and later modified bills in the 102d Congress to provide comprehensive changes. Key arguments against the current law included (1) inadequate control of environmental damage, (2) patenting of surface ownership for less than fair market value, (3) lack of financial return to the Government (royalties), and (4) nonmining abuses of claims.

On June 24, 1992, the House Committee on Interior and Insular Affairs approved, with amendments, a substitute to H.R. 918 offered by Mining Subcommittee Chairman Rahall. As in the original bill, the substitute gave jurisdiction over U.S. Forest Service lands to the Secretary of Agriculture; withdrew "common variety" materials and some "environmentally sensitive" areas from operation of the law; eliminated extralateral rights and patents, as well as the requirements for discovery; afforded claimants' exclusive rights of possession for mineral activities; and specified claim location and maintenance requirements, including a graduated per acre annual rental fee. It also required that mineral activities be compatible with land use planning and be covered by an approved plan of operation, including a reclamation plan and bonding for the full cost of reclamation. The bill established and funded an Abandoned Minerals Mine Reclamation Fund. Current claimants would be required to convert their claims within 3 years.

The substitute to H.R. 918 did. however. contain some significant changes from the original bill. changed the original diligence requirements to allow an offset in rental fees for the amount of diligent development expended and it established detailed reclamation standards. Instead of identifying all mineral lands on public domain lands as part of the land planning process, it required that land use plans be amended for all areas unsuitable for mineral activities and the criteria that could be used to determine unsuitability were greatly expanded. Amendments to the substitute added an 8% gross income royalty on production on mining claims located under the act and a small miner exemption to waive or reduce rentals and diligence expenditures. H.R. 918 was not considered by the full House in 1992.

Also during 1992, Senator Bumpers considered a significant amendment to his original bill S. 433. Although the original bill represented a complete restructuring of the law, the substitute preserved many of the current principles, including mining claim location, recordation, and patenting. Jurisdiction over Forest Service lands would have transferred to the Secretary Agriculture. The substitute, however, would have established a graduated per acre annual holding fee, to be split between the States and Federal Treasury, and imposed a term limit on mining claims of 15 years, with a possible 5-year Reclamation plans and extension. financial guarantees were required, and some reclamation criteria were specified. Neither S. 433, in its original nor proposed substitute, received further consideration by the Senate Energy Committee in 1992.

In his June 23, 1992, letter to House Interior Committee Chairman Miller, Secretary Lujan expressed his strong opposition to the Rahall substitute to H.R. 918, a position consistent with earlier Department comments on the text of H.R. 918 and S. 433. Although the Bush administration supported possible changes in the areas of annual labor, distinction between "common varieties" of mineral materials subject to sale and "uncommon

varieties" subject to location under the Mining Law, and the matter of obtaining a fair return to the Government for surface use and for issuance of a patent, it felt that any change had to support four principles of the current Mining Law: (1) self-initiation of mineral rights, (2) free access across public lands, (3) security of tenure to mineral deposits, and (4) diligence that is self-policing.

As in fiscal year 1992, the President's fiscal year 1993 budget request included a \$100 annual holding fee per unpatented mining claim, mill site, and tunnel site previously estimated to generate revenues of \$97.5 million in 1992. Of this amount, \$17.3 million would be retained by BLM to cover administrative costs and the remaining \$80.2 million would be deposited in the General Fund of the Treasury. H.R. 5503, providing appropriations for the Department of the Interior for fiscal year 1993, passed the House on July 23, 1992, and included the \$100 holding fee supported by the administration. It also contained a 1-year patent moratorium. When the Senate passed H.R. 5503 on August 6, 1992, the holding fee provision was retained, but a patent moratorium amendment offered by Senator Bumpers was replaced by an amendment providing Mining Law structural reforms sponsored by Senators Reid, Dominici, DeConcini, and Bryan.

The Reid reforms replace the extant \$2.50 and \$5 per acre patent fees with a requirement to pay fair market value for the surface estate. Patented claims would revert to Federal ownership if used for unauthorized or unapproved purposes. Surface reclamation requirements would be codified within the structure of the Mining Law. Following the failure of a motion to table the Reid amendment on August 5, 1992, by a vote of 45 to 52, the amendment was accepted to H.R. 5503 by voice vote. In addition, on August 6, 1992, an amendment to H.R. 5503 offered by Senators Reid and Bumpers to require reclamation bonding at the outset of mining operations was adopted by voice vote.

The Reid-sponsored, Senate-passed provisions did not survive the House/Senate Conference. The \$100

holding fee, however, adopted by both bodies, was nonconferenceable. Under this provision, a mining claimant must pay the fee unless (1) he or she is producing \$1,500 to \$800,000 per year of minerals on less than 10 claims, (2) he or she is exploring 10 or fewer claims, or (3) he or she has 10 acres or less of unreclaimed land, either in production or in exploration.

In the fall of 1992, the BLM developed regulations covering the payment of the \$100 holding fee. Existing claimants still were required to file the old affidavit of \$100 assessment work for the September 1, 1991, through September 1, 1992, mining year by December 30, 1992. Because Congress made the holding fee a 2-year requirement, claimants also are required to pay the fee for the September 1, 1992, through August 31, 1993, mining year and September 1, 1993, through August 31, 1994, mining year at the same time. Thus, many miners were required to make a double payment in August 1993. For claims staked after October, 5, 1992, claimants must (1) file the usual certificate of location with BLM with a \$10 payment, plus (2) pay immediately the \$100 rental for the mining year that runs through August 31, 1993.

Resource Conservation and Recovery Act

During 1992, considerable Environmental Protection Agency (EPA) activities focused on attempts to reissue its "mixture and derived-from" rules under the Resource Conservation and Recovery Act (RCRA). These rules were adjudicated invalid on procedural grounds by the U.S. Court of Appeals for the District of Columbia in late 1991. The court indicated that EPA had not elicited sufficient public comment on the rules prior to its finalization and remanded to the Agency for repromulgation. rules had required that any wastes mixed with or derived from a hazardous substance must be treated as hazardous wastes under RCRA. After the refusal of the District of Columbia Court to rule on whether or not its decision

retroactive, the Eighth Circuit overturned a RCRA conviction because of the invalidation of the EPA rules. Sources have commented that these developments could lead to relitigation of many cases by EPA.

Although RCRA was not reauthorized in 1992, significant congressional activity centered on consideration of relevant issues. Topics debated included toxic use reduction, enhanced chemical production reporting, and possible limitation of the statute to municipal solid waste concerns. H.R. 3865, the RCRA package of Representative Al Swift, Chairman of the House subcommittee on Transportation and Hazardous Materials and of the House committee on Energy and Commerce, was a major bill considered. Prior to markup by full committee, there were no provisions directly relating to mine waste management. During the markup, the subcommittee rejected an amendment that would have required EPA to consider the "practicable capabilities" of Senate Environment & Public Works Committee, chaired by Senator Quentin Burdick, and passed its RCRA reauthorization bill, S. 976, on May 20, 1992. This bill did not contain provisions directly impacting management of mine waste. However, sources have said that the bill faces an uncertain future because of industry's opposition to recycling requirements and to the bill's reporting demands for facilities that use toxic chemicals. The environmentalists contend that the demands of the bill are too weak.

Clean Water Act Reauthorization

Efforts to reauthorize the Clean Water Act (CWA) took a back seat to RCRA bills during 1992 and also encountered a divided Senate in approaches to reauthorization. The issue of how to reform wetlands provisions of the CWA became the critical hurdle that prevented progress in the Senate on reauthorization. The House did not take up comprehensive clean water reauthorization. When the 103d Congress convenes, CWA reauthorization is expected to be at the top of the legislative agenda.

Reauthorization proposals are likely to focus on watershed planning with pollution prevention and pollution from nonpoint sources receiving much attention. This focus may potentially have a significant impact on mining activities, especially for the control of wet weather runoff.

Stormwater Permits.—The 1987 amendments to the CWA mandated a two-phase program to control stormwater runoff. Under the program, municipalities and various industries must apply for permits. Phase 1 covers large municipalities and stormwater discharges associated with industrial activity. The industrial activity category covers about 31 sectors, including metal mining, coal mining, and mining and quarrying of nonmetallic minerals. In April, the EPA issued a final rule for the submission of individual permit applications by October 1, 1992. A permit model for individual industrial permits, outlining the classes of dischargers and data that must be reported, was issued in late September. Under the model, all facilities must develop a site-specific stormwater pollution prevention plan that describes on-site pollution sources and identifies pollution prevention measures controls. The number of pollutants to be monitored and amount of monitoring data needed have been subjects of controversy between industry and the EPA in developing the monitoring group criteria for the permits. It is expected that EPA will issue its final group application requirements in October 1993.

Wetlands.—The controversy over Federal wetlands regulatory reform continued during 1992. Several divergent wetland bills were given attention in Congress. The Wetlands Reform Act of 1992, H.R. 4255, had the backing of environmentalists seeking to boost wetlands protection by strengthening the EPA permitting role and expanding the number of activities requiring a permit. Another bill, the Comprehensive Wetlands Conservation and Management Act of 1991, H.R. 1330, was an industry

supported bill reintroduced in the 102d Congress that would limit the EPA wetlands permit veto authority. The bill also would classify wetlands into high, medium, and low value wetlands and would allow development to occur in the low value wetlands without a permit. Also at issue were which of several existing manuals to use for identifying wetlands. This issue may be resolved by a National Academy of Sciences study funded by Congress in the fall of 1992. The study will be completed by the fall of 1994 and will cover wetlands delineation.

In another wetlands development, EPA has developed a proposal as part of the settlement in the "Tulloch" case. The proposal should expand Federal authority to regulate a variety of wetland activities, including ditching, draining, excavation, and other development-related actions. This could significantly affect mining and other earth disturbing projects conducted in wetland areas.

Ecosystems and Endangered Species

Concern with the effects of economic activity on the environment continued, as reflected in the controversy over the Northwest Spotted Owl. Although most agreed with the objective of protecting the old growth forests that host the owl and other species, the high cost in jobs and incomes for northwest logging communities seemed high. The controversy illustrated what the Secretary of the Interior Bruce Babbitt referred to as a "train wreck"—the inevitable conflict and collision of environmental and economic interests under the current approach that focuses on a single specie (the owl, the desert tortoise, or limestone endemic plants in the California desert). During recent years, recognition of this problem has resulted in an "ecosystems" approach to the management of public increasingly, to other lands and, environmental issues. In this approach, the interactions of plants, animals, and their physical environment are considered in the development of environmental policy. The U.S. Forest Service, the BLM, the EPA, the Corps of Engineers, and the U.S. Fish and Wildlife Service are all involved in the development of this new approach and are currently working on definitions and guidelines. The evolution of policies awaiting reauthorization such as the CWA, and the Endangered Species, and any new environmental legislation are likely to be heavily influenced by the ecosystems approach.

Clean Air Act Amendments 1990

Passage of the Clean Air Act Amendments has significant and longterm consequences for U.S. minerals industry competitiveness. The act applies directly to metallurgical processing through the control of emissions of toxic substances. Indirectly, the act affects the cost of energy for the minerals industry as powerplants pass through higher compliance costs for acid rain reduction regulations requiring scrubbing or the use of higher cost low-sulfur coal. "Bureau studies have revealed that the average cost increase could be 2.5 to 4 cents per pound of aluminum metal, 2.5 to 4.5 cents per pound silicon metal, and 2 to 3 cents for ore-grade ferrosilicon, as a consequence of the acid rain provisions of the Clean Air Act. "1

Section 169B of the Clean Air Act Amendments of 1990 authorized the creation of visibility commissions to study regional impacts of emissions on visibility. The Grand Canyon Visibility Transport Commission (GCVTC) was created to study visibility issues in the socalled Golden Circle class I area encompassing large areas of Arizona, Colorado, New Mexico, and Utah, and is the prototype for future commissions. The work of the GCVTC continues. "The scope of the class I area of concern and the transport region shows that [GCVTC] findings will have potential to affect major portions of the western minerals industry."2

Title III of the Clean Air Act Amendments of 1990 requires the establishment of maximum achievable control technology (MACT) standards for major and area sources of hazardous air pollutants. For the smelters, EPA has initiated the MACT process with a study

of copper smelters. EPA is also gathering information related to potential revisions to the primary National Ambient Air Quality Standard (NAAQS) for sulfur dioxide (SO₂). Of primary concern is EPA's focus on a short-term SO₂ standard protective of exercising asthmatics. These two developments have potential to increase costs to nonferrous smelters.

Off-road diesel emissions is another potential cost raiser for mines, especially if the "construction equipment" category is extended to mining vehicles.

The EPA is developing new rules for prevention of significant deterioration (PSD) and nonattainment that pertain to construction and modification of major sources. Revisions to attainment and nonattainment areas for criteria pollutants such as SO₂ and PM-10 are being reported to EPA by States. These changes could impact minerals-related activities within these changing boundaries.

The EPA will issue a notice of proposed rulemaking in November 1993 regarding standards for secondary lead smelters under its hazardous air pollutant authorities.

Summarizing, new regulations will continue to add cost to minerals-related activities in the United States, and U.S. relative competitiveness will continue to be a concern.

NAFTA

On August 12, 1992, 14 months after the formal start of negotiations, the United States, Canada, and Mexico announced completion of the NAFTA. The NAFTA is a regionwide trade agreement that will progressively eliminate tariffs and nontariff barriers to trade in goods, improve access for service trade, establish fair rules for investment, strengthen protection of intellectual property rights, and create an effective dispute settlement mechanism.

The United States negotiated NAFTA under the "fast track" procedures of the Trade Act of 1974 and the rules set forth in the 1988 Trade Act governing the application of fast track procedures to bills implementing certain types of trade

agreements. Pursuant to those rules, the President notified Congress on September 18, 1992, of his intent to sign the NAFTA. The NAFTA text was initiated by Ministers at a meeting of the three heads of state on October 7, 1992, in San Antonio, TX. The three heads of state signed the NAFTA in their respective capitals on December 17, 1992. The next step will be consideration by the Congress of NAFTA implementing legislation.

Proposed Multilateral Steel Trade Agreement

On July 25, 1989, the administration established the Steel Trade Liberalization Program. The program's ultimate goal was to ensure that market forces, not governments, determine prices and the level and pattern in international steel markets.

The first phase of the program included the negotiation of 10 bilateral consensus agreements to eliminate trade-distorting practices in the steel sector and the extension of the steel VRA's. These agreements were terminated as scheduled in March 1992.

Under the terms of the program, after March 31, 1992, domestic producers would have to rely on domestic trade laws to remedy foreign trade distorting practices. On June 30, U.S. producers filed 84 antidumping and countervailing duty investigation reports against imports of certain flat-rolled steel from 20 countries. These petitions, and others on certain other steel imports, were investigated by the U.S. Department of Commerce and the International Trade Commission.

Anticipating the expiration of the VRA's and bilateral consensus agreements on March 31, 1992, the United States has concentrated its efforts on incorporating the obligations and disciplines of the bilateral agreements into a multilateral accord within the General Agreement on Trade and Tariffs (GATT). This multilateral effort builds upon the rules established in the bilateral consensus agreements.

More than 30 countries have been

participating in the multilateral steel negotiations, including the bilateral consensus counties and others, such as Argentina, Canada, and Sweden. The principal U.S. objectives for a multilateral agreement include prohibitions against most subsidies and the establishment of an effective mechanism to resolve disputes. Negotiations toward a multilateral steel agreement are expected to continue into 1993.

Lead-Acid Battery Recycling

Lead-acid batteries are the Nation's most recycled commodity. Lead-acid battery recycling has generally been increasing in recent years, reaching 97% in 1991. Fifteen companies operated 20 battery-breaking plants and 22 smelter-refineries in 1992.

Plant capacities ranged from 10,000 to more than 100,000 tons annually. Two such plants in Ohio and Tennessee remained temporarily shut down, and some others had curtailed operations. A major battery recycling plant in Alabama was permanently closed by the EPA early in the year. Operations were indefinitely suspended at a smaller battery recycler at midyear in Tennessee, but this was offset by Refined Metal's Memphis, TN, plant coming back on-stream. A new, small battery recycler came partially on-stream in Ohio, but was not producing at yearend owing to financial and technical problems.

The Doe Run Co.'s new \$38 million lead-acid battery recycling center in Boss, MO, (100 miles south of its headquarters) was in its first full year of operation and produced at full capacity. The facility is designed to produce up to 60,000 tons of refined lead from 120,000 tons of used batteries. It was designed to produce one-third the volume of hazardous waste normally associated with battery recycling operations.

Several bills relating to recycling of lead-acid batteries were introduced in Congress in 1991, but had not been acted upon. Most were not reintroduced in Congress in 1992. One bill, H.R. 2479 (essentially a revamping of H.R. 2922

introduced in 1991), was introduced in June 1993 by Representative Carden (Maryland). It was titled "The Lead-Acid Paint Hazard Abatement Trust Fund Act of 1993" and intended to tax all (both primary and secondary) lead production at \$0.045 per pound to pay for a \$1 billion trust fund for a lead abatement project. A parallel bill was introduced in the Senate by Senator Bradley (New Jersey).

A major reason for such a high recycling rate is the enactment of mandatory battery collection and recycling laws in 42 States. These States account for more than 85% of the Nation's population. These State laws are substantially based on a lead-acid battery collection and recycling reverse distribution system. Under this system. retailers, wholesalers, manufacturers, and automotive dismantlers accept used leadacid batteries from customers for delivery to secondary lead smelters, collection, or recycling facilities regulated by the States or subject to regulation by EPA under Federal law.

Basel Convention

The Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and Their Disposal "Basel Convention" is an international agreement dealing with the export and import of hazardous wastes. The United States signed the Basel Convention on March 1990. However, to implement the Convention in the United States, Senate ratification is required, and legislation must be passed to provide the necessary statutory authority.

The Basel Convention requires that hazardous wastes be disposed in an environmentally sound manner, regardless of the nation in which the disposal takes place, and requires that governments prohibit exports of hazardous wastes unless they can be sure that the hazardous wastes will be properly handled and disposed in the receiving nation. Although most scrap metal nonhazardous, almost all scrap metal still will be subject to the Convention, even when they are being transported for the purpose of recycling. If all metal wastes and scrap were subject to the Basel Convention procedures, it would be costly and disruptive to trade in the minerals and metals industries. Transactions would be unnecessarily delayed at best. Some transactions would be aborted because of delay, and added cost would alter the economics of the transaction.

The Basel Convention allows nations to make bilateral or multilateral agreements, as long as the underlying requirements are not compromised. Such agreements could modify the "notification," "consent," and "document" requirements. The United States already has agreements in place with Canada and Mexico. The United States also entered into an agreement to regulate the transboundary movement of hazardous recyclable materials among the Organization for Economic Cooperation and Development (OECD) nations. The negotiation of additional agreements with every nation with whom the U.S. trades may prove to be burdensome to the agencies involved; i.e., State and EPA. Much of U.S. trade in metal scrap is with other nations such as China, India, the Republic of Korea, and Taiwan.

The Convention entered into force on May 5, 1992, 90 days after ratification by Australia, the 20th nation to ratify. The first meeting of the Conference of the Parties (COP) to the Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and Their Disposal was held November 30 to December 4, 1992, at Piriapolis, Uruguay. The United States participated at the Initial Conference of the Parties as an observer. The second meeting of the COP to the Basel Convention will be scheduled for February or March 1994.

As of September 1993, 46 nations have ratified the Convention, but the United States is still not one of these. During the 102d Congress, none of the numerous draft bills continuing Basel Convention-implementing language was passed. In July 1993, the Clinton administration began the process of drafting new Basel-implementing legislation. This task will be completed

as an interagency process lead by the EPA, and the EPA will be negotiating with both houses of Congress to avoid conflicts as much as possible. The U.S. Senate ratified the Basel Convention on August 11, 1992, but the State Department is not delivering the instrument of ratification to the United Nations until implementing legislation is passed by Congress. After the instrument of ratification is delivered to the United Nations, a 90-day period must pass before the United States will be recognized as a party of the Convention.

Trade Issues

NAFTA.—The United States, Canada and Mexico on December 17, 1992, signed the NAFTA, a regionwide trade agreement that will progressively eliminate tariffs and nontariff barriers to trade in goods: improve access for services trade: establish rules for investment; strengthen protection of intellectual property rights; and create an effective dispute settlement mechanism. The three countries on August 13, 1993, completed negotiation of supplemental concerning labor, agreements environment. and import surges. NAFTA is scheduled to enter into force on January 1, 1994, subject to domestic approval and implementation procedures in the respective countries.

The 1917 Mexican Constitution makes subsoil resources and minerals the property of the Nation, and companies wishing to open mining operations must obtain concessions from the Government. Such concessions are only granted to Mexican nationals or majority-owned Mexican firms.

In September 1990, Mexico issued new mining regulations that included permission for foreigners to control up to 100% of mining properties through trusts for up to 12 years. In 1992, a new Mining Law was promulgated (published) under which the private sector, including foreigners, will be able to exploit coal, iron, potassium, phosphorous rock, and sulfur. The State will retain total or majority control over oil and hydrocarbons, salt, radioactive minerals,

deepsea suspended particles, and construction-grade stone. The law also sets the stage for the privatization of several State-owned mining companies.

Five years after the NAFTA takes effect, U.S. companies will be given national treatment and may obtain concessions on the same basis as Mexican companies.

GATT.—GATT market access talks continued in 1992 in Geneva. Australia, Canada, and the United States continued to pursue zero-for-zero in nonferrous metals. Zero-for-zero means the mutual elimination of tariffs among key trading partners. France continued to oppose tariff elimination in aluminum, but Japan's position on copper appeared to be softening.

In July 1993, the Quad countries (Canada, the European Community, Japan, and United States) reached agreement on the minimum elements necessary for a Uruguay Round market access package. This package included zero-for-zero in eight sectors. The Quad countries will continue to seek a solution in nonferrous metals and harmonization of other tariffs at a rate higher than zero.

In July 1993, Congress extended the fast track authority for the Uruguay Round for 10 months. Under the new authority, the President must notify Congress by December 15, 1993, of his intention to enter into a trade agreement. This means that all negotiations must be completed by December 15.

Public Land Use

A proposal by preservationists to establish the Emigrant Trail National Conservation Area in northwestern Nevada would prohibit mineral development on the pioneer-wagon Applegate-Lassen and Nobles trails and surrounding BLM lands. The USBM responded with a mineral assessment of the 1.7-million-acre region (MLA 7-93) to assist the BLM in its land use planning process.

In response to proposed legislation, H.R. 4370, "Bodie Protection Act of 1992," the USBM conducted a mineral resource evaluation and a study of the social and economic impacts of proposed gold mining adjacent to the Bodie State Historic Park in east-central California (MLA 5-93). The legislation would prohibit mining on about 6,000 acres of public lands to the east of and adjacent to the park.

The USBM published an evaluation of potential impacts on known and undiscovered metallic mineral development on 1.5 million acres of the California Desert by the land use bills H.R. 2929, S. 21 and H.R. 3066/S. 2393 entitled: Economic Analysis of the Minerals Potential of the East Mojave Scenic Area, CA (OFR 55-92 and 56-92).

National Defense Stockpile

In prior years defense spending was in the vicinity of \$300 billion per year, but significant cuts in defense spending are lowering current demand for many defense-related mineral-based materials. Further, the DOD informed Congress that the threat of major global war had diminished and that several previously vulnerable offshore sources of materials could now be considered more reliable.

For more than three decades stockpile goals estimated deficits-where reliable supplies fell short of military, industrial, and essential civilian requirements in a 3year major conventional war. Ever since World War II Canada has cooperated, culminating in the North American Defense Industrial Base Organization in which Canadian and U.S. military and atomic energy production are accorded parallel priorities and allocations treatment. At yearend, stockpile inventories were valued at about \$6 billion and stockpiles became obvious candidates for reduction. In the 1993 Defense Authorization Act, October 23, 1992, reductions of stockpile inventories approaching \$4 billion were authorized. To ensure that contemplated disposals would not unduly interfere with normal markets of producers, processors, and consumers, the act mandated two levels of review, each to consult with affected interests. The DLA manages the stockpile. The DLA longstanding Market Impact Committee was formalized by the act to include representatives of DOD; the Departments of State, Treasury, Commerce, Interior, Energy, and Agriculture; and the Federal Emergency Management Agency. A second committee to advise the President was mandated to include those agencies plus interested persons from the private sector.

At a time of general malaise in the economy. these authorized disposals caused domestic and foreign mineral producers, individually and through trade associations and embassies, deluge DLA with statements advocating caution lest the defense industrial base be imperilled and the economies of friendly foreign nations be undermined. Accordingly, in early 1993. DLA initiated a series of individual commodity meetings with interested producers, processors, and consumers to devise initial pilot disposals that would develop mutual understanding of pricing. timing. specifications. packaging. shipping, and hazardous materials precautions.

Despite stockpile disposals, most of the materials classified as 'strategic and critical' will continue to be so classified because the United States is still counting in large measure on existing productive capacity for those same materials in the United States, Canada, and other reliable sources. The USBM provides DOD with detailed information on world production capacity, country by country, for the next decade, as well as basic information on consumption in the United States and in most other industrialized nations.

Industrialized nations cannot have viable economies without some assurances of continued availability of essential materials. Further, as military material becomes increasingly reliant upon new or advanced materials, some of them will undoubtedly be designated as strategic and critical, not necessarily to be stockpiled but rather to be covered by other measures to create and maintain reliable productive capacity. fiber, currently displacing metals and alloys in aerospace applications, is an example: the 1993 DOD Appropriations Act, October 6, 1992, specified that DOD

shall ensure that a minimum of 75% of the coal and petroleum pitch carbon fiber requirement be procured from domestic sources by 1994. The Defense (DPAct). Production Act which authorizes priorities, allocations, and exemptions from the Antitrust Acts and maintains the Defense Industrial Base. was extended to September 30, 1995. The DPAct specifies that "energy" is a strategic and critical material. Under the DPAct the USBM maintains the Emergency Minerals Administration covering nonfuel mines, concentrators, smelters, and refineries. The Department of Energy covers fuel minerals and energy and it stockpiles fissionable materials and petroleum.

UNDERGROUND MINING

Mechanical Mining—Extraction

In 1992, the U.S. mining industry continued its efforts to increase production while reducing costs to maintain its position in an increasingly competitive world. Mechanical mining methods have received much attention because of the potential to increase production and reduce costs. Although in mechanical mining tend toward evolution than revolution, increasingly rather competitive markets mandate consideration of mechanical methods in more and more operations. Equipment manufacturers have responded to this interest with programs to design and produce more efficient and more robust mechanical mining machines. included improving existing designs, improving cutting tools, and developing machines that represent new directions in excavation technology.

The trend in mechanical mining equipment is toward more massive and powerful machines. The Voest-Alpine AM 105 roadheader design is one example. It features low speed, high torque cutterheads that use variable frequency electric motors. Low speed, high torque machines maintain better rock contact in harder rock and they reduce machine vibration due to cutter bounce that occurs in older systems.

Consequently, these designs transfer more of the machine's power to cutting the rock. In addition, some of the more powerful machines feature gripping devices that allow more thrust.³

The new Jarva MK27 is the most powerful TBM ever built and the only machine of its kind that can be modified for tunnel diameters varying from 6.4 to 12.4 meters (m) [21 to 40.7 (ft)]. The machine is powered by either six or eight 560-kilowatt (kW) [750-horsepower (hp)] electric motors, giving an installed power of 4,480 kW (6,000 hp) for the upper diameter range.

Innovations include double thrust bearings at the drive section in the rear and a single front bearing; stepless, variable-speed drive control combined with automatic thrust control for optimum penetration in all rock types; and a unique overbore system. The latter allows tunnel bore diameter to be temporarily increased where necessary by up to 0.45 m (1.47 ft) to provide room for extra rock support such as shotcrete and steel arches. This makes it possible to walk the TBM back through supported areas and minimizes lining costs.⁴

The new SR-700 miner redefines performance and durability standards for continuous miners and is manufactured by the Simmons-Rand Co. The unit features a 52,617-kg (116,000-lb) operating weight for stability in mining tough seams. The SR-700 was designed with a 711-millimeter (mm) [28-inch (in)] chassis and a 3,048-mm (120-in) cutting height for operation in all midseam The unit's 2.74-m-wide (9-ftwide) chassis with its 914-mm (36-in) conveyor offers the maneuverability of narrower-conveyor machines and the increased production of wider models. include Routine maintenance aids independent left and right cutterhead gear cases, access to all major components from the side of the unit, traction drives separated by function in left and right components, and pump motor and gathering motors that are interchangeable.5

The Jeffrey Div. of Indresco Inc. has introduced a new model 1024 low-seam continuous miner. It has a specially

engineered low profile, making it ideal for mining low coal seams down to 762 mm (30 in) high. Significant features include a gear-driven ripper chain cutterhead, a dual-drive arm-type gathering head, and an all-gear traction system. A 914-mm-wide (36-in-wide) conveyor provides high loading rates for low-seam operations.

A major factor is the 50,000-kg (110,230-lb) gross weight. With 508-mm (20-in) crawler pads to maintain a reasonable ground pressure, this heavyweight machine gives good mining rates and can mine hard top when necessary. The low profile unit has no operator's pit and is operated by radio or cable remote control. A dust collector system is available and can be built within the right or left side of the miner's low profile chassis.⁶

The 2048HPMB was developed by Dresser Industries and was designed especially for longwall development in Australia's poor roof conditions. It can install roof bolts as close as 1.2 m (3.94 ft) from the face. Features include: a specially designed lateral gathering chain that replaces the normal gathering arm or CLA-type gathering head, thus enabling roof drills to be located immediately behind the cutting drum; a lateral array of four roof drills, each mounted on pivots to allow variation of lateral roof bolt position; and incorporation of two separate rib drills to allow installation of rib bolts as the machine advances. The miner/bolter can cut seam thicknesses ranging from 2 to 4 m (6.6 to 13.2 ft).7

To meet the miner bolter challenge, Joy has introduced the 12ED18. It is a double-pass mining machine fitted with two bolting drills, located immediately behind the cutter drum to enable roof and rib bolts to be installed as close to the cut face as possible. According to Joy, the unique drill configuration permits the installation of more horizontal and vertical roof bolts than any other machine currently on the market. Like the 12CM18, it is fully certified for use in United Kingdom and European gassy environments and should be capable of 12 m (39.4 ft) advance per shift.

To permit the installation of bolts as

close to the face as possible, the 12ED18 does not use a gathering arm system. Coal is forced onto the conveyor by the scrolling action of the cutter drum. It also features a rear conveyor drive, which is more efficient than the conventional way of running the conveyor drive off the gathering arm system.

For multientry development or roomand-pillar production sections, Jeffrey offers the 1026HH and 1038HH continuous miners for seams 1 to 4 m (4.28 to 13.1 ft) thick. Each is equipped with AC-DC all-gear traction drive, a dual-drive gathering head with arms or CLA's, and can be configured with a chainless or ripper chain cutterhead. Options include radio control and an integral dust collector.

In more competent roofs, the Jeffrey 1038HCRB wide-head miner carries two onboard roof drills in fixed positions approximately 3 m (9.84 ft) behind the face. These roof drills carry separate timber jacks for erecting steel W-straps along with the roof bolts. It is also equipped with four hydraulic roof jacks that provide temporary roof support for the drill operators while they are drilling the roof and installing bolts.

Jeffrey's 1040HPSRB carries the onboard roof drill concept a step further by mounting the roof drills on an inverted "U" frame that straddles the miner and can traverse a distance of about 1.5 m (4.92 ft) atop the miner. Once the miner is in position for a new cut at the face, the frame is hydraulically raised off the miner's chassis and locked between the roof and floor. Thus, roof drilling and bolting can be accomplished from the U frame while the miner continues cutting up to two full sump-shear cycles, at which time the frame is lowered and repositioned on the chassis for the next mine and bolt cycle. The 1038HCRB and 1040HPSRB are typical of miners used successfully for longwall development in the Pittsburgh No. 8 seam in the eastern United States.8

The Earth Mechanics Institute (EMI) of the Colorado School of Mines has conducted research on the development of mechanical excavation technologies for hard-rock mining. Several types of

excavating systems, including short-radius tunnel boring machines and mobile continuous miners, are being investigated for use in mine development and production.

Hard-rock miners require large amounts of power. That problem has been a major impediment to the successful development of a miner that can provide acceptable production rates at costs competitive to drill-and-blast techniques. The large machine mass, to generate the high cutting loads necessary for efficient hard-rock excavation, results in reduced machine mobility and versatility. This limits the machine's usefulness in underground mining. The solution is to develop more efficient cutting tools that can break hard rock at lower machine thrust and power requirements. EMI has focused its research on such a tool.

Following computer modeling and testing, EMI developed a mini disk cutter, 127 mm (5 in) in diameter, with the ability to penetrate hard rock at load levels much lower than the current disk cutters. This means the new cutter can provide the same production rate as current cutters at much lower machine mass and power requirements. The new cutter also has a self-sharpening feature that prevents machine performance degradation as cutter wear occurs. It is believed that the mini cutter will find application in the development of hardrock mobile miners and narrow vein miners.9

Roof Bolting

Resin-grouted roof bolts, the most common form of ground support in U.S. underground coal mines, form a passive support system. An alternative to this system is an active support system—the mechanically anchored, tensioned roof bolt system. This system is designed to load the support during installation by using a mechanical anchor, coupling, or threaded nut after the resin has properly cured.

Bolt loads are checked by using a torque wrench to ensure active bolts have been properly installed. Unfortunately,

this practice presents potential safety hazards and has limited accuracy. Laboratory and field experiments also reveal that the torque-to-tension ratio developed on active support systems can vary by 50% among various bolts, which can induce stress concentrations that lead to roof failure.

The USBM has developed a support system that is independent of mechanical tensioning devices subject to frictional losses and system bleed-off. This support system offers predetermined uniform-installation load and reduces support costs by 30%. The support system uses resingrouted rebar bolts installed in such a manner that the system becomes "active" immediately upon insertion. The system requires minor bolter modifications, special bolt installation stingers, and a calibrated load cell.

The bolter is modified by installing a valve that permits 44.5 kilonewton (kN) (10,000 lb) of upward force to be developed at the installation head, on demand, through the operation console. The stingers were designed to withstand enormous repetitive axial and bending loads generated between the installation head and the roof bolt. The load cell is used to calibrate the upward thrust to any desired level prior to support installation. Laboratory testing and massive underground tests at sites in room-andpillar and longwall gate roads have demonstrated that this method is capable of installing bolts under uniform tensions equivalent to levels as high as 406.8 Newtonmeter (Nm) [300 foot pounds (ftlb)] of torque.10

A new JM-Truss system for controlling uneven and severely potted out roof has been developed by Jennmar Corp. The truss system features a unique shoe and U-bolt assembly. Made of cast, ductile iron, the shoe has a radial design with hammerhead configuration and is used with the U-bolt having an attached bearing block. Each truss accommodates four diameters-19.1 mm, 22.2 mm, 25.4 mm, and 28.6 mm (3/4 in, 7/8 in, 1 in, and 1 1/8 in). The headed U-bolt eliminates threads, thus reinforcing the assembly. The JM-Truss system is easy and fast to install under extremely severe

roof conditions. The system is adjustable to varying entry widths and has the fewest components of any system on the market. JM-Truss is a dynamic tension system providing an uplifting force to reduce or eliminate roof sag. The system can be installed during the mining cycle as primary support or installed later for additional support. It utilizes tensioned point anchor resin with angle bolts. The tie rod is adjustable to any entry width. 11

Cable bolt supports have been widely accepted as an effective ground control technique in hard-rock mines. They can be used as passive or active supports. They can behave as stiff or yieldable reinforcement, depending on their configuration, and can be placed at any angle in the rock. The use of cable supports contributes to safe, productive mining without the need to make changes in existing mining methods.

USBM engineers began evaluating the application of these supports in soft-rock mines, such as coal and trona, with an emphasis on using resin cartridges for grouting the cables. In longwall gate road applications, for example, cable bolt supports offer several advantages over traditional secondary support. enhance stress redistribution to pillars and gob areas, minimize or eliminate timber posts and cribs that complicate ventilation, reduce material handling injuries related to the placement of crib supports, and reduce ground control costs

More research into the mechanics of cable reinforcement continued with the implementation of equivalent materials models in finite element models developed at the University of Utah. Use of computer models to simulate development opening excavation, bolt installation, and subsequent mining provides valuable guidance to mine planning.

One full-scale test stope study was completed at the Homestake Mine. A second application of cable bolting for pillar recover at the Magmont Mine is underway. Both involve rock mass monitoring and large-scale computer simulation of the mining sequence. Understanding the fundamentals of

reinforcement interaction may lead to more efficient and reliable procedures.¹²

J. H. Fletcher & Co. has introduced two new low-profile, man-up roof drills that are designed to bolt in heights from 2 to 7.6 m (7 to 25 ft). The Model AR-D features dual tram-power systems. A diesel engine is used over long distances and trams up to 16 kilometers per hour (km/h) [10 miles per hour (mph)] with no trailing cable. An electric motor is used for inch tramming in the work area. It offers pinpoint positioning with little noise and no emissions. It is controlled from the operator's basket. An all-diesel version also is available. When drilling, the operator stands in the basket under a canopy. The telescoping boom raises to 45° and swings 45° either side of center. In tram configuration, the unit's overall length is 8.2 m (27 ft), its wheel base is 3 m (10 ft), and tram height is 1.8 m (6 ft). Turning radius is 5.8 m (19 ft).¹³

Fletcher's HDDR roof bolter is a dualhead unit with walk-through chassis. Optional independent, elevating operator platforms raise to allow the insertion of resin cartridges and checking of bolt torques. The booms separate from 1.2 to 6.1 m to enable several bolt installations from a single position. Heavy-duty booms allow operators to drill over rubble, near ribs, and over otherwise loose bottom areas. The bolting pattern is established relative to the roof, not the floor (for angled hole drilling). The HDDR can operate in seam heights from 1.5 to 6.1 m (4.92 to 20 ft).14

Simmons-Rand SR-250 hydraulically operated, planetary-drive roof bolter. It incorporates a dual boom arm with outfront automated temporary roof support (ATRS) that allows efficient and quick installation of roof bolts. The unit offers variable drilling torque up to 542.5 Nm (310 ft-lb) and bolt tightening torque up to 332.5 Nm (190 ft-lb). The SR-250 is 0.9 m (36 in) high and features a 228-mm (9-in) ground clearance. Vertical articulation incorporated in the chassis and steering design enables the unit to maneuver efficiently over uneven terrain. In addition, a 60-kilowatt (kW) [80-horsepower (hp)] AC motor and dualspeed settings allow the SR-250 roof

bolter to tram up to 39.6 meters per minute (m/min) [130 feet per minute (ft/min)] in the fast mode and up to 19.8 m/min (65 ft/min) in the slow mode. 15

Conveyor Advances

Sensor technology for nondestructive testing of conveyor belt reinforcement has expanded the capabilities of conveyor belt monitoring equipment.

Instrumentation for measuring the condition of a conveyor belt's reinforcing layer has been in operation for a number of years. Recent advances, however, have enabled new high-gain sensors to be used to detect damage and defects, which previously had been difficult to measure. In particular, cord plane deviations have proven almost undetectable in all but ideal measurement conditions. These new sensors, developed at the University of Newcastle, New South Wales, in association with Winders, Barlow and Morrison Inc. (WBM) of Denver, CO, demonstrated very high sensitivity to small changes in the magnetic field surrounding steel cord conveyor reinforcement.

The new equipment is in modular form and is extremely lightweight. This has significant advantages for both transportation and installation of the equipment on-site. Suitable for either permanent installation or temporary mounting, the system can detect damage and defects to the reinforcing layer in steel cord, fabric, and woven fabric conveyor belts.¹⁶

Continental Conveyor has devoted considerable research to improving intermediate booster drives for conveyors clearing coal from longwalls. Because the conveyors have to be constantly moved, components must be as compact and light as possible, and the design must be flexible enough to be modified as new terrain and conditions are met.

In the past, when drive powers or belt tensions were exceeded due to conveyor length, a new flight would be added. In some cases, this led to as many as three flights installed in a single panel. As the face retreated through each flight, mining was halted while drives and storage units

were removed. This sometimes meant several days of lost production.

Intermediate drive technology was developed to eliminate this excessive downtime and still keep conveyor belts, motors, pulleys, and other components as small as possible. With intermediate drives placed along the carrying side of the conveyor, belt and motor sizes are kept as small as possible, and only one storage unit is needed. Most importantly, as the longwall retreats through a booster drive station, it can generally be removed in a regular planned downtime period and no additional production time is lost.¹⁷

Mine Design

Mine design research at the USBM recognizes that many advances in mine ground control and mining methods arose from cooperation with the natural characteristics of the rock mass. Two examples are rock bolts that mobilize the strength of intact rock while at the same time immobilizing weak discontinuities, and the use of rock mass weakness in block caving. The term "geoconformal mining" is being used to describe a concerted effort to examine new ways in which mining can take advantage of the natural characteristics of a rock mass to improve the efficiency of mining.

One area being investigated is the natural variation of in situ stress before mining. USBM research, as well as case studies from throughout the world, has demonstrated that rock mass structures create a wide range of stress conditions that could increase mining efficiency if integrated into mining plans. instance, high-stress conditions that can result in localized rockbursts should be special mined with avoided or On the other hand, precautions. relatively destressed areas could be mined more aggressively, with larger extraction ratios and less support.

USBM researchers are developing computer programs to calculate stress in coal mines. One recently available program, MULSIM/NL, is a three-dimensional, boundary-element method program for stress and displacement analysis of coal mines. The program has

nonlinear material models that enable it to simulate yielding and crushing of coal pillars and the ensuing load transfer to other parts of the mine. The program also includes preprocessors and postprocessors that help the user generate a model and examine the output.

IC 9513, Proceedings of the Workshop on Coal Pillar Mechanics and Design, cosponsored by the USBM, expounds further on USBM research and presents the ideas of coal pillar design experts from around the world.¹⁸

A new system called GUIDE (Graphical User Interface for the DATAMINE Environment), is a fully interactive three-dimensional (3-D) graphical display into which drill holes, geological block models, wireframe models (triangulated surface lattices), and string data can be read and manipulated in a number of ways. GUIDE runs alongside the DATAMINE system, using the same data base structures, providing a 3-D environment with processing directed to solving mining and geological problems. The package operates in the same way on PC's and workstations. On workstations an extra 3-D visualization program GVP (GUIDE Visualization Program) also is available, which provides 3-D dynamic graphics with fullcolor surface rendering.

Because GUIDE has a data base structure underlying it, it is able to provide a great deal of flexibility to the user. For example, new design data can have constant or variable attributes assigned to string or wireframe data, providing considerable flexibility in identification of mining units, and allowing users to set up their own convention for identification of existing or designed underground features. The general graphics capabilities built in include many useful functions in such areas as string editing, smoothing, translation, conditioning, gridding, and string combination. To these general capabilities have been added the features required in underground mine design.¹⁹

The decision on how best to control the roof often is made arbitrarily or is based upon previous experience. As a result, when roof failure occurs,

questions arise about the contributing factors and how such failures can be prevented. The inherent stability of the rock comprising an entry's roof is recognized as a major factor in its stability. Other factors include abutment loads, horizontal stress, span width, pillar strength, and floor strength. USBM's Practical Roof Stability Classification system will provide a stability rating for the roof, which then can be used to help design longwall gate roads and aid in primary support selection. It also can be used as a guideline in decisions about wide or deep cuts. This system uses common geotechnical observation and simple field tests to gather data. The necessary rock properties are rock strength, bedding plane resistance. fracture spacing, cohesion, and geometry. Properties of the rock are then fed through an equation that considers several factors to arrive at the final roof rating from 0 to 100.20

Trends in Truck Haulage

Truck haulage has grown considerably owing to its versatility. Trucks of all sizes are used in underground haulage, from standard highway vehicles to small articulated vehicles for the narrowest, trackless mines. Articulated trucks are the most versatile of underground transport media. Their low loading height, narrow bodies, hydraulic power steering, and up to 45° articulation left and right permit tight turning circles. They also can cope with extreme grades. Manufacturers can be divided into those who make standard offroad vehicles, such as Caterpillar and Volvo, and those specializing in vehicles for underground transport such as Kiruna Truck, John Clark Inc. (JCI), Tamrock Toro, and Wagner.

Variations on standard end-dumping include side-dumping, arrangements for dumping in low ceiling heights, and detachable containers where one prime mover operates with two or more containers. In the latter and depending on distance, one truck can work with up to eight rock boxes, hauling a full one out while the others are being filled. The

concept gives major savings in the number of trucks required. Other advantages are that small loaders can be used and there is less wear and tear on the truck because the rock is loaded into stationary boxes resting on the ground.

Kiruna Truck AB was founded with the sole purpose of manufacturing low-profile container trucks for the Kiruna iron ore mine in Sweden. Today, the company builds two basic models: the 35-mt (38.6-st) payload K250 and the 50-mt (55.1-st) payload K501/503. The U-frame K501 "Combi" is the container version of the K503 and can accommodate a 60-mt (66.1-st) payload in containers custom-built to match the rock density.

JCI produces four articulated haulers with payloads from 6 to 24 mt (66 to 24.5 st). The larger 1504 and 2604 trucks come in two versions, standard end-dump trucks and container trucks (designated the C1504 and C2604). In contrast to the U-frame Kiruna "Combi" that has a split rear section to allow the truck to back over the container, JCI units use a "J" hook to pull the box off the ground into the forward hauling position. Separate hoist cylinders control dumping, simultaneously raising the container box and tailgate, thus allowing the container to be dumped like a normal end-dump truck.

Both Tamrock Toro and Wagner have patented arrangements for dumping in restricted height areas. Tamrock Toro manufactures two diesel articulated underground dump trucks, the 31.8-mt (35-st) capacity 35D and 37.3-mt (41.1st) capacity 40D. The latter is offered with an ejector tray option for dumping where height clearance is too limited for conventional dump trucks. The ejector tray is an integral part of the truck's rear body with a push plate at one end that is used to eject the load off the back of the truck. The push plate is mounted on a carriage, which is guided by rails on either side of the truck body and driven by three hydraulic cylinders. The plate has exchangeable wear pieces and the tailgate lowers over the rear axle and wheels to protect them while dumping. A full 16-cubic meter (m³) [565-cubic

foot (ft³)] payload can be dumped in 30 seconds. Wagner's special dump box for low ceiling areas is known as a Teledump and uses a telescoping feature to push the load out the rear.²¹

Mine Waste-Disposal Technology

A new technology, designed to dispose of mineral production waste (MPW), including mine tailings, back into surface and subsurface mine excavations, was announced by two companies who have filed for a process patent on the technology with the U.S. Patent Office.

The two companies, Hunter Services, **Environmental** Inc. environmental services company, and PBengineering KBB, Inc., an service company operational underground storage and technology, have agreed to form a joint venture to develop the technology for commercial application. The technology employs viscosity modified fluids to convey mineral production waste back into the geologic formations from which they were originally mined. The technology will aid in the reclamation of mine and processing facilities; eliminate emissions to air, surface water, and ground water; and assist in mitigation of surface subsidence. Returning the wastes to their original location is an environmentally sound practice.

In applying this technology, the waste is suspended in a liquid that is conveyed into the excavation. Phase separation of the suspension begins to occur after conveyance flow ceases. As settling by gravity progresses, the waste is dewatered and compacts, allowing the liquid to be recycled and leaving the MPW emplaced in its original formation. mechanisms of particle suspension, colloidal flow, and gravity dewatering provides the basis for handling mineral where the volumes significantly large and the location for emplacement waste may be inconvenient distance from the stockpile. Tests of the process have demonstrated that the technology is highly effective, economical, and environmentally superior when compared with current practices.²²

SURFACE MINING

In 1992, copper's fortunes continued to be exceptional. The expansions and new projects initiated by copper's high price started to come on-stream last year. Gold is no longer the most sought after commodity. This is due to the 30% reduction in its price in the past 2 years that has considerably lowered profit margins for gold.

Phelps Dodge's \$300 million, 3-year expansion program at its Morenci complex increased the company's copper production to 340,000 metric tons per year (mt/yr) [375,000 short tons per year (st/yr)]. About 154,000 mt (170,000 st) of that is from solvent extraction-electrowinning (SX-EW).

In Montana, the Seven Up-Pete Joint Venture (72.5% Phelps Dodge and 27.5% Canyon Resources) began the permitting process for the McDonald property near Lincoln. The property contains 188 Mmt (208 million st) of minable reserves grading at 0.7 grams per metric tons (g/mt) [0.02 ounces per short ton (oz/st)] gold. The projected capital costs for the proposed 27,000-metric-ton-per-day (mt/d) [30,000-short-ton-per-day (st/d)] heap-leach operation is about \$125 million. Operating costs are estimated at \$227/mt (\$250/st).

Phelps Dodge announced plans to develop the La Candelaria copper-gold deposit in northern Chile. The property contains about 350 Mmt (385 million st) of ore grading 1.14% copper, with 93.3 tons (102.8 st) of gold. The \$350 million project is expected to produce about 109,000 mt/a (120,000 st/yr) of copper and 2.48 mt/a (2.73 st/yr) of gold.

Production began at the \$62 million Lince Mine and SX-EW facility. It is 25% owned by Cia Minera Carolina de Michilla, 60% by Chemical Bank of New York, and 15% by Outokumpu Oy of Finland. Production is expected to be 18,000 mt/a (19,840 st/yr) of copper. The deposit contains 16 Mmt (17.6 million st) of 1.6% copper.

Cluff Resources announced plans to develop Ayanfuri gold mine in Ghana. The project is expected to produce 1.5 mt/a (1.65 st/yr) from 700,000 mt (771,600 st). Total reserves are 4,300 mt (4,740 st) grading 1.7 g/mt (0.05 oz/st). Capital costs are estimated to be \$22 million.²³

ASARCO Incorporated reported its Ray copper mine now contains more than 1,000 Mmt (1,102 million st) of ore grading 0.63% copper, making it one of only three U.S. properties to contain that much ore. The company just completed the ore reserve calculation at Ray, the first time since acquiring the property in 1986. When Asarco acquired the complex, reserves were 614 Mmt (677 million st) of ore grading 0.7% copper.²⁴

Cia Vale do Rio Doce (CVRD) and Anglo American Corp. approved a \$765 million joint-venture agreement to develop the Salobo copper-gold mine in Brazil's Amazon region. The 50-50 joint venture is through Mineracao Morro Velho, a Brazilian gold mining company 60% owned by Anglo American and state-owned CVRD. The mine is due into production by 1998 and will have a capacity of 150,000 mt/a (165,000 st/yr) of copper and 7.8 mt/a (8.6 st/yr) of gold. Ore reserves are estimated to be 1,200 Mmt (1.323 million st) grading 0.86% copper.²⁵

Minera Escondida Ltda. is to expand copper production at its Escondida Mine by 50%. Escondida was brought onstream at the end of 1990 with a design capacity of 320,000 mt/a (352,700 st/yr) copper in concentrate. Contained-copper production at Escondida, already the world's second largest copper mine, will rise to 390,000 mt (429,800 st) in 1993, to 420,000 mt (463,000 st) in 1994, and to 480,000 mt (529,100 st) in 1995. Very importantly, the extra production will be processed to copper in Chile. Up to date, all Escondida's production is exported as concentrate, most of it to smelters in Europe and Japan.²⁶

The Phosphorus Chemicals Div. (PCD) of FMC Corp. has opened a new phosphate rock mine at Dry Valley, ID, to supply the company's future phosphate needs. The new Dry Valley Mine highlights the continued investment being made by FMC, the largest producer of industrial phosphorus in North America,

to ensure the availability of phosphate for a wide range of industrial and consumer applications.²⁷

New Equipment

Shovels and Excavators.—The use of hydraulic shovels continues to increase in surface mines. This is primarily because the fast response of a hydraulic system can reduce swing time by up to 30% over rope shovels.

Caterpillar introduced several new lines of excavators. The 235 and 245 series is equipped with a 4.4-m³ [5.7cubic-yards (yd3)] bucket capable of loading 1,400 metric tons per hour (mt/h) [1,540 short tons per hour (st/h)], a 23% increase over the 245B it replaced. The new 320 and 325 excavators are available in 20 to 30 tons (22 to 33 st). Design efficiencies are improved by the Maestro system, which converts 98% of engine power to hydraulic power. Also, the new 130-tons (143-st) class hydraulic excavator machine delivers 535 kW (717 hp) and features the vehicle management and information system (VMIS). Four different buckets are offered.28

Komatsu's PC1000-1 excavator has state-of-the-art electronics that maximizes fuel economy and provides continuous fault monitoring. The unit is available in a front-shovel or backhoe configuration. It has bucket capacities ranging from 3.1 to 7 m³ (4.1 to 9.2 yd³). As a front shovel, the PC1000-1 can be equipped with buckets in three sizes: 5.5, 6.1, and 7 m³ (7.2, 8, and 9.2 yd³).

The PC1000-1 comes in three backhoe configurations. The PC1000-1 is the standard version. It is used for general purpose excavation and trenching. The PC1000LC-1, or long-track version. features extended track frames and wider track pads for improved flotation and lifting capacity. The PC1000SE (Super Earthmover) features a reinforced arm and shortened boom for maximum production. The three operating modes on the PC1000-1 permit the operator to select the match of engine speed to hydraulic power that will most efficiently accomplish the job. To support the three modes, the PC1000-1 is fitted with an electronic open-center load sensing system (OLSS). This system automatically controls hydraulic fluid flow from three variable capacity piston pumps to eliminate unnecessary flow and save fuel.²⁹

Andrew Golightly Ltd. has taken delivery of a Liebherr R992 face shovel. the first such model in the United Kingdom. This is the second largest machine in the Liebherr range, weighing slightly less than 140-mt (154-st) and fitted with a 7-m³ (9.2-yd³) bottom dump bucket. The new R992 is working at the Meadowdale opencast coal site. Bedlington. Northumberland. where Golightly is the main contractor. This site is scheduled to produce about 220,000 tons (242,500 st) of highcalorific value coal, destined for power stations. Work at the site started in April last year, with an overburden removal and rehandling expectation in the region of 6 million m³ (7.85 million yd³). On completion of coal extraction at the end of the 2 1/2-year contract, the ground will be restored, including 2 million m³ (2.62 million vd³) of compacted overburden.30

The new Litronic series of excavators that Liebherr introduced in 1992 provides an illustration of larger equipment to tackle heavy mining jobs. The new R 964 Litronic has an engine output of 268 kW (364 hp). Its performance has been raised by about 30% compared to that of its predecessor. The delivery rate of the hydraulic pumps also has been increased by 27%. The R 974 with an engine output of 321 kW (436 hp) is now 14% more powerful than its predecessor. The R 984 Litronic is now 15% more powerful than its previous model with an output of 431 kW (586 hp).

At the beginning of this year, Demag introduced its second-generation models of the 485 series, already the largest hydraulic shovel in the world with a service weight of 625 tons (690 st). The original 485 series was introduced in 1986. The new generation of 485's are heavier, more powerful, and can be equipped with large buckets than their predecessors. Some of the first of the new machines are already working at

CVRD iron ore mines in Brazil. CVRD already operates a number of 485 shovels loading iron ore and overburden into a fleet of 172-mt (190-st) trucks. Shovels like the 485 can easily maintain a production loading rate of about 3,500 mt/h (3,860 st/h) while peak loading rates of 5,000 mt/h (5,510 st/h) have been demonstrated.

According to Demag, one factor limiting shovel capacity is the size of hydraulic pumps available. Bigger, more powerful shovels would need bigger, more powerful pumps. Increasing the number of pumps on the largest size available is not an attractive solution. Demag's giant H 485 uses just six main pumps. Increasing this number to 10 or 12 would be undesirable.³¹

The P&H 2250 hydraulic mining excavator features Harnischfeger's latest technology in large hydraulic components, computer controls, and single-engine proficiency. Nominal capacity is 17.6 m^3 (23 yd³). excavator's working weight is 338 mt (372.5 st). Features of the 2250 include in-line power train for optimum efficiency and reliability, a closed-loop hydraulic swing system that provides 30% faster swing cycle, and a separate cooling compartment for the heat exchanger. Other features include the P&H hydraulic viscosity conditioning system automatic maintenance of proper oil temperature, a triple filtration system for the high-pressure circuit, mining shovel crawlers, and a walk-inside machinery house. Dipper capacity ranges between 11 to 24.6 m³ (15 to 33 yd³).

Harnischfeger also introduced its 2800XP Series B electric mining shovel. This shovel combines the basic features of the company's 2800XP/A model with improvements meant to simplify maintenance and increase productivity and durability. Several of the key features on 2800XP/B included an enlarged and redesigned machinery house for easier maintenance and a modernized operator compartment that adds greater visibility and ease of operation. An improved dipper handle and boom shipper shaft accommodates the industry's larger dippers. The shovel offers improved crawler shoes and larger lower rollers and front idlers in the crawler frame, as well as hoist cable with ferrule beckets and heavier, galvanized structural strand suspension cables.

Harnischfeger's 9020 walking dragline incorporates an improved A-frame and front-end geometry, precision gathering and planetary swing, and propel transmissions. The dragline's design uses finite element analysis to ensure structural while increasing integrity digging capability, dump height, operating radius, and bucket capacity. The 9020 handles bucket capacities of about 76.5 m³ (100 yd³). Boom lengths exceed 122 m (400 ft). Maximum suspended load ratings are more than 227 tons (250 st). walking dragline features a large-diameter roller circle for reduced loading on the rollers, rail, tub, and revolving frame. To maximize the availability of the dragline, an integrated diagnostic system monitors more than 200 critical control points.32

The "S" designation on Black Thunder mine's Bucyrus-Erie 2570-WS dragline stands for super. With its 110-m (360-ft) boom length, 122-m³ (160-yd³) capacity HPS bucket, and a load of technical innovations, this machine is definitely in a class by itself. Its bucket size and suspended-load rating of 306,180 kg (675,000 lb) provide a 33% increase in a capacity over the standard 2570-Ws with 92-m³ (120-yd³) buckets.

Erection of the dragline got under way in March 1991, and the machine was placed in service early in February 1993. It is conducting two-pass stripping on the southern portion of Black Thunder's property and is expected to move more than 30.5 million cubic meters per year (m³/yr) [40 million cubic yards per year (yd³/yr)]. Running on 22,000 volts, the 14,720-kW (20,000-hp) machine is the first of its kind to incorporate static AC drives.³³

An S-100 compact bucket wheel excavator manufactured by Krupp Fordertechnik GmbH is being used to cut Teutonia Marl at a rate of 800 mt/h (880 st/h). The new bucket wheel effectively mills the rock rather than excavating it by using buckets and precutters integrated

into the bucket wheel. This allows digging forces to be transmitted directly from the teeth to the wheel axis. There is also a larger number of precutters. The S-100 is the smallest standard version in the range with a bucket volume of 0.1 m³ (0.13 yd³), weight of 50 mt (55 st), and capacity of 420 m³/h (550 yd³/h).³⁴

Blasthole Drills.—Since acquiring the Gardner-Denver line of large rotary blasthole drills in 1991, Harnischfeger has updated the five models to the latest technology. Modifications includes the following:

- Upgrading of gearing to current Harnischfeger standards for hardness, dimensions, and geometry to increase impact strength, reduce wear, and extend service life.
- Increasing weld sizes to improve fatigue resistance in the main frame, side frames, and throughout the machines.
- Installing heavier-duty AC and DC motors with higher outputs and higher torques for longer life and enhanced performance.
- Redesigning main and auxiliary hydraulic systems to improve reliability and reduce maintenance.
- Increasing drill rotary torque at the higher speed ranges to provide up to 50% more torque at some portions of the speed-torque range.

These modifications are now standard on the P&H 70A, 70XHA, 70HA, 100A, and 120A models, as well as the new P&H 160, scheduled for the market in September 1993.

Ingersoll-Rand Co.'s Rotary Drill Div. has introduced the new DM-M3, a large rotary blasthole drill featuring advancements in drilling and nondrilling systems that maximize productivity and reduce overall drilling costs. With a rotary driven by dual-hydraulic motors, the DM-M3 delivers 13,560 Nm (10,000 ft-lb) of torque and rotation speeds to 200 rev/min, while its hydraulic cylinder feed system provides bit loading forces to 40,820 kg (90,000 lb).

These features mean that the drill can penetrate hard rock more rapidly and easily than competing models. To enhance nondrilling productivity, it incorporates a highly efficient "inside-thetower" drill changing carousel that minimizes the downtime associated with changing drill pipes. The handling system can hold four pipes each 273.1 mm (10.75 in) diameter and 12.19 m (40 ft) long. With one pipe under the rotary tophead, the rig offers onboard depth capability to 61 m (200 ft). The DM-M3 also has been designed to simplify angle drilling operations as the tower can be positioned and held at angles up to 30° in 5° increments from the operator's console.35

The Bohler TC 118 all-hydraulic crawler drill with the HS 464 drifter is designed for blasthole drilling in pits, quarries, and benches. It is equipped with an automatic drill-rod rack and hydraulic wrench for high-performance one-worker operation. The onboard compressor provides 8 cubic meters per minute (m³/min) [282.5 cubic feet per minute (ft³/min)] at 9 bar for adequate chip flushing in holes from 64 to 127 mm (2.5 to 5 in) diameter. Bohler says low fuel consumption is achieved by direct linking of the high-efficiency 125-kW (167.5-hp) KHD diesel engine to the hydraulic pump and compressor. Tramming speed is 0.85 meters per second (m/sec) [2.8 feet per second (ft/sec)] and grade climbing ability is 65%.36

The DK100B, a versatile new, crawler-mounted hydraulic drill, is recommended by Davey Drill Div. of Davey Kent, Inc. for a wide range of mining and quarrying applications. The new unit features improved tramming on a caterpillar undercarriage and an excavatorlike, turret-bearing drive that allow 360° rotation of the drill body about its crawler base. Powered by a 74.6-kW (100-hp) diesel engine, the DK100B utilizes a versatile universal boom for mast positioning to facilitate setup. The DK100B can be equipped for rotary, rotary-percussion, down-the-hole hammer, and double head drilling. As a result, it can be used for coring, site investigation, onshore and offshore blastholes, mine-shaft filling, dewatering holes, micropiles, and for work involving tie-back anchors. When equipped with optional rotators and grout pumps, the DK100B is ideal for geotechnical drilling applications needing ground stabilization and grouting of all types. With its crawler mounting, the machine can be moved to virtually any location regardless of conditions or terrain.³⁷

Bucyrus-Erie's (B-E) blasthole drills feature a Panelview console option that provides a full range of information ranging from machine status reporting to programmed drill-control settings. The Panelview system works in conjunction with an onboard, expandable PLC that handles lubrication system fault alarms. startup logic, motion limits, automatic leveling, and other functions. PLC/Panelview feature first appeared on B-E's 49-R drill introduced in 1985. The original 49-R product line was recently upgraded by B-E with the addition of three new variants: the 49-RII-75, -100, and -120. The 49-R-75, with 333.6 kN (75,000 lb) of pulldown force, is intended for high-speed drilling in relatively soft material such as that typically found in coalfields. According to B-E, the new 49-R drill can outperform B-E's older 60-R models by as much as 50%.

The 49-R-120 is a heavy-duty version developed primarily for use in taconite mining, capable of drilling 250- to 381-mm-diameter (9 7/8- to 15-in-diameter) holes with bit loading forces up to 533.8 kN (120,000 lb). The 49-R-100 model, available in diesel or electric versions, as are the others in the series, is designed for drilling 250- to 311-mm-diameter (9 7/8- to 12 1/4-in-diameter) holes and has single-pass depth capacity of 18.3 m (60 ft). The drill's DC-driven rack and pinion pulldown gear provides bit loading up to 444.8 kN (100,000 lb).

The 49-RII series drills feature an automatic leveling system also available on the 59-R, a more powerful model that drills holes up to 444.5 mm (17 1/2 in) dia. The leveling system consists of four hydraulic jacks activated by a single raise/lower switch in the cab. A preprogrammed sequence allows front-to-rear then side-to-side leveling that can accommodate most terrain and avoids

excessive torsional stresses on the drill's frame during the leveling process.³⁸

Trucks.—The Titan 3320 Mine-Haul truck from Marathon LeTourneau takes a new step in haul truck history as the largest mine-haul truck in the world. Its 290-mt (320-st) payload could allow greater production efficiency levels than any truck currently available. The eighttire, three-axle concept truck is designed to utilize proven component technology while affording vehicle balance during operation. The unique two-axle, four-tire steering and four-tire, single-axle drive are claimed to provide the optimum design configuration. A new Marathon TeTourneau "F-series" traction motor. designed specifically for the Titan 3320 and rated at 1,492 kW (2,000 hp), makes this single-drive axle concept a reality.

The Titan 3320 will be available with a choice of twin Cummins diesels rated at 1,194 kW (1,600 hp) each, twin Detroit Diesels rated at 1,194 kW (1,600 hp) each, or a single MTU diesel engine rated at up to 2,387 kW (3,200 hp), and a choice of gear ratios to allow power application to be matched to mine requirements. The truck is 17.56 m (56.6 ft) long and will use eight 44.00R57-size tires. The Titan 3320 mine-haul truck can be equipped with the Marathon LeTourneau Vital Signs Monitor and Digital Diagnostic systems.³⁹

The Caterpillar 86.2-mt (95-st) capacity 777C truck introduces a new electronically controlled Cat 3508 diesel engine that delivers 687 kW (920 hp). Electronic fuel injection and control module replace the mechanical system, providing precise timing, reliability, and coordinated engine and transmission control. Other benefits include simplified engine controls and elimination of mechanical governor adjustment; reduced smoke; and ability to recognize problems and stop operation. A second-generation controlled electronically power-shift transmission communicates electronically with the engine for high performance, including improved drivetrain service life, smoother shifting, and electronic control of driveline torque during forward and reverse shifts. The truck's cab now features the Caterpillar Contour Series Seat with eight adjustments, including lumbar support, operator's crank-up window, and tilt steering wheel.⁴⁰

Wagner Mining and Construction Equipment Co. introduced its Fullback 645 articulated dump truck for the mining and quarrying industries. The Fullback has a carrying capacity of 41-mt (45-st), a 72° dump angle, low-maintenance braking system, and an ergonomic cab. The 41-mt (45-st) capacity bed is designed with low sides for easy loading. The 72° dump angle is reached in 15 seconds for rapid discharge. Its fully enclosed, liquid-cooled brakes eliminate brake fade and wear. The Fullback's cab is fully climate controlled. Noise in the cab is suppressed and is pressurized for Safety features include dust control. centerline seating, full visibility to the front and sides, and heated convex mirrors.41

VME launched a new vehicle in its range of rigid haulers, the Euclid R60. The powerful 522-kW (700-hp) R60 has a 57-mt (63-st) payload capacity. The vehicle features a robotically welded, flat floor, sloped tail chute design and a body continuously heated by the engine exhaust. The new body is wider and the loading height lower than in previous models to ensure easier loading. The new Euclid is equipped with an advanced hoisting circuitry that reduces the body raise time considerably, thus, reducing dump cycle time and improving hauler productivity. 42

Wheel Loader Advances

During the past 5 to 10 years, the coal mining industry has seen large wheel loaders grow from 11.5 m³ (15 yd³) to 21.4 m³ (28 yd³). The change, however, has not been limited entirely to capacity; the role of the loader in mining operations has changed as well. Once thought to be a backup for primary loading equipment and a cleanup tool, it now is being found more in primary loading situations because of its mobility and versatility.

The design techniques for large wheel loaders have evolved from yesterday's

basic applied stress mechanics with calculators to today's computer-generated finite element analysis and solid-state analysis. Correlating computer models with physical testing has provided a high degree of accuracy in the final design stages.

Electronics is also an ever-changing aspect as technology advances. Onboard computers soon will become the standard, controlling most of the machine's functions and monitoring the rest. The loader of the future will have auto-load, auto-service. and auto-troubleshoot. Electronically controlled engines will become a must for fuel economy, noise control, and emissions. Onboard computers will control the engine at times other than starting and shutting down. The brakes of the future will be electronically controlled by monitoring axle loads and determining torque requirements.

Auto-load systems, where the computer controls the lift linkages, will determine the tractive effort, lift, and tilt requirements. Bucket loads will be measured, cycle times will be rated, and overloading errors will be lessened. Joystick controls are being used primarily with smaller sizes; eventually they could make a move into the larger wheel loader market.

Manufacturers claim that large wheel loader use in the mining industry is growing faster than had been anticipated. Most of the large wheel loaders are exceeding surface miner's expectations, especially in productivity, and have become an economic alternative to shovels in certain situations.⁴³

New Designs for Blasthole Drills

The past 5 years or so have brought a gradual change in the landscape of the drill manufacturing industry. Some well-known lines have disappeared, others have been taken over in whole or in part, and yet others endure on the market fringe where equipment that was originally developed for nonmining applications, such as water-well drilling. There have been a few new twists in drill development recently. These workhorse

rigs, capable of sinking 152.4- to 558.8-mm-diameter (6- to 22-in-diameter) holes to depths exceeding 70 m (200 ft), are big-ticket items in a small market. Worldwide, only about 350 large rotary drills are sold in any given year, and the competition among manufacturers is intense.

The trend toward larger earthmoving equipment in surface mining has contributed toward a new interest in drill purchases. Mine operators want units that can drill quicker, move faster, and withstand the rigors of higher production schedules. Customer demand for performance and reliability improvements, coupled with competitive pressure, drives most manufacturers to maintain a steady schedule of feature enhancements and new model introductions across their complete product lines.

Although progress in rotary drill-rig design tends to be incremental, recent technical advances have not been insignificant. Mechanical innovations such as independent track propel, elimination of propel chains in favor of planetary gearboxes, replacement of pipe-feed pulldown chains with rack-and-pinion drives, and the introduction of electric rotary-drive options have resulted in drills that are more maneuverable, reliable, and thus, more productive.

Features that stimulate buyer interest certainly include the availability of fieldproven electronics to improve drill performance, but customer preferences are primarily focused on improved mechanical systems that offer screw-type air compressors capable of maintaining high continuous air pressure levels; hydraulics that provide longer intervals between maintenance and that can be quickly repaired and restored to service in dirty mine environments; and convenient access to vital components maintenance and replacement tasks.

Manufacturers are paying more attention to design elements that keep the operator safe and away from moving equipment. Pipehandling features on recent models allow the operator to make and break pipe connections, break stuck joints with a hydraulic wrench, and automatically grease pipe threads without

leaving the cab. Telescoping mast braces and hydraulically actuated pins enable the operator to raise, secure, and lower the mast, also from inside the cab.

The range of drill improvements covers a spectrum that starts with increased mobility and extends to the high-tech areas of machine automation and remote data transfer. The next step in drill development seems to be aimed at eliminating a significant amount of the guesswork involved in drilling and blastpattern design. Drills of the not-toodistant future will carry an arsenal of technologically advanced tools that will provide an increasing amount of information about the drilling process. In addition to increasingly sophisticated drill-control systems, future models will be equipped with data collection systems that will allow material-recognition information to be recorded during drilling With the physical operations. characteristics of the overburden known beforehand, blasting and stripping operations can be fine-tuned for optimum cost-effectiveness.44

Trends for Hydraulic Excavators

Among all manufacturers of hydraulic excavators for the mining industry, a clear trend to larger machines to match larger trucks has been observed in recent years. The consensus is that hydraulic shovels are not going to go on getting bigger—yet. Instead, they are becoming tougher, more powerful, smarter (electronics), more available, and very importantly, are now able to claim that they can have service lives comparable to those of rope shovels. Technology is being used for higher performance and greater operating economy.

In the late seventies and eighties, hydraulic excavators started competing seriously with rope shovels in the 10- to 13-m³-size (13- to 17-yd³-size) range. They were so successful that they became the machines of choice for this size range, performing such tasks as loading 77.1-ton (85-st) trucks in three to four passes. In the nineties, the hydraulic excavator is strongly entrenched in the market for machines with 20-m³ (26.2-

yd³) buckets. That is, machines designed to load 154.2-mt (170-st) trucks in an economical and efficient three to four passes.

Among manufacturers is a trend to develop machines that are stronger and more powerful than their predecessors for increased life, durability, and reliability. Most big, new hydraulic excavators are delivered equipped with some form of electronic control and monitoring system. Effective job planning depends to a great extent on reliable equipment availability. All hydraulic shovel manufacturers emphasize how their various electronic control systems are the key to higher productivity and lower operating costs through reductions of unscheduled downtime and faster and more efficient servicing and repair. In the larger classes of excavator, there is a clear trend to electric drive instead of diesel for mining machines.

In the past, a large number of analog and illuminated displays had to be checked. Now the operator can read the same information at a glance on a single monitor screen. The engine speed, fuel level, water, and oil temperatures are displayed in the form of bar diagrams. The date, time of operating hours, outside temperature, engine oil pressure, and generator charging rate are given in digital display. Such systems greatly facilitate maintenance and service operations because the service personnel can call up and print out all default messages that have occurred since the last service. This saves lengthy troubleshooting and permits immediate recognition and elimination of operating problems. It is commonly held that hydraulic excavators have a shorter working life than rope shovels. The truth is that hydraulic shovels are being designed for long life. Furthermore, in the case of the largest machines, there is an element of "custom" building in each case, so that mines can select features that will suit the machine to cope with conditions that prevail at a particular operation.45

REMOTE MINING

Solution Mining

The term solution mining is commonly used to refer to heap leaching, dump leaching, slope leaching, in situ mining, and borehole slurry mining technologies. The USBM is continuing with research in these areas. Commercial application of these technologies is progressing.

There is an ongoing cooperative research project between the USBM and the Santa Cruz Joint Venture to evaluate in situ copper mining at a field site near Casa Grande, AZ. The project is currently in the environmental permitting stage. The USBM is preparing an environmental assessment for the project as part of the National Environmental Policy Act. The USBM is also continuing with laboratory experiments to study the leaching characteristics of atacamite ore from the field test site, as well as various aspects of the SX-EW process.46

The USBM is also investigating the possible use of stope leaching as an underground mining method. In stope leaching, a stope is filled with fragmented ore by blasting ore from the surrounding wall rock or transporting it from other parts of the mine. A dilute chemical solution is then used to leach metals from the fragmented ore within the underground stope. The leaching solution is collected, pumped to the surface, and processed to recover the target metal.

The USBM believes several advantages may result from incorporating the stope leaching method. First, ore would be processed underground, minimizing costs associated with transporting it to the surface. Second, lower production costs would allow the company to mine lower grade ores in the deposit, increasing recovery of the in-place reserves, and surface disturbance would be minimized because most of the waste would remain underground in isolated regions within the mine workings.

The USBM is addressing two areas critical to the successful development of stope leaching: the chemistry of leaching

run-of-mine ore and solution control. The first area deals with the feasibility of leaching large fragments that make up run-of-mine ore. Previous research focused predominately on ore that had been finely ground. The USBM is evaluating different leaching methods. including bioleaching, to extract metals from run-of-mine ore. The second critical area being addressed is solution control. Loss of escaping metal-bearing solution results in loss of the target metal, as well as possible contamination of the surrounding ground water.

The USBM is testing different methods to prevent solution loss in a simulated leaching stope at the Colorado School of Mines' Experimental Mine west of Denver, CO. This project will use only water and environmentally acceptable tracers to simulate leach solutions. Research is being conducted techniques to detect solutions escaping from the simulated leaching stope as well as developing control measures to block escaping solutions after detection. The USBM is also evaluating U.S. deposits as possible test sites for a future full-scale leaching stope. Results from current leaching chemistry and solution control research will be incorporated into engineering designs for a future full-scale stope leaching demonstration.⁴⁷

In a related study, engineers at the USBM are researching in situ leaching of gob-filled stopes to determine the feasibility of recovering ore that might otherwise be lost. There are numerous gob-filled stopes in mines throughout the Western United States. In many, the ore and waste occurred in alternating bands.

Miners would blast both at the same time and then rely on hand sorting to extract the higher grade ore. Lighting in these stopes was often very poor, and miners would often have difficulty selecting good ore from bad. The rejected ore was used to backfill the stope. Consequently, many of these stopes contain rock that, at today's standards, is considered high-grade ore. In situ leaching of gob stopes would make it possible to recover this ore that might otherwise be lost.

Advantages associated with leaching

gob-filled stopes include high permeability, no fragmentation required, low capital investments, low work force requirements, short lead times for production, and low energy consumption. Major disadvantages include potential loss of lixiviants because of natural rock joints and blast damage to the stope walls, difficulty in determining the size and shape of the stope, and recovering core samples of the gob material to determine ore content.48

Most heap-leach pads require agglomeration. The most common agglomerating agent is cement, which also provides protective alkalinity for the cyanide solutions. However, the amount of cement needed for pH control is usually more than that needed for agglomeration. Therefore, excess cement often is added, which can lead to reduced There is an ongoing gold recovery. search for improved agglomerating agents. Two that have recently come to attention are Leach-It and polymers.

The Chemstar Lime Co. of Phoenix, AZ, recently introduced Leach-It, which according to independent tests by McClelland Laboratories, offers the following advantages compared with cement:

- Increased gold recovery of up to 20% compared with that achieved by the use of cement.
- The area under leach could be reduced, possibly by one-half.
- Pregnant solution volume would be less, and at a higher grade.
- Potentially one-half the volume at twice the grade. This in turn would reduce the size of the solution recovery circuit and pumping and storage requirements.
- Cyanide consumption and water evaporation should decrease due to less solution exposure to the environment.

Leach-It is a lime-based combination of minerals that provides alkalinity for the necessary ion-exchange reactions and for the development of cementitious materials such as tobermorite and ettringite. These minerals have a dendritic structure that provides innumerable passageways for leach

solutions to penetrate and allows oxygen to circulate freely.

Betz Industrial has been pursuing polymers as substitutes for cement, an approach based on pioneering work in agriculture on their use to maintain the permeability of high-clay soils. Betz's tests show that polymer-agglomerated gold ores have leach rates and ultimate recoveries equal to those of cement.

Drain-rate tests showed acrylamide acrylic acid (AM/AA) copolymers were the most effective. Efficiency depends on the AM/AA ratio, molecular weight, and dosage. For a given ratio, effectiveness increases with molecular weight, the best agents being those with 70:30 to 90:10 ratios. The most effective combination is also ore dependent. Field trials for both Leach-It and polymers are currently being conducted, and their effectiveness will ultimately depend on relative costs and recoveries.49

Borehole Surveying and Detection Systems

For the first time, a miniature television is providing accurate and detailed visual information that allows engineers to perform analyses essential to maintaining ore production. Inco Ltd. is using the RC93 camera, designed by Rees Instruments, for a range of rock inspection tasks in Manitoba, Canada.

Effective mining relies on the correct location, identification, and efficient extraction of high-quality ore. To optimize the planning process, mine engineers use numerical models to plot ore location and simulated mine excavations. Creation of these complex models requires detailed logging of data collected by feeding the camera into exploration boreholes or production holes and recording the inspections for later review. The resulting video recordings yield data that allow the models to be calibrated and new workings simulated.

Once located, ore quality must be assessed. This is made possible by using the enhanced color definition of the RC93 system to examine the lithology of the rock. Precise color reproduction is used

to determine the mineral content. Visual observation of joint densities allows 3-D. structured mapping to further increase the accuracy of prospecting. The high resolution camera system already is proving to be an invaluable tool for the mining personnel. It has interchangeable heads that provide high power lighting, zoom lenses, wide angle or radial viewing in boreholes as small as 50 mm diameter (2 in diameter). Ideally suited for arduous conditions, the camera is robust and waterproof. It is fully remotely controlled from the control consol, which has a color monitor and VCR for recording all results. Use of the system has already greatly aided mine planning operations and future use looks to extend ore production efficiency further.50

Using the latest in laser and microprocessor technology, Analysis Geotech Ltd. has developed a rugged manportable survey tool able to gather comprehensive survey data from areas of difficult, dangerous, or impossible access in active or abandoned mine workings.

The system, known as Caveman, can be deployed down boreholes with a diameter of 120 mm (4.72 in) or greater, and can operate at depths to 300 m (984.2 ft) from its surface control unit. Once located within the cavity, the laserbased total station scans in a number of preprogrammed movements to enable complete excavations or particular areas to be surveyed. Once the system is scanning, the range plus horizontal and vertical angles are stored on RAM cards at the surface control unit. Once the survey has been completed, the data are processed by a customized geotechnical software package to facilitate prints, plots, and data conversion to allow input into a variety of sophisticated software packages.51

Crone Geophysics and Exploration Ltd. builds everything needed for a borehole Time-Domain Electromagnetic (TDEM) system. Its 3-D borehole, pulse-electromagnetic systems, that incorporate complete 3-component, TDEM borehole-logging, can be attached to a compatible surface system. They can detect conductive bodies up to 200 m (656.2 ft) from the hole to depths of

2,500 m (8,200 ft) or more determining conductor orientation, size, conductance, distance, and direction. The systems break down into manageable pieces for transport by one or two people and are fully tested, rugged, reliable, and flexible.⁵²

Continuous Miner Automation

The USBM is steadily progressing in its goal to improve the safety, health, and efficiency of underground mining operations through computer-assisted mining. A microcomputer-based control and monitoring network was developed by the USBM and installed on a continuous mining machine (CMM). The network consists of microcomputers, each of which was developed to provide a particular function in the control process. The USBM-owned CMM with machinemounted computers in conjunction with appropriate sensors, provides closed-loop control of the machine, navigation, and environmental monitoring. machine microcomputers provide remote control of the machine, sensor status, and a connection to the network so that external computers can access network data and control the CMM. The generic structure of the network will allow for installation on most mining machines. The CMM was evaluated in 1992 in a fully supported experimental section of a coal mine. Experiments on machine appendage control, machine guidance, sensors for the detection of the coal-roof boundary, and simple automated mining clycles using a script as the source of computer commands to the machine were successfully conducted.

Guidance plays an integral part of computer-assisted mining by keeping unstaffed continuous miners on their sights. The USBM has been investigating different land-navigation systems, and the modular azimuth and positioning system (MAPS) seems to show the most promise. By combining their efforts with a defense contractor, Honeywell's Military Avionics Div., the MAPS manufacturers are moving toward perfecting an underground navigational system.

MAPS uses a ring-laser gyroscope (RLG), which is an optical gyroscope. It differs from a mechanical gyroscope in that it does not have any moving parts. RLG's are laser-based, solid-state devices that are small and lightweight, have low power consumption and a fast response level requiring less-frequent recalibration, and are reliable in rugged environments.

MAPS has multiple configurations. Problems occur when operating on an odometer because of track slippage, so a zero velocity update is used. When the system determines the machine has reached zero velocity, an update starts automatically completing error corrections in less than 30 seconds. The dynamic reference unit is the heart of the MAPS system. It contains three RLG's, three accelerometers, and a control and display unit. A terminal displays information to the user, providing a means to input control commands and data.

Two underground tests were performed at an experimental five-entry section in a West Virginia coal mine. The MAPS unit, installed on a Joy 14CM, was modified by the USBM to collect data on the machine's x-y position, azimuth, pitch and roll, and vibration. The first test evaluated MAPS' operation and accuracy on a miner cutting a 6.1-m (20-ft) lift of coal. During the second test, refinements were applied to the system based on the original test. During the beginning of the first test, researchers collected both cutting-cycle sequence and machine-position data as the operator cut coal. To determine the actual machine position, a Leitz Set 3 electronic transit automatically computed surveying information.

A comparison of MAPS data for x-y position and data obtained from the transit showed an increasing MAPS error. After 30 minutes of operation, the easting error was 19.1 mm (0.75 in) and the northing error was 191 mm (7.5 in). After 60 minutes of operation, the easting error was 191 mm (7.5 in) and the northing error was 260.4 mm (10.25 in). Modifications to MAPS software and changes to the operational procedure of the machine significantly reduced this error by a factor of 3.7. The USBM

believes MAPS is a feasible guidance system for mining use and that most performance problems can be corrected by software modifications.⁵³

A USBM coal research project recently gained national recognition; the radar coal thickness sensor developed by the USBM's Pittsburgh Research Center to measure the thickness of coal remaining on the roof, floor, or rib of a mine was one of two "R&D 100" awards the Agency won. The award is presented by Research and Development magazine to 100 of the world's most innovative and technologically significant developments. The coal thickness sensor reportedly solves penetration and focus problems that have plagued earlier attempts to use radar to measure coal thickness. The sensor's coal thickness data are used for remote guidance of a computer-assisted mining machine.⁵⁴

BENEFICATION

Clean Coal Technology

The increasingly stringent specifications set by the market for both coking and steam coals have encouraged developments technical in coal preparation. Conventional coal cleaning mainly uses methods developed at least 40 years ago. Nevertheless, in recent years there have been major advances in instrumentation and control that have resulted in reduced costs and greater consistency in the cleaned product. There also have been advances in research into improved methods of cleaning, particularly deep cleaning.

Over the past 20 years, consumers have become much more aware of the costs and consequences of using coal containing unwanted mineral matter and Changing market needs impurities. reflect the need to control emissions and to minimize operating costs. Coal producers are consequently seeking improved cleaning methods, and there are significant opportunities for application of new coal-cleaning technology.

The Otisca T-Process.—The Otisca T-

process is intended to produce high-value ultraclean products. The feed is finely milled and slurried in water. Agglomeration of the clean coal particles is based on pentane, which can be readily recovered by evaporation. The pentane is immiscible in water, and, with proper dispersion in the water/coal/mineralmatter mixture, it can coat the coal particles and form agglomerates. The plant needs careful design and containment for safe operation.

Otisca Industries has been working for several years on the process. A 14-mt/h (15.4-st/h) demonstration plant has been built and operated. More than 125 tons (137.8 st) of ultraclean coal has been produced by this method with an average ash content of 0.8% (dry basis). Some coals have been cleaned to ash contents as low as 0.2% to 0.3% when they were milled to a mean size of about 2 microns. This is one of the most technically advanced deep cleaning processes currently available. Process costs will inevitably be high, although good carbon recovery can be expected.

The Gravimelt Process.—The use of sodium hydroxide solutions to produce cleaned coal for conversion into electrode carbon for the aluminum industry was developed in Germany during World War II. Although successful, the process never achieved sustained industrial production.

Since the mid-1980's the main work on the possible scale-up of coal cleaning by chemical methods has been based on the use of strong alkalis, particularly in the TRW Gravimelt process in the United States and the work of the CSIRO in Australia. The TRW Gravimelt process uses molten caustic in a rotary kiln reactor operating at temperatures between 325° C (617° F) and 415° C (779° F). The coal feed is conventionally cleaned and is relatively coarse. It needs only to be milled to minus 3 mm (0.118 in).

The caustic penetrates the coal matrix and dissolves out virtually all of the sulfur and mineral matter, including much of the organic sulfur. Even after washing, some of the caustic is retained in the coal. An acid wash is used to recover most of the caustic, together with iron and alkali metals. Typically, about 5% to 10% of the coal is lost as low molecular weight hydrocarbons that have a high specific energy. The condensable organic material formed, representing another 10% of the coal weight, has similar high heating value.

There is also dissolved organic matter and sulfur in the caustic. All these byproduct streams, contaminated in one way or another, must be dealt with and, if possible, converted to salable or usable products. It is possible to achieve extremely low ash contents of less than 0.2%, also sulfur contents of below 0.7%.

CSIRO Caustic Process.—The CSIRO in Australia has built a continuous pilot plant based on the use of caustic solution. The unit is capable of processing about 1 mt/h (1.02 st/h) coal. The intention is not only to study the effects of process conditions on different coals, but also to produce tonnage quantities of ultraclean coal for combustion and other testing.

The reactions are considerably milder than those used in the Gravimelt process. Coal feed slurry is treated with hot caustic solution at 200° to 220° C (392° to 428° F) for up to an hour in a digester. At this stage, quartz and pyrite are completely dissolved. Clavs are converted to sodalite (sodium aluminum silicare). The sodalite and any alkali minerals are dissolved in a subsequent acid-soak tank. The final process stage involves the recovery of mineral byproducts and the regeneration of reagents after treatment with lime. The full recycle stage has not yet been built. It is clear that chemical cleaning to produce ultraclean coals is and remains a high-cost process.55

Hyperbaric Drum Filters.—Based on the success of the hyperbaric disc filter in coal preparation, Andritz AG has now developed a hyperbaric drum filter. In addition, the company has developed what it claims to be the first pressure filter to operate with steam.

Very fine particles cause several

problems in the filtration of coal slurries. One drawback is that considerable quantities of liquid are attached to the very fine particles due to the latter's large specific surface area. Furthermore, fine particles also reduce the size of the capillaries in the filter cake, thus increasing the critical pressure that the filtration system has to exceed to achieve the desired final cake moisture.

The maximum filtration pressure of conventional vacuum filters is limited by nature itself and by practical aspects to approximately 0.75 bar. The hyperbaric filter combines the continuous operating principle with an increase in filtration pressure of up to 6 bar simply by placing the entire disc or drum filter inside a pressure vessel. Hyperbaric filtration thus combines the continuous operation of conventional vacuum filters with the low final-moisture contents previously only achievable with plate and frame presses.

Compared with vacuum filters, generally hyperbaric filters will reduce the final cake moisture of concentrates with 75% plus 30 micron by about 10%, while achieving four times the throughput. Data are also available on concentrates containing more than 58% plus 0 micron producing filter cakes with 8% moisture at five times the specific throughput of existing plate and frame presses. 56

Column Flotation.—Although column flotation is well accepted in the phosphate and mineral processing industries, its commercial use in coal is just now occurring. Columns 3 m (9.8 ft) in diameter are now operating in several coal preparation plants.

Column technology uses a concurrent flow of washwater that is added near the top of the froth. As the washwater flows downward through the froth beds, it carries the mineral particles that would have otherwise reported to the clean product. Conventional cell geometry does not allow for an effective use of wash water. The column's large length-to-diameter ratio allows deep, well-washed froths to be maintained.

Many similarities exist between brands of column cells. Most columns used for

coal preparation range from 6.1 to 12.2 m (20 to 40 ft) in height and 1.23 to 3.7 m (4 to 12 ft) in diameter. Most of the recent changes have been made in the airsparging systems, which employ two types of spargers: porous-stone and a foam jet sparger. Column cells are not wholly trouble-free. Two common application problems do occur with column cells—improperly metered air and deep froths that are too stable.⁵⁷

Work has been undertaken at Michigan Technological University (MTU) on packed columns. The packed column uses a vertical tube with conventional inline corrugated packing. This promotes intimate particle and bubble contact in the small flow passages. The separation of clean coal and ash takes place in a frothy mixture passing through the winding flow passages. It is claimed that the packed column overcomes the intrinsic problem of vertical mixing that can occur in an open column. The mixing can make scale-up more difficult. It is also claimed that effective flotation extends down to particles of only a few microns in size. The practical limitation is not the separation device, but the degree of liberation needed and the cost of grinding.

In laboratory tests, MTU has achieved clean coal products with ash contents from 1% to 3% at weight recoveries ranging from 46% to 94%. Subsequently, the pilot unit produced a 2% ash product with more than 95% recovery using a coal feed containing 4.3% ash. This was in a single stage with a feed of minus 100 micron. By regrinding the first stage concentrate to a top size of 30 micron and treating a second time, a clean coal of about 1% ash was obtained with a recovery of 80%. Se

Mineral Processing

Grinding.—A new micronizing technology, with applications in the minerals industry, has been developed by Oy Finnpulva AB. The Pulva FP opposed jet milling process can produce fine powders from hard as well as soft materials. The completely new technology is based on the use of

compressed air. The energy consumption can be 50% to 70% lower than that of conventional micronizing processes. Twelve installations have already been delivered worldwide.

In the Finnpulva opposed jet mill system, the particles to be ground are accelerated to a high velocity in specially designed acceleration nozzles by using compressed air. The carrier air is supplied by a compressor that produces clean, oil-free, hot air. The jets are directed to a small space where the rawmaterial particles collide, and this collision is the main contributor to the grinding process. Milling efficiency is considerably better and energy consumption lower than conventional jet milling. After grinding, the kinetic energy of the carrier gas and the solid particles is utilized in the classifier to separate the fine and coarse fractions by centrifugal force. Coarse fractions can be returned to the mill for regrinding or used as a separate product. The humidity of the material to be ground can be 0% to 10%. The fineness of the raw material does not affect the quality of the product. The size of the jet mill determines the maximum raw-material grain size, which typically is less than 2 mm (0.78 in); usually the raw material can be ground to this size using pressure rolls.⁵⁹

Image Analysis of Rock Size.—A USBM-developed prototype digital image analysis system has been on-line at USX's Mintac iron ore plant for more than a The system, designed by researchers at the USBM of Mines' Twin Cities (MN) Research Center, provides an automated measurement of the size distribution of fragmented ore. prototype system has been measuring runof-mine ore feed to a primary crusher. The system automatically determines a complete size distribution for every train car dumped into the 1.37-m (54-in) crusher. Additional studies conducted at the Coleraine Laboratory, Natural Resources Research Institute, University of Minnesota—Duluth, have proven the reliability and accuracy of the size distribution measurements provided by the USBM system. Cooperative research between the USBM and LTV Steel Mining Co. has been completed to develop a balling-drum control method, based on the same image-analysis system.

The size measurement system is based on an inexpensive solid-state television camera connected to, and controlled by, a computer interface card in an MS-DOS-based computer. The key to the system is an edge-defining, size-measurement algorithm that robustly and reliably interprets particle outline. No operator intervention is required, and there is little sensitivity to moderate changes in lighting conditions. A complete size distribution is determined every 12 to 15 seconds, but researchers expect to cut this time to less than 4 seconds.

The system has been successfully tested on a variety of minerals and ore types, including limestone, taconite, and granite. Applications for the sizemeasurement system include: measurement of the size distribution of rock broken after blasting; measurement of crusher feed and discharge: measurement and control of the ballingmill process; and measurement of the fine particles rotary-kiln discharge. in Research is continuing to improve the accuracy and sensitivity of this novel measurement technique. 60

Gold Recovery.-A new method of treating refractory arsenical gold concentrates has been proposed that avoids the costly conventional steps of pressure leaching or roasting. Instead, gold-bearing pyrite and arsenopyrite concentrates are subjected to an alkaline under intense agitation. Undecomposed sulfides are then floated from the leached pulp, fine ground to less than 10 microns, and recycled to the leach together with fresh feed. The float tails, which are essentially sulfide-free, are then cyanided using conventional resin-in-pulp or carbon-in-pulp techniques. Laboratory tests on a variety of Russian ores have yielded gold recoveries of 96% to 99%.

The main advantage of the process is that only a very small percentage of the concentrate needs to be reground. About 65% to 80% of the particles in a typical

95% minus 40-micron flotation concentrate will be less than 15 microns in size and will be decomposed during alkaline treatment. Furthermore, lamellalike and columnlike particles (the latter are characteristic of arsenopyrite) also will be decomposed. Thus, the only particles that will not be decomposed and will need ultrafine grinding will be those more than 10 to 15 microns in size. Depending on the character of the material being treated, these will be typically in the range of 5% to 12% by weight of the initial concentrate.

Other advantages of the process are low consumption of alkali compared with pressure leaching, the simplicity of the equipment because nearly all steps can be performed in flotation machines, and that the process does not allow undecomposed sulfides to pass to cyanidation. This guarantees stable and high extraction of gold under cyanidation. Preliminary studies indicate that the treatment cost will be about 80% that of the roast-cyanidation route. 61

Floatation Development.—The Contact Cell represents a different approach to pneumatic flotation that promises to be the forerunner of a new generation of flotation machines. The compact device provides very high air holdup rates (the percentage of air in the slurry) with contact times of less than 2 seconds. Results with a continuous pilot unit at various plants show notably higher recoveries than conventional cells, or column flotation, in roughing, scavenging, and cleaning applications. The Contact Cell consists of two parts: the Contactor, where the mixing of air and slurry takes place, and the Separation Vessel, where the mixture is allowed to disengage into concentrate and tailings. The latter functions as a column flotation unit.

Tests have shown that the Contact Cell does not conform with classical theories of flotation. Residence time is not significant compared with conventional cells, but does become significant when operating with contact times of less than 1 second. It is believed that once the air/slurry mixture enters the separation

vessel, collection has neared completion after 1 second. The most significant parameter seems to be the quality of air within the contactor. Thus, variables affecting kinetics are air rate, air holdup (i.e., bubble size), contactor pressure, contactor residence time, and slurry characteristics (i.e., percent solids, particle sizing etc.). Affecting the performance of the separation vessel are the bias rate, froth depth, and to some degree, dispersion characteristics.

There were many other important variables affecting the performance of the cell. To mention some: froth level had an impact in reducing froth dropback and increased feed rates had a positive effect on recovery allowing the cell to operate with lower contactor pressures. In many instances, frother was required to enhance froth stability so as to permit washwater addition. The washwater system and its behavior in the separation vessel is similar to that in conventional column flotation. The overall test results gave grade-recovery curves that were generally improved over those obtained by the plant using conventional cells. The Contact Cell's fast kinetics, froth washing characteristics, and compactness are likely to encourage the development of a new generation of flotation machines for processing plants.62

Researchers at the USBM Salt Lake (UT) Research Center developing process controllers for mineral beneficiation operations. Α personal-computer-based controller recently was demonstrated in a column flotation circuit. New process control theories, such as Fuzzy Logic Controllers (FLC), neural networks, and adaptive control, are being developed rapidly within the government and private sectors. These new theories offer greater flexibility and optimized productivity of unit operations. However, application of these control theories to industrial processes has been lagging. Improved technology to interface computer systems to mineral processing circuits is required. USBM research in this area is seeking to fill this technology gap.

The interface developed by USBM researchers for the column flotation cir-

cuit supports RS422 communications (a type of data communications software) and analog-to-digital and digital-to-analog optically coupled sensor data links. Thus, an almost limitless number of controller functions and sensor points are possible in the flotation circuit, and any supports RS422 computer that communications may be used to control flotation column operations. A great benefit of this system is that the controller then becomes software-based. As new control theories emerge, only the control software will need replacement. There will be little or no hardware costs to give increased system control provided by the new control software. control scheme is being tested using MS-DOS-based computers linked to a USBMdeveloped flotation column.63

Scientists at the USBM's Rolla Research Center have developed a froth-flotation process that removes heavy-metal-bearing minerals from process tailings. The process recovers the mineral components of the tailings while removing acid-forming minerals, making the wastes less susceptible to leaching of contaminants.

This novel process uses a combination of conventional and nonconventional flotation reagents to lower the metal content of tailings by as much as 95%. Because older tailings are extensively oxidized, the first step requires using sodium sulfide to reform metal sulfide coating on the surface. Conventional froth flotation processes then are used to remove the metal-containing minerals. As a unique part of the tailings decontamination and metal recovery program, researchers also investigating the feasibility of using a newly invented device called the Air Sparged Hydrocyclone (ASHC). ASHC has a throughput (tons per unit of time per cell size) that is 100 times greater than flotation cells. Successful development of this technology will result in a portable, compact unit for treating large volumes of tailings on-site without the usual expensive capital requirements.64

Lurgi Metallurgie GmbH has developed a new method for the flotation

of complex nonferrous sulfide ores. The Conox process will be applied for the first time in the Cayeli copper-zinc beneficiation plant, which is presently under construction in Turkey. Conox process provides for the optimum setup of several parameters to establish an electrochemical milieu that is favorable for the selective flotation of finely intergrown complex ores. Because Conox requires only a few additional pieces of equipment, it can implemented in existing plants. Owing to the resulting higher grade and improved recovery, the capital investment has a short payback period.65

A unique design in bubble generation technology applied to column flotation is being marketed by Control International S.A. in France and is known as Microcel. This technology was originally developed and patented at the Virginia Polytechnic Institute and State University, VA. The Microcel design recirculates part of the tailings flow of the column through an in-line static mixer. The high shear applied to the mixture of air and slurry in the static mixer produces microbubbles ranging from 150 to 800 microns with a very narrow bubble-size distribution. The bubble generator offers several advantages over other existing air sparger systems. These include the generation of very small bubbles, little risk of plugging, built-in scavenger system, no freshwater addition, no moving parts, and easy on-line maintenance. It has been installed successfully in full-scale production flotation columns in mineral processing and coal preparation plants.66

Ore Treatment.—Euro-Pulse, a new United Kingdom company specializing in mineral processing, has developed what it claims is a revolutionary method of ore treatment. The Ore Structure Modification process is the result of several years of fundamental studies that investigated rock behavior under an electrical field. It is said to modify internal rock structure and drastically increase its porosity by a highly selective application of electrical energy.

The process of ore structure

modification is initiated by a specific level of electrical stress applied across the rock sample (characteristic to each ore). Above this threshold, a highly nonlinear flow of electric current is generated that creates gradual expansion of the interfaces between the valuable mineral and its rocky matrix. The rock porosity increases and its mechanical strength decreases. Also, as the applied electrical stress increases the process of interface expansion is accompanied by interlinking expanded interfaces, which increases the permeability of the rock.

The process reportedly offers cost benefits over existing methods by reducing energy consumption and extraction time. A mineral processing test facility for investigating individual ore characteristics and response to the outline technology has been expanded and is now available for potential customers.⁶⁷

Pyrite Removal Using Bacteria

Many processes have been used to try to physically remove pyrite (FeS₂) from coal. Some processes attempt to chemically remove the pyrite, which can be expensive. In a joint venture, the Pittsburgh Energy Technology Center (PETC) and the USBM have teamed up with biotechnology to develop a simple and relatively inexpensive process based on the chemistry of coal itself.

A heap-leaching process uses ironeating and sulfur-eating bacteria to help increase the pyrite's natural oxidation rate. When the bacteria. Thiobacillus ferroxidans, are introduced to the coal, the bacteria eat at the pyrite and accelerates the normally slow oxidation process to about six times the normal rate. The oxidized pyrite dissolves and forms rhomboclase, a soluble iron sulfate salt. Rhomboclase can be washed away from the heap by irrigating it with water. The washwater is treated and reused. The recycled water does build up acidity and is later neutralized in a watertreatment system.

With this faster oxidation process, what had been accomplished in 1 year now takes approximately 2 months. Roughly 50% of the pyrite in the coal can

be removed using this leaching process. The goal of the bacterial leaching process is to determine its potential for removing pyrite from coal stockpiles at powerplants. 68

Bottom Blown Oxygen Converter

One of the most significant developments in the refining of metals is the Bottom Blown Oxygen Converter (BBOC). Although designed primarily for lead-silver refining, the BBOC can be used for virtually any duty where impurities need to be selectively eliminated by oxidation. Examples of these include refining of lead and copper electrorefinery slimes, secondary copper, and low-grade concentrates containing platinum-group metals.

The BBOC was developed by Britannia Refined Metals Ltd. (BRM) to improve on conventional cupellation where air is blown over the surface of the molten metal to progressively oxidize impurities. Cupellation is characterized by slow reaction rates, due to poor oxygen transfer, and the buildup of a slag layer on the surface.

In the BBOC in contrast, oxygen is injected directly into the molten bath through a nitrogen-shrouded lance mounted vertically in the base of the converter. The lance is consumed sacrificially and, when the furnace is tilted to discharge slag, the lance assembly rises clear of the bath and can be easily replaced during the operating cycle.

The main advantages of the BBOC are as follows:

- A reaction rate 15 to 20 times that of a conventional cupel, which leads to reduced cycle times, volume requirements, and preciousmetal inventories.
- A largely autogeneous process with substantial fuel savings. BRM reports fuel consumption that is only 20% of conventional cupellation-process.
- The slag layer can build up without hindering oxygen transport, which leads to improved slag/metal separation and predictable process

control.

- The oxygen is almost 100% consumed, which leads to low offgas handling and power requirements, and consequent excellent plant hygiene.
- Slag produced can be cast directly into anodes, eliminating the holding furnace. 69

HEALTH AND SAFETY

Mining Statistics

For the fourth year in a row, coal mining deaths declined in the United States in 1992, with last year's 55 fatalities representing the second-lowest total on record. Coal mining deaths have dropped from 60 in 1991, 66 in 1990, and 68 in 1989. The lowest total recorded by the Federal Mine Safety and Health Administration (MSHA)-53was in 1988. Overall, the death toll for the U.S. mining industry, including coal, metal, and nonmetal mines, was the lowest ever in 1992. The 98 deaths marked the first time the total dipped below 100 since Federal officials began keeping records.

Kentucky, a State that historically ranks high in coal mining deaths, recorded its lowest total ever with nine, one-half of its 1991 total. Although most States showed a decrease in mine fatalities, two States—West Virginia and Virginia—accounted for more than 52% of all coal-related deaths. Altogether, 29 miners were killed in the two States—17 in West Virginia and 12 in Virginia. West Virginia's total, nevertheless, is down from 21 in 1991 while Virginia's is up from 9 in 1991.

Kentucky placed third in mine fatalities in 1992. Next came Alabama and Tennessee, three each; Colorado, Illinois, and Pennsylvania, two each; and Indiana, New Mexico, Utah, and North Dakota, one each. There were no recorded fatalities in Wyoming, the Nations's leading coal producer, a repeat of 1991's performance. According to MSHA, 34 miners died in underground mines in 1992, compared with 21 in surface mines. In 1991,

those numbers were 40 and 20, respectively.

Powered haulage accidents accounted for 15 of the deaths last year. Second was roof falls, which claimed 10 lives. Fatal machinery accidents finished third with nine. Smaller mines, those with fewer than 50 employees, experienced 36 fatalities at 24 mines in 1992, compared with 19 fatalities at 19 mines with more than 50 employees. ⁷⁰

Personal Safety Alarms

Methane versions of the MiniGard III and MicroGard Portable Alarms have received approvals from the MSHA for use in underground coal mines. The alarms, manufactured by Mine Safety Appliances Co., are battery-operated devices that can be handheld or worn on a belt. Both are available with a 0% to 5% methane-byvolume calibration for mining applications.

The MiniGard III is designed for simultaneously monitoring concentrations of methane, oxygen, and carbon monoxide. Audible and visible alarms alert the use of dangerous gas and oxygen concentrations.

In addition to detecting methane, the MicroGard monitors the atmosphere for both oxygen-deficient and potentially explosive oxygen-rich conditions. If limits are exceeded, the alarm activates a buzzer and provides concentration levels on an easy-to-read liquid crystal display panel.⁷¹

Scientists at the USBM Twin Cities (MN) Research Center and at the University of Minnesota have developed a cost-effective sampler that can be used by the mining industry and regulatory agencies to determine the amount of diesel exhaust aerosol (respirable-size particles) present in mine atmospheres. The easy-to-use sampler is wearable by mine personnel, inexpensive, and compatible with current personal sampling protocols.

The USBM conducted this research in response to reports issued by the National Institute for Occupational Safety and Health (NIOSH) and the Department of Labor's MSHA. NIOSH has recommended in its report that whole diesel exhaust be regarded as a potential occupational carcinogen. MSHA has been directed by an advisory committee to establish a diesel exhaust aerosol standard and regulations to minimize exposure to diesel pollutants in underground coal mines. Later reports released by these Agencies point out the need for developing measurement techniques for respirable diesel aerosol, with the MSHA report specifically requesting support from the USBM and NIOSH to develop these techniques.⁷²

VLF Magnetic Systems' Canary mine messenger is a wireless communications system that improves safety and productivity of mining operations by instantly transmitting early-warning emergency signals or paper messages to underground workers. Recent tests have provided full coverage throughout the 3-mile-wide Central Canada Potash Mine in Saskatchewan.

Standard components include a transmitter, an antenna, a testing and reprogramming unit, custom operating software, and receivers. The Canary receiver and display screen is fully integrated into a helmet-light battery pack. The system was developed in conjunction with the Noranda Technology Centre, Montreal. 73

Seal and Stopping Advances

The MSHA critically examines any devices or materials used as ventilation controls. Of particular concern are the controls' structural effectiveness and resistance to fire.

MSHA's Industrial Safety Division (ISD) has developed performance criteria and possible designs for air check applications. The emphasis was placed on the development of a run-through, curtain-type of control that would provide the flexibility, ease of use, and low maintenance of hanging conveyor belting but with resistance to the spread of flame and smoke in the event of a fire. After testing many different types of heatresistant materials fabricated in a variety of manners, a final design was selected

that provided the best overall performance.

The curtain consists of a composite of double-layered, high-temperature ceramic fiber textile sewn together using ceramic thread and buffered on both sides with an approved 35-mil polyethylene plastic brattice. The brattice serves as a bumper to provide resistance to the abrasion caused by passing equipment. This curtain thermally degrades upon exposure to test fire. The ceramic fiber textile remains in place, providing a barrier to the spread of smoke and fire upwind. Fire spread upwind in mine fires is normally caused by radiation generated by flame temperatures in excess of 538° C (1,000° F). The ceramic fabric attenuates the temperatures generated by the test fire, preventing the spread of

This ventilation control provides the ease of use and flexibility of a synthetic curtain constructed with hanging conveyor belting, but also has the air separation and fire-resistant properties consistent with nonresilient masonry and ventilation control structural materials. The low maintenance and failsafe closing characteristics of the curtain make it an attractive alternative to the use of metal doors for this unique application.74

When conventional techniques no longer work in fighting a coal mine fire, the standard procedure is to construct permanent seals—bulkheads made from solid blocks. The speed at which these seals can be constructed is sometimes the difference between saving or closing a mine. In a mine fire situation, temporary seals are sometimes used to prevent air flow from reaching the fire, and also to keep smoke from contaminating other areas. Permanent seals, however, must be able to withstand a secondary explosion of at least 138 kPa (20 psi).

USBM researchers have been focusing attention on how different types of seals—solid-block bulkheads (conventional), rapid inflatable seals, and binary foam seals—react under disaster conditions. During full-scale tests by the USBM, only the solid-block, Mitchell-type seal withstood a 138 kPa (20 psi).

Similar pressure tests have been done on both the inflatable and rigid binary-foam seals. The inflatable seal, which takes about 10 minutes to erect, is made of nylon material and has structurally withstood small-scale tests. Eventually, the USBM hopes to fill the inflatable seal with a quick-setting foam for explosion tests. Both the small- and full-scale tests have shown promising results.

Permanent stoppings, traditionally constructed from concrete blocks, are used to maintain proper ventilation. The structural integrity of a permanent stopping is key in a mine fire situation. Miners fighting or escaping from a fire depend on permanent stoppings to prevent the spread of fire and also to keep toxins from reentering the intake side of the ventilation. The USBM has been investigating both concrete-block an galvanized-steel stoppings against fire endurance.

Both types of stopping were erected and subject to 70 minutes of an artificially re-created mine fire. Video cameras were used to determine if flames or smoke penetrated the stopping, while heat sensors monitored surface temperatures. Surface temperatures on the fire side exceeded 788° C (1,450° F). Both types maintained structural integrity with no flames or smoke penetrating the stoppings. A strong difference, however, did exist between the exposed-side surface temperatures. The exposed side of the block stopping had a temperature of more than 66° C (150° F), while the steel stopping had an exposed-side temperature of more than 482° C (900° F). When the exposed side of the steel stopping was coated with a 19.1-mmthick (3/4-inch-thick) coating of plaster. temperatures were reduced by almost 50%. From these results, materials probably should not be stacked against permanent steel stoppings.75

MSHA Regulations

Among the health issues addressed by MSHA in 1992 was the concern about lung hazards resulting from excessive exposure of workers to crystalline silica. The Agency carried out a program to

target operations producing finely ground silica for special monitoring. MSHA established a task force to work with NIOSH to recommend dust control improvements at selected operations.

The bag stacker job function at mineral processing facilities continues to be a major health concern of MSHA and to operators because of the dust exposures being recorded by these workers. One such technique, being considered for a number of years to reduce this exposure. was a bag and belt cleaner device. Because the majority of the bag stacker's dust exposure comes from product on the bag or belt, reducing this product accumulation could have a measurable effect on reducing the worker's exposure. A bag and belt cleaner device has been designed and fabricated by the USBM. This device is a 3.04-m (10-ft) section of conveyor that can be used at any mineral processing operation bagging 22.7 to 45.36 kg (50 or 100 lbs) of mineral product into paper bags. This device cleans the outside of the bags using a series of brushes and air knifes. The system is totally enclosed and under negative pressure so that no dust removed from the bags is emitted into the work environment, and thus a contaminant to plant personnel. The dust removed from bags is exhausted to a baghouse. A chain conveyor is used to transport the bags through this device, which also removes any product that has fallen on to the conveyor belt. Once exiting this cleaner device, the bags and the conveyor belt are free of product, which reduces the exposure of any plant personnel handling the bags, or any future users. Preliminary results on this device show it to be very effective at removing product from the bags and belt and reducing the exposure to plant personnel.

During 1992, MSHA continued its Special Emphasis Mine Program. The program addresses concerns at mines and mills that have the potential for fatalities or disabling injuries. These may be due to geological hazards or operating conditions such as the release of harmful chemicals into the atmosphere. In 1992, 19 operations were on the Special Emphasis Mine Program list. Of those,

12 were underground, 2 were quarries, 2 were open pit mines, and 3 were ball mills.

MSHA, in cooperation with State mining agencies, continued its Joint Mine Assistance Program. This program is designed to help small mine operators in the four States that accounted for 70% of all coal mining fatalities establish a tailormade accident prevention program. Federal and State mine inspectors offer assistance to mines in Kentucky, Pennsylvania, Virginia, and West Virginia.

Consideration of health standards for miners has been ongoing for several years. MSHA proposed new air quality regulations for coal and metal/nonmetal mines. While MSHA's proposed regulations are undergoing review, they have brought to light the need to prepare for dealing with air quality concerns in coal mines. The proposed rules were published in the Federal Register as applicable to coal mines in 1989. These proposed regulations are comprehensive. They provide protection in such areas as permissible exposure limits, carcinogens, exposure monitoring, and means of control. These changes contain standards for more than 140 substances that would be regulated for the first time in a mine environment. 76

Methane Research

The USBM evaluated the use of exhaust gas to keep explosive gas mixtures from forming while auger A combination of mining highwalls. gasoline and diesel engine exhaust gasses, produced by the augering machine, was forced into the drill hole using a short section of pipe near the collar. Gas samples were taken and analyzed on-site with infrared detectors for oxygen, carbon dioxide, methane, and carbon monoxide. Evacuated bottle samples also were taken and analyzed in a gas chromotology laboratory for content. The combined gas results were analyzed for explosibility. Coal samples from various depths were used to obtain the gas content of the coal.

Personal carbon monoxide exposure

levels also were monitored, and the maximum time-weighted average sample measured 20 ppm. The highest methane level observed was 9.6%. The levels of inert gas (carbon dioxide and nitrogen) were sufficiently high to prevent any methane ignitions. Results showed that for all conditions during mining, gas concentrations were nonexplosive. From the tests performed, the USBM has deemed this system a safe, simple, and inexpensive method for preventing explosions during auger mining.⁷⁷

USBM researchers at the Pittsburgh Research Center are looking at fiber optics as a new means of sensing potential gas hazards in underground coal mines. An engineering prototype methane monitor that uses fiber-optic sensing has been designed as part of the USBM's research to improve mine safety.

A significant hazard in coal mines is the ignition of methane gas. Because methane is odorless and explosive when mixed with air to a concentration between 5% and 15%, it must be continually However, most methane monitored. monitors now in existence are powered by electrical sources that must be shut down during an emergency. Backup batteries have a very limited life. Once these are depleted, monitors cease to operate, possibly allowing dangerous levels of methane to accumulate. The reliability of methane monitoring may be enhanced by eliminating the need for electrical power by replacing current monitors with a totally passive, intrinsically safe, fiber-optic system.

In recent years, both the Government and industry have conducted much research on fiber-optic sensing. Because of the small return on investment in the limited mining market, the research has not been directed to mining applications. However, the use of fiber on the ocean floor for communications systems has proven that it is sturdy enough for the hostile mining environment. There are many advantages to fiber, including easy maintenance, low cost, high capacity, and light weight. The abundance of silica ensures the availability of fiber far into the future. Because silica and plastic used to make

the fiber are nonconductors, electrical sparking is not a problem.

The results are encouraging, but further research on the fiber-optic methane monitor is required before mine usage will be possible. Errors induced by temperature, bending, and index of refraction of the measured gases must be decreased. Also, a method of monitoring multiple sites will be determined to make the system economically feasible. 78

Stockpile Safety

A stockpiling safety manual prepared iointly by the USBM and the National Mine Health and Safety Academy (Safety Manual No. 30) discusses hazards associated with the operation of mobile equipment on and around stockpiles. It reviews procedures that can be used to minimize the occurrence of accidents. The manual is a result of the USBM's research in stockpiling safety and strong foundation of stockpile safety work provided by MSHA Technical Support and MSHA Metal and Nonmetal Mine Safety and Health. The manual can be obtained from the National Mine Health and Safety Academy, Beckley, WV.

Operating mine haulage trucks near the crest of stockpiles and waste dumps is a potentially hazardous practice. It often results in a localized slope failure and a dump point accident. The USBM has developed a computer code (INSLOPE3) based on the kinematic method of limit analyses that determines an admissible truck weight for varying distances from the slope edge.

The program considers the material strength parameters, slope geometry, and inertial forces induced by vehicle braking. It can be used to assist in the determination of safe operating distances for a haulage truck from a slope edge, the development of safe vehicle operating procedures, and the admissible weight for a static concentrated loading near the crest of an otherwise stable slope.⁷⁹

Fire Detection

A classification system has been developed by the USBM that can give a

mine operator an estimate of locations where fire-related hazards are most likely to exist. This system is based on data obtained from a review of fires that occurred from 1970 through 1989 and were reported by MSHA.

The objective of this research was to determine if degrees of hazard relative to fire source or location could be construed from information contained in the reports. Specifically, the propensity for fires to cause injuries and fatalities as well as the need to seal areas were examined. Source-related fires were found to exist throughout most mines; consequently, their random appearance made hazard assessment impossible. Research. therefore, concentrated on examining fire locations. Relative to all underground locations, fires occurring in belt entries were most likely to cause injuries while those in main haulageways were most liable for fatalities as well as sealing of at least the immediate area to extinguish. Results indicated a level of fatalities in main haulageways far greater than one would expect from random fluctuation.

Redundant levels of safety that exist at various underground locations were examined. These levels of safety were found to vary from place to place within a mine. Face, near-face, and belt locations had the highest levels of redundant safety. Conversely, haulageways had the lowest. This lack of safety levels was most likely due to the fact that equipment and activities in this entry were so varied.

A second study was undertaken to investigate what fire sources in haulage entries were most likely to cause fatalities. Results indicated that the most prolific source of haulage entry fires was the inadvertent grounding of trolley wires. The largest segment, encompassing 15 of 40 trolley wire fires, resulted from not maintaining adequate clearance between the trolley wire and the vehicle. Several novel fire prevention and control ideas have been proposed in response to frequently occurring firerelated problems in haulage entries.

Researchers at the USBM's Pittsburgh Research Center have developed a unique fire detector that can discriminate between the occurrence of real mine fires and the presence of diesel engine smoke. Called a submicron particle detector (SMPD), the apparatus can be used in other applications, including environmental monitoring and "clean room" monitoring. The USBM is actively seeking to commercialize the SMPD for any, or all, of its potential applications by licensing this technology to industry.

The SMPD was developed to eliminate the occurrence of false fire alarms in underground mines caused by operating diesel-powered equipment. Most fire detection systems now used underground mines are based measurements of airborne combustion products, such as carbon monoxide or smoke particles. The effectiveness of these systems can be reduced by false alarms set off by diesel-powered equipment that produce the same combustion products. These false alarms can be expensive to the mine operation because of downtime and labor required to verify the alarm.

The detector has been extensively tested by the USBM and has undergone in-mine tests and evaluations at operating coal mines that use diesel-powered equipment. Tests also have revealed that the SMPD offers potential applications in environmental areas such as particulate monitoring of smoke stack emissions. Clean room applications also may exist as well as the area of fire detection that extends beyond the mining industry.⁸⁰

Estimated.	. Revised.						

¹Distribution of industrial explosives and blasting agents by consuming industry estimated from indicies of industrial production and economics reported by the Department of Energy, Federal Reserve Board, Department of Transportation, and Bureau of the Census.

²Data may not add to totals shown because of independent rounding.

³Less than 1/2 unit.

ABRASIVE MATERIALS

By Gordon T. Austin

Mr. Austin, a physical scientist with more than 30 years of industry and Government experience, has been the commodity specialist for abrasive materials since 1986. Mr. William Field, statistical assistant, prepared the domestic data tables.

The combined value of production of natural abrasives, which include tripoli, special silica stone, garnet, staurolite, and emery, decreased about 24% in 1992. The decrease in the value of tripoli production was the result of a decrease in total production. Emery decreased owing to a decrease in the volume of the material produced. Special silica stone experienced a significant increase in unit value and decrease in the quantity produced. Garnet showed a 6% increase in quantity and a 36% decrease in unit value. Staurolite decreased about 27% in the quantity produced and value compared with those of 1991.

The fused aluminum oxide industry showed a slight increase in the quantity produced and a 4% increase in the value of production. The silicon carbide industry saw a 7% increase in the quantity produced and a 10% increase in the value of production. Combined, the industries increased 4% in quantity and 6% in value compared with those of 1991.

The quantity of metallic abrasives sold and shipped increased slightly in quantity and 7% in value compared with those of 1991. The industry includes the primary producers of steel, chilled and annealed iron, cut wire shot and grit, and shot and grit reclaimed by primary producers. Shipments in 1992 were about 9% below the industry's high of 239,619 metric tons¹ in 1979. (See table 1.)

The United States continued as the world's largest manufacturer, exporter, importer, and consumer of synthetic industrial diamond. The estimated apparent U.S. consumption of industrial diamond stones was 5.9 million carats, an increase of 18% compared with that of

1991, but was still significantly greater than the 48-year low in 1987.

DOMESTIC DATA COVERAGE

Domestic production data for abrasive materials were from seven separate voluntary U.S. Bureau of Mines surveys. Of the 61 operations producing natural and manufactured abrasives canvassed, all responded, representing 100% of the total production shown in tables 1, 5, 6, 8, 12, and 14.

FOREIGN TRADE

The total value of abrasive materials, exports plus reexports, was \$383.3 million, about a 20% increase compared with the 1991 value.

The total value of abrasive materials imported was \$482.1 million, an increase of 7% compared with the 1991 value. The average total value for the past 10 years was \$405.1 million per year, with the high in 1990 of \$512.8 million and the low of \$289.9 million in 1983.

The United States has shown a trade deficit in abrasive materials for every year of the past 10 years. In 1992, the deficit decreased 25% compared with that of 1991. (See tables 2, 3, and 4.)

TRIPOLI

The category of tripoli, as broadly defined, is composed of extremely fine-grained crystalline silica in various stages of aggregation. The particle sizes usually range from 1 to 10 micrometers, but particles as small as 0.1 to 0.2 micrometer are common. Commercial tripoli contains 98% to 99% silica and

minor amounts of alumina (as clay) and iron oxide. Tripoli may be white or some shade of yellow, brown, or red depending on the percentage of iron oxide. The U.S. Bureau of Mines includes not only tripoli, but other finegrained, porous silica materials that have similar properties and end uses such as rottenstone and novaculite. It does not include fine-grained or porous silica materials included in other Mineral Annual Report chapters, such as pumice.

Production

In 1992, the quantity of crude tripoli produced decreased 4% to a new 10-year low and the value of production decreased slightly compared with those of 1991. The average production for the past 10 years was 100,589 tons per year, with a high of 112,928 tons in 1984 and a low of 84,777 tons in 1992. In the United States four firms produced tripoli. Malvern Minerals Co., Garland County, AR, produced crude and finished material. Malvern also produces a black material from novaculite. Tripoli Co. produced crude material in Ottawa County, OK, and finished material in Newton County, MO. Unimin Specialty Minerals Inc.'s Alco and Tamms plants, in Alexander County, IL, produced crude and finished material. Keystone Filler and Manufacturing Co. in Northumberland County, PA, processed rottenstone, a decomposed fine-grained siliceous shale, produced by B. J. Ulrich & Sons, also in Northumberland County, PA. (See table 5.)

Consumption and Uses

Processed tripoli, sold or used, increased 4% in quantity and 5% in value compared with those of 1991.

Tripoli is processed in mills that are iasper lined using flint or iasper pebbles in closed circuit with banks of mechanical classifiers. Material from the mechanical classifiers is fed to micronizing mills, in which it is ground and sized at the same time. Material that is 100% minus 10 micrometers and 96% minus micrometers is the smallest particle-size material sold. Even this very fine particle material is not the result of fragmentation of individual crystals; instead, clusters of quartz crystals, many less than 1 micrometer in size that are joined at their points, are broken apart. The ultrafine-grained tripoli is a collection of clusters and individual quartz crystals.

Tripoli has had unique uses as an abrasive because of its hardness and its grains lack distinct edges and corners. It is a mild abrasive, making it suitable for use in toothpaste and tooth polishing compounds, industrial soaps, and metal and jewelry polishing compounds. The automobile industry uses it in buffing and polishing compounds in lacquer finishing.

The end-use pattern for tripoli has changed significantly in the past 20 years. In 1970, nearly 70% of the processed tripoli was used as an abrasive. Today, 73% is used as a filler and extender in paint, plastic, rubber, caulking compounds, and enamel.

The largest use of tripoli is as a filler and extender in paints and is estimated to account for as much as 85% of the tripoli used as filler and extender. Its use in exterior latex paints is as a lowmicrometer-grade micronized product. In these paints, tripoli aids in tint retention, durability, leveling, and flowability. In enamels, it permits higher loading with no appreciable increase in vehicle demand and improves sheen. Because of its controlled grain or particle size, paints containing tripoli disperse easier and result in a uniform film. Additionally, because of its abrasive qualities, the paints are more resistant to wear and more resistant to chemicals than those in which water-ground whitings and other reactive fillers are used.

Plastics, rubbers, and resins each use about 5% of total annual tripoli filler and extender production. It is used extensively in plastics for electrical uses because of its dielectric properties and its effects on flexural and compressive strengths. Its chemical resistance, weatherability, and resistance to salt spray also are important to its use in plastics. Its physical properties allow high loading in most compounds, but its abrasiveness results in high wear in extruding nozzles and molds. The same properties that make tripoli useful as a filler and extender in plastics make it valuable to the rubber and resin industries.

Tripoli contains essentially 100% crystalline silica, so its use can cause silicosis and falls under the jurisdiction of the Occupational Safety and Health Administration's (OSHA) Hazard Communication Standard. The International Agency for Research on Cancer and other independent studies have determined that crystalline silica is a probable carcinogen for humans. As a result, OSHA is required to regulate materials containing more than 0.1% crystalline silica. To date, it does not appear that these regulations have adversely affected the use of tripoli, but all tripoli must be labeled in compliance with OSHA regulations.

In the filler and extender uses listed, ground calcium carbonate, ground silica sand, pyrogenic and precipitated silica, calcined kaolin, and talc can be substituted.

The use of tripoli as an abrasive decreased about 12% in 1992 to a 10-year low of 18,603 tons; 1992 was the eighth consecutive year of decline. During the 8-year period, consumption declined about 50%. The average annual consumption of abrasive tripoli for the past 10 years was 28,418 tons, with a high of 37,024 tons in 1984 and a low of 18,603 tons in 1992. The 1992 consumption was the lowest since 1949, when only 20,972 tons was sold or used.

After 4 consecutive years of decline,

from 1988 through 1991, the amount of tripoli used as filler increased. The 10% increase in 1992 followed a 7% decline in 1991, a 10% decrease in 1990, an 8% decrease in 1989, and an additional 4% decrease in 1988. The average consumption of filler-grade tripoli for the past 10 years was 61,583 tons per year, with a high of 71,160 tons in 1987 and a low of 52,334 tons in 1991. U.S. Bureau of Mines data show that tripoli use in the United States as a filler is about 76% of the total, with abrasive, 24%.

Prices

The average reported value of abrasive tripoli, sold or used, in the United States was \$149.38 per ton. The average annual value reported for abrasive tripoli for the past 10 years was \$117.91 per ton, with the high value in 1992 of \$149.38 and the low in 1983 of \$92.74. The value of abrasive tripoli has increased over the past 10 years at an annual compounded rate of 10% per year. The increase has been continuous; the annual rate of increase from 1985 to 1992 was significantly lower than the annual rate of increase from 1983 through 1984.

The average reported value of filler tripoli, sold or used, in the United States was \$196.62 per ton. The average annual value for the past 10 years was \$147.55 per ton, with a high of \$203.02 per ton in 1992 and a low of \$102.84 per ton in 1983. The value increased at an annual compounded rate of about 9% for the past 10 years.

SPECIAL SILICA STONE PRODUCTS

Special silica stone products include hones, whetstones, oilstones, stone files, grindstones, grinding pebbles, tube-mill liners, deburring media, and certain specialty products. These do not include products made from artificially bonded abrasive grains. Manufacture of these products was from novaculite, quartzite, or other quarried microcrystalline quartz rock.

Production

Plants manufactured oilstones, hones, whetstones, and files in Arkansas. Additional production includes grindstones in Ohio, deburring media in Arkansas and Wisconsin, and grinding pebbles and mill liners in Minnesota. Production of the crude materials was in the same State as the products manufactured.

The production of oilstones, hones, and grindstones files. whetstones. increased about 25% in quantity to 340 tons from its 10-year low of 272 tons in 1991 and 27% in value to \$4.6 million. The average annual production of the products for the past 10 years was 458 tons, with a high of 620 tons in 1984 and a low of 272 tons in 1991. The average value of annual production for the past 10 years was \$5.3 million, with a high of \$7.4 million in 1987 and a low of \$3.6 million in 1991. In the past 10 years, two distinct and different trends in the value of production appeared. One was from 1983 through 1984, when the average value of production was \$3.9 million per year. The other was 1985 through 1992, when the value of production was 68% greater at an average value of \$5.7 million per year. During 1985-92, the average annual quantity of production was less than the 10-year average and the average annual value of production was 8% greater than the 10year average. The change in average annual value was the result of a significant increase in the value per ton of manufactured products, starting in 1985. Production recovered significantly from the large decreases in 1991 that were attributed to one of the major producers in the industry entering into bankruptcy. (See tables 6 and 7.)

The industry manufactured four main grades of Arkansas whetstone. They ranged in grade from the high-quality Black Hard Arkansas Stone down to the Washita Stone. The Black Hard has a porosity of 0.07% and a waxy luster, while Washita Stone has a porosity of 16% and resembles unglazed porcelain.

Arkansas accounted for essentially 100% of the value and total quantity of

special silica stone products reported as sold or used by U.S. producers.

Consumption and Uses

The domestic consumption of special silica stone products is a combination of residential, industrial, leisure, and craft uses. The major residential uses were the sharpening of knives and other cutlery such as scissors, shears, and lawn and garden tools. Major industrial uses were the sharpening and honing of cutting surfaces, polishing of metal surfaces, and the deburring of metal and plastic castings. The manufacture, repair, and modification of guns also make use of stone files. The recreational uses were sharpening of sports knives, arrowheads, spear points, fish hooks, and other recreational items. Craft applications included uses in sharpening tools for wood carving, gun engraving, jewelrymaking, and other engraving work.

Prices

The value of crude novaculite suitable for cutting into finished products varied from \$19 per ton to \$1,266 per ton. The low value was for Washita grade and the high for Black Hard Arkansas grade. The manufacture of deburring media or special-purpose crushed stone is from material not suited for making oilstones. hones, or whetstones. The value of these materials ranged from \$11 per ton to \$440 per ton. The average value in 1992 of oilstones, hones, whetstones, and grindstones, sold or used by U.S. producers, was \$13,405 per ton. The average annual value of the same items for the past 10 years was \$12,068 per ton, with a high of \$14,741 per ton in 1989 and a low of \$6,411 per ton in 1984.

In the past 10 years, the unit value of special silica stone products followed three distinct negative trends. The first trend, a gradual decrease, occurred during the period 1983-84. The value per ton averaged \$6,985, with a high of \$6,985 and a low of \$6,854 in 1984. A second trend began in 1985 when the

value per ton more than doubled from \$6,411 to \$13,361. The average annual value per ton for the period 1985-88 was \$13,006, with a high of \$14,113 in 1986 and a low of \$12,229 in 1988. The third trend began in 1989 with a value of \$14,741 followed by 2 years of declining average values until 1992's slight increase. One possible explanation for the series of step-ramp trends is the introduction of new high-value products by a single manufacturer. The product encounters significant price competition from other producers in subsequent years. New products can be duplicated by competitors quickly because the special silica stone products industry is not high technology. This very quickly results in short-term price pressures.

Foreign Trade

The value of exported special silica stone products was \$7.6 million, an increase of 3% compared with that of The average annual value of 1991. exports for the past 10 years was \$4.5 million, with a 10-year high of \$10.4 million in 1990 and a low of \$2.0 million in 1987. The annual value of exports during the past 10 years did not appear to have established a trend. Instead, the value drifted between \$2.0 million and \$2.6 million with as many increases as decreases until the significant increases in 1989 and 1990, followed by the 1991 and 1992 lower values.

The value of imported products was a 10-year high of \$2.5 million, an increase of 39% compared with that of 1991. The average annual value of imports for the past 10 years was \$1.7 million, with a high of \$2.5 million in 1992 and a low of \$1.0 million in 1983. The trend for products imported to the United States was generally upward with some occasional decreases. The United States continues to be a net exporter of special silica stone products. A portion of the finished products imported was from crude novaculite produced within the United States and exported for processing.

In 1992, the trade surplus in special silica stone products was \$5.1 million, a

decrease of about 9%. During the past 10 years, the United States enjoyed an average trade surplus of \$2.9 million per year, with a high of \$8.1 million in 1990 and a low of \$0.4 million in 1985. The trend for the past 10 years had been one of declining surpluses until the 1989 and 1990 increases; the lower values for 1991 and 1992 are still almost twice the 10-year average.

GARNET

Technical-grade industrial garnet from the United States is a solid solution of almandite and pyrope that, when under pressure, breaks into sharp chisel-edged plates. Industry uses this garnet as an abrasive powder and to manufacture coated abrasives. Low-quality industrial garnet found uses primarily as airblasting or hydroblasting media and as filtration media.

Background

Definition, Grades, Specifications.—Garnet is a general name for a family of complex silicate minerals having similar physical properties and crystal form. The general formula for garnet is A₃B₂(SiO₄)₃ where A can be calcium, magnesium, ferrous iron, or manganese and B can be aluminum, ferric iron, chromium, or rarely titanium. The most common garnet species are Mg₃Al₂Si₃O₁₂ (pyrope) and Fe₃Al₂Si₃O₁₂ (almandite). Almandite and almanditepyrope solid solution garnets are the best abrasive garnets, but andradite. grossularite, and pyrope also are used. Garnet displays the greatest variety of color of any industrial mineral, having been found in all colors except blue. For example, grossularite can be colorless, white, gray, yellow, yellowish green. various shades of green, brown, pink, reddish, or black. Andradite garnet can be yellow green, greenish brown, orange yellow, brown, grayish black, or black. Pyrope is commonly purplish red, pinkish red, orange red, crimson, or dark red; almandite is deep red, brownish red, brownish black, or violet red. Spessartite garnet can be red, reddish orange,

orange, yellow brown, reddish brown, or blackish brown.

The Mohs hardness of garnet varies from 6.5 to 9.0. Grossularite and uvarovite have a hardness of 6.5 to 7.5; andradite is 6.5 to 7.0; and pyrope, almandite, and spessartite are 7.0 to 7.5 in hardness. There are reports of almandite having a hardness of between 8.0 and 9.0.

As with hardness, the specific gravity of garnet varies considerably. The specific gravity may be as low as 3.2 grams/cubic meter or as high as 4.3 grams/cubic meter depending on chemical composition.

Consumers purchase garnet that has been crushed, ground, and graded to different particle sizes for different end 11565 Descriptions of testing methods for materials to be used in the manufacturing of coated abrasives are contained in American National Standards Institute (ANSI) Specification B74.18-1977, "Specifications for Grading of Certain Abrasive Grains on Coated Abrasive Products. "2 Other specifications are contained in ANSI Specification B74.12-1976, "Specification for Size of Abrasive Grains-Grinding Wheel. Polishing, and General Industrial Uses. "3

If the garnet is to be used as a sandblasting medium at a U.S. Navy shipyard or a private shipyard working on U.S. Navy vessels, then it must meet MIL-A-22262(SH) specifications that qualify it for product list QPL-22262. These specifications set forth limits on the content of total metals, soluble metals, and radiation, specify the acceptable level of chemical conductivity, and require that the material be certified by the California Air Resources Board.

The California Air Resources Board (ARB) requires all loose-grain abrasives used in the State to be certified at the ARB testing facility. The testing is conducted according to "Methods of Test of Abrasive Media Evaluation," Test Method No. Ca 371-A, and as required under ARB's Title 17, Subchapter 6, entitled "Abrasive Blasting." Copies of these documents are available from the Compliance Division of the California Air Resources Board, Sacramento, CA. In

addition, air pollution control agencies in Louisiana, Minnesota, and Utah have adopted the ARB tests and require that only ARB-certified abrasives be used on State projects requiring sandblasting. The ARB's testing procedures and standards are focused on the environmental impact of sandblasting abrasives, not on their qualities or cutting performance and/or efficiency.

The Steel Structures Painting Council, a technical organization in Pittsburgh that has a committee on abrasives, is currently drafting abrasive specification SSPC-XAB1X, "Mineral and Slag Abrasives," which will address garnet specifically. The specification defines the requirements for selecting and evaluating mineral and slag abrasives used in blast cleaning steel and other surfaces for painting and other purposes.

The American Water Works Association (AWWA) has established specification B100-89, "Standards for Filtering Materials," but this specification does not cover high-density media such as garnet and ilmenite. The AWWA plans to include garnet and ilmenite in the updated specification B100-94. Ĭn general, specifications for filtration involve garnet's particle shape, specific gravity, effective grain size, coefficient of grain size uniformity, content of acidsoluble impurities, and content of radioactive and heavy metals.

The sale of garnet for sandblasting, water filtration, and abrasive cutting is by screen size. In U.S. sandblasting, the most widely used domestically produced garnet is -1.0 + 0.3 millimeter, followed by -0.59 + 0.21 millimeter. The most popular grade of imported garnet in the U.S. market is the -0.59 + 0.25millimeter grade from Australia. In U.S. multimedia water filtration systems, two grades of garnet are used, a coarse grade that is -4.75 + 1.41 millimeters, and a fine grade that is either -0.84 + 0.3 or -0.71 + 0.25 millimeter. Abrasive cutting applications' most popular grade of garnet is -0.25 + 0.177 millimeter, which may account for as much as 90% of the garnet used.

Compliance Division of the California Air Resources Board, Sacramento, CA. In testing the quality of garnet or any other

loose-grain abrasive except by actual There are tests and application. examinations that can indicate a garnet product's probable abrasive performance in use. The fracture, sharpness, shape, and structure of the garnet and the presence of inclusions all can be studied with a microscope. The hardness and friability of the garnet can be evaluated by placing a sample between two glass microscope slides and rubbing them together. The relative scratch hardness of the grains and their degree of breakdown (attrition) can be measured in this manner. Additionally, ANSI standard B74.8-1965, "American Standard Test for Ball Mill Test for Friability of Abrasive Grain," can be used to determine the friability of garnet grains.

The U.S. National Institute for Standards and Technology developed an apparatus for evaluating the abrasive quality of corundum. This tester can be adapted for use with any loose-grain Testing of loose-grain abrasives also can be performed with various production-scale and laboratory machines where the removal of glass from flat plates is evaluated. Data from such tests can be correlated with the anticipated performance of any abrasive grain relative to the other material to be abraded. In these tests abrasive performance is determined by the amount of stock removed, as found either by or by dimensional weighing measurements.

In judging the abrasive quality of garnet, stock removal is not the only important factor. Surface finish is just as important. If an abrasive is too hard or contains too-coarse grains for use on a certain material it can cause deep scratches in the surface, which cannot be removed in subsequent finishing operations. Additionally, if an abrasive does not have the proper grain shape or does not break down in such a manner as to resharpen itself, it will tend to burn or gouge the material being abraded, thus defeating the purpose of its use.

The California ARB's testing facility tests loose-grain abrasives for certification for use in the State. The test is focused

on the environmental impact of sandblasting abrasives, not on their abrasive quality.

Other firms or laboratories that test the quality of loose abrasive grains include three firms involved in the abrasive cutting industry, Flow International Corp., Ingersoll Rand Corp., and Jet-Edge, Inc., that have laboratories for testing and evaluating garnet for use in their systems. Most of the evaluations in these laboratories involve the comparative testing of various abrasive grits, including measurements of particle size distribution and mechanical properties.

KTA-Tator, Inc. of Los Angeles, CA, is a major consulting/engineering/testing firm whose laboratory tests and evaluates the quality of garnet and other abrasives. Much of its work is oriented to the Steel Structures Painting Council (SSPC) specifications. The SSPC also can carry out comparative testing of garnet and other loose-grain abrasives to determine whether they meet military specifications, how clean the material is, how well the cleans. the amount degradation during use, and other quality factors. SSPC is part of the Carnegie-Mellon Research Institute and must be careful not to conduct research that favors one abrasives supplier over another supplier who may be a member of the Council.

Industry Structure.—Currently four firms produce garnet from four plants in two States. Each domestic producer has distinctive products. The Barton Mines Corp., Warren County, NY, garnet is a mixture of almandite and pyrope and is at the top of the garnet hardness range. It occurs as large crystals and exhibits incipient lamellar parting planes that break under pressure into sharp chiseledged plates. It retains this chisel-edged shape even when crushed to a very fine Its garnet is used in coated size. abrasives, glass grinding and polishing, and metal lapping. The NYCO Div. of Processed Minerals Inc., Essex County, NY, and International Garnet Abrasive Inc., Clinton County, NY, garnet is a mixture of andradite and grossularite, and the crude garnet concentrate may contain diopside-hedenbergite (Ca[MgFe]Si₂O₆). NYCO recovered garnet as a byproduct from its wollastonite operation. It sold both crude garnet concentrate for additional refining and refined garnet for use as blasting and filtration media. International Garnet Abrasives produced refined garnet from NYCO's crude garnet concentrate for use as blasting and filtration media. Emerald Creek Garnet Milling Co. was purchased by Hawkeye Development Co., an Idaho corporation, in November 1991. Under the new name of Emerald Creek Garnet Co., it continued mining and milling operations in Benewah County, ID. Blasting and filtration media were the primary uses of the garnet.

Abrasive garnet production in the United States began in 1878 at the Gore Mountain site of Barton Mines, near North Creek, Warren County, NY. During the first year, production was less than 100 tons. It was used in coated abrasives, both paper and cloth. 4 Barton Mines Corp. mined and processed the abrasive-grade garnet on Gore Mountain until the company moved the mining operation and processing plant in 1982 to the adjoining Ruby Mountain. Barton Mines has been a family-owned operation since its formation. Reported past domestic garnet production was from California, Connecticut, Florida, Maine. New Hampshire, North Carolina, and Pennsylvania.5

Nine manufacturers at ten plants produced garnet-coated abrasive papers and cloths. The plants are in New York and Virginia, two in each, and Massachusetts, Michigan, Minnesota, Mississippi, Ohio, and Pennsylvania, one in each.

Geology-Resources.—Garnet is found as an accessory mineral in a wide variety of rocks. Most commonly it is found in gneisses and schists, but it also is found in contact metamorphic rocks, crystalline limestones, pegmatites, volcanic rocks, eclogites, and serpentinites. Additionally, garnet is found in the gangue of veins formed at high temperatures. Because garnet is resistant to chemical and mechanical weathering, it is common in

the sands of current or ancestral beaches, streams, and other types of alluvial deposits. Commercially attractive industrial garnet occurrences are not common. Many garnets that occur in deposits of economic size degrade during processing because of internal stresses. These stresses develop in the garnet crystal during formation and cooling. Stress relieving is not economical; therefore, these deposits have no commercial value as a high-grade abrasive material source.

Garnets are usually small in size. Grossularite crystals range up to about 15 centimeters in diameter. Almandite approximates the same range in size except at Gore Mountain and North Mountain, NY, where crystals range up to 60 centimeters in diameter. Spessartite crystals from Brazil can weigh as much as several kilograms. Most garnet crystals are less than 2.54 centimeters in size.

The majority of world garnet production is from alluvial deposits in the United States, Australia, China, and India. Possibly the world's highest quality garnet is mined, however, from almandite-bearing rock of uncertain origin in the Adirondack Mountains of New York.

New York and Maine have the only known high-quality garnet reserves in the United States. The Wing Hill garnet deposit, near Rangeley in western Maine, is one of the largest and highest grade garnet deposits in the world. The host rock is a homogeneous garnet granofels that consists of 50% to 70% almandite garnet. It is medium grained and consists essentially of garnet and andesine plagioclase along with biotite and minor quartz. The garnet is present as discrete, well-formed crystals from less than 1 millimeter to about 10 millimeters in diameter but averaging 1.5 to 2 millimeters. The granofels is an eastwest trending, tabular body more than 1,000 meters in length and as much as 700 meters thick. The garnet ranges in Mohs hardness from 7 to 8 and in density from 3.6 to 4.3 grams/cubic meter. When crushed, the garnet breaks into blocky grains, a shape that persists down

to the finest fragment. The garnet is amenable to gravity and magnetic concentration when the ore is crushed to -3.36 millimeters. The estimate of reserves in the igneous rock deposit near Rangeley, ME, is more than 1.8 million tons of garnet.

Deposits of industrial garnet are found at two locations in New York. In the Gore Mountain area, technical-grade garnet is mined as the primary product, and near the town of Willsboro, commercial-grade garnet is recovered as a byproduct of wollastonite mining.

The deposit near Gore Mountain is an almandite-bearing diorite of uncertain, igneous or metamorphic origin. The ore body is approximately 2 kilometers long and 15 to 90 meters wide. The ore grade varies from less than 5% to about 20% garnet and averages slightly less than 10%. Hornblende and plagioclase feldspar make up 40% to 80% of the host rock, while hypersthene, magnetite, biotite, apatite, and pyrite are present in minor amounts. A rough estimate suggests that more than 600,000 tons of high-quality garnet can be recovered from Barton Mines Corp. deposit on Ruby Mountain in New York. The garnet is present as imperfectly developed crystals surrounded by a rim of coarsely crystalline hornblende. The crystals range from about 1 millimeter to almost 1 meter in diameter but average about 100 millimeters in diameter. The garnet has a pronounced laminated structure. which enables it to naturally break into thin plates from about 2 to 6 millimeters in thickness. Garnet fragments maintain this platy particle shape even as they are crushed smaller and smaller.

Garnet is recovered as a byproduct from a wollastonite deposit on the western side of Lake Champlain near Willsboro. The deposit is in a belt of wollastonite-bearing rocks that is about 10 kilometers long and 0.4 kilometer wide. The largest zone of wollastonite rock within the belt is from about 9 meters to more than 20 meters thick but averages about 13 meters thick. The wollastonite is interbanded with almandite garnet and iron-rich diopside. The garnet and diopside together comprise 10% to 20%

of the ore. Both the garnet and diopside are feebly magnetic and are easily separated from the wollastonite by magnetic separators.

Alluvial deposits of almandite garnet were discovered in the early 1880's near Fernwood in Benewah County, but commercial mining did not start until the early 1940's. The deposits are on Emerald, Carpenter, and Meadow Creeks about 6.4 kilometers from a mica-garnet schist formation. The source schist is estimated to be about 1,200 meters thick. The garnet-bearing gravels are from nearly 1 meter to about 1.2 meters thick and contain 8% to 15% garnet. Garnets from these gravels range up to 40 millimeters in diameter, although about 95% of the garnet is smaller than 7 millimeters in diameter. The quantity of garnet-bearing gravels reported at Emerald Creek and Carpenter Creek in Idaho is large. A minimum of 450,000 tons of garnet is available in the Emerald Creek Garnet Co. deposits.

There can be little doubt that tremendous reserves of garnet similar to the lower priced materials can be located as needed.⁶ Also, the production of byproduct garnet from many current mining operations is possible if demand improved.

Reserves are significant in Australia, China, India, and the former U.S.S.R., but accurate data are not available. Huge inferred and undiscovered resources are likely to exist throughout the world.⁷

Technology.—Exploration.—Successful exploration for garnet deposits begins with selection of target areas based on the presence of known favorable host rocks. Geologic studies and maps, topographic maps, and aerial photographs are used to identify favorable metamorphic, igneous, alluvial, or eolian geological formations.

The second step is field examination of the selected targets. This may include geologic mapping and limited sampling, but in many cases reconnaissance studies are sufficient. The next step, if warranted, is to sample the deposit in detail, the purpose being to measure the physical parameters of the deposit, specifically its grade and size.

The method of sampling used depends upon the type of deposit. Hard-rock deposits, igneous or metamorphic, are sampled differently than alluvial or eolian deposits.

Hard-rock deposits can be either diamond core drilled or trenched. Trenches should be oriented perpendicular to the strike of the formation and can be dug by hand, with a dozer, or with a backhoe.

Placer deposits can be sampled by drilling, trenching, or by excavating pits or shafts. The physical nature of the deposit, its thickness, hardness, grain size, and whether it is above or below the water table influence the method of sampling chosen. For shallow deposits, hand augers or power augers can be used to drill sample holes. In deposits that are too hard to hand auger because of the presence of clay, iron oxide cement, or mild calcium carbonate cement, twoperson motor-driven augers or vehiclemounted augers (such as post hole diggers or telephone pole hole diggers) work well. However, augering does not always provide uncontaminated samples and is not effective below the water table.

Truck-mounted water-jet drills and rotary hammer drills are used to test thick deposits and deposits that are too hard to drill with other methods. A water-jet drill uses flush-jointed drill pipe with perforations near the bit to direct jets of water forward and downward from the bit. A hammer advances the drill bit and casing at the same time. Water from the jets flushes out the hole and returns cuttings to the surface in the annulus between the drill pipe and casing. Also, truck-mounted rotary drills equipped with double-pipe drill string and downhole hydraulic hammers can be used. Compressed air is forced down the inner pipe and returns samples to the surface in the annulus between the inner pipe and outer casing. Bits are selected depending on the type of material to be drilled.

Trenching can be carried out using either a dozer or a backhoe, depending on the size and depth of the deposit. In unconsolidated sediments it is difficult to maintain the stability of the walls of

trenches, and samples can be contaminated by material sloughing from above. Bulk samples can be collected from 1-cubic-meter pits or shafts. However, here again, wall stability can be a problem unless some form of shoring is used.

of Deposits.-The Evaluation evaluation of garnet deposits to determine suitability for commercial their production can be divided into five major (1) size and grade of the factors: reserves; (2) mining conditions; (3) quality of the garnet; (4) location of the deposit relative to markets and infrastructure; and (5) milling costs. The relative importance of each of these factors will vary from one deposit to another, but the final determination of economic viability will depend upon all of them.

- 1. Size and grade of reserves: An economic garnet deposit has reserves that are large enough and high enough in grade to provide full project capital recovery, meet all operating costs, and furnish a reasonable profit over the depreciable life of the project, which is normally at least 10 to 20 years. Generally, a deposit should contain a minimum of 2 million tons of ore. The cutoff grade used in calculating reserves will depend on the economics of the specific deposit, but cutoff grades for most deposits average about 20% garnet.
- 2. Mining conditions: Mining conditions greatly affect the economics of a deposit and can even control whether the deposit can be developed. Early field examinations should identify any conditions, such as nearby houses, historical sites, national monuments, archaeological or paleontological sites, wildlife refuges, municipal watersheds, etc., that could preclude mining the deposit. Local, county, and State zoning regulations, environmental regulations, and other constraints should be checked to establish their effects on mining the deposit.

Hard-rock garnet deposits are mined in benched open pits using conventional drill-and-blast methods. Some placer deposits are mined with dredges. The configuration and structure of the deposit should be such that there are no blocks of waste rock within the ore body and that the garnet is, ideally, uniformly distributed throughout the ore. All physical and chemical features of the ore and overburden will influence whether the deposit is amenable to open pit mining and will impact the total mining cost per ton.

- 3. Quality of the garnet: The garnet in a deposit must be tested to evaluate its performance and marketability as an abrasive. It should be recognized in this regard that most garnet used in abrasive applications is either the almandite or almandite-pyrope type. The garnet should be present in the deposit as discrete crystals that are at least 6 to 13 millimeters in size and that are liberated when the ore is crushed to -2 millimeters. The crystals should be free of any inclusions, such as quartz, hornblende, and feldspar, and also should be free of alteration. The garnet should be relatively uniform in hardness and density throughout the deposit. It should not be badly weathered or highly friable. If an incipient parting is present in the garnet crystals, the effect this parting has on the quality of the final product and the distribution of such crystals within the deposit should be determined.
- 4. Location relative to markets and infrastructure: The location of a garnet deposit must be evaluated relative to its proximity to the markets for garnet abrasives and filter media. If the deposit itself is not near major market areas, then it must be near adequate and inexpensive means of transportation, especially by rail or water. Deposits should be reasonably accessible from existing roads.
- 5. Milling costs: The type of milling required and the cost of processing the ore must be analyzed carefully. Ideal ore is that from which the garnet can be liberated with minimum crushing and can be recovered using gravity/density-based methods of mechanical concentration and where size classification of the concentrate yields a complete range of product sizes. In some cases portions of the concentrate will be ground to achieve proper particle size distribution.

ABRASIVE MATERIALS—1992 105

Mining.—At the Barton Mine in New York, the Ruby Mountain ore body covers approximately 41,000 square meters, which is nearly the entire mountain. The ore is mined by open pit methods with benches 9 meters high. The ore is drilled and blasted, a drop ball provides secondary breakage, and power shovels load ore into trucks for haulage to the mill, about 0.4 kilometer away.

At Emerald Creek and Carpenter Creek, Benewah County, ID, backhoes are used to strip 1 to 2 meters of overburden, which exposes the garnetiferous gravel. Mining is then carried out with draglines, and ore is trucked to a mill for processing.

Wollastonite mining at Willsboro, NY, yields a byproduct concentrate containing garnet, diopside-hedenbergite, and minor amounts of wollastonite. After drilling, blasting, and loading, the ore is transported 22 kilometers to the plant for separation of the wollastonite from the garnet-diopside.

Beneficiation.—The primary factors controlling the behavior of garnet ore during processing are the identity and characteristics of the minerals present, the percentage of each mineral present, and the size of the garnet grains. The major minerals associated with garnet in most deposits are feldspar, mica, hornblende, pyroxene, and quartz. Magnetite, pyrite, ilmenite, limonite, pyrrhotite, and occasionally chalcopyrite, rutile, zoisite, chlorite, and corundum may be present in much smaller amounts. Sodium feldspar is the most common feldspar, biotite is the most common mica, and hypersthene and diopside are the most common varieties of pyroxene present. The most important physical property controlling the behavior of the major and minor minerals during concentration of the garnet is their specific gravity.

At Barton Mines Corp.'s plant in New York, garnet is liberated, concentrated, and further processed by combinations of crushing and grinding, screening, tabling, flotation, magnetic separation, water sedimentation, drying, heat treating, and air separation. Occasionally, a single process will accomplish both sizing and

the removal of gangue minerals, but this usually requires several processes. Particle size control can be difficult but is important for the concentration processes to work effectively.

The process used by Barton Mines to recover garnet has evolved over time. It began in 1924 with construction of the first "modern" plant where separation was accomplished using jigs. In 1941, heavy-media separation was added to the system, and in 1945, flotation was added. The current state-of-the-art mill is a combination of heavy-media and flotation circuits. Ore crushed to -7 millimeters is screened to 3.36 to 2.38 millimeters with the coarse fraction going to a heavymedia circuit using a density of 3.02 grams/cubic meter for primary separation and a density of 3.20 to 3.40 grams/cubic meters for secondary separation. fine fraction from the screen goes to a flotation circuit where it is first ground to -0.3 millimeters in ball mills and then fed to float cells. The concentrate from the heavy-media circuit is roll crushed. combined with the float concentrate, and then dried and heat-treated in a rotary kiln.

At Emerald Creek Garnet Co.'s operation in Idaho, the ore is first processed through trommels to remove the gravel and is then concentrated in jigs and on shaking tables. The garnet concentrate is dried, crushed, and screened. The maximum grain size of finished products is 46 millimeters.

At NYCO Minerals' mill in New York, beneficiation of the wollastonite-garnet ore requires two stages. The first stage involves drying, crushing, screening, and recrushing the feed to -1.19 millimeters. In the second stage, the -1.19 millimeter ore passes over a series of screens to attain -1.19 + 0.84, -0.84 + 0.42, -0.42 + 0.25, and -0.25 millimeter splits. A battery of magnetic separators then removes the garnet from each of these fractions. Four sizes of final product are bagged for shipment.

Today, practically all grade-grain abrasive garnet is heat treated as a processing function, not to improve its inherent abrasiveness. Impurities picked up during processing stick to the garnet particle surfaces. These impurities destroy the cleanliness and capillarity needed in later processing to give adhesion for bonding. In the early 1960's. scientific investigations determined that heat treating only cleaned the particle surfaces and that too high a temperature could destroy the abrasive quality of garnet. In the mid-1960's, the coated-abrasive industry accepted uniform color standards. These standards ensured the cleanliness of the grain surface and a color most closely approaching the natural red color of abrasive garnet. The heat treatment needed to do this is the RT treatment.8

Annual Review

Production.—In 1992, the four U.S. firms produced 54,139 tons of crude garnet concentrate worth \$4.8 million, a 6% increase in quantity and a 36% decline in value compared with those of 1991. The average annual production for the past 10 years was 39,199 tons, with a high of 54,139 in 1992 and a low of 27,004 in 1983. The production trend for the past 10 years has been one of continued long-term growth with two downward adjustments. (See table 8.)

Consumption and Uses.—In 1992, the quantity of garnet sold or used by producers was 49,942 tons, an increase of 4%, and the value increased slightly to \$13.3 million. The average annual quantity of garnet sold or used for the past 10 years was 37,064 tons, with a record high of 49,942 tons in 1992 and a low of 25,104 tons in 1984. The trend for the past 10 years was one of steady annual growth, except for 4% decreases in 1984.

The major industrial use for high-quality, high-value garnet since before 1880 has been as loose-grain abrasives for applications such as optical lens grinding and plate-glass grinding. In recent years, its applications included the high-quality, scratch-free lapping of semiconductor materials and other metals. The finishing of wood, leather, hard rubber, felt, and plastics often requires

106 ABRASIVE MATERIALS—1992

the use of garnet-coated abrasive papers and cloths.

aluminum aircraft and The shipbuilding industries in California and the Pacific Northwest use lower quality, lower cost alluvial garnet, primarily from Idaho, for sandblasting. Similar uses in the Eastern United States are for the cleaning and conditioning of aluminum and other soft metals and for cleaning of metal by structural steel fabrication Mixed-media water filtration, shops. using a mixture of sand, anthracite, and garnet, has displaced older filtration methods because it is more reliable and gives a better quality of water. Garnet also is used in hydrojet cutting-it is entrained in a high-pressure stream of water to cut many different materials. Demand for these uses has greatly increased. The manufacturers of nonskid floor paint also use alluvial and other low-cost garnets.

Garnet has obtained an intermediate place in the coated-abrasive field between low-cost quartz sand and more costly synthetic abrasives (silicon carbide and fused alumina). Garnet is reportedly more efficient based on unit production costs than quartz sand. It also produces a more desirable finish on items made of wood, leather, hard rubber, felt, and plastic.

Garnet, especially the lower grades, cannot compete with synthetic abrasives for most metalworking applications requiring substantial metal removal because of its friable nature and lower hardness.

Prices.—The average value per ton of crude garnet concentrates was \$89, a 40% decrease compared with the 1991 average. The average value for the past 10 years was \$111 per ton, with a high of \$178 in 1990 and a low of \$88 per ton in 1986. During the past 10 years, the trend for the value of crude concentrates was one of general increase with decreases in some years.

In 1992, the average value per ton of garnet sold or used was \$283, a slight increase from that of 1991. The average value for the past 10 years was \$241 per ton, with a high of \$271 in 1991 and a

low of \$216 per ton in 1987. The price trend of garnet sold or used during the past 10 years has been one of stable prices with minor changes, except the 23% increase from 1987 to 1988.

Foreign Trade.—Garnet exports, as reported to the U.S. Bureau of Mines, by producers were about 7,600 tons, a 24% decrease from those of 1991. Export data on garnet were not available from the Bureau of the Census (Department of Commerce). Producers have reported exports to the U.S. Bureau of Mines for the past 6 years. According to reports by producers, exports, with the exception of those for 1992, increased significantly during the past 10 years.

Mineral brokers and other garnet importers reported to the U.S. Bureau of Mines about 12,100 tons of imported garnet, an increase of 142% compared with those of 1989, 1990, and 1991. Import data for garnet also were not available from the Bureau of the Census. U.S. Bureau of Mines data, which are available for only 6 years, showed garnet imports as stable for the past 3 years until the significant increase in 1992. The United States was a net importer of garnet in 1992 for the first time in history.

World Review.—The United States was the dominant world producer and consumer of garnet, accounting for approximately 45% of the estimated world output and nearly 40% of estimated world consumption. Target Mines Ltd. (a subsidiary of Barton Mines) continued to produce at near capacity from its Australian garnet sand operation. Chinese mines continued to increase production of garnet for the domestic and world market. Two mineral sand mining operations in India continued to produce garnet as a byproduct of mineral sands Turkey and the former production. U.S.S.R. primarily produce for local markets.

Outlook

The U.S. production and consumption

of industrial garnet during the next 5 years will be a function of the installed capacity and imports. Currently, the industry is operating at or near capacity. If capacity can be added, production and consumption will increase to approximately 60,000 tons per year by 1997. If garnet were not available, other abrasives could be used in its place, but in many cases with some sacrifices in work volume, quality of work, or cost.

Substitution of other natural and synthetic material is present to some extent for all major end uses of garnet. Fused alumina and staurolite compete with garnet as a sandblasting material in the transportation equipment industries. Ilmenite and plastics compete as filtration media. Diamond, corundum, and fused alumina compete for lens grinding and for many lapping operations. Finally, sand, silicon carbide, and fused alumina compete for grinding and finishing of plastics, wood furniture, and other products.

EMERY

Emery is a gray to black rock containing various minerals including corundum, magnetite, hematite, or hercynite, and trace minerals such as mullite, titania, silica, and magnesia. Its hardness ranges between 7 and 9 on the Mohs scale and its specific gravity ranges from 3.2 to 4.5, depending upon its composition. It is used as an abrasive aggregate for nonskid, wear-resistant floors, pavements, and stair treads; as tumbling or deburring media; and in the manufacture of coated abrasives.

Production

A single firm, Oregon Emery, Albany, OR, produced emery in 1992 using open pit mining methods. The U.S. production of emery decreased about 34% in quantity and value compared with those of 1991.

Consumption

The Bureau estimated that the United States consumed approximately 10,000 tons of emery in 1992. Imports from

Greece and Turkey accounted for most of the material consumed. Four firms processed and distributed emery for domestic consumption: Washington Mills Abrasives Co., Emeri-Crete Inc., Oregon Emery, and General Abrasives Co.

Foreign Trade

The United States did not export emery in 1992, nor has it done so in the past 10 years. During the past 10 years, the United States may have reexported a small amount of emery. The Bureau of the Census reports emery imports, exports, and reexports in mineral group categories; thus, exact data on emery are not available.

World Review

Turkey was the world's largest producer of emery. Its production is handled by Etibank in Ankara, by Ranar Minerals Industries Corp. in Istanbul, and by Lutfullah E. Kitapci Minerals Co., Ltd. in Izmir. Total production in 1992 was estimated to be in excess of 20,000 tons. Prices of Ranar emery ranged from \$34 to \$48 per ton for crude and from \$220 to \$460 per ton for micronized grades.

The second largest producer was Greece. In Greece, Government-owned deposits on the Island of Naxos are worked by villagers. It is estimated that 1992 production was about 10,000 tons.

STAUROLITE

Staurolite is a naturally occurring, complex, hydrated aluminosilicate of iron having a variable composition. The mineral most commonly occurs as opaque, reddish-brown to black crystals. It has a specific gravity ranging from 3.74 to 3.83 and Mohs' hardness of between 7 and 8.

Production

Georgia, North Carolina, and Virginia produced mineral specimen staurolite crystals. The crystals were in the cruciform twinned form commonly called "fairy crosses." E.I. du Pont de Nemours & Co. Inc. produced industrial- grade staurolite in Florida. Publishing production data would disclose company proprietary data, but production of industrial staurolite decreased 36% in quantity and value compared with those of 1991.

Industrial staurolite was a byproduct of heavy-mineral concentrates recovered from a beach sand deposit in Clay County, north-central Florida. Electrical and magnetic separators remove staurolite from the concentrates after scrubbing, washing with caustic, rinsing, and drving. The resulting material was about 77% clean, rounded, and uniformly sized grains of staurolite, with minor amounts of tourmaline, ilmenite and other titanium minerals, kvanite, zircon, and quartz. A nominal composition of this staurolite sand is 45% aluminum oxide (minimum). 18% ferric oxide (maximum), 5% silica (maximum), and 3% zirconium dioxide (maximum).

Consumption

During 1992, shipments of staurolite decreased slightly in tonnage and 17% in value compared with those of 1991. Staurolite, marketed under the trade name Biasill, was used as molding material in nonferrous foundries because of its low thermal expansion, high thermal conductivity, and high melting point. Its low softening temperature often restricts its use to nonferrous casting. The major use of staurolite was as an abrasive for impact finishing of metals and sandblasting of buildings. The blasting media trade names were Starblast (80 mesh) and Siasill (90 mesh). A coarse grade (55 mesh) also was used as an abrasive. Some portland cement formulations consumed a minor amount. As regulations limiting the amounts of free silica in airblasting media became more stringent, the demand for staurolite increased.

Foreign Trade

crystals. The crystals were in the Neither the Bureau of the Census nor cruciform twinned form commonly called the staurolite industry reported any

exports or imports of staurolite. Given the limited market and the low price per ton, no international market for staurolite should develop in the near term.

World Review

India continued to produce small amounts of staurolite for local consumption. Other countries sometimes produce small amounts of staurolite as a byproduct of mineral sands or gemstone production.

INDUSTRIAL DIAMOND

Industrial diamond is natural diamond that does not meet the standards of gem diamond because of its color, size, or other imperfection. Also, it may be a synthetic diamond that is tailor-made for industrial applications.

Background

Definition, Grades, Specifications.—Natural industrial diamond is diamond that, because of color, structure, size, or shape, is unsuitable for use as gemstones. Major categories are industrial stones (die stones, tool stones, and drilling stones), crushing bort, and grit and powder. The distinction between stone and grit is not well defined; generally, the dividing line is a range of sizes. Stones usually are particles larger than 16 to 20 mesh, grit from 16 to 20 mesh to 325 to 400 mesh. and powder as particles smaller than 325 to 400 mesh. These categories are subdivided further into more than 100 groups.9

Bort is natural diamond that occurs in finely crystalline aggregates and usually is crushed into finer material. Originally, the term was the name for all crystalline diamonds not usable as gems. Later it designated those diamonds not usable as gems, tool stones, die stones, or drill stones. Currently, the term refers to low-grade industrial diamond suitable only for use in a fragmented form.

Most synthesized diamond marketed to date is 20 to 30 mesh and smaller. Recently, producers began to manufacture

synthetic stones of 2 carats or larger. Marketing of these stones to date is of engineered pieces of the stones, not the entire stone. Polycrystalline synthetic diamond compacts and shapes can replace some larger stones. There are several types of synthetic diamond. They range from very friable material with a highly irregular shape to blocky, regular shapes with excellent crystal structure. The manufacture of industrial diamond stones is not commercially viable.

The metric carat, 0.2 gram, is the unit of measure for industrial diamond. One pound contains 2,268 carats, and 1 kilogram contains 5,000 carats. carat is equal to 100 points. Diamond grit and powder sizes are identified by U.S. standard screen classifications, by ANSI Specification B74.16-1971,10 by ANSI Specification B7420-1981,11 and by a proposed standard developed by the Industrial Diamond Association¹² for subsieve micron-sized diamond or cubic boron nitride powders. The terms "sand," "grit," and "powder" also describe decreasing orders of fine diamond.

Machine-shop waste containing diamond is sludge if obtained from wet grinding and is called swarf if obtained from dry grinding.

Industry Structure.—The original discoveries of diamond in India, Borneo, and Brazil, and later in South Africa, were due to chance finds by local inhabitants. Certain desirable characteristics in diamond were noted first in India and led to active search by open pit workings and to concentration by hand methods.

Probably the first industrial use of diamond was as diamond powder for polishing gem diamonds and other precious stones. The art of diamond cutting and polishing was known in India, probably well before A.D. 1400.

Glasscutting was an early application of diamond in industry. It was the most important use of industrial diamond until the 1860's.

England issued a patent in 1819 for drawing wire through a diamond die. Diamond wiredrawing dies gave close dimensional accuracy to wire, even after long periods of use.

The use of diamond for metalcutting began in the 1860's, but the high price of diamond tools was a drawback to their acceptance. As the economic advantages of using diamond tools became known, demand increased rapidly.

The use of the first diamond drill was in 1864. The discovery of diamond in South Africa in 1867 provided ample supply for the new and growing demand for diamond drill bits.

With the introduction of cemented tungsten carbide cutting tools during World War I, industrial diamond use increased. The cause of the increase was that diamond was the most effective agent in grinding tungsten carbide. Requirements for industrial diamond expanded tremendously because of World War II, when demand increased for grinding wheels, die stones, tool stones, drill bits, dresser stones, and polishing dust. The apparent supply of industrial diamond decreased rapidly following World War II.

In 1955, General Electric Co. announced the development of a process for the manufacture of diamond at its Schenectady, NY, laboratories. Commercial production started in 1957 at its plant in Detroit, MI. In 1969, production moved to Worthington, OH. In 1959, De Beers Consolidated Mines Ltd. announced the manufacture of industrial diamond at its laboratory in Johannesburg, Republic of South Africa. Since these two announcements, the production of synthetic diamond by General Electric, De Beers, and others continued to increase. Today it exceeds the production of natural diamond worldwide about five times.

Geology.—The major source of inplace diamond is kimberlite, an altered, dark-green basic rock of igneous origin. Throughout the world there are approximately 1,000 occurrences of kimberlite, but most do not contain diamonds or do not contain diamonds in economic quantities. The term "diamond pipe" refers to an occurrence of kimberlite large enough and sufficiently

diamondiferous to be mined. The size and shape of these pipes depend on the manner in which molten kimberlite passed through the country rock. They may be columnar, tabular, or irregular in shape. Where mining is deep enough, the diamond pipe always decreases in area and assumes a dikelike habit. diamond may contain inclusions of many minerals, and many of these minerals have inclusions of diamond. accessory minerals include olivine, garnet, diopside, ilmenite, magnetite, rutile, and phlogopite. Every mine has some diamond that is typical of it, but most diamond is indistinguishable from that of other mines.

Currently, approximately 40% of diamond is from alluvial deposits. These may be alluvial placers, recent or elevated marine beach placers, or glacial deposits. Often the distance of transport has been great. In many areas, the diamond-bearing, alluvial placers were deposited in former drainage systems unrelated to any present system.¹³

Technology.—Mining.—Currently, the United States has no commercial deposits of diamond. In other countries, mining methods range from very crude hand mining and panning to block caving of kimberlite pipes. Large-scale surface mining operations in Australia, Zaire, Angola, Namibia, and Sierra Leone¹⁴ use modern equipment, such as continuous bucket wheel excavators, power shovels, draglines, scraper-loaders, and motor trucks, to remove overburden and to mine and transport the diamond ore.

Processing.—The type of ore, size of operation, and other factors decide the types of processing equipment used. Crushing, where necessary, is done mostly with gyratory and roll crushers to avoid impact to diamond stones. Additional grinding is done with attrition and ball mills to further separate the gangue from diamond stones. Clayey ore may require the use of log washers. Diamond washing pans, jigs, heavymedium separators, or hydrocyclones collect the primary or intermediate concentrates. Depending on the types,

ABRASIVE MATERIALS—1992 109

shapes, and sizes of diamond present, various final treatments are used. They include the use of grease tables and grease belts, electromagnetic separators, electrostatic separators, optical sorters, X-ray sorters, and other devices. In all processing plants, hand sorting is the final recovery process.¹⁵

Reclaiming industrial diamond stones from drill bits and grit from the wastes generated in grinding, sawing, and other operations is common. This is because of the high unit value of diamonds. Reclamation processes include physical methods such as distillation to remove coolants and lubricants, followed by magnetic, or flotation electrostatic. Reclamation also uses separation. chemical methods, including combustion, acid treatment, and fusion with alkalies.16 The treatment used depends primarily on the contaminants present.

Commercial production of synthetic diamond grit is by two basic methods. Currently, the primary method used involves the application of ultrahigh pressure and high temperature to carbonmetal catalyst mixtures by powerful hydraulic presses. This method uses pyrophyllite and other materials for the reaction vessel. Pyrophyllite for this purpose is from the Republic of South Africa, where the local name for it is wonderstone. The major user of the method now uses synthetic reaction-vessel materials, alleviating the dependency on foreign sources for pyrophyllite. The material used for these replacement reaction vessels is proprietary. The other method employs explosive shock to the carbon-metal catalyst mixtures.

Industrial diamond particles of good quality up to 20 mesh and perhaps larger are produced. The shape and other characteristics can be controlled by proper manipulation of the variables, pressure, temperature, time, and catalyst type. Only micrometer-size particles are presently available from the explosive Other methods of diamond process. synthesis exist, but none are commercial use in the United States. Other countries produce diamond grit; all of these apparently use the ultrahighpressure, high-temperature method involving hydraulic presses.

Polycrystalline synthetic diamond compacts are a laminated structure of synthetic diamond powder bonded to a cemented carbide substrate. Their production is by a proprietary high-pressure, high-temperature process that gives the product excellent uniform physical properties.¹⁷

The polycrystalline synthetic diamond shape is a dense, nonporous, fully intergrown product that is thermally stable to 1,200° C. Production uses a proprietary high-pressure, high-temperature process using a special binder phase that is retained as an integral part of the product and results in high resistance to shock loading.¹⁸

Annual Review

Government Programs.—The National Defense Stockpile (NDS) for industrial diamonds, as of December 31, 1992, had a goal of zero carats and an inventory of 3.9 million carats for crushing bort. The goal for industrial stones was 3.0 million carats and the inventory was 7.78 million carats. There is currently legislative authority for disposal of 3.9 million carats of bort and 4.8 million carats of industrial stones. The inventory of small diamond dies was 25,473 pieces compared with a goal of 60,000 pieces, but no purchase authorization was issued.

Production.—The United States was the largest producer of synthetic industrial diamond. This has made the United States independent of foreign sources for crushing bort or similar diamond except for grit sizes larger than about 20 mesh. Having no production of natural diamond, it was dependent on other countries for its natural diamond supply.

Three domestic firms produced synthetic industrial diamond in the United States: Du Pont Industrial Diamond Div., Gibbstown, NJ; General Electric Co., GE Superabrasives, Worthington, OH; and Suprahards, Inc., Cedar Knolls, NJ. Two firms, Megadiamond Industries Inc., a subsidiary of Smith International

Inc., Provo, UT, and U.S. Synthetics Corp., Orem, UT, manufactured polycrystalline diamond from purchased synthetic diamond grit. Both firms had the capability to manufacture synthetic industrial diamond grit, but chose not to for economic reasons. Publishing production data would disclose company proprietary data. Domestic production did increase significantly. The United States continued to be the largest single producer of synthetic industrial diamond, a role it has enjoyed since 1957.

secondary U.S. production industrial diamond was from six firms. They were Amples Corp., Bloomfield, CT; Diamondsharp Corp., Keene, NH; Industrial Diamond Laboratory Inc., Bronx, NY; Industrial Diamond Powders Co., Pittsburgh, PA; International Diamond Services Inc., Houston, TX; and National Research Co., Fraser, MI. The firms reclaimed a total of about 4.5 million carats from used drill bits, diamond tools, and wet and dry diamondcontaining waste, an increase of 18% compared with that of 1991.

Consumption and Uses.—The United States continued to be the largest single consumer of industrial diamond. U.S. Bureau of Mines estimate of apparent consumption of industrial diamond was approximately 99 million carats, an increase of about 15% compared with 1991 consumption. Average annual consumption for the past 10 years was about 70.4 million carats. This was the result of the strong movement to industrial diamond in the U.S. manufacturing sectors because of the economic advantages in removing material and finishing surfaces using industrial diamond and diamond tools and wheels.

Diamond is far harder than any other natural or artificial abrasive material, so it was essential for some uses and much more efficient than other abrasives for many others. The principal uses of industrial diamond stones are in drilling bits and reaming shells, single- or multiple-point diamond tools, diamond saws, diamond wheels, abrasive, and diamond wiredrawing dies. Miscellane-

ous uses include: engraving points, glasscutters, bearings, surgical instruments, and special tools. Changes in technology and conventional wisdom have resulted in an increased use of synthetic industrial diamonds and polycrystalline diamond shapes (PDS) and compacts (PDC) for many of the uses previously listed. There has been an increased use of PDS, PDC, and matrix set synthetic diamond grit in drilling bits and reaming shells in the past 3 years. Diamond saws, diamond wheels, and diamond abrasive grit and powder are almost exclusively made from synthetic diamond. PDS and PDC are used in the manufacture of single- and multiple-point tools, and PDC is used in a majority of the diamond wiredrawing dies.

Mineral, oil, and gas exploration were the primary uses of drilling bits and shells. Foundation testing for dams, buildings, and other construction also used diamond bits and shells, as did masonry drilling in buildings for conduits and access and testing of concrete in various structures and other similar applications. The primary uses of diamond tools were for dressing and trueing grinding wheels and for cutting, machining, boring, and finishing. Beveling glass automobile windows also was a use. Cutting dimension stone, ceramics, and concrete in highway reconditioning were the major uses of diamond saws. The forming of refractory shapes for furnace linings also uses diamond saws. Diamond wire dies were essential for high-speed drawing of fine wire, especially from hard, highstrength metals and alloys.

Diamond grit, powders, and fragmented bort go into diamond grinding wheels, saws, impregnated bits and tools, and loose abrasives compounds for lapping and polishing.

Three major types of grinding wheels were made—resinoid, metal, and vitrified bonds—in many shapes and sizes designed for specific applications. The sizes range up to 1 meter in diameter for very large industrial wheels. Sharpening and shaping of carbide machine tool tips, grinding of dies, edging of plate glass, and optical grinding were among the

primary applications of diamond grinding wheels. Saws made with diamond grit were used for the cutting of concrete, stone, ceramics, and composite materials. Very fine saws sliced wafers from brittle metals and crystals for use in electronic and electric devices.

Finishing optical surfaces, jewel bearings, gemstones, wiredrawing dies, cutting tools, and metallographic specimens were the primary uses of polishing and lapping powder and compounds. Hundreds of other important items made from metals, ceramics, plastics, and glass also were finished with diamond compounds.

Prices.—The U.S. Bureau of Mines does not collect price data on industrial diamonds. The Bureau did track the average import value of various classifications of industrial diamonds. The average value of U.S. imports of natural grit and powder, synthetic grit and powder, and industrial stones was \$1.14 per carat, \$0.64 per carat, and \$4.56 per carat, respectively.

The average annual value of imported natural grit and powder for the past 10 years was \$1.28 per carat. The high value was \$1.57 in 1983 and the low was \$0.63 in 1989.

The average annual value of imported synthetic grit and powder for the past 10 years was \$1.18 per carat. The high value was \$1.47 per carat in 1983 and the low was \$0.64 in 1992.

The average annual value of imported industrial diamond stones for the past 10 years was \$8.38 per carat, with a high value of \$9.98 in 1983 and a low of \$4.56 in 1992.

Foreign Trade.—The United States was the largest exporter of industrial diamond grit and powder in the world. The United States exported and reexported a record 83.6 million carats of natural and synthetic grit and powder. The material was worth a record \$125.4 million. Additionally, the U.S. exported and reexported approximately 5.6 million carats of industrial stones, valued at \$36.7 million.

The average annual exports plus reexports of natural and synthetic grit and powder for the past 10 years were 51.3 million carats, with an average value of \$91.8 million. The highest level of exports plus reexports during the past 10 years was 83.6 million carats valued at \$125.4 million in 1992. The lowest was 42.3 million carats valued at \$82.5 million in 1983.

The average annual exports plus reexports of industrial stones for the past 10 years were 3.4 million carats per year, and the average value was \$29.3 million. The high was 5.6 million carats in 1992, and the low was 1.7 million carats in 1990.

The average annual imports of natural diamond grit and powder were 8.7 million carats per year for the past 10 years. The high was 13.0 million in 1988, and the low was 3.9 million in 1983.

The average annual imports of synthetic diamond grit and powder were 39.3 million carats per year for the past 10 years. The high was 86.7 million carats in 1992, and the low was 14.8 million carats in 1983. Imports in 1992 were about 46% more than those in 1991 and 486% greater than those in 1983.

The 10-year average for imports of industrial diamond stones was 7.6 million carats per year, with a high of 11.0 million in 1990 and a low of 3.9 million in 1987. The 1992 imports were about 29% more than 1991 imports. (See table 9.)

World Review.-Botswana and the Republic of South Africa were the largest producers of good-quality industrial diamond stones. Australia and Zaire were the world's largest producers of natural industrial diamond and were the primary sources of natural crushing bort as well as substantial producers of industrial stones. Estimates suggest that the former U.S.S.R. was the third largest producer of natural industrial diamond, but reliable data were lacking.19 next largest, in order of volume, were Botswana and the Republic of South Africa. Other smaller but significant producers were Angola, Brazil, China, Ghana, and Venezuela.²⁰ Total world output of natural industrial diamond in 1992 was approximately 51.8 million carats, a slight increase over that of 1991.

Synthetic industrial diamond production is significantly larger than the production of natural industrial diamonds. The countries that have synthetic diamond production, in declining order, are: the United States, Ireland, Russia, the Republic of South Africa, China, Germany, Sweden, Japan, Republic of Korea, Czechoslovakia, Romania, F. ance, and Greece.

Outlook

Diamond grit and powder should experience substantial increases domestic demand for every end use during the next 5 years. The increases for synthetic grit and powder are expected to be greater than for natural. The constant-dollar prices of these materials, especially the synthetic diamond products, should continue to decrease or at least remain constant. This is because planned production increases will make them more costeffective. The contract construction industry is an area in which the greatest increases will occur. This is because large quantities of saw-grade diamond will be required for highway and bridge repair and replacement. Large increases also are expected in the dimension stone industry as a cutting and polishing media. The stone, clay, and glass industries will increase their uses in cutting, shaping, and polishing media. Additionally, PDC and PDS will continue to displace natural diamond stone and tungsten carbide drill bits in the mineral services sector. The probable average annual growth rate in U.S. production is about 6%, based on estimates by the U.S. producers. U.S. production of synthetic material is sufficient to supply U.S. diamond grit and powder demand. The United States will continue to be a major exporter.

The major domestic end use for industrial stones in the next 5 years will continue to be in the oil, gas, and mineral industries. These stones are natural and

cannot yet be manufactured commercially. PDS and PDC have had a major negative impact on the natural industrial diamond stone markets. This will limit the growth of U.S. demand for stone during the next 5 years. U.S. consumption should average between 6 and 7 million carats per year for the next 5 years. Approximately 50% of the potential natural stone applications will be replaced by the synthetic compacts and shapes by the year 2000. (See table 10.)

MANUFACTURED ABRASIVES

Manufactured abrasives include fused aluminum oxide, silicon carbide, aluminazirconia oxide, and metallic shot and grit. Production data for fused aluminum oxide, silicon carbide, and aluminazirconia oxide were for the United States and Canada. Data for metallic shot and grit were for the United States only.

The fused aluminum oxide, silicon carbide, and metallic abrasives industries continued to undergo consolidation and reorganization during the year. (See table 11.)

Fused Aluminum Oxide

Government Programs.—The NDS, as of December 31, 1992, contained 227,152 tons of crude fused aluminum oxide and 46,169 tons of abrasive-grain fused aluminum oxide. There is no NDS goal for abrasive-grain fused aluminum oxide or crude fused aluminum oxide; all of the material is targeted for disposal.

Production.—At yearend, four firms were producing fused aluminum oxide at seven plants in the United States and Canada. Production of regular-grade fused aluminum oxide in 1992 was 142,545 tons, an increase of about 3% from that of 1991. The average annual production for the past 10 years was 142,757 tons. The high was 172,157 tons in 1988, and the low was 109,921 tons in 1983.

Production of high-purity fused aluminum oxide decreased slightly to 24,231 tons. The average annual

production for the past 10 years was 21,290 tons. The high was 32,634 tons in 1988, and the low was 13,835 tons in 1986. Total 1992 production of 166,777 tons was slightly more than that of 1991.

Consumption and Uses.—Fused aluminum oxide has a number of different end uses in the form of graded grain. The total value of sales of fused aluminum oxide-graded grain for all uses increased 30% compared with that of 1991, and was a 10-year high. Total value of sales by individual end use was up. The value of sales for use in bonded abrasives increased 40%. coated abrasives. 45%: refractories, 20%: tumbling media, 36%; blasting abrasives, 37%; polishing cake and buffing compounds, 70%; antislip abrasives, 29%; polishing abrasives, 14%; and all other uses, 8%. (See table 12.)

Prices.—The Bureau did not collect data on the prices of various grades of fused aluminum oxide. It did collect data on the value of fused aluminum oxide The average value of production. regular-grade fused aluminum oxide, as reported by producers, was approximately \$395 per ton. The average annual value for the past 10 years was \$368 per ton, with a high of \$395 in 1992 and a low of \$324 in 1988. In 1992, the average value of high-purity fused aluminum was \$594, down slightly from that of 1991, still less than the 1989 10-year high at \$635 per ton. The average annual value of the past 10 years was \$557 per ton, with a low of \$476 per ton in 1988. The average value of all grades of fused aluminum oxide in 1992 was \$424 per ton, a new 10-year high. The average annual value for the past 10 years was \$391 per ton, with a high of \$424 in 1992 and a low of \$348 in 1988. Mineral price quotations in various December issues of trade magazines listed prices for regular-grade fused aluminum oxide of \$832 to \$925 per ton, while high-purity was quoted at \$1,110 to \$1,221 per ton.

Foreign Trade.—The quantity of exports plus reexports of fused aluminum

oxide increased 11% to 11,968 tons; the value of exports plus reexports increased 12% to \$28.3 million. The average value per ton of fused aluminum oxide, exported or reexported, increased slightly to \$2,368. During the past 10 years, exports plus reexports have averaged 12,420 tons per year, with an average annual value of \$20.3 million and an average value per ton of \$1,653. The largest quantity of material exported in a single year in the past 10 years was 17,202 tons in 1989, and the smallest amount was 9,915 tons in 1986.

Imports decreased about 3% in 1992 to 136,000 tons, and the value of imports decreased about 7% to \$74.2 million. Average annual imports for the past 10 years were 127,654 tons, with a high of 158,770 tons in 1984 and a low of 98,000 tons in 1989.

Silicon Carbide

Government Programs.—The NDS, as of December 31, 1992, contained 37,305 tons of silicon carbide; the goal was zero. During 1992, the Defense National Stockpile Center of the Defense Logistics Agency disposed of 6,329 tons of silicon carbide. Existing legislation authorizes disposal of all of the silicon carbide.

Production.—During 1992, three firms produced silicon carbide at four plants in the United States and Canada. Production of abrasive-grade material increased 5% to 44,673 tons. Average annual production for the past 10 years of abrasive silicon carbide was 46,318 tons. with a low of 36,193 tons in 1983 and a high of 54,339 tons in 1990. Production of metallurgical-grade silicon carbide increased about 8% to 39,611 tons. Average annual production metallurgical-grade silicon carbide for the past 10 years was 52,475 tons, with a high of 64,998 tons in 1988 and a low of 36,562 tons in 1991. Total production of silicon carbide increased 7% in 1992 to 84,283 tons, compared with a 10-year average annual production of 105,399 The high was 123,917 tons in 1984, and the low was 78,943 tons in

1991. The level of production in 1991 was the lowest since 1955. (See table 11.)

Consumption and Uses.—Silicon carbide has a number of different end uses in the form of graded grain. The total value of sales of silicon carbidegraded grain for all uses increased about 12% in 1992 and was 76% of the 10-year high recorded in 1988. The total value of sales by individual end use was a mixture of increases and decreases. Sales for use in bonded abrasives were up 33%, coated abrasives were up 99%, refractories decreased slightly, tumbling media decreased 13%, blasting abrasive increased 9%, wiresawing abrasives were down 5%, polishing cake and buffing compounds were up 160%, antislip abrasives were up 21%, polishing abrasives were up 21%, metallurgical was down 17%, and all other uses were up 98%. (See table 12.)

Prices.—The Bureau did not collect price data on the various grades of silicon carbide. Data were available on the value of production of the various grades. The average value per ton of abrasivegrade silicon carbide, as reported by producers, was \$536, metallurgical-grade averaged \$493, and the average value of all grades was \$516. The average value per ton of abrasive-grade material for the past 10 years was \$497, with a high of \$571 in 1983 and a low of \$436 in 1985. Metallurgical-grade silicon carbide averaged \$443, with a high of \$481 in 1991 and a low of \$391 in 1988. For all grades the average was \$468, with a high of \$526 in 1983 and a low of \$417 in 1985. Mineral price quotations in various December issues of trade magazines listed prices for metallurgical grades of silicon carbide of \$1,110 to \$1,388 per ton, while abrasive grade was quoted at \$1,573 to \$1,758 per ton.

Foreign Trade.—Exports plus reexports of silicon carbide in 1992 were 13,547 tons, a 34% increase compared with that of 1991. While the total value of silicon carbide exported plus

reexported increased 11%, the value per ton decreased 17% to \$886, a 10-year low, and was only 48% of the 10-year high of \$1,865 in 1986. The average annual exports plus reexports for the past 10 years were 6,551 tons, with a high of 13,547 tons in 1992 and a low of 3,859 tons in 1986. The average annual value per ton of exports plus reexports for the past 10 years was \$1,410, with a high of \$1,865 in 1986 and a low of \$886 in 1992.

Imports of silicon carbide in 1992 increased 27% in quantity to 89,000 tons, 12% in total value to \$50.8 million, and decreased 12% in average value per ton to \$571. The average annual imports for the past 10 years were 79,066 tons, with a high of 101,600 tons in 1988 and a low of 56,250 tons in 1985. The average value per ton for the period was \$607, with a high of \$694 in 1990 and a low of \$539 in 1986.

Alumina-Zirconia Oxide

One firm produced fused aluminazirconia oxide in two plants, one each in the United States and Canada. Abrasive applications accounted for all the production. Publishing production data would disclose company proprietary data. Export and import data were not available.

Metallic Abrasives

Production.—Nine firms produced metallic abrasives in 10 plants in 1992. The quantity and value of steel shot and grit produced increased about 5% and 7%, respectively. The average value per ton was \$402, a slight increase compared with that of 1991. The average annual production for the past 10 years was 185,265 tons, with a high of 213,879 tons in 1990 and a low of 140,483 tons in 1983. The average value per ton during the period was \$363, with a high of \$402 in 1992 and a low of \$310 in 1987. Michigan, Pennsylvania, Virginia, and Ohio, in decreasing order of quantity, supplied the production of steel shot and

During 1992, two firms, one in

Michigan and one in New York, reported production of cut wire shot. Production of shot and grit other than steel inclined significantly in 1992, 94% in quantity to 11,477 tons and 49% in value to \$8.2 million. The average value per ton increased about 42% to \$722. The average annual production of these types of shot and grit for the past 10 years was 14,278 tons, with a high of 10,770 tons in 1988 and a low of 5,916 tons in 1991. The average value per ton for the past 10 years was \$566, with a high of \$934 in 1991 and a low of \$360 in 1987. (See tables 13 and 14.)

Consumption.—The quantity of steel shot and grit sold or used increased slightly to 205,623 tons, the total value increased 4% to \$85.7 million, and the average value per ton increased slightly to \$417. The average annual quantity of steel shot and grit sold or used for the past 10 years was 186,967 tons. The high was 214,787 tons in 1988, and the low was 139,377 tons in 1983.

The quantity of other shot and grit sold or used increased 5% to 12,089 tons. The value increased about 50% to \$8.7 million. The average value per ton increased 43% to \$723. The average annual quantity of these shot and grit sold or used for the past 10 years was 14,392 tons, with a high of 18,192 tons in 1984 and a low of 9,152 tons in 1985.

The estimated apparent domestic consumption of all types of metallic shot and grit increased 4% in quantity to 203,555 tons, decreased slightly in total value to \$79.0 million, and decreased 4% in average value per ton to \$388. The formula to calculate U.S. estimated apparent consumption is U.S. sold or used plus imports minus exports. The average annual estimated apparent consumption of metallic shot and grit for the past 10 years was 193,663 tons, with a high of 224,216 tons in 1988 and a low of 153,597 in 1983. The average value per ton for the same period was \$405, with a high of \$432 in 1985 and a low of \$375 in 1987.

Foreign Trade.—U.S. exports of metallic shot and grit increased slightly to

26,936 tons. The total value of exports increased 49% to \$24.3 million, and the average value per ton increased 43% to \$903. The average annual tonnage of metallic shot and grit exports for the past 10 years was 13,448 tons, with a high of 26,936 tons in 1992 and a low of 6,334 tons in 1986. The average value per ton for the past 10 years was \$750, with a high of \$948 in 1987 and a low of \$390 in 1989.

U.S. imports of metallic abrasives increased 39% in quantity to 12,779 tons, increased about 15% in total value to \$8.9 million, and decreased 18% in value per ton to \$699. The average annual imports for the past 10 years were 5,843 tons, with a high of 9,207 tons in 1991 and a low of 2,699 tons in 1987. The average value per ton for the period was \$935, with a high of \$965 in 1988 and a low of \$280 in 1984.

The United States was a net exporter of metallic abrasives in 1991, a position it has enjoyed by a significant ratio for the past 10 years with the exception of 1984.

TABLE 11 CRUDE ARTIFICIAL ABRASIVES MANUFACTURERS IN 1992

Company	Location	Product	
The Exolon-Esk Co.	Hennepin, IL	Silicon carbide.	
Do.	Thorold, Ontario, Canada	Fused aluminum oxide (regular).	
General Abrasive Triebacher, Inc.	Niagara Falls, NY	Fused aluminum oxide (regular and high-purity).	
Do.	Niagara Falls, Ontario, Canada	Fused aluminum oxide (regular) and silicon carbide.	
Saint-Gobain/Norton Industrial Ceramics Corp.	Huntsville, AL	Fused aluminum oxide (high-purity) and alumin zirconium oxide.	
Do.	Worcester, MA	General abrasive processing.	
Do.	Chippawa, Ontario, Canada	Fused aluminum oxide (regular and high-purity) a aluminum-zirconium oxide.	
Do.	Shawinigan, Quebec, Canada	Silicon carbide.	
Superior Graphite Co.	Hopkinsville, KY	Do.	
Washington Mills Electro Minerals (Canada) Corp.	Niagara Falls, Ontario, Canada	Fused aluminum oxide (regular).	
Washington Mills Electro Minerals			
(US) Corp.	Niagara Falls, NY	Fused aluminum oxide (high-purity).	
Washington Mills Ltd.	Niagara Falls, Ontario, Canada	Fused aluminum oxide (regular).	

^{&#}x27;Table includes data available through May 25, 1993. Total natural diamond output (gem plus industrial) for each country actually is reported, except where indicated by a footnote to be estimated. In contrast, the detailed separate production data for gem diamond and industrial diamond are U.S. Bureau of Mines estimates except Brazil (1988-90), and Central African Republic (1988-90), for which source publications give details on grade as well as totals. The estimated distribution of total output between gem and industrial diamond is conjectural, and for most countries, is based on the best available data at time of publication.

²Includes near-gem and cheap-gem qualities.

³Natural gem and industrial data may not add to totals shown because of independent rounding.

⁴Includes all synthetic diamond production.

⁵Reported figure.

⁶Figures are estimates based on reported exports and do not include smuggled diamonds.

⁷Figures do not include smuggled artisanal production.

⁸Formerly part of the U.S.S.R.

⁹All production in the U.S.S.R. from 1988-91 came from Russia.

¹⁰Other De Beers' Group output from the Republic of South Africa includes Kimberley Pool, Koffiefontein Mine, and Namaqualand mines.

¹¹Dissolved in Dec. 1991.

¹²Dissolved in Apr. 1992; however, information is inadequate to formulate reliable estimates of individual country production.

TABLE 12
END USES OF CRUDE SILICON CARBIDE AND ALUMINUM OXIDE (ABRASIVE GRADE)
IN THE UNITED STATES AND CANADA, AS REPORTED BY PRODUCERS

Use	1991			1992

ADVANCED MATERIALS

By William J. McDonough

Dr. McDonough, physical scientist, Branch of Materials, has more than 25 years of technical and managerial experience in both industry and the Federal Government. He has been with various departments of the Federal service for 19 years.

Advanced materials are polymers, metals, and ceramics fabricated as intermaterial compounds, alloys, or composites. The resultant components have higher strength-to-density ratios, greater hardness and wear resistance, and one or more superior thermal, electrical, or optical properties when compared with traditional materials. Advanced materials, the basis for many of today's emerging technologies, offer savings in total energy consumption, improved performance at reasonable cost, and less dependence on imports of strategic and critical mineral resources.

DOMESTIC DATA COVERAGE

Over the past 11 years, the publishers of Ceramic Industry magazine have conducted the only systematic survey of the ceramics industry, relying on companies volunteering their sales figures and on the magazine's own estimates for essential nonreporting companies. The information on advanced ceramics reported here is from the results of the Ceramic Industry surveys of 1990 through 1992. These data are generously provided in advance of publication by Ms. Patricia Janeway, Editor in Chief and Associate Publisher of Ceramic Industry.

Kline & Co., Inc. data are the basis for the reported 1990 through 1992 estimated markets for advanced polymer, metal matrix, and carbon-carbon composites. These data are provided by Mr. John M. Quarmley, Project Manager of Advanced Materials for Kline & Co., Inc. Additional data on polymer composites are obtained from Mr. Joel Broyhill, Statistical Division, Composites

Institute, Society of the Plastics Industry, Inc.

The Corporate Technology Directory, "Corp Tech," produced by Corporate Technology Information Services, Inc., Woburn, MA, is the primary source used for domestic industry structure data in the advanced materials area. The 1993 Corporate Technology Directory is a reference on more than 35,000 U.S. entities that manufacture or develop hightechnology products. The Corp Tech data used throughout this chapter for a particular technology identifies sales revenues into distinct ranges versus the number of companies reporting revenues for that particular revenue range.

Some definitions of what constitutes advanced polymer, metal matrix, and carbon-carbon (C-C) composites are required. For instance, the advanced polymer data include composites that are reinforced with advanced fibers. These fiber types include carbon, aramid, highglass, strength and other highperformance fibers and are usually incorporated as continuous filaments in composites designed for structural applications. Therefore, by definition, chopped fibers and conventional E-glass (low-strength) fibers are not included, except where complex composites do exist with both continuous fibers, chopped fibers, and other second-phase particulates commingled in the same composite. Data relating to the more general categories of polymer and conventional polymer composites are reported separately in the U.S. Bureau of Mines (USBM) "Nonrenewable Organic Materials" chapter of the 1992 Annual Report.

Composite(s) market revenues are usually valued at the fabrication feedstock For example, metric tons and stage. value of continuous fiber or matrix resin are common reported values; but lately, the total tonnage and value of both prepregnated stock and final fabrication stock also are included. One of the figures in this chapter (figure 10) is a simplified fabrication material flow sheet indicating both tonnage and value for individual stages in the fabrication of typical advanced polymer composites. This figure should give the reader a feel for the complexity involved in making composites.

Metal matrix composites are composed of a continuous metallic phase and dispersed reinforcing phase(s). The reinforcements are limited to those materials whose physical form and chemical composition are deleteriously changed during composite formation. Advanced metallurgical technologies, such as exothermic dispersion reinforcement and mechanically alloyed metals, fall outside this definition.

C-C composites are a family of materials that can be produced from a variety of fibers (pan, pitch, or rayon) and carbon-producing matrix materials. Many types of C-C materials have been included; however, the more technically important C-C composites usually exhibit higher density (1.4 to 2.1 grams per cubic centimeter), strength, and thermal conductivity.

Background

Advanced materials are critical to any nation's commercial competitiveness, as

ADVANCED MATERIALS—1992 125

evident today with numerous technologies under development by many industrialized nations, with the North American Community, the Pacific Rim Countries, and the European Community (EC) among the major competitors. Each of these three industrial groups have "Critical Technologies" lists, updated annually, biannually, or triannually, to guide them toward future commercial development. At the top of most lists are (1) communications and information technologies and (2) the synthesis and processing of electronic and advanced materials.

Products For Trade and Industry. - Advanced materials technologies are highly competitive fields throughout the world's industrial communities. The EC consortia are seriously challenging the United States through EC efforts to cooperatively "critical technologies," develop commencing with market driven research development (R&D) incorporating state-of-the-art flexible manufacturing techniques. Also, the EC is working to unify industrial standards and to remove existing trade barriers throughout Western Europe and the newly democratic countries of Eastern Europe and the former U.S.S.R. At the same time, the Pacific Rim countries, especially Japan, are challenging the United States with their prototype manufacturing and commercialization of advanced structural alloys, composites, ceramics, and superconductors. particular, the Japanese challenge is being accomplished mostly through large investments in new factories and updated process technologies, with the latter based on total quality manufacturing concepts. Meanwhile, other developing countries and industrialized nations, such as Australia, Canada, and the Republic of South Africa, recognize the need to move from the status of commodity mineral and materials suppliers to full manufacturing participants in advanced materials technologies.1

Economic Factors.—The continuing recession has made the United States

more aware of manufacturing competitiveness as the Nation attempts to sustain annual revenues generated by exports.² Adding to the uncertain export revenues is the realization that this current recession is worldwide. reunification of West and East Germany has caused high inflation rates in the new German Republic. The German Government raised interest rates to arrest its internal inflation, but the Deutch Mark is also the benchmark of the new EC. This anti-inflation action, primarily, plus other EC economic infrastructure problems, resulted in monetary chaos for most EC members. Collectively, these problems are adding to the continuing recession. Japan, meanwhile, is faced with falling currency ratios that make its products too expensive for global competition. For the first time in decades, Japanese companies are laying off employees and reporting business revenue losses.

In the United States, cuts in the U.S. Department of Defense (DOD) budget, the huge interest on the national debt, and the downsizing of large corporations by as much as 30% in personnel to cover business revenue losses all contribute to the scarcity of investment money necessary to fuel manufacturing growth.3 Truly, the nation or community that commercially emerges first from this current economic down cycle will be the one able to manufacture goods of very high quality at a marketable price while allowing a reasonable return on investment.4 The U.S. Government. under newly elected President Clinton, is still committed to assisting manufacturing competitiveness, but the paths toward achieving this success are by no means clear. Many feel that a broad-based, progressive technology government, industry, and university interaction is needed.⁵ but as 1992 ends. the actual role of the Federal Government is still being defined owing to the (1) change in Federal power structure and (2) the complexity of the economic and political problems inherent in creating such a technology plan.

Operating Factors.—Large companies

and the Federal Government use many small contractors, vendors. consultants to achieve manufacturing or service goals. For example, General Motors Corporation uses more than 10.000 subcontractors in all its business and manufacturing endeavors. Department of Commerce (DOC) data report that for the U.S. manufacturing sector, more than one-half of all goods are produced in companies with less than 500 employees. These small companies are limited in obtaining expensive upgrading such as automated machinery, just-in-time assembly, total quality management, etc. One of the big limitations is that these original equipment manufacturers (OEM's) must compete, most often on a yearly basis. for contracts to continue or followup with an already existing series of parts or assemblies. The reason is that both large corporations and governmental operations run on an annual fiscal year funding. Therefore, for many contractors, small and large, there is no guarantee of additional funding to continue their manufacturing or service efforts beyond 1 or 2 years. All these factors and many more not mentioned contribute to keeping small U.S. manufacturing companies operating below maximum return on investment. Hence, they are very susceptible when competing against the more modern manufacturing practices used by large and small foreign companies, with or without assistance from their national Government.6

The situation in the United States is improving as both the Federal and State government and industry go to longer term contracts. Many States and counties use a 2-year funding interval, and the new Clinton administration indicates that it intends to ask Congress for a 2-year budget cycle. DOD, in 1992, was funding many programs over a 3-year interval. In the industrial sector, the use of cooperative agreements between large corporations and their subcontractors is beginning to evolve into longer term business commitments. There is hope that the U.S. Congress will, by enactment of new laws, allow 3- to 5-year funding of programs, especially those programs aimed at "dual use" manufacturing, involving the initiation of flexible manufacturing, wherever possible.

Japan, as mentioned in last year's Annual Report, has a similar small business situation in the manufacturing small companies, There. area numbering more than 800,000 with less than 300 employees per company, produce 60% of Japan's goods and for the most part use new manufacturing technologies and other aids to maximize return on investment.⁷ The Japanese manufacturers, both large and small, operate under a business climate of longer term contracts and a nonserial, management style of business planning; e.g., quality circles, plus Governmentoperated technical assistance centers. The longer term contracts have an obvious cost and quality payoff for both the OEM companies and the large assembler corporations. Furthermore, the Japanese operate more than 170 public-assisted centers, called Kohsetsushi centers, that extend research services. technical assistance, training, testing, and guidance to small companies. These Kohsetsushi centers were started in the 1920's, along with their agriculture extension services. Both are based on the success of the U.S. Department of Agriculture extension services. Japanese, obviously impressed with the U.S. agriculture extension service centers concept, also extended this concept to their then-emerging industrial sectors.

The EC was quick to copy the success of today's Japanese economy and has expanded or set up more industry driven manufacturing service centers, for example, the 13 centers of the Max Planck Institute in Germany.

Industry Structure.—This entire document covers four broad-based technologies that make up the bulk of U.S. advanced materials manufacturing: advanced ceramics, advanced polymer composites, metal matrix composites, and C-C composites. The industry structure for the first three technologies is similar in their involvement of both large and small manufacturers. The C-C industry resulted from fabrication facilities

established within large aerospace corporations that were initially supported by the Federal Government for defense applications. The C-C industry structure will be discussed separately from the other three technologies.

broad-based The former three national technologies grew from laboratory and/or large company internal R&D (IRAD), and once a technology was ready for commercialization, fabrication was contracted out to smaller companies or specific divisions of large companies. Many examples exist in all advanced composites areas where the manufacturing companies include a few very large companies in addition to many small companies. Many of the small companies are subcontractors to the large But today, a significant companies. number of these small companies are entrepreneurial companies. They are founded by engineers or scientists and initially start with assistance from Government funding, such as the Federal Government's Small Business Innovative Research Programs (SBIR). various SBIR programs, in more than 10 Government Departments, competitively award funds to small companies ranging from \$25,000 for phase 1 and up to \$2 to \$4 million for final phase 3.

The C-C composites industry, in contrast to the other three advanced technologies, is related to the DOD's interest in faster and lighter as descriptive adjectives for its aircraft, tanks, ships, etc. The national laboratories, including and Aeronautics Space National Administration (NASA) facilities, and industry, assisted by Federal Government funding, collectively developed these composites to technical and engineering maturity. C-C composites are still very expensive to fabricate; reimpregnations with liquid matrix and refiring at high temperatures must be carried out on very expensive carbon fibers to produce reliable composites. Still, these composites have been successfully tested on combat and support aircraft for the military in addition to numerous aerospace applications. In the 1990's, increased use of C-C composites is called for in the commercial aircraft of

both the United States and the EC.

The companies manufacturing C-C composites are usually spinoff or licensee companies from the large aerospace and aircraft assemblers. U.S. companies such as LTV, Kaiser Aerospace, and today, divisions of various large chemical companies, are all key players in the commercialization of C-C composites. Many small licensee companies exist today to supply finished components to the military aerospace industries, and the future of these companies and indeed, the future of C-C composites, are tied to the ongoing "downsizing" of the DOD (owing to the ending of the cold war).

In summary, the advanced materials industry structure of the four broad-based technologies is a mixture of a few large companies (usually less than 10 in number) along with many smaller companies that supply the actual components. The smaller companies range in technical capability from entrepreneurial/high-tech to **OEM** subcontractors with good technical skills, reliable component fabrication records, and a history of reasonable component costs-all positive deliverables to the large assembler companies. The revenue mix of small companies versus large companies will be partially delineated in the individual subsections of this chapter.

Recycling Advanced Materials.— Material recycling is increasing worldwide as awareness grows that humankind should give an accounting of stewardship with regard to the Earth's finite resources. Recycling of aluminum containers has reached 70%, with steel container recycling at a respectible 40%, up from 34% from last year. Various polymeric materials are being preidentified at their manufacture for recycling purposes. The recycling of materials, advanced especially composites, is in various conceptual stages of defining their total environmental impacts. **Technical** advances in optimizing recycling are possible because the industry is small in volume and revenue and can start recycling as an advanced materials "system" concept.

Advanced materials recycling requires new thinking, starting with "design to recycle" concepts. These concepts are because a composite necessary component, when used structurally, could conceivably contain all four types of materials: polymer, metal, ceramic, and carbon fiber. Usually, these compound composites are designed using finite element analysis (FEA) to determine the material properties desired, based on projected use and the preliminary shape of the component. Computer-aided design (CAD) and computer-aided engineering (CAE), together with FEA, delineate the composite materials necessary to meet the expected stresses and strains during an estimated lifetime of service. In addition, once the materials are selected and the technical cost modeling completed, material substitution may occur to bring the costs down to competitive values with existing technologies.

One good example of a complex composite is the composite outer body panels on General Motors' all purpose vehicles.8 The recycling of these panels. as manufactured today, is complicated by the inexpensive ceramic filler material (30% by weight) mixed in with expensive polymer resin and fiber(s). Also, the use of two or three different fiber types to provide the designed-for stiffness, compression resistance, and impact resistance make these panels unfriendly to recycle. If the panels are ground up to make auto fluff. the high-tech components are degraded so as to make them uneconomically viable to recover. Besides, auto fluff today is usually deposited in municipal land fills that are rapidly closing due to socioeconomic reasons. Preliminary studies recovering or reusing auto fluff are ongoing in Europe and the United States in an effort to develop economical uses for ever-increasing amounts of auto fluff per vehicle.

The selection of the materials for these outer body panels 8 to 10 years ago did not consider the concept of design to recycle. That situation will change in the near future. Recycling awareness by U.S. manufacturers is just in its initial

stages, with the role model country being the German Republic. Under German law, manufacturers are setting up joint companies to study the recyclability of most material products, including anticipated advanced material types.⁹

The recycling of electronic components, such as circuit boards, to recover precious metals is a growing business in the United States and is driven by the high value of the precious metals.10 Advances in secondary (recycle, recover, or reuse) smelters and refineries allow for very high concentration rates. For example, concentration rates are, as follows, in the order of: a secondary smelter, 10 to 1; an electrolytic refinery, 200 to 1; and, a doré furnace/refinery, up to 100,000 to 1. Therefore, material containing as little as 300 parts per million of gold can be concentrated. Furthermore, estimated loss of precious metal per batch is as low as 2% to 3% precious metal.11 The evolution of more efficient smelters and refineries portends increased recycling of all metals in the quest for sustainable development.

Advanced structural ceramics are used in small quantities in the world today. and recycling considerations are only at an awareness stage. Besides, the value of advanced ceramics is in the value added. by the design, the processing, and the achievement of high-performance goals. The ceramic feedstock powders are made from abundant elements of the Earth such as silicon, nitrogen, carbon, aluminum. It is the high-purity, low cation and anion impurity content demanded by the high-performance goals that makes these powders expensive today. Also, today's high-purity raw materials are costly because the economyof-scale laws are not maximized. Therefore, the recycling of these materials may be limited because the "old component" exhibits little value in its recovered feedstock materials. On the other hand, these advanced ceramics are inert to the chemical and physical environment of the Earth and, thus, would not be pollutins.

Annual Review

The importance of advanced materials to the U.S. economy has been emphasized in 1992 through increased activities in Federal and State government participation, in industry awareness, and in university pronouncements. The Federal Government, through the establishment of Presidential councils targeting advanced materials, identified critical technologies in three groups: defense oriented, commercially driven. scientifically defined. governments increased their activities to create technology synergism among local industry, university, and State resources. The planning side of these various State activities are continuing to go forward even though the 10 big industrial States suffered severe losses in revenue generation because of the current economic downturn. Because all States must live with balanced fiscal budgets, State activities in establishing new incubator centers, State university technology transfer activities, and tax incentives for luring new business are all on reduced budgets.

Meanwhile, the industrial sector continues to create more joint ventures among companies, Federal laboratories, and university consortia, as well as international collaborations—all aimed at improving their competitive positions in the global marketplace.

The university sector, with funding assistance from various government agencies, continued to broaden R&D areas to include all aspects of manufacturing while graduating students skilled in solving and implementing advanced manufacturing techniques. especially as applied to manufacturing with advanced materials. The use of advanced materials and their complex processing to produce commercially marketable products are keys to U.S. business success.

The following sections on Government programs highlight the increased interest by the Federal Government in assisting and technically facilitating the modernization of U.S. manufacturing companies to compete in global markets.

Presidential Councils.—The Federal Government's role is established with the Office of Science and Technology Policy (OSTP) in the Executive Office of the President. The Director of OSTP, who is the Science Advisor to the President, also chairs the Federal Coordinating Council for Science, Engineering, and Technology (FCCSET). FCCSET has Assistant Secretary-level participation by all agencies having Federal programs involved with critical technologies. Input to both OSTP and FCCSET by industrial, State and local governments, and academia is accomplished through the President's Council of Advisors on Science and Technology (PCAST), also chaired by the Science Advisor. One subset of FCCSET is a Committee on (COMAT), Materials dedicated exclusively to the synthesizing and processing of advanced materials. Both FCCSET and PCAST report directly to the President.

"Critical Technologies" lists came forth from four different U.S. study groups in 1991, each group driven by its own individual missions. The following lists were generated: Defense Critical Technologies by DOD, Emerging Technologies by DOC, National Critical Technologies by the National Critical Technologies Panel of FCCSET, and the Commercial Airplane and Powerplant Critical Technologies by the Aircraft Industries Association. All four lists designate similar technology subgroups, such as materials, manufacturing. information and communications. biotechnology and life sciences, aeronautics and surface transportation, and energy and environment. Various crosscuts of these four lists, which are used in planning future funding requests, reside in the reports of the National Critical Technologies Panel of FCCSET. Altogether, about 20 technologies are identified as critical, with more than 10 technologies categorized in the technical subgroups of materials and/or manufacturing.

During this same time period, the United States placed increasing emphasis on the importance of critical technologies in the race for global technological

leadership. The major outcome of this emphasis was the National Competitiveness Technology Transfer Act of 1989 (Public Law 101-189), which empowered industry, universities, and national laboratories to accelerate the commercialization of new technologies. The law makes provisions allowing national laboratories to enter into cooperative research and development agreements (CRADA's); negotiate licensing agreements for inventions; exchange personnel, services. equipment with industry and universities: waive rights to inventions and intellectual property; and streamline the processing of agreements.

National Academy of Sciences and National Science Foundation.—In June 1992, a National Materials Advisory Board (NMAB) of the Academy of Sciences released a report on "High Performance Synthetic Fibers The report offered 14 Composites." conclusions and recommendations of how U.S. companies can compete with the Currently, Japan leads the Japanese. world in both quality and quantity of synthetic fibers, especially carbon fiber. A second NMAB study commissioned by the National Science Foundation on the state of U.S. technology reported a slight decrease in the total government and industrial R&D expenditures in the past 5 vears. The study estimated that an increase of \$25 billion in annual private and Federal spending on research, development, and engineering (R, D, & E) would be necessary for at least 5 years to allow the United States to catch up technically. Report data indicated that Japan spends 3% of its gross domestic product (GDP) on nonmilitary R&D, and the EC also spends 3% of its GDP on nonmilitary R&D, whereas the United States spends 1.9% of its GDP on nonmilitary R&D.12

The summary of a National Science Foundation workshop entitled "Report on the National Science Foundation Advanced Structural Materials and Processes Workshop" pinpoints the challenges before U.S. manufacturers in today's global economy. For instance,

the United States must not only develop and adopt new materials that offer improved performance, but it also must manufacture these new materials in proficient ways that utilize today's process engineering techniques. Examples of these techniques are "smart" processing with sensors, flexible and/or just-in-time manufacturing, and total quality control for all steps in the manufacturing, commencing with R&D on through final product inspection. This summary recommended a tripartite consortium made up of government, industry, and university sectors, with the U.S. Government acting as a facilitator. The actual markets can only be developed by customer demand for higher performance products. In the past, the U.S. Government, especially DOD, was the customer for most of the products developed by its own funding of R&D. Today, global markets dictate the market pull, and that situation requires a more complex global marketing strategy.¹³

Congressional Actions. -Congressional Acts, passed in 1989 and 1990 with appropriated funding commencing in 1991, addressed and refined U.S. needs for manufacturing competitiveness. For example, Defense Advanced Research Projects Agency (DARPA's) Precompetitive Consortia was funded in 1991 as a startup, along with the Advanced Battery Consortium and the High Performance Computing Project. The DOC Advanced Technology Program (ATP) (following in detail) and the National Center for Manufacturing Sciences funds were both increased in 1991, along with the National Science Foundation's Manufacturing Initiatives Also, other Congressional funds. legislation passed in 1991 created the Department of Energy's (DOE) National Technology Initiative. This initiative will concentrate on increased technology and cooperative research, transfer development, and engineering between the U.S. Government and industry.

The Comprehensive Energy Policy Act of 1992 contains funds that will enhance advanced materials in the following technical areas: near net shape

processing of ceramics, high-temperature composite ceramics, and smart and flexible process manufacturing of ceramics.¹⁴

The National Competitive Act of 1992 and the Manufacturing Strategy Act of 1992 contain add-on funds for (1) the ATP of the DOC (2) a Governmentbacked pool of venture capital to develop critical technologies, and (3) a White House-level "Council on Technology and Competitiveness." In addition, since the signing of the Federal Technology Transfer Act of 1989, the number of CRADA's formed has increased significantly. From September 1990, the total number of CRADA's went from approximately 500 to more than 1,600 in September 1992. This increase is attributed mainly to legislation allowing the 11 Federal laboratories in the Department of Energy to enter into CRADA's. The anticipation is that these CRADA's will spin off new technologies and manufacturing companies to increase U.S. competitiveness. 15

Department of Defense.—In 1992, the goals and missions of DOD are being reassessed with the ending of the cold war and the beginning of democracies and market economies in both the old Warsaw Pact countries of Eastern Europe and the Republics belonging to the Commonwealth of Independent States. The DOD is still the largest consumer of U.S. science and technology, with efforts funded through the National Laboratories. industrial laboratories, nonprofit research centers, and science and engineering universities. Many legislators regard the breakup of the former U.S.S.R. into separate nations, coupled with a sluggish U.S. economy, as ample reasons to justify reduced DOD expenditures. The DOD. however, recognizes importance of maintaining a level of expertise in critical technologies as necessary to keep U.S. national defense second to none at a minimum of cost. The use of advanced technology in the Persian Gulf war in 1991—smart bombs, stealth airplanes, and interceptor missiles—led to a rapid conclusion of the hostilities with a minimum loss of U.S. personnel. Besides utility in weapons of war, some of these technologies have "dual use" modes; i.e., a definite defense application plus a marketable commercial/industrial component. The industrial component is important because it also can be used to increase U.S. GDP through improving U.S. commercial competitiveness.

One example of the DOD's critical technologies implementation is DARPA's manufacturing "insertion" programs. Government "insertion" programs fund newer and usually more expensive manufacturing techniques than currently in use. Companies do not want to invest in new manufacturing techniques because of the initial cost and uncertainty of the market duration. Therefore, the Government assists companies in setting up newer techniques so that in a national emergency, the newer manufacturing lines will be able to respond to increased output or more flexibility in adding newer products at anytime in the future. The Government is actually pulling technology in that it buys the product, but also pays. in part, for the modern manufacture of the product. Defense was dropped from DARPA and the name changed to ARPA to increase public awareness of this Agency's commitment to dual-use technology development, up to and including manufacturing. **Because** advanced materials are essential components of many new technologies. they are to receive increased attention in the areas of precompetitive engineering. design, and prototyping segments that make up a total manufacturing facility. These ARPA programs are aimed at assisting companies by sharing the cost of developing new manufacturing skills; i.e., flexible manufacturing capabilities and/or total quality manufacturing techniques. These joint manufacturing insertion programs ensure ARPA that the latest state-of-the-art technologies will be available when needed for defense, and for the same dollar, the transfer of these newly acquired manufacturing skills to the commercial sector will improve U.S. competitiveness.

The National Defense Authorization Act of 1993 (Oct. 1992) allots \$100 million for dual use critical technology partnerships, \$100 million for advanced material manufacturing under various Manufacturing Technology (ManTech), Programs and \$200 million for dual use technology development in general, plus \$35 million for a new initiative on "agile manufacturing." 16

ARPA. through its Advanced Manufacturing Technology Programs for the microelectronic industry, wants to set up flexible manufacturing lines for a high-quality wafer output of about 1,000 per month. Currently, small quantity output is not available at a reasonable price per wafer. This, in reality, keeps many entrepreneurial people from designing a chip aimed at a niche market. For example, a niche market could be an electronic chip and appropriate sensors designed to "smart" control the ubiquitous household kitchen toaster to never burn From the military side, small qualities of specialized chips at a reasonable cost would allow more flexibility in designing chips for niche utilizations with possible dual-use civilian markets. 17

The U.S. carbon fiber manufacturers today have a 50% overcapacity and are seeking new markets as military orders decline and commercial aerospace is slowed by the recession. Some of this overcapacity is the result of DOD announcements made 5 years ago requesting that carbon fiber technology and capacity reside in the United States for defense efforts. The U.S. companies built the carbon fiber capacity from 1.6 thousand metric tons in 1986 to more than 3.6 thousand metric tons by 1990 and in 1992, the total capacity in the United States was about 5.4 thousand metric tons. However, today, just more than one-half of that capacity is idle, and many U.S. companies have sold off their carbon-carbon business to international firms or consortia. The nonmilitary use of carbon fiber is still very limited because of the high cost of fabrication. Additionally, the actual fiber costs are still between \$200 and \$2,000 per kilogram with the more desirable grades in the \$1,000-plus range per kilogram. ARPA is continuing to support carboncarbon and carbon-polymer development through its dual use technology programs. Meanwhile, the carbon fiber manufacturers are attempting to seek out niche markets in an effort to decrease their overcapacity.¹⁸

Agency Programs.—The Federal Government always has supported materials oriented "basic and applied R&D" through its various Agencies and Departments. The entire effort, loosely coordinated by oversight committees, contains Agencies such as NASA, the National Science Foundation. Environmental Protection Agency (EPA), in addition to the Departments of Commerce. Energy. Interior. Agriculture. Even unclassified ARPA and DOD projects are included. The 1990 funding level for all these materialsrelated projects was approximately \$1.5 billion annually, with an additional \$0.3 billion to \$0.4 billion for new facilities construction and equipment costs. In 1991, Cross Cut Strategy Plans were completed to focus and increase the effectiveness of this large multiagency effort in materials-related areas. coordinated and refocused program was initiated in late 1991 as the Advanced Materials and Processing Program (AMPP). 19 The AMPP is coordinated by FCCSET with industrial and university input as part of its planning and feedback mechanisms. Short-term goals are to make AMPP market driven, improve the science of manufacturing know-how, and plan future R&D projects as national goals (similar in operating objectives to Japan's Ministry of International Trade and Industry). A preliminary Government document outlining AMPP, released near the end of 1991, contained a chapter entitled "Introduction to the AMPP."

Tables 1, 2, and 3 show summary data from the 1992 AMPP indicating last year, present year, and projected funding levels.²⁰ Table 1, Total AMPP R&D Funding, by Agency, covers fiscal year 1992, fiscal year 1993 (appropriated), and fiscal year 1994 (submitted budget) for the 10 Agencies. Table 2 is Total AMPP R&D Funding, by Research

Component, for the same 3 fiscal years covering the following components: synthesis processing; and theory. modeling, and simulation: materials characterization; education and human resources: and national facilities/other. Table 3 delineates fiscal year 1993 Total AMPP R&D Funding, by Material Class. There are 11 "classes" of materials ranging from bimolecular to superconducting, the class identification resulting from the crosscut workshops sponsored by FCCSET. Note that table 1 clearly shows the DOD AMPP funding decreasing over the 3-year period while the Department of Energy, NSF, and NASA funding, in particular, are increasing along with various other Agencies. An approximate 9% increase overall in AMPP occurred from fiscal year 1991 to fiscal year 1992, while the total fiscal year 1994 (President's Budget Request) shows a 2.5% decrease relative to fiscal year 1992. This requested decrease reflects the overall budget decreases recommended by the outgoing Bush administration. President Clinton's budget requests with "budget balancing" will show up in fiscal year 1995. In the immediate past, Congress had, if anything, slightly increased this type of funding over the amount submitted by the White House Office of Management and Budget. A perusal of table 2 by research component indicates that national user facilities funding increases approximately 2.5% while the other components slightly decrease. The user facilities are important competitiveness because they allow companies and universities access to R. D, & E equipment, located in the national laboratories, at a reasonable service fee and usually in a timely manner. opening of more user facilities dedicated to improving manufacturing technology know-how also is included in this budget request. In table 3, material class funding relates the changes in funding levels as the U.S. Government targets very specific classes of advanced materials. For instance, note the substantial increases in biomolecular materials and advanced polymers. (See tables 1, 2, and 3,)

Another example of U.S. competitive awareness is the Department of Commerce's Office of Technology Administration (DOC-OTA), established in 1989.21 This office works closely with the President's Science Advisor in coordinating precompetitive manufacturing strategies and programs as a logical followup to AMPP's market driven R&D. The DOC-OTA oversees the ATP that focuses on precompetitive engineering. design, and prototyping for manufacturing technologies, such as computer-assisted machining and flexible manufacturing. Demonstration facilities exist in various countrywide to assist locales manufacturers and provide incentives for more rapid modernization commercial technology in the United States. In 1991, the ATP office awarded, through competitive solicitations, more than \$36 million to various industrial/university consortia and Congress voted funds for more than \$100 million in awards for 1992.

In addition to competitive awareness, the U.S. Government is responding to the shifting patterns of material use as more advanced materials enter the marketplace. These advanced materials represent an entire spectrum of finished products that did not exist 20 years ago. They range from a single material; e.g., polymerbased liquid containers, to complex composites made from polymer, ceramic, and metal. Examples of the latter are electronic circuit boards and outer-body panels for automobiles. The Government activities carried out by the USBM. Branch of Materials, consider material components from their sources of supply, lifecycle analyses, substitutional trends, recycling rates, and on through discards to the environment. This information is summarized focused and in multivolume series The New Materials Society.²² The Branch of Materials is the focal point for data gathering and analysis of overall raw and processed materials flows in society and is specifically responsible for the collection and interpretation of data on the nonfuel use of organic materials, commodity ceramics, and advanced materials.

A second example of USBM activity in

1992 was a manuscript entitled "Towards A New Materials Paradigm" by Lou Sousa, an economist in the Branch of Issue Analysis. It examines new thinking concerning U.S. competitiveness and the use of advanced materials. Mr. Sousa sees the materials paradigm gradually shifting from a resource-based and supplier-driven model to one that is increasingly technology based and customer focused. For example, the Federal R&D coordinating and planning committees are using more and more input from the industrial and university Furthermore, the Federal sectors. Government's role as a facilitator for the technology and industrial competitive needs of the U.S. economy appears to be Additionally, Federal under way. research priorities will always be shaped in a political setting, but objective analysis studies based on this new materials environment will counterbalance distortions caused by political compromise.23

The National Institute of Standards and Technology (NIST) began seeking partners during 1992 to develop a "Multipurpose Technology Development Center" in Gaithersburg, MD. Industry, State, local, and/or nonprofit organizations will share the \$7 to \$8 million building and the \$1 million annual operating costs. Cost sharing is the expected mechanism for new Federal partnerships such as this undertaking.²⁴

Multiagency funded Federal research programs in superconductivity in 1992 totaled \$250 million and produced the following highlights: improvements in the electrical properties of copper oxide superconductors, enhancements in the flexibility of superconductor wires, and advancements in thin film electronic circuit applications. Worldwide, a few thin film applications have been introduced into niche market areas. These early commercializations indicate the promise for this very high potential, high expectation technology that offers an improved standard of living for all humans.25

Government/Industry Highlights.— market is saturated and its cost of capital An industrial survey sponsored as a joint advantage is eroded by the decreasing

study reveals U.S. industrial leaders' thoughts on industrial competitiveness. The "Industrial Policy and American Competitiveness Survey," sponsored by Ernst & Young and Plant Engineering Magazine, compiled the responses of more than 475 industrial senior executives or plant managers. Five top-rated results commenced with customer service being most important for rebuilding competitiveness. Technology innovation was ranked second and organizational excellence was third. All three of these factors must go hand in hand to ensure a quality product at a reasonable return on investment. The fourth factor viewed good supplier relations as critical to technology innovation and organizational excellence. The fifth factor called for a national industrial policy that would stimulate capital investment. Industrial business leaders want an industrial policy that fosters cooperation, not confrontation, and see such a policy as the key to our country's future economic growth in the global marketplace.26

The U.S. semiconductor equipment manufacturers, with the help of Sematech Corp., are slowly regaining their revenue lead in the world market. Research, Inc. of San Jose, CA, reports \$9.9 billion in total sales by this group in 1991 or 43% of the total market. That total market grew in 1992 by 3%, and the United States reached the 47% share or parity with the Japanese. The gain by these U.S. firms is attributed to recapturing U.S. market share from the Japanese through significant improvements in technology and performance.²⁷

The World Semiconductor Trade Statistics Program, an association of semiconductor industry leaders, reported global sales in 1992 of \$58.8 billion, with U.S. chip sales increasing by a healthy 16.2%, reaching \$17.9 billion or 30.4% of the total. Japanese chip sales declined by 6.7%, falling to \$19.5 billion or 33.1% of the total. The Japanese electronics industry showed signs of maturity since its consumer equipment market is saturated and its cost of capital advantage is eroded by the decreasing

dollar-to-yen ratio. U.S. microcomputer companies continue to make sales in Japan by introducing personal computer's at one-half the price of Japanese personal computer's. Today's world monetary situation favors the U.S. electronics industry over the next 2 years in its effort to recapture its prior world leadership.²⁸

The Microelectronics and Computer Technology Corp. (MCC), a consortium between the DOD/ARPA (and other Agencies) and U.S. computer manufacturers, is establishing a new Field Emission Display Consortium to build high-volume capacity "flat panel displays." This technology, originally researched in the United States, is being actively developed at the manufacturing level by three Japanese companies with assistance from Japan's Ministry International Trade Industry (MITI). Even today, all flat screened computers; i.e., laptops, notebooks, etc., black and white and especially color. manufactured in Japan. This complex technology, especially for "active matrix" liquid crystal displays, has very high rejection rates. The Japanese admit to rejection rates commencing as high as 80%, but today those rates are closer to 40% and are decreasing. These high rejection rates are the result of the millions of operations per screen that must be successfully completed in the manufacture of one laptop screen; that is, the numbers of pixels per screen area—each displaying tricolor capability. This new U.S. consortium is tasked with building the necessary manufacturing to build these displays (screens) for defense use and for commercial use in the booming laptop and notebook computer market. A huge market just over the horizon is the use of flat panel displays in the new high definition television Technical competitiveness (HDTV). could be restored if U.S. companies are successful in this endeavor manufacture high-quality displays at a reasonable cost and a fair return on investment.²⁹

The Telecommunications Industry Association, comprised of about 550 U.S. telecommunications equipment manufacturers and suppliers, petitioned the Congress and the White House in 1992 to modify the export control regulations to allow U.S. firms to compete globally in new markets opening up in East Europe, the former U.S.S.R., and China. The projected market for telecommunications to the year 2000 is about \$20.0 billion for these regions, and U.S. companies would like to compete. Currently, restrictions and regulations prevent "defense sensitive equipment" from being exported. Congress is considering major modifications to export control laws, and some regulations have been changed to allow increased trade. The telecommunications industry relies heavily on advanced materials for its state-of-the-art "solid-state devices" necessary for today's communication networks or those planned by the year 2000.30

The U.S. Advanced Battery Consortium, a joint U.S. Governmentautomaker consortium, awarded \$54 million in contracts in its efforts to develop a suitable energy source for electric vehicles. Two of the more promising batteries considered under these contracts are the lithium-polymer battery and the lithium-metal sulfide battery. The strategy for introducing electric vehicles, mandated by California law, for 1996 calls for initial use of "advanced" lead-acid batteries, followed by a shift to other types as they develop and reach the marketplace. Α breakthrough in low-cost, high-power density-per-weight batteries would drastically change the dominant role that internal combustion engines have had on the lives of all Americans.31

Industrial Production.—The Industrial Research Institute's survey on research and industrial/internal development (IRAD) funding for 1992 reported a decline owing to the current Funding declines ranged recession. between 2% to 4% with very few companies indicating a planned increase in IRAD for 1992. Companies, in general, were beginning to question the effective use of IRAD and whether or not some of their IRAD investments would be better utilized in upstream sectors of manufacturing such as engineering, prototyping, and manufacturing itself. A high-performance product must still maintain high quality control to be cost effective in the global marketplace and provide a reasonable rate of return to the manufacturer.³²

The revenue created by U.S. manufacturing has been decreasing by approximately 1% per year over the past 15 years, but over the past 3 years the adjusted annual revenue appears to be leveling.³³ One reason for this revenue leveling is that U.S. companies are staying competitive, whenever possible, by investing in new equipment for design, engineering, prototyping, and manufacturing. They are using techniques such as computer-aided design, computer-aided engineering, stereo lithography for prototyping, and employing "just in time," "design to assemble," and "total quality" concepts coupled to flexible manufacturing facilities.34

At the same time, the U.S. industry in 1992 continued the trend of making ventures and partnerships with foreign companies by jointly developing new technology, especially technology requiring advanced manufacturing processes.35 In addition, the outright purchase of U.S.-based high-technology companies by foreign enterprises continued. For example, the top three U.S. companies involved in advanced ceramics (in sales and in R&D) are now foreign-owned, with the Norton Co. sale being finalized in 1991.³⁶ Also, more U.S. companies manufacture "offshore" to remain product cost competitive globally. One of the key reasons for these observed business trends is the large amount of investment capital necessary to develop advanced technology once an R&D idea is proven in the prototype stage. To bring these U.S.-derived R&D technologies to the marketplace at a competitive price requires multiple-client partnerships in today's global economy.

The U.S. Robotic Industries Association (RIA) pointed out the large disparity between the Japanese and the U.S. use of robotics in manufacturing. Total quality manufacturing and "6

Sigma" quality control statistics (3 rejects or mistakes per 1 million operations) are going to be necessary to globally compete against these already existing standards in Japan. The Japanese attainment of these quality goals in manufacturing in large part can be attributed to robotic use. Data show that about 400,000 robots work in Japanese factories compared with 45,000 in the United States. Japanese have about 290 robots for every 10,000 workers while the United States has about 30 robots per 10,000 workers. The Japanese MITI has spent \$120 million between 1983 and 1990 on advanced robot technology and is currently spending \$200 million on microrobotics for the 1992-95 period. In Japan, companies can obtain 10-year financing for robots at about 5% interest. The RIA also reported that Japanese small businesses can obtain interest-free loans up to \$240,000 to buy robots. In 1992, the supplementation for all applications to small businesses by the Japanese Government is 20 times the allocation of funds by the U.S. Government. Most major industrial countries rely on small businesses for more than 60% of all their manufactured goods. Therefore, the RIA is lobbying the Federal Government intensively to be aware of the vital role that robotic technology plays in global competition where quality and performance at a price make the difference.³⁷

The foreign ownership of U.S. companies in 1992 is revealed in the following data: 7% of all U.S. manufacturing is foreign controlled, 10% of all U.S. shipments of goods is foreign controlled, and 21% of all U.S.-based chemical companies is foreign controlled.³⁸

World Review.—The methodology of presenting data for this document has changed in the past 2 years because the world markets themselves are changing; the advanced materials marketplace is becoming more global with regard to both customers and suppliers. The international flavor of corporations has evolved to the point that these corporations are now "multinational."

This definition causes data gatherers to concentrate on multinational companies with the hope that the data these corporations release contain revenue breakdowns according to country of For instance, Ceramic Age origin. magazine, which supplies this document with advanced ceramic materials data. changed its sales and marketing questionnaire to reflect the uncertainty of country of origin for manufacturing the products in question. This document reflects these global trends by presenting data showing domestic coverage and world coverage for either revenue or weight of product produced and/or delivered.

For instance, table 4 shows domestic and world data coverage for 1990, 1991, and 1992 for the four technologies covered in this document (advanced ceramics, advanced polymers, metal matrix composites, and C-C composites). Data are in U.S. dollar revenues generated and metric tons produced. Note, in table 4, the reported values by two different sources are in reasonable agreement and the data overall reflect the continuing world recession. For just 1992, table 5 lists estimated world revenues and metric tons by regions of the world: Pacific Rim. North America. Western Europe, and Total. The table 5 footnotes give "value per weight data" per technology or per world region for comparison purposes.

The many projections of world markets for advanced materials, as presented in either sales revenue or tonnage of product sold, have undergone drastic downward revisions. These downward revisions are the result of both technical and economic changes occurring in the world. Figures 1 and 2 show these revisions in trends by graphically comparing a 1988 forecast with a 1991 forecast. Figure 1 depicts advanced materials trends and forecasts for the United States, and figure 2 contains similar data for advanced materials trends and forecasts for the world. In 1988. technically "user friendly" advanced materials were projected to economically available today based on R&D knowledge of 5 to 10 years ago. Even 5 years ago, positive incremental changes in the way some advanced materials yielded to processing innovations in the pilot plant stage led to underestimation of the technical problems involved in composites overall. difficulty in assembling matrix materials and property enhancing reinforcements into large-volume, low-cost finished products was severely underestimated when the composites were in the R&D Today, the process in laboratories. making advanced materials user friendly is occurring but not at the pace projected 5 to 10 years ago. On the economic side. changes brought about by the demise of the former U.S.S.R. and other fiscal and economical factors caused recessionary times in 1990-92 for the United States. the EC, and the Pacific Rim countries. Unemployment in 1992 is running as high as 7% in the EC and 4% to 6% in the United States. These economic factors have caused market revenues for advanced materials to remain level or to decrease slightly. Downward trends can be expected to continue into the 1992-94 timeframe. Information obtained from open literature indicates that the feasibility and pilot plant studies for the commercialization of products using advanced materials are continuing. The ability to manufacture new products or retrofit an existing product to reduce its manufacturing costs or to enhance an existing product's consumer performance appeal can usually be accomplished by utilizing new materials: i.e., advanced materials.

European Community Highlights.— Leadership in advanced materials is shifting toward mainland Europe, with the United Kingdom having difficulty in keeping up in composites and fibers. At the same time, the reunification of the Federal Republic of Germany (FRG) has placed a large fiscal burden on its Government funding programs. Many existing programs have been momentarily downsized, and that includes FRG funding for advanced materials development. Meanwhile, France has been reaping the benefits of strong Government support in its research

laboratories and industry. The group of 12 countries in the EC may be joined in the future by Finland, Norway, Sweden, and Switzerland. Also, the former Warsaw Pact countries may become associate or full members. Incorporating these countries, particularly less-developed economies, will pose economic pressures, cultural challenges, and strains upon the existing EC infrastructure.³⁹

E.I. du Pont de Nemours & Co. (DuPont) opened its European Composites Development Center in Bad Hamburg, Germany. Amid announcements that a few international companies had sold off their composites ventures or have dramatically scaled back their investments in advanced materials. DuPont dedicated a new European center and presented an upbeat perspective for continuing the commercialization of advanced composites. DuPont is aware of all the technical problems with these materials in addition to their high cost. but continues to be optimistic because real progress has been accomplished. For instance, 8% nonmetallic components are in today's automobiles and composites are 80% of the structure of the next generation helicopter, 35% to 50% of a combat aircraft, and 8% to 12% of a commercial aircraft. Also, composites are being used more in aircraft engines and in areas of sports recreation and medicine.40

Multinational companies, such as International Business Machines Corp. (IBM), DuPont, Ford Motor Co., and General Motors, already have a presence in Europe and feel secure in their research and marketing positions. Other companies that have marketed in the United States and Europe without European domestic content are seeking joint manufacturing and research linkages. 41

Current research trends for electronic ceramics were discussed at the Third International Conference on Electronic Ceramics held in Maubeuge, France, in June 1992. Market Intelligence Research Corp. expects the total world revenue for electronic ceramics to double between 1991 and 1997, from \$8.1 billion to \$19.1 billion, with a compound annual

growth rate of 5%. The European market is expected to reach almost \$2 billion by 1995, with Germany currently dominating at \$531 million, followed by France at about \$257 million. The trend for ceramic substrates, currently a \$250 million worldwide market, is expanding at a 9% annual rate. Japan leads this market with \$140 million and an 11% growth rate, followed by the United States at \$70 million and 9% growth, and Europe at \$40 million and 10% growth. Even though alumina currently dominates the market share for substrates, aluminum nitride is expected to replace alumina for certain applications and will therefore have growth rates as high as 40% (Japan) to 60% (Europe).42

Significant multinational research efforts within the EC are addressed under the framework of the European Research in Advanced Materials (EURAM), which is coordinated with Basic Research in Industrial Technologies for Europe (BRITE) and the European Research Coordination Agency (EUREKA). Major technical areas concerning advanced materials focused on the following selected themes:

- Metallic materials and matrix composites.
- Materials for magnetic, optical, electrical, and superconducting applications.
- High-temperature nonmetallics.
- Polymers and organic matrix composites.
- Materials for specialized applications; e.g., biomaterials, packaging, and civil engineering.

In the realm of metallic alloys, emphasis is placed on aluminum, titanium, magnesium alloys, electrical contact and magnetic materials, coatings, tooling materials, and development of thin-wall castings. For engineering ceramics, property optimization, ceramic composites, and high-temperature are being studied. Within the area of composite materials, metal and organic systems are to be addressed.⁴³

Western Europe still represents a "developing country" in the semiconductor business. The per capita consumption of semiconductor products is

double in the United States (\$64) and sixfold in Japan (\$183). In fact, Western Europe is the only one of the three countries producing fewer semiconductors than it consumes. Hence, Europe should have an excellent semiconductor growth market, and the political transformation of Eastern Europe promises additional market potential in the long term.⁴⁴

The European Polymer Federation (EPF), part of the European Science Foundation, redefined its science and engineering goals with increased emphasis on the development of advance polymer materials. The EPF identified a number of topics that will have higher priorities in the overall European Community The four areas include: Programs. optoelectronics, polymers with supramolecular architecture, reactive processing of polymers, and computeraided polymer research. The European Science Foundation, the equivalent of the U.S. National Science Foundation, is joining with other EC agencies to go beyond R&D toward industrial pilot plants and commercialization. Like the NSF, the ESF is commencing rapid technology transfer to industry as the EC prepares for increasing competitiveness for global markets.45

European composite programs push ahead on primary structure applications. In particular, introduction of the Airbus composite wing structure is planned for all future aircraft manufactured by the Weight savings throughout the aircraft could amount to 1,000 kilograms. In addition, a graphite/epoxy monocoque skin for the European Fighter Aircraft has a new fabrication method that can be automated and/or mechanized production. Finally, thermoplastic composites are being moved into fullscale aircraft production of interior panels, cargo compartment covers, airfoil-shaped ribs, and wing panels.46

The advantages of using advanced ceramics in aircraft turbine engines was enunciated in a 1992 study by Rolls Royce Industries of United Kingdom. Based on a maximum allowable temperature of 1200° C, a currently designed airliner with 300 seats and a range of 7,564 kilometers would exhibit

the following technical enhancements:

- 10.0% saving in engine weight,
- 2.3% increase in thrust,
- 12.5% increase in thrust/weight ratio, and
- \$7.0 million reduction in life-cycle costs to the customer.

This study clearly shows why R&D is continuing on advanced ceramic composites, which hold promise of eventually being "man rated" for use in commercial airliners. The life-cycle reduction costs of \$7 million are significant for a new airliner priced between \$70 million and \$100 million, depending on accessories. This study also relates to R&D on advanced metal matrix composites, which can increase the turbine engine efficiency and offer reduced life-cycle costs over existing turbine engines.47

Germany is currently the European leader in producing rare-earth magnets. It has 60% to 65% of the overall market worth approximately \$17 million. German auto equipment firms are pioneering the applications trail. Total permanent magnet sales in Europe were estimated at \$470 million in 1992. 48

The Joint European Submicron Silicon (JESSI), created in 1989 to help European microelectronics on its way, highlighted certain flagship research projects for 1992. These projects concentrate on:

- High-definition television
- Broadband telecommunications
- Safety electronics for automobiles
- Digital audio broadcasting
- Cellular mobile phones

These projects are part of an overall strategy to strengthen and improve the focus of the EC on microelectronics by sponsoring R&D that will lead to EC competitiveness in their own marketplace against Japanese and U.S. companies.⁴⁹

The Third European Conference on Diamond, Diamond-like, and Related Coatings was held in Heidelberg on August 31 through September 5, 1992. Highlights from this conference featured visually transparent polycrystalline films that can approach the thermal conductivity of natural single crystal diamonds at room temperature or higher.

Numerous papers addressed the issue of thermal conductivity as a function of crystalline size. These diamond films can be used as interfaces for diamond-coated tools. In addition, highly oriented diamond films were reported to be grown on silicon substrates. These films appear destined for protective coatings for infrared detector windows, radomes, and similar applications. 50

The use of "engineering plastics (EP's)" continues to grow in European Out of the automotive applications. approximately 1.2 million metric tons of all types of plastics used in automobiles, 40% was "engineering plastics." growth of EP's is projected at a modest 16% over the next 5 years, mainly in high-temperature applications such as oil pump gears, water pump bodies, impellers, and CAM-phase adapters. The specter of European automotive companies buying back their old vehicles to recycle them might require that all plastic materials be of one family of polymers. "Design to recycle" is being considered even as major European car manufacturers propose pilots plants to study vehicle disassembly. An example "Pravda" recycling project is the involving all major car manufacturers. A similar project called "Accord" is ongoing in the United Kingdom. Preliminary conclusions indicate that for today's vehicles roughly one-quarter of the "plastic" components can be recycled into primary or secondary car applications. Investigations to improve the percentage of plastics recycled and decrease the costs to recycle will eventually result in "designed automobiles for recyclability."51

The EC is making an effort to unify and harmonize member differences by focusing on the developing sciences and technologies related to the commercial sector, especially aerospace and manufacturing competitiveness. Small-to medium-size enterprises are receiving emphasis in design, manufacture, and quality assurance. 52

Pacific Rim Highlights.—The Japanese Science and Technology Agency (STA) released its report on the research activities of Japan's private-sector manufacturing firms. The STA surveyed 1,301 firms, eliciting a 64% response. Some important facts concerned the ratios of R&D funding to sales for various sectors, for example, medical sector, 11.0%; communications sector, 8.6%; machine tool, 6.6%; and an overall average of 3.6%. The survey indicated that most Japanese manufacturers expect global competition to increase and suggested ways to decrease the tension. One group, 36%, suggested cooperative R&D internationally, while 28% offered technology transfer. and 12% recommended overseas research facilities. In the latter situation, the Japanese responders expected that technology will be both exported and imported. The survey contains many tables and charts and offers a terse view of Japanese industrial thinking as of 1992 on R&D aimed at the global marketplace.53

Japan's R&D efforts in metal matrix composites continue to grow. Japan has continued to pursue this technology not only with increased R&D but with projects to develop applications in several The collective focus is on areas. economically viable materials in the commercialization of metal composites. The Japanese interests range from applications relevant to a company's overall activities, such as copper-matrix composites for electronic substrates at Toshiba to interests driven by larger government programs, such as research on NicalonTM fiber-reinforced aluminum for high-temperature strength. Understandably, high emphasis is placed on processing with a slight surge in R&D toward "the wetting of reinforcement phases by molten metals." This large coordinated program has been ongoing for at least 10 years and continues today at an aggressive pace based, in part, on successful products entering marketplace.54

Pacific Rim buildup of engineering resin plant capacity will dramatically increase global production of polycarbonate, acetal, polybutylene terephthalate, and acrylonitrile-butadienestyrene by 1995. Some say this buildup could create an era of massive worldwide

oversupply. The expansion estimates a 30% rise in global polycarbonate production, a 20% increase in acetal capacity, and an additional 12 to 17 thousand metric tons per year of polybutyleneterephthalate. Polycarbonate is the biggest buildup with 254-thousandmetric-tons-per-year capacity scheduled to be completed in Taiwan (two new plants), Japan (two startups and two expansions), and the Republic of Korea (three grassroots polymerization facilities) by 1995. The other major expansion is 60 thousand metric tons per year of acetal also in Taiwan, Japan, and the Republic of Korea. One-half of these plants are new ventures, and it appears that tough competition lies ahead.55

An assessment of C-C composite research in the Pacific Rim countries revealed both an ever growing production capacity for carbon fibers, coupled with increased R&D funding for C-C composites. For example, Toho Rayon Co., Ltd., the largest producer of fibers in Japan having a total capacity of 10,000 metric tons per year, is producing 4,000 metric tons per month for acrylic and rayon fibers and 170 metric tons per month for carbon fibers. Toho weaves about 5,000 square meters per month and prepregs 200,000 square meters per month of undirectional, roving, and fabric materials. All portions of the fabrication are performed in this plant, from manufacturing of the fibers precursors for densification, to weaving of the preforms, to impregnation and final heat treatment. Overall Japanese funding for "improved process control" of C-C composites was slightly increased in 1992. As the Japanese technical efforts continue to make progress and products, the lack of U.S. research information may eventually limit U.S. companies in their ability to develop improved C-C composites. Japanese companies appear to be on a technical learning curve for bringing advanced C-C composites into commercial competition.⁵⁶

The Society for the Advancement of Materials & Process Engineering's (SAMPE) second exposition was held in Japan in December 1991, spotlighting new markets:⁵⁷

- Construction—carbon-fiber rebar was displayed, but Japan's construction industry has not yielded the hoped-for market for advanced composites.
- Cars—Honda showed off its metalmatrix components and is using carbon-reinforced aluminum for engine cylinder liners in its Preludes.
- Trains—Japan Railways displayed a model of its MLU002 test vehicle, which included glass- and carbonfiber composites to make a maglev train. The MLU002 was destroyed by a fire on October 3, 1991, and taught a bitter lesson in material selection.
- Bicycles—Ashi Engineering displayed a paper bicycle employing main tubes of epoxy matrix with washi, traditional Japanese construction paper.

The strong Japanese effort to enter the commercial aviation market as a builder of airframes may be reflected in the joint U.S.-Japan F-16 fighter plane being built in Japan. The latest advances in carbon fiber-polymeric matrix composites are Japanese developed and are being transferred to the fighter plane in exchange for Japan learning the complex technology of building airframes incorporating advanced materials. Japan reportedly spent an estimated \$2.0 billion on the composite technology and the tooling necessary to incorporate its latest advanced composites in the F-16 airframe. This military learning curve should allow the Japanese an easier technology learning curve for building their own commercial aircraft in the notto-distant future.58

Outlook

The world and U.S. domestic outlook for increasing revenues from utilizing advanced materials will continue to be optimistic, based on a number of factors. Open literature citations pertaining to the science and engineering aspects of advanced materials are continuing to increase, as are the number of trade magazines devoted to the technology

development of advanced materials. More universities and colleges offering associate degrees list courses pertaining to advanced materials-both processing and manufacturing aspects. As a further example, trade magazine announcements show that more types of advance polymeric materials and composites are being studied in corporate laboratories and pilot plants of large chemical companies.⁵⁹ Also, DOC data indicate that the slowly decreasing manufacturing revenues (total dollars for all areas) over the past 10 years have not affected chemical companies.60 companies have remained competitive in the marketplace and have, indeed, increased their revenues from successfully competing in global markets.

Additionally, advanced materials in the form of engineered composites allow the customer cost savings if the new structural component is designed to replace or combine two or three existing components (performance and cost driven). The continuing efforts toward lighter weight automobiles and aircraft offer new uses for composite materials, especially fiber-reinforced thermoplastic polymers, without sacrificing existing safety standards.

A California law requiring 40,000 "zero pollution" passenger vehicles registered in the State by the year 1998 translates into urban/suburban electric vehicles. A European consortium won the initial contract to manage the earlier phases of this electric vehicle project. These vehicles are to be built in California utilizing advanced polymer composites, along with other advanced composites, and many people believe it will mark the beginning of a large industry based on lightweight vehicle technologies.

A second technology related to the internal combustion engine and diesel engine is the "automotive ceramic gas turbine engine" program. The DOE and private industry have been funding this project, known under various project names, for more than 20 years. The successful commercialization of the ceramic gas turbine engine is estimated about 10 to 20 years from now. The

timetable became shorter in 1988 when the Japanese announced their own country's effort to commercialize ceramic gas turbine engines for both the automobile and the diesel truck.⁶²

ADVANCED CERAMICS

Background

Definitions, Grades, and Specifications.—Advanced ceramics are relatively new types of high-performance ceramics with significant potential for future economic impact. Advanced ceramics include electronic and electrooptical ceramics as well as structural ceramics. Advanced ceramics range in component form from single-phase monoliths to complex composites. They differ from traditional ceramics by the nature of their specialized properties, such as unique electrical, electronic, optical, or thermal characteristics. addition, engineered properties, such as high-temperature strength, high fracture toughness, and higher resistance to chemical corrosion, are engineered into advanced ceramic composites. These materials require more expensive, controlled particle size and very low level impurity powders as starting feedstocks. Additionally, sophisticated fabrication techniques are necessary to optimize their unique engineered physical properties.

Today, the marketplace potential for advanced ceramics has captured the interest and attention of scientists, engineers, and policymakers. interest results from the current competition between the United States and other industrial nations to develop new commercial applications advanced ceramics. The attention given advanced ceramics is most pronounced in Japan with its term "fine ceramics" symbolizing high-technology ceramics manufactured from very fine (small) powders of uniform size and shape. The EC is also interested in advanced ceramics. Worldwide, the development of advanced ceramic technologies by large numbers of nonceramic manufacturers, in competition with ceramic oriented companies, is evidence that advanced ceramics are nearing commercialization.

Ceramics are commonly defined as "inorganic, nonmetallic materials processed or consolidated at high temperatures." Traditional ceramics are primarily based on aluminosilicate compositions, more commonly known as clay minerals, such as the kaolin clays used in pottery, brick, and classical porcelain. Traditional ceramics are most often commodity minerals of the Earth with very little chemical alteration of the naturally occurring clays or minerals. On the other hand, advanced, hightechnology ceramics include a wide variety of high-purity, single-phase oxides, nitrides, carbides, borides, and others. Their feedstock powders usually result from chemical reactions designed to yield single-phase powders of high purity. Both cation and anion impurities must be minimized to realize their desired unique physical properties. Combinations of these high-purity materials into chemical compounds or in the form of second-phase additives (particulates, platelets, whiskers, and fibers) result in engineered advanced ceramics. properties of these inorganic materials enable applications ranging from electronic components to heat- and wearresistant parts to optical devices. Additional properties range from hightemperature strength, controlled thermal and/or electrical conductivity. resistance to high-temperature corrosion and/or erosion. Therefore, depending on the specific application, these materials can be engineered to exhibit optimum mechanical. electrical. electronic. magnetic, and optical properties.

The number of chemical compositions and processing variables necessary for high-performance advanced ceramics is quite large because both cations and anion species are involved in the chemical reactions. However, potentially important feedstock materials; i.e., powders, whiskers, and fibers, often are limited both in quantity and quality. The reasons for these limitations are attributed to (1) incomplete understanding of the complex chemical reactions, (2) very expensive scientific methods necessary to

produce high-purity, single-phase feedstock materials, and (3) batch "pilot plant size" production runs (limited nearterm market demand prevents massive economy of scale). Nevertheless, progress in producing high-purity. uniform, and batch-repeatable feedstock materials at low cost is continuing. Advanced ceramic components of proven performance are found today in many niche markets. Their entry into massive markets, such as automotive engine components, is expected in the near future as feedstock and processing costs decrease while performance reliability characteristics increase.

Some of the more common high-purity powders available are alumina (Al₂O₃), boron carbide (B₄C), silicon carbide (SiC), silicon nitride (S₃N₄), sialons (solid solutions of silicon nitride and alumina), and various forms of zirconia (ZrO₂). Other feedstock materials, such as whiskers and fibers, occur as natural growth phenomena, meaning the materials capable of exhibiting this behavior are rare even in nature. Therefore, scientific techniques employed today to grow whiskers and fibers result in small yields, and the products tend to be very expensive. Today, this high cost situation exists in carbon graphite fiber production where 1 kilogram of fibers costs more than \$1,000. Continued R&D on feedstock technologies offers the potential for low-cost powders, second-phase additives, whiskers, and fibers. statement is based on similar history and feedstock cost reduction efforts, such as aluminum and stainless steel in the metals industry and polymeric fibers (yarns) in the chemical industry.

Products for Trade and Industry.— Aluminum oxide (alumina) is traditionally used for a wide variety of ceramic products, including refractory brick, cements, and castable refractories. Higher purity aluminum oxide compositions, 75% to 99% Al₂O₃, are high-value materials used because of their electrical resistivity for semiconductor and integrated circuit substrates, high-frequency insulators, holders and spacers for printed circuits, and spark plug

insulators. Furthermore, the high strength and hardness of aluminum oxide make it suitable for a host of other applications requiring strength, hardness, and wear resistance. The high heat of formation of aluminum oxide gives it excellent chemical resistance to a variety of corrosive materials.

For high-temperature use, aluminum oxide retains about 90% of its mechanical strength up to 1,100° C. However, its high thermal expansion coefficient results in poor thermal shock resistance, which can be positively controlled in transformation-toughened aluminum oxide. Additionally, aluminum oxide fibers are now commercially available. These fibers are spun from solutions of alumina-containing precursors (1% to 3% SiO₂), followed by heat treatment. They are available as woven preforms, thin sheetlike paper, and mats and have use temperatures up to 800° C.

Boron carbide (B₄C) is harder than all known materials, other than diamond and cubic boron nitride. It is used mainly as an abrasive, in abrasion-resistant components, and in ceramic armor applications for airplanes and helicopters. The latter armor applications also benefit because of boron carbide's low density. In addition, boron carbide's high neutron cross section allows its use in the nuclear industry as reactor control elements, radiation shields, and control rod moderators.

Silicon carbide (SiC) is used traditionally as an abrasive and as a component of electrical heating elements. More recently, high-purity silicon carbide is used as a super refractory in many forms: as a monolith, as a fiber, or as a deposited coating. For example, highpurity silicon carbide, with less than 1% impurities, is a prime candidate for automotive engine structural applications requiring high-strength at hightemperatures with good wear resistance. In addition, high-strength silicon carbide fibers are produced by chemical vapor deposition techniques while platelets and whiskers are under development as second-phase reinforcements for ceramic, metal, and polymer composites.

Silicon nitride (Si₃N₄) exhibits

corrosion and oxidation resistance over a wide temperature range and retains its high strength up to 1.300° C. Silicon nitride is being evaluated for components in gas turbine engines, heat engines, and high-temperature bearings; in cutting tools; in industrial wear parts; and in ceramic armor. Sialons, solid solutions and compounds from oxynitrides of silicon and aluminum, are similar in physical structure and properties to silicon nitride but with slightly lower operating temperatures. Although silicon nitride and sialons are still being developed, niche markets uses; e.g., as lubrication-free bearings, rocket nozzles, and gas shrouds for orbital welders. increase their commercialization potential.

Zirconium oxide (ZrO₂), produced from the mineral zircon (ZrSiO₄, zirconium silicate) or recently from nuclear-grade zirconium metal, exists in different crystalline depending on temperature. Historically, this most refractory oxide was detrimentally restrained in optimizing its physical properties by the natural presence of low melting silicates or by its polymorphic transformations initiated at various temperatures. These solid-state transformations physically destroy any monolithic component in its natural state by massive spalling of the structure once a transformation temperature is reached. increased But bv research understanding its phase diagrams, scientists recently have learned how to toughen zirconium oxide with small amounts of other oxides that are included in the crystal structure during synthesis. By incorporation of several percent of stabilizing oxides, a phenomenon called transformation toughening occurs. The resulting physical properties are enhanced over the naturally occurring zirconium oxide phases and are not degraded when taken to or past prior transformation temperatures. This improved performance allows these transformation toughened materials to be used in lowtemperature applications, such as die draw heads, hot-metal scissors, etc., and cutting materials, especially where impact toughness is required. Hammerheads of zirconium oxide have been used to

demonstrate that a metallic-like toughness in ceramics is obtainable by applying the principles of engineered materials. Both lower cost feedstocks and processing R&D efforts are under way in a number of countries aimed at large-volume commercialization of these transformation toughened components.

A host of other advanced ceramic materials are being evaluated for applications that require optimization of electronic properties, mechanical properties, high-temperature properties, and erosion-corrosion properties. After laboratory pilot plant operations, the next steps in their commercialization are reduction in feedstock and processing costs, while marketing efforts attempt to move the components from low-volume to high-volume applications based on improved performance and pertinent total quality manufacturing practices.

Industry Structure.—The largest U.S. producers of advanced ceramics in 1992 were Corning Inc., Corning, NY, \$1,115 million; Cooper Industries, Houston, TX, \$557 million as Champion Spark Plug CO; AC Spark Plug Div. of General Motors Corp., \$324 million, mostly spark plugs; Allied Signal, Morristown, NJ, \$220 million, as Autolite Spark Plug Div.; and Coors Ceramics Co., Golden, CO, \$186 million. (See table 7.)

The largest worldwide producers of advanced ceramics in 1992 were Kyocera Corp., Kyoto, Japan, \$2,787 million; Murata Mfg. Co. Ltd., Kyoto, Japan, \$2,109 million; Compagnie de Saint-Gobain, Paris, France, \$1,392 million; Phillips Electronics N V, Netherlands, \$1,145 million; and Corning, Inc., Corning, NY, \$1,115 million. (See table 7.)

The top 10 worldwide advanced ceramics producers with 1992 sales of more than \$300 million are primarily manufacturers of spark plugs, optical fiber, electronic components, and porcelain insulators. The smaller companies with sales of less than \$50 million are the major producers of advanced structural ceramics. In the United States, many of these are privately held entrepreneurial companies. Many

U.S. advanced materials companies, large and small, have changed owners through mergers and acquisitions with and by foreign companies. The Carborundum Co. and the Norton Co. are now divisions of BP America (United Kingdom) and Saint-Gobain (France), respectively. Additionally, large foreign companies such as Kyocera (Japan) and Hoechst (Germany) have set up research laboratories and manufacturing facilities in the United States. For example, Kyocera America Inc. has plants in nine locations within the United States and even more mergers and/or foreign plant startups are reported in trade magazines. Table 7 shows that only 3 out of the 10 world's largest producers of advanced ceramics for 1992 are U.S. based.

The Corp Tech ceramic producer/ company data profiles, as depicted in figure 3, are useful in identifying how mature a particular industry is. 63 For the U.S. advanced ceramics companies, the number of companies, in the sales ranges of high, medium, and low, resemble a bell-shaped curve. As shown in figure 3, these companies represent a skewed bellshaped curve. The shape of any bell curve (Gaussian distribution mathematics) allows comments to be drawn about the distribution. In figure 3, a bell-shaped curve skewed toward the high-range sales volume is indicative of a mature, more fully developed industry where the long-standing companies have invested in R&D and are reaping market share with their advanced materials products. (See figure 3.)

Technology.—The following three examples are emerging technologies that can impact the commercialization of advanced materials by allowing these materials to be prototyped and manufactured with greater technical reliability, product repeatability, and cost effectiveness than currently exists today.

Solid Freeform Fabrication for Rapid Prototyping.—Advanced materials usually enter the marketplace as "niche market" products, and one advanced material may be the basis of four or more products. Because the

number of parts per component is small in a niche market, the cost of prototyping increased in relationship to manufacturing costs. The first successful attempt at rapid and lower cost prototyping is called "stereo lithography." Stereo lithography allows CAD/CAM designed components to be transformed rapidly from computer output into a geometric prototype in minutes. photopolymeric liquid in a vat is turned into a point source solid under the controlled intermittent firing of a focused laser energy beam. The rastering and firing of the focused laser energy fashions the CAD/CAM drawing into a threedimensional prototype of any scale desired (see detailed explanation following). The resulting photopolymeric prototype can then be used to refine the component design and any new changes in the CAD/CAM drawing rapidly turned into a new solid prototype. However, in many applications seeking to use rapid prototyping, the resultant photopolymeric materials are not resilient enough.

The next logical outgrowth of stereo lithography is to sinter powders into solid prototypes without using molds or forms, hence the terminology "solid free form fabrication" (SFF). The use of sinterable powders would thereby allow many more prototype applications. The new technique builds solid prototypes by selective laser sintering of powders in a process similar to using liquid feedstock in stereo lithography. Starting at the bottom or base line, a thin layer of powder is automatically machine spread over the constant area of the fabrication container. The rastering (moving) computer-controlled laser beam rapidly sinters any powder in the path of its beam. The path the laser beams follow in this two-dimensional array determined by the CAD/CAM input. Once the first sintered baseline prototype shape is a finished thin film solid, the next layer of powder is automatically machine spread over the same constant area of the fabrication container. Then, by repetitive actions, through laser rastering coupled to selected laser and thin layer powder sintering spreading, the SFF part is finished. Any

three-dimensional shape (with holes, cutbacks, channels, etc.) can be prototyped with a high degree of accuracy and repeatability. For example, using wax as a powder feedstock and selectively sintering the wax powder into a solid shape results in lost-wax pattern(s) for investment castings, tools, molds, and short production runs of prototype parts. Initially, wax, polycarbonate, and polyvinyl carbonate powder feedstocks were successfully utilized. Today, nylon and other polymeric powders along with metal and ceramic powders are being investigated as candidate feedstocks to increase the family of powders amenable to selected laser sintering. Preliminary results indicate that solid free form fabrication of parts can be produced 60% cheaper and 80% faster than machined prototype parts.

Continued R&D into rapid prototyping using advanced materials as feedstocks is ongoing today. The ability to go from CAD/CAM three-dimensional solids generated on a computer to finished prototypes is a manufacturing asset. Also, using prototypes to test, evaluate, and provide feedback to structureproperties analysis programs allows for rapid optimization of the design and engineering aspects of any advanced material component. The total cost savings and time savings are prime drivers for future applications involving rapid prototyping as many companies seek ways to optimize their return on investment.

Machinable Green State Billet Stock.—Technically, machinable billet stock(s), incorporating advanced materials and designed to produce high-quality components, are fabricated in the following manner. The billet stock is held together for the machining stage by polymeric materials. The polymeric material(s) must be removed, after machining, without degrading the chemistry of the ceramic sintering aids. Additionally, removal of the polymeric materials must not compromise the component shrinkage necessary to achieve fully dense ceramic parts. Additionally, when firing the machined part to remove

the polymeric binders, early stage (lowtemperature) component sintering must occur, otherwise the machined shape will sag under the force of gravity or worst case, just fall apart to powder. This machinable billet stock technology requires multifunctional ceramic sintering aids (added initially as very fine wet powders designed to coat the matrix powders). The lower temperature sintering aids start to sinter the matrix powders together as the polymer binders decompose (as gases or as char) due to the rising temperature. The final stage (high-temperature) sintering aids must replace or augment the low-temperature sintering aids without distortion of the part as the still rising temperature approaches the final ceramic sintering In reality, the ceramic temperature. sintering aids and their interactions with each other and the matrix powder(s), all as a function of rising temperature, are complex solid-state reactions being studied today as state-of-the-art science.

The precedent for producing and commercially selling machinable billets resides in the metals industry for metals as common as steel billets and as high technology as cutting tool billets. Largevolume, high-tech materials companies are developing ceramic billets for their own internal use. In some material categories, these billets have become commercially available owing to market shifts and large company business refocusing. The commercial selling of ceramic billet stock will allow small companies interested in developing niche markets an opportunity to pursue these markets without being a fully integrated vertical producer. R&D is continuing at industry, national laboratories, universities in the area of machinable billet stock ceramics, and that fact will eventually allow more small companies entry-level status to advanced ceramics.

Low-Cost In Situ Composites of Silicon Nitride.—Silicon nitride, a strong ceramic material with good chemical and oxidation resistance at elevated temperature (1,300° C), is the prime candidate material for advanced heat engines. The operation of any heat

engine at a "higher temperature" results in improved thermal efficiency. Today, most heat engines employing metals use liquid or gas cooling to prevent meltdown of the metals. This external cooling considerably lowers the thermal efficiency of most metal heat engines and engine designers from prevents developing more thermal efficient heat engines. R&D continues to develop more efficient engines through thermal newer high-temperature engineering materials.

For instance, the DOE's Ceramic Automotive Gas Turbine Program utilizes silicon nitride materials in all critical components, including the turbine rotor. Initial program goals, augmented by ongoing tests and evaluations of monolithic (nonreinforced) silicon nitride. call for a 3,000-hour turbine lifetime. This lifetime can be compared to the 2,000-hour lifetime of today's metal internal combustion engines. At the end of 1992, monolithic silicon nitride turbine components approached 1,000 hours in The lifetime limiting lifetime tests. factors are all related to intrinsic brittle fracture of silicon nitride. Once processing-induced flaws are minimized by extreme care in fabricating and final machining of the components, intrinsic mechanisms, such as high-temperature diffusional or grain boundary creep, cause almost all in-service failures. Silicon nitride, like most monolithic ceramics, has low resistance to fracture and must use reinforcements to improve its toughness and creep resistance to acceptable performance levels (lifetimes). R&D of the past 5 years has produced prototype silicon nitride materials, reinforced with fibers and whiskers, that, at 1,300° C, have both the strength and fracture toughness that mild steel exhibits at room temperature. The silicon nitride composite at 1,300° C has acceptable performance levels and is entering inservice lifetime testing. Even if this reinforced silicon nitride is technically successful, its costs are very prohibitive in the highly competitive heat engine business of today because it is a composite material.

Composite materials cost more because

the number of processing steps is larger more complex compared to For example, monolithic materials. advanced ceramic composites require processing under high pressure at elevated temperature to sinter the matrix phase together. The "inert" reinforcements (between 20% to 30% volume to optimize toughness) must be completely surrounded by matrix; i.e., no porosity. This can be accomplished by using high-pressure inert gases to squeeze the composite together at high temperature during processing.

These most promising technical results for silicon nitride composites have led many researchers to pursue making in situ composites of silicon nitride. Because most materials adhere to a structure-properties-process-performance paradigm, attempts to duplicate composite through structure(s) chemical selective grain growth techniques have prior histories of success, according to citations in the technical literature. R&D funds from industry and government agencies to develop in situ composites of silicon nitride have produced preliminary results indicating limited success. Improved strength and fracture toughness data have been reported by tailoring the grain structure through annealing techniques using selective second-phase additions. The premise is that if compositelike microstructure(s) are produced by processing techniques not requiring high pressure at temperature, then low-cost, in situ composites of silicon nitride will rapidly advance the introduction of ceramic components in cost effective gas turbine engines and other technologies requiring higher temperature performance, such as heat exchangers, etc.

Annual Review

Industrial Production.—The companies involved in the worldwide ceramics industry range from ceramics-only producers to ceramic divisions within large multinational corporations. Part of table 4 and all of tables 6, 7, and 8 contain information available for calendar year 1992. The data were

obtained from a Ceramic Industry magazine survey and from Kline & Co.,

The U.S. sales data for individual subtechnologies of advanced ceramics: e.g., capacitors or substrates, are not available, commencing with 1990. However, U.S. sales data for total advanced ceramics for 1990, 1991, and 1992 are shown as part of table 4. In table 4. U.S. and World Production for Advanced Materials, the 1990 and 1991 data are from Ceramic Industry magazine survey forms, while the 1992 data are estimated data supplied under contract to Kline & Co., Inc. The 1992 data of U.S. revenue for total advanced ceramics are at this time single point data, and no comments on changes can be inferred. However, the 3% decrease in worldwide advanced ceramic revenues for 1992 versus 1991 can be compared with a 12% sales increase in worldwide revenues for 1991 versus 1990. For both the United States and the world, the 2 years of data most probably reflect the worldwide recession, which is still continuing into 1993.

Tables 6, 7, and 8 show the changes in emphasis instituted by Ceramic Industry magazine and Kline & Co., Inc. due to the emergence of multinational corporations. Table 6 lists the world's top 10 advanced ceramics producers by revenue sales as reported from their survey forms. Table 7 shows estimated 1992 U.S. sales and quantities sold (metric tons) for three advanced ceramic technologies: electronic ceramics. and engineering ceramic coatings, ceramics. Table 8 contains survey data for 1992 worldwide sales for six advanced ceramic technologies: voltage porcelain, capacitors/packaging, engineering ceramics, other electronics, optical fiber, and "other."

Figure 3 is in the Corp Tech data format and lists U.S. ceramic producers by total annual sales in 1992. The total number of U.S. companies is plotted against sales volume where the sales volumes are broken into histogram subset of arbitrary sales amounts. The interpretation of figure 3 is that the ceramic industry total is a mature

industry with quite a large number of large revenue-producing companies. Unfortunately, Corp Tech data do not allow the generation of similar results for advanced ceramics companies. The reason is basically that Corp Tech data come from annual company reports, and most large corporations do not break down sales revenue in subcategories. Also, large corporations do not want competitors to know how much revenue was gained from its advanced ceramics segment.

Figures 4 and 5 are histogram plots of the data in tables 4 and 5 for better analysis. Figure 4 is the estimated U.S. market for advanced ceramics by end use for 1992. Figure 5 is the estimated world market for advanced ceramics by end use for 1992. The category of electrical/electronic ceramics dominates the revenue produced and is still the fastest growing technical sector.

Current Research.—Synthesis of New Matrix and Fiber Materials.—The R&D funds available for advanced ceramics technologies for structural, electronic, optical, magnetic, and medical uses are at a high level in the Federal, industrial. and academic sectors. The current recession has resulted in a slight decrease in industrial R&D funds. However, the Federal Government's Advanced Materials and Processing Program (AMPP) for 1992 reported an increase in funding related to defense programs while the overall AMPP decreased slightly.

The 1992 funding for ceramics is \$152.1 million plus an unknown percentage of \$184.7 million for composites funding. In addition, the DOC ATP for R&D on precompetitive engineering, design, and manufacturing was funded at \$80 million this year, with more than \$100 million requested for 1993. An unknown percentage of the ATP is targeted for ceramic manufacturing, depending on the proposals submitted for competitive awards. Summaries of selected technologies requesting R&D funds within advanced ceramics are listed helow.

Current research is aimed at

developing new matrix materials with improved properties, such as highfracture toughness, higher use temperatures, more erosion and corrosion protection, unique physical properties, etc., and low-cost processing for highquality components. For advanced ceramics, part of the current research is aimed at higher purity feedstock powders, alloy powders with sintering additives deposited on powder surface, and uniform and low-cost powder whisker or powder fiber blends. For colloidal state ceramics, research will target the development of many more low-cost sol gel powders from the solution precursor routes, including alloys or coprecipitated powders. For advanced ceramic composites, researchers want to develop more homogeneous alloy powders suitable blending with second-phase reinforcements. low-cost matrix deposition techniques for building matrix fiber preassembly tapes, and more refractory alloys systems for advanced gas turbine engines.

The effectiveness of fibers reinforcements in advanced material composites depends on the fibers' intrinsic strengths, surface condition(s) (failure is initiated at surface flaws), and the strength of the interfacial bond between the fiber and the matrix. Research efforts directed toward improved fiber reinforcements cover a variety of silica, aluminosilicate, boron, silicon nitride, silicon carbide, carbon, graphite, and organic fibers. Fibers are incorporated into matrix materials to improve the composites structural properties and occasionally to add other properties such as directional thermal conductivity. Research is ongoing to develop new fiber types and at the same time to lower the very high cost of most fibers.

Engineering, Design, and Prototyping.—R&D efforts are expanding into the upstream areas of product processing as international competition indicates total quality management is necessary for all phases of a product's manufacture. The steps of going from laboratory specimen to an

acceptable prototype are now being investigated in a scientific fashion. The use of finite element models for stress calculations coupled to CAD/CAM software techniques is being optimized. Rapid prototyping through various techniques results in less time and capital spent on developing a final part for manufacturing. Flexible manufacturing lines allow companies an economy of scale as well as product versatility. Intelligent processing brings total quality management to a manufacturing process. And finally, computer numerically controlled (CNC) machining ensures product repeatability for finish machining and/or other steps in a manufacturing process requiring machining. These areas, and many others necessary to bring high-quality products to a competitive international marketplace, are being researched in this country. The U.S. companies that are employing these cost effective and quality providing techniques are enjoying a marketplace advantage in the worldwide economy today. Soon. more U.S. companies will utilize these modern manufacturing techniques as these techniques prove themselves in the marketplace through a higher return on investment.

Nondestructive Evaluation (NDE).—Advanced materials, especially those containing second-phase reinforcements, must rely on cost effective NDE in a more interactive manner than any products made in the past. The reproducibility of advanced materials at the time of manufacture and the lifetime reliability under actual service require more accurate and sophisticated NDE techniques. In recent years, computer-aided NDE gives both quality control and quality assurance to newly manufactured composite(s). Information is obtained on matrix defects, fiber breakage during fabrication, poor fibermatrix adherence, and existence of voids and inclusions. All these process-induced defects are potential causes for premature in-service failure. At the present time, techniques are external examinations of a component for asprocessed flaws, but in the near future,

NDE techniques will act as both external evaluators and proactive internal sensors. The latter, proactive internally positioned sensors, allow real-time detection of timeand stress-related events such as material fatigue and creep. Defect sensitive NDE capabilities have increased to the point where internal sensors in a component output information on the time-stress status of the component. This need to monitor component performance under in-service use has come together with the use of computer-aided NDE and the implanting of internal sensors as a permanent part of complex composite materials. The marriage of these two interrelated NDE technical developments has been demonstrated in laboratory R&D.65

Adding to the extrinsic aforementioned processing flaws are failure modes caused by advanced composites undergoing stress-related formation of microcracks during service. These microcracks grow under stress and coalesce to cause brittle failure. In a fiber composite, the growth of the matrix microcracks is arrested by the fibers in the microcrack's path. But if the chemical bond between the fiber and the matrix is not optimized, the result is weakening of the fiber-matrix bond, and eventually, fiber breakage and complete brittle failure of the composite. Further mechanisms for brittle failure are caused by environmental conditions. Exposure to chemical agents, ultraviolet radiation, heat, atomic oxygen (in space), and ionizing radiation all contribute toward degrading the properties of these materials. Also, the lack of experience in longtime use of advanced materials incomplete contributes to an understanding of complex failure modes. This lack of understanding is coupled to today's lack of high-quality and fully characterized materials data necessary for engineering and designing reliable structural composites. Also. variability in the final properties and structures from one production run to the next run result from lack of complete understanding of the processing variables.

Reproducibility can be increased by using computer-aided NDE for process interactive control. The detection of

unacceptable defects early in the manufacturing process cycle would increase production yields and provide technical feedback for optimizing and correcting certain stages in the process flow sheet. Current R&D areas for the NDE characterization of composite properties include NDE of advanced materials, correlation of NDE signatures and material properties, in situ NDE for investigating fracture mechanisms and damage assessment, in situ NDE for process and quality control during manufacture, and in situ NDE for lifetime assessment based on intrinsic and extrinsic changes in the component because of its service history.

Today, inspection of each component before incorporation into a finished assembly requires a multiplicity of NDE techniques. For example, these methods include ultrasonic inspection, infrared thermography, thermographic stress analysis, X-ray tomography, eddy current measurement, acoustic emission measurement, fluorescence spectroscopy, magnetic resonance imaging (MRI), and pulsed nuclear magnetic resonance (a variation of MRI).

New NDE techniques are being developed both for external examination and for the actual intelligent processing of materials during manufacture. characterization of aluminum alloy matrix components reinforced with silicon carbide particulates at various stages in the process flow sheet by NDE is an example of such techniques. This family of metal matrix composites is slowly entering the automotive engine marketplace as reciprocating (rotating) components. Various NDE techniques are used during the entire processing stages, and R&D is well along on incorporating sensors to intelligently control the manufacturing steps. The various sensors in use today in the electronics industry and the evolution of intelligent processing will be a special topic in the 1993 chapter. As an example, two of many concepts presently under development use pressure and acoustic sensors. The first method incorporates pressure sensitive detectors (piezoelectric or light emitters) coupled with wires or optical fibers to transmit data to computer-aided NDE. The second method involves sound detectors to receive acoustic emissions from critical stress-bearing regions in the component for transmittal to an analyzing NDE computer (sound is emitted when microcracks grow).

For advanced ceramic materials, such as the ceramic rotors under development for automotive turbo chargers or the ceramic turbine engine, research is continuing on using X-rays from compact synchrotrons or other X-ray sources to penetrate up to 6 centimeters of dense ceramic and identify flaws as small as 20 micrometers (typical flaw size that can grow to cause brittle failure). technique would operate similar to computer-aided tomography (CAT scans in medical profession) and be most helpful during the prototyping of ceramic structural components or during the initial setup and on-lining of a new ceramic processing facility.

NDE techniques being developed today offer the necessary process control both externally and internally (intelligent processing) for the advanced composites of tomorrow to be cost effective, to offer high performance, and to change positively the materials sustainability sought for the near future.

Outlook

The recession in the industrial countries of the Northern Hemisphere makes the economic data reported for 1992 similar in total value to revenue data for 1990 and 1991. The 1992 revenue highlights appear in niche areas, such as modest revenue gains for engineered ceramics, fiber optics, and the category of other electronics. Total revenues for 1992 in advanced ceramics decreased over the previous year, and if 1990 through 1992 are viewed collectively, total revenues appear to be level or are slightly decreasing. But both data sources projected an increase of 6% to 8% for the next 2 years, and most marketing analysis groups think this recession will cease in the near future.

Ceramics and composites R&D

funding, two separate classifications under the Government AMPP, increased in 1992. Larger increases in AMPP funds are projected for 1993 with a modest decrease scheduled for 1994. The 1994 budget request reflects the beginning of the Clinton administration's planned cutback in Federal expenditures of about 5% in each of the next 4 to 6 vears. In addition, the ATP funding for precompetitive advanced manufacturing contains funds for ceramic processing itilizing intelligent processing techniques. Noth of these Governmental programs are expected to grow in the funding made available to advanced ceramics because advanced materials are listed in the top four categories of the Nation's critical technologies lists. Critical technologies are targeted to receive more funding by both Government agencies and industrial R&D. These technologies represent commercial areas (determined by U.S. study groups) best suited to marketplace success in the near future by matching the best of R&D talents with rapidly increasing skills in modern manufacturing techniques.

The outlook for next year's advanced ceramic revenues is projected to be either flat or show a slight increase. Funding increases from both the Government and industry sectors for optimizing the techniques of modern manufacturing have been allocated for 1992. The United States appears poised to challenge global competitiveness in the area of advanced materials (ceramics).

POLYMER MATRIX COMPOSITES

Background

Composites combine the desired characteristics of two or more materials to create a new material with a combination of properties not available by traditional methods of manufacture. Initially, polymers resins called epoxies were combined with low-cost, low-strength, continuous glass fibers. The processing techniques for glass fiber manufacture yielded thin diameter yarn such that the glass fiber was

commercially available on spools similar to synthetic fibers, such as rayon and nylon. The continuous fibers were woven into a cloth before incorporation into the resin epoxy. The combining of matrix feedstock materials (polymer, metal, ceramic, or carbon based) and second-phase reinforcements, such as woven fibers, evolved into the ever growing array of composites known today.

Definitions, Grades, a n d Specifications.—From a consumer-use viewpoint, polymer materials can be polymer divided into two classes: commodity materials and polymer composites. Polymer commodity materials are characterized as highvolume, low-cost materials with the only feedstock material being low-cost matrixforming resin(s). On the other hand, polymer composites are low-volume, higher- to high-cost composites that usually require specialized processing techniques and utilize more expensive matrix resins in addition reinforcements. Initial polymer matrix composites were first used as substitute materials in nonload-bearing applications. From these early beginnings, polymer composites evolved into two basic types: polymer composites that directly substitute for existing materials in the commercial marketplace and advanced polymer composites (APC's) designed for structural loads and greatly improved performance. technical reinforcements include long or continuous fibers in various morphological forms (tape, woven sheets, three-dimensional shapes), chopped or short fibers, whiskers (strong single crystals shaped like sewing needles), and second-phase particles (second phase means chemically not reactive with the matrix under designed operating conditions). Therefore, an individual polymer composite, utilizing a low-cost commodity resin, may contain all known types of reinforcements. However, a polymer composite that utilizes either commodity resins or newer high technology resins plus continuous fibers as the primary source of reinforcement is defined as an APC. The incorporation of continuous fibers as all or part of the reinforcement, usually to improve significantly mechanical properties, requires more costly and time consuming processing to achieve the designed properties. These continuous fibers used in APC's are typically high-strength glass (S-glass), carbon fibers, boron, ceramic, aramid, or other organic fibers. Additionally, polymer composites that contain short fibers incorporated into matrices of advanced polymer resins; e.g., a thermoplastic resin with hightemperature capabilities, would be considered APC's based on their matrices.

Polymers matrices are classified as two basic types depending of the chemistry of the polymer resin(s): thermoset and thermoplastic. Thermoset matrices are those polymers that form by irreversible chemical reaction and consist of strongly cross-linked chains. Thermosets cannot be remelted and reformed but, rather, decompose at elevated temperatures. Because of the cross-linking, thermosets are strong and heat resistant but tend to be brittle. Examples of thermoset matrices are epoxies, phenolics, vinyl esters, polyesters, and urethanes. On the other hand, thermoplastic matrices are polymers, with less cross-linking, that can be remelted and reformed. They tend to be less brittle (tougher), more and flexible, exhibit bidirectional mechanical properties. Thermoplastics are stronger in the direction parallel to the strongly linked polymeric chains than in the direction perpendicular to these linked chains. Consequently, if many chains are aligned, the resultant thermoplastic polymer matrices are much stronger in one direction than the others. In addition, these APC's besides incorporating long or continuous fibers as the primary reinforcement, also may contain secondary reinforcements in the form of short fibers, whiskers, or particles.

APC's exhibit excellent strength-todensity ratios, high stiffness, high fracture toughness, etc., and are usually fabricated utilizing specialized processing technique(s). Normally, the resulting

properties tend to approach theoretical maximums attainable from the particular combination of materials used as feedstocks to form the composite. Organic resins used as polymer matrices may consist of epoxies, polyimides, polyacrylates, polyesters, or a number of other high-temperature polymer resins. The continuous fibers may be selected from families of high-strength glasses, carbon/graphites, or various ceramics, such as aluminum oxides and silicon carbides. or high-strength organic materials. In general, the most important physical properties of APC's are determined by the properties of the fibers, so a myriad of polymer resins, polymer resin fillers (chemically inert ceramic powders used to displace the expensive polymer resins), copolymer alloys may be used together as matrix feedstocks.

The polymer matrix resins most often used for APC's are the thermoset epoxies and the engineering and high-performance thermoplastic resins. The epoxies presently are used in more than 90% of APC's. Detailed definitions, grades, and specifications for the hundreds of available polymer matrix materials are beyond the scope of this work but can be readily obtained in the Plastics Encyclopedia.66 Specifications for the composites themselves (matrix plus reinforcement) are not written as are commodity materials; instead. specifications are written for each individual application.

The fact that the great majority of APC's manufactured today are composed of epoxy reinforced with carbon fiber or high-strength glass fiber is mainly the result of two factors. First, when property and performance specifications were written for current aerospace systems about 15 years ago, epoxies were the only materials sufficiently developed and understood to be used successfully as composite matrix materials. Second. epoxy composites are relatively easy to fabricate because the resin-catalyst mixture has a low viscosity and is suitable for a variety of "prepreging" discussed below, and forming operations. Moreover, epoxy resins wet reinforcing

fibers very effectively, producing a strong bond between them. Epoxy matrices possess the strength, stiffness, corrosion resistance, and high-temperature stability needed for many high-tech applications. Epoxies have some disadvantages, however. Though strong, they do not have high-fracture toughness; i.e., they are brittle and do not resist high impacts. Epoxy matrices are thermosets; they are difficult to recycle because they are formed by irreversible chemical reactions. They do not soften or melt upon heating but decompose instead.

Products for Trade and Industry.— The Society of Plastics Industries' Composites Institute, compiles an annual list of U.S. polymer composites shipments (in thousands of metric tons) for nine market categories. Composites Institute shipment data do not distinguish between polymer composites and APC's although both data are included in figure 6 and its tabular form, table 9. Therefore, the Kline & Co. data for U.S. advanced polymer composites, which is about 90% of the data contained in this section, are included in the SPI data under market categories such as marine, transportation, corrosion-resistant equipment, aircraft/aerospace/military. etc.

The weight percentage of APC's contained in the U.S. polymer composites shipments, figure 6, can be determined by summing the estimated U.S. market for APC's by end use, figure 8. The estimated 7,500 metric tons of APC's yields less than 1% of the 1.2 million metric tons of polymer composites shipped. No dollar value data were available from the Composites Institute on polymer composites, while the APC's in figure 8 calculate to an average of \$295 per kilogram.

An example of one dominant use of polymer composites is in the area of corrosion-resistant equipment, where the average composite value is closer to \$29 per kilogram. Corrosion-resistant equipment represents 13% of total polymer composites shipments. In this market sector, polymer composites are used in piping, chemical storage and

process tanks, pollution control equipment, walkways, platforms, etc. It has become possible to fabricate and field install large custom hoods and ducts for pollution control systems. Polymer composites' high strength, low density, and relative ease of assembly, as well as resistance to corrosion, has resulted in the replacement of other materials.

On the other hand, APC's, because of their high cost, are used most notably in defense, aerospace, and in sporting goods, where performance benefits outweigh cost considerations. In defense and aerospace they are used in helicopter rotors, blades, and tail assemblies, and in weapons systems such as rocket motor cases on missiles and space vehicles. They are finding increasing use in secondary aircraft structures, such as control surfaces (flaps, rudders, and stabilizers) or fairings (streamlining covers for aerodynamics) and more recently as primary structures, such as wing, tail, and fuselage sections. Composites use in McDonnell Douglas aircraft's military planes, for example, has increased from about 2% in the F-15 to 27% on the AV-8B Harrier currently in production.⁶⁷ Boeing Co. has teamed with Sikorsky Aircraft to make the new LH helicopters, both having airframes and skins largely constructed of epoxycarbon composites.

For commercial aircraft, the major airframe manufacturers are planning to increase use of APC's in new generation planes. Boeing, for example, plans to increase the composite content of its highly successful 757 line from 3% in 1990 to 24.5% by the year 2000.68

In sporting goods, the desire for better performance regardless of cost has created a market for fiberglass and carbon reinforced APC's in tennis rackets, golf club shafts, skis, sleds, toboggans, fishing poles, and bicycles.

A particularly interesting aspect of trade in APC's is the use of "prepreg." This is short for "preimpregnated" composite. A prepreg is a combination consisting of a measured amount of polymer (matrix) and fiber (reinforcement) assembled—but not processed completely—to produce tows, fabrics, and tapes for

final parts producers. These manufacturers then form the composite to the desired shape and cure the resin to complete fabrication of the product. Thus a composite manufacturer has the option of purchasing polymer and fiber or buying prepreg and processing it to produce a part. A major portion of composite materials are traded as prepreg. Total prepreg shipments amount to slightly more than the total weight of fiber traded worldwide.

The recent introduction of APC's to the industrial segment devoted exclusively to manufacturing industrial tool forms is growing rapidly and now accounts for 5% of the total U.S. advanced composites shipments.⁶⁹ Technically, tooling forms provide the contour configuration that an in-fabrication part assumes as it is finally Metals such as aluminum and cured. steel and electroformed nickel are commonly used as tooling materials. But APC tooling has advantages over metal. There is a better match of coefficient of thermal expansion between the composite being made and the tool form. APC tools are easy to prepare by lay up over a plaster mold. Their good heat transfer properties allow increased productivity through more rapid cycling of the process.

Other applications for APC's are developing. For example, robot arms made using APC's with less inertial mass than metals, contribute to greater speed and lower systems and energy costs in automated manufacturing.

Industry Structure.—The industry structure in the APC sector is such that the APC materials area is dominated heavily by a few large companies. Meanwhile, there are many smaller companies involved in the actual fabrication of commercial parts using APC's. In 1992, more than 90% of the world production of APC's were produced by the members of Suppliers of Advanced Composite Materials Association (SACMA), a trade association with less than 30 member companies—about a dozen in the United States, about 10 in Europe, and a few in Japan. Figure 7, in the Corp Tech data

format, shows the 27 member companies of SACMA plotted as total number of companies versus APC sales volume for sales volumes ranging from less than \$1 million to greater than \$500 million annual revenue. As shown in figure 7, it is the many companies that are intermediate to small in sales volume that actually fabricate most of the APC parts. On the other hand, the membership of the Composites Institute, the largest organization inside the Society of Plastics Industries, is about 450 members. Because most companies in SACMA also belong to SPI, the remaining companies in SPI are involved in fabricating and producing polymer composites, not the main thrust area of this discussion.

Technology.—Processing.—Most polymer composite processing technologies influence the properties of the finished product, perhaps far more than metals or ceramics, whose properties are somewhat more intrinsic.⁷⁰

The most widely used techniques for the fabrication of APC's are the open mold methods. The open mold methods include hand lay up or spray up (contact molding), pultrusion, filament winding, continuous laminating, and centrifugal casting. These technologies account for 65% of the APC's produced. On the other hand, the closed mold methods include reaction injection molding, high-pressure laminating, and match die (low-pressure) molding. These closed mold methods are used to manufacture the remaining 35% of domestic APC production.

Two high-volume techniques, hand lay up or spray up (open mold, contact molding), and continuous laminating, are used to fabricate 62% of the production of the open mold methods or slightly more than 40% of the total APC production. The remaining open mold methods, filament winding, pultrusion, and centrifugal casting, comprise the remaining 38% of the open mold production and 25% of the total.

The most common closed mold method is reaction injection molding, accounting for 58% of the closed mold production or 20% of the total APC's production.

Other closed mold methods include highpressure laminating and match die (lowpressure) molding, which are used for about 40% of the closed mold production or 14% of total APC production.⁷¹

It is possible to control properties by varying conditions under which materials are processed. In particular, fibers and films can be made by processes that include close control of polymer chain orientation by drawing the polymeric material under controlled temperatures. Orientation of polymer chains affects stiffness, and elevated strength. temperature properties. For example, polyethylene terephthalate (PET) bottles can now be made under controlled conditions to achieve thermal stability at temperatures up to 88° C (newer method). This capability allows the use of PET in the hot-filled food packaging market. Both the old and new methods produce a material that is chemically the same. PET. But changes in processing alter the internal structure of the material, resulting in greatly enhanced properties.

Mold design or tool form is an important prefabrication step. molding process must result in the desired surface appearance, and the mold must be able to withstand corrosiveness of both the material and the process. process chosen must also match the flow properties of the resin, the geometry of the part, and the mold materials. An example showing the importance of proper processing and mold design is in the manufacture of continuous fiber reinforced thermosets. Because the long fibers in the thermosets are broken up and/or do not flow into the thinner sections, the use of transfer or plunger molding will result in degraded reinforcing fibers and lower strength compared to using compression molding. Furthermore, fibers may flow off into thin, intricate sections of a composite product during compression molding. In such a case, equal properties may be available from a less expensive material that can be injection molded. important to consider all of the following: the desired properties of the part, the various materials that can be used to make it, the various mold materials available, and the molding process itself, when designing a manufacturing process for an APC.

Joining Methods.—Although the number of component parts required for a system is generally fewer with polymer composites than with metallic systems. particularly in aerospace systems, parts must still be assembled with fasteners or adhesives. If the strength of the joint is less than that of the composite parts, much of the advantage of using the composite part is nullified. joining methods are receiving a great deal of attention. Improved polymer and metal materials for use as bolts and rivets are being developed, and high-strength adhesives and direct bonding methods are being researched. Perhaps more importantly, computer-aided design methods—CAD. CAM. and Finite Element Analysis (FEA)—have been utilized to predict stress levels within the composite and at the joints of assemblies. This enables engineers and designers to develop structures in which stresses are minimized in critical areas, such as ioints.

Applications.—Polymers have been replacing glass, ceramics, metals, and paper in many applications. Engineering polymer composites are being used in applications from microwave packaging to sporting goods and satellites. APC's special properties have been exploited by design engineers in structural applications. Polymers seem to possess many favorable properties and characteristics. In general, they are corrosion resistant, higher in strength-todensity ratios, and usually allow fabrication of a complete assembly using fewer individual parts at a higher performance level.

The first application of APC's was in the defense/aerospace industry, beginning in the 1970's. This is still the dominant area of application, with the current shift being from military to civilian aircraft and to the automotive industry in the future. APC's have been used extensively in smaller military aircraft and military and civilian rotorcraft. They

also are used in stealth aircraft and the Beech Starship. These advanced composites have superior strength-toweight ratios and stiffness compared to the metals they replace in these applications. Resulting weight savings range from 10% to 60% over metallic designs, with a 30% saving being typical. Weight savings can be used to increase payload capacity, speed and maneuverability, and/or to reduce fuel consumption. The high value of weight reduction makes advanced aircraft the ideal market for these new materials. Because of its polymeric matrix, these composites have superior vibrationdamping properties and resistance to fatigue and corrosion compared with metals.

The automotive industry is becoming a more likely candidate for greatly increased use of APC's as regulations and consumer desire call for lighter cars. So far, most applications of polymer composites have been in body panels, usually through the use of the sheet molding compound (SMC) method. A recent example was the Pontiac Fiero allcomposite exterior. Composites have also found applications in automobile structural parts, in addition to drive shafts and leaf springs. The prime substitution appears to be in inner and outer body panels. Today, the roof and liftgate of the 1992 General Motors Saturn are made from SMC. Later models of the Camaro and Firebird also have composite body panels.72

The latest American high-performance sports car, the Dodge Viper, has glass-reinforced acrylic body panels. It is Chrysler's first composite-intensive vehicle. APC's also have found applications in sporting goods, robotics, and medical devices.

Recycling.—Although relatively low recycling rates have been considered a problem for polymers in general (with about 60% of current production going to landfills annually) and with composites in particular, it is encouraging to note a high level of attention to finding solutions. The number of composite industry executives who feel that recyclability is

very important has risen steadily from 25% in 1988 to 55% in 1992.75

R&D engineers have begun to consider the desirability and feasibility of recycling in the early designs of new materials and products. Some polymer composites are already being recycled in significant amounts. Azdel, a long, continuous glass-reinforced polypropylene composite produced by a joint-venture corporation formed through cooperation between General Electric Co. and PPG Industries. Inc. is a good example. In tests to show recyclability, Azdel parts containing 40% glass fiber reinforcements were reheated and formed by compression molding five times, with property tests after each refabrication. There was no loss in tensile or flexural strength and only a minimal loss in toughness.76

The first large recycling attempts are being studied and undertaken in the European automobile industry, especially in the Republic of Germany with its proposed "German Refuse Act for Car Recycling." Although the polymers used in automobile components did not usually contain continuous fibers, some of these parts can be considered complex composites. For example, outer body panels can be made of two different polymer resins, one for the smooth outer panel for spray painting and the second resin to contain the filler and a variety of chopped and continuous fibers. The fibers can be, for instance, aramid fibers (Kevlar) for impact or shear strength, glass fibers (E thru S series) for compression strength, and carbon fibers (PAN and Pitch types) for tensile strength. Some fiber preforms or prepregs are actually mixtures of chopped fibers and continuous fibers, all added to satisfy economically technical performance criteria indicated CAD/CAM and finite element analyses.

The proceedings of an international conference on polymer composites contained a first-ever session entirely devoted to recycling automobile polymer components (48th Annual Conference, Composites Institute, Society of the Plastics Industry, Inc., Feb. 8-11, 1993). A summation of two or three papers indicated that recycling of the components

is possible by first grinding up the scrapped component to yield one or two end products. The more common end product and the least in cost is fiber-rich recyclate made up of fine particle residue containing groundup resin, ceramic filler, and chopped-up fiber(s). These fiber-rich recyclate powders are then added as part of the total "filler volume" to fabricate a new component.

After complete reprocessing, physical property tests indicate that the mechanical properties begin to degrade rapidly when the recyclate powders are between 10 and 20 volume percent of the total filler amount (based on original feedstock formulations).78 The degradation problem appears to be related to the stiffer fluidity (viscosity) of the resin-with-filler-plusrecyclate residue when compared to the original resin-filler system. Increasing the processing temperature does not allow the recycled system a mechanical property parity with the original feedstock system except at recyclate residue loadings between 10 to 20 volume percent original filler. Lesser volumes of filler are not profitable. A German consortium, called ERCOM, has been tasked with recycling polymer automobile components for reuse into new parts-no down-cycling to secondary markets, such as garden posts, park benches, etc. The output of ERCOM are two end products in each of three different sizes available for experimentation to all countries. The fiber-rich recyclate powders mentioned above are the main ERCOM output. However, through further and more costly processing, small factions of groundup resin and filler, sans fibers, also are available for reprocessing studies.79 Using this secondary ERCOM sans fiber recyclate to reprocess new components results in an excess of resin and related outflow problems when fabricated under the same processing conditions as the original components. Investigations to optimize these processes are continuing today.

A report from Japan indicates that since 1991, Japanese "Recycling Law" has called for the complete dismantling and shredding of all reinforced polymers, including the hulls of ships, large storage

tanks, bathtubs, and other constructed structures. The shredded parts are then put into landfill sites. But Japan, like Europe and the United States, is also looking at reusing groundup polymer recyclate powders to fabricate like-value new products. In June 1992, Nissan and Fuji Heavy Industries announced a joint recovery program for "bumpers" that are damaged or removed from Nissan cars. The joint venture agreed to pick up the spent "bumpers" throughout the Japanese islands, where they will eventually be reprocessed to fabricate new bumpers. ⁸⁰

APC's were the central focus of a U.S. paper by Owens-Corning personnel on recycling continuous fibers. report covered recent efforts in the recycling of reinforced composites, in general, but with special emphasis on the role of glass fibers. Among the approaches discussed are direct remolding of thermoplastic composites, grinding of thermoset composites for use as a reinforcing filler, recovery of "clean" fiber and its reuse as reinforcement in new products, and remelting of recycled glass fibers as raw feedstock for the manufacture of new fibers.81 Its R&D indicates that the chemical and/or thermal processes necessary to recover both thermoset and thermoplastic resins can damage the surface of the glass fiber in such a manner that the recovered fibers can only be remelted in order to be recycled into a new product of acceptable value.

Another R&D effort on polymer "design for aimed at composites. under in an is way recycling," international effort. Groundup sheet molding compound (containing fiberglass reinforcements) from Fiat body parts has been added to polypropylene along with a Union Carbide reinforcement derived from organosilicon precursor chemicals. The properties of the resulting "recycled" composite did not completely match the properties of a similar composite made from polypropylene and virgin fiberglass, but the properties obtained make the material worthy "recycled" consideration for other applications of similar economic value.82

For APC's, the main recycling

problem is how to separate the fibers from the resin and filler and reuse all of them economically. Recycling APC's containing carbon fibers preforms may become economically feasible because of the high cost of carbon fibers (currently between \$500 and \$1,000 per kilogram depending upon higher strength modulus). The matrix materials currently used are predominantly thermoset epoxy resins. much of the research Therefore, conducted has been for the recycling of this type of composite matrix.83 In the uncured or unset condition, epoxies are soluble in organic solvents, such as acetone or methyl ethyl ketone. After the epoxy is dissolved, the recovered carbon fiber can be reused. After curing or thermosetting, however, epoxies are Fortunately, most scrap insoluble.84 consists of prepreg sections so this technique can be readily utilized. Cured epoxies also can be decomposed thermally below 400° C in air or at higher temperatures under an inert gas (to protect the carbon fiber from oxidation). The fibers may be recovered; however, the fiber surface is affected so that lower fiber-matrix adhesion is observed in new Fiber breakage may be products. sufficient to render fibers useful only as discontinuous reinforcement.

Fiber-matrix recycling should be easier for the newer thermoplastic matrix composite with APC's. Α thermoplastic matrix can be softened or recycled simply melted and reprocessing. While the matrix is fluid a new component can be fabricated with physical properties the same as the original or slightly lower. Most complex polymer composites employ a low-cost, inert ceramic powder filler mixed into the expensive resin to decrease the total amount of resin necessary. Typically, 30 to 50 volume percent of an APC is ceramic filler, and the recycling of APC's causes slight property degradation owing to complex interactions among the resin, the filler, and the fiber preform. Because the matrix material melts at high temperatures (rather than decomposing), separation is possible even after curing, and both the fibers and the matrix (with filler) may be recycled.

Economic Factors.—The defense and aerospace industries have remained the principal driving forces behind the growth of APC's. The next area for expansion will be in commercial transport aircraft.

Currently, the United States is the leader in applications of APC systems, but growing foreign activity is a definite threat to U.S. competitiveness in the commercial airplane industry. In 1990, the U.S. aerospace industry led all U.S. manufacturing sectors by posting a positive trade balance of almost \$30 billion. This decreased to a \$27 billion positive trade balance for 1991. For 1992, a positive trade balance of \$28.3 billion, or a 0.05% increase, was attributed to the U.S. aerospace industry. 85

Survival in the aerospace industry depends on which airplane consortium produces the most reliable, fuel-efficient product. The consortium with advanced composites technologies that have been proven and tested will win the largest orders. Another factor that weakens U.S. competitiveness is the increasing U.S. dependence on foreign suppliers for such raw materials as advanced fibers. Japan and Western Europe are primary suppliers of both high-grade fine ceramic powders and advanced fiber reinforcements for composites; the new DOD requirement for at least one-half of the Polyacrylonitrile (PAN) carbon fibers purchased to be domestically produced will not apply to commercial aircraft manufacturers. This is very important because it is hoped that anticipated DOD budget cuts will be balanced by increases in commercial applications of advanced composites.86

To compete effectively with traditional materials in the aerospace market (metal alloys based on aluminum, steel, and titanium), producers of advanced composites need to market aggressively their new materials. Current material use (by weight) in the Boeing 767 airliner is as follows: 80% aluminum, 14% steel, 2% titanium, and only 4% nonmetallics.

The DOC has reported that the consumption of advanced composites has been growing at a rate of 20% annually, with 70% of that growth occurring in the

aerospace industry.87

Annual Review

Government Legislation and **Programs.**—Important governmental decisions may affect the polymers industry within the immediate future. The main factors are the Clean Air Act and the Resource Conservation and Recovery Act (RCRA). The proposed 1992 revision or modification of the Clean Air Act is likely to require regulation of the polymer industry in general, including the production of composites. In 1992, Congress momentarily shelved the reauthorization of the RCRA. The Superfund Act has taken priority over RCRA due to budget constraints and the change to the Clinton administration. The RCRA legislation, as written currently, will impact heavily on solid waste regulations. ultimately will dictate national recycling goals. In light of these possibilities, a standing task force of the Society of the Plastics Industry is reviewing the industry's stand on workable policies regarding resource conservation, pollution abatement, and energy.

In addition, the Corporate Average Fuel Economy (CAFE) Act also affects the polymer composite industry. By requiring greater fuel economy in automobiles, this law encourages the use of lightweight polymer composites for body panels and structural components.

Production.—Generally, production has risen to meet increased demand in the polymer composite sector for the past decade, with an average annual growth rate of 5% for the 1980's. composite growth process was mainly one of substitution for other materials in applications. Composite production grew at a rate twice that of the growth in gross domestic product (GDP) from 1983 to 198888 but in the past 4 years has followed the GDP, reflecting the current recession. The entire economy, world and domestic, has slowed in recent years, and composite production entered a near-no-growth phase. Production is expected to resume,

growing at a rate twice that of the GDP in the 1990's.

The growth in production for APC's has been mostly a process of developing new applications or performing certain high-tech jobs at greater efficiency through lighter, stiffer, stronger, etc., materials. Production growth for this sector has been almost entirely for military and aerospace applications, where high costs were not a great concern. This dependence on military applications brought 20% annual growth rates to some areas but also a large volatility in demand owing to current and anticipated cuts in defense acquisitions. Unless costs can be cut and products developed for the civilian consumer sector, the utilization of increased production capacity will result only in oversupply.

and Consumption Uses.—U.S. polymer composite markets, which include the APC shipments at less than 1% of total, can be divided into nine subcategories: aircraft-aerospacemilitary, construction, consumer products, appliance-business equipment, corrosion-resistant equipment, electricalelectronic, marine, transportation, and other. Table 9 presents the shipments of these materials by market category for the years 1987-92 with estimated 1993 data. released in February 1993. Data for this table were compiled by the Society of the Plastics Industry.⁸⁹ Figure 6 is a plot of the data listed in table 9 with the following difference: the consumer. business, and other market categories are shown as one "block" for clarity of interpretation.

The U.S. aircraft-aerospace-military shipments showed no growth from 1988 to 1991 with a decrease recorded for the past 2 years. After peaking in 1989, the 1990 and 1991 shipments dropped approximately 5% compared with those in 1989. The 1992 shipments dropped further, to approximately 22% of 1989 shipments. The 1993 forecast equals the 1992 level. The appliance-business equipment market shipped 12% less in 1991 than the high level period of 1990. But in 1992, total appliance-business

shipments increased 5% over those in 1991 and the forecast 1993 projecting levels are comparable to those of 1990. Clearly, the appliance-business equipment shipments are increasing in spite of the continuing recession.

The U.S. construction industry also appears to have recovered from the recession. In 1991, construction shipments dropped 10% from the 1990 level. Construction shipments in 1992 rebounded 13%, while 1993 estimated shipments call for an increase of 8% over those of 1992. At some time between the 1992 shipments and the estimated 1993 shipments, the construction industry is expected to exceed the record shipments of 230,000 metric tons recorded in 1987.

The U.S. consumer products shipments from 1987 to 1992 are exhibiting a pattern similar to the construction industry. With consumer products shipments in 1990 as a baseline, shipments decreased by 10% in 1991 but increased 8% in 1992. Consumer products shipments for 1993 are estimated to increase another 8%, exceeding shipment levels not recorded before.

Taking 1990 and 1991 as a baseline, the U.S. corrosion-resistant shipments recorded a 9% loss. Even the 1993 forecast estimates indicate only a very modest increase over 1992. Polymer composites appear to be holding their share in this market sector. The decline and holding values of 1992, along with estimated 1993, probably are reflecting the general economic recession. This latter statement is more believable than a reversal of the trend for composites to replace other materials in places where corrosion resistance, high strength, and ease of assembly are required.

Shipments to the electrical-electronic market saw a small decrease (less than 1%) in 1991 when compared with those of 1990. But 1992 witnessed a 12.4% increase relative to 1991. The 1993 forecast for the electronic-electrical market is estimated at a 4% growth over 1992 shipments. The 1992 and estimated 1993 shipments, together, are most probably reflecting the price wars and computer company shake-outs occurring

in the PC industry. With revenue increases of 18% and 22%, respectively, for the past 2 years, and with PC performance increasing rapidly, the large number of PC's sold in the past 2 years (more than 5 million) contribute to the increased electrical-electronic shipments. (See table 10.)

The popularity of fiberglass boats over the past decade made the marine market the fastest growing user of polymer composites at that time. The current economic slump left retailers with excess inventories, resulting in a market decline starting in 1989. Continued high retail inventory caused the 1990 market to shrink even further, and coupled with the current recession was the 10% excise tax the U.S. Congress added to luxury items that cost more than \$100,000. Marine trade associations relate that many luxury boat building companies went out of business as wealthier people chose not to buy expensive items and pay the 10% excess tax. Therefore, marine shipments for the boating industry continue to decline. For 1990, shipments declined 11% relative to those in 1989. The year 1991 recorded the lowest marine shipments or a 35% decrease relative to 1990, for 1992 recorded a 6% increase over 1991. It seems that the marine market for polymer composite shipments hit a low in 1991 and is slowly increasing (6% increase for 1992 relative to 1991). Also, the U.S. Congress is in the process of repealing the 10% excise tax but it can only do so if it finds other items to tax so that there is no net loss of revenue to the Federal Government. Repeal of this 10% excise tax is predicted to assist the marine boating industry in recovering from its current slump.

The U.S. polymer composite shipments for the transportation market in 1990 stood at 320,000 metric tons. Comparing 1990 shipments to those in 1992, an increase of 6% was recorded. This increase plus the estimated 1993 increase of 6% indicate that the transportation market for polymer composites is not affected by the current recession. Automobile trade magazines seem to be reporting increased uses of polymers in all types of automobile

applications from outer body panels, nonstructural shrouds, to structural bearing components. The transportation market shipments are expected to increase gradually as the quest for better fuel economy drives this industry toward continually striving to decrease the weight of the automobile without compromising safety.

The "other products" market uses polymer composites in medical equipment, orthopedic appliances, and dental materials along with many other niche market areas or specialties. From 1990 to 1991, this market decreased 7%, saw increased shipments in 1992 to 5% over those of 1990, and for 1993 estimated "other product" shipments to increase 6% over those of 1992.

The Corp Tech data format (discussed early) is shown in figure 7, where the total numbers of APC producers are plotted against sales volume. The sales volume(s) are broken in incremental ranges to give the figure the look of a histogram. Figure 7 relates that the key producers have large sales volume and that many large companies are in competition with each other. These large companies are necessary because of the significant investment necessary to be a supplier of APC's. Because this type of composite is usually "load bearing" and may be "man rated for service," many different engineering and technological skills are required to bring these composites to the marketplace in a timely and cost effective manner.

A large portion of the data used in this advanced materials document obtained from Kline & Co. Its data are estimated and contain not only shipment value in metric tons, but more importantly, sales revenues for different market segments of what Kline & Co. call APC's. Kline & Co. defines the APC market segments as: aircraft. missiles and space, recreation, armor, and industrial/other. Because Kline & Co. generates market surveys for inquiring customers, its market studies are focused on contemporary market niches. For example, figure 8 is estimated U.S. market for APC's, by end use, for 1992, giving data for both metric

tons shipped and dollar value. The estimated total weight of APC's in the U.S. market for 1992 was 7.450 metric tons at a value of \$2.20 billion. Therefore, the average value of U.S. APC's calculates to \$295.40 per kilogram (\$134.27 per pound). An interesting observation about figure 8 is that the cost per kilogram of missile and space hardware is 1.6 times greater than the cost per kilogram of aircraft hardware, reflecting the cost of putting the maximum amount of systems into the smallest volume at the lightest-possibleweight payload. The cost to miniaturize these systems is revealed in the cost per kilogram data. Comparison of 1991 estimated data with 1992 estimated data shows little decline in total value or amount shipped. The overall market forces of the current recession apparently have not had an effect on these highvalue-per-weight niche markets, especially those directly related to military and space applications. Changes will occur as most industrialized nations of the Northern Hemisphere downsize from both the end of the cold war and the current lingering recession.

World Review.—Figure 9 shows the estimated world market for APC's, by end use, for 1992, giving data in both metric tons shipped and dollar value. The estimated total weight of APC's in the world market for 1992 was 13,670 metric tons (U.S. share at 7,450 metric tons or 54%) and at a world value of \$4.335 billion (U.S. share at \$2.202 billion or 51%). Therefore, the average value of the world market for APC's calculates to \$317.12 per kilogram (\$144.14 per pound).

An overview of the world APC's industry for 1992 is given in figure 10. Figure 10 is unique in that it is in the form of a process flowsheet. This figure has both weight of materials in metric tons and the value added after each processing step in dollars. The total weight and dollar value going to the end user are the same total values presented in figure 9, 13,670 metric tons with a value of \$4.335 billion or \$145 per kilogram (\$65 per pound). Note that

processing steps include fiber weaving, prepregging, scrap, and fabrication. This schematic flowsheet gives a simplistic look at a very complex process. The challenge with APC's is to make them "user friendly" to the fabricator so that their value per weight will decrease to tens of dollars per kilogram and APC's will become very competitive in the marketplace.

In table 10, 1992 worldwide data for estimated APC shipments, by end use. are presented with emphasis on the "worldwide" segment being broken down into "U.S." and "rest of world." Additionally, projected data are listed for the year 2002 and an analytical guess put forth on the average annual growth rate(s) over this next 20 years for each of these APC market subsegments. The United States share of the world market is estimated at 54% in 1992 and projected at 58% in the year 2002. The fastest growing market sector is the automotive. with a projected growth of 26.7% worldwide and a large growth of 50% for the United States by the year 2002. The use of APC's in automobiles will lead the way to more fuel efficient and less polluting vehicles. In this automotive sector. the performance of these composites to accomplish the aforementioned goals will offset their initial high value per kilogram.

Current Research. - New Materials.— Current research to develop new matrix materials is aimed at overcoming the disadvantages of epoxies, such 28 low-fracture toughness. processing by irreversible reactions, and high viscosity. A number of epoxy blends with greater fracture toughness than single epoxies and lower viscosity than thermoplastics have been formulated and are being evaluated.90 These materials may find uses in areas demanding improved impact resistance, but they will still be difficult to repair or recycle.

Increased repairability and toughness are the main driving forces for the greater implementation of thermoplastic resins as matrix materials. Polyetherethereketone (PEEK), introduced in 1982, is a leading

contender for more applications. Formable by heat and low pressures, it also has a preprocessing advantage over thermosets (mostly epoxies) in that PEEK prepregs do not require refrigeration for storage and shipment. Thermoplastic processing technologies, being more automated, result in shorter cure and production times, and in increased productivity. Newer thermoplastic resins being developed as matrix materials are polyphenylene sulfide (PPS), thermoplastic polyimides, polyarylates, and polyetherimide (PEI).91

Liquid crystal polymers also are being developed as matrix and even stand alone materials. Their internal structure is such that the molecular chains forming the resin become oriented parallel to each other and the resultant material becomes reinforcing." This reinforcement produces exceptionally high strengths. These materials can be processed at high temperatures, are thermally stable, and are solvent resistant. They are lower in density than epoxies. Although it is expected that they eventually will find implementation in large structural applications, they are likely to be used first in large volumes as injection molded chip carriers in the electronics market.92

New Fibers.—The effectiveness of fibers as reinforcements in APC's depends on their intrinsic strengths, surface condition (failure is initiated at surface flaws), and the strength of the interfacial bond with the matrix. Research directed toward finding improved reinforcements remains intense, although development efforts have declined owing to general economic conditions. A variety of silica. aluminosilicate, boron, silicon nitride, silicon carbide, and organic fibers are being researched and evaluated for use as reinforcements for improved composite structural materials. A new highperformance E glass, Star Stran 748, has been introduced commercially by Schuller International (formerly Manville). This fiber was designed specifically for injection molding, using PPS or PEI as matrix materials.93

Nondestructive Evaluation (NDE).—Fiber breakage during fabrication, poor fiber-matrix adherence, and existence of voids and inclusions in polymer composites are potential causes of failure in service and are not detectable by visual inspection because the flaws are internal. Because composite production methods do not yield 100% products at or above specifications, the only way to ensure complete quality control is to examine each component before the assembly of critical structural parts. Several methods are under development or are being used for this These include ultrasonic purpose. inspection, infrared thermography, thermographic stress analysis, X-ray tomography, eddy current measurement, acoustic emission measurement. fluorescence spectroscopy, magnetic resonance imaging (MRI), and pulsed nuclear magnetic resonance (a variation of MRI).

Owing to the lack of experience in longtime use of APC's and the variability of properties resulting from lack of uniformity in processing, much effort is being expended to evaluate new materials for deterioration of properties while in Nondestructive evaluation service. methods are being developed for both periodic inspection of components in use, as well as methods based on continual monitoring during service. Two methods presently under development involve the incorporation of pressure sensitive detectors (piezoelectric or light emitters) into an assembly to detect deformation of a component or sound detectors to receive acoustic emissions from critical points in a component as a way to detect internal changes occurring in the component.

Although perfect adhesion at the fibermatrix interface is generally thought of as the desirable condition, for certain applications the opposite may be true. For polymer composites used for ballistic armor, poor interfacial adhesion has been found to result in even better ballistic performance. S-2 glass fiber is used for reinforcement in this composite. In most cases, the desired phenomenon is for excellent fiber-matrix adhesion to allow

stresses to be transferred from matrix to fibers. But in this application, controlled less-than-perfect adhesion maximizes the dissipation of impact energy because the loosely bound fibers are able to "give" and absorb and distribute more of the impact energy from a ballistic projectile.94 This composite offers the same structural performance and ballistic protection, has better corrosion resistance, and weighs 16% less than aluminum in the same application.95 This is a good example of how control (achieved during processing) of structure can result in the improvement in properties desired for a specific application.

Outlook

The outlook for polymer composites is somewhat cloudy, reflecting the general economy. The transportation industry, however, is expected to continue to dominate the polymer composite market in the near term. The current recession may continue its no-growth-to-negative impact on 1993 shipments. The largest slump is expected in the aerospace sector, which had been holding firm in spite of poor general economic conditions. The largest gains are expected in the construction and transportation markets, which had slumped badly in 1991, and exhibited a modest gain in 1992. Gains of 6% and 7% are forecasted, respectively. Most sectors are expected to hold steady or achieve small increases 1993. Major U.S. for manufacturers plan to produce cars and more plastic small trucks with components, ranging from fenders (some 1993 Chrysler models) to all-body panels (General Motor's planned electric cars for 1994). An increased use of APC's is expected as they are employed to meet the demands for fuel efficiency, which is most readily achieved by weight With anticipated price reduction. reductions, due mostly to improved processing methods, polymer composites and APC's should resume penetration of the aerospace, industrial products, and electrical-type markets. The long-term outlooks for polymer composites and APC's are for continued growth.

The increased use of polymer composites in military aircraft during the past 20 years has proven that they can perform in critical applications. The concern for increased fuel efficiency in the commercial aerospace market is driving the penetration of APC's into this field of application. Long-range projections for commercial aircraft indicate record growth. It is expected that almost 10,000 planes valued at \$626 billion will be delivered between 1995 and the year 2005, according to a Kline & Co. report. 96

Starting in 1992, after having increased percentages annually, the DOD requires that a minimum of 50% of PAN carbon fiber procured for the military be obtained from domestic sources. This requirement has driven increases in domestic capacity. But expected cuts in defense orders have dampened expectations of continued growth at rates greater than 15% to 20% annually for this advanced reinforcing element. 97

Reduction of costs through more efficient production and the development of more nonmilitary applications are factors that should brighten the outlook for APC's.

ADVANCED ALLOYS, METAL MATRIX COMPOSITES, AND CARBON-CARBON COMPOSITES

Background

Definitions, Grades, and Specifications.—Metallic alloys are materials formed by combining one metal with other metal(s) or nonmetal(s) to develop a new material that has physical, mechanical, and/or thermal properties superior to the original materials. Steels (iron-carbon), stainless steels (ironchromium-nickel), brasses (copper-zinc). bronzes (copper-tin), and aluminum alloys are the most widely known alloys. New compositions of these and other alloys constantly are being developed. Advanced alloys are usually highly such as complex materials, superalloys that contain nickel or cobalt

with significant amounts of chromium, and are used frequently at temperatures above 500° C. The superalloys are perhaps the oldest of the advanced materials, originally developed for aircraft engines during and right after World War II. Even though alloys originated so long ago that we use some of them to name the ages of humankind, there recently have been major advances in developing superalloys, powder metal applications, light metal alloys, metal matrix composites (MMC's), and others, as well as new processing technology. Both new alloy development and new process development on existing alloy systems have been major contributors to the current interest in advanced materials.98

For many years, aluminum alloys, superalloys, and titanium alloys have been the "backbone" high-performance metals used in both civilian and military aerospace systems. With the military applications leading the way, these systems have long represented the highest of "high tech" in structural materials. Aluminum alloys have been the main material for airframes, while the heavier superalloys and, for some components, titanium alloys, have been the enabling technologies for aircraft engines. Although new processing techniques have resulted in performance improvements in these alloys. they currently approaching their technological limits. The development of a new generation of materials is necessary to achieve the dramatic performance improvements needed to sustain U.S. dominance in the worldwide aerospace industry. advanced ceramics and advanced polymer matrix composites will undoubtedly be significant members of this new family of materials, new metal-based systems also will be important. Included among the most promising of these new metal systems are MMC's, intermetallics, and new aluminum alloys.

MMC's are metals or metal alloys reinforced with ceramic fibers, whiskers, or particulates. Because of their superior mechanical strength and unique physical characteristics, such as low thermal

structural and nonstructural components alike. They combine metallic properties (ductility and toughness) with ceramic properties (high-temperature strength and high stiffness) to offer greater strength in shear and compression and higher surface temperature capabilities. laboratory development of MMC's began in the 1960's, but the first commercial application was an MMC diesel engine piston introduced in 1983 by Toyota. Since then nearly every automobilemaker has done some R&D on MMC application. The continued increased interest in MMC's for applications in aerospace, automotive, and other markets has been enhanced by the availability of relatively inexpensive reinforcements. For example, the average price for "good grade" silicon carbide particulate, used in aluminum MMC's, is about \$5 per kilogram today, compared with more than \$25 per kilogram 10 years ago. Also helpful are the techniques of simply "inserting" parts made of new material into existing assemblies when the match is close enough in geometry and properties between the old and new part. These techniques give manufacturers valuable experience in the utilization of new materials.

Aluminum alloys are heavily predominant as metal matrix materials, followed by magnesium, copper, and titanium alloys. Reinforcement materials for MMC's include the compounds silicon and boron carbides (SiC, B.C). silicon and aluminum nitrides (Si₂N₄, AlN), and oxides (Al₂O₃, SiO₂), as well as elemental materials, such as carbon. Examples of use include silicon carbide in aluminum and magnesium MMC's in all three standard forms (fiber, whisker, and particulate). Carbon is used ordinarily as continuous fiber reinforcement. Discontinuously reinforced MMC's employ particulates, whiskers, or short fibers as reinforcing components. The suitability of these materials for fabrication by standard metalworking processes has brought considerable attention to this class of MMC's in recent vears.

C-C composites have unique

high strength, and maintain their properties to temperatures above 2.000° C (3,650° F) in nonoxidizing atmospheres. Above 800° F, they must be coated or contain oxidation inhibitors to be used long term in an oxidizing atmosphere. C-C composites have high modulus and low creep, meaning they are stiff and deform only slightly at high temperatures under load over time. Their high strength and low coefficient of thermal expansion provide good thermal shock resistance.

Industry Structure.—Neither MMC's nor C-C composites have reached a mature industry level. Both are still growing, not only in the number of applications but also in the amount and value of material produced. Figure 11 shows MMC producers for 1992 related to sales volume ranges. A large portion of the companies had annual revenues of less than \$25 million for 1992. Figure 12. in the same data format, shows C-C producers for 1992. In the C-C composite data, small numbers companies exist with total revenues at less than \$50 million while five companies showed annual revenues greater than \$250 million. These latter companies are large chemical industry corporations that were requested by DOD to increase carbon fiber/filament output so that the U.S. military needs—at least 50% capacity—could be met by U.S. fiber manufacturers. As discussed earlier in this chapter, the United States now has excess carbon fiber and C-C composite making capacity as a result of the end of the cold war. Some of this excess capacity already has been sold to foreign interests, although the physical plants still reside inside the United States. remaining U.S.-owned companies have asked the new Clinton administration for economic assistance to convert C-C technology to civilian uses through DOD insertion-type programs. This same assistance also has been requested by the smaller entrepreneurial MMC companies. These DOD insertion programs allow higher cost technology to substitute for existing lower cost technology, with the expansion, MMC's find applications in | properties. They are lightweight, have | U.S. Government paying the difference.

The concept is that companies will be able to manufacture, in limited quantities, new technological products, and, if ever needed in a new war, these same companies will be able to increase production in a timely manner. Emerging technologies are thereby nurtured by the Federal Government. This DOD concept is being considered for other types of emerging technologies as various legislative proposals are now in congressional review.

Technology.—Processing.—Metal refining methods, such as vacuum induction melting, vacuum arc remelting, and electroslag remelting, have allowed metallurgists to produce alloys of high cleanliness and extremely low impurity levels. These higher purity levels allow further development of the material's intrinsic properties and create "engineered materials" to achieve the highest possible New processing performance goals. methods. such as directional solidification, single crystal growth, hot isostatic pressing, mechanical alloying, and rapid solidification, are being used to fabricate alloys with refined and controlled microstructures, resulting in the achievement of tailormade properties. Knowledge of the resultant physical properties as a function of the microstructure and the processing methods for a designated metal system give today's metallurgists the ability to produce engineered materials.

Unconventional processing techniques have increased the number of alloy systems available to the metallurgist to study, delineate, and ultimately engineer. In some cases these new processes enable the production of "impossible alloys" or metastable alloys. Just as oil and water "do not mix." some metallic elements do not form liquid solutions or solid solutions with each other. Through ordinary solidification, these insoluble metals would separate into at least two separate phases, and any product made would likely be brittle. By a method called Rapid Solidification Processing (RSP), many liquid solutions are rapidly cooled (through millions of degrees temperature change per second) so that the atoms of the different metals are "frozen" together before they have time to separate, forming a solid solution that could never be produced with conventional solidification. There exist many different ways in which RSP can be achieved. One method is to pour hot liquid metal alloy into a very fine stream and let it drop onto a rapidly spinning disk. The individual liquid droplets are quickly splat cooled on the spinning disk and thrown off as solid particles. The powders are gathered, beneficiated, and used in the many fabrication processes amenable to metal powders.

All of the aforementioned techniques produce powders or metal feedstock that can be further processed into MMC's. MMC's are composite materials in the sense that second-phase fibers, whiskers, or particulates are added to improve one or more physical properties. example, aluminum and magnesium alloys have low-to-moderate tensile strength but excellent fracture toughness. For many applications in aerospace and automotive, where high strength and low density is a must, these alloy systems can only be effectively strengthened by introducing a second-phase material not originally derived from precipitation mechanisms engineered into the original "matrix" alloy.

Therefore, the fabrication of MMC's can range in complexity, from simple pouring of molten metal into molds containing preformed fiber reinforcement skeletons, to intricate methods involving partially solidified metal, vigorous agitation to mix in the second-phase, and/or the use of high pressure or vacuum to quickly force the molten metal into a mold bearing the second-phase preform. Each method offers its own particular advantages in terms of cost, protection of reinforcement, adaptability. A number of processing methods suitable for advanced structural ceramics are also applicable to MMC's.

MMC's are often processed in two stages. First, a special process is used to produce a composite "preform" containing the specified amounts of reinforcement and matrix. Then standard metalworking processes are used to shape

the composite to the desired configuration. For example, composite preforms can be fabricated by coating carbon fibers with condensed aluminum vapors using either chemical or physical vapor deposition. These carbon fiber coated aluminum preforms are subsequently consolidated using hot pressing techniques. Hot rolling or hot isostatic pressing also could be used for the consolidation step.

"Compocasting" is another technique for preparing MMC's. The reinforcing particles are introduced into a vigorously agitated, nearly solidified melt or slurry. The viscosity of the melt or slurry is controlled to maintain a uniform distribution of the reinforcement. The Duralcan process involves adding SiC powder to aluminum alloys. Proprietary pretreatment of the particles and a specially designed stirrer to mix the particles in the melt are the technical keys After mixing, the to the process. composite is solidified relatively quickly using a direct-chill, water-cooled mold. This preserves the uniform distribution of reinforcement particles. The ingots produced are then remelted and cast into the desired shapes. More than 70 foundries have successfully remelted and cast ingots from this process.⁹⁹ An upper limit of approximately 15 to 25 volume percent of second-phase particles can be added with this technique. When SiC whiskers are the second-phase additive to the liquid melt, the volumetric amount decreases slightly because the whiskers tend to ball up into lumps due to their needlelike shape. Laboratory development indicates that maximum engineered properties occur at about 50 volume percent second phase. The Duralcan process is impressive in its achieved strength enhancements and definitely has market areas were Duralcan alloys offer unique properties.

Another method of adding secondphase strengtheners that are not continuous fibers is to use powder metallurgy (PM) approaches. Second phase(s) and powder matrix are mixed, blended, and prepared for hot pressing or hot isostatic pressing. Up to the desired 50 volume percent second phase can be

added and desirable physical properties displayed. Materials under development for the High Speed Civilian Transport (HSCP) or the orbitor National Aerospace Plane (NASP) use SiC whiskers as the second phase. One of the engineering problems to be solved in the PM approach is how to sufficiently out-gas the cold pressed powder/whisker compact before pressing or rolling temperature. Because the matrix is never melted, the micro surface area of 1 gram of powder or whisker could equal 10 to 15 meters squared per gram. The failure to remove this absorbed species on the surface does degrade the physical properties by forming undesirable grain boundary precipitates.

NASP materials development and manufacturing involves these two techniques as the NASP project attempts to scale up these processes to make skin panels and structural members for the plane. Other governmental uses for these aluminum alloy SiC materials include structural sections for the space station and the myriad of platforms involved in the Strategic Defense Initiative. The latter projects are declining in funds due to today's changing world conditions. Transferring MMC technology to civilian uses will require that the intended application(s) be extremely performance oriented to compete with existing commercial material system(s). Like many advanced composite systems under development today. achievement of high-performance goals is accomplished at great cost.

Applications.—MMC's are used in many applications and have a history going back at least 20 years. The F-111 all-service fighter-bomber employed boron fiber (boron deposited on tungsten filament) as a second-phase fiber reinforcement in the U.S. Navy version of the plane to lighten the aft end of the plane for carrier landings. Spun-off from that application and others were boron-fiber-reinforced aluminum tubes used as cargo bay struts in the space shuttle. Similar type composites found utility in some sporting and recreational goods such as skis and bicycle frames. Today,

R&D has evolved technically better second-phase reinforcements such as fibers; low-cost, high-purity refractory ceramic powders; and newly discovered ceramic whisker types. reinforcement types are added to aluminum-, magnesium-, and titaniummatrix MMC's for additional applications in airframes, other aircraft applications. and industrial products. Both continuous and discontinuous reinforcements are evolving rapidly as R&D focuses on finding technically compatible metal alloys for these many reinforcement types. The ultimate goal is to develop MMC's toward maximizing their full performance capabilities.

Lockheed is using MMC's in the vertical tail fins for the Advanced Tactical Fighter. This application results in a 25% weight reduction over current tail fins. Pratt and Whitney Aircraft is developing a fan blade for jet engines, utilizing an aluminum matrix composite with continuous boron fiber reinforcement wrapped around a titanium core. Aerospace optical systems requiring high stiffness and low coefficient of thermal expansion (CTE) have been produced using Duralcan composites.

The prime mover in turbine engine development is the DOD's Integrated High Performance Turbine Engine Technology (IHPTET) program. goals are turbopropulsion capabilities twice that available using today's technologies. This long-range program is coupled to both the High Speed Civilian Transport (HSCT) and NASP with intermediate results scheduled for use in the High Speed Civilian Transport. 100 In addition. the Enabling Propulsion Materials (EPM) program, a joint effort of NASA and industry, has been established to develop the hightemperature composite materials technology that will increase turbine engine efficiency, resulting in a reduction of NO, emissions and sufficient noise reductions at airports. 101

The aircraft turbine engine companies are developing MMC's for all sections of their engines and are starting to look at intermetallic alloy systems, such as the nickel, titanium, or niobium aluminides.

Although these aluminides are currently not classified as MMC's, ongoing R&D seems to point to using second-phase reinforcements to enhance the strength and/or fracture toughness. Both of these physical properties are maximized inversely as the operating temperature increases. For instance, an aircraft engine must be capable of repeatedly going from room temperature to a hightemperature stable condition and back to room temperature for aircraft take-offs, flight path, and landings. The fracture toughness property is a function of temperature, usually going from brittle fracture (unacceptable) at some low temperature to acceptably high values at the designed high-temperature stable In the case of the conditions. intermetallic MMC's. the lowtemperature fracture toughness values are not acceptable for these materials. Hence, ongoing R&D using second-phase reinforcements to improve room temperature fracture toughness. Intrinsic chemical reinforcements [precipitated and/or diffusion-controlled secondphase(s)] can be optimized in most materials, but the use of extrinsic secondphase reinforcement(s) allows for the technical possibility of a versatile "engineered material." 102

Commercial MMC applications have only just begun to be cost effective, based on certain high-performance benefits. For example, automotive brake rotors save one-third of the weight of cast iron rotors and have low thermal expansion. better wear resistance, and excellent thermal conductivity. Automotive pistons take advantage of this composite's high wear resistance, low CTE, and high-Additional temperature strength. automotive applications will include rocker arms and cylinder heads. Other MMC products include microelectronics packaging, electro-optical platforms, ballistic armor, and various structures requiring stiffness and good hightemperature properties. 103

Duralcan automotive brake rotors save one-third of the weight of cast iron rotors and have low thermal expansion, better wear resistance, and excellent thermal conductivity. Automotive pistons take advantage of this composite's high wear resistance, low CTE, and high-temperature strength. Additional automotive applications will include rocker arms and cylinder heads.

MMC's are included in the "critical materials" lists targeted for joint partnerships between the U.S. Government and industry. The next 5 years should indicate whether this country can learn to use flexible and agile manufacturing techniques to make MMC's commercially competitive products of the U.S. economy.

Recycling.—Multialloyed metals owe their high-performance achievements to the value added by processing and postprocessing treatments, both the result of many years of R&D. These metals must be completely refabricated, commencing with remelting. Whether it is economically better to use "scrap" or virgin feedstocks depends on the individual alloy system, the current application requirements, and other technical concerns, all driven by cost. MMC's are complicated alloy systems in that deliberate, extrinsic second-phase reinforcements are added to multialloyed matrix to achieve certain performance goals. Therefore, the recycling situation for MMC's is complex because the second-phase reinforcements could become contaminants if allowed to remain mixed with the matrix alloy(s) during remelting. 104 For example, because MMC's are engineered materials, the initial mechanical design program could call for second-phase continuous fibers. When this particular end product is scrapped, remelting to remove the multiphase alloy leaves behind a metallized continuous fiber preform of possibly little economic value. Remember that 1 kilogram of high modulus carbon fiber costs about \$1,000 today, and this "feedstock material" may not lend itself to being recycled into a high-cost product. In addition, fibermatrix reactions in a component during its "designed" elevated temperature lifetime, or at any remelt operation, could render the fibers, in any morphological form, unsuitable for reuse. The same line of reasoning holds true for other second-phase reinforcements such as ceramic particulates, whiskers, or ceramic type continuous fibers. R&D is ongoing to find technical and economic methods for reclaiming these second-phase reinforcements for reuse as value-added materials approaching the technical quality of virgin "feedstock" reinforcements.

In other recycling situations, "scrap" segregation of MMC's nonreinforced alloys may be necessary before recycling. For example, USBM research has shown that it is possible to separate conventional Ti-6Al-4V allov scrap from the same alloy scrap reinforced with SiC or B₂C fibers using eddy current measurements. USBM researchers have demonstrated scrap separation of aluminum alloys from aluminum-lithium alloys using eddy current measurements. Because these techniques make use of differences in electrical conductivity to make the separation, they should work for separating aluminum MMC's from unreinforced aluminum alloys.

If the metal or metal alloy and its reinforcement do not interact chemically at the melting point of the matrix, a physical separation, such as liquid or solid filtration, would be effective in separating matrix material reinforcements. USBM has conducted preliminary research on this approach using various filter media. 105 However, if significant chemical reactions occur, the fibers usually are damaged, and often special techniques would be needed to clean up the contaminated melt. Currently, the amount of MMC's producing obsolete scrap is very low, but recycling is expected to increase significantly as the acceptance of these materials increases.

Significant amounts of recycling already occur with certain MMC's. Contrary to the commonly held impression that MMC's are always difficult to recycle, the Duralcan MMC foundry ingot is inherently recyclable. When remelted and cast to shape in the foundry, the reinforcing particles remain well distributed with only gentle stirring

and there is no loss of physical properties. Theoretically, when its useful life is completed, the product could be remelted and cast still another time. Currently, most of the Duralcan process scrap recycled is prompt scrap, gates and risers from foundry ingot, extrusion butts, cut extrusion scrap, etc. This material is recycled back through the basic Duralcan composite stirring process.

If desired, the reinforcing particulate can be removed from the molten composite by the same fluxing methods, such as salt fluxing, used to remove oxide films, etc., from ordinary aluminum alloys. The result is an aluminum alloy, free of particulate, "reclaimed" to its original alloy state before the composite was produced.

It can be generally stated that MMC use will increase rapidly in the near future. These MMC's offer superior technical performance, capable of being engineered into the MMC's. superior performance usually cannot be achieved by conventional materials in use today. Therefore, the recycling of these complex composites becomes very important to their overall lifecycle. Because MMC's are posed for entry into commercial applications, many material designers are incorporating the concept of "design to recycle" into these future MMC applications. R&D is continuing into all lifecycle phases of MMC's, and recycling will be a significant factor in engineering MMC's.

Annual Review

Consumption and Uses.—Metal Matrix Composites.—The estimated 1992 U.S. market for MMC's, shown in table 11 and figure 13, is \$28.9 million for 202 metric tons shipped with market subsegments or end uses identified as automotive, aerospace, recreation, and industrial/other. From table 11 (1990-92), the 1992 data show a 12% decrease in value for a 35% increase in total tons shipped when compared to 1991. This most noticeable change occurred mostly in the automotive segment where 50% more product was shipped in 1992 but at

a dollar value almost equal to 1991. The 1992 automotive market continued to be the largest segment tonnagewise, with approximately 60%, while the aerospace market is the largest segment valuewise at 83%. The aerospace market stayed the same for 1991 and 1992 for both tonnage and dollar value and is not yet reflecting the DOD cuts in military spending.

Carbon-Carbon Composites.—The estimated 1992 U.S. market for C-C composites, shown in table 13 and figure 14, is \$120 million for 167 metric tons shipped with market subsegments or end uses identified as aircraft brakes, rocket nozzles, nose tips/ablatives, racing brakes, and industrial/other. From table 13 (1990-92), the 1992 data show a 2% decrease in value for a 4% decrease in total tons shipped when compared to 1991. This most noticeable change occurred with a decrease in military-type product (aircraft brakes, rocket nozzles, and nose tips/ablatives) of 9%, offset by an increase in nonmilitary product of 14%, or a net decrease in dollar value of approximately 2%. The 1992 aircraft brakes market continues to be the largest segment tonnagewise, with approximately 67%, while the nose tips/ablatives market is the largest segment valuewise at 50%. The slight decrease in 1992 for both tonnage and dollar value may be reflecting DOD cuts in military spending.

World Review.—Metal Matrix Composites.—The estimated 1992 world market for MMC's is \$56.1 million (558 metric tons). This represents a 7% decrease in value but a 2.5% increase in weight compared with 1990 data. The world data also reflect the observation that more lower value products were shipped in 1992 than in 1991. Figure 15 shows the 1992 world market by end-use industry while table 11 compares the same categories for 3 years, 1990-92 (Both Kline & Co. data). Analysis of table 11 reveals world automotive MMC dollar value for 1992 returning to 1990 levels but the aerospace dollar value for 1992 decreased 10% compared to that in 1990. Notice that the world aerospace tonnage shipped in 1992 was lower in

value than the tonnage shipped in 1990. The 1992 worldwide automotive market continues to be the largest segment tonnagewise, with approximately 79%, while the worldwide aerospace market is the largest segment valuewise at 67%.

From table 11, a comparison, for 1992, of the worldwide value per weight in the automotive category to the aerospace category yields the following: for automotive, \$35 per kilogram (\$16 per pound); and for aerospace, \$405 per kilogram (\$184 per pound). This indicates that the average cost of MMC's for aerospace applications is 10 times higher than those for automotive and other applications. These higher costs are attributed to labor-intensive fabrication and low-volume production.

The estimated 1992 worldwide and projected year 2002 worldwide MMC shipments are shown in table 12. For 1992, the U.S. share of the total MMC market is 36% and is expected to increase to 43% by the year 2002. The fastest growing market segment worldwide in the next 10 years is the automotive market in the United States with a projected 12% annual increase, while the slowest growth rate was indicated for the U.S. aerospace market at 6% annually. The rest of the world category is expected to have a total MMC growth of 7.4% annually while the United States is projected at 6.1% annually.

Carbon-Carbon Composites.—The estimated 1992 world market for C-C composites is \$171 million (229 metric tons). This represents a 14.5% decrease in value and a 25% decrease in weight compared to 1990 data. The world data also reflects both lower total value and lower total shipments in 1992 than in 1991. Figure 16 shows the 1992 world market by end-use industry while table 13 compares the same categories for 3 years, 1990-92 (Both Kline & Co. data). Analysis of table 13 reveals world nose tips/ablatives dollar value for 1992 approaching the record 1991 level while the world aircraft brakes and rocket nozzles dollar values decreased approximately 5% to 10% in 1992 compared to 1991. All other end-use

categories decreased in 1992 compared to 1991.

The 1992 data are a decrease over 1991; this decrease is due, in part, to an overall sluggish economy combined with current and anticipated cuts in defense spending and to the quickness of the military success in the Persian Gulf war. Table 13 reveals only worldwide growth in the areas of racing brakes and industrial/other (dollar value in the shipments in the former, latter). Furthermore, table 13 indicates the 1992 worldwide aircraft brakes continues to be the largest segment tonnagewise, with approximately 62%, while the worldwide nose tips/ablatives market is the largest segment valuewise at 49%. The 1992 value per weight shipped for aircraft brakes segment is compared to the nose tips/ablatives segment: for aircraft brakes, \$257 per kilogram (\$117 per pound); and for nose tips/ablatives, \$3,002 per kilogram (\$1,365 per pound). Remember that the densities of C-C composites are about one-half that of typical MMC's so that a \$3,000 per kilogram C-C composite structure needs only one-half the weight to carry the same structural load as an MMC. Also, C-C composites can be almost twice as strong (elastic modulus) as MMC's, therefore, only about half as much material is needed compared to an MMC. These density and strength factors help to offset the very large costs of processing C-C composites at temperatures in excess of 2,000° C. However, the higher costs of C-C composites are also attributed to labor-intensive fabrication and lowvolume production that are inherent in many of today's composites.

The estimated 1992 worldwide and projected year 2002 worldwide C-C composite shipments are shown in table 14. For 1992, the U.S. share of the total C-C composite market is 72% and is expected to remain at 72% by the year 2002. The fastest growing market segment worldwide in the next 10 years is the industrial/other market in the United States, with a projected 11.3% annual increase, while negative rates were indicated for the U.S. nose tips/ablatives at -2% annually and rocket nozzles at -3% annually.

Current Research.—Matrix adherence is an important factor in determining MMC properties. Optimum adherence of the matrix to the reinforcement often involves some degree of chemical reaction between the matrix and the reinforcement. However, if the reaction is too extensive, degradation of the reinforcement may limit the strength of the composite. The lithium added to aluminum alloys to enhance wetting during the formation of aluminumalumina fiber composites (in addition to adding strength and stiffness to the matrix) reacts strongly with the fibers. The composite must be infiltrated and cooled quickly or the Al₂O₃ fibers will lose their integrity and will add nothing to the properties of the composite. In another example, nonheat-treated boron fiber-reinforced aluminum fails during fracture through debonding at the fibermatrix interface. After heat treatment of the composite at 300° C, in an inert atmosphere, the room temperature strength increases and fracture occurs within the fiber itself, rather than along the fiber-matrix interface. Through a properly controlled reaction, the interface has become stronger than the fiber. Additional research is necessary to improve the ability of the materials engineer to control the reactions at the fiber-matrix interface to develop optimum adherence between the reinforcing phase and the matrix.

The most recent developments in MMC technology utilize the wrought alloy series rather than the casting alloys as a basis for matrix materials. BP Metal Composites in England is developing composites based on Alloy 2124, a highstrength, fracture tough alloy, and Al-Li Alloy 8090, a new, strong, stiff alloy with lithium, using 17% SiC particles for reinforcements for both. The resulting composites have excellent stiffness. Composite billets are made using powder metallurgy techniques. Conventional and superplastic metalworking techniques are then used to form sheet, plate, extrusions, forgings, or specific parts. Access panels, extruded floor-beam struts, and missile control fins have been fabricated as demonstration aerospace parts. 106

Advanced Composite Materials Corp. (ACMC) of Greer, SC, also is developing aluminum composites based on the wrought alloy series. Its composite 2009/SiC has the strength and density of high-strength 7XXX aircraft alloys and the stiffness of titanium. Alloy 2009 contains 3.6% copper and 1.3% manganese. Powder metallurgy techniques are used to produce billets, which are then extruded, rolled, or forged. They can be processed by any metalworking operation that does not require melting. The finished products are stronger and more ductile than equivalent ones made from cast billets. Any desired product can be fabricated using conventional shop procedures. Lockheed is currently testing prototypes of a vertical tail stabilizer for an advanced jet fighter made from this material. 107 ACMC also is exploring the 6XXX series aluminum alloys (which contain magnesium and silicon as alloying elements) and high-temperature aluminum alloys made by rapid solidification for use as matrix materials for composites. 108

Outlook

The already intense intermaterial competition between different materials systems for the various sectors of industry will increase in the near and long term due to anticipated decreases in defense spending. For the materials systems that have been able to take advantage of the performance-at-any-price philosophy of military procurement, there is danger of near-term downturns in applications because this philosophy can no longer prevail. In the ordinary consumer world, the materials that provide adequate performance at the best price will prevail; the continued success of much of the new materials industry will be dependent on the ability of developers to find effective nonmilitary applications of these materials. For any materials that are heavily dependent on military applications, the picture has become cloudy, at best. The bright side of this phenomenon is that more work in the development of commercial applications will become imperative, rather than an afterthought. With more emphasis on commercial applications of these new materials, the United States is more likely to succeed in the economic "wars."

New alloys that are lighter, stronger, tougher, and more fatigue and corrosion resistant are likely to find increasing use if they can be manufactured at competitive prices. Thus, new aluminum and magnesium alloys will continue to chip away at the dominance of steel where lower density has become a desired property, as in the automobile industry. New titanium alloys will be applied in cases where lightweight and good high-temperature properties are important.

MMC's experienced a drop in nearly all areas in 1992. The only bright spot was in the total tonnage shipped for the year, which increased 26% over that of 1991, mainly from the automotive market. The total dollar value decreased 12%. The aerospace market for MMC remained the same in 1992 as in 1991, a more than 80% share of total MMC dollar value, indicating that the DOD procurement cuts have not caught up with MMC's in 1992.

Because of its heavy use in defense applications, perhaps the picture for C-C composites is the most cloudy. To meet the mandated requirement for a 50% domestic supply of PAN fibers, domestic capacity has been increasing over the past few years. Demand has not kept up. Capacity has outstripped demand both domestically and worldwide. At slightly more than \$300 per pound for an average price, this material is quite expensive. Accordingly, most of its growth must occur in sectors where no competing material can come close to doing the job. Therefore, opportunities for growth appear to be somewhat limited for the near term, until more varied applications of this material can be found.

SILICON INTEGRATED CIRCUITS

Background

This segment is a highly condensed version of the USBM Working Paper "Material Process/Product Flows in the U.S. Semiconductor Industry: Focus on the Silicon Integrated Circuit," by Kristin Tressler.

The semiconductor industry is divided into three distinct areas: (1) integrated circuits (IC's), (2) discrete (or individual) semiconductors, and (3) "other" semiconductors, such as light-sensitive or light-emitting devices. 109 Of these three types of semiconductor devices, integrated circuits are by far the leading devices in terms of consumption of materials and worldwide revenues. Discrete devices, which ranked second, are either transistors or diodes. Transistors are used to amplify electronic signals or to turn electrical current on or off, whereas diodes are mainly used to convert alternating-current signals to direct-current signals. The third area is light-sensitive and light-emitting diodes, which include solar cells and photodiodes. The majority semiconductor devices end up collectively as parts for integrated circuits. An IC is merely a collection of various discrete devices built into and interconnected on a semiconducting silicon substrate. Most IC's are monolithic, meaning that all functions are performed on a single silicon wafer, and are manufactured of two basic types: bipolar or metal-oxidesilicon (MOS). Bipolar IC's are more difficult to manufacture than MOS IC's. Because bipolar IC's process information faster, they are used mainly as logic circuits in high-speed computers. MOS IC's are used primarily for data storage, but also find uses in microprocessors and microcontrollers.

Definitions, Grades, and Specifications.—IC's represent the majority of semiconductor device revenues and, in 1992, accounted for approximately 70% of total factory shipments. MOS IC's are the fastest

growing group of semiconductor devices and alone accounted for 39% of total device revenues in 1992. Total factory shipments of semiconductor devices have increased approximately 53% from 1981 to 1990. IC's are categorized by trade associations in the following subgroups:¹¹⁰

Integrated Circuits:

IC type:
 MOS IC's
 Bipolar IC's
 Other hybrid IC's
IC function:
 IC's for power control
 IC's for signal processing
Diodes and Rectifiers:
 Light-emitting
 Other
Other Semiconductor Devices:
 Thyristors
 Solar Cells
Other

Products for Trade and Industry.—IC's are considered enabling technologies and are used in some of the United States' most important industries, including data processing, communications, industrial machinery, consumer products, military electronics and controls, and transportation systems. For example, the revenue distribution for 1992 indicates more than 40% sales generation from data processing alone, with industrial and the military accounting for 15% each. This 40% number represents a doubling of data processing revenue over this 10year period (1983-92).111 Except for the rapidly expanding category of data processing, revenue data from the past 10 years for all other IC uses have increased steadily while maintaining the same degree of revenue proportionality among the various categories.

Industry Structure.—Succinctly, IC's are made by first cutting thin sections or wafers from single crystal boules of ultrahigh-purity silicon metal. Then multistep processing prepares the wafer surface for the as-designed IC products; e.g., computer chips. These initial prefabrication steps are unique in that they are usually carried out by specialized companies. Major wafer suppliers to

U.S. wafer-fabrication plants include MEMC Inc., Wacker Siltronic Corp., and several Japanese suppliers. It should be noted that there are currently no U.S.owned silicon wafer suppliers. MEMC and Wacker have plants in the United States but are owned by German interests. However, IBM, a captive U.S. company (wholly owned by U.S. interests), produces extremely large amounts of silicon wafers for its own inhouse use. U.S. consumption of merchant (usually imported) and captive (U.S. origin) silicon and merchant epitaxial (single crystal layer deposited) wafers has increased steadily for the period 1986-92. In 1992, the value of silicon wafers in the United States measured \$1,051 million, making silicon by far the greatest revenue earner in the semiconductor materials market. 112

The actual fabrication of the IC's in the United States is carried out by four or five large U.S. corporations and by corporations that are foreign-owned. The U.S.-owned companies are Motorola, National Semiconductor, and Intel Products Group. Foreign-owned companies in the United States include Philips Semiconductor, NEC Electronics, and Toshiba America. The fabrication of IC's requires large investments in plants and equipment plus a very astute marketing arm to ensure a good return on investment in this rapidly changing electronics market. 113 Intel announced that the plant necessary to fabricate its new "Pentium" chip in numbers large enough to satisfy estimated market demand will cost \$500 million.

Technology.—Processing.—The semiconductor industry is constantly evolving with new advancements in processing and fabrication technology, particularly with regard to integrated circuits. 114 The technical focus is on the materials used in the processing and fabrication. IC processing and fabrication involves seven basic steps, of which several are repeated throughout the manufacturing process. The sequential order of the processing steps is by no means fixed and may not be the actual order for all IC's manufactured. Figure

18 is a schematic flowchart for IC fabrication and includes end uses and types of waste anticipated is this hightechnology industry. The first step in the manufacturing process, crystal growth and wafer preparation, is not actually part of the fabrication of the IC itself. However, it is a necessary step and has a relatively high consumption of materials. Steps two through seven usually include wafer cleaning operations, photolithography, etching, doping, diffusional and/or depositional "additive" processes, and metallization. Several of these 7 steps will be discussed in general terms, as follows.

Before actual IC fabrication can begin, raw semiconducting materials must be converted into highly purified, polished wafers that must meet very stringent requirements before being used to manufacture IC's. 115 Silicon is by far the most commonly used material for the manufacture of IC's. Other semiconductor materials are gallium arsenide, gallium arsenide phosphide, and indium phosphide. These materials each have distinctive properties that separate them from silicon and make them particularly useful for specialty semiconductor devices; e.g., gallium arsenide in lightemitting diodes (LED'S), superfast computers, and realtime control circuits.

Silicon metal is extracted from ordinary sand, and this impure silicon is purified through chemical reactions to produce semiconductor-grade polycrystalline silicon. Conversion from polycrystalline silicon to single crystal silicon is usually performed using the Czochralski Method. This method involves heating the polycrystalline silicon and small amounts of a dopant to a liquid state. The dopants used usually are boron, phosphorus, arsenic, or antimony. A single crystal "seed" is placed just above the melt and selected crystal faces actually contact the liquid. As the seed is systematically raised from its initial position, heat is extracted by external means and the melt in the meniscus freezes, forming more single crystals on the seed. This method of crystal growth produces crystals that can be several feet in length and up to 12 inches in diameter. After the crystal boule is grown, it goes through a series of cutting, slicing, cleaning, and polishing procedures before the final wafers are ready for use in the fabrication of IC's. These wafers are then evaluated for surface defects and other impurities and are packaged in "clean rooms" to be shipped to various IC fabrication facilities.

IC's are designed to perform specific functions depending on what end-use products will receive the circuits. 116 The actual circuitry is designed as a series of sequential patterns that are stacked in horizontal layers and interconnected. The completed physical scheme contains all the electronic devices and electrical current pathways necessary to accomplish the IC's goals. To fabricate an IC, the individual patterns are singularly "transferred" to the wafer surface(s) at the appropriate fabrication stages through a process called photolithography. Photolithography is an extremely crucial step in IC fabrication because it determines where the devices will be positioned on the wafer and what dimensions these devices will have, two specifications that must be highly accurate for the effective operation of the IC. Coupled with the photolithography operations are wafer surface processes designed to modify selected wafer regions to achieve the IC's goals. For example, wafer surface modification processes could remove surface material to get to a sublayer; i.e., a selected region of insulating material removed to get to a metallic sublayer. Another process could remove surface silicon metal to allow deposition of a dopant, which, after thermal diffusion treatment, is a region known as an electronic junction. Further processing in this selected region could make it into a current control gate. A final example could be the selective removal of a wafer's prior deposited top insulating material layer to expose a small region of metallic sublayer. The exposed metallic sublayer, for this device, is the attachment region for a connecting wire leading to another device.

Physically, the photolithography

patterns allow light and dark contrasts, similar to light shining through a 35millimeter slide, to project the slide's contents onto a large viewing screen. However, the photolithic focusing lenses or devices miniaturize the pattern(s) to fit the wafer size. In practice, the entire wafer surface is coated with a photosensitive material. After exposure, the dark lines or dark areas on the pattern "mask" or prevent the photoresist coating on the wafer from being exposed to the radiation source. The photoresist material must have two attributes—the ability to change chemical composition in the regions exposed to the radiation and the ability of the nonradiated regions to resist being dissolved by chemicals specific to dissolving the irradiated regions. Through careful engineering of this entire process, the goals are achieved to obtaining designated regions of the wafer surface suitable for additional fabrication.

The photolithographic/wafer surface modification processes involve five basic steps: (1) applying liquid photoresist to the entire wafer surface; (2) processing the photoresist coating with radiation to produce chemically susceptible and chemically inert photoresist surface regions; (3) removing by chemical or physical (plasma) means the susceptible photoresist surface regions, thus exposing the underlying wafer surface; (4) etching or modifying these wafer surface regions to remove, deposit onto, or by diffusion change the wafer surface chemistry; and (5) stripping the remaining photoresist coating to allow the next sequential operation to commence. Step (4) is done to the wafer surface regions exposed by the removal of the chemically susceptible photoresist.

The IC is composed of a silicon wafer with thin layers of either conducting or insulating films created by deposition and dopant processes onto the wafer's surface. The initial stages of these processes, which lay down deposition and/or dopant materials, usually occur at or near room temperature. Later thermal treatments stages (diffusional treatments) at high temperatures are necessary to diffuse "dopants" into the surface film or

chemically bond one thin film to another or to the actual silicon wafer surface. All of these processes normally are repeated often in IC fabrication. The most common deposition materials are epitaxial silicon, polycrystalline silicon, silicon dioxide, and silicon nitride. materials are deposited by an "additive" process such as chemical vapor deposition (CVD). CVD is defined as the formation of a nonvolatile solid film on a substrate by the reaction of vapor-phase chemicals (reactant gases) that contain the required constituents. These reactant gases are introduced into a chamber where they decompose and react on the heated substrate(s) surface to form the new thin film. There are other "additive" processes currently being used for the deposition of materials. However, CVD is the most common process because of the following advantages: (1) high-purity deposits can be achieved, (2) a large variety of chemical compositions can be deposited, (3) some films cannot be deposited with adequate film properties by any other method, and (4) good economy and process control are possible for many films. Thermal energy is used to enhance appropriate reactions by heating either the chamber or the wafer or both.

Almost all of the silicon wafers used today for the fabrication of IC's contain a layer of CVD-deposited epitaxial silicon. It is in this layer of the IC that the semiconductor part of the device is actually formed by using the appropriate dopants. The preferred gas for CVD deposition of epitaxial silicon is silicon tetrachloride. However, other gases also are used, including silane, dichlorosilane, and trichlorosilane. Select epitaxial silicon layers are heavily doped to make regions that are good conductors of electricity by moving either electrons or their electrical analog-holes. Which type of dopant(s) employed results in increased current flow in these regions and are designated "n-type" "p-type" conductors. The positioning of these "n" and "p" regions and their junctions allow for the controlled movement of current through electrical "gates" that allow "go or not go" and "or and nor" situations.

The "go" gate stops and starts current flow along a single pathway while the "nor" gate selects one of two pathways for current flow. The multiplexing of these two gate types allows today's complex computers to be built because they are the electrical equivalent of binary logic, when combined with Boolean algebra (the complex interactions possible with binary logic), allow today's computers not only to exist but to continue to evolve. The only IC limitations appear to be the number of gates capable of being formed in an everdecreasing space that makes up the central processing unit of a computer.

The gates themselves are made up of gate insulating silicon oxide and current carrying polycrystalline silicon, both individually CVD deposited. These polycrystalline silicon layers replace other metals in many IC technologies because these layers have the additional advantage of being chemically compatible with epitaxial silicon. Silicon dioxide, an insulator, is deposited by either CVD, as are most other materials, or by thermal oxidation of the silicon substrate. CVDdeposited silicon dioxide films are most widely known for their use as insulators around the various gates and as a final passivation layer covering the completed wafer to protect it from the natural environment. However, oxide films also are used as insulation between polysilicon and metallization layers, between multimetallization layers, as doping barriers, as diffusion regions, and as isolation regions.

A second insulating material, silicon nitride, also is deposited by CVD and is considered to be superior to CVD-deposited silicon dioxide because it is harder, is a better moisture and sodium barrier, has a higher dielectric strength, and resists oxidation. Uses for these films include passivation layers, masks for selective oxidation of silicon, and intermetal dielectrics. Silane plus ammonia, silane plus nitrogen, and dichlorosilane are the gases most frequently used for the deposition of silicon nitride.

Metals are generally deposited onto the wafer surface by either CVD or physical

vapor deposition (PVD). PVD, or sputtering, is a procedure conducted in a vacuum chamber with the appropriate electrical potentials and connections. The deposition rate of the PVD process is not directly dependent on the temperature of the wafer substrate. In most situations, the film receiving substrate is or can be at room temperature. In the sputtering chamber, the material to be deposited is called the target and is deliberately biased—electrically negative. The target material, a one piece solid, is placed in the vacuum chamber above the silicon wafer. Then, an inert gas, usually argon, is fed into the chamber through selected openings and ionized. Because the gas ions are positively charged, they gain momentum as they are electrically accelerated toward the negatively biased target. These gas ions strike the target material and cause the atoms from the target to scatter and eventually come to rest on the wafer surface. The metallic atoms freed from the target material by the ionized gas stream are deposited on the silicon wafer and form a physical bond with the wafer surface. The high vacuum in the chamber plus prior cleaning of the wafer surface allow the target atoms to atomically bond to the wafer surface and eventually form the desired thin film. PVD has become the most widely used method of metal deposition for most materials. Metals deposited include aluminum, aluminum alloys, gold, and platinum. Before the development of advanced integrated circuits, pure aluminum and aluminum alloys were the metals of choice for the interconnection of semiconductor devices. They are still widely used today in semiconductor device fabrication. However, advanced IC's require materials with extremely low resistivities and low contact resistances, two attributes of refractory metals and their silicides. Refractory metals include molybdenum. tantalum, titanium, and tungsten. These materials and their silicides can be deposited either by sputtering (PVD) or by CVD.

For metallic deposition, CVD, a process described earlier in this report, offers a less-expensive, less equipment-

intensive alternative to PVD and is the preferred method for deposition of refractory metals and/or their silicides (both used for electrical interconnections). Tungsten is the most frequently deposited refractory metal. CVD of tungsten is accomplished by using tungsten hexafluoride gas to produce tungsten silicide on the wafer surface. Titanium tetrachloride is the common source liquid used to form titanium silicide from titanium.

Etching of metals is accomplished by the same two methods as nonmetallic material etching: wet etching and dry etching. Aluminum and aluminum alloys are generally wet etched in heated solutions of phosphoric acid, nitric acid, acetic acid, and water, with phosphoric acid making up 80% of the solution. However, problems exist with this procedure because of the formation of tiny hydrogen bubbles that form on the wafer surface and inhibit etching. Therefore, dry etching is the preferred method of etching for aluminum and aluminum alloys. Refractory metals and their silicides are etched using dry methods involving both chlorine- and fluorine-containing gases. Etching of these materials is difficult but accomplished with the use of mixtures of

The use of metals is crucial to the processing of IC's because the metallic attachments interconnect the many lavered structures within an individual device and intraconnect the many individual devices built onto the "wafer surface." In addition, selective metallic areas of the finished wafer must provide regions to which external connecting leads can be attached. Often, there are several different layers of metal incorporated onto one wafer just as there are many layers of nonmetallic materials. The concepts of deposition and etching discussed earlier for nonmetallic materials also can be applied to metals.

These variously described processes are repeatedly carried out until the originally designed IC is completed. It is important to note that the majority of advanced integrated devices manufactured today are highly sophisticated devices.

Many of them consist of multiple oxidation and metallization layers and several p-n junctions for the IC to perform very complicated operations. However, the materials and techniques used to fabricate these more advanced devices are the same as those outlined for this report. Note that millions of such devices comprise an advanced IC and that hundreds to thousands of IC's are contained on a single silicon wafer.

Environmental Issues.—Until the early 1980's, the semiconductor industry was believed to be a "clean industry" compared to the older "smokestack industries," which were noted for environmental degradation. However, the discovery of contaminated ground water at several wafer fabrication facilities in California in 1981 revealed that semiconductor manufacturing at that time was not environmentally safe. Today, after many years of State and Federal regulatory laws and suits against the industry, 117 the semiconductor industry is approaching a "clean industry" not only in the manufacturing of semiconductors devices but in maintaining environmental goals. The industry uses large quantities of solvents, gases, acids and bases, and metals. The improper technical handling of some of these materials prior to, during, and after their use in device manufacturing poses concerns about possible environmental pollution. All of the above materials occur in nature, but it is their concentration by industry for manufacturing purposes that causes possible hazards to the environment. Today, the proper handling of these materials has become more widely known industry through governmental regulations, internal industry awareness, and the alertness of citizen The possible environmentalists. environmental implications of these four categories of materials are outlined with emphasis on proper utilization of these materials and/or eventual replacement of these materials with less harmful materials.

The first category of possible pollutants from the manufacture of semiconductor devices is solvents.

Solvents are widely used in the semiconductor industry because of their ability to dissolve other materials. Perhaps, the most publicly "visible" class of solvents is chlorofluorocarbons (CFC's). In the mid-1980's, CFC's, or freon, were identified as substances that deplete the ozone shield in the upper atmosphere, which protects the earth from excessive amounts of ultraviolet light. The major use for CFC's in the electronics industry is for defluxing printed circuit boards; however, they also are used as cleaners. photoresist strippers, and etchers in the fabrication of integrated circuits. In the mid-1970's, the use of CFC's was thought to be extremely safe as they emerged as good substitutes for trichloroethylene (TCE) and 1.1.1-trichloroethane (TCA), both of which are very hazardous solvents (still used today, but in diminishing quantities). In 1985, when a hole in the ozone layer was discovered over Antarctica, scientific experts began to take a serious look at CFC use. At that time, the electronics industry consumed 20% of all CFC's used. Since then, the 1987 Montreal Protocol, calling for the reduction of worldwide CFC use, was amended in June 1990 and again in November 1992 to accelerate the phaseout of CFC's. U.S. manufacturers must now cease production of CFC's by the end of 1995. On May 15, 1993, a new law went into effect, mandating that all products manufactured using ozone-depleting chemicals (mainly CFC's and TCA) be labeled: "Warning: Manufactured with (name of substance), a substance which harms public health and the environment by depleting ozone in the upper atmosphere. *118

For several years, researchers have been trying to find less environmentally harmful substitutes for TCE, TCA, and CFC's. 119 HCFC's (hydrochlorofluorocarbons) have been found to be less damaging to the ozone layer but also may be banned early in the next century. For wafer cleaning processes, companies are experimenting with just using surfactants (soap) and water and are having some success. Lockheed Missiles and Space Co. is experimenting with blasts of frozen

carbon dioxide pellets (dry ice) to clean wafer surfaces. Plasma-cleaning processes may prove to be the best alternatives to the use of toxic chemicals but are not effective enough for commercial use as of now.

Another group of solvents that are extremely environmentally hazardous are ethylene-based glycol ethers. These materials have been used since the 1970's to thin photoresist in the manufacture of IC's. Ongoing government research citing the possible hazards to humans and other mammals from these glycol ethers have prompted several "user" companies to begin using alternative materials. Three viable substitutes have been found to date: propylene glycol monomethyl ether acetate, ethyl-3-ethoxypropionate, and ethyl lactate.

The second category of potential pollutants includes some of the gases used in the U.S. semiconductor industry.¹²⁰ These gases range from highly toxic (arsine, phosphine, diborane, and silane) to relatively harmless (hydrogen, nitrogen, oxygen, and argon). Arsine, phosphine, and diborane are used as dopants in silicon wafer processing. Arsine is the most toxic gas used in the manufacture of semiconductor devices. Exposure to extremely small amounts may be fatal. Phosphine is pyrophoric and flammable, besides being toxic. Diborane is an extremely reactive gas and immediately damages the respiratory tract. Silane, used in the process of CVD, also is highly toxic and ignites spontaneously when in contact with air. These gases, if released into the air in very high concentrations, can be extremely harmful to the environment because they are deoxidizers to living things. Finding replacements for these highly toxic gases is a continuing quest today. For example, American Cvanamid Co. introduced two low-vapor substitutes for arsine and phosphine: tertiarybutylarsine (TBA) and tertiarybutylphosphine (TBP). It is known that these liquid replacements are much less hazardous than their gaseous counterparts but cost 15 times more than the cost of the gases. Also, Lam Research in Fremont, CA, has replaced

diborane with a less toxic substitute, alcohol triethylborate (TEB).

Acids and bases comprise the third category of potential pollutants. Acids and bases are widely used in the U.S. semiconductor industry for cleaning. etching, and photoresist stripping. Acids commonly used include hydrochloric acid, sulfuric acid, nitric acid, and hydrofluoric acid. Bases commonly used sodium hydroxide, potassium hydroxide, and ammonia and ammonium compounds. Acids, in extremely high concentrations, are particularly dangerous to the environment and are designated as hazardous materials under RCRA. Of the acids currently used in the semiconductor industry, the largest contributor to the hazardous wastestream is hydrofluoric acid. Other acids usually are found in wastestreams in dilute form, but still pose a possible threat to the environment.

The fourth and final category for potential pollutants resides in the use of metals.¹²¹ Several harmful metals are used in the semiconductor industry. including antimony, arsenic, beryllium, cadmium, and lead. Many of these are used in the actual fabrication of an IC: for example, arsenic trioxide is used as a solid dopant source and is extremely dangerous. When IC's are cleaned at various stages of the fabrication process. dissolved metals become part of the discarded solution. If this wastewater is discharged into the sewer system, the metals can be highly toxic to fish, birds, marine mammals, and humans. Today, many companies already have instituted systems to guard against contamination of ground water by toxic metals.

Annual quantities of emissions of some of the most harmful chemicals currently used in the U.S. semiconductor industry have been reported by the EPA, 122 beginning in 1987, the first year in which companies were required to publicly disclose chemical releases to environment in the EPA's Toxic Release Inventory (TRI). The EPA has vigorously enforced compliance by conducting more than 2,300 site visits, filing approximately 550 complaints, and levying fines of more than \$16 million since 1989. This data represent quantities of emissions released directly to the environment or through offsite transfers.

The term environmental release refers to discharges onsite to the air, water, underground injection, or land. emissions are by far the largest contributors to total releases in the U.S. semiconductor industry. However, levels of air emissions have decreased 29% from 1987 to 1990. 123 Surface water discharges from the semiconductor industry have shown the sharpest decrease for the period 1987-90, from 2,140,733 kilograms in 1987 to 94,241 kilograms in Underground injection is a 1990. disposal method by which chemical wastes are injected into deep underground wells. Underground injection releases were minimal for the U.S. semiconductor industry from 1987-90. On-site land releases refer to releases to the land on the premises of the reporting facility and fall into one of four categories: landfills, land treatment/application farming, surface impoundments, and other land disposal. For the period 1987-90, land releases have remained relatively constant. measuring approximately 400,000 kilograms. Offsite transfers include releases sent offsite for treatment, storage, or disposal and fall into two categories: publicly owned treatment works (POTW's) and other offsite transfers. POTW's are owned by a State or municipality and include any devices used in the storage, treatment, recycling, and reclamation of domestic sewage or a combination of domestic sewage and industrial wastewaters. Other offsite transfers include transfers to incinerators, underground wells, landfills, and other sites not on the premises of the reporting facility. 124

Annual Review

U.S. semiconductor device revenues totaled approximately \$23 billion for 1990 and \$27 billion for 1992. This 8% annual increase in revenues has been sustained since 1986 but the revenue share of IC's is increasing. (See table 19.) For instance, IC's represent the majority of semiconductor device revenues and, in 1992, accounted for

approximately 70% of total factory shipments, up from 45% in 1989. In fact, the Metal Oxide Semiconductor (MOS) IC segment is the fastest growing of the semiconductor devices and alone accounted for 39% of total device revenues in 1992. This reflects the rapid change in the PC market in the past 3 The price of a PC has been reduced twofold while the computing power of a PC has increased four times. The result has been a doubling in the number of PC's sold, therefore, the number of MOS IC's sold. Total factory shipments of semiconductor devices have increased by approximately 53% from 1981 to 1991 and are projected to continue to increase through 1994. 126 (See figure 17.)

Outlook

The continued increase in total IC revenues of approximately 8% per year over the past several years is different from the almost level revenues exhibited most advanced material technology industries. In general, a slight downturn for 1991 and 1992 is attributed to the general economic conditions rather than a real softening or leveling of demand for these industries. But, the annual revenue increases for all IC's are caused mostly by the MOS IC's revenue increases, driven by the fierce market competition in the personal computer industry over the past 2 to 3 years. The result is greatly increasing numbers of PC's being sold, each with a MOS IC as its computer processing unit. Manufacturers. Issues in Sci. and Tech., Spring 1992.

Region	Quantity (thousand metric tons)	Value (million dollars)	Quantity (thousand metric tons)	Value (million dollars)						
Pacific Rim	355.9	8,768	353.0	7,926	2.7	817	0.2	12	(1)	14
North America	152.1	5,994	144.0	3,608	7.5	2,236	.2	29	0.2	121
Western Europe	93.9	3,137	90.0	1,839	3.4	1,247	.1	15	.1	36
Worldwide ²	601.9	17,900	583.0	13,373	13.7	4,300	.6	56	.2	171

Note A.—Value per kilogram (value per pound) per region (all advanced materials).

Pacific Rim = \$24.60 per kilogram (\$11.18 per pound).

North America = \$39.31 per kilogram (\$17.87 per pound).

Western Europe = \$33.33 per kilogram (\$15.15 per pound).

Total Worldwide = \$29.68 per kilogram (\$13.49 per pound).

Note B.—Value per kilogram (value per pound) per technical category.

Worldwide advanced materials = \$29.68 per kilogram (\$13.49 per pound).

Advanced ceramics = \$22.88 per kilogram (\$10.40 per pound).

Advanced polymer composites = \$313.24 per kilogram (\$142.38 per pound).

Metal matrix composites = \$100.76 per kilogram (\$45.80 per pound).

Carbon-carbon composites = \$746.44 per kilogram (\$339.29 per pound).

¹Less than 50 metric tons.

²Data may not add to totals shown because of independent rounding.

ALUMINUM, BAUXITE, AND ALUMINA

By Patricia A. Plunkert and Errol D. Sehnke

Ms. Plunkert, a physical scientist with 24 years U.S. Bureau of Mines experience, has been the commodity specialist for aluminum since 1987. Domestic survey data for aluminum were prepared by Shonta E. Osborne, statistical team leader; and international data tables were prepared by Audrey D. Wilkes, international data coordinator.

Mr. Sehnke is a physical scientist with 19 years of minerals industry and U.S. Bureau of Mines experience. Domestic survey data for bauxite and alumina were prepared by David W. Chilton, statistical assistant; and international data tables were prepared by Harold D. Willis, international data coordinator.

Aluminum is the second most abundant metal element in the Earth's crust after silicon, yet it is a comparatively new industrial metal that has been produced in commercial quantities for slightly more than 100 years. It weighs about one-third as much as steel or copper; is malleable, ductile, and easily machined and cast; and has excellent corrosion resistance and durability. Measured either in quantity or value, aluminum's use exceeds that of any other metal except iron, and it is important in virtually all segments of the world economy.

World demand for aluminum remained at depressed levels throughout 1992. The increase in aluminum activity evident in the United States did not occur in most of the other areas of the world. Despite some small decreases in the production of primary metal, world inventory levels continued to rise. The United States continued to be the world leader in primary metal production, producing more than 4 million metric tons of metal with an estimated value of \$5.1 billion.

World production of bauxite and alumina, feedstocks for the aluminum industry, decreased by modest amounts in response to the faltering world economy, stagnation in primary aluminum metal output, and a continued flow of aluminum exports from the newly independent republics of the former U.S.S.R. Mine production of bauxite was reported from 28 countries, and alumina was produced in 29 countries.

DOMESTIC DATA COVERAGE

Domestic production and consumption data for aluminum, bauxite, and alumina are developed by the U.S. Bureau of Mines (USBM) from five separate, voluntary surveys of U.S. operations. Typical of these monthly, quarterly, and annual surveys is the "Aluminum" survey. Of the 13 companies canvassed by this form, all responded, representing 100% of the total domestic primary aluminum production.

BACKGROUND

Definitions, Grades, and Specifications

Bauxite is a naturally occurring, heterogeneous material composed primarily of one or more aluminum hydroxide minerals and various mixtures of aluminosilicate (clay, etc.), iron oxide, silica, titania, and other impurities in minor or trace amounts.1 The principal aluminum hydroxide minerals found in varying proportions within bauxites are: gibbsite, Al(OH)3, the trihydrate; and the monohydrate polymorphs boehmite and **Domestic** diaspore, both AlOOH. bauxites and those imported from Brazil and Guyana are of the trihydrate gibbsitic type. Imports from the Sangaredi deposit of Guinea and the north coast of Jamaica are predominantly gibbistic, but they also contain 4% to 10% of the monohydrate mineral, boehmite. In most European and northern Asian bauxite deposits, boehmite is the principal alumina mineral. Recovery of the aluminum oxide in boehmite requires a higher temperature and higher caustic concentration than is called for in processing gibbsite.

Free moisture in crude bauxite, as mined, may range from 5% to 30%. To produce dried bauxite, most of the free moisture is removed by heating crude bauxite in rotary drying kilns at about 315° C. Calcined bauxite is produced by heating bauxite to 925° to 1,040° C to reduce total volatile matter, including chemically combined water, to less than 1%. Approximately 2 tons of crude ore is required to produce 1 ton of calcined bauxite.

Aluminum metal has a relatively low density, high electrical and thermal conductivity, good resistance to corrosion, and good malleability. It is nonmagnetic, nonsparking, and highly reflective. It may be alloyed and treated to yield a high strength-to-weight ratio.

Ingot is a cast form of primary or secondary metal that is convenient to handle and store and is suitable for fabricating or remelting. Commercial-size ingots normally weigh about 13.5 kilograms (30 pounds); however, some ingots weigh up to 9 tons. A portion of both primary and secondary metal is sold and transported in molten form.

Commercially pure aluminum usually contains about 99.7% aluminum. In the annealed condition, it has low strength and is relatively soft. However, it is available in strain-hardened conditions of higher strength and reduced ductility. Metal with more than 99.7% and up to 99.85% aluminum is available at higher cost than standard commercial metal.

Superpurity aluminum contains minimum of 99.99% aluminum.

Aluminum alloys have been developed that, after cold rolling, heat treating, annealing, or age hardening, have strengths approaching those of mild steels. More than 100 commercial alloys are available, and several new alloys are developed each year. The alloys offer a wide variety of combinations of mechanical strength, ductility, electrical conductivity, and corrosion resistance.

Aluminum alloys are generally divided into two major groups: wrought and casting. The Aluminum Association Inc. uses a code to designate the purity and alloy content of wrought alloys and to register the composition of casting alloys and ingot.

New aluminum-base scrap, generated in the production of intermediate and end products of aluminum metal, may be pure (unalloyed), segregated (one alloy type), or mixed (two or more alloys). It includes solids, such as new casting scrap; clippings or cuttings of new sheet, rod, wire, and cable; borings and turnings from the machining of aluminum parts; and residues, drosses, skimmings, spillings, and sweepings.

New scrap is further defined as either "runaround" (home) scrap or purchased scrap. Runaround or home scrap is new scrap that is recycled by the same company that generates it; such scrap by definition never leaves the company generating it and, therefore, is never marketed as scrap. Purchased scrap is new scrap that is purchased, imported, or treated on toll by secondary smelters, the original aluminum product suppliers, or others. New aluminum scrap that is purchased from manufacturers of end products may be referred to as consumer scrap. Purchased new scrap is sometimes referred to as prompt industrial scrap.

Old scrap, all of which is considered as purchased, comes from discarded, used, and worn out products. It includes aluminum pistons or other aluminum engine or body parts from junked cars, aluminum used beverage cans (UBC) and utensils, and old wire and cable. Sweated pig is scrap that has been sweated or melted into a pig or ingot form for

convenience and economy in shipping and storage. Obsolete scrap is new, unused, but technologically obsolete aluminum end products, outdated inventory materials, production overruns, and spare parts for machines and equipment no longer being used. In the United States, both sweated pig and obsolete scrap are considered old scrap.

Industry Structure

The aluminum industry is truly a worldwide industry. It is impossible to discuss the domestic industry without relating it to the total world aluminum industry. To more fully understand the global market in which the U.S. industry is competing, it is necessary to discuss the U.S. position in each of the individual components of aluminum supply—bauxite, alumina, and aluminum metal.

World bauxite resources (reserves plus subeconomic and undiscovered deposits) are currently estimated to be 55 to 75 billion tons. These resources are mainly in South America (33%), Africa (27%), Asia (17%), and Oceania (13%). Mine production during the past 30 years has moved from North America and Europe to these bauxite-endowed regions of the world. U.S. mine production has decreased from about 2 million tons in 1960 to only 588,000 tons in 1988, the last year for which releasable data were available from the USBM.

Presently. there are only three companies conducting bauxite mining operations in the United States. Their mines are in Alabama and Georgia, and they do not produce bauxite for metal production. The bauxite produced by these operations traditionally has been used for refractory, chemical, and other specialized applications. The United States is entirely dependent on foreign sources for metallurgical-grade bauxite. What aluminum metal resources the United States does have are low-grade bauxite substitute materials, which are not currently economic to exploit. To utilize these domestic alternative sources of alumina, an entirely new processing industry would have to be designed and developed. The United States currently

receives most of its metallurgical-grade bauxite from Australia, Guinea, and Jamaica.

Bauxite imports are shipped to five domestic alumina plants, which produce smelter-grade alumina for the primary metal industry. These alumina refineries are in Louisiana, Texas, and the U.S. Virgin Islands. Even if these five refineries operated at full capacity levels and sold their product exclusively to the domestic metal smelters, the U.S. supply of alumina would be inadequate to meet the demand of the country's primary metal industry. Therefore, the United States must use imported alumina to supplement its domestic requirements, and Australia has become the principal source of these imports. A developing trend in world alumina production patterns has been the construction of alumina plants near areas of bauxite mining. More and more nations with bauxite reserves are realizing the economic advantages of processing the bauxite ore closer to the mine site and exporting the higher valued alumina product. In addition to providing a value added product for the material-producing country, this practice also reduces the bulk transportation requirements of the aluminum industry.

In the 1960's, the United States accounted for more than 50% of the world's production of alumina. By the mid-1970's, Australia had surpassed the United States as the world's predominant alumina producer. In addition to this change in the world alumina production picture, several countries, which either did not have an alumina industry or were very minor producers in the 1950's and 1960's, have taken on a much stronger role. Some of these countries with an expanding or newly developed alumina industry are Brazil, Greece, India, Ireland, Spain, Suriname, and Venezuela.

Although the United States continues to be the leading producer of primary aluminum metal in the world, its dominance in the industry has begun to wane. As late as the mid-1960's, the United States accounted for about 40% of the world's production. However, by 1992, the U.S. share of world production

had decreased to 21%. Most of the restructuring of the world aluminum industry began in the late 1970's and continues to this day. Australia and Canada have emerged as major metal producers. Japan, which had produced more than 1 million tons of aluminum as late as 1980, today produces only about 20,000 tons of primary metal. Other countries that have recently entered the world market are Brazil, China, Norway, Venezuela, and several countries in the Persian Gulf region.

The driving force for most of these changes was the cost of energy. In the early 1980's, the price of aluminum ingot decreased, an oversupply situation existed, and energy costs increased. These factors put pressure on aluminum companies to close their plants with high operating costs and low energy efficiencies. This was especially evident in the United States and Japan. Recent smelter expansions and new plant construction have been focused on areas of the world with access to low-cost energy and labor. Brazil, Canada, and Venezuela, for example, have access to hydroelectric power sources. Countries in the Persian Gulf are planning to use their abundant natural gas reserves to generate the electricity required for their announced new smelters.

Unlike past practice, when most of the cost for new aluminum plant construction was taken on by a single company, today's new plant construction costs typically are borne by a number of different aluminum companies in joint ventures. Even though the number of different companies producing aluminum has been increasing, there are seven major companies that still control more than 40% of the total Western World primary aluminum production capacity. The leading company is the Aluminum Co. of America (Alcoa), followed by Alcan Aluminium Ltd., Reynolds Metals Co., Alumax Inc., Pechiney, Kaiser Aluminum & Chemical Corp., and Alusuisse-Lonza Holding AG. Most of these companies can be described as fully integrated, having interests in all aspects of the aluminum industry from bauxite mining through semifabricated materials and, in some cases, even end product facilities.

Beginning in 1991, additional pressure was put on an aluminum market already straining under an oversupply situation caused by a slowdown in world economic activity. The pressure came in the form of aluminum metal exports from the republics of the former U.S.S.R. Before the breakup of the U.S.S.R., very little Russian metal appeared in Western World markets. Most of this metal was traded inside the block of centrally planned economy countries. However, with the emergence of newly independent countries, many of the old trading blocks were dissolved, and the search was on for new trading partners.

The dissolution of the U.S.S.R. also has placed strains on economic activity inside these independent republics to the extent that aluminum metal exports were being used as a form of currency to barter for other goods and services. As a result, exports of metal from the former U.S.S.R. averaged about 1 million tons per year in 1991 and 1992. In a market already being hit by a slowdown in economic activity, exports to Western World markets of this magnitude have caused inventory levels to rise and prices to fall. It will take time for the world markets to adjust to this new and potentially major player in the market world economy.

Some of the most dramatic changes in the domestic aluminum industry occurred in the past 12 years. In 1980, there were 11 companies operating 33 smelters with a total annual domestic production capacity of 5 million tons of metal. By 1992, the number of operating companies had increased to 13, but the number of smelters had decreased to 23 with a total annual capacity of about 4 million tons. Low aluminum prices and high operating costs forced domestic aluminum companies to close some of their higher cost operations. Even though 10 smelters were forced to close, the number could have been even greater were it not for some newly formed companies that purchased some of the marginal plants and negotiated new contracts with labor unions and electric utilities that helped to reduce their overall operating costs.

Another new phenomenon that appeared in the domestic industry was the appearance of tolling operations, in which an aluminum plant charges an outside company a fee for converting alumina to metal. In the mid-1980's, some power companies negotiated supply contracts that tied electricity rates to the price of aluminum ingot. The Bonneville Power Administration, which provides power to 10 smelters in the Pacific Northwest. operates under such an arrangement. This pricing method provided domestic aluminum companies with a measure of relief by ensuring lower power costs during times of depressed prices. Major labor unions also provided concessions by negotiating lower hourly wage increases in exchange for a share in company profits.

Another factor that should be considered in analyzing the domestic aluminum industry is the growing importance of secondary aluminum to the domestic supply situation. Secondary aluminum is defined as aluminum recovered from both new and old purchased scrap. In 1960, almost 400,000 tons of aluminum was recovered from new and old scrap. In 1992, almost 2.8 million tons of aluminum was recovered from scrap. More than 1.6 million tons of this secondary aluminum was recovered from post consumer, or old, scrap.

Growing concerns over waste disposal have placed increased emphasis on the recycling of materials. Both in the United States and abroad, aluminum companies are promoting the fact that aluminum has a mature recycling industry. Not only does recycling of aluminum help to conserve landfill space, it also helps to save energy. It has been estimated that the recycling of aluminum consumes only about 5% of the energy required to produce aluminum metal from bauxite ore.

The United States remains the largest consumer of aluminum in the world. The container and packaging industry accounts for about 30% of domestic aluminum consumption. This industry is followed by the transportation, construction, and

electrical industries. The U.S. demand profile, however, does not reflect the demand pattern found in other parts of the world. World demand patterns, in general, show a much larger percentage of aluminum consumed by the construction and transportation industries and less by the packaging industry.

ANNUAL REVIEW— ALUMINUM

Domestic primary aluminum production decreased in 1992 for the first time since 1986. Despite this slight decrease, the United States remained the world's largest producer of primary aluminum metal. The average annual metal price decreased, continuing a trend that began in 1989, and reached its lowest level since 1986. Despite continuation of depressed metal prices, domestic smelters, with the exception of the Troutdale, OR, smelter that was closed at the end of 1991, continued to operate at or near their rated capacity levels during most of the year.

The domestic secondary aluminum industry recovered more than 2.7 million tons of metal from purchased new and old scrap. Aluminum recovered from discarded aluminum products (old scrap) accounted for about 60% of this total. UBC scrap continued to be the major component of processed old scrap. The aluminum industry reported that the recycling rate for all-aluminum beverage cans reached a record high of 67.9%. Almost 30% of the apparent demand for aluminum was met by metal recovered from old scrap.

The domestic consumption of aluminum increased in 1992, reflecting an increase in economic activity that was not evident in other areas of the world. With the overall weakness of economic activity in the rest of the world, U.S. exports decreased for the first time since 1986. U.S. imports, however, rebounded and reached their highest level in 5 years. (See table 1.)

Legislation and Government Programs

In 1990, the Defense Logistics Agency

(DLA) awarded a contract to Alcoa for the upgrade of bauxite to aluminum metal ingots for the National Defense Stockpile (NDS). Delivery of the metal was completed, and the metal began to appear in the published NDS stockpile listings in March 1992. The total quantity of metal delivered under this contract was 55,121 tons, all of which appeared in the NDS inventory publication by June. As of December 31, the NDS stockpile inventory was 57,010 tons of aluminum metal.

Production

Primary.—Domestic primary aluminum production decreased slightly compared with 1991 production levels. At the end of 1992, 1 smelter remained temporarily closed, and the other 22 primary metal smelters were operating at or near full capacity levels.

Ravenswood Aluminum Corp. announced plans to return its 168,000-ton-per-year primary aluminum smelter in Ravenswood, WV, to full capacity production levels at the end of September. The company reported that it would restart the remaining one-half of the smelter's fourth potline that had been out of service since an electrical storm damaged it 11 years ago.

In June, the United Steel Workers of America (USWA) and Ravenswood Aluminum announced that a new 3-year labor contract had been signed, ending a 19-month labor dispute at the primary aluminum complex in Ravenswood, WV. Workers were scheduled to report back to work on June 29. The new contract reportedly included a \$2,000 payment for each worker affected by the labor dispute and a \$1.25-per-hour wage increase spread over the life of the contract.

In November, the USWA also ratified a new labor contract that covered workers at Ormet Corp.'s Hannibal, OH, primary aluminum smelter. The new agreement, which replaced the old contract set to expire on May 31, 1993, covered the period through May 31, 1996. The new contract reportedly included wage increases of 25 cents per hour in 1993, 20 cents per hour in 1994, and 15 cents

per hour in 1995. Officials also announced that employees would receive a signing bonus of \$750 on or before December 15, 1992, plus additional unspecified bonuses in 1993 and 1994. The company also announced that the existing profit-sharing program would remain in effect and a new achievement bonus plan had been introduced, under which quarterly bonuses of up to 50 cents per hour worked reportedly would be paid when specified levels of improvement were reached.

Alcan Aluminum Corp. and the Aluminum, Brick, and Glass Workers International Union (ABGWIU) announced the ratification of a new 3-year labor contract covering workers at the 180,000-ton-per-year primary aluminum smelter in Sebree, KY. The new contract reportedly included a \$1,500 signing bonus and an additional \$500 bonus payable in 1993. Also, the agreement reportedly did not include a pay increase in the first year, but did include hourly increases of 25 cents and 40 cents. respectively, in the succeeding 2 years. The new contract was set to expire on October 28, 1995.

Alcoa and Reynolds announced that an agreement had been reached with the USWA and the ABGWIU to extend for 1 vear the labor contract that was set to expire on May 31, 1992. Included in the extension agreement was a \$1,000 cash signing bonus. some pension improvements, and the offer of another \$500 bonus if a new labor agreement was reached by October 2. However, by vearend, negotiations had failed to bring about a new long-term labor contract, and this 1-year extension was set to expire on May 31, 1993.

The Bonneville Power Administration (BPA) reported that it had reduced by 25% the energy that it normally supplied to its Direct Service Industries (DSI's) on August 21. The restrictions remained in place through the rest of the year. DSI's are large electricity users that include 8 aluminum companies operating 10 smelters in the Pacific Northwest. BPA reported that the cutbacks were necessary owing to the continuation of severe drought conditions, which has lowered

water runoffs in the tributaries of the Columbia River that supply BPA's hydroelectric dams. Adding to the power supply problem was the shutdown of the Washington Nuclear Plant #2 for repairs. Despite the 25% reduction in BPAsupplied power, the affected aluminum smelters, with the exception of Reynolds' Troutdale, OR, smelter, which had been closed at the end of 1991, continued at or near their rated capacity through the end of 1992. This occurred because the DSI's, with BPA acting as agent, were able to secure replacement power, albeit at a higher cost than BPA-supplied electricity.

Logan Aluminum Inc., jointly owned by Atlantic Richfield Co. and Alcan Aluminum, announced the awarding of a \$23 million contract to Fluor Daniel Inc. for the expansion of its rolling mill in Russelville, KY. The contract was for engineering, procurement, and construction services for a third melting and casting area in the plant. Fluor Daniel designed and built the original mill in the early 1980's. Since then, Fluor performed Daniel had ongoing maintenance at the facility and reportedly was continuing to work on an expansion project involving the rolling mill and finishing equipment, which was awarded in 1991 and scheduled for completion in late 1993.

Reynolds announced plans to build an aluminum fabricating plant in Auburn, IN. The company indicated that the plant should start production in late 1993 and would produce aluminum extruded products for the automotive industry, such as bumper systems, door extrusion beams, and sunroof tracks. The facility, which would include a 3,000-ton extrusion press, reportedly would have a capacity of 6,350 tons (14 million pounds) per year of extruded products.

Reynolds also reported that it was exiting the North American aluminum conductor cable business with the sale of its cable plants to BICC Cable Corp. The facilities, which were purchased in September, reportedly represented about 100,000 tons of annual capacity and were in Malvern, AR; Marshall, TX; Longview, WA; and La Malbaie,

Quebec. In October, BICC announced plans to close the Longview, WA, plant by the first quarter of 1993.

Jupiter Aluminum Corp. announced that it had acquired Advanced Aluminum Products Inc. The Hammond, IN, rolling mill had moved under the protection of U.S. bankruptcy laws in August 1991. (See table 2.)

Secondary.—In 1992, the number of companies covered by the USBM aluminum scrap survey increased. This was partially responsible for the large increase in recovered secondary aluminum compared with that of the previous year. Also, the secondary data for 1991 were revised downward, owing to a double-counting error that did not become evident until this year.

According to a survey conducted by the Aluminum Association Inc., the Institute of Scrap Recycling Industries, and the Can Manufacturers Institute, the recycling rate for all-aluminum beverage cans reached a record high; 62.74 billion aluminum UBC's were recycled in 1992. The recycling rate was 67.9%, up from the 1991 rate of 62.4%.

The three largest domestic automakers, Chrysler Corp., Ford Motor Co., and General Motors Corp., announced the formation of the Vehicle Recycling Partnership (VRP) to research and promote the recovery and reuse of materials from junked cars. According to the companies, the partnership was expected to propose methods for increasing the amount of recycled materials used in autos and trucks as well as recovering more from the vehicles. The automakers also stated that the partnership was expected to look into developing industry guidelines in such areas as materials selection and compatibility, bonding methods and materials, painting, and design for disassembly. Research in these areas reportedly would be carried out in the laboratories of the three automakers and by other industries, universities, and research institutes.

Barmet Aluminum Corp. and IMCO Recycling Inc. announced plans to construct a \$16 million, 120,200-ton-per-

year (265-million-pound-per-year) aluminum recycling facility to be situated near Barmet's Urichsville, OH, rolling mill. Under the reported agreement, IMCO would have the exclusive rights to recycle Barmet-purchased scrap at this plant for a period of 10 years. As the new plant comes on-stream, Barmet's recycling plant at Urichsville will be phased out. The plant, which reportedly would recycle UBC's and dross and would increase IMCO's aluminum recycling capacity by 50%, was expected to be fully operational by mid-1993.

U.S. Reduction Co. reported that construction had begun on a new 27,220-ton-per-year (60-million pound-per-year) aluminum recycling plant in Tipton, IN. The company expected the plant to reach full capacity by the second quarter of 1993. The plant reportedly would provide specification liquid metal and ingot to aluminum automotive diecasters and foundries.

Aluminum Smelting and Refining Inc. reported that the company had closed its secondary aluminum plant. The decision to close the privately owned plant reportedly came after months of attempts to sell the company had failed. (See tables 3, 4, and 5.)

Consumption and Uses

The container and packaging industry remained the largest domestic consumer of aluminum products, representing about 28% of total U.S. shipments of aluminum products. The Can Manufacturers Institute reported that almost 92.8 billion aluminum beverage cans were shipped in 1992, representing about 97% of the total metal beverage can shipments.

Anheuser-Busch announced the development of a new can design that reportedly would save the company about 9,000 tons of aluminum per year. Anheuser-Busch, which filled and marketed about 17 billion aluminum cans per year, also reported that it planned to offer the new design to other soft-drink and beer companies. The new can had a lid 0.32 centimeter (one-eighth inch) smaller in diameter than lids used by most of the industry and maintained the

same label area and stackability as previous designs.

Reynolds and Ball Corp. announced the development of a new beverage can necking process and equipment that reportedly would permit the use of smaller can ends and reduce metal requirements for can bodies. company reported that the Spin Flow machine could process more than 2,000 cans per minute and reduced metal requirements because the machine could form can necks shorter than those formed with other necking methods. machine reportedly was also able to form a range of beverage can neck diameters with minimal downtime for size changeover. The companies announced that the first Spin Flow machine was to be installed at Ball's Tampa, FL, plant, and a second machine would be placed at 1.2-billion-can-per-year Revnold's Walkill plant in Middletown, NJ.

Automakers continued to explore increased and new applications for aluminum in their vehicles. Chrysler reported that it was developing a prototype small car with aluminum frame and body components. Cross-members, frame rails, floor pans, engine cradles, radiator supports, and many other structural components in the test car were expected to be made of aluminum, along with door frames, roof, body side panels, and probably most of the hinged components, including the hood and deck In addition, the car would use lid. aluminum in the engine cylinder head. transaxle case, and numerous other components that used aluminum casting Chrysler announced plans to introduce the model in about 2 years with an annual production rate of 200,000 to 250,000 units.

Chrysler also announced that it was developing a low-displacement aluminum V-8 engine for use in niche cars in about 3 years. According to Chrysler engineers, the engine, as designed, would contain at least 68 kilograms of aluminum. The engine reportedly was earmarked for use in special luxury or sports cars built off the company's new LH platform, and also possibly for its luxury minivans. Currently, the only | products, and scrap at reduction and other

aluminum-block/aluminum-head engines in Chrysler's entire line were the verylow-volume V-10's used in the Dodge Viper sports cars, which were produced in volumes of only a few hundred vehicles annually.

Ford announced that it had begun testing prototypes of its next generation of small car automatic transmissions that were expected to consume between 9,000 and 11,000 tons of aluminum alloy 380 each year once full production was reached in 1994. Ford sources said the new transmissions would go into production early next year but would not reach significant volume levels for 6 to 7 months.

Ford also announced plans to produce both aluminum blocks and heads for its next generation of V-6 engines and some of the blocks for its modular V-8 engines at its Windsor, Ontario, casting plant starting in 1995. Ford sources stated that once full production levels were reached in 1996, almost 16,000 tons of aluminum was expected to be consumed annually at this plant, and additional applications could increase consumption above 22,500 tons annually 1 or 2 years later.

GM announced that it had finalized plans to equip its first electric cars with aluminum spaceframes and plastic bodies. In addition to the structural or frame components, the company stated that the wheels, front brake calipers, rear brake drums, heat exchangers, heat pump compressor, and additional smaller components would be made of aluminum.

GM also announced plans to put aluminum driveshafts into some of its compact-size pickup trucks beginning with the 1994 models. GM sources said the shafts would be extruded and drawn from 6061 alloy and could require more than 450 tons of metal per year. GM used aluminum driveshafts in its bigger trucks, but this would be the first application for aluminum shafts in their smallest pickup trucks. (See tables 6, 7, and 8.)

Stocks

Inventories of aluminum ingot, mill

processing plants, as reported by the U.S. Department of Commerce, increased from a revised total of 1.775 million tons at vearend 1991 to 1.875 million tons at vearend 1992.

The London Metal Exchange (LME) reported that its U.S. warehouses held a total of 213,525 tons of primary aluminum metal ingot at yearend 1992, an increase from the 167,550 tons of metal reportedly held in these warehouses at vearend 1991.

With the introduction of its secondary aluminum alloy ingot contract, the LME began storing aluminum alloy ingot in its warehouses around the world (see Market and Prices). At yearend 1992, the LME reported that its U.S. warehouses held a total of 10,120 tons of aluminum alloy ingot.

Markets and Prices

The monthly average U.S. market price of primary aluminum, as reported by Metals Week, fluctuated throughout the year without establishing any kind of a definitive trend. The monthly average prices reached a high of 61.034 cents per pound in April, and posted a low of 52.763 cents per pound in November. The average price for the year was 57.519 cents per pound, slightly less than 2 cents per pound lower than the 1991 annual average price of 59.461 cents per pound. The LME cash price for highgrade primary aluminum ingot followed the same general trend as the U.S. market price. The 1992 average annual LME cash price was 56.894 cents per pound.

Purchase prices for aluminum scrap, as quoted by the American Metal Market (AMM), fluctuated during the year and closed the year at higher levels than those at the beginning of the year. yearend price ranges for selected types of aluminum scrap were as follows: mixed low-copper-content aluminum clips, 45 to 46 cents per pound; old sheet and cast aluminum, 38 to 39 cents per pound; and clean dry aluminum turnings, 39 to 40 cents per pound.

Prices for UBC's also fluctuated during the year, but closed about 8 cents per pound higher than prices at the beginning of the year. Aluminum producers' buying prices for processed and delivered UBC's, which began the year at a range of 32 to 37 cents per pound, reached a high for the year of 44 to 47 cents per pound in late April. The price range at the end of the year was 40 to 42 cents per pound.

Secondary aluminum ingot prices, as quoted by AMM, fluctuated during the year, but closed higher than prices at the end of 1991. The yearend 1992 price ranges for selected secondary aluminum ingots were as follows: alloy 380 (1% zinc content), 68 to 69.5 cents per pound; alloy 360 (0.6% copper content) and alloy 413 (0.6% copper content), 71.5 to 72.5 cents per pound; and alloy 319, 69.5 to 71 cents per pound.

Metals Week instituted an A-380 aluminum alloy price with the following specifications: 8% to 9.5% silicon, 1% iron, 3% to 4% copper, 0.5% manganese, 0.1% magnesium, 0.5% nickel, 0.35% tin, and 2.9% zinc. The price was for standard ingot in 20,412kilogram (45,000-pound) truckload amounts delivered customer works. The price represented a range of spot transaction prices conducted by a survey of major suppliers and buyers. Weekly and monthly quotations began in July. The 1992 annual average price, based on 6 months of prices, was 57.081 cents per pound.

In May, the LME announced the introduction of a secondary aluminum alloy contract. Three-month trading began on October 6, and cash trading began on January 4, 1993. Trading was conducted in U.S. currency. The LME based its contract on three secondary aluminum alloy specifications—U.S.380-1, Japanese ADC12, and German DIN226.

Foreign Trade

Exports of all forms of aluminum from the United States decreased for the first time in 5 years. However, exports in 1992 remained at approximately twice the level of those of a decade ago. Canada and Japan remained the major recipients of U.S. aluminum materials, accounting for slightly less than 70% of total exports. Exports of UBC's, which were included in the scrap category, increased to 3,383 tons compared with 2,805 tons in 1991. Argentina, the Republic of Korea, and the United Kingdom were the principal destinations of UBC's exported, accounting for almost three-fourths of the total in 1992.

Imports for consumption of aluminum increased compared with those of 1991. Canada remained the major shipping country to the United States, supplying more than 80% of the total imports in 1992. Imports from the former U.S.S.R. increased significantly. Although the level of these imports was relatively low, it was indicative of the increasing presence of former U.S.S.R. aluminum metal in the Western World markets. UBC imports in 1992 totaled 44,089 tons compared with 31,602 tons in 1991. Mexico replaced Canada as the major source of UBC imports in 1992. Mexico and Canada combined to supply 84% of the total UBC imports for the year. (See tables 9, 10, 11, and 12.)

World Review

World production of primary aluminum metal decreased slightly in 1992 compared with that of the previous year. The continued slowdown in world economic activity, most notable in Europe and Japan, and high inventory levels, especially inventories held by the LME, kept world metal prices at depressed levels. For the second year in a row, exports of metal from the former U.S.S.R. were estimated to be in the area of 1 million tons. There were some announced decreases in smelter operating capacity during the year, but the quantities involved were not significant enough to provide any long-term effect on metal prices.

Primary aluminum inventories held by members of the International Primary Aluminium Institute (IPAI), which represent the bulk of stocks held outside the former centrally planned economy countries and the LME, decreased from 1.754 million tons at yearend 1991 to

1.717 million tons at yearend 1992. IPAI reported that total metal inventories, including secondary aluminum, decreased from 3.349 million tons at yearend 1991 to 3.283 million tons at yearend 1992.

Inventories of primary aluminum metal held by the LME continued to increase dramatically during the year. LME inventories at the beginning of the year totaled 987,150 tons. By the end of the year, inventories held by the LME had increased by almost two-thirds and totaled 1,578,625 tons. In addition, the LME held 15,540 tons of aluminum alloy by yearend.

Australia.—Comalco Aluminium Ltd. announced an agreement had been reached with the Queensland government for the purchase of the 1,600-megawatt (MW) Gladstone power station by a Comalco-led consortium. The sale was subject to the commercial viability of adding a third potline at the Boyne Island Comalco and its partners smelter. expected to complete the feasibility study on the addition of a 200,000-ton-per-year potline by December 31, 1993. If a decision is made to expand the Boyne Island smelter, the smelter's annual capacity would increase to 460,000 tons per year, making it one of the world's largest smelters.

The government of Victoria announced the sale of a 10% interest in the Portland aluminum smelter to the Marubeni Corp. of Japan. Upon completion of the sale, the government's share in the smelter, held through Aluminium Smelters of Victoria Pty. Ltd. (Aluvic), would be reduced to 25%. The other shareholders would remain unchanged-Alcoa of Australia (45%), China International Trade & Investment Corp. (10%), and First National Resource Trust (10%).

Austria.—Alusuisse announced the sale of Salzburger Aluminium GmbH to the company's management. Included in the sale were the 12,000-ton-per-year primary aluminum smelter at Lend, casting facilities, two power stations, and a truck parts factory. The Lend smelter, which uses Soderberg technology, was built in 1899.

Austria Metall AG reported that it had completed the permanent closure of its 80,000-ton-per-year primary aluminum smelter in Ranshofen. The plant had been phasing down operations since the intention to close was first announced in June 1991.

Bahrain. — Aluminium Bahrain B.S.C. (Alba) announced the completion of the \$1.5 billion expansion program at its primary aluminum smelter. The completion of the smelter's fourth potline reportedly increased capacity at the smelter from 225,000 tons per year to 460,000 tons per year, making this one of the world's largest smelters. The expansion program also included a new 800-MW powerplant that runs on natural gas using combined cycle turbines. increasing the company's dedicated power system to 1,340 MW. At the end of the year, Alba announced that it had signed a \$10 million loan agreement with 10 regional banks to finance a link between Alba's power system and Bahrain Electricity. The link, which was scheduled to be completed by June 1994. would enable Alba to provide up to 300 MW of power to the national supply grid during peak demand periods and would allow Alba to draw additional capacity from the grid to meet any unexpected shortfalls.

Brazil.—Alcan Aluminio do Brazil announced the temporary closure of 27,000 tons per year of metal capacity at its 57,000-ton-per-year Aratu primary aluminum smelter. In early November, the company reportedly began turning off one of the two potlines at the plant.

Latas de Aluminio SA (Latasa), a joint venture between Reynolds International do Brazil (35%) and two Brazilian banks, Bradesco (35%) and Credibanco (30%), announced plans to invest in canmaking facilities in Brazil and Argentina. Latasa announced plans to build a 700,000-canper-year facility, probably in southern Rio de Janiero State, and a 500,000- to 600,000-can-per-year plant in Argentina, probably near Buenos Aires. The new facility in Brazil would be in addition to Latasa's 1.3-million-can-per-year plant

currently in operation in Pouso Alegre, Minas Gerais State.

Canada.—In February, Alumax announced the start of production at its new 215,000-ton-per-year Lauralco primary aluminum smelter at Deschambault, Quebec. The company stated that the smelter, which uses Pechiney 300KA technology, would cast T-ingot only.

Aluminerie Alouette Inc. reported the start of production at its 215,000-ton-peryear primary aluminum smelter at Sept Iles, Quebec, in June. Aluminerie Alouette is owned by an international consortium—Vereinigte Aluminium—Werke AG (VAW) (20%), Austria Metall AG (20%), Hoogovens Groep BV (20%), Societe Generale de Financement du Quebec (20%), Kobe Steel Ltd. (13.33%), and Marubeni Corp. (6.67%). The company expected the plant to be operating at its full capacity at yearend.

In September, Alcan Aluminium reported that it was reactivating 67,500 tons of annual primary aluminum smelter capacity that had been idled since the autumn of 1991. The restarted potlines included a 21,000-ton-per-year potline at Shawinigan, 24,500 tons per year at Isle Maligne, and 22,000 tons per year at Arvida. The company cited improvements in water levels at its hydroelectric powerplants as one of the factors that led to this decision.

In May, Alcan Aluminium and the Federation des Syndicats du Secteur Aluminium announced the signing of a new labor contract covering about 5,000 workers at Alcan Aluminium's primary smelters at Arvida, Laterriere, Isle Maligne, and Beauharnois. The new 3-year contract reportedly included a wage increase of 8.6% spread over the life of the contract, with part of the increase retroactive to March 1991 when the previous contract expired.

Reynolds and the Confederation of National Trade Unions also announced the signing of a new 3-year labor contract covering workers at the 400,000-ton-per-year Baie Comeau primary aluminum smelter. The new contract reportedly included cost of living adjustments and

increases in retirement benefits and vacation bonuses.

Chile.—Feasibility studies, at various stages of completion, were being conducted on three different joint-venture primary aluminum smelters. Noranda Aluminum Inc. and Proyectos de Aysen had completed most of the preliminary studies and were putting together the financial package for a \$1.5 billion. 230,000-ton-per-year smelter in the Aysen area of southern Chile. Comalco and Geo-Estudios SA Santiago announced the completion of a prefeasibility study on a \$2 billion, 240,000-ton-per-year smelter in the Punta Arenas area near the Straits of Magellan. The third potential project was led by Endesa, Chile's largest energy producer. Endesa reported that it was being joined by Bechtel Corp., Comalco, and Marubeni Corp. in commissioning a feasibility study on a \$1.5 billion. 220,000-ton-per-year smelter in the Aysen area of southern Chile. All of these projects would require extensive infrastructure work, including the construction of hydroelectric plants and port facilities.

China.—The Southwest Aluminium Fabrication Plant announced plans to install an aluminum coating line, the first in China, at its facilities at Chongquing in the southern part of the country. The new coating line would apply paint and lacquer to coiled aluminum strip at a throughput rate of almost 11 tons per hour. The products produced were geared for applications in the architectural, automotive, appliance, and container industries.

Egypt.—Aluminium Co. of Egypt (Egyptalum) reported that it had begun switching from the use of Soderberg to prebaked electrodes at its primary aluminum smelter at Nag Hammadi in Upper Egypt. The switchover was expected to be gradual, at the rate of about 100 cells per year. Upon completion, in about 3 to 4 years, the smelter's capacity was expected to reach 240,000 tons per year.

France.—Pechiney announced that its new 215,00-ton-per-year primary aluminum smelter at Dunkirk reached full production levels in May. Pechiney stated that the Dunkirk smelter was the first to use its 300,000-ampere technology in a single potline to reduce capital and staffing costs. Most traditional smelters of similar size reportedly had two or three potlines.

Pechiney also announced plans to reduce production capacity, both temporarily and permanently, at other smelters. Temporary reductions of 20% of capacity were expected by January 1993 at the company's 120,000-ton-per-year St. Jean de Maurienne smelter, the 44,000-ton-per-year smelter at Auzat, and the 44,000-ton-per-year Lannemezan smelter. Pechiney also announced plans to permanently close its 31,000-ton-per-year Venthon smelter in the French Alps. The smelter was expected to be closed over a period of about 18 months with a full shutdown expected in early 1994.

Germany.—VAW announced the temporary closure of 105,000 tons per year (26%) of annual primary aluminum metal capacity at its Toging and Norf smelters. The reduction included the 33,000-ton-per-year reduction at these two plants that had been announced in October 1991. Company officials stated that the closures would probably stay in place at least through the end of 1993.

Pechiney Aluminium Presswerk (PAP) announced plans to construct a new extrusion plant at Burg, in eastern Germany. The plant, which was expected to be operational by mid-1994, reportedly would add 12,000 tons per year to PAP's aluminum extrusion capacity. The company stated that the new plant would enable it to respond to growth in demand for aluminum extrusions expected by the building and construction industries in that area of the country.

Greece.—Aluminum extruder Soulis SA announced the installation of a new 630-ton press at its plant in Lamia that will enable the company to produce thinwalled, lightweight extrusions. The 10-

ton-per-day press reportedly produced extrusions with a minimum wall thickness of 0.7 millimeter (mm). The plant's other two presses, a 2,000-ton press and a 1,650-ton press, produced minimum wall thicknesses of only 1.3 mm. About 80% of the plant's production was for the export market and supplied the automotive, aerospace, machinery, and air conditioning industries.

Hungary.—Hungarian Aluminium Corp. (Hungalu) and an unnamed Ukrainian company reported the signing of a 5-year deal that would allow the 35,000-ton-per-year primary aluminum smelter at Inota, originally scheduled for closure in 1992, to continue to operate. The deal reportedly called for the Inota Aluminium Works to deliver aluminum semis to the Ukraine in return for electricity at a 30% discount.

Alcoa and Hungalu announced the signing of a joint-venture agreement involving Hungalu's subsidiary, Kofem The \$165 million agreement Kft. reportedly gave Alcoa a majority interest (50.1%) in Alcoa-Kofem Kft. Kofem plant, 56 kilometers southwest of Budapest in Szekesfehervar, produced about 110,000 tons of rolled products and 30,000 tons of extrusions per year. Alcoa stated its initial investment was \$50 million, and the remaining \$115 million investment would be spread over 5 years to improve product quality and to upgrade the environmental systems and safety at the plant.

Italy.—At the end of May, Alumix S.p.a., the state holding company for Italy's aluminum sector, announced the closure of its 30,000-ton-per-year Fusina II smelter.

The Italian Government decreed that electricity prices would be reduced for Alumix's primary aluminum smelter at Porto Vesme. Effective July 29, electricity rates reportedly decreased from 41.6 lire per kilowatt hour (kW•h) (33.5 U.S. mills per kW•h) to 20 lire per kW•h (16.1 mills per kW•h). The 36,000-ton-per-year Fusina I smelter did not appear to be eligible for the reductions.

In July, the Italian Government also issued a decree liquidating Efim, the state holding company that controlled a range of industrial companies, including the aluminum company, Alumix. The Government reportedly approved the establishment of a 3-year restructuring program, which would run to the end of 1995, with a view to eventual privatization.

Japan.—An independent Osaka-based aluminum fabricator (Alcut K.K.), Sumitomo Light Metal Industries Ltd. (SLM), and Mitsubishi Aluminium announced the commissioning of a new aluminum coil processing facility. The plant, commissioned in November, was operated by Alcut K.K. and had a capacity of 600 tons per month. The companies expected the first year output to be 50 tons per month, increasing to 300 tons per month by 1994 and reaching full capacity by 1995.

Kobe Steel Ltd. announced that construction had begun on a new aluminum and magnesium alloy casting and forging plant in Daian, Mie Prefecture. The company stated that it planned to move its castings and forgings operations in stages from its Nagoya plant, which lacked space for further expansions, to Daian. The new plant was expected to have 60% more capacity than the Nagoya plant. The target date for completion of the new plant was 1995.

Hokkai Can Co. reported the start of construction of a new aluminum can plant in Kora, Shiga Prefecture. The new plant, scheduled for completion in 1993, was expected to have an annual production capacity of 500 million cans.

Mitsubishi Materials Corp. announced plans to expand its aluminum can production capacity from its current level of 3 billion cans per year to 5 billion cans per year by 1995. The company stated that the expansion in capacity would be achieved by renovating and expanding its four existing can plants.

U.S.-based aluminum companies continued to enter into joint agreements with various sectors of the Japanese aluminum industry. Alumax announced the formation of Alumax Japan Inc., a

new subsidiary to handle Far Eastern sales and to seek partnership venture opportunities in Asia. Two aluminum automotive sheet joint ventures formed by Alcoa and Kobe Steel reportedly began production and marketing operations at Kobe's Moka plant and Alcoa's Davenport, IA, plant. Revnolds and SLM announced the signing of a 3-year agreement of technical collaboration on aluminum sheet for the automotive industry. Kaiser Aluminum announced that an agreement had been reached with the Kawasaki Steel, Furukawa Electric, and Furukawa Aluminium group to form a study group to assess the viability of forming a joint venture to produce aluminum sheet in Japan for the automotive industry.

Republic of.—Kaiser Korea. Aluminum announced the signing of a 5year technology licensing and technical services agreement with Samyang Metal Co. Ltd. Under the agreement, Kaiser Aluminum reportedly would provide technology, technical expertise, and training for Samyang's new rolling mill under construction at Yongju. The new plant was expected to produce a full range of aluminum sheet and plate products, including can stock. Under a separate agreement, Kaiser Aluminum reportedly would market the Yongju rolling mill products in North America.

Malaysia.—Kobe Steel of Japan announced the formation of a wholly owned subsidiary, Kobe Precision Technology Sdn Bhd (KPT), that would begin producing aluminum substrates in April 1993 at the initial rate of 1.2 million pieces per month. **Plans** reportedly called for KPT to oversee the construction of a new manufacturing facility in Malaysia and to market the substrates to computer and hard disk drive manufacturers throughout Southeast Asia. Aluminum blanks, the material for substrates, would be supplied by Kobe's Moka plant in Tochigi Prefecture, Japan.

Japan's Marubeni Corp. reported the finalization of an agreement to take a 19.2% stake in Malaysia's Aluminium Industries Snd Bhd (AISB). AISB

operated a plant in Johore Bahru that produced about 6,000 tons per year of rolled aluminum products, including finstock for use in air conditioners.

Mexico.—In February, Alcoa announced the closure of the third and last potline at its 44.3%-owned primary aluminum smelter in Veracruz. Later in the year, Alcoa announced that it had sold its 44.3% interest in Grupo Aluminio, which included the 66,000-tonper-year Veracruz smelter, to Grupo Carso, a diversified Mexican company.

Netherlands.—Pechiney Nederland NV announced an additional 8% temporary cutback in production at its 170,000-ton-per-year primary aluminum smelter in Vlissingen. By January 1994, production at the smelter was expected to be reduced by 20%.

Alumax reported the start of production at its new facility at Kerkrade. The Kerkrade plant, owned by Alumax's subsidiary Alumax Aluminium BV, reportedly used a smelting system that produced billets from a mix of aluminum scrap and ingots. At full capacity, the plant would produce a minimum of 50,000 tons per year of aluminum extrusion billets.

New Zealand.—Severe drought conditions prompted the Electricity Corp. of New Zealand (ECNZ) to restrict the supply of electricity to Comalco's 260,000-ton-per-year Tiwai Point primary aluminum smelter. In June, Comalco temporarily closed one potline at the smelter, which reportedly reduced the smelter's monthly output from 22,000 tons to 14,500 tons. However, improved rainfall in July allowed ECNZ to restore full power to the smelter, and Comalco returned its smelter to full production status by the end of the year.

Nigeria.—Reynolds reported that construction progressed on a 180,000-tonper-year primary aluminum smelter. Reynolds agreed to acquire a 10% equity interest in the Aluminum Smelter Co. of Nigeria (ALSCON) with the Nigerian Government and private interests holding the remaining equity. As part of the arrangement, Reynolds reportedly would purchase 140,000 tons of metal annually from ALSCON when the smelter reached full capacity. An initial capacity of 45,000 tons per year was expected to be in production in 1995.

Russia.—In September, an international aluminum conference was held in St. Petersburg. At this conference. representatives of the Russian aluminum industry presented papers that described the aluminum industry in the former U.S.S.R. and presented data on the engineered capacity of primary aluminum smelters. The Russian primary aluminum smelters and their rated annual capacities are as follows: Bogoslovsk, 162,000 tons: Bratsk, 844,000 tons; Irkutsk, 262,000 tons: Kamensk-Uralsk, 70,000 tons: Kandalaksha, 63,000 tons; Krasnovarsk, 755,000 tons; Nadvoitsky, 68,000 tons; Novokuznetsk. 284,000 tons: Sayanogorsk, 274,000 tons; Volgograd, 168,000 tons; and Volkov, 20,000 tons. Annual capacity data for the primary smelters in the independent republics were also presented, as follows: Sumgait, Azerbaijan, 58,000 tons; Tadjik, 517,000 Tadiikistan. tons: and Zaporozhye, Ukraine, 110,000 tons.

Spain.—Industria Navarra del Aluminio, S.A., a 77%-owned subsidiary of Reynolds International Inc., announced the completion of a 4-year, \$25 million expansion of its foil operations in northern Spain. Foil capacity at the Pamplona plant increased by 42% to 18,600 tons per year.

Switzerland.—Alusuisse announced the closure of its primary aluminum smelter in Chippis. Capacity at the smelter, which was built in 1908, had been decreasing gradually in recent years, from 40,000 tons per year to about 6,000 tons per year.

United Kingdom.—Coca Cola-Cadbury Schweppes UK Ltd., the bottling company, announced plans to use aluminum cans for all of its canning operations in the United Kingdom. To

accommodate the increase in demand for aluminum cans, Nacanco planned to convert three canmaking lines at its Milton-Keynes plant to aluminum, and CMB Packaging announced plans to convert one line at its Braunston plant to aluminum.

Venezuela.—The 300,000-ton-per-year Alcoven primary aluminum smelter project, announced last year, was postponed indefinitely.

Aluminio del Caroni SA (Alcasa) reported the startup of a new rolling mill, Laminacion Puerto Ordaz. The mill reportedly had an annual rolling capacity of 60,000 tons for canstock and other products.

Yugoslavia.—In an interview with Metal Bulletin in December, Slavko Ostojic, president of the bauxite, alumina, and aluminum producers association of the former Yugoslavia, gave the following assessment of the status of the primary aluminum smelters in that country.

The 75,000-ton-per-year Boris Kidric smelter in Sibenik, Croatia, was damaged during the war and was not expected to restart production until 1994 at the earliest. However, the smelter continued to operate its rolling mill and semifabrication facilities using metal imports from the former U.S.S.R.

The Energoinvest smelter in Mostar, Bosnia-Herzegovina, stopped production in April because of war damage. Although the damage was not serious, Ostojic did not think that the 92,000-ton-per-year smelter would be restarted given the port and general transport difficulties the war had created.

The 75,000-ton-per-year Unial smelter at Kidricevo, Slovenia, had not reduced production from prewar levels. However, owing to depressed market conditions, the smelter was producing at 10% to 20% below capacity.

The Podgorica smelter, formerly the Titograd smelter, in Montenegro had been disrupted by sanctions. Exports had stopped, and the smelter was suffering from a lack of raw materials that previously had been imported from the

west. At the end of the year, the smelter reportedly was producing metal at 80% to 90% of its 102,000-ton-per-year capacity, but it was unclear how long this would continue. Estimates ranged from 1 to 3 months, depending on its stockpile of raw materials. (See table 13.)

Current Research

According to researchers at Sandia National Laboratories, aluminum implanted with a thin layer of oxygen ions in concentrations as low as five atomic-percent produced an alloy about five times stronger than other highstrength aerospace aluminum alloys. The new alloy also reportedly had greater resistance to friction and wear than other aluminum alloys and retained its strength superiority even when subjected to high temperatures. Ion implantation is a 20year-old technique used to introduce additional elements into solid materials. It initially used for doping semiconductors to achieve specific electrical properties. Sandia researchers bombarded the surface of 1.87centimeter-diameter pure aluminum disks at room temperature with oxygen ions at energies between 25 and 200 kiloelectron volts. By varying the energies used, a uniform layer of implanted aluminum was produced from the surface to a depth of about 0.5 micrometers. The strength was evaluated using an ultralow load indentation test system, which probed the surface by applying a small force on a diamond-tipped pin.²

At the 121st Annual Meeting of The Minerals, Metals, and Materials Society (TMS) held in San Diego, CA, March 1992, more than 100 papers were presented in such topic areas as alumina and bauxite, reduction technology, carbon technology, cast shop technology, and recycling. Among the papers presented at the reduction technology sessions were several on the topic of handling spent potliner (SPL) waste. The generation and safe disposal of SPL produced through the electrolytic reduction of alumina had become one of the industry's biggest environmental concerns. SPL had been classified as hazardous in several countries because of its leachable cyanide content. Several companies had begun to seek alternatives to the practice of storing and landfilling SPL, which was becoming increasingly more difficult and expensive.

Revnolds reported the development of a process for detoxifying SPL in which the SPL was blended with limestone and an antiagglomeration agent and thermally treated in a rotary kiln. The company reported that the process was very effective for destroying cyanides and significantly reduced the concentration of soluble fluorides in the kiln residue. The cvanides were destroyed by oxidation and the majority of soluble fluoride salts were converted to stable, insoluble calcium fluoride by reaction with limestone. The process was developed and utilized for more than 2 years on an industrial scale at Reynolds idled Hurricane Creek Alumina Plant in Bauxite, AR. More than 300,000 tons of SPL reportedly was treated successfully during this period.³

Alcoa reported the results of tests it had conducted on the reuse of SPL in bench-scale carbon cathodes as an alternative to disposal. The studies included an effort to verify detrimental effects of aluminum carbide and aluminum nitride, the determination of fluoride evolved at temperatures attained in cathode baking. measurements of swelling owing to sodium absorption during electrolysis and of electrical resistivity for conventional cathodes and those produced from SPL. Alcoa researchers reported that limited plant trials confirmed that untreated SPL could be used in cathode blocks and seams without adversely affecting cell operating parameters. However, they also stated that a number of issues. including those involving industrial hygiene and the environment, baking furnace refractory deterioration, and the ability to produce consistent blocks and/or seams from a variable material would need to be addressed before commercialization.4

An alternative treatment known as the COMTOR process was developed at Comalco's Research Center in Melbourne, Australia. A 5,000-ton-per-year demonstration plant was constructed

in Queensland, Australia. Preliminary results from the demonstration plant and details on the process itself were presented. The company described the process as having three distinct stages feed preparation, calcination, and fluoride Crushing the SPL before recovery. treatment reportedly improved the rate and quality of the detoxification process. The COMTOR process utilized a new type of calciner, known as a Torbed. Calcination reportedly was the most effective method for reducing the leachable cvanide content of the SPL. Ash treatment recovered the fluoride values for recycling directly to the electrolytic cell. Once the cyanide was destroyed and the fluorides either recovered or stabilized, the residue reportedly passed the standard leach tests and was no longer considered toxic.5

OUTLOOK—ALUMINUM

The world demand for aluminum metal continued to be weak during the first half of 1993. The oversupply of metal, the economic downturn, and the continuation of high levels of exports from the former U.S.S.R. should continue to depress the world aluminum market. This slowdown may continue well into 1994. When world economic activity does begin to recover, an oversupply condition will probably continue for an extended period of time until the inventory levels that have been building over the past few years return to a more economically acceptable level. Thereafter, the longterm growth rate for aluminum metal should average about 2% per year.

ANNUAL REVIEW—BAUXITE AND ALUMINA

World production of bauxite and alumina decreased during 1992 in response to the continued slow pace of primary aluminum metal output; bauxite production fell by 4% and alumina output was 2% below the previous year's total. Mine production of bauxite was reported from 28 countries. Domestic consumption of bauxite in 1992 fell below 1991 consumption levels, with the

downward pressure driven by weak metal market requirements for primary aluminum. Within the specialty products area, consumption of abrasive-grade bauxite increased beyond 1991 usage, but bauxite consumption by the chemical and refractory industries decreased in 1992. Demand for alumina was soft throughout the year, mainly in response to reduced primary aluminum smelter operating levels. Owing to continued weak national economic conditions, U.S. production and shipments of smelter-grade alumina in 1992 declined by moderate amounts. U.S. alumina consumption moderated slightly from the high levels of 1991 and a continued softening of the alumina market developed throughout 1992 as a buildup occurred in alumina stocks. Alumina reportedly was produced in 29 countries around the world. (See table 14.)

Legislation and Government Programs

Early in 1992, the implementation of sanctions on U.S. imports of Chinese bauxite and other commodities was avoided when the U.S. and Chinese Governments reached agreement over the protection of U.S. copyrighted and patented property. China had been identified by the U.S. Trade Representative (USTR), under provisions of U.S. trade law, for its failure to provide adequate and effective protection of U.S. intellectual property. bauxite traders and consumers lobbied strongly to keep Chinese bauxite off the USTR's proposed list of sanctioned items.

There were no announced additions of bauxite to the NDS in 1992; however, 437,000 tons of bauxite was reportedly released in compliance with a contract to upgrade NDS metallurgical-grade bauxite to aluminum metal. An additional solicitation to upgrade a further 166,000 tons of NDS bauxite to aluminum was canceled by the DLA in light of revised NDS materials requirements. yearend, DLA reported an inventory of 12.4 million tons of Jamaica-type and 5.0 million tons of Suriname-type metallurgical-grade bauxite in the NDS. The NDS calcined refractory-grade bauxite inventory was listed as 280,500 tons at the close of 1992.

Under a new Department of Defense Annual Materials Plan for Fiscal Year 1993, released in mid-December of 1992, DLA planned to offer for sale 762,000 tons of metallurgical-grade bauxite—508,000 tons of Jamaica-type and 254,000 tons of Suriname-type. In addition, as a part of this program, DLA intended to dispose of 51,000 tons of refractory-grade bauxite in fiscal year 1993. These were the maximum amounts recommended for disposal during the fiscal year, and the actual level of sales would depend on prevailing market conditions.

Production

The total U.S. bauxite production during 1992 was 9% less than that reported for 1991. Most of this sluggishness was attributed to general weakness in the U.S. economy. The only currently active bauxite mines remaining in the U.S. are the surface operations in Alabama and Georgia that produce bauxitic materials, a natural mixture of bauxitic clay and bauxite with a very low iron oxide content, primarily used for the production of refractory grogs. Demand for these domestic ores remained relatively weak during 1992, and mine output was intermittent. Within this market sector, the Harbison-Walker Refractories Div. of INDRESCO Inc. shipped bauxite from mines in Alabama to its local calcining plant and to Carbo Ceramic Co.'s proppant plant at Eufaula, AL. Throughout the year, C-E Minerals continued to operate and maintain its mines in Alabama and Georgia, with the raw ore shipped to its Andersonville, GA, facility for the production of refractory products.

Alusuisse-Lonza Services reportedly signed an agreement with Virgin Islands Alumina Corp. (VIALCO), a unit of Clarendon Ltd., under which Alusuisse would provide its proprietary alumina precipitation technology to VIALCO's alumina plant located at St. Croix, U.S. Virgin Islands. The technology should assist VIALCO in improving and

maintaining the quality of its alumina product, while providing the basis for increasing the plant's production capacity.

Kaiser Aluminum Corp., operating through its subsidiary Kaiser Aluminum & Chemical Corp., remained a major international producer and marketer of alumina. Its alumina plant at Gramercy, LA, set a new output record by producing 1.06 million tons of alumina in 1992. Kaiser's entire worldwide alumina production amounted to 2,939,300 tons for the year; approximately 68% of the alumina was sold to outside customers.

Reynolds Metals Co. indicated that its 1.7-million-ton-per-year capacity Sherwin alumina plant near Corpus Christi, TX, operated at a reduced production level in 1992. This was a result of the company's effort to balance its alumina supply system following the temporary closure of its primary aluminum smelter at Troutdale, OR. At the close of 1992, the Sherwin plant was reported to be operating at 77% of its annual rated capacity.

Conoco Inc. reportedly commenced shipping reclaimed fluorinated alumina from its 138,000-barrel-per-day Ponca City, OK, petroleum refinery to Kaiser Aluminum & Chemical Corp.'s aluminum smelter at Mead, WA. In July 1992, Conoco signed an agreement to sell reclaimed fluorinated alumina to Kaiser with the material to come from Conoco's 49,500-barrel-per-day Billings, refinery as well as its Ponca City facility. The Ponca City petroleum refinery reportedly would be able to reclaim approximately 115 tons per year of fluorinated alumina and the Billings facility, approximately 90 tons. In the case of the Ponca City refinery, this amounts to the elimination of nearly 155 of nonhazardous cubic meters wastestream material that no longer has to be disposed of in an approved landfill. (See tables 15 and 16.)

Consumption and Uses

Weak demand for smelter-grade alumina lowered the consumption of crude and dried metallurgical-grade bauxite to a level below that of 1991.

Consumption of bauxite by the abrasives industry increased modestly during 1992, and consumption within the chemical and refractory industries decreased moderate amounts. Approximately 93% of the bauxite consumed in the United States during 1992 was refined to alumina, and an estimated average of 2.13 tons of dried bauxite was required to produce 1 ton of calcined alumina. Twenty-two primary aluminum smelters reported a consumption of 8.13 million tons of calcined alumina in 1992, barely down from the consumption level reported for 1991. This slightly lower level of consumption, coupled with the minimally higher rates of U.S. alumina imports, resulted in the development of a modest oversupply of smelter-grade alumina on the domestic alumina market. An estimated 91% of the alumina shipped by U.S. refineries went to domestic primary smelters for metal production. Consumption in various forms by the abrasives, chemicals, refractories, and specialties industries accounted for the balance of the alumina usage. (See tables 17, 18, 19, and 20.)

Markets and Prices

Contract terms for the purchase of metallurgical-grade bauxite and smelter-grade alumina in world markets are not normally made public, and, consequently, prices for these commodities are not published by trade journals. Price quotes are generally limited to certain specialty forms of bauxite and alumina for nonmetallurgical uses.

In 1992, the USBM estimated the average value of domestic crude bauxite shipments, f.o.b. mine or plant, to be \$17 per ton. The average value of calcined domestic bauxite was estimated to be \$170 per ton. Base prices quoted by Industrial Minerals magazine independent sources for imported calcined refractory-grade bauxite were as follows: Chinese, typical 85% alumina (Al₂O₃), f.o.b. barge, Burnside, LA, \$85 to \$120 per ton; and Guyanese, f.o.b. rail car, Baltimore, MD, or f.o.b. barge, Gulf Coast, \$175 ton. Abrasive-grade bauxite, minimum 86% Al₂O₃, c.i.f. main

European ports, was priced at \$95 to \$108 per ton. Base prices were subject to adjustment for various grain-size specifications, size of order, and fuel cost factors.

A growing alumina surplus on world markets led to prices easing from the very high levels established during the previous 2 years. The average value of domestic calcined alumina shipments was estimated to be \$205 per ton. Trade data released by the Bureau of the Census indicated the average value of imported calcined alumina was \$182 per ton, f.a.s. port of shipment, and \$194 per ton, c.i.f. U.S. ports. Beyond these current prices, medium-term projections support a reasonably resilient market outlook for alumina toward the mid-1990's.

For 1992, the International Bauxite Association (IBA) recommended that its members set their minimum c.i.f. price for metallurgical-grade bauxite between 2% and 2.5% of the composite reference price for primary aluminum ingot, and for metallurgical-grade alumina between 14.5% and 16.5% of the composite reference price for primary aluminum ingot. Before Australia's withdrawal from the IBA in late 1992, the organization's members accounted for approximately 77% of the total world bauxite output and about 47% of the alumina production. **Following** Australia's departure, IBA member countries produced 38% of the world's bauxite and 18% of its alumina. (See table 21.)

Foreign Trade

Dried bauxite exports from the United States totaled 54,400 tons in 1992, a moderate increase over the 1991 total of 37,800 tons; Canada received 98% of the 1992 exports. U.S. exports of calcined refractory-grade bauxite totaled 5,500 tons for 1992; Mexico received 91% and Canada 9%. Exports of all other grades of calcined bauxite (chiefly abrasive grade) amounted to 3,000 tons for the year. Mexico received 68% of this total. Specialty aluminum compounds exported included 5,100 tons of aluminum sulfate, 6,300 tons of aluminum chloride, 10,400

tons of aluminum oxide abrasives, and 15,000 tons of various fluoride-based compounds of aluminum, including synthetic cryolite and aluminum fluoride.

Imports for consumption of crude and dried bauxite decreased by 8% from the level of 1991 receipts, and the three principal suppliers, Jamaica, Guinea, and Brazil, in order of shipments, provided 82% of the total. As in previous years, China and Guyana remained the dominant suppliers of calcined bauxite to the United States. Australia continued to be the primary source of U.S. alumina imports, accounting for approximately 75% of the total receipts for the year. (See tables 22, 23, 24, and 25.)

World Review

World production of bauxite and alumina declined in response to a continued sluggishness in demand for primary aluminum metal and the continued flood of aluminum from the former U.S.S.R. Twenty-eight countries reportedly mined bauxite in 1992, and the total world production of bauxite declined to 103.6 million tons, a decrease of 4% below 1991 production. Australia. Guinea, Jamaica, and Brazil, in order of volume, accounted for slightly more than 70% of the total bauxite mined during the year. The corresponding world output of alumina decreased to 41.5 million tons, which was 2% below the 1991 production level. The three principal producing countries. Australia. the United States. and Jamaica, in order of volume, supplied approximately one-half of the total world production.

Capacity.—The 1992 world annual rated capacity of plants producing alumina increased by 3% above last year's level. At the same time, apparent worldwide refinery capacity utilization for 1992 was estimated at approximately 87% and represented a decrease of about 3% from that of the previous year. As has been the case in recent years, further increases in smelter-grade alumina production capacity are expected to develop primarily from incremental expansions of existing plants and only in

very special situations from new greenfield refineries, which normally demand a 4- to 5-year design, engineering, and construction period, plus very significant levels of capital investment.

Argentina. - Aluminio Argentino SACI (Aluar) reportedly began to take advantage of the Mercosur Regional Integration Trade and Agreement involving Argentina, Brazil, Paraguay, and Uruguay. The regional agreement has induced Aluar to alter its longstanding policy of purchasing all of its alumina feed from Alcoa of Australia. Instead, has commenced purchasing approximately one-third of its smelter-grade alumina from Alcoa of Brazil. This exempts the company from a 5% duty on raw materials imposed by the Argentine Government in November 1991. The new Brazilian alumina supply arrangement also saves on shipping costs, and there are expectations that further accords among the Mercosur nations may result in the removal or lowering of tariff barriers between member countries. which could result in additional savings for Aluar.

Australia.—In 1992, production levels dropped in Australia, the world's largest bauxite- and alumina-producing country. Bauxite output was down by about 1.4% and alumina dropped by nearly 0.8%.

The export shipping facilities of Comalco Ltd. at Weipa, Cape York Peninsula, Queensland, were temporarily closed due to damage sustained from a tropical cyclone that struck the region on January 10, 1992. In spite of this disruption, Comalco announced that a historic landmark was achieved during its business quarter ended June 30, 1992, when the 200 millionth ton of bauxite was shipped from Weipa since mining commenced at the site in 1963.

Comalco's initial long-term contract for the supply of bauxite to the participants in the Queensland Alumina Ltd. (QAL) refinery at Gladstone, Queensland, expired at the end of 1992. Reportedly, agreement to extend these contacts with two of the QAL joint-

venture participants had not been reached by yearend, and renewal terms were the subject of litigation. In the interim, existing terms were to apply for ongoing QAL bauxite requirements through 1993.

The joint Comalco-Alcan feasibility study for a new 1-million-ton-per-year alumina plant based on undeveloped bauxite deposits in northern Queensland's Weipa region reportedly was nearing completion at the end of 1992. The viability of various Queensland coastal plant sites had been assessed, and a decision on the next phase of the evaluation program was expected near the end of 1993.

In addition, Comalco indicated that significant changes to the work environment were initiated at its Weipa operations in 1992, including job redesign and the elimination of compulsory union affiliation as a condition of employment.

In further developments at Weipa, Comalco opened a new land use and environmental research center designed to provide scientific and technical support for the rehabilitation of the approximately 8,000 hectares of land that is expected to be impacted by the company's bauxite mining operations over the next 30 years.

During the latter part of 1992, Alcoa of Australia announced the completion of its expansion project at the Wagerup alumina plant in Western Australia. The expansion increased the plant's capacity by 630,000 tons to an annual 1.5 million tons. Even a further level of expansion that would raise the plant's capacity by an additional 250,000 tons per year was reportedly under consideration at yearend. This newly contemplated expansion would involve the addition of a third ball mill to the facility and, if implemented, would come on-stream in early 1994.

The new A. J. Parker Cooperative Research Centre at Curtin University in Perth, Western Australia, announced the establishment of an extensive research program devoted to the development of new hydrometallurgical techniques for use in the processing of minerals. Alumina was specifically identified as a principal focus of this work. The research effort was developed as a cooperative venture funded by Australia's Federal and State

governments in conjunction with private industry.

An International Bauxite Tailings Workshop (Bauxite Washing and Bayer Process Residues) was held in Perth, Western Australia, November 2-6, 1992. The meeting represented a continuation of an international program convened for the purpose of supporting scientific research into bauxite tailings disposal and a continuing search to develop possible commercial applications for these wastestream materials.

Effective October 1992, Australia withdrew as a member of IBA, a producers' organization that Australia helped to create in 1974. Australia indicated that its membership in the IBA was no longer warranted, particularly in light of the escalating organizational costs (estimated at approximately \$295,000 per year).

Brazil.—Industry sources indicated that a formal decision by potential Japanese participants in the long stalled Alumínio do Norte do Brasil S.A. (Alunorte) alumina plant near Belém in northern Brazil continued to be delayed and any further judgement on the project would not likely be made until mid-1993.

Mineração Rio do Norte S.A. (MRN), Brazil's largest bauxite producer, exported 250,000 tons of bauxite from its Trombetas Mine in the Amazon region to alumina plants within the newly independent republics of the former U.S.S.R. Negotiations were conducted during the year to finalize export contracts for future shipments of bauxite to Kazakhstan and Ukraine. Bauxite prices for these supply agreements were expected to range between \$22.50 and \$23.00 per ton.

In May, the Alumínio do Maranhão S.A. (Alumar) alumina plant at São Luis, Maranhão, in the northeast of Brazil, achieved an alltime record for equipment availability—99.1%. In the following month, the Alumar facility recorded its lowest real-term costs for alumina production since the facility commenced operation in 1984.

Canada.—The two new primary

aluminum smelters that were commissioned in Quebec during 1992, Alouette and Lauralco, reportedly had secured their alumina supplies through contracts with Australian producers. The alumina for the Alouette smelter would initially be supplied by Gove Alumina for a period of 3 years. The smelter's six owners agreed that a single source of alumina was essential for smooth and efficient operation of the facility. In view of the fact that each of the joint-venture partners had its own alumina source and some of the contracts were with suppliers other than Gove, an interchange system was developed to ensure that all of Alouette's alumina would come from one source. Lauralco's alumina requirement reportedly would be supplied on a long-term contract from Alcoa of Australia's Kwinana refinery in Western Australia.

China.—The Chinese central Government reportedly has committed additional funds for the modernization of the 600,000-ton-per-year Zhengzhou alumina plant in Henan Province. The allocation of these funds was part of an effort by the Government to increase domestic alumina production, thereby reducing imports that were reported to have reached record levels.

Ghana.—The Ghana Bauxite Co. Ltd. projected that its total 1992 sales of washed bauxite would reach the 375,000-ton level at yearend. A modernization plan undertaken to improve the railway system used for shipment of bauxite from the Ichiniso Mine, near Awaso in western Ghana, to the port of Takoradi was completed in 1992. In addition, the wharf and loading facilities at the port were rebuilt to allow the loading of barges for the movement of bauxite to self-loading ships located off shore.

Greece.—Bauxites Parnasse Mining reportedly suspended bauxite production until February 1993 and commenced drawing down inventories in response to declining sales to the former U.S.S.R. and Romania.

In addition, the proposed

700,000-ton-per-year Greek-Russian alumina project planned for Thisvi, near Athens, remained on hold in 1992. The project's principal controlling interest, state-owned Hellenic Industrial Development Bank (ETVA), initiated a search for third party investors to participate in the \$850 million project.

Guinea.—Friguia, the sole alumina producer in Africa, was scheduled to receive approximately \$18.5 million from the European Investment Bank for modernization of its alumina plant at Kimbo and improvement of the railway link between the plant site and the port of Conakry. Under the plan, annual production capacity would be increased from 642,000 tons per year to more than 700,000 tons per year. The entire project was slated for completion within 2 years.

It was announced that the state-owned Office des Kindia (OBK) had been transformed into a limited company named Societe des Bauxites de Kindia (SBK). This restructuring effort was apparently designed to increase the company's operating efficiency, and there reportedly were related plans to seek sources of private business capital.

Belgium's Tractebel Industrie SA declared that it had signed an engineering services agreement to undertake the rehabilitation and expansion of the Compagnie des Bauxites de Guinee (CBG) bauxite treatment facilities in Guinea. The agreement was related to the first phase of CBG's project to upgrade its Kamsar ore treatment plant (drying and calcining kilns). The entire improvement project was designed to maintain CBG's 12-million-ton-per-year level of bauxite production and reportedly would cost \$170 million, 70% of which will be financed by a loan from the African Development Bank (ADB). The expansion portion of the program provides for the development of the Bidi-Koum deposit to offset the decline in production at CBG's Sangaredi Mine. The rehabilitation elements of the ADBsupported project involve the Kamsar ore treatment plant upgrade, installation of a new power station, and renovation of the Sangaredi to Kamsar railroad system.

Guyana.—The Government of Guyana commenced restructuring the administration of its bauxite industry in an attempt to cut losses and lift productivity before the intended sale of its bauxite interests during the coming 2 years. To prepare for this privatization move, an 18-month contract for the management and reorganization of the bauxite industry was awarded to Minproc Engineering, Australia. Minproc was also assigned responsibility for marketing Guyana's metallurgical and calcined grades of bauxite.

Hungary.—Late in 1992, HungAluker, the trading arm of Hungary's aluminum group, Hungalu, signed an agreement with the Russian trading organization Raznoimport and the Russian aluminum smelter at Volgograd. The contract involved the export of 150,000 tons of alumina from Hungary by railway via Ukraine to Volgograd, in exchange for 27,500 tons of aluminum ingot that would be used as feed to produce semis at Hungalu's operations in Hungary.

The 7th International Congress of ICSOBA (International Committee for the Study of Bauxites, Alumina, and Aluminium) was held at Balatonalmádi and Tapolca, Hungary, in mid-June. Principal sponsors of the conference included the United Nations Development Program (UNDP) and Hungalu, plus its associated subsidiary companies.

India.—The Indian Government reportedly has provided its preliminary approval to three export-oriented alumina projects that were to be developed in India's eastern State of Orissa. The companies that received permission from the Government to construct the plants were: an Indian Aluminium (Indal) and Tata Industries joint venture, the engineering company Larsen & Toubro, and the R.P. Goenka Group. Each proposed plant would initially produce 1 million tons of alumina per year.

In a related matter, India's National Aluminium Co. (Nalco) reportedly signed an agreement with Norway's Hydro Aluminium A.S. to commence work on a detailed feasibility study for setting up a

\$600 to \$800 million, 900,000-ton-per-year alumina plant in the Koraput district of Orissa.

Additionally, the Hindustan Aluminium Corp. Ltd. (Hindalco) has begun increasing the capacity of its alumina plant at Renukoot in Uttar Pradesh from 300,000 tons per year to 350,000 tons per year. This 50,000-ton expansion project should be completed by the end of 1993. The company reportedly also has retained Lurgi AG of Germany to investigate the feasibility of a further expansion of this facility, as well as methods to improve the energy efficiency of the operation.

It was announced that Bharat Aluminium Co. Ltd. (Balco) had acquired control of a new bauxite mining property at Maniper, Sarguja district, Madhya Pradesh, in central India. The mine reportedly has proven reserves of 8 million tons and it has, for the present, alleviated Balco's immediate concern regarding the depletion of its bauxite reserves. It was also expected that an additional bauxite deposit with a 6-million-ton reserve base would be leased by Balco in the near future.

Gujarat Mineral Development Corp. (GMDC) proceeded with its previously declared plans to construct a 50,000-ton-per-year bauxite calcination plant in western India. GMDC expected the plant to be in operation by mid-1993, producing both refractory- and abrasive-grade bauxite, primarily for domestic markets.

Indonesia.—In 1992, a sharp decline in bauxite exports to the United States brought Indonesia's production of washed bauxite to the lowest level in 5 years. This drop was largely attributed to a lapse in shipments to a principal U.S. bauxite customer. The outlook for 1993, however, appeared much brighter because PT Aneka Tambang, the country's only producer of bauxite, had entered into a 5-year agreement to supply approximately 500,000 tons per year to Reynolds Metals Co.

Iran.—It was reported that Iran and Bahrain had agreed to construct a joint-

venture alumina plant on Iran's Persian Gulf island of Qeshm, in the Strait of Hormuz. The site selected for this planned alumina facility would be near the proposed \$1.35 billion, 220,000-ton-per-year Al-Mahdi aluminum smelter project at Bandar 'Abbas that was to be constructed by Iran and the Dubai-based International Development Corp.

In another development, Iran signed an agreement with Guinea for the formation of a joint-venture company to mine Guinean bauxite. Guinea will hold 49% of the new company, and the remaining 51% will be shared between three unnamed Iranian firms. In addition, Iran has reportedly invited the Malaysia Mining Corp. Bhd (MMC) of Malaysia to participate in this and other proposed African mining ventures.

Ireland.—At the close of 1992, the Aughinish Alumina Ltd. refinery, near Limerick, achieved a previously unattained annual alumina production record of more than 1 million tons. It was through the completion of a major expansion plan, initiated in 1989, to raise the plant's annual capacity from 800,000 tons per year that Aughinish Alumina was able to reach the record breaking 1,007,000 tons produced in 1992.

In a related development, late in the year, Billiton B.V. announced that it planned to sell most of its downstream business operations, including its 35% share in Aughinish Alumina Ltd. Alcan of Canada was the holder of the remaining 65% equity share in this alumina operation.

Italy.—Eurallumina SpA, Italy's alumina producer, was to be included in the 3-year restructuring plan being developed for the country's state-owned aluminum sector, comprising Alumix SpA and its subsidiaries. The primary objective of the effort was to return the Alumix group to profitability within the next 3 years and to prepare these business entities for eventual privatization.

Jamaica.—The Jamaican Government reportedly entered into negotiations with

Russia's foreign trade organization Raznoimport in an attempt to recover about \$4.5 million in payments for bauxite that Jamaica delivered under an agreement with the former U.S.S.R. in 1991.

In mid-1992, a new 2-year labor agreement was reached between Alumina Partners of Jamaica (Alpart) and its workers' unions. The contract provided Alpart's 2,000 employees with a 112% wage increase during the first year of the agreement and a 28% raise in the second. Alpart remains a joint-venture company owned by Kaiser Aluminum Corp. of the United States (65%) and Hydro Aluminium A.S. of Norway (35%).

capacity increases proposed by Jamaica's alumina producers come on-stream as planned, alumina production in the country would increase by approximately 50% through 1997. Alpart has announced plans to raise its annual production capacity from a current 1.2 million tons per year to 1.5 million tons by mid-1993 at an estimated cost of \$180 million. Jamalco (Government of Jamaica 50% and Alcoa 50%) planned to increase capacity at its Clarendon plant from 800,000 tons per year to an annual rate of 1 million tons. Alcan, in the meantime, proposed to boost the combined capacity available from its two Jamaican alumina plants by 200,000 tons to 1.2 million tons per year.

Additionally, the Jamaica Bauxite Institute (JBI) commenced a program to assess the feasibility of constructing a caustic soda plant to serve Jamaica's alumina industry. It has been estimated that Jamaica presently consumes about 300,000 tons per year of caustic soda. primarily imported from North America. The study was designed to examine the viability of establishing a caustic soda plant based on locally available limestone and imported soda ash. To assist the JBI with this project, the European Investment Bank of Luxembourg approved a loan of approximately \$350,000 to fund the feasibility work. The loan was provided on a contract liability basis such that if the project proceeds to a commercial-scale operation then the loan would be repaid; if not, the loan would be forgiven. Work on the 6to 7-month study was expected to commence in November with an initial market assessment that, if favorable, would be followed by a technical and engineering design study.

At the close of 1992, after about 6 months of delay, plans to reactivate the Lydford bauxite mine near Ocho Rios, Jamaica, were approved by Ukraine, and the formation of a mining joint venture awaited receipt of final financial guarantees. Under the agreements, the Nikolayev Alumina Plant in Ukraine, Jamaica Bauxite Mining Ltd., and American business interests proposed to reopen the mine, which Reynolds had closed in 1984.

Japan.—In 1992, Nippon Light Metal's Shimizu alumina plant in central Japan hosted a trial run of Alcan's new technology for alumina production. The process reportedly saves energy and materials, thereby reducing production costs. Alcan currently holds a 45.3% interest in Nippon Light Metal Co., Ltd.

Korea, Republic of.—The Korea General Chemical Corp. (KGCC), a state-owned enterprise, reportedly awarded a contract, valued at approximately \$215 million, to Kaiser Engineers Australia for the design and construction of a 215,000-ton-per-year alumina plant in the Mokp'o area of southeastern Korea. KGCC officials anticipate that the plant should commence production by mid-1995. The plant's output of high-purity alumina trihyrate has been targeted to supply domestic markets for specialty aluminas, such as those used in chemical and ceramic applications.

Malaysia.—In 1992, Alcan exchanged its participation in Johore Mining and Stevedoring Co. Sdn Berhad for additional shares in Nippon Light Metal Co., Ltd. (NLM) of Japan. The mining operations at Pengerang, Johor, supply bauxite to NLM's Shimizu, Japan, alumina plant and to third parties.

Netherlands.—Billiton Marketing and

Trading (BMT) commenced a 7-year contract for the supply of alumina from Suriname to the Aluminium Delfzijl aluminum smelter in the Netherlands. Under the terms of the contract, BMT was to supply 150,000 tons of alumina in 1992, and then would supply 100,000 tons per year for the remaining years of the contract.

Russia.—One of the principal issues addressed at the International Aluminum Conference held in St. Petersburg, Russia (September 15-18), was the supply of raw materials to the aluminum industry of the former U.S.S.R. It was estimated that the Russian state-owned aluminum consortium, Aluminiy, would need to import approximately 4 million tons of bauxite and about 1.7 million tons of alumina for its primary metal production facilities in 1992.

Preliminary plans were presented in 1992 to develop the Sredniy-Timan bauxite deposit in the northern Russian autonomous Komi republic. Government officials proposed that a joint stock company be set up to carry out development of this bauxite mining project.

For 1992, it was reported that the Russian Ministry of Industry allocated to Russia's primary aluminum producers export quotas totaling 930,000 tons of metal. Of that total amount, 615,000 tons was to be sold for the purchase of raw materials through the foreign trade organizations Raznoimport and Tsvetmetexport, and 315,000 tons was designated to be traded for the purpose of replenishing Russia's hard currency reserves.

At midyear, it was announced that Russia would impose a new series of mineral production levies on companies extracting mineral resources from within its territory. The taxes were retroactive to June 1 and applied to both domestic and foreign firms. In the case of bauxite production, the levy was placed at the 3% level.

Sierra Leone.—The Sierra Leone Ore and Metals Co. Ltd. (Sieromco), a wholly owned subsidiary of AlusuisseLonza, reportedly continued its bauxite | per year. (See tables 26 and 27.) exploration program in the Gbonge Hills region, to the southeast of Gondama, and it was anticipated that mining operations would commence at the site in the near future.

South Africa, Republic of.-Alusaf Pty. Ltd. has developed long-term alumina supply contracts with Alcoa and Billiton to provide the 900,000 tons per vear of alumina required to feed its planned 466,000-ton-per-year greenfield primary aluminum smelter at Richards Bay, Republic of South Africa.

Spain.—It was reported that Inespal's subsidiary Alumina Espanola entered into an agreement to purchase 1,404,000 tons per year of bauxite for its San Ciprian alumina plant in northwestern Spain. The supply contract with Alcan was scheduled to run until 1995.

Suriname.—Late in 1992. Government of Suriname prepared a currency reform package to help eliminate the gridlock that had developed in new aluminum industry investments. Reportedly, the principal obstacle to bauxite-alumina-aluminum expansion in Suriname had centered on the currency exchange rates that the foreign producers were required to contend with in their daily business operations. The reform package recommended sizable devaluation of the local currency, elimination of various price and trade control measures, plus a tighter check on the nation's budget deficit.

Venezuela. - CVG-Interamericana de Alumina, C.A. (Interalumina) reportedly set the first half of 1996 as the startup date for a third production line based on Alusuisse technology at its Puerto Ordaz alumina plant. This would result in Interalumina's total capacity being increased from 2 million tons per year to 3 million tons per year. Accordingly, to accommodate this alumina expansion, Venezuela's CVG-Bauxita Venezolana C.A. (Bauxiven) ultimately would need to increase domestic production at its Los Pijigauos bauxite mine to 8 million tons

Current Research

In 1992, the USBM reported on research conducted as part of a previously funded program to study processes for the extraction of alumina from domestic resources.⁶ In this project, a bench-scale evaporative crystallizer was operated with solutions of impure aluminum chloride hexahydrate (ACH). The primary purpose of the research was to determine the distribution of impurities in the bleedstream section of a proposed clay-HCl process for production of alumina. Phosphorus was established to be the principal contaminant that affected operation of the crystallizer. Chromium, magnesium, potassium, and sodium impurities were found to require smaller bleedstreams than would be necessary for phosphorus.

The Florida Institute of Phosphate Research (FIPR) reportedly has developed a dewatering process that may achieve promising results on red mud waste streams from Bayer process operations. The FIPR process consists of adding pulp fibers (3 to 6 mm in length) with a polyacrylamide flocculant. The fibers assist in the formation of large flocs that have the physical stability to withstand normal industrial dewatering techniques.

Biological methods of converting sodium oxalate (Na₂C₂O₄), a hazardous substance generated from Bayer-process production of alumina, have reportedly been tested independently at the pilot plant level by Alcan in Jamaica and Worsley Alumina Pty. Ltd. in Australia. The use of micro-organisms to dispose of sodium oxalate was said to be far simpler and cheaper than the currently employed burning and landfilling methods of disposal. It was reported that Worsley Alumina had operated a 8-ton-per-year pilot plant since early 1992 and has commenced work to optimize the process for application to its 1.6-million-ton-peryear alumina plant at Collie, Western In the Worsley Alumina Australia. process, sodium oxalate filter cake from a caustic waste liquor was slurried with water and placed in an aerated tank along with bacilli, which converted the Na₂C₂O₄ into sodium carbonate and bicarbonate. It was determined that this biological process operated best when the pH was between 9 and 11.

The method employed by Alcan at its Ewarton, Jamaica, alumina plant utilized the micro-organism. pseudomonas oxalaticus. to consume the sodium oxalate. Alcan's pilot plant work has achieved a 95% level of sodium oxalate elimination with the corresponding destruction of 2 tons per month of this hazardous waste. In the Alcan process, sodium oxalate precipitate was dissolved in water, at a concentration of about 10 to 15 grams per liter. The solution was then introduced into a biological contactor, where the bacteria, immobilized on disks, rotated between the solution and air to convert the oxalate into sodium carbonate. The pH level was maintained between 9 and 9.5, and some fertilizer was added as a nutrient. Alcan reportedly was considering plans to scale up the pilot plant in 1993.

In 1992, researchers from BHP Co. Ltd. reported on continuing investigations dealing with the use of manganese dioxide (MnO₂) for carbon removal from Bayer liquors.⁷ Their work showed that the selective oxidation of alumina plant liquors by MnO₂ can result in substantial increases in alumina yield. Manganese dioxide treatment also was found to cause a beneficial decrease in the soda content of the alumina and that a small reduction in the total organic carbon levels with this treatment also may be significant in improving the viscosity of the liquor. Additionally, preliminary financial calculations developed in this BHP study demonstrated that the MnO₂ process was most economically viable when applied as a sidestream process treating a spent liquor and used in combination with a subsequent sodium oxalate removal step, at an increased level of liquor causticization.

Engineers at Southwest Research Institute (SWRI), San Antonio, TX, reportedly have developed a new series of composite materials known as MIMLC's (micro-infiltrated, macro-laminated composites). These materials are suitable for use in armored vehicle and spacecraft shields by providing the structures with resistance to high-velocity impact and protection against multiple impacts. A SWRI developed MIMLC, consisting of alternating layers of nickel and aluminanickel, recently was successfully tested as an armor material against tungsten heavy alloy-based penetrators.

Researchers at Yoshida Kogyo Co. (YKK) have developed a ultrafine, hexagon-shaped alumina with a grain diameter of approximately 1 micron and a thickness of approximately 0.1 micron. The newly developed alumina has fluidity characteristics similar to those of clay, offering possible applications in ceramics, papermaking, cosmetics, and coating products.

OUTLOOK—BAUXITE AND ALUMINA

Known world bauxite reserves are sufficient to meet cumulative world demand well into the 21st century. Considering the high probability of discovering additional bauxite deposits and assuming reasonable energy costs, plus the added possibility of employing lower grade bauxite deposits and other alternative sources of alumina, world resources of aluminum remain adequate to satisfy demand for the foreseeable future.

The shift of alumina production facilities from the aluminum-producing industrial countries with high energy costs, in North America and Europe, to the bauxite-producing countries of the world is expected to continue. If the costs of imported bauxite and alumina increase for U.S. companies, alternate domestic sources of alumina may become economically more attractive. Alternatively, high fuel prices tend to nonbauxitic make materials less competitive because the processes for treating substitute materials require considerably greater energy inputs than Bayer-processed bauxite. Therefore, it seems evident that nonbauxitic sources of aluminum would become viable only within the context of a prolonged national emergency or international embargo extending over a period of several years.

Imports of primary aluminum metal from countries with low electrical energy costs and secondary production from recycled aluminum appear likely to be used in ever-increasing proportions to meet the domestic demand for aluminum.

In the future, the continued and extended economic restructuring of Eastern Europe and the newly independent republics of the former U.S.S.R. appear to provide substantially increased market opportunities for the firmly established bauxitealumina-producing countries of the world. The quality and quantity of bauxite resources within the former Eastern bloc nations are believed to be incapable of sustaining an economically sound market-based aluminum industry. become truly competitive in the "new global economy," major amounts of imported bauxite and alumina feedstocks will be required to supply the primary aluminum production facilities of the former U.S.S.R. The most crucial element in the development of this trade pattern will be the implementation of adequate and reliable payment mechanisms for the transfer of these vital raw materials from their producers to the aluminum industry of the former U.S.S.R.

Beyond alumina's principal use as a feedstock for the production of primary aluminum metal, the future will include an increased demand for alumina in specialty markets (abrasive, ceramic, chemical, new materials, and refractory applications). Economic forecasts project that these very specialized markets will become significant profit centers for the world's principal bauxite and alumina producers.

Total of all scrap consumed 6	"98,216	2,944,955	2,960,674	82,497

Revised.

¹Includes imported scrap. According to reporting companies, 3.87% of total receipts of aluminum-base scrap, or 112,286 metric tons, was received on toll arrangements.

²Includes inventory adjustment.

³Includes data on foil, can stock clippings, and other miscellaneous.

^{*}Used beverage cans toll treated for primary producers are included in secondary smelter tabulation.

⁵Includes municipal wastes (includes litter) and fragmentized scrap (auto shredder).

⁶Data may not add to totals shown because of independent rounding.

⁷Data revised to zero.

PPreliminary. 'Revised.

Source: The Aluminum Association Inc.

¹Positive figure indicates a decrease in stocks; negative figure indicates an increase in stocks.

²Metallic recovery from purchased, tolled, or imported new and old aluminum scrap expanded for full industry coverage.

³Apparent aluminum supply available for domestic manufacturing less recovery from purchased new scrap (a measure of consumption in manufactured end products).

¹Data may not add to totals shown because of independent rounding.

Estimated. Revised. W Withheld to avoid disclosing company proprietary data.

The U.S. Bureau of Mines defines primary aluminum as "The weight of liquid aluminum as tapped from pots, excluding the weight of any alloying materials as well as that of any metal produced from either returned scrap or remelted materials." International reporting practices vary from country to country, some nations conforming to the foregoing definition and others using different definitions. For those countries for which a different definition is given specifically in the source publication, that definition is provided in this table by footnote. Table includes data available through June 2, 1993.

Reported figure.

³Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁴Formerly part of Yugoslavia; data were not reported separately until 1992.

⁵Primary ingot.

Exchades high-purity aluminum containing 99.995% or more as follows, in metric tons: 1988—13,628; 1989—15,696; 1990—16,292; 1991—19,652; and 1992—20,000 (estimated).

⁷Primary unalloyed ingot plus secondary unalloyed ingot.

⁸Primary unalloyed metal plus primary alloyed metal, thus including weight of alloying material.

Dissolved in Dec. 1991.

¹⁰Dissolved in Apr. 1992.

¹¹Data may not add to totals shown because of independent rounding.

¹Excludes calcined bauxite. Includes bauxite imported to the U.S. Virgin Islands.

TABLE 15 PRODUCTION AND SHIPMENTS OF ALUMINA IN THE UNITED STATES

Estimated. Revised. W Withheld to avoid disclosing company proprietary data; not included in "Total."

¹Table includes data available through June 15, 1993.

²Reported figure.

³Formerly part of Yugoslavia; data were not reported separately until 1992.

⁴Dry bauxite equivalent of crude ore.

⁵Less than 1/2 unit.

Bauxite processed for conversion to alumina in Jamaica plus kiln-dried ore prepared for export.

⁷Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁸Public-sector production only.

Dissolved in Dec 1991. In addition to the bauxite reported in the body of the table, two of the former Republics of the U.S.S.R. produce nepheline syenite concentrates and alumite ore as sources of aluminum. Nepheline syenite concentrate produced in Russia was as follows, in thousand metric tons: 1988—1,639; 1989—1,697; 1990—1,650 (estimated); 1991—1,500 (estimated); and 1992—1,000 (estimated). Estimated alumite ore produced in Azerbaijan was as follows, in thousand metric tons: 1988—625; 1989—600; 1990—550; 1991—500; and 1992—300. Nepheline syenite concentrate grades 25% to 30% alumina, and alumite ore grades 16% to 18% alumina; these commodities may be converted to their bauxite equivalent by using factors of 1 ton of nepheline syenite concentrate equals 0.55 ton of bauxite and 1 ton of alumite equals 0.34 ton of bauxite.

¹Figures represent calcined alumina or the total of calcined alumina plus the calcined equivalent of hydrate when available; exceptions, if known, are noted.

²Table includes data available through June 15, 1993.

⁴Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁵Formerly part of Yugoslavia; data were not reported separately until 1992.

⁶Hydrate.

⁷Data presented are for alumina for metallurgical use. Gross weight of aluminum hydrate for all uses was as follows, in thousand metric tons: 1988—778; 1989—863; 1990—890; 1991-864; and 1992-718 (estimated).

⁸Dissolved in Dec. 1991.

Dissolved in Apr. 1992.

¹⁰Data may not add to totals shown because of independent rounding.

ANTIMONY

By Thomas O. Llewellyn

Mr. Llewellyn, a physical scientist with more than 30 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for antimony since 1987. Domestic survey data were prepared by Elsie Isaac, statistical assistant; and international data were prepared by Ted Spittal, international data specialist.

Reported consumption of primary antimony products increased slightly in 1992 compared with that of 1991. Production of primary antimony increased considerably. Exports and imports of antimony products were also up from those of the previous year. The U.S. International Trade Commission (ITC) unanimously determined that imports of refined antimony trioxide from China did not materially injure or threaten to injure the U.S. antimony trioxide industry, as claimed by a coalition of five domestic antimony trioxide producers.

DOMESTIC DATA COVERAGE

Domestic primary production data for antimony are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the six operations to which a survey request was sent, all responded, representing 100% of the primary smelter production shown in table 1. (See table 1.)

BACKGROUND

Antimony, from the Greek anti plus monos, means "a metal seldom found alone." Although the name was intended to describe the metal's mineralogical association in ores, it also properly describes the use of antimony in modern industry because the metal is usually used as an alloy with other metals. natural sulfide of antimony, stibnite, was known and used in Biblical times as medicine and as a cosmetic for eyebrow painting. A vase found at Tello. Chaldea, reportedly cast in metallic antimony, indicates that in about 4000 B.C. the Chaldeans knew the art of

reducing the sulfide to metal.

The known domestic deposits of antimony ore have generally been small and uneconomical when compared to foreign producers, resulting in a dependence on foreign sources of supply by the United States. Bolivia, China, Mexico, and the Republic of South Africa have historically been the principal sources of supply.

Definitions, Grades, and Specifications

Antimony is seldom found in nature as native metal because of its strong affinity for sulfur and the metallic elements such as copper, lead, and silver. Antimony in its elemental form is a silvery white. brittle, crystalline solid that exhibits poor electrical and heat conductivity properties. The National Stockpile Purchase Specification P-2a-R4, June 10, 1980, covered two grades of refined antimony metal ingot form. Grade A has a minimum antimony content of 99.8% and the following impurity maximums: arsenic, 0.05%; sulfur, 0.10%; lead, 0.15%; and other elements (copper, iron, nickel, silver, and tin), 0.05% each. Grade B material is composed of 99.5% antimony as a minimum with maximum impurity levels of 0.1% arsenic, 0.1% sulfur, 0.2% lead, and 0.1% each of other elements.

Chemical-grade ore is that which is sufficiently pure to be used directly in producing the trioxide, chloride, or other industrial chemical compound. For chemical-grade sulfide ore, total impurities, including arsenic and lead, must not exceed 0.25%, and no single metallic impurity can exceed 0.1%.

Antimony trioxide, the most important

of the antimony compounds, is used in flame-retarding formulations for many materials. Most commercial grades of antimony trioxide contain between 99.2% and 99.5% antimony trioxide with varying amounts of impurities such as arsenic, iron, and lead. Commercial suppliers offer various grades of antimony trioxide based on the relative tinting strength of their product, which is related to average particle size. In general, the tinting strength increases as the particle size decreases.

Industry Structure

In 1992, antimony production from domestic source materials was largely derived from recycling of lead-antimony batteries. Recycling plus mine output supplied less than one-half of the estimated domestic demand. Primary antimony was recovered as a byproduct from the smelting of domestic lead and from silver-copper ores.

Antimony metal and trioxide producers in the United States are essentially large, integrated companies with a variety of activities in marketing and manufacturing of base metals and chemical compounds. A few producers and processors of antimony have interests in foreign operations. Most purchase raw materials from mine and smelter operations either directly or through dealers.

Geology-Resources

Estimates of the abundance of antimony in the Earth's crust range from 0.2 to 0.5 parts per million. Antimony is chalcophile, occurring with sulfur and the heavy metals, copper, lead, and silver.

More than 100 minerals of antimony are found in nature. Stibnite (Sb₂S₃) is the predominant ore mineral of antimony.

Simple antimony deposits consist principally of stibnite or, rarely, native antimony in a siliceous gangue, commonly with some pyrite, and in places a little gold and small amounts of other metal sulfides, principally silver and mercury. Antimony ores commonly are associated with igneous activity and have common genetic association with such intrusives as granite, diorite, and monzonite. The mineralogy of the veins and their almost invariably shallow depth suggest a low temperature of formation at near-surface positions, possibly related to the configuration of the water table at the time of deposition. Most of these geologically simple stibnite deposits do not individually contain more than several thousand tons of ore. Deposits of this type are found in the world's most productive antimony districts, including those of Bolivia, China, Mexico, and the Republic of South Africa.

Complex antimony deposits consist of stibnite associated with pyrite, arsenopyrite, cinnabar or scheelite, or of antimony sulfosalts with varying amounts of copper, lead, and silver, as well as common sulfides of these metals and zinc. Ores of the complex deposits generally are mined primarily for gold, lead, silver, tungsten, or zinc.

Most of the antimony produced in the United States is from complex deposits. The tetrahedrite ores found in the Coeur d'Alene district of Idaho are outstanding examples of complex deposits.¹

Principal identified world antimony resources, at about 5 million tons, are in Bolivia, China, Mexico, the Republic of South Africa, and the former U.S.S.R. U.S. resources are mainly in Alaska, Idaho, Montana, and Nevada.

Technology

Antimony deposits are seldom explored in advance of actual mining because the deposits are generally small, irregular, and difficult to appraise.

Many of the typically small mines contain irregular and scattered ore bodies

that cannot be readily exploited by large-scale mining methods. Mining methods used in mines that recover metalliferous ores, of which antimony is a minor constituent, are designed for producing the principal metals such as gold, lead, or silver.

The antimony content of ores determines the method of recovery. In general, the lowest grades of sulfide ores, 5% to 25% antimony, are roasted; 25% to 40% antimony ores are smelted in a blast furnace; and 45% to 60% antimony ores are liquated. At some mines in Bolivia and the Republic of South Africa, the high-grade sulfide ore is concentrated by hand-cobbing and sold as lump sulfide ore, 60% antimony content. As higher grade deposits have become depleted, increasing emphasis has been placed on upgrading low-grade ores by flotation.

Roasting of the ore to yield a volatile trioxide or the stable nonvolatile tetroxide is the only pyrometallurgical procedure suitable for low-grade ores (5% to 25% antimony content). The sulfur is oxidized and removed from waste gases, and the volatilized antimony oxide is recovered in flues, condensing pipes, a baghouse, precipitators, or a combination of the aforementioned. The temperature and quantity of available oxygen determine the kind and quantity of the oxide produced. The oxide produced by this method is generally impure and can be reduced to metal. However, careful control of volatilization conditions will produce a high-grade oxide that can be sold directly to consumers.

Water-jacketed blast furnaces are used in several plants to reduce ores containing 25% to 40% antimony. Oxides, sulfides, or mixed ores, residues, mattes, slags, and briquetted fines or flue dusts can be used as blast furnace charges. A high smelting column and comparatively low air pressure are used, and the slag and metal are separated in the hearth.

Antimony sulfide can be separated from the gangue of sulfide ores by melting in a reverberatory furnace. A reducing atmosphere is kept to prevent oxidation. The solidified product is called liquated or needle antimony and may be used as sulfide or converted to

antimony metal by iron precipitation.

Some complex ores can be treated by leaching and electrowinning to recover the antimony. A typical process uses an alkali hydroxide or sulfide as the solvent. The filtered leach solution containing sodium thioantimonate, Na₃SbS₄, is electrolyzed in a diaphragm cell using an iron or lead anode and an iron or mild-steel cathode. The cathode metal obtained is 93% to 99% pure antimony.²

Antimony metal is also produced as antimonial lead, which is an important product of the secondary lead smelter. A blast furnace charge containing used or discarded battery plates, type metal, and bearing metal is reduced to a lead bullion. The bullion is refined in reverberatory furnaces and melting pots to meet specifications.

Byproducts and Coproducts

Most of the domestic primary antimony production is a byproduct or coproduct of mining, smelting, and refining other metals and ores that contain relatively small quantities of antimony. In 1992, domestic production of antimony was mainly a byproduct of treatment of tetrahedrite, a complex silver-copper-antimony sulfide ore. An undisclosed amount of antimony was also recovered as a byproduct of the processing of lead ores.

The antimony deposits of the Republic of South Africa contain gold. High-grade Bolivian antimony ores contain variable and minor values of gold and tungsten and objectionable amounts of arsenic, copper, and lead in some deposits. Chinese ores contain some tungsten.

Substitutes

Compounds of chromium, tin, titanium, zinc, and zirconium substitute for antimony chemicals in paint, pigments, frits, and enamels. A combination of cadmium, calcium, copper, selenium, strontium, sulfur, and tin can be used as substitutes for hardening lead. Selected organic compounds and hydrated aluminum oxide are widely accepted alternative materials

in flame-retardant systems.

Economic Factors

Antimony and antimony trioxide are taxed under the new Superfund Amendments and Reauthorization Act of 1986, Public Law 99-499. The taxes, to be collected from producers and importers, were \$4.90 per ton of antimony metal and \$4.13 per ton of antimony trioxide. The taxes have been rescheduled to end on December 31, 1995.

Antimony producers are granted a depletion allowance of 22% on domestic production and 14% on foreign production.

Under the new Harmonized Tariff Schedule of the United States, which took effect January 1, 1989, antimony ore and concentrates imports from most favored nations (MFN) and non-MFN were duty free. Antimony and articles thereof, including waste and scrap, and antimony oxide were duty free for MFN. However, from non-MFN a statutory duty of 4.4 cents per kilogram was imposed.

Operating Factors

Environmental and ecological problems associated with the processing of antimony metal and ores are minimal because emissions and affluents are controlled at the processing site.

The major conservation practice of the antimony industry is the recycling of the metal in used storage batteries, type metal, and babbitt. Antimony metal and antimonial lead from intermediate smelter products such as slags, drosses, flue dusts, and residues generated at copper and lead smelters are recovered at lead smelters.

Energy requirements for the production of antimony metal and antimony trioxide from stibnite ores are 163 million British thermal units (Btu's) per net ton of antimony metal and 186 million Btu's per net ton of antimony trioxide.³

An estimated 210 persons are employed in the domestic production of

antimony ores and in conversion of antimony ores and raw materials to antimony metal and compounds.

ANNUAL REVIEW

Legislation and Government Programs

On April 25, 1991, a coalition of five U.S. antimony trioxide producers and/or manufacturers of antimony trioxide-base products filed an antidumping petition with the U.S. ITC and the U.S. Department of Commerce (DOC), charging China with unfair trade practices.

The coalition members requesting the initiation of an investigation, on behalf of the U.S. refining antimony trioxide industry, were: Anzon Inc. and Atochem North America, Inc. of Philadelphia, PA; Laurel Industries Inc. of Cleveland, OH; U.S. Antimony Corp. of Thompson Falls, MT; and U.S. Antimony Sales Corp. of Natick, MA.⁴

On February 28, 1992, the DOC announced its final determination that Chinese antimony trioxide entering the United States should be assessed the following weighted-average dumping margins: China National Metals & Minerals Import Corp. (Minmetal), 80%; China National Nonferrous Metals Import & Export Corp. (CNIEC), 13.05%; and all others, 33.10%. However, in April 1992, the ITC unanimously determined that imports of refined antimony trioxide from China did not materially injure this particular U.S. industry.

Strategic Considerations

Antimony was included in the National Defense Stockpile because of its strategic uses in flame-retardant compounds, friction bearings, and batteries. Under the 1992 Annual Material Plan, Public Law 102-484 of October 23, 1992, the Department of Defense was authorized to sell about 1,820 metric tons of antimony metal in addition to about 1,690 metric tons that was previously authorized on September 30, 1992. No inventory acquisitions or sales were made during the year, and, as of December 31, 1992,

the stockpile inventory was 32,658 metric tons of antimony metal.

Domestic Production

Mine Production.—Sunshine Mining Co. produced antimony as a byproduct of the treatment of tetrahedrite, a complex silver-copper-antimony sulfide ore, from the Coeur d'Alene district of Idaho.

Smelter Production.—Primary.—The producers of primary antimony metal and oxide products were ASARCO Incorporated, Omaha, NE; Amspec Chemical Corp., Gloucester City, NJ; Anzon Inc., Laredo, TX; Laurel Industries Inc., La Porte, TX; Sunshine Mining Co., Kellogg, ID; and U.S. Antimony Corp., Thompson Falls, MT.

Secondary.—Old scrap, predominantly lead battery plates, was the source of most of the secondary antimony output. New scrap, mostly in the form of drosses and residues from various sources, supplied the remainder. The antimony content of scrap was usually recovered and consumed as antimonial lead. (See table 2.)

Consumption and Uses

Reported domestic consumption of primary antimony products increased slightly in 1992 compared with 1991. Lead-antimony alloys were used in starting-lighting-ignition batteries, ammunition, corrosion-resistant pumps and pipes, tank linings, roofing sheets, solder, cable sheaths, and antifriction bearings.

Antimony compounds were used in plastics both as stabilizers and as a flame retardant. Antimony trioxide in an organic solvent was used to make textiles, plastics, and other combustibles flame retardant. Antimony was used as a decolorizing and refining agent in some forms of glass, such as special optical glass. The estimated distribution of antimony uses was flame retardants, 72%; transportation, including batteries, 10%; chemicals, 10%; ceramics and

glass, 4%; and other, 4%. (See tables 3, 4, and 5.)

Markets and Prices

The New York dealer antimony metal price, published by Metals Week, started the year ranging from \$0.82 to \$0.84 per pound, held steady during the first quarter, but by the end of the second quarter the price range was at \$0.78 to \$0.88 per pound, and remained constant at that level for the rest of 1992. The price range for high-tint antimony trioxide was \$1.10 per pound at the beginning of the year and remained constant for the rest of 1992.

The European price range quotation for clean antimony sulfide concentrate (60% antimony content), published by Metal Bulletin (London), held steady at \$14.50 to \$16.50 per metric ton unit for the first 9 months of 1992 and decreased to a range of \$14.00 to \$15.50 per metric ton unit by yearend. The European price range quotation for lump antimony sulfide ore (60% antimony content) held steady at \$15.50 to \$17.00 per metric ton unit for the first three quarters of 1992; it decreased during the fourth quarter and closed at \$14.50 to \$16.00 per metric ton unit.

Foreign Trade

Total imports of antimony materials increased about 8% from those of 1991. China supplied about 61% of the total imported materials in 1992. Exports of antimony oxide were about 28% higher than those of the previous year. (See tables 6, 7, 8, and 9.)

World Review

Antimony was produced from ores and as a byproduct of the smelting of base metal ores in about 26 countries. China, the world's leading producer, accounted for about 60% of the total world estimated mine production during 1992. China, together with the other five major producing countries, Bolivia, Kyrgyzstan, Mexico, Russia, and the Republic of South Africa, accounted for about 93% of

the total world estimated mine antimony production. (See table 10.)

The Confederation of European Chemical Industries filed an antidumping petition with the European Commission, charging that imports of Chinese refined antimony trioxide were being dumped in Europe. The Commission determined that there was reasonable evidence to initiate an antidumping proceeding. Antidumping procedures take more than 1 year to be completed; therefore, a report of this investigation is expected to be completed by mid-1993.

Capacity.—Rated annual production capacity for mines and refineries was defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable, long-term operating rate, based on the physical equipment of the plant and routine operating procedures for labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. The total world antimony mine production capacity for 1992 estimated at about 100,000 metric tons of content antimony, and the refinery capacity for the same year was estimated at 110,000 metric tons.

Bolivia.—Empresa Nacional de Fundiciones (ENAF), the state-owned smelting company, increased crude antimony trioxide production at its Vinto smelter by about 25% during 1992. The entire ENAF crude oxide production is shipped to Laurel Industries' plant in La Porte, TX, for a final refining stage.

Japan.—Antimony trioxide production, mainly from imported materials, was estimated at 11,227 tons, a decrease of about 6% compared with 1991 production. Antimony metal production also decreased from 262 tons in 1991 to about 165 tons in 1992.

OUTLOOK

Antimony metal prices remained steady at a low level during 1992, and all indications are that the market will probably not change much within the next 2 years. Domestic antimony trioxide producers struggled to compete with cheaper foreign imports.

The oversupply of antimony products from China that has saturated the market in the past 4 years will continue during 1993, and unless China's policy of offering discounts from the world market price shows signs of changing, the prospects for Western antimony trioxide producers will not improve.

BARITE

By James P. Searls

Mr. Searls, a physical scientist and economist with 16 years of institute, Government, and U.S. Bureau of Mines experience, has been the commodity specialist for barite since 1991. Domestic survey data were prepared by Maria Rosa Arguelles, statistical assistant; and international data were prepared by Virginia Woodson, international data coordinator.

Domestic sales of barite decreased 27% to 326,000 metric tons while apparent consumption decreased 49% to about 637,000 tons. A different measure of domestic consumption, which is referred to as "shipments from crushers and grinders" of both domestically produced and imported barite, indicated a less drastic trend. These operations reported a decline in sales of 21% to 999,000 tons. Exports fell strongly to 12,000 tons, 1989 and 1990 levels, while imports declined very strongly, about 62%, to 323,000 tons.

DOMESTIC DATA COVERAGE

Domestic production data for barite are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the 47 operations to which a survey request was sent, all responded, representing 100% of the crushed and ground production sold or used shown in table 1.

BACKGROUND

Definitions and Specifications

The term "primary barite," as used in this report, refers to the first marketable product and includes crude barite, flotation concentrate, and other beneficiated material such as washer, jig, heavy media, table, or magnetic separation concentrate. Most primary barite requires fine grinding before it is used for drilling muds, the principal end use. This grinding may or may not be done at the mine site.

Barite is the mineralogical name for

barium sulfate and was derived from the Greek word "barus," meaning heavy. In commerce, the mineral is often referred to as "heavy spar" or "barytes." "Spar" means almost any transparent or translucent, readily cleavable, crystalline mineral having a vitreous luster.

Specifications for barite vary according to different uses. Material for weighing muds must be finely ground, dense, and chemically inert; consequently, barite for this purpose must have a specific gravity of 4.2 or higher, it must be free of soluble salts, and 90% to 95% of the material must pass through a 325-mesh screen. A small percentage of iron oxide is not objectionable. In chemical manufacturing, purity is the principal concern, and a maximum of 1% each of ferric oxide (Fe₂O₃) and strontium sulfate (SrSO₄) and a trace of fluorine usually are specified, with a minimum of 94% barium sulfate (BaSO₄). If the mineral is to be used in the production of lithopone, the SrSO₄ content may be somewhat Mesh size is important to higher. chemical manufacturers: if the material is too fine, dust is lost, and if it is too coarse. mixing with carbonaceous material is poor. Most chemical manufacturers specify a size range of 4 to 20 mesh; some purchase lump barite and grind it to their own needs.

Products for Trade and Industry

The principal use for barite, as a weighing material in well-drilling muds, accounted for more than 89% of total U.S. consumption in 1992. Drilling muds have five main functions: (1) transport drill cuttings to the surface, (2)

control formation pressures, (3) maintain borehole stability, (4) protect producing zones, and (5) cool and lubricate the bit and drill string. Barite's lack of hardness (Mohs scale 3 to 3.5) is a plus in this application. The principal function of the barite constituent is as a weighing agent to suppress high formation pressures and prevent blowouts. The deeper the hole, the more barite is needed as a percentage of the total mud mix because hydrocarbon pressures rise strongly with increasing depth after about 2,100 m of depth. The added weight of the barite in the column of mud in the drill string is used to counteract the dangerous pressures when deep reservoirs of hydrocarbons are encountered. High-pressure hydrocarbons, if uncontrolled, can cause extremely dangerous pressure releases and/or fires at the drilling rig.

The use of barite as a filler or extender and other uses accounted for about 11% of total U.S. consumption in 1992. Barite has a high specific gravity, low oil absorption, easy wettability by good sanding qualities. and Unbleached barite may be substituted for bleached barite when brightness is not a factor. In painting automobiles, barite is used as a filler for the primer coat where the barite contributes to the gloss of the topcoat. When the primers are applied by the electrodeposition process, the body structure is dipped into a tank containing water and paint primer. The method eliminates one of the primary coats, thus reducing the quantity of barite used.

Barite also is used as a filler or extender in some plastic and rubber products. Processors of polyurethane foam use barite in manufacturing such products as floormats and carpet-backings to add weight and improve processing qualities. Barite is used in white sidewalls for tires; sidewalls consist mainly of rubber, zinc oxide, and a small quantity of barite.

Other industries use small quantities of barite fillers. In the paper industry, the white and dense barite coatings serve as a base for the sensitized layers in photographic prints. In the printing industry, barite is used in inks.

In glassmaking, barite is added to the glass melt to reduce the heat-insulating froth that forms on the melt surface, thus saving fuel, and to act as an oxidizer and decolorizer, making the glass more workable and increasing its brilliance. Glass manufacturers usually require a minimum of 95% BaSO₄ with a maximum of 2.5% silicon dioxide (SiO₂) and 0.15% Fe₂O₃. The particle size range generally preferred is -30 to +140 mesh. Finely ground barite can be substituted when crushed material is not available. In glass manufacture, barite reduces seeds and annealing time and increases toughness and brilliancy.

Minor uses include ballast for ships, heavy concrete aggregate for radiation shielding and pipe-weighing in low-lying areas, friction products, and applications in foundries.

Barite also is a raw material for barium chemical manufacturing. major barium chemicals are carbonate, chloride, oxide, hydroxide, nitrate, peroxide, and sulfate. The most important barium chemical is precipitated barium carbonate, which is a raw material for production of many of the other compounds. It also is used in brick and tile manufacturing to control scum caused by gypsum or magnesium sulfate in the clay (the barium combines with the sulfate to form the insoluble barium sulfate) and to diminish porosity and prevent discoloration in brick. Other uses are in television picture tubes as a radiation barrier, optical glass, ceramic glazes, porcelain enamel, ferrites, and miscellaneous ceramic products. Bariumbase glass (using barium carbonate) is considered to be more brilliant than lime glass and more durable than lead glass. Barium carbonate is replacing lead oxide in television tube faceplates to stop X-ray radiation. The same amount of strontium carbonate will be used with the barium as was used with the lead. The X-rays occur when the high voltage electrons from the "gun" that excite the phosphors have been stopped quickly at the faceplate.

Blanc fixe, chemically precipitated barium sulfate, is used as a white filler in paints, rubber, inks, and other material where a degree of purity higher than natural barite is required. Lithopone (a white pigment composed of a mixture of barium sulfate, zinc sulfide, and zinc oxide), formerly manufactured in large tonnages for use as a white pigment in paints, has been largely replaced by titanium dioxide.

Barium chloride is used in casehardening and heat-treating baths, in leather and cloth, in making magnesium metal, in preventing scum on brick, in water treatment, and as a laboratory reagent. Fused barium chloride may be electrolyzed to produce barium metal.

Barium metal also is produced by reduction of barium oxide. The metal is used as a "getter" to remove traces of gas from vacuum tubes, or in alloys for spark plugs and electronic emission elements in electronic tubes.

Barium nitrate is used in green signal flares, tracer bullets, primers and detonators, and enamels. Barium oxide is used in electric furnace ferrous metallurgy to increase the life of acid furnace linings, to give a quieter and steadier arc, to reduce the sulfur content of the iron, and to lower the slag viscosity.

Barium hydroxide is used to prevent scumming in ceramics, to make soap for lubricating oils and greases, and to recover sugar from molasses by the barium saccharate process. **Barium** titanate finds use in miniature electronic and communication equipment.

Uses and Products for Trade and **Industry**

Domestic barite production began in

years later, production began in Missouri. In 1880, Tennessee became the third barite-producing State, and 1901 and 1903 saw Georgia and Kentucky, respectively, become producers. California began producing in 1914, Nevada in 1916, and Arkansas in 1941.

Barite was first used as a filler in white paints; however, in 1842, with the advent of the domestic lithopone industry, a second important market opened. In 1908, Chicago Copper Refining Co. (Chicago Copper & Chemical Co., closed since the 1970's) began manufacturing barium chemicals at Blue Island, IL. The first washers and jigs used in the industry were installed in Georgia and Tennessee in 1914-16 and in Missouri in 1923-24. A fourth market for barite came into existence in 1916 when a patent was obtained on the use of barite as a weighing agent in rotary drilling muds; today this is the largest consumer of barite. In 1941, the deposit of barite at Malvern, AK, was opened when Magnet Cove Barium Corp. successfully separated barite from associated minerals by flotation. In 1977, IMCO Services Co. completed a multimillion dollar plant at Mountain Springs, NV, that produced barite concentrate using jigs, concentration tables, and flotation. This combination of beneficiating methods was unique in the barite industry.

Industry Structure

Currently, much of the barite industry, which supplies the drilling mud industry, is supplied by barite from India and China. Many U.S. firms import barite and grind the barite to size in plants along the gulf coast instead of producing it from U.S. mines. Seven mining firms continue to compete in the industry, down from eight in 1991. Only two mining firms continue to compete in the barium chemical industry using domestically mined barite. Several have shut down owing to imported semipure barite.

Geology

Barite is the only commercial source 1845 in Fauquier County, VA. About 5 of barium and barium compounds in the United States. Witherite (BaCO₃) has been produced from the Settlingstones Mine in England, and small quantities enter the United States every year.

Pure barite has a specific gravity of 4.5. Barite varies considerably in appearance depending on source and treatment. It is a moderately soft crystalline material with a Mohs hardness between 3 and 3.5. In residual deposits, it ranges in size from large boulders to fines. Shades of white to dark gray and black, depending on impurities and surficial coating, are common in commercial deposits.

Vein and cavity-filling deposits are those in which barite occurs along faults, joints, bedding planes, and other solution channels or sink structures. These deposits are found most often in limestone. Most of the vein deposits are believed to be of hydrothermal origin.

In central Missouri, barite occurs in circular deposits in karst or collapse and sink structures. These ores are rich, but the deposits are generally small in overall extent. These deposits are also important as the source of the residual ore upon weathering.

Residual barite deposits are formed by weathering of preexisting deposits. The principal residual deposits are found in southeastern Missouri; the Appalachian region; Sweetwater, TN; Cartersville, GA; and in the Rio Grande area of Texas. A concentration of at least 60 to 180 kg of barite per cubic meter is required in a commercial deposit. In Washington County, MO, the residuum is 3 to 5 meters thick, while in Cartersville, GA, the ore is 45 meters thick in some spots. This form of deposit has been of considerable economic significance.

The most important commercial deposits are of bedded barite. These are principally in Arkansas, California, and Nevada. The barite in these areas is generally dark gray to black and has a characteristic fetid odor when struck with a hammer. The beds, which vary in thickness from a few centimeters to more than 15 meters, occur interbedded with dark chert and siliceous siltstone and shale. In most of the deposits, the barite is laminated. In some areas, barite

nodules and rosettes make up a large part of the beds. Many of the beds contain 50% to 95% barite. Originally it was thought that these deposits were the result of the replacement of carbonate rocks; however, current thought is that the deposits are of sedimentary origin. The actual environment of deposition has not been established, but theories range from submarine volcanic emissions to hydrothermal solutions to recycling of barite from preexisting rocks.

Technology

Exploration.—In the past two decades, geological exploration has led to the discovery of bedded barite deposits in Canada, India, Mexico, and the United States. Bedded deposits have not been sought in many parts of the world. If the search for barite expands in the coming years, it is likely that more bedded deposits will be discovered.

Mining.—Residual deposits of barite are generally mined by draglines in open pits after removal of overburden by conventional methods using elevating scrapers, trucks, dumpers, bulldozers, and front-end loaders. The ore is then beneficiated in washer plants equipped with rotary breakers, log washers, trommel screens, and jigs to separate barite from other material. Fine barite in the overflow from the log washers is recovered by tabling and flotation while the jig concentrate is magnetically separated.

Bedded and vein deposits may be mined by open pit or underground methods depending on local conditions. The bedded deposits of Arkansas have been mined by both methods. The ore is crushed and ground for beneficiation by flotation. Bedded barite in Nevada is mined by open pit methods using a combination of bulldozers with ripping teeth and conventional blasting. The ore is picked up by front-end loaders and loaded into dump trucks that haul the ore to a processing plant. In some deposits, the ore is of sufficient grade to be either screened and direct shipped or washed, crushed, screened, and shipped to a

grinding plant; however, much of the ore requires beneficiation by jigging or flotation.

Processing.—Barite grinding is usually accomplished by heated airswept Raymond mills, a type of roller mill; however, ball mills are used when iron contamination is not important, as in drilling muds. Barite is ground either wet or dry. For use in well drilling, barite is ground dry. If the barite requires upgrading by flotation, it is ground wet. Barite also is ground wet when it is to be bleached for filler use: impurities are subsequently removed by treatment with sulfuric acid. bleached barite pulp is then settled and separated, washed, dried, sized, and bagged.

A small amount of barite is converted into a soluble form before its use in the manufacture of lithopone or other chemicals. Crushed barite is roasted with coke in a kiln at about 1,200° C to reduce the barium sulfate to the more soluble compound, barium sulfide, commonly called black ash. The sulfide is leached from the clinker with hot water. By adding zinc sulfate to the leach liquor, an intimate mixture of barium sulfate and zinc sulfide called lithopone is precipitated.

The leach liquor from black ash is also a precursor of a number of barium chemicals. The addition of sodium sulfate precipitates a pure barium sulfate (called blanc fixe). Barium carbonate is precipitated by either carbonating or adding sodium carbonate to the leach liquor. Hydrochloric acid added to the leach liquor produces a solution of barium chloride. Barium carbonate and barium chloride are the starting compounds for the manufacture of many other barium chemicals.

ANNUAL REVIEW

Legislation and Government Programs

The International Trade Administration/Import Administration (ITA/IA) of the U.S. Department of Commerce made a determination not to

revoke the antidumping duty against precipitated barium carbonate from Germany.² The same agency also made a determination that China National Chemicals Import and Export Corp. (SinoChem) had no shipments of barium chloride (2827.38.00) during the period October 1, 1990, through September 30, 1991. The ITA/IA continued the deposit rate previously established of 60.84%.³

The Occupational Safety and Health Administration preliminarily concluded "...that exposure to the soluble compounds of barium causes eye, skin, and mucous membrane irritation and respiratory, gastrointestinal and central nervous system effects."

This does not include barium sulfate, which is quite insoluble and becomes soluble only with an unusual alternating series of anaerobic and aerobic conditions whereby certain micro-organisms can reduce sulfate to sulfite, mobilizing the Ba⁺⁺ ion.

Sales

Of the 47 operations that were surveyed, 6 were idle during the year and 3 were closed, although 1 operation is in the process of being moved, for a total of 38 operating mines, beneficiating plants, and crushing and grinding operations.

Run-of-mine barite sales, the lowest cost primary barite sold or used by producers, dropped to less than 10% of last year's sales as a Nevada firm converted to beneficiation of its mine production. (See table 1.)

For 1992, beneficiated product was 96% of total sales. Shipments from crushers and grinders of both domestically produced and imported barite declined 21% to nearly 1.0 million tons. The difference between "shipments by crushers and grinders" and "apparent consumption" may be a drawdown of importers' stocks. Sales from Nevada were about 73% of the U.S. total from barite-producing States. One mining and beneficiation operation closed during the year, and the remaining operations produced less barite for a slightly higher average price. The barite sales for the principal end use, as a weighing agent in oil- and gas-well-drilling fluids (muds), declined 24% and accounted for 89% of U.S. shipments by crushers and grinders. (See tables 2 and 3.)

For end of year 1992, week-average oil futures prices rose by less than 1% relative to the same week of 1991 while the natural gas price rose by about 17.5% on the same basis.5 The price increase in natural gas occurred later in the year. By October, the Baker Hughes monthly average active U.S. rig count (of 803 rigs) was above the previous year's monthly average for the first time in 18 months. More than one-half of the rigs were drilling for natural gas. For the last full week of the year the Baker Hughes rig count was 928 rigs. The average depth of wells drilled and completed increased from 1,506 m in 1991 to 1,625 m in 1992. There were 10,301 wells deeper than 1,524 m completed in 1992. Deep gas drilling completions (below 1,524 m) were 860 wells in the first quarter, increasing from 866 wells in the second quarter to 1,004 wells in the third quarter and to 1,229 in the fourth quarter. Total gas wells declined from 9,230 in 1991 to 7,145 in 1992. The total number of wells completed (oil, gas, or dry) deeper than 1,524 m was rather stable through the year at 2,534 for the first quarter, 2,498 for the second quarter, 2,690 for the third quarter, and 2.579 for the fourth quarter.

Standard Slag, Inc. idled its Nevada mine and mill and did not sell any barite in 1992. In September, the Baroid Drilling Fluids Inc. announced plans to reopen the Rossi Mine near Dunphy, NV.

Consumption and Uses

The consumption of crushed and ground barite decreased about 21%, from 1.3 million tons in 1991 to nearly 1.0 million tons in 1992. The apparent consumption, as calculated by "sold or used by producers" minus exports plus imports, fell by 49%. The difference could be explained by sales from "crusher's and grinder's stocks." The oil- and gas-well-drilling industry completed fewer than 21,800 wells and drilled nearly 35.4 Mm of hole; 6 these

figures were 25% lower and 19% lower, respectively, than the revised figures for 1991. (See table 4.)

Prices

Price quotations in Industrial Minerals for American Petroleum Institute grade remained unchanged at \$93.70 per ton throughout the year while the Chemical Marketing Reporter showed a significant price rise (\$0.20 per kg to \$0.31 per kg) in the southern United States in September for offcolor dry ground barite. These prices may serve as a general guide but do not reflect actual transactions, some of which are on longterm contracts and some are confidential, negotiated prices. representative of the drilling mud barite industry felt that the price had stayed constant throughout the year.

The reported average value per ton of domestic barite, based on reported value of direct-ship, beneficiated, and floated material, increased nearly 27%, f.o.b. plant, from \$47.57 to \$60.22. average value of crushed or ground barite, sold or used by processors, was \$84.49 per ton, a 4% increase from the \$81.24 per ton reported in 1991. Within this group, the average value of barite for well-drilling end use was \$74.55 per ton, down 1% from \$75.45 per ton, while the average value for barium chemicals, filler and extender, and glass, was \$163.22 per ton, up 10% from \$140.08 per ton. The average customs value of exported barite was \$144.84 per ton, up 90% from that of 1991. The average c.i.f. value of imported crude barite was \$40.09 per ton, while the c.i.f. value of imported ground barite was \$141.99 per ton.

Foreign Trade

Exports of natural barium sulfate or barite fell to just above 1990 levels, from about 43,300 tons to about 12,500 tons. Export data provided by the Bureau of the Census did not indicate the grades of barite traded; however, based only on the per-ton value of individual shipments, which varies from about \$40 to nearly \$2,000 per ton, drilling-, filler-, glass-,

chemical-, and pharmaceutical-grade were all exported. (See table 5.)

Imports for consumption of crude barite declined about 62% from those of 1991 to less than 323,000 tons. The principal source countries, in descending order, were China, which fell 69% to 216,000 tons of crude barite; India, which fell 19% to 100,000 tons of crude barite; and Mexico, which fell 44% to 19,600 tons of ground barite. The higher priced material was chiefly crude filler and extender-quality barite. Most of the crude barite entered through customs districts along the gulf coast for delivery to grinding plants in the area. (See tables 6 and 7.)

World Review

change in overall barite production around the world occurred because production has occurred more in the areas of petroleum drilling. former U.S.S.R. and Asia are the areas of present and future petroleum exploration and development. It is less likely that barite will be hauled long distances to these areas given barite's worldwide distribution. Some areas will produce more barite in the near future and some, probably including the United States, will produce less as drilling becomes less profitable in those countries. The forecast for the United States is not perfectly clear as gas exploration may be profitable due to the environmental friendliness of gas consumption according to the new administration.

Brazil.—The Government of Brazil imposed a 92% tax on imports of barium carbonate from China for 5 years.

Italy.—A new firm has reportedly started up in Sardinia.⁷ Compagnia Mineraria Sarda (Cominsar), near the village of Desulo, plans to produce about 20,000 tons per year of pigment-grade barite.

Turkey.—Etibank, a state-owned mining, metallurgy, and banking

company, invited participation in the barite, fluorite, and rare-earth deposit near Eskisehir in the Sivrihisar province. It would be an open pit mine with 31% BaSO₄ ore. (See table 8.)

OUTLOOK

With several countries moving away from socialist beliefs and toward greater acceptance of international development of petroleum resources for expertise and financial backing. the petroleum exploration and development effort has moved away from North America and into the former U.S.S.R. and countries in the Pacific Basin. The large volume of barite that will be needed for exploration will more likely be supplied from mines and mills nearby to those regions and not from the United States. Drilling will continue in the United States, albeit at a slower pace, and for gas.

The domestic barite industry may change its production away from drilling mud barite, dominated by China and India, and toward higher valued products, planning to displace imports from several countries.

Estimated. Revised.

¹Table includes data available through June 1, 1993.

In addition to the countries listed, Bulgaria also produces barite, but available information is inadequate to make reliable estimates of output levels.

³Data are for fiscal year beginning Mar. 21 of that stated.

⁴Reported figure.

⁵Formerly part of Yugoslavia; data were not reported separately until 1992.

⁶All production in Yugoslavia from 1988-91 came from Bosnia and Herzegovina.

Barite concentrates.

⁸Data are for fiscal year beginning Apr. 1 of that stated.

Dissolved in Dec. 1991. This commodity is believed to be mainly produced in Georgia and Kazakhstan; however, information is inadequate to formulate reliable estimates of individual country production.

¹⁰Sold or used by producers.

¹¹Dissolved in Apr. 1992.

BORON

By Phyllis A. Lyday

Mrs. Lyday has covered boron for 14 years. Domestic survey data were prepared by Pam Shorter, statistical assistant; and international data were prepared by Harold Willis, international data coordinator.

U.S. production and sales of boron minerals and chemicals decreased during the year. Domestically, glass fiber insulation was the largest use for borates, followed by sales to textile-grade glass fibers, and soaps and detergents.

California was the only domestic source of boron minerals. The United States continued to provide essentially all of its own supply while maintaining a strong position as a source of sodium borate products and boric acid exported to foreign markets.

Supplementary U.S. imports of Turkish calcium borate and calcium-sodium borate ores, borax, and boric acid, primarily for various glass uses, continued.

DOMESTIC DATA COVERAGE

Domestic data for boron are developed by the U.S. Bureau of Mines from two separate, voluntary surveys of U.S. operations. Of the three operations to which a sold and used survey request was sent, three responded, representing 100% of the total boron sold or used shown in tables 1 and 8. A Bureau canvass of the three U.S. producers also collected data on domestic consumption of boron minerals and compounds shown in tables 3 and 4. (See table 1.)

BACKGROUND

Definitions, Grades, and Specifications

Few of the many minerals that contain boron are commercially valuable. Only colemanite and ulexite minerals, primarily imported from Turkey, are marketed in the United States. The boron oxide content of both minerals is usually marketed at about 40%. (See table 2.)

Tincal and kernite ore and brines are the U.S. source of refined borate chemical compounds. The most common refined borates, borax pentahydrate and its derivative anhydrous borax, are marketed in technical and agricultural grades. Lesser quantities of borax decahydrate are produced in technical, United States Pharmacopeia, and special quality grades.

Boric acid is a white, odorless, crystalline solid sold in technical national formulary and special quality grades as granules or powder. Boron oxide is a hard, brittle, colorless solid resembling glass that is ground and marketed most often under the name anhydrous boric acid.

Elemental boron is a dark brown powder in the amorphous form and a yellowish-brown, hard, brittle solid in the monoclinic crystalline form. Boron is marketed in grades from 90% to 99% purity.

Ferroboron is a name given to a variety of boron-iron alloys containing 0.2% to 24% boron used primarily to introduce small quantities of boron into specialty steels.

In the boron hydride series are diborane, a gas; pentaborane, a liquid; and decaborane, a solid. These compounds range from 31,220 British thermal units (Btu) per pound for diborane to 27,850 Btu per pound for decaborane. Government documentation concerning boron fuels projects begun after the Korean War were declassified and included in a book that describes the pilot plant production at the Malta Rocket Test Station. The chemical and

engineering challenges involved in the work are detailed.¹

Boron nitride, a soft, white, highly refractory solid resembling graphite, can withstand significant oxidation to temperatures up to 650° C. Boron nitride produced in fibrous form equals glass fibers in strength and modules of elasticity, but is lighter in weight and more resistant to high temperature. When subjected to extremely high pressure and temperature, boron nitride forms cubic crystals that rival the hardness of diamond.

Boron carbide, produced by reacting carbon and boric acid at 2,300° C, is a highly refractory material and one of the hardest substances known. Most commonly used for both abrasive and abrasion-resistant applications as well as nuclear shielding, boron carbide is marketed in technical and high-purity grades.

Geology

At the Kramer borate deposit of the Boron open pit mine, tincal consists of more than 80% of high-grade beds, with claystone only between the crystals. In low-grade beds, tincal is less than 50% of the beds and is disseminated in a claystone matrix. The lower portions of the beds consist of kernite, a secondary mineral formed by the dehydration and recrystallization of borax resulting from high temperature and pressure. Probertite is found radiating prismatic crystals, or rosettes, commonly within claystone and exclusively where kernite is the dominant sodium borate. The sodium borate facies is enveloped by ulexite. colemanite, and barren claystone facies.

The barren facies contain calcareous nodules but are barren of borates.²

Technology

Problems with the discovery, processing, and transporting of boron minerals and compounds from remote and hostile locations became a part of the history of the borax industry. location of the ore and the methods of production remained a guarded secret for many centuries. It was not until the end of the 17th century when Amsterdam had replaced Venice as the center of borax production that the mineral source and methods of process were commonly known. Producers of boric acid from the steam vents of Tuscany, Italy, prospered because of a lack of competition in the world market. Large reserves of borates were found in Turkey in 1865 and in the Western United States in 1856. With the discovery of new minerals, new processes were developed. The history of boron production and processing has continued for thousands of years because of the benefits derived from using the product. The use and processing have varied little over the past 100 years. Modern changes in processing are a result of improved equipment and processing controls.3

Byproducts and Coproducts

More than four-fifths of the U.S. production comes from mineral deposits mined only for their boron content. The remainder is produced from lake brines, which also supply sodium carbonate, sodium sulfate, potassium sulfate, and potassium chloride. Turkish colemanite, ulexite, and tincal ores are worked only for their boron content. Most Soviet borates are also mined only for their boron content, but the Gulf of Kara-Bagaz-Gol and the Sivash (lagoon) borates are extracted with coproduct chloromagnesium from brines. American boron has been mined from ores and also has been produced as a coproduct of nitrate and iodine production.

Owens-Corning Fiberglas began using purchased cullet in the late 1970's and

has raw material specifications for cullet for fiberglass manufacturing. broken or refuse glass, is added to fiberglass in the melt. Sulfate is used to remove the carbon dioxide formed from Cullet contains low the carbonates. amounts of carbonates. Therefore, no sulfur dioxide formation occurs with the use of 100% cullet. Fiberglass is a technically sophisticated product that demands consistent and high-quality raw material. For instance, a 2% shift of sodium oxide in a cullet comprising 25% of a fiberglass batch would cause a shift in glass viscosity of 11° C. A shift of this magnitude could cause significant effects in fiberizing and is well beyond the target control of $\pm 3^{\circ}$ C for glass ASTM has written a viscosity. specification for cullet used in the container industry. Owens-Corning and fiberglass manufacturers are other working within the ASTM Committee on Waste Disposal to develop a standard for cullet used in making insulation fiberglass.⁴ On the basis of data, the effect of each 10% increase in cullet level can decrease gas heat by 114,000 Btu/metric ton of glass.5

Economic Factors

Costs.—Energy costs are especially high for producing anhydrous products. The anhydrous products were originally introduced to decrease freight costs per ton of contained boron oxide. Both domestic producers now use cogeneration facilities to reduce the cost of energy for processing and supplying excess electricity for sale.

Depletion Provisions.—The domestic and foreign depletion allowances for boron are 14% of gross income and may not exceed 50% of net income without the depletion deduction.

Operating Factors

Naturally occurring boron compounds have relatively low toxicity for humans and other mammals. United States Borax

& Chemical Corp. (US Borax) submitted a Toxic Substance Control Act Section 8(e) risk report (No. 2002) to the U.S. Environmental Protection Agency. Results of a teratology study of boric acid reported no observed adverse effects.⁶

Occupational Safety and Health Administration's (OSHA) Hazard Communication Standard went into effect November 1985 and May 1986. It is OSHA's most comprehensive worker protection regulation. It provides for information and training for workers encountering chemical exposures in the workplace. The standard requires the use of labels and material safety data sheets for all regulated chemicals. Part of the standard includes the Threshold Limit Values (TLV) from the American Conference of Governmental Industrial Hygienists. TLV's refer to airborne concentrations of substances and represent conditions under which nearly all workers might be repeatedly exposed day after day without adverse effect. The only hazard listed for boron chemicals produced at the mine site was a Time Weighted Average for borax decahydrate, listed as 5 milligrams per cubic meter per 8-hour workday, 40-hour workweek, to which nearly all workers may be repeatedly exposed without adverse effect. Sodium borates, boric acid, and boron oxide are not present to any significant degree in air and are placed in the same hazard category as general dust.7

Small quantities of boron are essential for all plant life. Boron is added in trace levels to fertilizers; however, quantities well below concentrations affecting humans and animals are so extremely toxic to vegetation that boron compounds are also used commercially as herbicides. Concentrated boric acid is used to control certain insects and in dilute solutions as a preservative to control the growth of bacteria.

Owens-Corning detailed the results of four new studies on fiberglass and human health, which were completed during the past year. One of the four studies was an extensive animal inhalation study. The studies, in conjunction with epidemiology, provided strong evidence that working with fiberglass does not pose

a significant human health risk.8

ANNUAL REVIEW

Legislation and Government Programs

Debate opened before the full House Interior Committee on the California Desert Protection Act. Under the proposed bill, 4.3 million acres (1.8 million hectares) of public land would be designated wilderness. In addition to the wilderness designation, the bill would add 1.3 million acres (0.5 million hectares) of Federal lands to the existing Death Valley National Monument and 200,000 acres (83,000 hectares) to the Joshua Tree National Monument. The land under discussion contains numerous mineral deposits, including most known boron reserves. At yearend, H.R. 2929 had passed the House and was sent to the Senate for further consideration. The U.S. Bureau of Mines published OFR 62-92 (NTIS:PB 92-238237/AS) in May of 1992 that presents nine case histories to highlight the diversity of deposits, commodities, and markets represented in the California Desert Conservation Area.

The Department of Commerce published in the November 25, 1992, Federal Register that national securitybased validated licensing requirements to export pyrolytic boron nitride (PBN) were removed by the publication of the Commerce Control List effective September 1, 1991, following multilateral review by the Coordinating Committee for Multilateral Export Controls. Foreign policy controls continue to apply to PBN articles, including those PBN articles covered by the foreign availability finding.

The National Institute of Standards and Technology (NIST) was organizing a consortium of producers of plastics and rubber products and instrument makers interested in improving products by developing technology. The consortium will be based on improving uses of fluorescence spectroscopy to monitor processing steps in advanced polymers.⁹

The California Occupational Health and Safety Administration established a permissible exposure limit of 1 milligram

per cubic millimeter for sodium borate dust. Sodium or calcium are the most frequent forms of boron-containing minerals. The best known commercial inorganic borates are boric acid and disodium tetraborate decahydrate, commonly referred to as borax. Owing to the powdered nature of many products, inhalation of sodium borate particulate dust is the predominant route of exposure in the work environment. There are an estimated 420,000 workers in the United States who have potential occupational exposure to sodium borates. hundred and ninety-eight volunteers participated in a chronic effects study. Much of the data were collected in 1988, but the study continued over a 2-year period. The final report was issued in January 1991. The study confirmed that borate dust is, at most, a very mild nose and throat irritant. The results suggest no serious respiratory health consequences from borax dust exposures. Based on preliminary results OSHA decided to maintain the borate dust standard at 10 Mine Safety and Health mg/m³. Administration was using the dust study to revise the borate standards. 10

Production

The majority of boron production continued to be from Kern County, with the balance from San Bernardino and Inyo Counties, CA.

American Borate Co. (ABC), a wholly owned subsidiary of Owens-Corning, was sold in December 1990 to a private firm. ABC renewed its mine permits and began to mine small amounts of colemanite and ulexite from the Billie Mine during 1991. Colemanite was processed at Lathrop Well, NV. Storage and grinding facilities were at Dunn, CA.

North American Chemical Co. operated the Trona and Westend plants at Searles Lake, in San Bernardino County, to produce refined sodium borate compounds and boric acid from the mineral-rich lake brines. At the Trona plant, a differential evaporative process produced borax with potash as a byproduct. Boric acid was produced by solvent extraction. The Westend plant

used two lines to supply brines to the plant. The first line fed lake brine to the Argus plant where sodium carbonate was produced. The effluent borax-rich brine then is pumped to the Westend plant where it supplied about two-thirds of the brine feed. The effluent was blended with fresh lake brine from a second feed line that supplied about one-third of the brine feed. The blended brine was then cooled to 18° C to precipitate decahydrate borax. The effluent was cooled to 8° C and the precipitated Glauber's salt was used to produce sodium sulfate.

US Borax, a part of Borax Consolidated Ltd. of the RTZ Corp. PLC of London, United Kingdom, continued to be the primary world supplier of sodium borates. RTZ is traded on the New York Stock Exchange.

US Borax mined and processed crude and refined sodium borates, their anhydrous derivatives, and anhydrous boric acid at Boron, in Kern County, CA. A second plant at Boron used a proprietary process to produce technical-grade boric acid from US Borax's extensive kernite ore reserves. The boric acid was produced to compete with imported colemanite used in glass manufacture.

The majority of material was shipped to US Borax's storage in Wilmington, CA. Products made at Wilmington included ammonium borates, potassium borates, sodium metaborates, and zinc borate.

Consumption and Uses

U.S. consumption of borates increased. Glass fiber insulation and glass fiber primarily used as reinforcement for plastics continued to be the largest consuming industries.

The use of borates in glass fiber thermal insulation, primarily used in new construction, was the largest area of demand for borates. Cellulosic insulation, the seventh largest area of demand, decreased.

The second major market for borates, manufacturing high-tensile-strength glass fiber materials for use in a range of products, showed an increase in demand.

The nonconductive and low dielectric | glassproperties of high-strength materials make them reinforced transparent to radar and thus valuable for Carbon-fiber-"stealth" applications. reinforced resins can be stronger than metals and, with higher modules, more stable. Although composites can be 10 times more expensive than typical aerospace-grade aluminum, the flexibility they offer in design and consolidation of parts allows large, complex structures to be fabricated to exacting specifications. In addition, their light weight and ability to withstand high temperatures have made them the material of choice for a variety of aerospace applications.

Owens-Corning will enter the specialty fabrics market through a 50-50 joint venture with Hexcel Corp. Specialty fabrics are composed of single or multiple layers of woven or nonwoven fiberglass and other reinforcements that are either knitted, woven, stitched, or bonded together. The joint venture will Specialty be based in Seguin, TX. fabrics are widely used in marine and aerospace industries and have potential applications in bridge overwraps, reinforcements road systems, automotive parts. 11

As a result of nearly four decades of developing, fiberglass reinforced plastics (FRP) have been widely used in flue gas desulfurization (FGD) processes. Usage is expected to grow. Fabrication of essentially the entire FGD system of FRP composites for new large central station units is being considered. This will represent the largest single use of FRP composites in the world. Field fabrication techniques now permit construction of FRP vessels in excess of 100 feet (30 meters) in diameter. 12

FRP was compared for installation cost for 33 corrosion-resistant piping systems. Many engineers look only at material cost because the figures are relatively simple to estimate. Installation cost can account for more than one-half of the total investment made in a piping system. Pipeline construction costs can be broken into material, line schedule and diameter, complexity of the layout, fabrication and erection, and labor.

Three FRP systems were evaluated and were less expensive than 21 of the other materials evaluated. 13

Consumption of borates in borosilicate glasses remained the third major end use, and demand decreased. Boron added in amounts of between 4% and 15% to glass reduced the viscosity of the melt, assisted with fiber formation during processing, allowed for improved specific optical increased resistance properties, aqueous or chemical attack, enhanced certain mechanical properties, reduced the thermal expansion coefficient and thermal shock resistance of the product. Boron oxide provides a range of favorable benefits to the melting of nonspecialty and container glass and the final glass properties. Each 1% of boron oxides reduces the melting temperature of the glass 20° C.14

Special glasses can be divided into five types, as follows: borosilicate glass (10% to 13% boron oxide); opal glasses (0% to 13% boron oxide); potassium glasses (0% boron oxide); glass ceramics (0% boron oxide); and fiberglass for reinforcing (0% to 9% boron oxide). Alumina contained in glass contact refractories can have a positive effect to prevent corrosion, but in specialty glasses can generate bubbles. The use of zircon refractories can present an alternative in the manufacturing process if crystallographic stability is considered.¹⁵

Glassman America '92, the fifth Glass Manufacturing International Exhibition, attracted 100 suppliers at its New Orleans, LA, meeting June 9-10. Twenty-one organizations provided exhibits. Since first staged in 1986, more than 200 separate firms have participated, representing the primary glassmaking sector's core supplier base. Of particular relevance to glass scientists, 58 papers were presented, including an invited plenary lecture by Rolf Bruckner, University of Berlin, Technical Germany.16

Boron compounds continued to find application in the manufacture of biological growth control chemicals for use in water treatment, algicide, fertilizers, herbicides, and insecticides. Boron can be applied as a spray and incorporated in

herbicides, fertilizers, and irrigation water. The Potash & Phosphate Institute of Atlanta, GA, recommended one-half pound (0.9 kilogram) of boron for every ton of expected yield of alfalfa in the spring 1992 Agi-Briefs. The brief recommended that micronutrient levels in the soil be monitored by soil testing. The Tennessee Valley Authority published Commercial Fertilizer 1992 that listed total boron compounds consumed as secondary and micronutrients by region in the United States for 1991 and 1992.

A growing and important use of zinc borate, ammonium pentaborate, and boric oxide is as fire retardants in the plastics industry. Zinc borate is of commercial importance because it is water insoluble and does not release water until heated to 290° C. There are advantages in partially replacing alumina trihydrate (ATH) used as a halogen-free fire retardant in ethylene-vinyl acetate polymers with zinc borate. Partial replacement of ATH with zinc borate results in a tenfold increase of char and a changeover from the glowing to smoldering combustion mode.¹⁷

Boron compounds were also used in metallurgical processes as fluxes, shielding slag in the nonferrous metallurgical industry, and components in electroplating baths. Small amounts of boron and ferroboron were constituents of certain nonferrous alloys and specialty steels, respectively.

Boron nitride solids have been produced by The Carborundum Co. of Amherst, NY, since 1954. The advanced synthetic ceramic material is available in solid, powder, liquid, and aerosol spray for use in thermal, electrical, and mechanical applications.

Boron is also used as a bleaching agent in detergents and cleaning products, such as compact washing powders. Perborates are used more frequently in Europe where wash temperatures are higher. Procter & Gamble Co. introduced the first laundry detergent with perborates after developing and patenting a low-temperature activator. During 1992, a second company incorporated a perborate bleach. E. I. du Pont de Nemours & Co. stated that a second production line was added in 1992 for the production of

sodium perborate monohydrate. The use of compact powders has had a significant impact on the increased use of the perborate.¹⁹

Sodium borohydride is used in the removal of color and metals from solutions of dyes used for textiles. Reduction methods were developed for the treatment of six paper dyes for which other reductive methods were found to be ineffective. The processes developed involve bisulfite catalyzed borohydride reduction in combination with precipitation and removal of the reduced species by addition of a cationic agent and a flocculent. These processes are done at a pH 6 and ambient temperature. Decolorization indicated metal removal was complete within 15 minutes. The dyes were azo dyes that included metallized azo, copper phthalocyanine, and stilbene dyes. 20 (See tables 3 and 4.)

Prices

Prices for anhydrous boric acid and technical borax remained the same. All other reported prices increased. (See table 5.)

Foreign Trade

The majority of material from the US Borax facility in Boron was shipped to storage, loading, and shipping facilities at Wilmington, CA. A large part of the output was exported to Western Europe from Wilmington to Botlek, Netherlands. (See tables 6 and 7.)

PPG Industries Inc. announced that four wholly owned fiberglass manufacturing plants have been registered as meeting the requirements of International Standards Organization (ISO) 9002. ISO registration is a quality standard recognized around the world, but is especially important for companies doing business in Europe. Two of the four plants are in North Carolina.²¹

World Review

Argentina.—Boroquimica SA continued production of tincal from the Salar del Hombre Muerto and boric acid from Tincalayu. In addition, Minera del Boro also produced borates.

Bolivia.—During March 1992, Boron International Inc. entered into an agreement with Teck Corp. to finance an \$8 million expansion at Capina for the production of 60,000 tons per year of calcium borate manufactured from ulexite. Current mining in the area of 30,000 tons annually resulted in 8,000 tons of ulexite (40% boron oxide), 4,000 tons of boric acid, and 1,500 tons per year of sodium ocataborate.²²

Compania Minera Tierra Ltd., a small company formed in 1988 for producing borates in an area of the Department of Potosi, has important concessions of ulexite and sulfur near the Chilean border in the southwestern tip of the country. About 120,000 tons of ulexite per year is exported to Brazil and other neighboring countries. In 1990, the company employed 120 persons.

The company has interest in ulexite mineral concessions that cover an area of 4,800 hectares, and reserves have been estimated by the company to exceed 13 million tons of raw ulexite with grades ranging from 20% to 37%. Ulexite is extracted and dried by turning by tractor. The dried ulexite is washed and roasted. The processed ulexite of about 42% borate content is bagged and exported by trucks and rail.

Various borate deposits are in the southwestern part of the Altiplano. Llipi Llipi, in the south of Salar de Uyuni, contains an estimated 12 million tons of ulexite. Copla Ltda. was mining ulexite for export. Production of ulexite in 1989 was 9.609 tons.²³

Chile.—Boratom Quimica Processes Ltda. had operated in Chile since 1986 by providing technology and sales support to producers. In 1986, Boratom shipped 3,000 tons of ulexite to the United States in connection with Borichem Inc. Ulexite

mines are in the I and II Regions of Chile, and Ulexite operates a refining plant near Iquique. In March 1992, Boratom's assets and technology were sold to Boron International Inc. (Canada). In November, Boron entered into an agreement with Teck Corp. called Boron Chemicals Processes Chile S.A. A \$1.4 million upgrade of the plant was expected to be completed by yearend.²⁴

Quimica & Industrial del Borax (Quiborax) was the main producer of boric acid and concentrated ulexite. The second stage of an expansion was completed in 1992. Included in the expansion were about 70,000 square meters of evaporation ponds, a ulexite washing plant, water purification osmosis plant, and boric acid plant. Quiborax operated a mine at Surire, Parindacta, with a crude annual output of 1,000,000 tons per year of ulexite. The ulexite is washed and upgraded from 30% to 40% boron oxide by centrifugal action and flotation prior to filtration. borate is produced by adding calcium hydroxide to the washed ulexite.25 Beginning in 1993 the boric acid production was estimated to be 20,000 tons and calcium borate production was expected to be 20,000 tons. The plant facilities are at El Aguila, Arica.²⁶

The National Boraxx Corp. (Cleveland, OH) packages and distributes boric acid in the United States for Quimica E Industrial del Borax Ltda. (Quiborax Ltda.)²⁷

Compania Minera Salar de Atacama (Minsal) is a joint-venture project between AMAX of the United States. Molibdenos Y Metales (Molymet) of Chile, and Corporacian de Fomento de la Produccion (CORFO). **CORFO** established the joint venture as a result of an international public licitation in 1986, in which the Lithium Corp. of America (LITHCO) was the only other bidder. The project was designed to produce lithium carbonate, potassium chloride, potassium sulfate, and boric acid from the Salar de Atacama in the II Region. Future production was expected to be 26,000 tons of boric acid per year. In February 1991, the project was placed on hold for a second year, under the terms of AMAX's original contract. Sociedad Quimica y Minera del Chile (SQM) acquired the 63.75% stake held by AMAX. Plans were to limit the production to about 300,000 tons per year of potassium chloride and possibly lithium. SQM planned to finalize contracts by May 1993 and has indicated a target date of mid-1995 for production.²⁸

China.—The Borates in the salt lakes of China are mainly found on the Qinghai-Xizang (Tibet) Plateau. Boron is distributed in many saline lakes from the southern side of the Gilian Mountains to the north side of the Gangdisi-Tanggula mountains.

Former U.S.S.R.—Several distributors were marketing boron compounds produced in the former U.S.S.R. Among the materials listed were boric acid, borax decahydrate, anhydrous borax, sodium perborate, and calcium borate.²⁹

Primorsky Industrial Amalgamation, in Dalnegorsk, has been in production since 1953. Amalgamation produced a range of boron minerals and compounds from datolite containing 20% boron oxide. The complex has about 10,000 people. Employment includes 1,000 persons in mining, 2,000 persons in manufacturing, and 7,000 persons in support operations. Amalgamation is part of the Russian Agricultural Joint Stock Co. known as ROSAGROCHIM. ROSAGROCHIM coordinates the activities of about 100 companies.

Mining is by open pit. The ore is about 9% boron oxide content. The ore is calcined to 18% boron oxide content. The calcining is to conserve the use of sulfuric acid. About 75% of the ore is treated with sulfuric acid to create boric acid, calcium sulfate, and silica. The sulfur is imported from Poland and Canada. About 18% of the ore is used to manufacture calcium borate of 43% to 44% boron oxide content. The Dalnegorsk plant supplied about 85% of the boron oxide market in the former U.S.S.R. The nearest railway station is

about 200 kilometers from the plant. The products are trucked in loads of 15 to 17 tons. To ship the product to Europe, the product is transferred at the Black Sea.

Iran.—At Deh-e-Shotoran near Sirjan, the region is of tourmaline-rich granites that have invaded metamorphosed sandstones. Ulexite is found in depressions. At Tonkar near Sabzevar, there are several sources of borates in consolidated sediments of thin beds of limestone, marl, and clays. Ulexite also occurs close to the village of Ashin near Anarak.³⁰

Peru.—The boron concessions in Arequipa, including Cia. del Boro y Derivados S.A., were merged into Compania Minera Ubinas S.A. as well as the chemical processing company Quimica Oquendo S.A., which produces boric acid at Callao.³¹

Sweden.—Owens-Corning announced that it would close its plant at Falkenberg and increase the capacity of its other European facilities by 25%. The company stated that it planned to spend \$110 million in reorganizing its European facilities over the next 3 years. The changes are a result of structural changes in the industry and cyclical changes in the economy. The world economy has changed, and the dollar has declined and continues to trade at a low level. In certain major market segments, products are selling at 1982 prices.³²

Turkey.—Turkey's boron operations are under the control of the Government corporation, Etibank, that mines boron from major deposits at Bigadic, Kirka, and Emet. Etibank operates refining facilities to produce refined sodium borates and boric acid from tincal concentrates at Bandirma. Boron minerals and compounds are shipped from the Port of Bandirma on the Sea of Marmara and Izmir on the Aegean Sea.

United Kingdom.—Borax Consolidated, a subsidiary of RTZ Corp., planned to build a 60,000-square-foot

(5,580-square-meter) technical center at the University of Surrey Research Park, near Guildford. The move will involve a total of 120 people from the research, technical, and development functions and the technical marketing operations.³³ (See table 8.)

Current Research

Owens-Corning introduced a new fiberglass insulation concept that can increase the energy efficiency of Unlike refrigerators and freezers. urethane foam insulation, the fiberglass insulation requires no chlorofluorocarbons (CFC's) for blowing. CFC's are to be phased out by 1995. The new fiberglass insulation is contained within a steel foil container and has a heat insulation ability six times that of urethane foam insulations used in today's refrigerators. Owens-Corning is seeking a joint-venture partner that would market and produce the product on a commercial scale.³⁴

A consortium was formed to study the feasibility of building an earthquake-resistant highway bridge from advanced composites made of glass, carbon, and polymer fibers. The materials are lighter, stronger, and more durable than steel and concrete. If constructed, the bridge would be the first structure of its kind.³⁵

A silicon-base agent was developed from the reaction of a boron acid with sodium silicate. With the addition of borax, the pH range for gel forming becomes alkaline, and the boron changes its geometry from triangular to tetrahedral ions that are precipitated easily by hydroxides and base salts of metals and are absorbed by dispersed aluminum silicates, such as those used in welldrilling muds. This resulted in gel strength and improved water loss characteristics and a decrease in sticking characteristics, thus improving the flow of the drilling mud.³⁶

OUTLOOK

Production and consumption of boron minerals and compounds have decreased between 1983 and 1992. There are

several factors that may lead to misleading outlooks in consumption. One is that production and imports reported in 1 year may be utilized over a period of years. In addition, environmental concerns may change the demand for boron significantly in a short period. The regulation of fire retardants in products has resulted in changes in boron usage as a fire retardant. More recent decreases in domestic consumption have been attributed to decreases in glass consumption because of less demand resulting from a recession.

Agriculture

Boron usage in agriculture reached a low in 1982 and has continued to decline until 1992. The primary reason was attributed to the decline of the number of farms during the same time period. Farming exports are showing increased strength, and demand for boron usage in agriculture increased during 1992.

Ceramics and Glass

Boron usage increased over the 1980's, reaching a peak in 1984 that was a 36% increase over that of the prior year. This spike was probably a demand to balance the sharp decline of 1982 of 41%. Ceramics and glass have both faced competition with polymers. The U.S. fiberglass industry was reported to be feeling the effects of recessionary pressures. The sagging economy produced a decline in demand for fiberglass reinforcements that expected to end during 1992. Fiberglass is closely related to construction and transportation.

Coatings and Plating

Primarily used as a protective coating for steel products and as a glazing on ceramic tiles, usage increased during the year.

Fabricated Metal Products

Boron usage decreased in metal products during the past decade. Many

traditional metal products that require soldering now are produced from polymers as one piece. Usage in specialized metal was expected to increase.

Soaps and Detergents

This usage declined primarily as chlorine bleaches and coldwater washes replace boron soap powders. Recent concern for environmental effects of chlorine has reversed the decline. Perborate bleaches have returned to name brand soap products. The usage of boron in soaps and bleaches was expected to increase by 4% per year over the next 5 years.

Estimated. Revised.

¹Table includes data available through May 18, 1993.

²B₂O₃ equivalent.

³Data are for years beginning Mar. 21 of that stated.

Less than 1/2 unit.

⁵Concentrates from ore.

⁶Dissolved in Dec. 1991. This commodity is believed to be produced in Kazakhastan and possibly other former Soviet Republics; however, information is inadequate to formulate reliable estimates of individual country production.

Minerals and compounds sold or used by producers, including both actual mine production and marketable products.

²Reported figure.

Data may not add to totals shown because of independent rounding.

BROMINE

By Phyllis A. Lyday

Mrs. Lyday, a physical scientist with the U.S. Bureau of Mines, has been the commodity specialist for bromine for 14 years. Domestic survey data were prepared by Gail Mason, statistical assistant; and international data tables were prepared by Doug Rhoten, international coordinator.

Production of bromine worldwide in 1992 was as follows: United States, 45%; Israel, 36%; the United Kingdom, 7%; and other countries, 12%. The U.S. portion of world production has decreased steadily since 1973, when the United States produced 71% of the world supply. The decrease in world share has been a result of environmental constraints and the emergence of Israel as the world's second largest producer. **Domestic** capacity decreased 14% during the same period of time. The quantity of bromine sold or used in the United States was 171 million kilograms (Mkg). Estimated uses of bromine compounds were in flame retardants (27%), agriculture (15%), petroleum additives (15%), well-drilling fluids (10%), and other (33%).

DOMESTIC DATA COVERAGE

Domestic production data for bromine was developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the six operations to which a survey request was sent, six responded, representing 100% of total elemental bromine sold or used. (See table 1.)

BACKGROUND

Definitions, Grades, and Specifications

In the elemental form, bromine is a very dark, reddish-brown liquid. Bromine is the only nonmetallic element that is liquid at ordinary temperature and pressure. The natural form of bromine is a solution of sodium bromide in natural

brines, saline deposits, salt lakes and seas, and oceans.

Elemental bromine is marketed in a "purified" grade with the following specifications: Specific gravity not less than 3.1 at 10° to 20° C; bromine, not less than 99.7%; iodine, none; and chlorine, not more than 0.1%. Specifications for the various grades of bromine compounds include technical bromine. 99.5% pure, with the chief impurities consisting of chlorine, traces of moisture, and organic matter. Specifications of the United States Pharmacopoeia and the American Chemical Society Committee on Analytical Reagents allow 0.3% chlorine, 0.05% iodine, 0.0002% sulfur (0.006 % as sulfate), and no more organic matter in 1 milliliter than will saturate 50 milliliters of 5% sodium hydroxide solution. The term "chemically pure" signifies a minimum of impurities.

Geology-Resources

Bromine is widely distributed in the Earth's crust, but in small quantities. By far the largest potential source of bromine in the world exists in the oceans. At a concentration of only 65 parts per million (ppm), large amounts of seawater are processed to obtain the bromine.

Arkansas brines contain about 5,000 ppm at depths of 2,591 meters (8,500 feet) in limestone of the Smackover Formation of Jurassic age. In Michigan, brines containing about 2,600 ppm of bromine occur in the Sylvania Sandstone Formation of the Detroit River Group of Devonian age.

In Israel, bromine is produced as a

byproduct of salt, sodium chloride, and potash production from the Dead Sea. The waste brines contain 14,000 ppm bromine.

Technology

Processing.—The Arkansas Geological Commission reports three east-west bromine-rich brine fields. Wells are drilled to the brine level, and a submersible pump is lowered to pump the liquid to the surface. Brine is separated by gravity from any residual gas at the surface and pumped to one of six processing facilities.

At the processing facility, bromine is separated from the brine by a steamingout process. The brine is pumped into the top of a tower constructed of granite and filled with ceramic packing. As the brine falls through the packing material, it reacts with chlorine and steam that are injected at the bottom of the tower. One pound of chlorine yields 1 kg of bromine. About 95% of the bromine, or about 0.7 to 0.8 kilograms of bromine per barrel of brine, is recovered if the raw brine is first acidified to a pH of 3.5. chlorine replaces the bromine in the brine, and the gaseous bromine rises with the steam out of the top of the tower: there it is condensed to a reddish-brown liquid. Bromine is separated from gases. The bromine liquid can be further purified or reacted with other materials to form bromine compounds. vapor, a little chlorine, and water vapor are captured at the top of the tower. Hot bromine-free liquor emerges from the bottom of the tower. After neutralizing

with lime, the waste liquor is pumped through a heat exchanger to a waste pond. Brine from the pond is reinjected into the same producing zone to maintain hydrostatic pressure.

Seawater contains about 60 to 70 ppm of bromine as sodium bromide or magnesium bromide. Production of bromine from seawater uses the blowingout process. Raw seawater is acidified by adding sulfuric acid and then chlorine. Air is drawn into the base of the tower and rises as the brine descends. containing bromine passes to the In the absorption absorption tower. tower, bromine reacts with sulfur dioxide to form a hydrogen bromide. bromine is separated by adding acid to the solution and is distilled by steam. The gaseous bromine is condensed, separated, and purified.

Recycling.—Bromine containing waste from other processing is recycled into elemental bromine. The waste is reprocessed through the absorption towers to produce a high-quality elemental bromine. It was estimated that about 90 Mkg of elemental bromine was produced by recycling during 1992.

Byproducts and Coproducts

Some bromine-bearing brines contain hydrogen sulfide gas. This gas has a disagreeable odor, is highly toxic, and when burned, will oxidize to sulfur dioxide, an acid-producing gas. prevent the emission of the gas to the atmosphere where sulfur dioxide may form, environmental regulations require the recovery of the sulfur. Hydrogen sulfide gas was chemically removed from the incoming brine and converted into elemental sulfur or other nontoxic sulfurcontaining compounds. The cost of recovery was greater than the selling price of the sulfur, but recovery prevented emission of a gas that may contribute to the formation of acid rain.

Substitutes

Various materials are used in flame retardants as replacements for bromine in | corrosive and must not be allowed to

and high-performance engineering thermoplastic polymers and blends, and polymeric composites. The distinguishing characteristic of engineering polymers is that they have properties that lend themselves to structural applications over a wide range of temperatures, high mechanical stress, and harsh chemical and physical environments. The highperformance polymers also distinguished by their special properties such as extremely high-temperature tolerance and outstanding optical properties or conductivity, but they are not necessarily designed for structural integrity.

Economic Factors

Costs.—The cost of drilling and maintaining a bromine-producing well is estimated to be in excess of \$1 million per well, with about 100 wells in operation. Chlorine, the largest manufacturing cost factor, represented about 30% of the manufacturing cost of bromine. Other cost factors include brine (22%), operating cost (15%), utilities (14%), overhead (12%), and other (7%).

Taxes.—During 1992, brines produced in Arkansas required the payment of \$2 per 1,000 barrels in severance taxes, and capital equipment was subject to the payment of property taxes. produced in the United States was subject to Superfund taxes of \$4.91 per metric ton (\$4.45 per short ton). Bromine was manufactured using chlorine, which was subject to a Superfund tax of \$2.98 per metric ton of chlorine (\$2.70 per short ton).

Depletion Provisions.—Bromine producers (domestic and foreign) are granted a 5% depletion allowance under the Federal Income Tax Law on the value of bromine produced from brine wells. The depletion allowance can be calculated by the actual cost method.

Operating Factors

Toxicity.—Bromine is highly toxic and

escape into the atmosphere. Many bromine compounds are also poisonous or irritating and must be packaged in leakproof containers to avoid personal injury. If bromine spills on paper, rags, wood shaving, etc., it will generate considerable heat, which may lead to spontaneous combustion. Bromine reacts with living tissue and must be removed immediately to avoid serious injury.

Bromine vapors are hazardous to the eyes and lungs. Any concentration above 1 ppm in the air for an 8-hour exposure is considered a health hazard. Bromine can be detected by its odor even at this level. Exposure to concentrations of 500 to 1,000 ppm for as little as one-half hour is lethal. The Occupational Safety and Health Administration (OSHA) regulates the working conditions of bromine plants.

When handling bromine, a person should use safety goggles, a face shield, rubber gloves, rubber boots, and under self-contained conditions, a breathing apparatus. Bromine spills are neutralized with a solution of sodium Gaseous bromine is thiosulfate. neutralized with controlled amounts of gaseous ammonia. All metal, such as electrical switches and connections, that may be exposed to bromine vapors should be made of corrosion-resistant materials and/or completely sealed from contact with the room air.

OSHA established a phase-in schedule that gives operators until 1996 to complete process-hazard analyses (OSHA 29 CFR 1910.119) for any operator who uses, stores, manufacturers, handles, or moves highly hazardous chemicals that include bromine, bromine chloride, bromine bromine pentafluoride, trifluoride, and propargyl bromide. The fines that apply to the new standard are the same as those specified by other OSHA safety regulations. A willful violation can result in a fine up to \$70,000. A serious violation can result in a fine up to \$7,000 per violation. A criminal violation can result in fines up to \$250,000 to any responsible individuals and up to \$500,000 against the corporation. Jail terms may be imposed for criminal violations.

Employment.—During 1992 an estimated 1,600 employees were employed by the bromine industry in Arkansas. About 1,175 are employees of the companies and about 450 are contact workers.

A notice of proposed rulemaking was published bv the Environmental Protection Agency (EPA) in the Federal Register of September 30, 1991, to conform its stratospheric ozone protection regulations (40 CFR, part 82) to the requirements of title VI of the Clean Air Act Amendments of 1990, Public Law 101-549. The notice proposes amended regulations implementing the 1992 and later requirements of section 604, as well as the related provisions of sections 603, 607, and 616, in a manner consistent with the United States' continuing obligations under the Montreal Protocol, as amended.

Energy Requirements.—The manufacturing cost of bromine was heavily dependent on chlorine and brine cost. Of the total brine cost, 46% was power related and 53% was maintenance cost. Brine cost is dependent on well maintenance cost and energy cost associated with well pumping. Approximately 14% of the bromine manufacturing cost was energy related.

Transportation.—The Research and Special Programs Administration (RSPA), U.S. Department of Transportation (DOT), published rules for hazardous substances (49 CFR, parts 171 and 172). The action complies with a 1986 amendment (Public Law 99-499) to section 306(a) of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980 (Public Law 96-510). The law mandates that RSPA regulate all EPA-designated hazardous substances. The amendment required shippers and carriers to identify CERCLA hazardous substances, to comply with the hazardous materials regulations (HMR) (49 CFR, parts 173.193 and 228), and to make the required notifications if a discharge of a hazardous substance occurs.

The DOT RSPA listed a final rule for performance-oriented packaging standards

that included several bromine compounds under HMR. The rule comprehensively revises the HMR with respect to hazard communication. classification, packaging requirements. On January 1, 1991, the new DOT/United National Performance Oriented **Packaging** Standards (POPS) were phased into the current DOT HMR. On that date, compliance with domestic shipping was voluntary. However, shipping materials internationally or domestically by air or international waters must comply with the POPS regulations. POPS involves changes to every aspect of shipping activities, including selecting packages; preparing shipping documents; and labeling, marking, and placarding shipments of hazardous materials and waste.

ANNUAL REVIEW

Legislation and Government Programs

EPA listed methyl bromide's ozone depletion potential (ODP) between 0.44 to 0.69. The Clean Air Act (CAA) of 1990 requires a production phaseout by the year 2000 of any substance with an ODP of 0.2 or greater. Although there are not foreseeable alternatives to methyl bromide use for quarantine treatments requiring 100% effectiveness, recovery can approach 90% of current emissions from fumigation chambers.¹

Methyl bromide is produced naturally from marine algae and giant kelp. About 300,000 tons is produced annually from natural sources. Methyl bromide also is produced by volcanoes.²

Researchers say the ozone depletion problem appears to be heading toward solution before they can find any solid evidence that serious harm was or is being done. Ozone is destroyed by the absorbing ultraviolet (UV) energy, and, paradoxically, ozone is created by UV radiation. Ozone is a renewable resource. Because of its constant movement, the amount of ozone above any given spot on the planet, and hence the amount of ultraviolet light filtered out, can vary widely from hour to hour. Ozone concentrations also change more

predictably on separate natural cycles. Over the tropics, where the sun's angle is high all year long, there has been no observed ozone depletion. The rising trend in skin cancer is not the result of ozone depletion or increased UV, but of lifestyle changes such as wearing skimpier clothing in summer, spending more time outdoors, and spending more time in southerly latitudes.

In January 1993, the EPA ordered a phaseout by the year 2000 of the pesticide methyl bromide. The directive complies with the provisions of the 1990 amendments to the CAA that require the EPA to update its list of ozone depleting chemicals and take steps to eliminate their use. Methyl bromide is used as a fumigant in soils to kill pests that are attracted to vegetables and fruits, to protect commodities such as grains while in storage, to fumigate fresh fruits and vegetables that are imported, and to kill insects in buildings.³

The EPA distributed to the chemical industry a preliminary list of chemicals and emission sources that will be covered by the CAA. The act dictates that standards must be developed for 40 source categories that emit 1 or more of the 189 hazardous air pollutants listed. EPA intended to regulate air emissions from five source categories that include process vents, wastewater treatment operations, storage facilities, transfer operations, and equipment leaks. The five source categories will be covered by technology-based National Emissions Standards for Hazardous Air Pollutants (NESHAP) standards. The Agency estimates that about 388 of the total 663 synthetic organic chemicals production subcategories meet 1 of these 2 tests.4

The Maximum Achievable Control Technology (MACT) changed the CAA from a health-based evaluation to a technology basis. Brominated compounds, including bromoform, methyl bromide, and vinyl bromide, will be promulgated by November 15, 1994. Existing sources have 3 years to comply.⁵

EPA announced that test data on the content of four brominated substances were received.⁶ EPA granted a section 18 exemption to four States for the use of

bromoxynil to control weeds in rice.7

Production

Ethyl Corp. and Great Lakes Chemical Corp. produced and marketed bromine chemicals from plants in Arkansas. Small amounts of unpurified bromine were produced as a byproduct of magnesium production in Michigan and reprocessed for consumption in Arkansas. The Arkansas plants accounted for 97% of U.S. elemental bromine capacity at yearend 1992 and 100% of bromine sold or used.

Kampen, chairman. Emerson president, and chief executive officer of Great Lakes, received the chemical industry's annual Kavaler Award for Chief Executive Excellence. He was chosen by the votes of a selection committee composed of 63 leading chemical industry analysts from 49 investment firms in Canada, England, and the United States. The industry's highest recognition for executive achievement. the award is presented by the Schnell Publishing Co., publisher of the Chemical Marketing Reporter and Chemical Business.

Tetra Technologies Inc. reached a definitive agreement with Dow Chemical Co. to complete the purchase of a bromine-derivatives plant in southwestern Arkansas. The agreement dated to 1987 when Dow sold it bromine business to Ethyl. To satisfy Federal antitrust concerns Dow was required to divest its clear brine fluids to a third party, Tetra. Dow retained repurchase rights.

Plant capacity was dependent upon brine supplies, concentration of the bromine in the brine, and individual plant extraction processes. In Arkansas, one supply and one disposal well were required for each 4.5 Mkg per year of bromine produced.

Bromine concentrations in the brine decrease as waste brine depleted of bromine is returned to its source. New wells must be drilled to provide adequate reserves to ensure future demands of elemental bromine. Each supply well requires an investment in excess of \$1 million and has an average life of about

10 to 15 years. (See table 2.)

Consumption and Uses

Regulation requires that methyl bromide be used for fumigation of imported produce. About three-quarters of the 29,000 tons consumed domestically is for soil application. In colder climates, the onset of winter controls pests and diseases. But in California and Florida, where it is relatively warm year-round, farmers fumigate the soil to kill insects, weeds, fungi, nematodes, and other organisms that attach to roots of seedlings.⁸

Fire retardants were primarily tetrabromobisphenol-A (TBBA) decabromodiphenyl oxide. Great Lakes expand TBBA production capacity at its El Dorado, AR, facility to meet growing demand as a flame retardant for acrylonitrile-butadiene-styrene polymers. The expansion increased Great Lakes' capacity by 25%. Ethyl began a \$20 million expansion of its brominated flame retardants plant in Magnolia, AR, that was expected to be completed by yearend. The products are for use in polymers used in electronics and business equipment applications and contain about 67% bromine.

The U.S. International Trade Commission (USITC) publication entitled "Synthetic Organic Chemicals, 1990" (SOC) listed Ethyl and Great Lakes as the only producers of hexabromocyclododecane. Sales of flame retardants account for one-half of the worldwide plastic additives market and are growing. Brominated hydrocarbons are the major materials used to make flame retardants.

There is demand for ethylene dibromide (EDB) for use as a scavenger for lead antiknock in gasoline additives. SOC listed Great Lakes and Ethyl as the only producers of EDB used in gasoline additives.

SOC reported that the Dyes & Pigments Div. of Mobay Chemical Corp. produced pigment red 168, dibromoanthranthrone orange. Red 168 was used in automotive metallic applications because of its transparency.

Bromine was used in clear brine

drilling fluids used in workover and completion fluids and other uses.

Halogenated synthetic rubber consumption has grown between 1980 and 1992. Exxon Chemical Co. is the manufacturer of only domestic bromobutly rubber. This rubber is more heat resistant than other types of rubber used primarily in truck tires. International Institute of Synthetic Rubber Producers in Houston, TX, projected growth rates of 2.1% per year through 1996 for all synthetic rubber consumption, with the exception of polychoroprene.

Great Lakes announced plans to halve its 1986 production capacity for halons by the end of this year. Du Pont shut down its only halon facility last year and now has a toll manufacturing agreement with Great Lakes. Great Lakes implemented a program in 1991 through its subsidiary E/M Corp. to collect and reprocess halons from the fire industry at a plant in the Los Angeles Basin. EPA approved two halon substitutes that the firm manufactures. FM 100 can replace halon 1211 in portable handheld fire extinguishers and it has an ozone depletion potential value (ODP) of 0.5. Substitution of FM 100 for halon 1311 would require evacuation of the room. FM 200 has zero ODP and offers a direct replacement for halon 1301. Both substitutes are manufactured at the El Dorado site.9

Sodium bromide in bulk and drums is used in treating cooling water and wastewater. These products are specially made to ensure purity and are registered with the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act. Bromine has a higher activity than chlorine and minimizes the amount of halogens released into the environment.

Prices

Prior to 1982, the price of bulk elemental bromine reported by U.S. producers, f.o.b. plant, was an average value of the quantity of bromine reported as sold. Statistical data published beginning in 1982 reported the total bromine sold and used for quantity and

value. The total has been revised for the years 1982 through 1991 to be equivalent to a weighted average of the value of bromine used by the producing company plus the value of bromine sold to other companies, as reported prior to 1982.

Bromine was sold under contracts negotiated between buyer and seller. Price quotations do not necessarily represent prices at which transactions actually occurred, nor do they represent bid and asked prices. They were quoted in table 3 to serve only as a guide to yearend price levels. (See table 3.)

Foreign Trade

Under section 4672(a) of the Internal Revenue Code, a substance should be listed as taxable if more than 50% by weight or more than 50% of value of its constituents are taxable. EDB, a colorless liquid, is derived from the taxable chemicals ethylene and bromine. The predominant method of producing EDB is via ethylene reaction with bromine. Imports are taxed at a rate of \$4.51 per ton. This is based upon a conversion factor for ethylene of 0.149 and a conversion factor for bromine of 0.851.

Israel received duty-free treatment on its bromine products in all major world markets except the United States, where duties are paid on two significant bromine products, sodium bromide and potassium bromide. The duty on all bromine products from Israel will drop to zero in 1995. (See tables 4 and 5.)

World Review

Methyl bromide emissions was the topic at a workshop convened at the United Nations Environmental Program's (UNEP) request. The workshop brought together participants to discuss use, alternatives, and substitutes. Methyl bromide total production and sales rose from 42,000 tons in 1984 to an estimated 63,000 tons in 1990. About one-half of the methyl bromide used is emitted into the atmosphere, or about 30,000 tons per year. Its use is considered vital for the economic viability of some agricultural

products and for quarantine treatment of certain products in international trade. At the international level, opposition to a phaseout has been strong from developing countries and from Israel, which like the United States, is a major producer of methyl bromide. In the United States, Great Lakes is the biggest producer. Other producers are located in Japan and Europe where producers are Atochem, Enichem A nic, and Eurobrom B.V. Many developing countries rely heavily on fumigation of exported products to control pests.

The European Community (EC) proposed restricting the use of brominated flame retardants in EC Directive 76/769. The draft proposal restricts the use of all noncommercial brominated diphenylethers (BDPE) to less than 0.1% immediately on adoption and bans commercial BDPE, namely deca, octa, and penta BDPE. ¹⁰

Canada.—Brine had been seeping into Potash Corp. of Saskatchewan Inc.'s Cory potash mine near Saskatoon since 1971. The brine composition is reported to contain 4,890 ppm bromine. Subsurface formation waters in Alberta range in composition from almost fresh to brines with a total dissolved solids content many times that of seawater. Brines constitute a potential commercial source of bromine.¹¹

China.—Nine bromine plants are reported to have an annual production capacity of 7,000 tons per year, or more than 80% of the total bromine output. The source of the bromine is underground bitterns that are used for salt production. The location of the plants are in East China in Shandong Province near Laizhou Bay.

France.—Ethyl acquired Potasse et Produits Chimiques (PPC) from the French companies Rhone Poulenc S.A. and Entreprise Miniere et Chimique at yearend 1992. PPC is Europe's largest producer of organic and inorganic brominated compounds, used primarily as photographic, agrichemical, and pharmaceutical intermediates.

Great Lakes through Octel Associates purchased the remaining 50% interest in Octel Kuhlmann by acquiring a 25% interest each from Rhone Poulenc and Elf Atochem. Octel Kuhlmann has a plant in Paimboeuf that produces lead-base antiknock compounds for motor fuels.

Germany.—Great Lakes purchased Bayrol Chemische Fabrik GmbH, a producer of swimming pool and spa water disinfection chemicals and equipment. Bayrol was headquartered in Munich and included sales and distribution centers in France, Italy, and Spain through wholly owned subsidiaries. Bromine-base water-treatment chemicals are a fast growing market in the Mediterranean as well as expected to emerge in Central and Eastern Europe. The recreational water markets are limiting the use of chlorine because of environmental concerns.

Hungary.—Great Lakes acquired a 75% interest in Chemol RT, the former state-owned chemical trading company. Headquartered in Budapest, Chemol imports and exports chemicals through an extensive sales force coupled with a network of subsidiaries, joint ventures, and 40 warehouses. It had 200 employees. The acquisition was expected to provide effective distribution for bromine clear fluids to complement the recent expansion of manufacturing operations in Germany and the United Kingdom.

Israel.—Israeli Chemical Ltd. (ICL) planned to issue about 31% of its share onto the U.S. market by yearend as part of the privatization program that includes Dead Sea Bromine (DSB), a subsidiary of ICL. The Government began efforts in 1985 to sell a share of ICL to offset an Much of the investment program. organic and inorganic chemical activity takes place within the framework of the massive ICL, which in 1986 was composed of 28 companies with a work force of 7,000. During 1990, formal bids were accepted for 50% of ICL, but a number of Government representatives favored a public sale rather than to a foreign investor. Great Lakes was part of

the only foreign consortium that bid on | ICL in 1990.

In 1991, privatization terms for ICL were approved. Some conditions for the privatization appear to conflict in terms of how much control the Government will exercise over ICL. The state retained the "power of supervision" over the natural resources controlled by ICL, such as bromine and reserves of potash in the Dead Sea. During 1992, 21% of ICL was sold and 30% was to be offered by vearend.

During 1992, Dead Sea Works received a court order to ensure that it seeks approval from the necessary authorities before it builds any more plants in Israel. This follows revelations that during the past 30 years the company has planned and built plants without receiving official approval. The problems gained exposure because of the privatization program underway.

In September, Dead Sea Bromine Group announced a \$12 million chlorine expansion at Sdom, Israel. Chlorine is the main raw material used in the production of bromine. The expansion will result in an increase in bromine production of 180,000 tons per year.

Waste brines from the bromine are used operation to produce magnesium. Plans are to build a \$300 million magnesium plant using the Russian electrolysis process.

Japan.—Israel has enjoyed a margin of tariff preference for imports of bromine compounds into Japan because the Israeli Government-owned company DSB is based in a "developing country." DSB is the world's largest single producer and accounts for 60% of all international trade in bromine and bromine chemicals in a \$1.3 billion market.

In 1989, Japan unilaterally eliminated its 3% tariff on elemental bromine to allow U.S. producers equal access with DSB. The U.S. industry faces tariffs on other brominated products that range from 3.8% to 4.6%.

United Kingdom.—On March 16,

Shell U.K. Ltd.'s stake in Octel Associates and the Associated Octel Co... Ltd. for \$138 million. Octel Associates is the world's largest producer of certain motor fuel antiknock compounds. more than 75% of the supplying refineries outside of North America. Octel operates manufacturing facilities in France, Italy, and the United Kingdom. The purchase increases Great Lakes' share from 52% to 87.8% of Octel with Chevron, British Petroleum, Texaco, and Mobil retaining the balance of the ownership interest.

ICL Americas Inc., a producer of halon 1211, a fire extinguisher, announced plans to end production by 1993. The main fire-fighting alternatives to halon-water and carbon dioxide-are unsuitable for protection of computers. electronics, and passenger aircraft. (See table 6.)

Current Research

The EPA-proposed fluorescent indicator adsorption (FIA) test for monitoring the potential for ozone forming emissions in reformulated gasoline is subject to significant bias and impressions. A more accurate test is the use of a bromine number. The bromine number is the number of grams of bromine that will react with 100 grams of the olefin sample. The number obtained varies with temperature, catalysts, and method. The first test was published in 1951. With modern instrumentation, the bromine number titration is automated and can be more precise and easier to use than the FIA procedure. 12

The Federal Register reported the results of a Health and Human Services's National Toxicology Program on June 3, 1992. There was no evidence of carcinogenic activity. Under conditions of these 2-year inhalation studies, methyl bromide caused degenerative changes in mice. 13

Agricultural biotechnology firms are developing herbicide-resistant crops. One of the herbicides that would be affected is Bromoxynil, a brominated compound that inhibits photosynthetic electron transport. Great Lakes announced the purchase of Although farmers will pay more for

herbicide-tolerant plant seeds, they will pay less for the herbicides used to control the weeds. The savings result when the herbicide is used as a postemergent agent rather than a preemergent agent. 14

OUTLOOK

Sales of bromine, primarily in compounds, have decreased about 25% since 1979. This represents an annual rate of decrease of about 2% per year. These decreases have been offset by increased use of bromine in fire retardants, sanitizers, and well-drilling fluids. Bromine is expected to increase in demand at the same 1.1% rate through the next 5 years. Demand as a fire retardant will offset any decreases in other uses. Bromine usage in welldrilling fluids was expected to increase.

Petroleum

Demand for bromine as a gasoline additive has declined each year since the EPA issued regulations in the 1970's to reduce the lead in gasoline. Bromine in the form of EDB is used as a "scavenger" for the lead to keep the lead from depositing in the engine. In 1979, the amount of bromine sold reached a peak of 225 Mkg. The rapid decline to 141 Mkg in 1986 was a direct result of the limits on lead in leaded gasoline. During 1991, the EC continued discussions to reduce lead levels in gasoline.

Federal laws enacted to encourage alternative forms of power in automotive engines are likely to have a depressive affect on increases in petroleum demand. The Clean Air Act Amendments have an amendment that will require mobile sources, such as cars and trucks, to use the most effective technology possible to control emission. Electric cars that do not require bromine gasoline additives are already on the market in California.

Sanitary Preparations

Bromine has found usage in swimming pools, hot tubs, and whirlpools. The sanitary preparation field is an area where bromine has been found to be safer than the chlorine substances that it substitutes. Sodium bromide was the fasting growing biocide intermediate with sales expected to grow 4% per year through 1995. The use of bromine will continue to grow in this area, closely following the gross national product in real growth.

Fire Retardants

Federal regulations covering flammability of private and public building materials and furnishings have required greater amounts of flame retardant chemicals to be used in these materials and furnishings. Chemically, the compounds are bromine and chlorine compounds, antimony and phosphorus compounds, and aluminum compounds. Alumina trihydrate is an important fire retardant that represents 32% of the market. Fire retardants are expected to grow between 2% and 4% with between 5% and 6% in the brominated fire retardant varieties as organic materials replacing metals in transportation, infrastructure, and packaging. Brominated flame retardants are about 32% of the total flame retardant market. Several State governments continue to support strong consumer laws that protect State residents from products with potential fire hazards produced in other States.

Other Uses

Usage of calcium bromide and zinc bromide in well-drilling fluids decreased during the 1980's as the domestic petroleum industry suffered a severe recession. Both the Baker Hughes and the Smith rig count published each week in the Oil & Gas Journal showed a 20% increase in activity during 1992 when compared with that of 1991. Oilfield chemicals used in drilling, completion and workover, and production operations have remained significantly more profitable internationally than in U.S. operations.

CADMIUM

By Thomas O. Llewellyn

Mr. Llewellyn, a physical scientist with more than 30 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for cadmium since 1987. Domestic survey data were prepared by Gloria A. Peebles, statistical assistant; and international data were prepared by Ted Spittal, international data specialist.

Cadmium has several important applications due to its unique properties. Cadmium used in secondary batteries has grown in importance during the past two decades and now represents the major use for cadmium. Cadmium coatings on aluminum, brass, iron, and steel make these metals highly resistant to corrosion in most conditions and especially in marine and alkaline environments. Cadmium pigments are stable inorganic coloring agents that have a high temperature stability, high resistance to degradation by light, and a wide range of excellent brilliant colors and opacity for applications such as ceramics, coatings, plastics, and artists' colors. Other uses for cadmium and cadmium compounds are stabilizers, alloys, solar cells, nuclear reactor controls, and several other minor uses.

Domestic production of cadmium metal decreased slightly in 1992 compared with that of 1991. Four companies operating four plants produced all of the domestic primary cadmium. The New York dealer-price range of cadmium metal, at \$1.90 to \$2.05 per pound at the beginning of 1992, followed a downward trend and closed the year at \$0.60 to \$0.70 per pound. The steady price decrease was attributed to a considerable decrease in demand owing to a global economic slowdown and the environmental concerns, together with the specific regulatory final ruling by the Occupational Safety and Health Administration (OSHA), related to the presence of cadmium in the workplace.

DOMESTIC DATA COVERAGE

Domestic production data for cadmium

metal and compounds are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the four metal-producing plants to which a survey request was sent, all responded, representing 100% of the total cadmium metal production shown in tables 1 and 3. Of the 10 operations that produced cadmium compounds to which a survey request was sent, 8 responded. representing 80% of the cadmium content of production of cadmium compounds shown in table 2. Production of nonrespondents was estimated using previous years' data adjusted for general industry trends. (See tables 1, 2, and 3,)

BACKGROUND

Cadmium is mainly a byproduct of refining zinc metal from sulfide ore concentrates. It is also produced as a byproduct of beneficiating and refining lead ores or complex copper-zinc ores. Cadmium was discovered in Germany in Germany produced the first commercial cadmium metal later in the 19th century, and it was the only important producer of cadmium until World War I, recovering the metal as a byproduct of the smelting cadmium-bearing zinc ores of Upper Silesia. Production in the United States began in 1907 when the Grasselli Chemical Co. of Cleveland, recovered metallic cadmium byproduct of zinc smelting. **Before** cadmium production started in the United States, about 85% of the cadmium content of the zinc concentrates was lost in roasting the concentrate and fractional distillation of zinc metal.

In the early 1900's, cadmium was

imported from Germany as metallic sticks and as cadmium sulfide pigment. As supplies from Germany were curtailed during World War I, domestic production, which started in 1907, increased dramatically. By 1917, the United States became the world's leading producer of cadmium and held that position for more than 50 years.

In the early part of this century, cadmium sulfide was used in this country mainly as pigment. Minor amounts of metallic cadmium were used in amalgams and other alloys. The common dental amalgam of those days consisted of 26% cadmium and 74% mercury.

During World War I cadmium was used mainly as a substitute for tin. The consumption of tin in the manufacture of food containers for U.S. and Allied troops (combat rations, popularly known as "C-rations") resulted in a scarcity of tin in the United States. To conserve tin, the quantity of tin metal in solder formulas was reduced, and cadmium was used in solders as a substitute for tin.

After World War I, prices of cadmium declined steadily, leveled off in 1925 at about \$0.60 per pound, and remained stable for the next 5 years. However, there was a decline in demand for cadmium in all industrial applications during the depression in the 1930's, which resulted in a price of \$0.55 per pound, the lowest ever quoted.

The U.S. Government regulated the domestic cadmium industry during World War II and the Korean conflict to provide adequate supplies for defense requirements. The price of cadmium metal has fluctuated widely in the past 40 years, and in 1988, the domestic price rose to an unprecedented value of \$7.90

per pound. The price increase was attributed to tight supply of cadmium, heavy speculative trading, world labor disputes, and an increased demand by the nickel-cadmium battery industry, particularly in Japan. Cadmium prices followed a downward trend the past 4 years, and the average price for cadmium metal for 1992 was only \$0.92 per pound.

The adoption of cadmium electroplating for rustproofing parts and accessories by the automobile industry was an important factor in making plating the biggest end use for cadmium for many years. Manufacturing of storage batteries using nickel-cadmium cells started in the United States during World War II. For the period 1940-45, the estimated consumption of cadmium in batteries was less than 1%, while that of plating was about 70%. However, by 1992, the consumption of cadmium in batteries reached 55% and plating had gone down to 14%.

Definitions, Grades, and Specifications

Cadmium is a soft (hardness of 2 on Mohs' scale), malleable, ductile, and bluish-white metal. The cadmium metal crystalline structure is a distorted form of hexagonal close packing. The atomic number of cadmium is 48; symbol, Cd; atomic weight, 112.40; density, 8.65 grams per cubic centimeter at 20° C; melting point, 321° C; and boiling point, 765° C.

The National Stockpile Purchase Specification P-8-R2, March 7, 1979, covered metallic cadmium in the form of balls and sticks. This specification requires a minimum cadmium content (by difference) of 99.950% with maximum impurity content of zinc, copper, tin, and antimony, 0.001% each; silver, arsenic, and thallium, 0.003% each; and lead, 0.005%.

Uses and Products for Trade and Industry

Commercial grades of cadmium metal have 99.95% to 99.96% minimum purity, but for special applications such as semiconductors, grades up to 99.9999% purity are produced by vacuum distillation. Cadmium metal is produced in a variety of shapes such as slabs, ingots, and sticks that are used in alloying, pigments, and in production of cadmium oxide. Balls and sheets are used for plating anodes.

Geology-Resources

Cadmium minerals are not found alone in commercially viable deposits, and its abundance in the Earth's crust is about 0.2 parts per million (ppm). Greenockite (CdS) is the only cadmium mineral of importance. It is not found in any isolated deposits, but is nearly always associated with sphalerite (ZnS). Cadmium is usually produced as a byproduct in the recovery of primary zinc from zinc ores and from some lead ores or complex copper-lead-zinc ores. However, it is generally agreed that the cadmium in lead and copper ores is associated with the zinc sulfide present rather than with the other minerals.

Domestic reserves of cadmium were estimated at about 70,000 metric tons, and the total world's reserves at about 535,000 tons. Cadmium reserves were estimated by applying recovery factors to zinc reserve data. A recovery factor of 0.4% was used for the United States, 0.5% for Mexico, and 0.3% for the rest of the world. The world's largest reserves of cadmium are in the United States and Canada.

The temperature of formation of zinc deposits has a partial bearing on cadmium concentration. In general, contact metamorphic and replacement deposits formed at a relatively high temperature have less cadmium content than intermediate hydrothermal ores and sedimentary-type deposits.

Technology

Mining, Beneficiation, and Refining.—Cadmium is mainly a byproduct of mining, beneficiating, and refining of zinc metal from sulfide ore concentrates. The mined zinc ores are crushed and ground to liberate the zinc

sulfide particles from the waste host rock. The ground ore is usually treated by a differential flotation process to separate the zinc-bearing particles from the waste rock, yielding a high-grade zinc concentrate and a waste product called tailings. The cadmium content of the zinc concentrate is usually about 0.3% to 0.5%. An estimated 90% to 98% of the cadmium present in zinc ores is recovered in the mining and beneficiating stages of the extraction process.

Refining of zinc and its cadmium content can be accomplished by treating the zinc concentrates and/or zinc-bearing secondary materials using either a hydrometallurgical or pyrometallurgical process. In both processes, the concentrate is converted from zinc sulfide to zinc oxide by roasting, and at the same time most of the sulfur is removed as sulfur dioxide (SO₂). The SO₂ offgas is stripped of all entrapped dust and other impurities and then converted to sulfuric acid in an acid plant.

In the hydrometallurgical process, cadmium, copper, and zinc are dissolved in the sulfuric acid leach of the roasted zinc ore. The copper and cadmium are among the most common interfering impurities that are removed before the purified solution is subjected to electrolysis for zinc recovery. Copper is precipitated from the solution using a determined amount of zinc dust. Most of the cadmium is precipitated in a second zinc dust addition, and any remaining dissolved cadmium is precipitated by a third stage of zinc dust addition. The purified zinc sulfate solution is sent to the cellroom, and metallic zinc is recovered from the solution by electrowinning. The cadmium precipitate is sent to the cadmium plant where it is filtered and formed into a cake containing cadmium. zinc, and minor amounts of copper and lead. Through various steps purification the impurities are separated, and a sufficiently pure cadmium sponge is dissolved in sulfuric acid. Metallic cadmium is recovered by electrolyzing this solution where cadmium is deposited on cathodes. After deposition, the cathodes are removed from the cells and stripped and the cadmium metal is melted and cast into desired shapes. In the pyrometallurgical process, cadmium is volatilized during the roasting and sintering of zinc concentrates, and the resultant fume and dust are collected as flue dust in baghouses or electrostatic precipitators. The initial cadmium content of the flue dust can be as high as 10%. A great deal of cadmium collects with the zinc metal and may be removed by refining the zinc by fractional distillation (the boiling point of cadmium is 767° C and that of zinc is 906° C).

The following process is usually used to obtain cadmium produced from flue dust collected at lead or copper smelters. Concentrates of copper, and especially lead, contain considerable amounts of cadmium. In copper smelters, the cadmium reports in flue dusts, which are collected and recycled through the smelter system to upgrade the cadmium content. At the lead smelters the cadmium is fumed off and collected in the blast furnace baghouses. The baghouse dust is recycled to upgrade the cadmium content and is later used as feed material for the cadmium refinery plant.

The cadmium-upgraded dusts are charged into a tank and dissolved with sulfuric acid. The resulting solution is filtered to remove impurities and to obtain a purified cadmium sulfate solution. Next, metallic cadmium, called sponge because of its appearance, is precipitated from the solution using zinc dust. The sponge is usually briquetted, remelted, and cast into ingots. Some plants produce cadmium oxide and/or metallic cadmium powder. Cadmium oxide is produced by melting the ingots and keeping a controlled oxidizing atmosphere in the retort. To produce metal powder, the melted ingots in the retort are kept under an inert atmosphere while cadmium is distilled into a condenser as metallic powder.

The availability of cadmium is in most cases dependent on the amount of zinc production. However, smelter residues from which cadmium is recovered may be stockpiled in times of low demand, low prices, or both and can be used to recover metal at a later date.

Recycling.—Cadmium recycling has been practical only for nickel-cadmium batteries, some alloys, and dust generated during the operation of electric arc furnaces used by steelmaking industries. The amount recycled is not known.

Almost all of the cadmium used in coating and plating, plastic stabilizers, and pigments occur at low concentrations of metal and involves a large number of products that are difficult to identify. Collection and recycling of such products is almost impossible to achieve.

Cadmium from spent nickel-cadmium batteries and cadmium alloys can be recovered using pyrometallurgical or hydrometallurgical processes. Generally, recycling plants employ pyrometallurgical processes for the recovery of cadmium from spent nickelcadmium batteries. Large cadmium batteries, normally heavier than 2 kilograms, are emptied of their electrolyte and dismantled mechanically. separators are then removed together with the plastic casings, and the cadmium is recovered by distillation from the plates. The plastic casings and separators of the small sealed batteries are burned off at a lower temperature prior to a higher temperature treatment required volatilization and condensation cadmium content.

In this country, a collection and sorting infrastructure is not in place to generate a supply of spent household Ni-Cd batteries for feed material capable of sustaining a commercial recycling operation.

INMETCO, an American company located 56 kilometers northwest of Pittsburgh in Ellwood City, PA, started commercial recovery of metal values from stainless steel wastes in 1978; since 1990, cadmium from industrial Ni-Cd batteries has also been recovered as cadmium dust, which is then sent to Horsehead Resource Development Co. (HRD), Palmerto, PA, for further purification treatment.²

Saft Nife Inc., at its Greenville, NC, facilities, collects Ni-Cd industrial batteries. The electrolyte of the batteries is emptied and purified for later use, while the dry batteries are packaged and

shipped to the Saft Nife recycling plant in Sweden.

In Sweden, the batteries are dismantled, and the positive electrodes, composed of some graphite, iron, and nickel, are sold to the stainless steel manufacturing industry. The cadmium from the negative electrodes is recovered by distillation using furnaces.³

Cadmium is present as a trace element in the raw materials used in the manufacture of iron and steel products. These materials included iron ore, coal, limestone, scrap steel, and the lead and zinc metals used to coat or treat specialty steel products. In the steel industry, cadmium is generated as a fugitive emission from electric arc furnaces (EAF) and open-hearth furnaces.

At current production levels, the total EAF dust generated per year, which is collected in baghouses, is estimated at more than 0.5 million tons containing approximately 250 tons of cadmium.

HRD. together with its company, Zinc Corp. of America (ZCA), are currently recovering cadmium, iron, lead, and zinc from EAF dust. separation of the contained metals in EAF dust is made by a two-stage-kiln volatilization process. In the first stage all nonferrous metals are volatilized to produce a marketable iron metal. In the second stage cadmium, chloride, fluoride, and lead are selectively volatilized to separate them from the zinc oxide. The fume product, known as lead-cadmium concentrate, is used to produced cadmium metal and a lead-silver-rich intermediate product that is sold to lead smelters.4

Substitutes

Among the possible substitutes for nickel-cadmium batteries are lithium, nickel-hydrogen, nickel-zinc, and silverzinc batteries. However, nickel-cadmium batteries are less expensive, have a greater service lifetime, and are less sensitive to abuse due to overcharging.

Coatings of zinc and/or vapordeposited aluminum substitutes for cadmium-plating applications. Bariumzinc and calcium-zinc stabilizers are replacing barium-cadmium stabilizers used in flexible polyvinyl chloride (PVC). Organotin stabilizers have been found suitable for flexible PVC applications. Indium, silver, and/or zinc can be used in brazing alloys to get lower melting temperatures without cadmium.

Economic Factors

Under the new Harmonized Tariff Schedule of the United States, which took effect January 1, 1989, cadmium sulfide and pigments and preparations based on cadmium compounds imports from most favored nations (MFN) are subject to a 3.1% ad valorem duty; for non-MFN a 25% ad valorem duty was retained. Imports of unwrought cadmium, waste and scrap, and powders are duty free for MFN, whereas a statutory duty of \$0.33 per kilogram was imposed on these materials for non-MFN.

Cadmium is taxed under the Superfund Amendments and Reauthorization Act of 1986, Public Law 99-499. The tax, to be collected from producers and importers, was \$4.45 per ton of cadmium metal. The tax, which was scheduled to expire on December 31, 1991, was rescheduled to end on December 31, 1995.

Cadmium producers are granted a depletion allowance of 22% on domestic production and 14% on foreign production.

Operating Factors

Cadmium has long been recognized as a toxic metal that must be handled with care to avoid prolonged exposure to cadmium fumes and/or dust. Cadmium poisoning can result from inhalation of cadmium dust and fumes or the ingestion of contaminated food and water. Chronic exposure to cadmium can lead to kidney dysfunction.

Concerns over human exposure to cadmium have generated a greater interest on the subject by Government agencies and the general public. The U.S. Bureau of Mines published an open file report on cadmium that presents a concise review on sources, processes, supply, and historical use patterns of domestic cadmium. It also covers a preliminary

estimated cadmium material balance for 1989. The data in this report were obtained from both known published and/or unpublished sources of information.⁵

Based on a 1976 report, the energy requirement for the production of cadmium metal from zinc plant fume and dust using a pyrometallurgical process is 166 million British thermal units (Btu) per net ton of cadmium metal. The energy requirement for the production of cadmium from cadmium filter cake using an electrolytic process is 154 million Btu per net ton of cadmium metal.⁶

ANNUAL REVIEW

Legislation and Government Programs

On August 3, 1992, the Department of Commerce (DOC) notified the public of its intention to revoke the antidumping duties on cadmium metal from Japan, which were established on August 4, 1972. Because DOC received objections to the revocation and following the Department's regulations, on December 29, 1992, DOC notified the public that it no longer intended to revoke the antidumping duties on cadmium metal from Japan.⁷

On August 31, 1992, OSHA, meeting a court-imposed deadline, issued its final decision on permissible 8-hour exposure limit (PEL) to airborne cadmium in the workplace. OSHA's final ruling requires that cadmium fumes or dust levels be lowered to an average of 5 micrograms per cubic meter of air over an 8-hour period. The previous allowable average PEL levels for an 8-hour period were 100 micrograms per cubic meter for cadmium fumes and 200 micrograms per cubic meter for cadmium dust.

OSHA has determined that some processes in six industries would be unable to achieve the PEL of 5 micrograms per cubic meter through engineering controls and work practice alone. Therefore, OSHA established separate engineering control air of either 15 or 50 micrograms for those processes. The six industries were nickel-cadmium battery manufacturing, zinc and cadmium

refinery, pigments manufacturing, plastic stabilizers, lead smelting, and plating. These final standards took effect 90 days from their publication in the Federal Register dated September 14, 1992.8

On October 23, 1992, the President signed the Defense Authorization Act for Fiscal Year 1992 (Public Law 102-484). This law, under Title XXXIII—National Defense Stockpile, authorized the disposal of obsolete and excess materials currently contained in the National Defense Stockpile (NDS) in order to modernize the stockpile. Disposal of the entire inventory of cadmium was authorized. However, the legislation does not establish a set timetable to accomplish the disposal of all the cadmium.

On December, 18, 1992, the Defense Logistics Agency (DLA) issued a draft sale invitation for bids for 45 tons of cadmium metal and planned to hold an industry forum on January 6, 1993, to hear industry's views on the terms and provisions of the draft sale solicitation. DLA expected to have the final invitation for bids by mid-February, and the initial bid opening was scheduled for March 22, 1993.

The U.S. Environmental Protection Agency (EPA) sponsored a technical forum in Providence, RI, on December 2-3, 1992, to promote discussion on the potential source reduction of cadmium, lead, and mercury in municipal solid waste (MSW). These three metals were selected following a set of criteria developed to identify those products which, according to EPA, are significant contributors to the total heavy-metal content in MSW. In reference to cadmium, EPA target products selected were nickel-cadmium batteries and Most cadmium-base stabilizers. participants in the nickel-cadmium batteries workshop recognized that an effective recycling program of spent batteries would considerably lower the amount of batteries entering the MSW stream. As for cadmium-base stabilizers, substitution has already taken place, and more barium-zinc and calcium-zinc stabilizers are replacing barium-cadmium stabilizers used in PVC. Furthermore, the industry began manufacturing cadmium-free stabilizers in the mid-1980's, and it expects most stabilizers to be cadmium-free in 5 years. EPA expects to distribute the final forum report in the second quarter of 1993.

Strategic Considerations

Cadmium is included in the NDS because of its importance in specialized military applications such as plating, where substitutes may be in short supply or unsatisfactory. In addition, the United States depends on imports to meet part of its requirements. The purchase of cadmium under the Strategic and Critical Minerals Stockpiling Act began in 1948, and the initial stockpile requirements were completed in 1955. Cadmium was also acquired for supplemental stockpile from 1956 through 1963 under provisions of the Agriculture Commodity Credit Corp. to barter surplus perishable goods for foreign-produced cadmium metal. Government shipments from stockpile excesses for 1964-76 totaled 3,918 tons. In April 1980, the stockpile goal for cadmium was set at 5,307 tons.

Under the 1992 Annual Material Plan, Public Law 102-484 of October 23, 1992, the Department of Defense was authorized to sell the entire cadmium inventory. No inventory acquisitions or sales were made during the year, and, as of December 31, 1992, the stockpile inventory was 2,871 tons of cadmium metal.

Domestic Production

Primary cadmium was produced by ASARCO Incorporated, Denver, CO; Big River Zinc Corp., Sauget, IL; Jersey Miniere Zinc Co., Clarksville, TN; and Zinc Corp. of America, Bartlesville, OK. The companies in Illinois, Oklahoma, and Tennessee recovered cadmium as a byproduct of smelting domestic and imported zinc concentrates. The company in Colorado recovered cadmium from other sources such as lead smelter baghouse dust.

Consumption and Uses

Apparent consumption of cadmium increased compared with that of 1991. Although the U.S. Bureau of Mines does not collect actual consumption data, apparent consumption by use categories in 1992 was estimated as follows: batteries, 55%; coating and plating, 14%; pigments, 16%; plastics and synthetic products, 10%; and alloys and other, 5%. (See table 3.)

On January 24, 1992, Ferro Corp.'s Color Div. announced its decision to withdraw from the cadmium pigment market for paints and plastics in the United States. A shrinking market, more stringent environmental regulations. increased availability of alternative pigments, and potential liability for pigments suppliers and consumers under the hazardous waste regulations were given as reasons for discontinuing the sale of cadmium pigments effective February 1, 1992.

Stocks

Inventories of cadmium metal held by metal producers decreased during the year, although metal held by cadmium compound manufacturers increased during 1992. (See table 4.)

Markets and Prices

The New York dealer price for cadmium metal at the beginning of 1992 ranged from \$1.90 to \$2.05 per pound. The price range for cadmium metal followed a steady downward trend during the first 6 months of the year and reached a low range of \$0.60 to \$0.70 cents per pound by June 25, 1992. July showed some signs of recovery in the cadmium market, and the price range for the next 3 months remained stable at \$0.80 to \$1.00 per pound. However, during the last quarter of 1992, once more prices followed a downward trend and closed the year at a range of \$0.60 to \$0.70 per pound. The steady price decrease was attributed to a considerable decrease in demand due to a global economic slowdown and the environmental concerns, together with the specific regulatory final ruling by OSHA, related to the presence of cadmium in the workplace.

Foreign Trade

Exports of cadmium products increased about 13% in 1992 compared with those of 1991. Cadmium metal imports for consumption decreased about 4% in 1992 compared to those of 1991. The principal supplying countries, in descending order of receipts, were Canada, Belgium, Mexico, and France. (See tables 5 and 6.)

World Review

Industry Structure.—World refinery production of cadmium was estimated at 18,750 metric tons in 1992. Japan was the largest producer of refined cadmium in 1992, followed by the United States, Canada, Belgium, China, Australia. Kazakhstan, and Russia. These eight countries accounted for approximately 62% of the world's refined cadmium production in 1992. Because cadmium is recovered mainly as a byproduct of zinc ore processing, many producers of zinc and zinc compounds produce primary cadmium as an integral part of their operation. In some cases, residues and flue dusts from zinc producers are used directly by cadmium producers. Some cadmium may also be recovered from flue dust generated at various lead and copper smelters; however, the amount of this production is not known. (See table 7.)

Capacity.—Rated annual production capacity for cadmium refineries was defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable, long-term operating rate, based on the physical equipment of the plant and routine operating procedures for labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought

into production within a short period of time with minimum capital expenditure. The total world cadmium refinery production capacity for 1992 was estimated at 25,000 tons.

Belgium.—Vielle Montagne, a subsidiary of Belgian-owned Acec-Union Miniere SA, closed its overpelt zinc smelter and cadmium refinery in February 1992. The closure represented a loss of about 500 tons of cadmium refinery capacity per year.⁹

United Kingdom.—Sir Clive Sinclair, a known British inventor, has produced an electric bicycle power by 20 high-capacity, D-size rechargeable nickel-cadmium batteries. The specially designed and manufactured batteries are recharged in 1 hour, and in return they provide about 1 hour of continuous service. ¹⁰

Current Research

The Cadmium Association, London, England: The Cadmium Council Inc., Reston, VA, and the International Lead Zinc Research Organization, Research Triangle Park, NC, held the Seventh International Cadmium Conference in New Orleans, LA, April 5-8, 1992. Major topics of discussion covered all aspects of production and uses of cadmium. methods of controlling cadmium losses to the environment, and the current regulatory scene around the Sponsoring organizations world. expected to have the conference proceedings published by the first quarter of 1993.

Developments in cadmium technology during the year were abstracted in Cadscam, a quarterly publication available through the Cadmium Association, 42 Weymouth Street, London, WIN 3LQ, England.

OUTLOOK

Despite an application decline of cadmium in pigments, stabilizers, and coating, the cadmium industry remains

optimistic about the metal and its compounds future applications in other areas. Nickel-cadmium batteries will continue to capture a greater share of the cadmium consumption market, and other high-technological developments in the use of cadmium, such as cadmiumtelluride-base solar cells, appear to have a great potential for both terrestrial and extraterrestrial (ET) power sources. As an ET important application of cadmium, National Aeronautics and Administration's (NASA) missions have relied almost exclusively on nickelcadmium batteries as a secondary power source, and this Agency will probably continue using such batteries in its future spacecrafts.

On the supply side, there is an increased interest on cadmium recycling from all secondary sources, besides spent batteries, EAF dust, and alloys. Electroplating sludges, process wastes, and possible cadmium pigments contained in plastics are being considered as a source of secondary cadmium production. However, if cadmium prices keep deteriorating, there would be no economical incentive to recover cadmium metal from these secondary sources.

Estimated. Revised.

¹This table gives unwrought production from ores, concentrates, flue dusts, and other materials of both domestic and imported origin. Sources generally do not indicate if secondary metal (recovered from scrap) is included or not; where known, this has been indicated by a footnote. Data derived in part from World Metal Statistics (published by World Bureau of Metal Statistics, Ware, United Kingdom) and from Metal Statistics (published by Metallgesellschaft, Frankfurt am Main, Germany). Cadmium is found in ores, concentrates, and/or flue dusts in several other countries, but these materials are exported for treatment elsewhere to recover cadmium metal; therefore, such output is not reported in this table to avoid double counting. This table includes data available through Apr. 2, 1993.

²Reported figure.

³Reported preliminary estimate.

⁴Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁵Formerly part of Yugoslavia; data were not reported separately until 1992.

⁶Dissolved in Dec. 1991.

⁷Includes secondary.

⁸Dissolved in Apr. 1992.

CEMENT

By Cheryl Solomon

Ms. Solomon, a physical scientist with 7 years of U.S. Bureau of Mines experience, has been the commodity specialist for cement since 1992. Domestic survey data were prepared by Gail Mason, statistical assistant; and international survey data were prepared by Ron Hatch, international data coordinator.

Cement is the most widely used construction material in the United States. The industry's main product, portland cement, makes up 97% of the total domestic production. The remainder comes from masonry, hydraulic, and aluminous cements.

In 1992, U.S. demand for cement increased by approximately 3%. Domestic production of portland cement increased by 5%. Cement imported for consumption declined for the fifth year to 6.8 million short tons. Portland cement prices stayed approximately the same.

The U.S. International Trade Administration suspended its antidumping investigation involving imports of gray portland cement and cement clinker from Venezuela. The basis for the suspension was an agreement by producers or exporters of cement from Venezuela to make all necessary price revisions to eliminate completely any amount by which the foreign market value of their merchandise exceeded the U.S. price of the subject merchandise.

DOMESTIC DATA COVERAGE

Domestic production and consumption data for cement are developed by means of the portland and masonry cement voluntary survey. Of the 120 cement manufacturing plants to which an annual survey collection request was made, 108 responded, representing 93% of the cement production and consumption data shown in table 1. Estimates were made for nonrespondents using monthly survey data and data received from previous annual surveys. (See table 1.)

BACKGROUND

Definitions, Grades, and Specifications

Section 4 of the Annual Book of the American Society for Testing and Materials (ASTM) publishes standards, test methods, definitions, recommended practices, classifications, and specifications for cement, lime, and gypsum.¹

Following is a brief discussion of various types of hydraulic cements and the materials from which they are made.

Clinker.—Clinker is produced by heating a properly proportioned mixture of finely ground raw materials containing calcium carbonate, silica, alumina, and iron oxide in a kiln to a temperature of about 2,700° F at which partial fusion occurs. The fused material, which ranges from fine sand grains to walnut size, is ground with small amounts, 3% to 5%, of calcium sulfate, usually gypsum or anhydrite, to make portland cement.

Portland Cement.—ASTM Designation: C-150 covers five types of portland cement: Type I, for use when special properties specified for other types are not required; Type II, for general use, especially when moderate sulfate resistance or moderate heat of hydration is desired; Type III, for use when high early strength is required; Type IV, for use when a low heat of hydration is desired; and Type V, for use when high sulfate resistance is required. ASTM specifications also include Type IA, Type IIA, and Type IIIA for the same uses but with the addition of air entraining compounds to protect concrete against freeze-thaw damage.

White Cement.—White cement is made from iron-free materials of exceptional purity, usually limestone, china clay or kaolin, and silica. The clinker is burned with a reducing flame in the kiln and rapidly quenched in a water spray to keep any iron in the ferrous state to avoid coloration by ferric ions. The clinker is then ground with high-purity white gypsum using ceramic balls and liners in grinding mills. White cement is used in decorative concrete, including terrazzo, highway lane markers, and architectural concrete.

Masonry Cement.—Masonry cement is a hydraulic cement used in mortars for masonry construction. It contains one or more of the following materials: portland cement, portland-pozzolan cement, slag cement, or hydraulic lime, usually with hydrated lime, limestone, chalk, calcareous shale, talc, slag, or clay interground for plasticity. ASTM Designation: C-91 contains specifications for masonry cement.

Blended Hydraulic Cement.—ASTM Designation: C-1157 first developed in 1992 covers blended hydraulic cements for both general and special applications.² This is a specification giving performance requirements. There are no restrictions on the composition of the cement or its constituents. The specification classifies cements by type based on specific requirements for general use, high early strength, resistance to attack by sulfates, and heat of hydration. As a performance

standard and not a rigid formula of | cement. ingredients, it does not replace ASTM's existing standards (C-595 for blended cement described below) but is an additional way to specify blended cements.) ASTM Designation: C-595 covers four kinds of blended hydraulic cements, each with an optional provision for air entraining.

Portland-Blast Furnace Slag.—This is essentially an intimately interground mixture of portland cement clinker and granulated blast furnace slag, or an intimate and uniform blend of portland cement and fine granulated blast furnace slag in which the slag constituent ranges between 25% to 70% of the total weight of the cement.

Pozzolan.—Pozzolan is a siliceous and aluminous material that in itself possesses little or no cementitious value but will, in a finely divided form and in the presence of moisture, chemically react with calcium hydroxide at ordinary form compounds temperatures to possessing cementitious properties. Fly ash is a pozzolanic material obtained from flue gases produced by coal combustion. Natural pozzolans are naturally occurring materials such as diatomaceous earths, opaline cherts and shales, tuffs, volcanic ash, and pumicites. ASTM C-618 covers fly ash and natural pozzolans.

Cement. Portland-Pozzolan Portland-pozzolan cement is produced by intergrinding portland cement clinker and pozzolan, by blending portland cement or portland-blast furnace slag cement and finely divided pozzolan, or a combination of intergrinding and blending in which the amount of the pozzolan is between 15% and 40% of the total weight of the cement.

Pozzolan-Modified Portland Cement.—The constituents in this type of cement are the same as those for portland-pozzolan cement, methods of production are also the same. However, pozzolan makes up less than 15% of the total weight of the blended

Slag Cement.—Slag cement is a finely divided material made from a uniform blend of granulated blast furnace slag and hydrated lime. The slag constitutes at least 70% of the total weight of the blended cement.

Oil-Well Cement.—Oil-well cement was developed to seal oil and gas wells under pressures of 18 to 20,000 pounds per square inch and temperatures up to 400° F in oil and gas wells and 500° F in steam wells. This cement must remain fluid up to about 4 hours to be effective. The cement is modified by service companies to fit individual well conditions using additives. The average well depth is 4,600 feet, but can range from grass roots depth to 30,000 feet.

The American Petroleum Institute (API) specifications cover requirements for manufacturing eight classes of well cements-A, B, C, D, E, F, G, and Hand Grades O-Ordinary, MSR-Moderate Sulfate-Resistant Grade, and HSR-High Sulfate Resistant Grade.³ Changes in the API specification were set down in 1991, including the elimination of specific well depths in classes A-H cement and the abolition of mandatory testing for classes A, B, and C cement among other The physical and chemical changes. down previously requirements set remained the same.

Expansive Cement.—Expansive cement is a hydraulic cement that tends to increase in volume after setting during the early hardening period. There are three types of expansive cements, types K, M, and S. Expansive cements are used primarily in shrinkage-compensating **ASTM Specification C-845** concrete. covers all expansive cements.

Aluminous Cement.—Sometimes known as calcium aluminate cement. or high-alumina cement, aluminous cement is a hydraulic nonportland cement. Special applications of aluminous cement are based on its rapid-hardening qualities, resistance to sulfate action, and refractory

properties when used as "castable refractories" and mortars for furnaces and

Concrete.—Concrete is a proportioned mixture of coarse mineral aggregates of sand and gravel or crushed stone, bound together by a paste of hydraulic cement and water. Volume 4.02 of ASTM standards covers concrete and aggregates.

Admixtures.-Admixtures allow the concrete to be altered to the particular job. Factors such as the durability. appearance, versatility, and cost effectiveness of the concrete, can be manipulated. Most additives modify the hydration of portland cement in some way, by changing the speed of reaction or by dispersing the cement particles more thoroughly throughout the mix. Admixtures reduce the water-cement ratio required in the concrete mix.

The following are admixtures in cement:4

Plasticizers.—Plasticizers are waterreducing agents that effectively reduce the quantity of cement required to achieve certain strength or workability characteristics.

Superplasticizers.—Superplasticizers produce highly workable flowing concrete that, for example, can be used for pumping applications. Superplasticizers also can produce high-strength concrete that has a reduced water content and a high compressive strength.

Air-Entraining Agents.-Airentraining agents cause microscopic air bubbles to be distributed uniformly throughout the concrete. These act as reservoirs for the water when it freezes. allowing it to expand without harming the structure of the concrete. They also can act as crack inhibitors by preventing small cracks enlarging beyond the extent of the nearest air void. Concrete may be air-entrained to give protection from Air-entraining freeze-thaw cycles. mixtures may entail loss of compressive and tensile strength, and thus may be used with plasticizers to restore the strength properties. Fly ash and slag have an air-entraining effect.

Accelerators.—Accelerating admixtures increase the hardening rate of concrete, giving high early strength development. Calcium chloride is the most common accelerator and has been in use since 1885. Accelerators are used mainly in cold weather to normalize the setting time for concrete in a similar way that retarding plasticizers may be used in hot weather to slow down the process.

Waterproofing Aids.—Waterproofing aids are chemical admixtures that provide protection against the wind and rain and reduce the intake of ground water. Waterproofing aids form a water repellent surface on the concrete and thin hydrophobic layers and voids within the concrete structure.

Polypropylene Fibers.—Polypropylene fibers can inhibit cracks. The fibers take up the stress from drying concrete, thus reducing the tendency for it to crack. They add little to the overall strength of the hardened concrete; however, they impart elasticity during the initial plastic stage of the concrete, which is important for the inhibition of cracks.

Products For Trade and Industry

Portland cement makes up 97% of total domestic output; the remainder is mostly masonry cement with white, expansive, portland slag and pozzolan, waterproof, and a variety of miscellaneous cements accounting for a small percentage of the remainder.

Industry Structure

The industry is composed of 120 cement-producing plants in 38 States. Multiplant operations were being run by 18 companies. Seventeen independent importers have constructed terminals to receive foreign cement for markets near coastal areas.

The cement industry has been very active in vertically integrating the cement companies since 1985, when the Federal

Trade Commission removed the ruling that prevented vertical integration in the construction materials industries. Vertical integration would include owning ready-mix concrete, concrete products. aggregate, and construction businesses that buy the cement. In addition, the cement companies own crushed stone. sand and gravel, hot-mix asphalt, and precast and prestressed concrete companies. Other companies may own fly ash, slag, chemical admixtures. colored cement, waste material including fuel, and cement distribution companies. Therefore, cement companies have moved beyond simply acquiring the cement consumers, but also are owning the fuel and cement distribution companies.

In 1992, one of the activities in the U.S. cement industry with respect to vertical integration was the acquisition by Sunbelt Enterprises, the U.S. subsidiary of Cementos Mexicanos (Cemex), S.A., of C.L. Pharris Sand & Gravel, Inc. and a substantial portion of the assets of the Pharris Group based in southern California. Pharris had significant sand and gravel reserves in California.⁵ Lone Star Industries Inc. sold the assets of the San Vel ready-mixed concrete and aggregate operation to Aggregate Materials Corp. for \$5.5 billion.⁶

Most of the cement companies in the United States that were vertically integrated were foreign owned.7 Such companies included Beazer U.S.A., owned by Hanson Industries; Blue Circle Cement Inc.; Calaveras Cement of Cimenteries CBR, S.A.; Dragon Products Co., owned by Cementos del Norte; Essroc Corp., owned by Ciments Français; CSR; Lafarge Corp.; National Cement Co., owned by Ciments Vicats; Mitsubishi Cement Corp.; California Portland Cement, owned by Onoda Cement; and Tarmac. Southdown Inc., a wholly owned U.S. cement company, was integrated in California.

Resources

Primary raw materials required for cement clinker production are, in order of importance, limestone, clay and shale, and iron ore. In instances where essential chemical components are not present in primary raw materials in the required amount, other mined materials or industrial products may be used as additives to correct these deficiencies. Gypsum is added during the clinker grinding process to make finished portland cement.

Although raw materials for cement manufacturing have not been quantified, they are abundant in most countries. Some countries deficient in raw materials meet their requirements by importing. Many domestic companies have reported reserves of raw materials exceeding 100 years of supply.

Technology

Principal steps in manufacturing portland cement consist of crushing, grinding, mixing, and burning raw materials and grinding the resultant clinker. About 1.8 short tons of raw materials is required to make 1 short ton of cement.

Raw Material Grinding.—Both dry and wet grinding are used to obtain a fineness that may range from 75% to 90% passing through a 200-mesh sieve. In wetmilling, water is added with the mill feed to produce a slurry containing about 65% solids. The raw material then is dried and ground for burning.

Burning.—Burning is the most important operation in manufacturing cement because fuel consumption is a major expense, plant capacity is measured by kiln output, and strength and other properties of cement depend on the quality of the clinker. Burning takes place in a rotary kiln that is a refractory-lined steel cylindrical shell. It rotates on an axis inclined at 3/8 to 1/2 inch per foot toward the discharge end. U.S. kilns range in size from 116 to 760 feet long and 8 to 24 feet in diameter.

Byproducts and Coproducts

There are no major byproducts and coproducts in manufacturing hydraulic

cement in the United States. Flotation, a method of beneficiation used by some remove undesirable companies to constituents from raw materials and usually to increase the calcium carbonate content of the kiln feed, produces waste such as silica sand or mica fines that may be marketed. Waste rock quarried in selective mining of usable raw material has been sold for riprap and fill materials or crushed and sold as aggregate for concrete or for road base. Some kiln dusts with high alkali content have been collected and used as fertilizer or processed to recover potash.

Economic Factors

Prices.—Cement prices are greatly influenced by local or regional markets and by the availability of energy and raw required materials for cement manufacturing. Discounts for cash and large-quantity purchases, absorption of freight charges, and the cost of packing bags and pallets add to the complexity of cement price patterns. Competition among producers and, in some instances, stiff competition from imports are also factors that contribute to depressed prices and ultimately limit investment dollars available for capital improvement or expansion.

Costs.—The cement industry has cut energy consumption and costs considerably over the past 30 years by modernizing the kilns, utilizing secondary fuel burning, and improving efficiency. Energy costs account for about 35% of the total production costs for cement. Plant operating costs may make up 70% of the value of cement.

Tariffs.—For countries with most-favored-nation status, duties are imposed only on white cement in the amount of \$0.22 per metric ton, including the weight of containers. Other hydraulic cement and clinker are duty free. The statutory import duty for countries without most-favored-nation status is \$1.76 per metric ton and \$1.32 per metric ton for white cement and for all

other types of cement and clinker, respectively.

Operating Factors

Environmental Requirements.—The U.S. Environmental Protection Agency (EPA) was involved in a number of studies involving cement kilns. study, due in 1993, was of cement kiln dusts, the last of the Bevill Amendment wastes that were excluded from regulation as hazardous wastes until studies had been completed. Another study was of the process of using wastes in making cement. The study was to serve as a basis for a regulation targeted for late 1994 that would "reduce unnecessary regulatory barriers to the appropriate use of hazardous waste in the production of cement and other building materials."8

The EPA also was to conduct a major overhaul of Federal regulations for waste combustion, requiring full risk assessments and new permits, to include "an appropriate dioxin standard."9

Energy Requirements.—The U.S. cement industry consumed an average of 4.8 million British thermal units per short ton (Btu/short ton) in 1992. Types of fuel consumed in the cement kiln were natural gas, bituminous and anthracite coal, and petroleum coke. High sulfur petroleum coke may be blended with coal and used as fuel in the cement kiln.

The cement industry also has been derived from other using wastes industries as fuel for cement kilns since the 1980's. The waste fuel market is divided into two broad areas: hazardous waste and nonhazardous waste.11 The hazardous-waste area contains wastes such as printing inks and dyes, paints, solvents, chemicals, plastics, and any other materials that have come into contact with these industrial wastes. Nonhazardous wastes include scrap tires, medical waste, used oil, nonhazardous plastics and chemicals, and municipal

Over the past 6 years, there has been a steady increase in the use of hazardous waste derived fuels. Cement kilns are

said to be ideal waste disposal units because the clinkermaking process requires high temperatures, long burning times, and a high level of turbulence. Liquid wastes, solvents, used motor oil, and scrap tires can be burned effectively, cutting down on fuel costs.¹²

Currently, liquids are used more commonly as hazardous waste derived fuels. Solids and sludges can be introduced into the kiln in a variety of ways. Solids can be suspended in liquids and pumped into the kiln or injected directly into the calcining zone. Preprocessed solids and sludges are dried, ground into powder, and air-conveyed into the hot end of the kiln.

With any of these three processes, as fuel is consumed, the organic compounds are destroyed. The inorganic compounds recombine with the raw materials and are incorporated into the matrix of cement.

Cement kilns may need to be modified to burn some of these wastes. kilns already have been retrofitted to use waste oil. Using scrap tires as fuel for preheater kilns is well known, but had not been an option for long kilns. New technology will allow whole tires to be inserted into the calcining zone. One automated bulk tire feeder can run unattended with a programmable The costs involved in controller.14 converting to using wastes as fuel depend upon the type of waste, with hazardous waste the most expensive and tires the least expensive. However, the cement kilns are paid approximately \$50 per short ton for using hazardous liquids and \$250 to \$400 per ton for solids.

Other waste fuels that cement kilns may be recycling in the future could be municipal wastes or waste timber.¹⁵

ANNUAL REVIEW

Legislation and Government Programs

The EPA has a mandate under the Bevill Amendment of the Resource Conservation and Recovery Act (RCRA) to study cement kiln dusts and to present a Report to Congress by yearend 1993. 16

Issues

One of the main issues facing the cement industry seemed to be whether the cement industry could increase profitability by retiring old plants, cutting costs, improving its efficiency, and raising prices. Another crucial issue for the cement industry was the environment and the use of alternate fuels to make cement. (See sections on Environment Requirements and Energy Requirements of this report.) Other issues were that the cement industry continued to pursue vertical integration, or acquisition not only of downstream customers, but also of competitors or companies that would source fuel. (See Industry section of this report.)

These issues were interconnected. For example, the use of alternate fuels aided the cement industry with respect to cutting costs and increasing profitability. In addition, cement companies pursued vertical integration with respect to the buying of waste companies to ensure a fuel supply. Vertical integration in the cement industry has been undertaken to attempt to improve efficiency in supply of materials, fuel, and customers.

Production

One State agency and 49 companies operated 120 plants in 38 States. In addition, two companies operated two plants in Puerto Rico, manufacturing hydraulic cement. The production data obtained are listed by State or groups of States that form cement districts. A cement district may represent a group of States or a portion of a State. The States of California, Illinois, New York, Pennsylvania, and Texas are divided to provide more definitive marketing information within those States, as follows:

California, Northern.—Points north and west of the northern borders of San Luis Obispo and Kern Counties and the western borders of Inyo and Mono Counties.

counties in California.

Chicago, Metropolitan.—The Illinois counties of Cook, DuPage, Kane, Kendall, Lake, McHenry, and Will.

Illinois.—All other counties in Illinois.

New York, Western.—All counties west of a dividing line following the eastern boundaries of Broome, Chenango, Lewis, Madison, Oneida, and St. Lawrence Counties.

New York, Eastern.—All counties east of the aforementioned dividing line, except Metropolitan New York.

New York, Metropolitan.—The five counties of New York City (Bronx, Kings, New York, Queens, Richmond) plus Nassau, Rockland, Suffolk, and Westchester Counties.

Pennsylvania, Eastern.—All counties east of the eastern boundaries of Centre. Clinton, Franklin, Huntingdon, and Potter Counties.

Pennsylvania, Western.-All other counties in Pennsylvania.

Texas, Northern.—All counties north of a dividing line following the northern borders of Burnet, Crockett, Jasper, Jeff Davis, Llano, Madison, Mason, Menard. Milam, Newton, Pecos, Polk, Robertson, San Jacinto, Schleicher, Tyler, Walker, and Williamson Counties.

Texas, Southern.—All counties south of the aforementioned dividing line.

Clinker.—Clinker production in the United States, excluding Puerto Rico, stayed approximately the same as that in 1991. California continued to lead all States in clinker production, followed by Texas, Pennsylvania, Missouri, and Michigan.

By yearend, multiplant operations were being run by 19 companies. The size of individual companies, as a percentage of total U.S. clinker production capacity, California, Southern.—All other ranged from 0.3% to 12%. The 5 largest

companies with clinker capacity provided 38% of total clinker capacity; the 10 largest companies with clinker capacity provided a combined 60%. The 10 largest companies, in decreasing order of size of clinker production, were Holnam Inc.: Lafarge Corp.; Southdown Inc.; Lone Star Industries Inc.; Blue Circle Inc.; Lehigh Portland Cement Co.; Ash Grove Cement Co.; Essroc Materials Inc.; California Portland Cement Co.; and Medusa Cement Co.

Portland Cement.—Portland cement production increased by 5% to 74.3 million short tons. The reason was attributed to increased demand for cement, primarily in the Mountain, East/West North Central, and East/West South Central States.

The industry operated 120 plants, including 8 grinding facilities, to produce various types of finished hydraulic cement.

The size of individual companies, as a percentage of total U.S. finished cement production capacity, ranged from less than 0.01% to 11.8%. The top 10 producing companies, in declining order of production, were Holnam Inc.; Lafarge Corp.; Lone Star Industries Inc.; Southdown Inc.; Lehigh Portland Cement Co.; Blue Circle Inc.; Ash Grove Cement Co.; Essroc Materials Inc.: Medusa Cement Co.; and California Portland Cement Co.

Masonry Cement.—Production of masonry cement increased by 8% to 3.1 million short tons. At yearend, 82 plants were manufacturing masonry cement in the United States. One plant producing masonry cement exclusively was Riverton Corp., Riverton, VA.

Aluminous Cement.—Aluminous cement continued to be produced by Lehigh, Buffington, IN; Lafarge, Chesapeake, VA; and Aluminum Co. of America, Bauxite, AR.

Fuel Consumption.—According to the Portland Cement Association, a survey of its members indicated that coal and coke

accounted for 69.5% of the energy consumed. 17 The consumption of electrical energy represented 9.9% of the fuel used. Fuel used in wet-process plants was 5.9 million Btu per short tons, or 34% higher than the dry process of 4.4 million Btu per short tons. Kilns without preheaters averaged 5.4 million Btu per short tons, those with preheaters averaged 4.3 million Btu per short tons, and those with precalciners averaged 3.9 million Btu per short ton.

Changes.—Arawak Corporate Cement Co., a 1,000-metric ton-per-day, dry-process plant in Barbados, was advertised for sale. The plant, brought on line in 1984, was owned by the Governments of Barbados and Trinidad and Tobago.18

Ash Grove Cement West was merged into the Ash Grove Cement Co., the U.S. cement and lime manufacturer. 19 Boxcrow Cement Co., Midlothian, TX, filed for chapter 11 bankruptcy in December. Holderbank, which had been managing the operation, let its contract expire in September. CBR, owner of the Calaveras Tehachapi plant in northern California, modernized the plant, which came on-stream during the year.

Italcementi, Italy's largest cement manufacturer, purchased 54.6% Societe des Ciments Français' capital to increase its international presence.20 Italcementi produced 16.5 million metric tons, or approximately 35% of the Italian cement market. In North America, Ciments Francais operated under the name Essroc and had cement plants in Indiana, Maryland, Michigan, Ohio, Pennsylvania, and Ontario, Canada. Italcementi already had holdings in the United States: River Cement, Hercules, and Signal Mountain.21

Cemex acquired two Spanish cement companies. Compania Valenciana de Cementos Portland and Auxiliar de la Construccion (Sanson). In the United States, Valenciana had a joint venture with Scancem in Norval, an import terminal in Brooklyn, NY.22

Heracles General Cement Co. was acquired by Calcestruzzi, subsidiary of Ferruzzi Finanziaria, a large Italian

industrial group. The acquisition was to be a joint venture between Calcestruzzi and the National Bank of Greece. Heracles, which was controlled by the Greek Government, was Greece's largest cement company.23

Hanson PLC asked the Federal Trade Commission to approve the sale of its 50% interest in Cencal Cement Co. to Cencal's other co-owner. SsangYong Cement.24

Holnam Inc. closed its cement production plant in Okay, AR.25 The two-kiln operation was closed because of its age (it was built in 1929) and the cost of operating the facility, as well as overcapacity in its market area.²⁶

Lone Star Industries Inc., which filed for bankruptcy in 1990, planned to sell its cement plant in Nazareth, PA, as part of its proposed reorganization plan. It also planned to reorganize its board of directors.²⁷ Lone Star Industries also sold all of the capital stock of Compania Argentina de Cemento Portland to Loma Negra Compania Industrial Argentina for \$38 million.

Medusa Corp. signed a letter of intent to purchase the Demopolis cement plant from the Lafarge Corp.²⁸ million transaction included nine cement distribution terminals in Alabama. Florida, Georgia, and Tennessee. The decision by Lafarge to sell the 15-yearold plant was made to rationalize the company's existing cement asset base in the southeastern U.S. and Mississippi River markets.²⁹

Red Rock of Minnesota opened a new terminal south of Cincinnati-Grey Stone of Kentucky. Grey Stone was to receive its cement from Spain, which would ship the cement up the Mississippi and Ohio Rivers.30

Tarmac America Inc. and Titan Cement Co. of Athens, Greece, completed their joint-venture agreement to operate Roanoke Cement Co. Titan was to be the majority partner. 31 Twentyfive million dollars was to be invested in modernizing the plant.

Consumption and Uses

United States, excluding Puerto Rico, increased by 5%. According to U.S. Department of Commerce (DOC) data, housing starts declined 14% to 860,000 units. The value of new construction put in place increased 6.5% to \$427 billion. The value of residential construction put in place increased 17% to \$184 billion, primarily in single-unit structures. The value of nonresidential construction put in place declined 13% to \$85.5 billion owing primarily to decreases industrial, office, and other commercial building construction. Public construction increased by 5% to \$52.9 billion, caused in part by spending for highways and streets, hospitals and schools, and conservation and development.32

Among the consuming States, California continued to lead all areas in the amount of portland cement consumed. followed by, in order of shipments received, Texas, Florida, Illinois, Pennsylvania, and Ohio. Together, these States consumed 39% of total U.S. tonnage.

On a regional basis, all of the census regions but the Pacific experienced increases in consumption. The largest increases were experienced by the Mountain, West North Central, East South Central, New England, and East North Central, with 18.9%, 14.8%, 9.2%, 8.5%, and 7.7%, respectively. The West South Central, South Atlantic, and Middle Atlantic experienced increases of only 5.2%, 3.6%, and 2.3%. respectively. The Pacific Region experienced a 3% decrease in consumption.

Shipments of domestically produced portland cement from U.S. mills increased by 7% as shown in table 9, shipments while masonry cement increased by 8%. (See table 9.) Readymix concrete producers were the primary consumers of cement, accounting for about 69.4% of the total, followed by concrete product manufacturers with 12.9%, highway contractors with 4.9%, building material dealers with 4.4%, and other contractors with 3.1%. Smaller amounts were consumed by Federal, State, and other government agencies and Consumer demand for cement in the | by a variety of other miscellaneous users.

Markets and Prices

The average mill value of portland cement per ton stayed approximately the same at \$49.54 per short ton, and the value of masonry cement showed a decrease of 2% to \$67.78 per short ton. The average value of cement by yearend reported by Engineering News-Record (ENR) was \$61.81 per short ton. The ENR prices are based on an average per short ton value of cement delivered to 20 cities. The prices ranged from a low of \$61.81 in August and October through December to a high of \$63.45 in January. The average price change for portland cement for December 1992 decreased by 1% compared with December 1991.33

Foreign Trade

On February 27, 1992, the DOC suspended its antidumping investigation involving gray portland cement and cement clinker from Venezuela.34 The basis for the suspension was an agreement by Venezolana de Cementos, S.A.C.A. and Cementos Caribe, C.A., which accounted for substantially all imports of these products from Venezuela, to make any necessary price revisions to eliminate completely any amount by which the foreign market value of their merchandise exceeded the U.S. price of the subject merchandise. The investigation began in 1991 when three Florida-based producers filed antidumping petitions with the United States International Trade Commission (ITC). The three producers were Florida Crushed Stone Co., Southdown Inc., and Tarmac America Inc. Venezuelan cement exports to the United States in 1992 were 60,000 metric tons compared with 0.9 million metric tons in 1991 and 1.5 million tons in 1990.

In 1992, the DOC increased the dumping margin on Cemex, S.A. cement from 58.38% to 59.91% and "all others" from 58.05% to 59.91%.³⁵ Mexico exported only 909,000 short tons of cement to the United States in 1992. The United States traditionally received the bulk of Mexico's cement exports, which peaked in 1988 at 5 million short tons.

In 1989, the United States received 4.4 million short tons of cement from Mexico. This amount, however, was halved in 1990, when the ITC and DOC determined that Mexico was dumping cement and dumping duties were collected.

That year 2.3 million short tons of cement was exported to the United States; and only 1 million short tons was exported to the United States in 1991.

A panel of the General Agreement on Tariffs and Trade (GATT) ruled that the DOC had improperly applied the stiff antidumping duties to imports of Mexican cement and recommended that the United States return the \$30 million in duties it had collected. Because GATT does not have the authorization to enforce that recommendation, it was unlikely that the United States would return any antidumping tariffs.

According to trade data reported by the DOC, Bureau of the Census, cement imported for consumption in the United States and its possessions and territories was 6.8 million short tons or 22% below the level of 1991. This was the fifth year of decline following 4 consecutive years of record-high imports from 1984 to 1987. The decline corresponded to the marginal decrease in total demand resulting from reduced construction activity. Canada, Mexico, and Colombia were the principal import sources, respectively accounting for 49%, 13%, and 8% of the total. Clinker accounted for 1.73 million short tons or 25% of total imports, which represented an increase of 8% over that of 1991. Clinker imports as a percentage of total imports reached 32% in the peak year of 1985. This percentage then gradually declined from 24% in 1986 to 17% in 1991. The value of foreign cement and clinker, including cost, insurance, and freight, delivered to U.S. ports averaged \$43.72, down 6% from that of 1991.

The passing of the North American Free Trade Act (NAFTA) was debated in 1992. NAFTA had among its objectives the elimination of barriers to trade in and to facilitate the cross border movement of goods and services between the territories of Canada, Mexico, and the United States

and to promote conditions of fair competition in the free trade area.³⁷ It was unclear whether NAFTA would have a significant effect on the cement industry.

Exports of hydraulic cement and clinker, as reported by the Bureau of the Census, increased 26% to 698,000 short tons. Canada received 74% of the total.

New York led all States in the amount of imports received, with 17% of total Sixty-four percent or U.S. imports. 732,345 short tons of New York imports was shipped through the Buffalo Customs District. Eighteen percent or 208,349 short tons was shipped through the New York City Customs District and 18% or 203,332 short tons was shipped through the Ogdensburg Customs District. These imports comprised 17% of New York's portland cement consumption compared with 8% of apparent consumption nationally. Eighty-two percent of imports into New York came from Canada, 12% came from Greece, 2% came from Spain. and 4% came from the United Kingdom. Michigan was the second largest recipient of imported cement, receiving 1.09 million short tons or 16% of the total. All of the Michigan imports were shipped through the Detroit Customs District, and all came from Canada.

In 1992, China exported 21,000 short tons of cement to the United States for the first time. The shipment arrived at the Lone Star Northwest Seattle, WA, and Portland, OR, terminals in December. The cement was manufactured by a plant built by Onoda Cement of Japan and jointly owned by Onoda and the Chinese Government. The new plant was brought on-line in July.³⁸

World Review

World cement production increased by 5% to 1.4 billion short tons. China continued to lead all nations with 24% of production, followed by Japan with 7%, and the United States with 6%. Countries with excess capacity continued to export cement to the United States. Twenty-three countries exported cement to the United States in 1992, one more

than in 1991. The amount of cement imports declined by 22% because of increased demand within exporting countries and because of a continued decline in demand in certain U.S. markets.

During the year cement industries were privitized in such diverse countries as China, the Czech Republic, Egypt, Estonia, Greece, and the Slovak Republic. In other countries, foreign investment in cement companies continued.

Capacity.—In the United States, 44% of the clinker production capacity was concentrated in five States: California, Michigan, Missouri, Pennsylvania, and Texas. At yearend, 210 kilns at 112 plants were being operated, excluding Puerto Rico. The average annual kiln capacity increased to 394,000 short tons, compared with 388,000 short tons in 1991.³⁹

Australia. - Australia produced less than 6 million metric tons of cement in 1992, which was more than 8% lower than the more than 6.5 million metric tons sold in 1991.40 There was reduced demand for cement, with oversupply of the market, lower prices, and decreased foreign imports. There also was increased vertical integration of cement companies, with cement companies linked up with the raw material suppliers and end-product users. Falling demand and lower prices made it uneconomical to export cement to Australia. More than 60% of cement was used in the production of premixed concrete. Most of the cement production was located on the eastern coast with most of the population in this area. There were five major cement companies: Adelaide Brighton (ABCL), Australian Cement Co. (ACL), Cockburn Cement, Blue Circle Southern Cement Co., and Queensland Cement Co. Late in the year, ABCL acquired the Geelong Cement works of Australian Cement Holdings, and at yearend, ABCL had the largest clinker capacity in Australia. During the year ABCL completed the upgrade of its

Birkenhead plant, and ACL upgraded the Goliath Cement plant at Railton in Tasmania.41 Queensland Cement had spent \$38 million on a cement milling and storage plant at Gladstone and \$22 million on a cement port terminal at Townsville to improve its international competitiveness and cost efficiency. Cement would be shipped from Gladstone to Townsville, which would have Australia's largest cement storage silo of 30,000 metric tons. 42 A major expansion of Goliath Portland Cement Co. in Tasmania, Australia, took place in 1992.43 A joint venture by Holderbank (QCL) and EC Levy, known as Australian Steel Mill Services or ASMS, was to process 2.65 million metric tons of slag per year, which could serve as a cement substitute.44

Bahamas.—Cementos Mexicanos acquired a 50% share in Concem Ltd. and Contrade Ltd., which market and distribute cement in the Caribbean region. 45 Concem Ltd. had a shipping terminal in Freeport and Contrade, with its headquarters in the Bahamas.

Bangladesh.—The Bangladesh cement industry was expected to expand from a 1991 total production base of 275,000 metric tons per year to double its production capacity by 1993. 46 Part of the production expansion was to come from new plants such as the Modern Structural Services' cement mill, which began producing 60 metric tons per day in April. Clinker grinding projects of Confidence Cement and Sena Kalyan Sangstha were to begin operating in 1993, while the Chittagong Cement Clinker Grinding Co. was to be privatized.

Barbados.—The Arawak Cement Co., jointly owned by the Government of Barbados and the Republic of Trinidad and Tobago, requested offers for its dryprocess cement manufacturing plant.⁴⁷

Belgium.—Cement production was approximately 8 million metric tons, up slightly from 7.9 million metric tons in 1991. Exports of cement and clinker in

1992 were estimated to be 3.3 million metric tons compared with 2.5 million metric tons in 1991. The building and construction industries were not affected by the economic downturn as were other industrial sectors. 48 No cement plants or plant expansions were built; however, significant investments were made in the modernization of storage, handling, and dispatching plants. Cimenteries CBR integrated the main Czech producer, CVM Mokra, into the CBR group.49 This represented CBR's first foothold in central Europe. Improvements made at the Tehachapi and Tilbury cement plants were operational. Several acquisitions in the ready-mix concrete and aggregate sectors strengthened the group's presence in Belgium, the Netherlands, North Rhine-Westphalia, Alberta, Canada, and the States of California and Washington in the United States.50

Bosnia and Herzegovina.—In 1991, cement production was given as 765,000 metric tons.⁵¹ The war in the former Yugoslavian Republic severely impacted the cement industry. The 276,000-metric ton-per-year plant, Tvornica, at Lukavac, about 100 kilometers north of Sarajevo, was damaged by shelling. This plant and another plant at Kakanj, about 20 kilometers west of Sarajevo, stopped cement production. The road and railway communications would have to be restored before production could begin again.⁵²

Brazil.—Production of 30.98 million metric tons of cement was slightly higher than the 30.3 metric million tons that had been produced in 1991. This represented the highest production figure ever.

Brazil experienced political problems in 1992. The Government had a restrictive monetary policy with high interest rates and was reluctant to invest. The cement market was reportedly overpriced. Exports, however, increased from 1991's approximate 54,000 metric tons to 66,000 metric tons. The main problem facing the cement industry was the utilization of installed capacity, with 50% of capacity being

used as a whole and 35% in some regions. One plant came on-line, the Camargo Correa Industrial Apiai plant.⁵⁴

Cimento Caue S.A. the largest company in the Caue group, was expected to invest \$20 million in its plants at Pedro Leopoldo and Mesquita in 1993 and 1994. The Pedro Leopoldpo plant was to invest \$19 million for the automation of its industrial processes, a slag-drying and milling unit, and environmental projects.55 Cimento Bahia SA was to invest \$20.8 million in its Brumado plant to increase the plant's capacity to produce 476,000 metric tons of cement per year.56 Construction companies in Brazil formed consortia to import cement from such countries as Turkey, or countries in Eastern Europe. due to the high price of cement offered by the small group of Brazilian cement manufacturers.⁵⁷ Approximately 70% of the national cement market was supplied by two companies.

Canada.—Canada produced 9.4 metric million tons of cement in 1992. This was a decrease of approximately 10% from that of 1991. However, consumption of cement was 7.2 million metric tons compared with 6.8 million metric tons in 1991. The Canadian economy had not recovered yet from the recession, which was strongest in 1990 and 1991. Canada was the largest exporter of cement to the United States, having exported 3.3 million metric tons of hydraulic cement and clinker. The Canadian cement industry was highly integrated, both vertically and horizontally, compared to that in the United States. There were eight Canadian cement companies. The three largest companies, Lafarge Canada. a subsidiary of France's Lafarge Coppee; St. Lawrence Cement; and St. Marys Cement; together accounted for 75% of capacity. Foreign ownership of Canadian cement amounted to 77% of capacity. Lafarge, Holderbank, CBR, and Ciments Francais were the major foreign owners.58

Chile.—The production of portland cement in Chile increased to

approximately 3 million metric tons compared with 2.5 million metric tons in 1991. Although exports dropped by 54% to 35,500 metric tons, imports rose by 60% to 8,000 metric tons.⁵⁹

Chile had four cement plants, three of which did not have suitable limestone deposits nearby, making it necessary to use unconventional methods to obtain this resource.60 Industria Nacional Cemento SA (INACESA) had a plant near Antofagasta, which was fortunate to extract limestone from a traditional opencast quarry. Cementos Bio operated the plant Talcahuano, a slag-cement plant in Concepcion. INACESA and Bio were affiliated. Cemento Melon operated La Calera, about 120 kilometers north of Santiago. Cemento Melon, the largest and oldest company, put the Super Center terminal of Cemento Melon, a sales and distribution center, in operation in 1992. Cemento Polpaico operated Cerro Blanco, approximately 50 kilometers north of central Santiago.61 Downstream integration into aggregates and ready-mix continued at a rapid rate. For example, Petreos, the concrete division of Cemento Polpaico, opened 23 batching plants in 1992.62

China.—China, with abundant raw materials, continued to be the largest cement producer in the world. China produced approximately 270 million short tons in 1991. Eighty-five percent was made by local plants and 15% by state key plants.63 The quality of the cement was varied. High-grade 525 cement was produced, as well as 425- and 325-grade More than 60 varieties of cement could be produced in China. In 1991, China exported 11.8 million metric tons of cement, valued at \$443 million, to 60 Asian, 24 European, and 16 African countries. More than 99% of the exports went to Asia. According to 1989 statistics of the State Bureau of Building-Material Industry (SBBMI), headquarters in Beijing, China was to open more construction projects to foreign participation as part of its drive to build up national infrastructure. Companies would be allowed to invest solely, or jointly, with Chinese partners

in the construction of motorways, bridges, and tunnels, and solely in building docks and private waterways. Foreign cooperation also was to be encouraged in managing loading, unloading, and packaging at docks.⁶⁴

Japan was planning to enter the Chinese cement market with three Japanese cement firms in various stages of planning joint ventures with Chinese concerns. Mitsubishi Materials Corp. announced that it would sign a contract to establish a joint-venture cement company in China. The agreement covered the construction of a 1-million-metric-ton-peryear plant in Yantai, Shadong Province, by the end of 1994 at a cost of 15 billion yen or \$120 million. Japanese companies, including Mitsubishi, were to provide 70% of the capital, and Chinese concerns were to supply the remainder.65 Onoda Cement formed a joint venture for the new Dalian plant and had plans for another at Nanjing City.66 Nihon Cement announced that it was planning to launch a joint venture with the Chinese trading house Marubeni Corp. to develop a 1.4million-metric ton cement works in Oinhaungdao, east of Beijing.⁶⁷

The Republic of Korea also was planning that nation's largest to date investment in China, a US\$300 million cement factory in Shangdong Province. The factory was to be in Jilan City with an annual production capacity of approximately 2.8 million metric tons. The plan was to be approved by the South Korean Government, with the project to be completed by 1995. Large amounts of cement were to be sold for export.⁶⁸

Croatia.—Production and consumption has continued to decline since 1982. During the first 6 months of the year, cement production was reduced to approximately 934,000 metric tons. Cement consumption was expected to increase in the next few years as the country rebuilt its war-ravaged areas. Foreign investment also was expected to increase. Exports of cement from Dalmatian cement plants of St. Caius and St. George near Split were approximately 72,000 metric tons and 597,000 metric

tons, respectively, to Mediterranean countries, such as Italy and Spain. The Bosnian market for 331,000 metric tons of Croatian cement and the continental Croatian market of 276,000 metric tons of cement were disrupted owing to the fighting in the former Yugoslavian Republics,⁷¹

Cuba.—According to the International Cement Review, cement production reached about 1.4 million metric tons with a production capacity at approximately 5.5 million metric tons. Exports jumped by 80%, from 154,000 metric tons in 1991 to 276,000 metric tons in 1992.72 The Bahamas, Dominican Republic, and the Windward Islands were among the countries to which Cuba had exported cement. Brazil was seen as an important new market. Most sales were of bagged cement; however, investments in bulk handling facilities could make sales of bulk cement equal to those of cement. Prices were bagged approximately \$43 per bag and \$36 for bulk.

Cyprus.—Sante Trading Co. and Yazd White signed an agreement to construct a 551-metric ton-per-day-capacity white cement plant at a cost of \$38 million. Sante was to be the lead contractor and would finance the project via the Middle East Trading Co., based on the Isle of Man. Machinery and technology for the plant were to come from Europe, but 30% of the equipment would be bought from Iran. Construction was scheduled to take 3 years. Sante would export at least one-half of the output, most likely to the Persian Gulf States. ⁷³

Czech Republic.—The Czech Republic signed bilateral trade agreements with the Baltic States of Estonia, Latvia, and Lithuania. Trade with the three republics was expected to total approximately \$36 million, with the Baltic States said to be interested in buying Czechoslovakian cement, machine tools, and other products. A Cimenteries CBR finalized a partnership agreement with the Czech National Assets Fund and the

cement and lime manufacturing company Cementarny a Vapenka Mokra, near Brno in Moravia. CBR was to acquire 35% of the capital of Mokra, which was to increase to 72% by 1995. With 2.4 million metric tons of cement capacity per year, CVM Mokra was the leading Czech cement producer and operated two cement plants Mokra and Malomerice. To

In addition, Heidelberger Zement of Germany bought 40% of the Czech Republic cement factory, Kraluv Dvur, with the remaining 60% staying in the hands of CEVA-Holding of Prague.

Holderbank had signed an agreement with the Czech Republic for a 30.4% stake in the cement company CEVA Prachovice. The Prachovice plant is 100 kilometers east of Prague and had the capacity for 1.2 million metric tons of cement per year. The facilities were the most efficient of their kind in the Czech Republic.7

Denmark.—The domestic market for cement was weak and was expected to remain unchanged in 1993. Aalborg Portland in Aalborg, Denmark, invested money to burn process residues from the paper recycling industry in its cement kilns. A cooperative venture with Blue Circle of the United Kingdom led to increased exports in 1992 of both grey and special cements.⁷⁸

Egypt.—Egyptian cement production decreased slightly to about 18 million metric tons. The main production centers were south of Cairo in Helwan and Tourah, west of Alexandria in Assiut, and in Suez. No cement imports were reported, but there were exports of about 194,000 metric tons.⁷⁹

The Government of Egypt publicly invited private firms with experience in operations and management of cement factories to undertake the implementation of the major restructuring of three large Egyptian cement companies, Tourah Portland Cement Co., Helwan Portland Cement Co., and the National Cement Co. National Cement Co. was one of Egypt's largest cement producers with a 2.65-million-metric-ton-per-year plant at

El Tabbin. A 1.1-million-metric-ton-peryear plant was designed by Kobe Steel and Kawasaki Industries of Japan and was scheduled to go on-stream in 1993. The exact role of foreign ownership in the privatization process continued to be discussed.80 The Suez Cement Co., which had completed a preliminary study for expansion at its Suez plant, also was designated to be returned to the private sector. Amerijah Cement Co., Assiut Cement Co., and Alexandria Cement Co. were other Egyptian cement companies that were owned by the Government that could be owned by private investors in the future.81

Estonia.—An agreement establishing Kunda Nordic Cement Corp. marked the largest privatization and foreign investment project in Estonia since its independence from the former U.S.S.R. in 1991. The Kunda Cement Works, the oldest cement factory in the region and one of Estonia's largest industries, was to be transferred from state ownership to the new company, in which a consortium of European and U.S. cement companies would take 35% equity participation in the Estonian plant.82 The new company, Kunda Nordic, was to modernize the plant to meet western cement and environmental standards. A feasibility study also was designed to study the construction of a major new cement production and port facility, which would make Kunda a major producer and exporter in the Baltic region. The foreign partners in the project were Atlas Cement LP (United States); Holderbank (Switzerland), Euroc (Sweden), and Lohia and Partek (Finland).83

Greece.—Privatization of the cement industry was a major goal of the Greek Government. Heracles General Cement Co., Greece's leading cement producer and one of its largest industrial companies, was privatized by the Greek Government, according to the Financial Times. Heracles had been 70% owned by Greece's state-owned industrial holding company. Heracles was acquired by a large industrial group and the

National Bank of Greece.84

The sale of Halkis Cement Co. to the Italian company Calcestruzzi was to have occurred by November 1992. By yearend, the sale had not occurred; however, the sale was expected to occur when a financial agreement was reached between Calcestruzzi and Halkis.⁸⁵

Hong Kong.—Total cement demand within Hong Kong was expected to drop to 4.3 million metric tons. The Hong Kong cement industry included one fully integrated cementworks, owned by Green Island Cement Holdings Ltd. One other grinding facility was closed in 1992. Bulk and bagged import terminals, such as the Far East Cement, Nihon, and Kowloon Cement terminals, were in operation. It was estimated that Green Island produced 1.9 million metric tons of cement. Hong Kong imported almost 4 million metric tons of cement and clinker and exported 330,000 metric tons of cement. 86

Japan.—Japan was the second largest country in world cement production. Cement was also Japan's largest market by volume for industrial minerals. Leading consuming sectors were portland cement, ready-mix concrete, and various cement products.87 Exports of cement. 12.57 million metric tons, increased substantially, by 57%, compared to those of 1991. The exports went primarily to Hong Kong, the Republic of Korea, Taiwan, and Thailand. Imports amounted to only about 1.2 million meritc tons. down 41 % from 2.02 million metric tons. and came mainly from the Republic of Korea and Taiwan.88

China and Japan signed a \$16 million contract to form Yantai-Mitsubishi Cement Co. The jointly run company was to be managed by the Yantai City building materials company, the State Energy Investment Corp., the Mitsubishi Business Corp., and other Japanese companies and associations. Japanese investment amounted to 70% of the total funds in the project, and advanced technology developed by Mitsubishi would be used to produce high-grade cement.⁸⁹

The Japanese cement industry made capital investments of 160 billion yen or \$1.3 billion. No cement plants were built, nor were plans announced for new plants in 1993 or 1994. However, Nihon Cement Co. Ltd., Japan's leading cement producer, announced its intention to build a 1.32-million-metric-ton-per-year plant through China's State Administration of Building Materials Industry.

The cement industry was using recycled materials and industrial waste as raw materials, fuel substitutes, and admixtures to cement. The cement industry estimated that it consumed 60% of the blast furnace slag produced in Japan, 27% of the fly ash, and 18% of the waste tires. 90

After the discovery of illegal cement cartels in 1991, Japanese cementmakers took steps to ensure that their activities were firmly within the country's Anti-Monopoly Law. Top companies such as Nihon Cement and Mitsubishi set up executive watchdog committees and groups to monitor any potential violations of the law.⁹¹

A marketing agreement between Chichubu Cement Co. and its subsidiary, Tsugura Cement Co., was to provide a greater concentration in the Japanese cement market. Under the agreement, the parent company was to take direct control of Tsugura's distribution and sales division. Tsugura sold about 1.4 million metric tons of cement annually. The parent company was to reach 8.8 million metric tons annually.⁹²

In response to a request by Onoda Cement, the DOC conducted an administrative review of the antidumping order on gray portland cement and clinker from Japan, which took place in 1991. As a result of the review, the DOC preliminarily determined to assess dumping duties equal to the calculated differences between the U.S. price and the foreign market value. 93

Korea, Republic of.—Cement demand was expected to fall in part owing to the Government's policy to put a hold on new construction permits. Cement production was estimated to be 47 million metric tons, with imports of 6.1 million

metric tons. Domestic demand was 51.4 metric million tons, and exports were 1.90 million metric metric tons. Significant capacity growth was being made in slag-cement facilities, with POSCO, the world's second largest steelmaker, providing a source of slag. The cement producers were expected to concentrate on exporting cement to make up for export market share lost when domestic demand boomed in the 1980's and early 1990's. Thus, cement exports were expected to increase by about 24% in 1993.94

Mexico.—The Mexican cement industry produced 29.6 million metric tons of cement, 7.1% more than in 1991. Mexico concentrated on improving its infrastructure, which had not been adequately maintained or modernized in the 1980's. Projects included the construction and rehabilitation of the highway and road systems, improvements in ports and airports, and building houses and mass transit systems among others. Mexico also continued to experience a housing shortage, which in 1992 was approximately 6 million units. Therefore, while a large part of the Mexican cement produced had gone to exports in prior years, in 1992, Mexico was using more of the cement produced internally. Eighty-seven percent of the cement produced was for the domestic market and 13% was exported.95 Cemex, the largest Mexican cement producer. exported 1.43 million metric tons of cement, 12.7% less than in 1991. Mexican exports to the United States were 0.9 million metric tons, 4 million metric tons less than the peak in 1988. (See Foreign Trade Section.)

There were 30 cement plants, including Cemex, with 16 plants, and the second largest producer, Apasco, with two plants. Partially owned by Holderbank of Switzerland, Cementos Cruz Azul was a workers' cooperative with two plants. Most Mexican cement plants had switched to fuel oil from natural gas because the first priority for natural gas was Mexico's petrochemical industry, followed by industries with environmental problems.

Cementos Mexicanos, the world's fourth largest cement company, saw its net profits increase to \$548 million in 1992, an increase of 13% over that of 1991. 6 Cemex held 63% of the market share. Cemex subsidiaries operated 16 cement plants and 28 strategically located distribution terminals in Mexico. This infrastructure served more than 5,000 Mexican distributors throughout the country. Cemex continued to increase its production capacity, mainly in central Mexico, where growth in the demand for cement was high. The Cemex expansion of the 0.5-million-metric-ton Atotonilco plant was completed at a cost of \$27 Work continued on the million. Huichapan plant, which was to increase the plant's annual production capacity by 2 million metric tons. Operations were expected to commence during 1993. Construction of a new \$400 million plant at Tepeaca, in the State of Puebla, was well advanced.97 It was to be the largest and most modern on the North American continent and was to produce 3.3 million metric tons of cement annually. During 1992, only 12% of all the cement produced by Cemex reached consumer as concrete. Therefore, this sector had great potential for growth as the Mexican economy recovered further.

The concrete division began operating 19 new plants during the year. Cemex's concrete production capacity, measured in distribution units, increased by 24% during the year. Three hundred seventyone million dollars was invested in the cement and concrete divisions. This was part of the \$1 billion that Cemex planned to invest from 1992 to 1994 in an expansion program. This expansion was expected to increase the group's annual cement production capacity in Mexico by 8.8 million metric tons. When the expansion program was completed, Cemex expected to invest an average of \$400 million per year to maintain its share of the Mexican cement market and to increase its penetration of the concrete market. Cemex was actively promoting the use of concrete in areas that had not traditionally used concrete in Mexico, such as in the use of slip form concrete for road surfaces and roller-compacted

concrete for the construction of highways, which was a new concept in Mexico. Cemex also planned to invest \$100 million from 1992 to 1994 in equipment and measures to protect the environment. In the second half of the year, Cemex began negotiations to integrate a cement-producing plant in northeast Mexico into the group. The plant has an annual production capacity of 500,000 metric tons.

During 1992, Cemex continued to consolidate its position as the world's fourth largest cement producer. group purchased the two main Spanish cement producers, Compania Valenciana de Cementos Portland, S.A. and La Auxiliar de la Construccion, S.A. (Sanson). Cemex already held 24.9% of Compania Valenciana and bid \$1.25 billion for this company. Valenciana operated four cement plants in Spain and held a joint venture in the United States with Scancem in Norval, a Brooklynbased import terminal. Valenciana was the second largest cement producer in Europe and held 15% of the Spanish market.98 Cemex purchased Sanson for a With both reported \$600 million. acquisitions, Cemex controlled five cement plants and a clinker grinding operation in Spain.99 These strategic acquisitions increased annual cement production by 11.5 million metric tons, making Cemex the largest cement producer in Spain with a 29% market share. It also made the group one of Spain's main producers of ready-mixed concrete, with an annual production capacity of 14 million cubic meters. The investment of \$1.84 billion in Spain was part of the group's policy globalization. The Spanish acquisitions were to give Cemex access to the cement markets in Europe.

Cemex assimilated the Tolteca and Anahuac Groups, facilitating the integration of the Spanish operations into the entire Cemex Group. Cemex acquired C.L. Pharris, based in southern California. With this acquisition, Cemex had 40 concrete mixing plants in the United States. C.L. Pharris was a company with considerable strategic importance because of its aggregate

reserves, which were among the 10 largest in the United States. These reserves would allow Cemex to offer an integrated supply of cement, concrete, and aggregates to the construction industry of the region. During 1992, Southern Materials, a company based in Austin, TX, also was integrated into the group. This company operates six concrete mixing facilities and one aggregates plant, and its acquisition allows Cemex to increase its sales in the Houston and Austin areas.

Cemex agreed to supply 800,000 metric tons of cement over 2 years for the construction of the Huites Dam in Mexico. The dam was to be built on the River Fuerte in the northeast Sinaloa region by the construction consortium Consorcio Mexicano Constructor de Huites. The cement was to be supplied by the Cemex subsidiary Cementos del Yaqui, which has a production capacity of 1.65 million metric tons. retaining wall of the dam was to be one of the highest in Mexico, holding 4 million cubic meters of water. It would be capable of generating 875 million kilowatts per year. The dam would provide irrigation water for the States of Sinaloa and Sonora. 100

Cemex began the operation of a new Pro-Ambiente, S.A., to company, develop the disposal, treatment, and use of waste fuels. In a \$20 million joint venture with Mobley Environmental Services in Texas, the company was to recycle industrial waste into kiln fuel for Cemex plants. 101 One of the first steps of Pro-Ambiente was building two fuelblending plants. In addition, Mexico has recycled more than 100,000 used tires annually. Alternative fuels provided 15% of the energy of one of the kilns in Ensenada, Baja California. 102 Cementos Apasco was planning to build a new cement plant, the production line of which was scheduled for commissioning in early 1994.103

In April, the U.S. Court of International Trade upheld the ITC's 1990 decision that U.S. cement producers were injured by Mexican cement. The result of the ruling was that the antidumping order was to remain in effect and that

importers of cement from Mexico were to be required to pay estimated duties of up to 60% on all imports of Mexican cement. The DOC reconsidered its ruling with respect to the dumping margin on Cemex, the largest Mexican producer and exporter of cement, and increased the margin from 58.38% to 60%. 104

In November, in the Ad Hoc Committee of the Arizona, New Mexico, Texas, and Florida producers of Gray Portland Cement vs. United States, a lawsuit challenging the DOC's final determination of sales at less than fair value of gray portland cement and clinker from Mexico, the Court of International Trade affirmed the DOC's redetermination on remand. As a result, the final dumping margin for one of the respondents, Cemex, S.A., increased from 58.38% to 60.33%; all other margins increased from 58.05% to 59.91%. 105

The GATT ruled that the United States improperly applied stiff antidumping duties on Mexican cement imported into because of the United States and urged the United States to return the more than \$30 million in duties that it had collected. However, the recommendation would have had to be approved by the full GATT Trade Association. Therefore, it was not likely that the duties would be removed. ¹⁰⁶

Saudi Arabia.—High demand for cement was likely to continue in 1993. Construction had boomed since the end of the Gulf War in 1991. 107 Most of the publicly traded companies announced expansion plans, totaling about \$1.1 billion, that were to raise production by 4 million metric tons to about 20 million metric tons. Yammama Saudi Cement reported tripled profits at nearly \$68 million. Saudi Kuwaiti Cement revealed a 145% rise in net profit to nearly \$45 million. Two hundred twenty thousand metric tons of cement was imported to make up for the increased demand.

Slovak Republic.—The Swiss cement group Holderbank was expected to sign an agreement with the Slovak Republic

for a 34% stake in ZCV Rohoznik, a cementworks near Bratislava. cementworks was Slovakia's largest and most modern plant. Holderbank's stake would be raised to a majority holding by the end of 1996 through a series of capital increases. 108 ZCV Rohoznik was renamed Hirocem A.S. and ran a cementworks and limeworks with an annual capacity of 1.7 million metric tons of cement and 100,000 metric tons of The plant was 30 kilometers northwest of Bratislava and linked to the rail network. It had shipment facilities on the Danube and was close to the Bratislava-Prague motorway.

Spain.—Following the 1992 Olympic games and International Expo in Seville, the demand for cement fell, sparking a price war. Production of cement in Spain was estimated at 29 million metric tons. Spanish cement producers alleged that cement imports into Spain were "dumped" at unfairly low prices. There was to be a European investigation of imports of Tunisian, Turkish, and Romanian cement into Spain. 109

Compania Valenciana de Cementos Portland, the second largest cement producer in Europe, and Auxiliar de la Construccion (Sanson), Spain's second largest cement company, were purchased by Cemex. Portland Valderrivas and Cementos Portland merged to form the largest Spanish-owned cement company. Further mergers were expected in the future. 110 Cemex thus controlled five cement plants and 28% of the Spanish market.

Taiwan.—In 1992, 20.5 million metric tons of clinker was produced. Exports of 1.28 million tons of cement were 22% higher than in 1991.¹¹¹ Two new plants came on-line: Asia Cement Corp. with a 1.6-million-ton Hualien plant and Taiwan Cement Corp. with a 1.6-million-metric ton Suao plant.

Venezuela.—According to the Associacion Venezolana de Productores de Cementos, 6.2 million metric tons of cement was produced, similar to that in

1991.¹¹² Cement and clinker imports were approximately 69,000 metric tons compared with 22,000 metric tons in 1991. Exports of cement and clinker totaled 1.41 million metric tons compared with 2 million metric tons in 1991, a decline of 30%.

No new plants were built, but Consolidada de Cementos installed a 800,000-ton-per-year production line in its San Sebastian plant. It was expected to begin production about mid-1993.¹¹³

The antidumping investigation involving gray portland cement and clinker from Venezuela was suspended following an agreement to not sell Venezuelan produced cement and exports in the United States for less than the price it was sold in Venezuela. (See Foreign Trade section of this report.)

Cement exports from Venezuela to the United States, 60,300 metric tons, fell by 93% in 1992. Much of this decrease was due to increased domestic demand. However, in 1990, imports of Venezuelan cement were 1.5 million metric tons compared with 923,000 metric tons and in 1991. Although the dumping investigation had been resolved by early 1992, because of long lead times in contracts, exports to the United States were still very low in 1992. Exports to the United States were expected to increase in 1993. 114

Current Research

The main chemical aspects of portland cement hydration were highlighted at BP Research in Middlesex, United Kingdom. Reactions of the major cement phases. differences in the hydration behavior of different types of portland cement, and descriptions of blended cements were Understanding the basis of hydration was an essential prerequisite for appreciating the chemical effects admixtures that have been incorporated into cementing systems. understanding can help to address any problems of long-term durability of cement pastes, mortars, and concretes that use chemical admixtures.

Concrete Hitech, a specialist cement technology group with headquarters in

France, announced that it had a new product, formulated to provide a ceramictype concrete. 115 The product was a ceramic white cement capable of withstanding normal weathering effects and carbonation, among other things. One of the major factors affecting concrete durability is its permeability and porosity. The challenge has been to stop water from infiltrating the concrete. The solution was to eliminate the pores throughout the concrete and not allow the water to pass. Samples of the white concrete comprising a crushed granite coarse aggregate set in a matrix of natural sand and cement paste containing an additive showed zero porosity during tests.

Concrete structures may be subjected to sulfate salts, usually of sodium, magnesium, or possibly calcium, that exist naturally at varying concentrations in many soils, ground waters, and the sea. Sulfate salts do not attack concrete unless they are present in solution. Attack of hydrated cement can take place by the reaction of sulfate with calcium hydroxide and calcium aluminate hydrate to form ettringite and often gypsum. The formation of ettringite was mainly responsible for large-volume expansion, which often led to cracking and disintegration of the concrete matrix. Factors influencing the rate of attack on inland structures were the concentration and type of sulfate solution and the pH in soil or ground water, the watertable, and the mobility of ground water. Concrete exposed to seawater also is vulnerable to sulfate attack, which could be aggressive particularly in the warmer oceans. The constituents of the concrete mix and the curing regime employed, as well as the form of construction, had a strong influence on sulfate attack.

At the Department of Engineering, University of Aberdeen, United Kingdom, the influence of initial curing on the sulfate resistance of blended cement concrete made with ordinary portland cement and using pulverized fuel ash (pfa), silica fume, and ground granulated blast furnace slag for partial replacement of cement was investigated. 116 It was found that the sulfate resistance of

concrete increased with replacement of cement with 22% fly ash, 9% silica fume, and 80% ground granulated blast furnace slag. The possible common factor that led to improved sulfate resistance was the reduced Ca(OH)₂ content, which led to a smaller volume of the expansive reaction products with sulfate ions. The effect of initial curing at high temperature (45° C) was significantly harmful to the sulfate resistance of plain concrete but much less so to the blended cement concretes.

As a result of their significantly better performance in durability, both microsilica- and slag-blended cements have been projected as cementitious materials with potential for use in harsh environments. Damage caused by alkali silica reaction has received considerable attention in the Middle East. Tests were carried out on plain, microsilica, and blast furnace slag cements at the King Fahd University of Petroleum and Minerals in Saudi Arabia. 117 Some of the conclusions were that incorporation of 10% to 20% microsilica and 60% to 70% slag reduced expansions from nine times the permissible expansion to safe values ranging from one-tenth to one-half the allowable expansion. Blast furnace slag was shown to be an active remover of alkalis and was especially effective in medium-alkali cements, where, for equal alkali contents, the performance of 60%slag cement was comparable with that of 10% microsilica cement.

High strength concrete in high-rise buildings could provide many advantages over medium strength concrete, such as improvements in stiffness and durability and reduction in construction cost. Development of compressive strength and pulse velocity for high-strength concrete were studied in relation to cementitious material types and curing conditions at the University of Technology in Sydney, Australia. 118 Nondestructive test methods for the evaluation of concrete strength have been the most popular tests because of minimum cost, rapid testing, and minimal damage to concrete structures. In the ultrasonic pulse velocity method, an ultrasonic wave is sent through concrete and the time taken by the pulse to travel through a known path length is measured. Through the relationships between pulse velocity and modulus of elasticity and between compressive strength and the modulus of elasticity, strength can be correlated to the pulse velocity of concrete. Normal portland cement, blast furnace slag cement, and silica fume were used individually or in combination. Among other findings, the presence of silica fume in concrete increased the pulse velocity at all ages and curing conditions.

Characteristically, a mortar or concrete element developed strength primarily as a result of hydration and hardening of the cement paste and the resultant bond at the paste-aggregate interface. The phenomenon of hydration is both time and temperature dependent. The latter condition has been of particular importance in those regions of the world that experienced hot weather conditions during most of the year. phenomenon was studied in the Department of Civil Engineering at King Abdul Aziz University in Jeddah, Saudi Arabia. 119 Adverse effects of long-term exposure of plain cement mortars and concrete to hot weather conditions had been emphasized in previous publications of the authors. With the current trend in concrete technology and practice of using admixtures and/or replacing cement partially by pozzolanic materials, it has been important to understand the behavior of these modified or blended materials that still retain their conventional form and nature at higher than normal exposure temperatures. The beneficial influence of certain pozzolans resulted from their particle size, surface texture. The slow and pozzolanic reactions. hydration characteristics of most pozzolans, when compared with ordinary portland cement (OPC), made them suitable for an environment where the ambient conditions were hot.

In the present study, OPC was blended with powdered tuff, powdered slag, and silica fume, and compressive strengths of mortar and concrete specimens were determined at regular intervals after exposing them continuously to 25° C, 35° C, or 50° C. A superplasticizing

admixture also was used in one set of experiments. Plain OPC paste specimens were tested to compare the strength development characteristics of identical specimens under various curing temperatures. According to the study, mortar and concrete specimens that contained OPC underwent a deterioration in terms of compressive strength when exposed to air temperatures higher than 25° C for a long period. The detrimental effect of temperature was related to either the weaker formation of cement paste hydrates or the differential thermal expansion of matrix components. Blending of OPC with pozzolanic materials, such as powdered tuff, slag, and silica fume, helped to improve the performance of mortars and concrete on higher-than-normal exposure to temperatures, particularly in the range of 35° C to 50° C. Reduction of water content in the mix by a suitable admixture also was beneficial in hot weather conditions.

In September 1991, an international conference was held in Sheffield, United Kingdom, on blended and composite cements. Approximately 50 papers from nearly 30 countries were presented, and some of them were published in 1992. The papers presented included the following: Freeze-Thaw Durability of Air-Entrained Condensed Silica Fume Concrete, Influence of the Method of Fly Ash Incorporation on the Sulfate Resistance of Fly Ash Concrete, Effect of Microsilica and Blast Furnace Slag on Pore Solution and Alkali-Silica Reaction. A Review of Limestone Additions to Portland Cement and Concrete, Use of Ash Derived From Refuse Incineration as a Partial Replacement of Cement, Pulverized Fuel Ash Concrete Mix Design for the 1990's, and Measurement of the Heat of Hydration of Cement, among many others.

The need for more durable concrete and in particular, improved resistance to freeze-thaw exposure in the presence of salts, motivated investigations on condensed silica fume concrete. The investigations included studies of air pore system characteristics, ice formation and pore structure, freeze-thaw tests with and without deicing salts, and chemical resistance. A study on the freeze and thaw durability of concrete incorporating various amounts of condensed silica fume (csf) was conducted at the Polytechnic Institute of Wales in the United Kingdom. The incorporation of the condensed silica fume in concrete improved the compressive and flexural strength. The air entrainment decreased appreciably with increasing csf content.

Other studies dealt with problems arising from grinding of multicomponent cements containing clinker, pozzolans, slag, and fly ash. At the National Technical University of Athens, Greece, a review of the intergrinding phenomenon of the great number of additives used in cements was undertaken. 121 A special procedure, based on the separation of the cement components, was applied to determine the specific surface that each component developed during the final grinding. The relation between the cement composition, the cement specific surface, and the component fineness were obtained. With the proposed relationship and a computer program, the appropriate mixing ratio of clinker with one or more of the additives used was extracted. The mixing was based on the specifications for the cement composition and the minimum specific surface that each component must develop during the intergrinding. Then, the behavior of cement components during their intergrinding was studied, resulting in the easier treatment of a multicomponent cement grinding.

Controlled low-strength material (CLSM), a flowable, cementitious material used as backfill in lieu of compacted fill, has been used extensively to backfill trenches and open excavations near structural foundations. Other terms used to define this material are flowable fill, unshrinkable fill, plastic soil-cement, and soil-cement slurry, among others. A bibliography was available for a potential or current user of CLSM to investigate the properties, applications, characteristics of the material. 122 CLSM has been defined by American Concrete International as a material having a compressive strength of 1,200 pounds per

square inch or less. The materials and flow characteristics for CLSM vary depending upon local conditions. Sand, cement, fly ash, and water are the predominant materials for CLSM, although others such as coarse aggregate may be used.

In another study on soil cement slurry, various materials were experimented with to serve as slurry walls to build around hazardous waste sites to prevent contamination of soils and ground water by waste chemicals and leachate. 123 The most widely used technique for such construction has been the slurry wall method. The two common types of cutoff walls were the cement bentonite (CB) and soil bentonite walls. In a CB wall, the slurry was composed of bentonite and cement, which was left in place to act as an "impervious barrier." Soil bentonite walls utilized backfill materials consisting of sodium bentonite and soils, displacing bentonite slurry, and formed the impervious barrier. investigation was on mixtures consisting of calcium bentonites from cement, slag, and fly ash using flexible wall permeameter. The majority of the data indicated that the hydraulic conductivity soil-sodium bentonite mixtures increased severalfold, with many of the chemicals found at waste disposal sites. The investigation was funded by the Industry/University Cooperative Center for Research in New Jersey.

In the management of low- and medium-level, short-lived (approximately 30 years) radioactive wastes, stored in shallow-ground disposal facilities, storage safety has demanded the isolation of the wastes from the biosphere during the time necessary for the virtual disappearance of the radioactivity; in other words, for about 300 years. The alternative selected for the containment of radioisotopes in a stable engineered environment consisted of a series of barriers designed to stop radiation and to protect them against the action of external agents such as water and human intrusion, which could disperse them in the natural environment. A portland and a blended cement (containing slag and fly ash) were stored at constant pH's of 13, 11.5, and 4.6 in solutions without aggressive salts. 124 The structural and textural variations of the pastes were investigated over 3 years.

Reprocessing of nuclear fuel from Magnox reactors has been carried out at the Sellafield, Seascale Cumbria, the United Kingdom, plant for more than 30 years. 125 A number of radioactive wastes were generated by these operations, which required storage on-site pending a disposal route being identified. intermediate level waste, Magnox Swarf, arises after mechanical decanning of fuel from Magnox reactors and had been stored at Sellafield in water-filled silos since the early 1960's. A number of different cement systems were evaluated to encapsulate the Magnox swarf, including blends of sand, blast furnace slag (BFS), and pulverised fuel ash with OPC. For all three cement systems, a high OPC replacement was required, typically 75% to control the product hydration exotherm. Based on initial studies BFS/OPC was selected as the reference cement system for developing the Magnox encapsulation process. Extensive development work then showed that the Magnox swarf could successfully be encapsulated in BFS/OPC systems. It was necessary to control the physical and chemical composition of the BFS and OPC powders to satisfy process and product requirements for encapsulation of Magnox swarf.

OUTLOOK

The cement industry was expected to continue to focus on increasing the profitability of the industry by not substantially increasing capacity and by trimming plant operating and personnel costs. The cement industry was expected to propose price increases following a decade of flat or decreased prices.

The cement industry would continue to invest in downstream industries, such as ready-mix concrete, and other construction industries. In addition, the cement industry would continue to acquire interests in industries dealing with admixtures into cement, such as fly ash and slag, as well as companies supplying wastes as fuel to cement kilns. Revised. W Withheld to avoid disclosing company proprietary data; included in "Total or average."

¹Includes Puerto Rico. Includes data for three white cement facilities as follows: California (1), Pennsylvania (1), and Texas (1). Includes data for grinding plants (8 in 1991-92) as follows: Alaska (1), Florida (2), Iowa (1), Michigan (1), Pennsylvania (1), and Texas (2).

²Grinding capacity based on fineness necessary to grind Types I and II cement, making allowance for downtime required for maintenance.

Includes imported cement. Source of imports withheld to avoid disclosing company proprietary data.

Includes cement produced from imported clinker (1991-1,759,197 tons, 1992-2,056,394) tons.

TABLE 13 AVERAGE MILL VALUE, IN **BULK, OF CEMENT IN THE** UNITED STATES1

(Per short ton)

Year Portland cement		Prepared masonry cement ²	All classes of cement		
1988	48.55	68.48	49.36		
1989	48.93	69.08	49.71		
1990	49.47	68.88	50.20		
1991	49.60	69.15	50.33		
1992	49.54	66.92	50.23		

Includes Puerto Rico. Mill value is the actual value of sales to customers, f.o.b. plant, less all discounts and allowances, less all freight charges from producing plant to distribution terminal if any, less total cost of operating terminal, if any, less cost of paper bags and pallets.

¹Includes Puerto Rico.

²Mill value is the actual value of sales to customers, f.o.b. plant, less all discounts and allowances, less all freight charges to customer, less all freight charges from producing plant to distribution terminal if any, less total cost of operating terminal, if any, less cost of paper bags and pallets.

Includes waterproof, low-heat (Type IV), and regulated fast-setting cement.

Data may not add to totals shown because of independent rounding.

⁵Does not include cement consumed at plant.

²Masonry cement made at cement plants only.

XX Not applicable.

¹F.a.s. value is the value of exports at the U.S. seaport, or border port of export, based on the transaction price, including inland freight, insurance, and other charges incurred in placing the merchandise alongside the carrier at the U.S. port of exportation. The value excludes the cost of loading.

²Includes 58 countries in 1990; 47 in 1991; and 59 in 1992.

¹Customs value price actually paid or payable for merchandise when sold for exportation to the United States, excluding U.S. import duties, freight, insurance, and other charges incurred in bringing the merchandise to the United States.

²Cost, insurance, and freight import value represents the landed value of the merchandise at the first port of arrival in the United States. It is computed by adding "import charges" to the "customs value."

Source: Bureau of the Census.

CHROMIUM

By John F. Papp

Dr. Papp, a physical scientist with 21 years of U.S. Bureau of Mines experience, has been the commodity specialist for chromium since 1983. Domestic survey data were prepared by John Macke, statistical assistant; and chromite world production data, by country, were prepared by Audrey D. Wilkes, international data coordinator. Cost of production data were prepared by Edward H. Boyle, Minerals Availability Field Office, Division of Statistics and Information Services. (All tonnages are in metric tons unless otherwise specified.)

Chromium has a wide range of uses in metals, chemicals, and refractories. It is one of the Nation's most important strategic and critical materials. Chromium use in iron, steel, and nonferrous alloys enhances hardenability and resistance to corrosion and oxidation. The use of chromium to produce stainless steel and nonferrous alloys are two of its more important applications. applications are in alloy steel, plating of metals, pigments, leather processing, catalysts. surface treatments. refractories.

Because the United States has no chromite ore reserves and a limited reserve base, domestic supply has been a concern during every national military emergency since World War I. World chromite resources, mining capacity, and ferrochromium production capacity are concentrated in the Eastern Hemisphere. The National Defense Stockpile (NDS) contains chromium in various forms. including chromite ore. chromium ferroalloys, and chromium metal in recognition of the vulnerability of long supply routes during a military emergency.

Research is conducted by the Federal Government to reduce U.S. vulnerability to potential chromium supply interruption. That research covers both domestic resource utilization and alternative materials identification. Domestic chromium resources include mineral deposits and recyclable materials. The U.S. Geological Survey and the U.S. Bureau of Mines evaluate U.S. territory for chromium mineral deposits. The U.S. Bureau of Mines also studies

minerals extraction and processing and materials substitution and recycling. Alternative materials research also is conducted by the National Aeronautics and Space Administration, the National Institute of Standards and Technology, the Department of Defense, and the Department of Energy.

World chromite ore reserves are more than adequate to meet anticipated world demand.

DOMESTIC DATA COVERAGE

Domestic data coverage of the primary consuming industries—chemical, metallurgical, and refractory—are developed by the U.S. Bureau of Mines by means of the voluntary monthly "Chromite Ores and Chromium Products" survey. The companies listed in table 10 by industry accounted for 100% of the chromite consumption data by industry in the current year of table 12. All of the metallurgical, refractory, and chemical companies that consumed chromite in 1992 reported to the Bureau.

Domestic production data for chromium ferroalloys and metal are developed by the U.S. Bureau of Mines by means of two separate, voluntary surveys. These two surveys are the monthly "Chromite Ores and Chromium Products" and the annual "Ferroalloys." Production by the metallurgical companies listed in table 10 represented 100% of the domestic production shown in the current year of table 11.

BACKGROUND

Chromium owes its prominence as a commodity to its use in stainless steel. Stainless steel was invented in the early 1900's. Soon thereafter electric furnaces evolved that could smelt chromite into ferrochromium. Before about 1960, ferrous alloys required the addition of as little carbon as possible because carbon could not efficiently be removed from molten steel. Thus, the production of low-carbon, high-chromium alloys (typically less than 0.1% carbon and more than 65% chromium) in or near steel-producing centers, was the common practice. To make this ferrochromium, high chromium-to-iron ratio ores were required (ratios greater than about 2:1).

Since 1960, major changes have occurred in the chromium industry because of changes in steelmaking technology. The development of ladle refining techniques (i.e., processes that permit the chemical modification of liquid metal), such argon-oxygen as decarburization, permitted the steel industry to shift from the more costly low-carbon ferrochromium to the less costly high-carbon ferrochromium as its major source of chromium units. This shift in ferrochromium grade has been accompanied by a shift in quantity of production among ferrochromiumproducing countries. Since the 1970's, chromite ore-producing countries have developed their own ferrochromium production capacities. As a result. ferrochromium production has moved from the major stainless steel-producing centers in Japan, the United States, and

Western Europe, to chromite-producing countries—Finland, the Republic of South Africa, Turkey, and Zimbabwe. With the exception of Japan, only minor ferrochromium production remains in the major stainless steel-producing countries. In particular, the Republic of South Africa, whose ores have a chromium-to-iron ratio of about 1.2:1, has increased its high-carbon ferrochromium production dramatically. Significant, but declining, quantities of ferrochromium continue to be produced in Japan.

Once chromium is incorporated into stainless steel, it is used in many different ways. Stainless steel is used in many industrial applications that benefit from oxidation or corrosion resistance or in applications that benefit from the ease with which stainless steel may be cleaned. Uses that are common to the experience of many people include kitchen and eating utensils, sinks, and automobile exhaust components or systems. Chromium also is used in chemicals for a variety of purposes.

Chromite, the mineral from which chromium is derived for use in the metallurgical and chemical industries, is used directly by the refractory industry to produce heat-, spalling-, corrosion-, and abrasion-resistant bricks for metallurgical and high-temperature industrial mineral processing applications. Chromite is not mined domestically; thus, the United States is 100% import dependent to meet domestic chromite demand. Some domestic chromium demand is met by recycling. Chromium is a critical and strategic material contained in the NDS to ensure adequate supply in the event of a national defense emergency.

Definitions, Grades, and Specifications

U.S. industry sets chemical and physical specifications for chromium materials through the American Society for Testing and Materials (ASTM). Other organizations also make specifications for chromium materials. The Defense Logistics Agency (DLA), in cooperation with the Department of Commerce, maintains purchase specifications for chromium materials

contained in the NDS. The Department of the Treasury, in cooperation with the Department of Commerce and signatories to the General Agreement on Tariffs and Trade, maintains definitions of chromium materials for the purpose of recording trade and applying tariff duties.

The import category "chromite ore and concentrates made therefrom" subdivided by chromic oxide content as follows: containing not more than 40% chromic oxide, containing more than 40% and less than 46% chromic oxide, and containing 46% or more chromic oxide. Producers of chromite ore and concentrate typically specify chromic oxide content; chromium-to-iron ratio; and iron, silica, alumina, magnesia, and phosphorus contents. They also specify the size of the ore or concentrate. Typically, chromic oxide content ranges from 36% to 56%, with values in the 40% to 50% range being most common. Chromium-to-iron ratios typically range from about 1.5:1 to about 4.0:1, with typical values of about 1.5:1 to 3.0:1. In trade, the chromite ore also is called chromium ore, chromite, chrome ore, and chrome.

The import category "chromium is subdivided ferroallovs" ferrochromium and ferrochromiumsilicon. Ferrochromium-silicon, also called ferrosilicon-chromium chromium silicide, is not further classified. Ferrochromium is classified by its carbon content as containing not more than 3% carbon, more than 3% but not more than 4% carbon, or more than 4% carbon. Producers of ferrochromium typically classify their material as low- or high-carbon or charge-grade ferrochromium. Charge-grade ferrochromium also is called charge Producers of chromium chrome. ferroalloys typically specify chromium, carbon, silicon, phosphorus, and sulfur contents and material size. Ferrochromium-silicon typically contains 24% to 40% chromium, 38% to 50% silicon, and 0.05% to 0.1% carbon. Ferrochromium typically contains 50% to 75% chromium and 0.05% to 8% carbon. Low-carbon ferrochromium typically contains 55% to 75% chromium and

0.02% to 0.1% carbon. High-carbon ferrochromium typically contains 60% to 70% chromium and 6% to 8% carbon. Charge-grade ferrochromium typically contains 50% to 55% chromium and 6% to 8% carbon.

Products for Trade and Industry

Chromium is primarily used in the metallurgical industry as an alloying element. Small quantities of chromium are alloyed with a base metal to achieve certain desired properties not attainable with the base metal alone. Before its use as an alloying element, chromium was used predominantly in chemicals to make pigments or to plate metals. Chromite is used as a refractory material. Refractories resist degradation when As a pigment, exposed to heat. chromium provides color to many end products and corrosion protection to ferrous metals. As a plating material, chromium provides a lustrous or a hard finish and corrosion protection to the As a refractory, substrate metal. chromite found major use in blast furnace iron production. The decline in use of process has resulted in a decline in chromite corresponding refractory use. Environmental concern over hexavalent chromium contamination has resulted in reduced use or increased expense of chromium use in pigments and plating. Chromium is traded primarily as chromite ore or as ferrochromium. of chromium amounts Substantial chemicals, pigments, and metal also are traded.

Industry Structure

Stainless steel was developed in about 1900. Since then, stainless steel has grown to become the major end use of chromium. Chromium is used in stainless steel production in the form of ferrochromium, a product of smelting chromite ore with a carbonaceous material (chemical reductant) and silicious materials (flux material). The production of stainless steel evolved in association with the major steel-producing centers. The production of ferrochromium

developed in conjunction with the production of stainless steel at those steel-producing locations.

In a trend toward vertical integration, chromite-producing countries have been developing ferrochromium and stainless steel production capacity. This trend has worldwide impact. Formerly, ferrochromium was produced mainly by Europe, Japan, and the United States, the major steel producers. The U.S. trend to obtain chromium in the ferroalloy form is a result of the world trend to produce ferrochromium in chromite-producing countries.

The structure of the chromium industry from a material processing perspective begins with mining of chromite ore. (See figure 1, chromium material flow.) Once mined, ore that is not sold directly is beneficiated. The resulting chromite ore or concentrate made therefrom may be consumed in the refractory, chemical, or metallurgical industry. Chromite ore is consumed in the refractory industry for its chromite mineral content. The chromite is typically crushed, ground, and sized. It then is mixed with magnesite to make chrome-magnesite bricks that are subsequently consumed in the steel, glass, or cement industry. The chromite refractories are used to line steelmaking furnaces, cement kilns. or heat exchangers associated with production. (See figure 1.)

Chromite ore consumed in the chemical or metallurgical industry is processed to extract the chromium from the chromite mineral. Chromite ore consumed in the chemical industry is kiln roasted. Using water, the chromium is leached out of the kiln roast product in the form of sodium chromate. sodium chromate is processed further to make chromic acid, sodium bichromate. and other chromium chemicals and pigments. Chromic oxide is a chemical industry product. Chromite ore consumed in the metallurgical industry is smelted to produce ferrochromium. In effect, the oxygen is removed from the iron-chromium-oxygen mineral, leaving an iron-chromium alloy, ferrochromium. Ferrochromium is produced to meet a

variety of chemical and physical specifications. Several variations of the ferrochromium production process are practiced; the submerged electric arc furnace is central to each process. Ferrochromium is the source of chromium units for alloys, especially ferrous alloys. When nonferrous alloys require chromium and the iron is undesirable, chromium metal is used. Chromium metal is produced from ferrochromium by an electrolytic process or from chromic oxide by an aluminothermic process.

The major vertical structure of the chromium industry is mining-smeltingstainless steelmaking. In some instances, the ownership of mining operations, smelters, and stainless steel production facilities is integrated. In many other cases, integration is limited to mining and smelting or to smelting and stainless steelmaking. Often the ownership of operations is shared. Major mining, smelting, or stainless steel production facilities are typically privately owned by large companies or groups of companies. (See tables 1 and 2.)

Geology-Resources

The geology of many chromium deposits has been characterized.1 data in table 21 are rated reserves and reserve base for major chromite ore-The data on producing countries.² chromite reserves and resources are categorized according to a general U.S. Bureau of Mines-U.S. Geological Survey classification system applicable to all minerals. The definition of reserves and reserve base are published in Geological Survey Circular 831, "Principles of a Resource/Reserve Classification Minerals." The distribution of chromite deposits into reserves, reserve base, and resources categories is determined by the physical and chemical nature of the ore (physical factors) and by mining and market economics (economic factors). Resources are a concentration of naturally occurring material from which a commodity may currently or potentially be extracted. Resources are divided into identified and undiscovered. As used

here, resources refers only to identified resources that are further subdivided into demonstrated and inferred resources. The reserve base is the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. The reserve base includes those resources that are currently economic, marginally economic, and some of those that are currently subeconomic.

Reserves are that part of the reserve base that could be economically extracted or produced at the time of determination. Reserves include only recoverable materials. Reserve values are included in reserve base values.

The term "reserves" is commonly used with a variety of definitions. Even when the definition given here is used, the quantitative value of reserves could vary owing to differing physical and economic criteria applied to a deposit by different analysts.

Technology

Mining.—A wide variety of mining technology is applied to the surface and subsurface mining of chromite ore. Most ore comes from large mechanized mines. However, small labor-intensive mining operations contribute to world supply.

Beneficiation.—The amount of beneficiation required and the techniques used depend on the ore source and enduse requirements. When the chromite is clean, only hand sorting of coarse material and gravity separation of fine material may be required. When the ore is lumpy and mixed with host rock, heavy-media separation may be used. When the chromite mineral occurs in fine grains intermixed with host rock, crushing may be used in conjunction with gravity separation and magnetic separation.

Smelting.—The smelting of chromite ore to produce ferrochromium requires electric arc furnace technology. Early electric furnaces having power ratings in the kilovolt-ampere range have developed into modern furnaces having power ratings of about 50 megavolt-amperes. Closed and partially closed electric arc furnaces replaced open furnaces in the 1970's to improve pollution control, efficient furnace operation, and safety.

Ferrochromium is produced from chromite ore by smelting a mixture of the flux materials (e.g., quartz, dolomite, limestone, aluminosilicates), and a carbonaceous reductant (wood, coke, or charcoal) in an electric arc furnace. If the ore is lumpy, it can be fed directly into the furnace. However, if the ore is not lumpy, it must be agglomerated before it is fed into the (See Energy Requirements furnace. **Efficient** under Operating Factors.) operations recover chromium lost to furnace fume by collecting and remelting the dust and recover chromium lost to slag by crushing and beneficiating the The chromium content of the ferrochromium is determined by the chromium-to-iron ratio of the chromite

The shift from high-chromium, lowcarbon ferrochromium to low-chromium, high-carbon ferrochromium, commonly ferrochromium, charge-grade called permitted the use of low chromium-toiron ratio ore for smelting to ferrochromium. The Republic of South Africa is the most abundant and low-cost source of such ore. Unfortunately, this ore is friable (breaks easily into small pieces), and the finer fractions of such ore are blown out of a furnace before it can be smelted. Agglomeration technology has been developed to permit the use of fine chromite ore in the electric arc furnace. Both briquetting and pelletizing are practiced. **Efficient** production technology uses prereduced and preheated pelletized furnace feed. Industry is developing new production technologies using high-temperature plasmas or using alternatives to electrical The new production power supply. technologies are expected to be more cost competitive than traditional production technology under some conditions. Advanced smelting technologies that use abundant friable ore have been and are being developed. Plasma processes,

including both transferred and nontransferred arc processes, have been applied to ferrochromium production. The kiln roasting prereduction process has been applied to ferrochromium production.

Recycling.—Recycling is the only domestic supply source of chromium. Stainless steel and superalloys are recycled, primarily for their nickel and chromium contents. As much as 50% of electric furnace stainless steel production can result from recycled (i.e., new and old) stainless steel scrap. Advanced stainless steel production technology such as continuous casting reduces prompt scrap generation and permits a higher product yield per unit of raw material feed. See figure 2 depicting the general recycling of chromium material flow industry structure. (See figure 2.)

Byproducts and Coproducts

Chromite ore is mined as a primary product. Chromite is not a byproduct or coproduct of the mining of any mineral, nor are there byproducts or coproducts associated with chromite mining. Chromite has the potential of becoming a byproduct of platinum mining in the Republic of South Africa or of lateritic nickel mining. Platinum and chromite are both present in the UG2 seam of the Bushveld Complex in the Republic of South Africa. At present, most platinum mining is from the Merensky Reef. However, as platinum mining from the UG2 seam continues and as new mining operations that exploit the UG2 seam are developed, chromite-containing tailings will continue to grow. The feasibility of utilizing these resources has been demonstrated, and new ferrochromium production facilities under development by Samancor Ltd. are designed to permit the use of these resources. It appears to be only a matter of time before economic conditions favor the use of those tailings, thereby making chromite a byproduct of some platinum operations.

Economic Factors

Prices.—Inadequate supplies ferrochromium in the late 1980's resulted from strong demand for stainless steel in all three major producing regions: the United States, Japan, and Europe. This inadequate supply resulted in increasing ferrochromium prices until mid-1989, when supply exceeded demand and prices began to decline. In 1989 and 1990, new ferrochromium plants and plant expansions were under construction or being completed. Increased supply of ferrochromium, resulting from producer expansions and new plant construction, resulted in declining ferrochromium prices in 1990. The dissolution of the U.S.S.R. in 1991, along with political and economic reforms and reduced for materials in demand Commonwealth of Independent States (C.I.S.), permitted C.I.S. chromite ore and ferrochromium producers to enter western markets, further exacerbating excess supply and low prices.

The historical values of chromite ore by grade, ferrochromium by grade, and chromium metal imported to the United States are shown in tables 3 and 4. These values show that as chromite ore is processed to ferrochromium and to chromium metal, the added value is quite On a per unit of contained chromium basis for recent years, the value of ferrochromium is about 5 times that of chromite ore and the value of chromium metal is about 30 times that of chromite ore. Variations of the value of ore are shown to follow those of ferrochromium, indicating values of chromite ore change in response to demand, with ferrochromium value first changes.3 to reflect demand Ferrochromium values show greater variation than those of chromite ore. The unit value of chromium materials has increased by 10% to 15% per year in actual value since 1963. (See tables 3 and 4.)

Costs. 4—Operation and transportation are the two major components of chromite ore cost in the marketplace.

Operating cost includes mining (the production of run-of-mine ore) beneficiation (the production of marketable chromite ore or concentrate from the run-of-mine ore). Mining cost is typically in the range of 70% to 90% of operating cost but exceeds 90% in some cases. Labor cost is the major component of mining and of beneficiation cost. Labor cost is typically in the range of 20% to 70% of mining cost and from 25% to 90% of beneficiation cost, but can be higher.

Excluding the delivered cost of chromite ore, electrical energy, other raw materials, and labor are the major components of smelting (i.e., production of ferrochromium from chromite ore) cost. (Note that smelting cost excludes the cost of chromite ore feed material.) Electrical energy cost is in the range of 20% to 55% of smelting cost; raw materials (excluding chromite ore), 15% to 35%; and labor, 10% to 30%.

The U.S. Bureau of Mines has studied the availability of chromium. Bureau analyzed the cost and availability of chromium materials. The chromium materials included exportable chromite products (metallurgical. chemical. refractory, and foundry sands) and chromium ferroalloy products in 10 market economy countries (MEC's). These various chromium materials were simultaneously analyzed for cost and availability. The product breakdown among chromium materials was based on mine and smelter production capacities and known operating relationships circa the 1987-88 time period.

A total of about 874 million tons, gross weight, of in situ material containing about 203 million tons of chromium was analyzed. Extraction and beneficiation of this material was estimated to yield about 475 million tons of chromite products, of which 289 million tons would be available for export and the remaining 187 million tons would be smelted in the country in which it was mined to produce about 80 million tons of chromium ferroalloys. The chromium ferroalloys would then be available for use in the country of production or for export. The 80 million tons of chromium

ferroalloys included about 74 million tons of high-carbon ferrochromium, 4 million tons of low-carbon ferrochromium, and 2 million tons of ferrochromium-silicon.

The countries of the Republic of South Africa and Zimbabwe contained about 80% of the in situ chromium contained in chromite ore. Finland and India accounted for an additional 11% of the contained chromium; another 8% of the contained chromium was fairly evenly split among Brazil, the Philippines, Turkey, and the United States; and the remainder was in Greece and Madagascar.

Based on Cr₂O₃ content of in situ chromite ore, the 10 MEC's split into 2 groups, a high-grade group and a lowgrade group. The high-grade group. those with ore grades ranging from 34% Cr_2O_3 43% included India, Madagascar, the Republic of South Africa, Turkey, and Zimbabwe. low-grade group, those with ore grades ranging from 9% to 27% Cr₂O₃, included Brazil, Finland, Greece, the Philippines, and the United States. The grade differences between the two groups resulted in a wide disparity in their respective weighted average Cr₂O₃ contents. The high-grade group averaged 39% Cr₂O₃ and the low-grade group only 16% Cr₂O₃.

Table 5 shows the results of the Bureau's analysis. Chromium material costs were calculated on a weighted average basis, f.o.b. ship at the port of export. Chromite costs shown in table 5 include chromite ore mining and beneficiating (including mine capital and operating costs and taxes) and chromite product transportation to port facilities. Chromium ferroallov costs include chromite ore but exclude smelter capital cost. On a weight basis, the Bureau's analysis shows that the Republic of South Africa and Zimbabwe could produce about 78% of metallurgical chromite ore. 93% of chemical chromite ore, 85% of refractory chromite ore, and 93% of foundry chromite ore that could be produced at their respective estimated break-even cost. The Republic of South Africa and Zimbabwe also could produce about 69 % of the high-carbon

ferrochromium, 89% of the low-carbon ferrochromium, and 100% of ferrochromium-silicon that could be produced at their respective estimated break-even cost. (See table 5.)

low-carbon ferrochromium availability curve is shown in figure 3; high-carbon ferrochromium is shown in figure 4. The costs shown in figures 3 and 4 include mining and beneficiation operating and capital costs, transportation to specific smelters, smelting operating costs, taxes, and transport costs to specific port cities for export. Recovery of initial capital costs at ferrochromium smelters has not been included. Figure 3 shows that the MEC's studied support total production of 4 million tons of low-carbon ferrochromium at a cost ranging from about \$0.42 to \$0.95 per pound, contained chromium. for 0 percent discounted cash-flow rate of return. Figure 4 shows that the same MEC's studied support total production of about 74 million tons of high-carbon ferrochromium at a cost of about \$0.28 to \$1.07 per pound, contained chromium, at a 0 percent discounted cash-flow rate of return. (See figures 3 and 4.)

Consumer cost and producer competitiveness can be significantly impacted by currency exchange rates. Ferrochromium is usually sold on a U.S. dollar basis. Production costs are mostly based in local currency. In the short term, a ferrochromium producer whose local currency declines in value relative to the U.S. dollar, without a change in its local production cost structure, achieves a competitive advantage. It can earn the same amount of local currency while selling its product for fewer U.S. dollars because of the change in exchange rates. In the long term, the producer may become less competitive if it must buy new equipment, replacement parts, or get capital in U.S. dollars.

An economic analysis of the South African ferroalloy industry⁵ identified those business factors that were perceived as most important to determining new plant feasibility. In descending order of importance, the study found those factors to be: market opportunities for the salable product, local metal-ore deposits, energy costs and availability, and exchange-rate projections. Factors of less importance, again in descending order of importance, were as follows: capital costs and availability, escalation in other production transport costs. State export incentives, skilled work force availability, domestic consumption of the final product, and other (including taxation and labor relations). The study found that domestic processing of South African ore increased from 6.8% in 1960 to 61% in 1988 and estimated that domestic processing could reach 80%. The cost distribution of charge-grade ferrochromium production in the Republic of South Africa was found to be, in dollars per ton of product: electricity (at 4,390 kilowatt-hours per ton), \$135; transport (from plant to market), \$122; ore, \$75; carbon materials, \$58; labor, \$36; fluxes, electrodes, etc., \$16; working capital, \$10; and other direct costs, \$97. In this study, exchange rate stability was found to be important because lack of exchange rate stability makes projected income indeterminate in cost analysis studies.

Tariffs.—Import tariffs are typically imposed to protect the domestic industry. Where there is no domestic industry, such as chromite ore production in the United States, there is no tariff. (See Foreign Trade section of this report for tariff duties on chromium U.S. In some cases, such as materials.) ferrochromium imports to the European Community, import tariffs are used with import quotas. That is, a duty-free quota is allocated to member countries. The quotas may be revised as necessary to meet the needs of domestic consumers and producers. Only in a few cases, such as ferrochromium exports from China and certain grades of chromite ore exports from India, are export duties applied.

Operating Factors

Environmental Issues.—Chromium is an essential trace element for human health. However, some chromium

compounds are acutely toxic, chronically toxic, and/or carcinogenic. Chromium releases into the environment are regulated by the Environmental Protection Agency (EPA). Workplace exposure is regulated by the Occupational Safety and Health Administration.

Health.—Chromium is a trace mineral required by the human body for good health.⁶ A daily intake in the range of 50 to 200 micrograms has been recommended. Chromium is a cofactor for insulin, a hormone that participates in carbohydrate and fat metabolism. cofactor is a material that acts with the The dietary chemical material. compound form of chromium is trivalent. Because humans cannot convert trivalent (III) chromium to hexavalent (VI) chromium. the carcinogenicity of hexavalent chromium compounds bears no relevance to the nutritional role of trivalent chromium.

Toxicity.—The effect of an element on the human body depends on several factors. These factors include the chemical or class of chemical, the route of exposure, the quantity and duration of exposure, and characteristics of the exposed subject.⁷

The chemical distinctions typically made about chromium chemicals include whether the compound is synthetic or naturally occurring. Synthetic chromium compounds are typically classified by Trivalent and their oxidation state. hexavalent chromium compounds are two Exposure to such classifications. chromium compounds could typically occur through one or more of three routes: skin contact, ingestion, or inhalation. Exposure can also vary in intensity (concentration of the chemical) and duration (length of time for which exposure occurs). Response to chemical exposure is dependent on such human characteristics as age, sex, general health, and sensitivity. The effect of chemical exposure on the human body can be good Chromium is one of those or bad. elements that is both essential to good health and detrimental to good health. The detrimental effects of chemical

exposure are classified as acutely toxic when small amounts of the chemical cause significant damage in a short time; chronically toxic when exposure over a long time causes measurable damage; and carcinogenic when exposure can result in cancer.

Background levels of chromium may be estimated from natural abundances. At about 185 parts per million, chromium is the 13th most common element in the Earth's crust, and at 0.2 parts per billion, the 26th most common element in seawater.

Under some conditions, chromium compounds cause systemic damage to the human body.8 Because experimentation on human subjects is morally unacceptable, most toxicity data result coincidental, or workplace. from accidental human exposure or animal experimentation. EPA concluded that there is sufficient evidence in animals and humans for the carcinogenicity of chromium (VI) compounds, while evidence for the carcinogenicity of chromium (III) compounds in humans and animals is largely nonpositive. The acute toxicity of chromium (III) compounds is low whereas the acute toxicity of chromium (VI) compounds is in the high to moderate range. Chronic toxicity of chromium (III) is considered low.

Chromium generally forms chemical compounds in which chromium has either the hexavalent or trivalent oxidation state. Hexavalent chromium compounds are generally recognized as toxic. Chronic occupational exposure to hexavalent chromium has been associated with an increased incidence of bronchial cancer. The toxic status of trivalent chromium However. compounds is not clear. trivalent chromium compounds are less toxic than hexavalent chromium Chemical compounds compounds. containing chromium in lower valence states are generally recognized as benign.

Environmental Releases and Transfers. —The EPA regulates and monitors industrial impact on the environment. As part of its monitoring activity, EPA collects data on toxic chemicals; that information is made

available in the Toxic Release Inventory (TRI). TRI is mandated under title III of the Superfund Amendments and Reauthorization Act (SARA) of 1986.

Chromium has been identified as a toxic material by the EPA. Companies that release chromium-containing materials into the environment are required to report those releases to EPA. In turn, EPA collates the reported information and makes it publicly available in the form of the TRI data base.

EPA has been collecting environmental release information since 1987 from manufacturing facilities that employ 10 or more persons and used a threshold amount of chromium contained in chromium compounds. [A manufacturing facility is one whose product is included in Standard Industrial Classification (SIC) Division E Codes 20 through 39. EPA does not cover Division B, Mining, Groups 10 through 14.] The threshold amount decreased from 1987 to 1989. after which time it remained constant. The threshold limit for a facility that manufactured or processed chromium compounds was about 34 tons of contained chromium in 1987, about 23 tons in 1988, and about 11 tons in 1989 and subsequent years. The threshold limit for facilities that otherwise used chromium compounds has been and remains about 5.4 tons. (Note that EPA has definitions for the terms manufacture. process, and "otherwise use" for the purpose of reporting releases.) When reporting chromium releases, a facility must add up the chromium released from all sources that exceed a de minimis The de minimis amount for amount. chromium compounds is 0.1%. Facilities report the amount of chromium released to the air, water, and earth environment; the amount of chromium recovered onsite: and the amount transferred to offsite locations. The collected data are called the TRI. EPA reported total releases and transfers of chromium in chromium and chromium compounds.

Energy Requirements.—Electric arc furnace ferrochromium production is an electrical energy intensive process

(requiring about 4,000 kilowatt-hours per ton of ferrochromium produced) that produces similar volumes ferrochromium and slag. However, heat recovery can reduce energy requirements. Energy efficient processes preheating can reduce the energy requirements to about 2,500 to 2,800 kilowatt-hours per ton of ferrochromium produced. Typically, all of the energy required to smelt chromite is supplied in the form of electricity. Electrical energy by requirements can be reduced preheating or prereducing charge material using alternative energy sources such as coal, natural gas, or fuel oil. Advanced production technology permits the use of liquid or gas fuel to provide part of the energy required. Alternative production technology is being developed that would permit nonelectrical energy sources to supply a significant fraction of the energy required to smelt chromite ore. Western World power consumption per ton of ferrochromium product was estimated to range from 2,000 kilowatt-hours to 5,000 kilowatt-hours and averaged 3,950 kilowatt-hours from 1988 to 1991.10

Transportation.—Chromite ore is typically transported by trackless truck or conveyor belt from the mine face to storage or processing facilities on the mine site. From there it is transported by truck from the mine site to the local railhead. It is then transported by rail to ports or to smelters. Smelters that do not have associated loading and unloading facilities for ships transport their product by rail to ports. Following transport by ship to consumer countries, chromium materials typically are barged or hauled by truck and/or rail to end users who have no loading and unloading facilities for ships.

ANNUAL REVIEW

In 1992, chromium apparent consumption was about 414,000 tons of contained chromium. The reported consumption of chromite by the chemical and metallurgical industry and by the refractory industry decreased. Chemical and metallurgical industry chromite

consumption includes material consumed as part of the NDS program to convert chromite ore to ferrochromium. Imports of chromite ore increased. Reported consumption of chromium ferroalloys increased while imports increased. (See table 6.)

U.S. supply consisted of recycled and imported chromium materials. The United States recycled about 568,000 tons, gross weight, of stainless steel scrap and imported about 662,000 tons of chromite ore, ferroalloys, chemicals, and pigments valued at about \$330 million. The United States exported about 41,000 tons of chromium materials valued at about \$42 million. In 1992, both quantity and value of imports of chromium materials increased, while both quantity and value of exports decreased compared with those of 1991.

Legislation and Government Programs

The International Trade Commission of the U.S. Department of Commerce included ferrochromium among those commodities covered that are duty free under the Generalized System of Preferences (GSP). GSP status was changed effective July 1992. Countries that are expected to benefit from this change in ferrochromium status include Brazil. the Philippines, Turkey, Yugoslavia, and Zimbabwe.11 Countervailing duties on South African ferrochromium were applied at the rate of 3.47% ad valorem. South African producers petitioned to have the duty reduced. 12 The Department of Commerce started a study of the duty. The Bureau of Export Administration of the Department of Commerce requested public comment on the market impact of disposal of chemical-grade chromite ore. metallurgical-grade chromite ore, refractory-grade chromite ore, and highcarbon ferrochromium currently held in excess in the NDS.13 Public comment was being sought for inclusion in the 1994 Annual Materials Plan, a plan for stockpile acquisition and disposal created by the DLA (Department of Defense) in consultation with other Federal Government agencies.

Dissolution of the U.S.S.R. into the C.I.S. and other independent states at the transition from 1991 to 1992 resulted in the reevaluation of the NDS. absence of a single large adversary encouraged many to advocate getting rid of the NDS or substantial parts of it. argued that history Others demonstrated the need for a stockpile because periods of relative peace have been interlaced with conflict and that there is no reason to expect this pattern to Based on new international political conditions, the DLA submitted a revised annual materials plan to Congress for 1992.

In accordance with the President's November 1982 directive and Public Law 99-591, the DLA continued to upgrade NDS chromite ore to high-carbon ferrochromium. The Agency reported conversion of chromite ferrochromium on a contract year basis. DLA signed a contract with Macalloy Corp., Charleston, SC, in 1990 to upgrade NDS chromite ore. The contract period covers the years 1990-94, the last 2 years of which are optional for DLA. DLA contracted with Macalloy to have chromite ore converted to about 73,000 tons of ferrochromium between September 1992 and October 1993. DLA has the option of extending its contract to have about 7,000 additional tons produced to satisfy the public law mandating the program. (See table 7.)

As part of its plan to modernize the NDS, DLA contracted with Elkem Metals Co., Marietta, OH, to upgrade NDS nonspecification-grade low-carbon ferrochromium into electrolytic (vacuum melting-grade) chromium metal. Elkem converted low-carbon ferrochromium to chromium metal in 1989, 1990, and 1991. In 1992, DLA contracted with Elkem to convert low-carbon ferrochromium to about 1,600 tons of chromium metal. (See table 8.)

The EPA, as required under section 112(c) of the Clean Air Act, identified major sources and areas of sources of hazardous air pollutants. To identify these sources of hazardous air pollutants, EPA must find a threat of adverse effects from the area sources. EPA identified

chromium electroplaters and anodizers as an area source of hazardous air pollutants that warrant regulation under section 112 of the Clean Air Act and described that source's adverse impact. The chromium electroplating industry includes hard chromium platers (usually a thick chromium coating on steel for wear resistance of hydraulic cylinders, zinc diecastings, plastic molds, and marine hardware), decorative chromium platers (usually over a nickel layer on aluminum, brass, plastic, or steel for wear and tarnish resistance of auto trim, tools, bicycles, and plumbing fixtures), and surface-treatment electroplaters anodizers (usually a chromic acid process to produce a corrosion-resistant oxide surface on aluminum used for aircraft parts and architectural structures subject to high stress and corrosive conditions). EPA estimated that 1,540 hard chromium electroplaters, 2.800 decorative electroplaters, and 680 chromic acid anodizers nationwide are affected. EPA estimated that electroplaters collectively emit 175 tons of chromium per year, most of which is hexavalent and carcinogenic in humans. EPA estimated that the resulting U.S. nationwide population risk is an additional 110 cases of cancer per year resulting from that emission. EPA estimated the resulting individual risk in the proximity of particular facilities ranged from less than 2 chances per 100,000 for small chromic acid anodizing operations to 5 chances per 1,000 for large hard plating operations. Worker exposure at chromium electroplater and chromic acid anodizer operations is currently controlled by the Occupational Safety and Health Administration.14

The Forest Service, U.S. Department of Agriculture, announced that it is preparing an environmental impact statement in cooperation with the State of Montana, Department of State Lands, to disclose environmental effects of a proposed chromite ore production rate increase from 1,000 tons per day to 2,000 tons per day.¹⁵

EPA regulated the wood preservation industry. As a result of the Resource Conservation and Recovery Act (1988),

EPA promulgated regulations on the wood preserving industry (1990) to control inorganic preservatives containing chromium labeled F035 by EPA. In the Code of Federal Regulations (CFR), EPA specified standards for drip pad design, operation, inspection, and closure, specifically in 40 CFR 262, 264, and 265. EPA announced an administrative stay on the regulation F035 waste, thereby extending the effective date of drip pad standards until October 1992. In effect, EPA required wood preservers to upgrade their drip pad or build new ones to meet EPA standards. ¹⁶

EPA regulated the emission of chromium from toxic waste incinerators. The Resource Conservation and Recovery Act (1976) made EPA responsible for managing hazardous waste disposal. EPA regulated particulate emissions from incinerators. However, EPA found that the particulate standard may not provide sufficient protection if a substantial fraction of the particulate emissions were regulated metals, leading EPA to promulgate separate regulations for toxic Incineration is a waste incinerators. desirable method of toxic waste disposal because organic waste is destroyed, leaving no future cost to society. EPA proposed regulation of chromium emission from devices burning hazardous waste in 1987 and promulgated regulations in 1990. Regulation involves control of chromium (contained in the waste stream) feed rates, chromium emission limits, and site-specific risk assessment. Based on field studies, the emission limits of chromium were complicated by the fact that stainless steel (a chromium-containing alloy) was used in the production and transportation processes.17

Albania, a significant producer of chromite ore, gained most-favored-nation status recognition from the United States.

Strategic Considerations

Supply Security.—There is no production of chromite ore in the United States; primary consumption of chromium by U.S. industry is by companies that use chromite ore to produce ferrochromium,

chromium chemicals, and chromite refractories and by chromium metal producers that use ferrochromium. World chromite ore reserves are abundant, ensuring adequate long-term supply. However, supply sources are few and remote from the United States, making supply vulnerable to disruption. The problem for the United States is one of national security. Ferrochromium is essential to stainless and some alloy steel production, which are in turn essential to both the domestic economy and to the production of military hardware.

chromium U.S. dependence southern African nations was reevaluated. In general, four options were identified as potential countermeasures against a potential national security threat owing to foreign mineral dependence. These are: stockpile the material. encourage domestic production, find alternative sources of the material, and develop alternative materials. Stockpiling of chromium material is currently practiced by the United States. (See Stockpiling section of this report.) The United States has chromium resources and a reserve base but deposits are of low grade or small size, making them commercially insignificant. Adequate monetary incentives could bring domestic chromite into production to augment foreign supply, but could not replace commercially used volumes. The major world chromite ore producers include Kazakhstan and the Republic of South Africa at about one-third of world production each. Many smaller producers make up the remaining onethird. If production from either of the two major world producers were unavailable to the world market, the remaining producers would have to double production to meet demand—a large increase. In its major strategic and commercial end uses, there is no substitute for chromium. Chromium demand could be augmented by the development of alternate materials. The study found that the United States is dependent on foreign chromium supply and is vulnerable to supply disruptions.18

The National Technical Information Service published a literature search on chromium as a strategic material.19

Use.—Strategic use of chromium is primarily in the metallurgical and chemical industries. Chromium is used in stainless steel and nickel- and cobalt-base superalloys. There are no substitutes for chromium in these uses. Stainless steel is essential to many industrial applications. Superalloys are essential to the production of gas turbine engines and to other high-temperature applications. Chromium chemicals are used for metal surface treatment and pigments.

Stockpile.—The NDS contains the following chromium materials: chromite ore, chromium ferroalloys, and chromium metal. The purpose of the NDS is to supply military, essential civilian, and basic industrial needs of the United States during a national defense emergency; by law, the stockpile cannot be used for economic or budgetary purposes. addition to private and Government stocks, there exists a large unreported inventory of chromium contained in products, trader stocks, and scrap. The amount of these stocks varies with demand and price of the material. Under severe price pressures resulting from primary chromium shortages, recycling of consumer materials could add to the supply.

Chromite ore must be converted to ferrochromium before it can be used to make steel. Prompt response during a national defense emergency requires that conversion be carried out by domestic industry. However, domestic ferrochromium production capacity is not adequate to meet anticipated domestic demand under mobilization conditions. To ensure prompt NDS response to a national defense emergency, the President chose to convert stockpiled chromite ore to ferrochromium. Changes in industrial capacity and new manufacturing and technological developments have rendered selected chromium materials in the NDS inventory obsolete, either in quality or form or both, and in need of upgrading. Subsequent to legislative mandate, DLA

began modernizing chromium materials in the NDS by converting nonspecificationgrade low-carbon ferrochromium into chromium metal. (See Legislation and Government Programs section of this report.)

As a result of reduced threat to the territory of the United States, stockpile goals have been reduced and may be reduced further. Disposals of stockpile material have been made and were expected to continue until all excess material is disposed. Disposal takes the form of sale or payment for services contracted by DLA. In 1992, the DLA disposed of 27,000 tons of metallurgical-grade chromite ore and 7,000 tons of high-carbon ferrochromium, together containing about 12,720 tons of chromium. (See table 9.)

Issues

World ferrochromium production capacity in 1992 significantly exceeded demand, resulting in low capacity utilization. Strong demand ferrochromium, resulting from high levels of stainless steel production worldwide in 1987-89, resulted in ferrochromium plant expansions and new plant construction. Since 1970, the trend has been for ferrochromium production capacity to move from major stainless steelproducing countries (e.g., Japan, the United States, and Western Europe) to major chromite ore-producing countries (e.g., Finland, the Philippines, the Republic of South Africa, Turkey, and Zimbabwe). This has occurred through the creation of new plants or furnaces in chromite ore-producing locations and the closure of furnaces in other geographic areas where ferrochromium production was formerly strong. The increase in and change in location of world annual gross weight production capacity has continued that trend. Most of the added capacity was in chromite ore-producing countries. All of the capacity contraction was in nonchromite-producing countries. largest addition to national annual capacity was in the Republic of South Africa, increasing the Republic of South Africa's capacity by about 30% in the

1989-90 time period. The supply shortage in 1988 was estimated to have been about 200,000 tons or about 5% of 1988 world production capacity. The expansion of 1989 and 1990 represented about 16% of 1988 world production capacity.

Stainless steel is the major chromium end use. Despite strong stainless steel production in 1992, ferrochromium production capacity exceeded demand, and weak prices resulted. Ferrochromium producers limited production and planned plant closings to reduce supply of ferrochromium in the expectation that reduced supply would stimulate prices to increase.

With Western World stainless steel production growing at a long-term average annual rate of 3% to 4%, it is estimated that it will take until 1995 (about 5 years of average industry performance) for demand to catch up with added capacity. Experience shows that short-term variations in chromium consumption and production can be significantly larger than long-term trends. The integration of the former U.S.S.R. with Western country economies started with the dissolution of the U.S.S.R. in This event complicated the 1991. introducing by recovery process additional chromite ore and ferrochromium supply capacity. As a result of political and economic changes, demand for chromium materials in the former U.S.S.R. declined. It was anticipated that a new world market balance would be achieved and that demand in the former U.S.S.R. would recover as production facilities in that region converted to cost-based pricing systems.

Production

The major marketplace chromium materials are chromite ore and chromium metal, ferroalloys, and chemicals. In 1992, the United States produced chromium metal, ferroalloys, and chemicals, but no chromite ore. (See tables 10 and 11.)

Chrome Corp. of America, a subsidiary of Boulder Gold (Australia), continued to study possibilities for the

development of its chromite resources in Montana. Chrome Corp. reportedly studied the possibility of producing stainless steel in the United States using Montana chromite ore and discussed agreements to supply chromite ore to a potential Canadian low-carbon ferrochromium producer and to a potential Canadian chromium master alloy producer.

Macalloy Corp. converted chromite ore to high-carbon ferrochromium for the NDS under a contract with the DLA. Elkem Metals Co. converted nonspecification-grade low-carbon ferrochromium into chromium metal for the NDS under a contract with the DLA. (See Legislation and Government Programs section of this report).

Macalloy planned to construct a plasma arc furnace in cooperation with the South Carolina Research Authority at a cost of about \$10 million. The new furnace was planned to have a daily production capacity of about 60 tons and electrical capacity of 12 megawatts. The furnace was planned to become operational in 1993.

Consumption and Uses

Domestic consumption of chromite ore and concentrate was 362,055 tons in 1992. Of the total chromite consumed, the chemical and metallurgical industry used 334,624 tons, and the refractory industry, 27,431. Much of the chromite consumed and ferrochromium produced by the metallurgical industry were part of the NDS conversion program. (See Legislation and Government Programs section of this report.)

Chromium has a wide range of uses in the three primary consumer groups. In the metallurgical industry, its principal use in 1992 was in stainless steel. Of the 371,688 tons of chromium ferroalloys, metal, and other chromium-containing materials reported consumed, stainless steel accounted for 79.3%; full-alloy steel, 9.9%; high-strength, low-alloy, and electric, 3.1%; cast irons, 1.7%; superalloys, 1.6%; and other end uses, 4.3%. The primary use of chromium in the refractory industry was in the form of

chromite to make refractory bricks to line metallurgical furnaces.

The chemical industry consumed chromite for manufacturing sodium bichromate, chromic acid, and other chromium chemicals and pigments. Sodium bichromate is the material from which a wide range of chromium chemicals are made. (See tables 12 and 13.)

Stocks

Reported consumer stocks of chromite in the United States decreased from 321,225 tons in 1991 to 320,973 tons in Chemical and metallurgical 1992. industry stocks decreased while refractory industry stocks increased. At the 1992 annual rate of chromite consumption, consumer stocks represented about 11 months of supply in the chemical and metallurgical industry and 6 months of supply in the refractory industry. Producer stocks of chromium ferroalloys, metal, and other materials decreased from 11.832 tons in 1991 to 5,723 tons in 1992. Consumer stocks decreased from 18,800 tons in 1991 to 17,629 tons in At the 1992 annual rate of 1992. metal ferroalloy and chromium consumption, producer plus consumer stocks represented about a 0.8-month supply. (See table 14.)

Prices

Chromite ore price data in 1992 were mixed. Published prices indicated an increase for South African ore and a decrease for Turkish ore while trade data indicated a small decrease. The published price of the Republic of South African Transvaal chromite, 44% Cr₂O₃ (no specific chromium-to-iron ratio), increased from a range of \$42 to \$50 per ton, f.o.b. the Republic of South African ports, to a range of \$50 to \$60. The published price of Turkish ore decreased from a range of \$120 to \$130 per ton, f.o.b. Turkish ports, to a range of \$105 to \$110.

Ferrochromium prices generally declined. The published price of domestic high-carbon ferrochromium

(50% to 55% chromium) increased from 49 to 52 cents per pound of chromium content (¢/lb-Cr). The published price of domestic low-carbon [0.05% and 0.015% (Simplex) carbon] ferrochromium remained unchanged.

The published price of electrolytic chromium metal remained at 370 ¢/lb throughout the year. The price of elchrome-grade electrolytic chromium metal remained at 450 ¢/lb. (Elchrome is a vacuum degassed chromium metal product produced by Elkem Metals Co.)

The published price of imported highcarbon (50% to 55% and 60% to 65% chromium) ferrochromium varied throughout the year. The published price 50% to 55% high-carbon ferrochromium started at a range of 48.5 to 49 ¢/lb-Cr and ended the year at 36 to 39 ¢/lb-Cr. The published price of imported 60% to 65% high-carbon ferrochromium started the year at a range of 46.75 to 47.5 ¢/lb-Cr from which it decreased to a range of 33.5 to 34.5 ¢/lb-The published price of imported low-carbon (0.05% carbon) ferrochromium decreased from a range of 85 to 86.5 ¢/lb-Cr to a range of 71.5 to 74 ¢/lb-Cr. (See table 15 and figures 5 and 6.)

Foreign Trade

Chromium material exports from and imports to the United States included chromite ore and chromium metal, ferroalloys, chemicals, and pigments. (See tables 16 through 20.)

World Review

Industry Structure.—The chromium industry is composed primarily of chromite ore producers, ferrochromium producers, and stainless steel producers. Other industry components are chromium chemical and chromite refractory producers. Brazil, Finland, India, Japan, the Republic of South Africa, and Russia are countries that mine chromite ore, produce ferrochromium, and produce stainless steel. In Finland, Outokumpu Oy, a major share of which is stateowned, owns and operates the only

chromite mining, ferrochromium production, and stainless steel production facilities, making it completely vertically integrated. In the Republic of South Africa, chromium-related companies are privately owned. Typically, major shares of a company are owned by other companies and the remainder, if any, is openly traded. Samancor owns and operates chromite mining, ferrochromium production, and the only stainless steel production facilities. In Brazil, the mining and smelting of chromium is vertically integrated, but stainless steel production is independent of the miningsmelting operations. The major mining companies are subsidiaries of Cia. de Ferro Ligas da Bahia S.A. Stainless steel is produced primarily by Companhia Acos Especiais Itabira. Other chromite operations in Brazil are also vertically integrated. Bayer AG (Germany) owns a chromite mine and chromium chemical plant. Refractory chromite operations are also vertically integrated from chromite production through refractory material Chromite mining and production. ferrochromium production in India is mostly vertically integrated. Ferro Alloys Corp. is the only stainless steel producer in India that is integrated from chromite ore mining through ferrochromium and stainless steel production. In Japan and Russia, chromite ore production is minor. In Japan, some ferrochromium producers are associated with stainless steel plants by location, ownership, or both. Russia. production facilities are Government owned. In Kazakhstan. chromite ore mining and ferrochromium production is vertically integrated.

The chromium industry of Turkey is composed of both large and small chromite ore producers, with one major producer, Etibank, integrated from mining through ferrochromium production. (See figure 8.)

The chromium industry of Zimbabwe is composed of large companies vertically integrated from chromite mine production through ferrochromium production, small independent chromite mines, and chromite mines operated independently on behalf of the large vertically integrated companies.

Capacity.—Rated capacity is defined as the maximum quantity of product that can be produced in a period of time at a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor. energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Because not all countries or producers make production capacity information available, historical chromium trade data have been used to estimate production capacity. Rated production capacity changes result both from changes in facilities and changes in knowledge about facilities. Capacities have been rated for chromite ore. ferrochromium. chromium chemical, and chromium metal industries. (See table 21.)

Reserves.—The United States has no chromite ore reserves. However, the United States has a reserve base and resources that could be exploited. (For further information on domestic reserves, reserve base, and resources, see Geology-Resources section of this report.) (See table 21.)

Production.—World chromite ore production in 1992 was estimated at about 10.9 tons, a substantial 20% reduction from that of 1991. World ferrochromium production in 1992 was estimated at about 3.04 million tons, a 14% reduction from that of 1991. (See tables 22 and 23.)

Albania.—National Developments.—
The development of international contacts and studies of the mining industry are a departure from Albania's previously isolationist position. Albania gained most-favored-nation status recognition from the United States. Albania pursued development of its chromite mining industry by discussing an agreement with Sweden to improve chromite mining and by making an agreement with Turkey to jointly carry out mining surveys.

Albania, in its effort to promote western investment in its chromite mining industry, sought investors with the assistance of the European Bank for Reconstruction.

Chromite Ore.—The geology and mineral processing of Albania was reviewed. The majority of chromite deposits were formed in the Mesozoic geologic era, during a period of mountain building. Albania operated six chromite processing plants at Bulqize, Diber, Kalimash, Krasta, Kukes, and Mat using sedimentation and concentrating tables. Despite good ore reserves, chromite production has been declining since 1985 because of weak local economic conditions and deteriorating mining operations. Although chromite deposits are faulted, they are not extensively dislocated, resulting in deposits of chromite with geological resources in excess of 10 million tons. Reserves were estimated at 30 million tons, of which 7 million tons was graded at more than Mine production was 46% Cr₂O₃. estimated at about 1 million tons in recent years, of which 300,000 tons exceeded 42% Cr₂O₃. All of Albania's chromite mines are underground operations using open-stoping or cut-and-fill methods, and its major mines are Bulqize and Bater. The reserve base at Bulqize was estimated at 5 million tons at 52% Cr₂O₃. It was reported that, given the current state of the mining industry, investment in exploration and technology could increase production by a factor of three without reduction in grade. Miners at the Bulgize Mine went on strike for about 10 days during November and December, demanding better wages and working conditions.

Ferrochromium.—Albania also operated two ferrochromium plants at Burrel and Elbasan, each with production capacity of about 35,000 tons per year using 9-megavolt-ampere furnaces. The Elbasan ferrochromium plant was reported closed because of a shortage of operating capital. The plant is 40 kilometers southeast of Tirana and has a ferrochromium production capacity of

about 35,000 tons per year.

Australia.—Dragon Mining continued development of its Range Well lateritic chromiferous deposit. Dragon increased its ownership interest in the chromiferous deposit to 95%, took a 20-ton bulk sample, and started smelting trials.

Brazil.-National Developments.-Electrobras, Brazil's electrical energy supplier, planned to increase its electrical energy price from \$52.12 per megawatthour to \$72 per megawatt-hour. Current electrical energy cost fraction of ferrochromium production in Brazil was in the range of 22% to 26%. Other country ferrochromium producers were reported to have substantially lower electrical energy costs: \$27 per megawatthour in the Republic of South Africa and \$19.8 per megawatt-hour in Turkey. A 6% surcharge was imposed on highcarbon ferrochromium imported from South Africa for 4 months starting in October. Low-carbon ferrochromium from South Africa reached 3,700 tons in 1991 compared with domestic production of 7,400 tons. The Ministry of Industry and Commerce started an antidumping investigation of low-carbon ferrochromium from Kazakhstan, Russia, and Ukraine. January-October imports of low-carbon ferrochromium reached 3,000 tons in 1992 compared with domestic production of 12,000 tons from a production capacity of 14,000 tons. Chromite production of lump and concentrate increased from 256,453 tons in 1990 to 366,900 tons in 1991.

Chromite Ore and Ferrochromium.— Companhia Ferroligas do Amapá (CFA) increased the production capacity of its chromite ore concentrator from a range of 120,000 to 150,000 tons per year to about 250,000 tons per year. Utilization of that production capacity was dependent upon market demand. CFA reported sales of 50% Cr₂O₃ into Europe and Japan on long-term contract at \$70 per ton f.o.b. at the port of Santana.

Canada reviewed its chromium resources.

Chromite deposits were in British Columbia, Manitoba, Newfoundland, Ontario, and Quebec. However, only the Quebec and Manitoba deposits were found to be of economic importance. The Bird River deposit in Manitoba is of stratiform type, and the deposit at St. Cyr, Richmond County, Quebec, is of podiform type. Reserves in Quebec were 5.5 million tons at an average grade of 6.63% Cr₂O₃ at the Reed-Belanger property and 1 million tons at an average grade of 4.5% at the Hall deposit. The Bird River Sill had measured plus indicated resources of 19 million tons at an average grade of about 9% Cr₂O₃.

Ferrochromium.—Sherwood Metallurgical Corp. sought a site on which to locate a low-carbon ferrochromium plant south of Lethbridge in Alberta. Sherwood arranged with Boulder Gold (Australia), parent company to Chrome Corp. of America, for chromite ore supply from the Stillwater deposit (United States). The plant was planned to have a production capacity in the range of 20,000 to 25,000 tons per year.

The Provincial government of Manitoba studied the possibility of producing master alloy containing chromium and nickel for the stainless steel industry. Chrome Corp. of America was a potential chromite supplier.

Resources Minières Coleraine Inc. planned a high-carbon ferrochromium plant with production capacity of about 20,000 tons per year. Coleraine holds reserves of about 1 million tons at 4.55% average Cr₂O₃ content at its Hall deposit. That chromite could be upgraded to about 180,000 tons graded at 48.8% Cr₂O₃ with a chromium-to-iron ratio of 2.4:1 at a recovery rate of 85%. That ore could produce a 63% chromium, high-carbon ferrochromium. Coleraine continued to study the American Chrome deposit south of the Hall deposit. The ore was planned to be mined by open pit. Beneficiation was planned to include crushing followed by heavy-media separation. A 1,000-tonper-day beneficiation plant was estimated to cost about \$800,000.20 The smelter was estimated to cost approximately \$26 million. The plant was planned to be near Atlas Steel, a stainless steel producer in Tracey, Quebec. Coleraine estimated that ferrochromium productivity could be increased by 15% while saving electrical energy if molten ferrochromium could be supplied to the stainless steel plant. Coleraine also sought to obtain low-grade chromite ore to augment its high-grade supply. Coleraine, a publicly owned company with no shareholder in excess of 20%, is a part of the Morisco Group.

China.—National Developments.— China reported trade statistics for 1991. Chromite ore imports decreased from 641,267 tons in 1990 to 544,648 tons in 1991. Ferrochromium exports increased from 11,463 tons in 1990 to 29,767 tons in 1991.

Ferrochromium.—Xibei Ferroallov Works, Gansu Province, planned to start production of ferrochromium converting furnace(s) from ferrosilicon to ferrochromium production. Xibei has been operating four 12.5-megavoltampere, six 5-megavolt-ampere, and two 25-megavolt-ampere furnaces ferrosilicon production. An overland rail link was established between Kazakhstan and Gansu Province in 1991 permitting Xibei to import chromite ore from the Donskov Chromite Ore Dressing Complex.

Jiangyin City Iron Alloy Plant, Jiangsu Province, started operation of two 6-kilovolt-ampere electric furnaces for the production of ferrochromium with an annual production capacity of about 20,000 tons.

Croatia.—Dalmacija Dugi Rat operated a two 20-megavolt-ampere furnace smelter with annual high-carbon ferrochromium production capacity in the range of 72,000 to 74,000 tons. Dalmacija closed one furnace in June followed by the second in July owing to shortage of electrical power. One furnace was restarted in October with plans to restart the second when electrical power availability was restored. Poor market conditions caused Dalmacija to close again by yearend. Dalmacija had

adequate stocks to maintain shipments through the closure. Dalmacija reported production at about 52,000 tons in 1992. Dalmacija's export markets include Austria, Belgium, Italy, Sweden, and the United States. The company attributed loss of market share to the movement of C.I.S. producers into Dalmacija's traditional markets.

Cuba.—Cuba reported chromite ore reserves of 18 million tons.

Egypt.—Chromite occurrences in the Eastern Desert were sampled from two locations, El Galala and Abu Dahr. Samples were found to contain Cr_2O_3 in the range of 7.55% to 51.93% and to have a chromium-to-iron ratio in the range of 1.12 to 4.18.

European Community.—European ferroalloy producers alleged Kazakhstan, Russia, and Ukraine dumped low-carbon ferrochromium (i.e., less than 0.5% carbon) in Europe. The European Commission initiated an investigation of the complaint. Electrowerk Weisweiler (Germany) and Acciaierie e Ferriere Lombarde Falck (Italy) are the two European companies with low-carbon ferrochromium production capacity in the EC. Aktubinsk (Kazakhstan), with an 80,000-ton-per-year capacity, and Serov (Russia), with a 120,000-ton-per-year capacity, are among the exporters. C.I.S. producers increased EC market share from 4,550 tons (8.9%) to 7,404 tons (19%) in 1991. At the same time, EC capacity utilization dropped from 72% in 1988 to 53% in 1991. reason for excess low-carbon ferrochromium in Russia is the transition to more efficient stainless steel production technology. The Chelyabinsk stainless steel plant (Russia) introduced argonoxygen-decarburization in 1991, resulting in decreased low-carbon ferrochromium demand.

Finland.—The chromium industry of Finland is vertically integrated from chromite mining through stainless steel production under Outokumpu Steel Oy. The Kemi chromite deposit was

discovered in 1959, followed by a decision to mine in 1964 and industrial scale production in 1968. It is 7 kilometers northeast of Kemi city. Reserves are about 150 million tons of 26% Cr₂O₂ average grade and chromiumto-iron ratio of 1.55. Open pit mining results in an annual production of about 1 million tons from a 12-meter bench. which is drilled and blasted. Overburden in the range of 2 to 25 meters necessitates the annual removal of 200,000 to 300,000 cubic meters (4 to 7 million tons) of waste rock. About 500,000 cubic meters of water is pumped from the pit annually. Ore beneficiation includes crushing, heavy-media separation, grinding, cone concentrating, spiral separation, highintensity magnetic separation, tabling, and The beneficiation plant dewatering. annual production capacity is 320,000 tons of lumpy ore, 320,000 tons of (fine grained) concentrate for metallurgical or chemical use, and 20,000 tons of foundry sand. Run-of-mine production in 1991 was 900,000 tons, which was beneficiated to 200,000 tons of lump and 300,000 tons of concentrate. The ferrochromium plant is 20 kilometers west of Kemi city. The smelter has an annual production capacity of 220,000 tons from two furnaces: one megavolt-ampere and one 75 megavolt-ampere. Ore concentrate is sintered before smelting. The sinter plant annual capacity is 350,000 tons. The ferrochromium plant set a maximum annual production record in 1991 at 190,000 tons graded at 52% chromium and 6% to 8% carbon. The plant conserves energy by capturing carbon monoxide from the smelting process and using it in the stainless steel production process. About one-half of the ferrochromium is exported and the remainder is consumed by Outokumpu to produce stainless steel. About 70% of internally consumed ferrochromium is in molten form.

Germany.—Metallgesellschaft planned to purchase Chromeurope (France) through its wholly owned French subsidiary MG France. Metallgesellschaft planned to purchase Chromeurope for \$3.5 million²¹ then to invest \$7.0 to \$8.7

million to convert the former ferrochromium producer to a stainless steel dust recycler.

Greece.-Hellenic Ferroalloys SA (HFA) closed June 1991 and, under Government administration, was offered for sale. The Government planned to sell Hellenic Ferroallovs, which includes the ferrochromium smelter at Tsingeli and three mines at Vourinos and Skoumisa in Macedonia. The smelter produced highcarbon ferrochromium graded at 52% production chromium with annual capacity of about 50,000 tons from one 27-megavolt-ampere furnace built in 1984 by Krupp (Germany). The Vourinos Mine produced chromite ore with a runof-mine annual production capacity of 100,000 tons and a concentrator with annual production capacity of 50,000 The Skoumisa Mine produced tons. chromite ore with a run-of-mine annual production capacity of 180,000 tons and a concentrator with annual production capacity of 80,000 tons.

India.-National Developments.-The Indian Bureau of Mines reported national chromite ore reserves at about 182 million tons in 1990, of which about 96% was in the Cuttack district of Orissa State. Several ferrochromium producers Orissa in or near State. are Ferrochromium production is an electrical energy intensive process. Electrical energy is produced and distributed by the Orissa State Electricity Board, which coordinates with State boards in the adjacent States of Bihar and West Bengal. among others, to make up the eastern region. In the 1960's Orissa had excess power, but not in 1992. Successful State efforts of industrialization had used up available electrical power. About 60% to 65% of power was hydropower. As such, it is rain dependent. Except during monsoon season, power availability is inadequate. A major problem for ferrochromium had been getting adequate Power intensive industries' power. power supply had been cut by 75% to 80%. As a result, several ferrochromium producers have installed captive powerplants at a cost of about \$1.25

million per megawatt of capacity to augment electrical energy when supply is restricted. When proposals were made to export ore from Orissa for smelting elsewhere in India, new export laws were proposed. Eastern region projections indicate growing power deficits in the region.

Chromite.—The podiform chromites in mantle peridotites from the Indus ophiolite belt, Ladakh Himalaya, India, were confined to residual mantle peridotites. Chromites were mostly aluminum-chromite and some chromian spinel. Chromites in dunite and wehrlite were graded in the range of 42% to 63% Cr_2O_3 .²²

Indian Metals and Ferroalloys operated three mines in Orissa State with reserves of 7 million tons. Two of the mines were Chingudipal and Nuasahi. The third was a new operation near Nuasahi. Nuasahi is an open pit mine that was purchased from Serajuddin and Co. and is being developed to increase production from its 1991 level of 13,000 tons.

Tata Iron and Steel Co. commissioned a lump ore processing plant with an annual feed capacity of 200,000 tons at its Sukinda Chromite Mine at a cost of about \$500,000. Fines rejected from the lump processing were used as feed material to the existing beneficiation plant. Tata started exporting high-grade chromite ore concentrates from a beneficiation plant built in 1990. Chromite ore grades produced were 58% to 60% Cr₂O₃, chromium-to-iron ratio of 3.5; and 61.0% to 61.5% Cr₂O₃, chromium-to-iron ratio of 3.9.

Ferrochromium.—Ferro Alloys Corp. (Facor) produced ferrochromium at its Ferro Alloys Works (Shreeramnagar, Andhra Pradesh State) and Charge Chrome Plant (Randia, Orissa State). Facor commissioned an electrical powerplant consisting of two 10.5-megawatt electrical generators at its charge-grade ferrochromium plant in Orissa State. This fuel-oil fired powerplant has the capacity for the addition of a third generator.

Indian Metals and Ferro Alloys Ltd.

operated two ferrochromium plants, Indian Charge Chrome Ltd. (ICCL) at Choudhar and Indian Metals and Ferro Alloys (IMFA) at Therubali. operated one 48-megavolt-ampere furnace with an annual charge-grade high-carbon ferrochromium production capacity of 50,000 tons and a captive 108-megawatt coal-fired, powerplant. ICCL produced for export and negotiated a toll refining agreement with Tata Iron and Steel Co., which was to become effective in 1992 and remain in effect for 5 years. ICCL purchased the closed Kemanord smelter (Sweden) and planned to dismantle the plant and reassemble it at Choudhar. IMFA operated one 10-megavolt-ampere furnace and one 24-megavolt-ampere furnace with an annual charge-grade highferrochromium production carbon capacity of 50,000 to 52,000 tons. IMFA produced about one-half for domestic consumption and the remainder for export.

Navchrome, Raipur district, Madhur Pradesh State, converted from ferrochromium to ferromanganese production owing to weak ferrochromium market conditions. Navchrome planned to add a 7.5-megavolt-ampere furnace to its current 3.6-megavolt-ampere furnace.

Sarada Ferro Alloys, Srikakulam district, Andhra Pradesh State, expanded its annual ferrochromium production capacity from 6,000 to 10,920 tons by increasing its transformer capacity.

Iran.—Chromite ore production was reported to have been 128,000 tons run-of-mine (79,000 tons lump and concentrate) in 1990 and 165,000 tons run-of-mine in 1991 (95,000 tons lump and concentrate).

Japan.—Japan operated a two-part stockpiling program, Government and private. Japan's long-term goal was to acquire a stockpile of chromium materials adequate to serve the needs of Japanese industry for 60 days. Japan planned to have the Government finance and stockpile 70% of the material; the private sector would stockpile and finance the remaining 30%. The 60-day supply target was planned to be reached in 1995.

Metal Mining Agency of Japan, under the supervision of the Ministry International Trade and Industry. operated the Government stockpile, while Japan Rare Metals Stockpiling Association operated the private stockpile. Japan acquired 2,710 tons of ferrochromium in fiscal year 1991 (April 1991-March 1992), reaching a stockpile quantity of about 66,300 tons or about 45.4 days of supply. Japan planned to add about a 2.3-day supply of ferrochromium to its stockpile in fiscal year 1992. It was reported that stockpiled material was acquired from domestic producers. Japan planned to substantially increase its rate stockpiling to meet the 1995 target date.

Japan planned to make its ferroalloy industry eligible to receive employment adjustment subsidy in 1993. The subsidy benefits an industry that is not expected to recover from a 5% output decline with no employment increase over 3 months (compared to the same time period of the previous year). Mining Agency of Japan planned a geological research and drilling program to look for chromite on the island of Hokkaido. The program was to cover a 12,000-square-kilometer area around Hidaka city over a 3-year period starting in April 1993. Japan operated a two-tier import tariff system applied to ferrochromium. During 1992, 28,100 tons of ferrochromium from developing nations was permitted to be imported duty free.

Japan imported 724,983 tons of chromite ore. 459,608 tons of ferrochromium, 991 tons of chromium metal, and 175,564 tons of stainless steel scrap. Japan's ferroalloy industry produced about 299,706 tons of ferrochromium, a decline of 0.7% compared to that of 1991. (Japan's annual ferrochromium production has ranged from 260,000 tons to 360,000 tons in the 1980-92 time period.) Japan reported stainless steel production of 2,645,808 tons in 1992, a decrease of 6.8% compared to that of 1991. Japan exported 1,367 tons of ferrochromium and 839.520 tons of stainless steel. Ferrochromium imports represented 60%

of the market share, while stainless steel exports represented 31.7% of production.

Nippon Denko reported converting an idle ferrochromium furnace to ferroboron production at its Hokuriku plant in Toyama Prefecture.

Reduced production of stainless steel, low ferrochromium prices, and a strong yen reduced the competitiveness of Japanese ferrochromium producers, making profitable ferrochromium production difficult.

Kazakhstan.-Chromite Ore.-The Donskoy Ore Dressing Complex, near Khromtau, started chromite ore production in 1938 and currently operates surface and underground chromite mines and ore beneficiation plants. Proven reserves were estimated to be about 300 million tons with inferred and estimated reserves at about 1,000 million tons. Production at Donskoy was reported to be about 3.6 million tons per year with plans to increase that rate to 4.0 million tons per year by the year 2000. Donskov started exporting chromite ore in 1985 and reached an export volume of 950,000 tons in 1992 with export for 1993 planned to be 1.2 million tons. Donskoy exported to Asian markets (China and Japan) through the Russian port of Vanino north of Nahodkha. Donskoy operated two ore beneficiation plants with an output capacity of 4.9 million tons of crushed ore and 1.9 million tons of concentrate. Plant development was to increase concentrate output to 3.9 million tons.

Donskoy planned to increase exports into western and Asian markets by entering into joint ventures to develop ore processing capacity and capability. Kazamchrome, a joint venture between AIOC (a U.S. trading company) and Donskoy, was formed in 1991. Donskoy supplies chromite ore and AIOC supplies trade resources (financing, marketing, transportation), beneficiation equipment from the Republic of South Africa, and represents Donskoy chromite ore in the Ore screening plant world market. construction started in June for a 300,000-ton-per-year-capacity Donax, a joint venture between Axel Johnson and Donskoy, is constructing a

chrome briquetting plant and planned to start production in 1993. The briquettes were planned to be sold to the ferrochromium production industry. In addition to briquettes, Donskoy planned to construct a 700,000-ton-per-year-capacity pelletizing plant. Karatau Corp., in cooperation with Donskoy, planned to produce 10,000 tons of low-silica chromite in 1993 with target capacity of 100,000 tons per year.

Ferrochromium.—Aktubinsk Ferroallov Works started production in 1943 and currently produces ferrochromium with an annual net production capacity of about 300,000 Yermakovsky Ferroalloy Works produced ferrochromium with an annual net production capacity of about 270,000 Aktubinsk and Bettino Flavio (Italy) planned a joint venture to recover chromium concentrates from high-carbon ferrochromium slag. The chromium concentrate was to be sold to Fucinati (an Italian ferrochromium producer) as a raw material feed for ferrochromium production. The ioint venture was planned to produce 100,000 tons of chromium concentrate from 800,000 tons of slag annually using Flavio magnetic separation equipment. Aktubinsk planned to convert ferrochromiumsilicon furnaces to ferrochromium production.

Korea, Republic of.—Korea reported consumption of 90,797 tons of ferrochromium, a 6.4% decrease over that of 1991.

Madagascar.—Madagascar planned the construction of a ferrochromium plant. Feasibility studies for the location and construction of high-carbon and lowcarbon ferrochromium plants were completed.²³

New Caledonia.—The Bureau de Recherche Géologique et Minière (BRGM) (France) planned the development of a lateritic chromite deposit 40 to 50 kilometers from Noumea. The deposit was thought to have reserves of 2 million tons capable of producing 100,000 tons per year of

product graded at 46% to 48% $\rm Cr_2O_3$ with a chromium-to-iron ratio in the range of 2.2 to 2.3 to 1. Feasibility studies were planned for 1993 and 1994; production was planned for 1995.

Norway.—In May, the Norwegian Parliament decided to continue charging ferroalloy producers for electrical energy at 50% of the commercial rate. In December, the Parliament approved a refinancing package for Elkem in which it planned to invest about \$29 million. Elkem Rana AS, a subsidiary of Elkem As (Norway), reduced production because of weak demand.

Oman.—Oman Chrome Co., a private company, was formed to exploit about 2 million tons of chromite reserves about 600 sites. distributed over Resources were estimated in the range of 5 to 10 million tons. Oman Chrome Co. was capitalized at about \$7.5 million The Oman through share sales. Government owns 15% through the petroleum and minerals ministry. Private companies own 45%, and the remainder is held in private shares. Oman Mining Co. is the largest private company shareholder with 10%. Oman Chrome Co. planned to produce chromite for the refractory and chemical industries at an annual capacity of about 13,000 tons. Geologic characteristics of one chromite deposit in the Maqsad area were studied.24

Philippines.—National Developments.—Mindanao Island experienced severe power shortages that resulted in power reductions. A power reduction of 60% in January dropped to 40% in June, then to 20% in August. Ferrochromium producers are on Mindanao. Electrical power in this area is hydroelectric based on water supply in Lake Lanao. Several years of low rainfall has resulted in low water levels in the lake.

Chromite Ore.—The Governments of Japan and the Philippines started a chromite mineral exploration project targeting Panay and Palawan Islands. Merlin Mining (Australia) bought Voest

Alpine's (Austria) interest in the Santa Cruz Mine operated by Acoje Mining. Santa Cruz Mine produces metallurgical-grade chromite and has been producing from stocks. Merlin planned to rehabilitate the mine and to produce about 100,000 tons per year of concentrate.

Ferrochromium.—Ferrochrome Philippines Inc. (FPI) restarted its furnaces in August after closure in December 1991. Lack of electrical power caused the closure. FPI produced and built stocks until December, when it shut down furnaces owing to deteriorating power supply. Integrated Chrome converted a ferrosilicon furnace to ferrochromium production in 1991. The furnace was not started until August 1992 when power supply shortages were relieved.

Russia.—Russia planned to increase trade with the west. Serov Ferroalloy Works and Klyuchevsk Ferroalloy Works entered a joint venture with Minerais (Luxembourg) to form Ferromaximin, a trading company to represent chromium ferroalloy sales in the west. Serov is Russia's largest chromium ferroalloy producer with an annual ferrochromium production capacity in excess of 200,000 tons.

Slovenia.—Tovarna Dušika Ruše produced high-carbon ferrochromium.

South Africa, Republic of.—South African economic policy is one of vertical integration of its industry based on its mineral assets. To this end, the chromium industry of the Republic of South Africa has moved from being a major world chromite ore supplier to being the major supplier of both chromite ore and ferrochromium to western markets and is planning its expansion in stainless steel production.

Chromium production capacity utilization in the Republic of South Africa was low in 1992. The high price of ferrochromium in 1988-89 that resulted from stainless steel demand that could not be meet by existing ferrochromium producers put working capital in the

These high prices producers' hands. stimulated investment in new ferrochromium plants and equipment. In 1990, existing ferrochromium producers increased their production capacity by acquiring smaller producers or by expanding their production facilities. At this time, Consolidate Metallurgical Industries (CMI) added a furnace and acquired Purity Ferrochrome, a new producer; Samancor added furnaces at its Tubatse smelter: Middelburg Steel & Alloys (MS&A) started construction of a new ferrochromium production facility using a new production process (kiln furnace prereduction followed by electric furnace smelting) at Middelburg and increased the transformer capacity of its direct current transferred plasma arc furnace at Krugersdorp; and Chromecorp Technology added a furnace. (Feralloys made no changes.) In 1991, Samancor bought MS&A. During and following the introduction of this new ferrochromium production capacity in South Africa and other capacity around the world, Western stainless steel production continued to However, because grow steadily. ferrochromium production capacity was added faster than stainless steel demand growth, the ferrochromium market moved into excess supply and prices declined. In addition, the collapse of the U.S.S.R. followed by the integration of C.I.S. republics into western economies, a process that may continue changing markets for years to come, changed the chromium markets. Economic recession in the East resulted in declining chromium demand in Eastern markets and the entry of Eastern raw materials suppliers into Western markets exacerbating chromium excess supply and adding to the downward pressure on prices.

With an annual ferrochromium production capacity of nearly 1.6 million tons (gross weight) per year, nearly one-third of world ferrochromium production capacity, the Republic of South Africa is greatly impacted by these changes. Ferrochromium accounts for nearly one-half of South African ferroalloy export earnings and ferroalloys are about the third largest export earner following gold

and coal and about equal to that of platinum-group metal export earnings. South Africa has lost chromium market share because of changing market conditions resulting in low-capacity utilization. South African chromium producers planned mine closings, furnace shut downs, and production rate reductions to accommodate changing market condition.

By yearend 1992, South African ferrochromium producers ranked, by annual gross weight production capacity, as follows: Samancor, 1,000,000 tons; CMI, 320,000 tons; CCT, 200,000 tons; and Feralloys, 100,000 tons. Samancor's annual chromite ore production capacity was about 4,000,000 tons or nearly one-third of world annual production. Hernic's annual chromite ore production capacity was about 300,000 tons.

The Republic of South Africa's Minerals Bureau reported 1991 South African (including Bophuthatswana) chromite ore production at 5,110,000 tons, an increase of 11% over that of 1990. The Minerals Bureau reported 1991 chromite ore sales to have been as follows: domestic, 3,477,000 (up 37% over that of 1990); and foreign, 1,328,000 tons (down 14% over that of 1990). The Minerals Bureau reported 1991 chromium ferroalloy production at 1,126,700 tons, an increase of 10% over that of 1990. The Minerals Bureau reported 1991 sales to have been as follows: domestic, 69,680 tons (up 53% over that of 1989); and foreign, 967,200 tons (up 6% over that of 1990).

The South African Ferroalloy Producers Association petitioned the U.S. Department of Commerce to review the countervailing duty order for ferrochromium. The current deposit rate on South African ferrochromium imported into the United States is 3.47%.

Chromite Ore.—The Cashan Mine was worked out. Chromecorp Technology (CCT) purchased rights to Cashan to use Cashan's shaft for access to CCT's Chroombronne Mine.

CMI studied the feasibility of starting a new chromite mining operation. CMI planned an operation with an annual marketable production capacity to 600,000 tons, primarily to feed its smelter but also for export.

Eerste Geluk Chromite Venture (a joint-venture exploration project between Trojan Exploration and Rhombus Exploration), by drilling, delineated reserves of 25 million tons at depths of 200 to 600 meters with a chromium-to-iron ratio of 1.6:1 in the LG-6 seam. The property is between the Winterveld (Samancor) and Lavino Mines (Anglovaal).

Hernic Pty. Ltd. started operation of additional spiral separators installed in 1991. The additional processing capacity increased Hernic's annual production capacity from 250,000 tons to 300,000 tons. Hernic's production in 1991 was about 130,000 tons. Hernic produces metallurgical-grade concentrates graded at 44% chromic oxide and chemical-grade concentrate graded at 45% to 46% chromic oxide and less than 1% silica.

A group of investors (Switzerland) planned a chromite mine and ferrochromium plant development. The mine was in the Brits, Transvaal, with 23 million tons of reserves in the MG-1 and MG-2 chromite seams. Ferrochromium annual production capacity near the mine site was planned at about 130,000 tons from two furnaces.

Ferrochromium.—CCT operated one ferrochromium plant at Rustenburg with an annual ferrochromium production capacity of about 150,000 to 180,000 tons from three electric furnaces. beneficiation equipment was installed, adding about 20,000 tons per year of production capacity. CCT also operated captive chromite mine. Chroombronne Mine. CCT operated at less than 30% of capacity in the first quarter of 1992 and less than 60% of capacity for the remainder of the year. CCT diversified into the production of other raw materials for the steel industry.

CMI, a subsidiary of Johannesburg Consolidated Investment Co. Ltd., operated two ferrochromium plants: CMI at Lydenburg with about 210,000 tons annual production capacity and Purity at Rustenburg with about 120,000 tons annual production capacity. CMI also operated Purity Chrome Mine, a captive chromite mine associated with its Rustenburg plant. CMI closed one furnace at Lydenburg and one at Rustenburg owing to weak demand, operating at about 40% of capacity in the first part of the year and increasing capacity utilization to about 70% in the third quarter.

Feralloys, a subsidiary of Associated Manganese Mines of South Africa, operated a ferrochromium plant at Machadodorp with an annual production capacity of about 100,000 tons.

Samancor operated five ferrochromium plants: Batlhako with an annual production capacity of about 20,000 tons, Ferrometals at Witbank with an annual production capacity of about 300,000 tons, Tubatse at Steelpoort with an annual production capacity of about 300,000 tons, Middelburg plant at Middelburg with an annual capacity of about 280,000 tons (including the yet to go into commercial production kiln process), and Krugersdorp plant at Krugersdorp with an annual capacity of about 100,000 tons. Samancor has a total ferrochromium production capacity of about 1,000,000 tons. Owing to weak demand, Samancor reduced its production by closing some furnaces to reach from 40% to 60% of production capacity. Samancor closed all except one of its ferrochromium furnaces in the first half of the year then restarted one furnace at each plant in the second half of the year and was operating at about 50% of capacity at yearend. Samancor planned to lay off about 2,000 of its 7,000 employees as a result of production cutbacks.

Stainless Steel.—Columbus Joint Venture (CJV) was organized and scheduled for formal recognition as a new company in January 1993. CJV was to be co-owned by Highveld Steel & Vanadium, Samancor, and Industrial Development Corp. (a state-owned corporation). CJV planned to develop Southern Cross Stainless production from its current annual capacity of 120,000 tons to 500,000 tons in 1995.

Sudan.—The Ministry of Energy and Mining Authority for Geological Research studied the chromite deposits of Blue Nile Province, Sudan. Fourteen deposits were identified, mostly in the Ingessana area.²⁵

Swaziland.—Boulder Gold of Australia planned to construct a ferrochromium smelter with production capacity of about 120,000 tons per year. In 1992, Boulder planned to use the CODIR production process developed by Krupp (Germany) application to ferrochromium The process is currently production. owned and being implemented by Samancor (Republic of South Africa) at its Middelburg ferrochromium plant. The project may be delayed because Samancor has not yet completed startup of the new MS&A plant owing to the need to improve equipment and the excess world ferrochromium production capacity.

Taiwan.—Taiwan reported ferrochromium production and consumption for 1991. No ferrochromium was produced, compared with a 1990 production of 5,952 tons. Ferrochromium consumption was 45,017 tons, up from 1990 consumption of 34,905 tons.

Turkey.—Etibank is Turkey's major chromite producer operating mines in the Guleman and Muğla Provinces. Etibank is also Turkey's only ferrochromium producer and operated a low-carbon and a high-carbon ferrochromium plant. Low-carbon ferrochromium production started at Antalya in 1963. It is exported from that location. Antalya has reached annual production levels of more than 12,000 tons. Low-carbon ferrochromium is graded at 68% to 70% chromium. High-carbon ferrochromium production started at Elazig in 1977. High-carbon ferrochromium is shipped by rail to İskenderun for export. Elaziğ has reached annual production levels of 72,500 tons from a theoretical annual capacity of 150,000 tons. Production at Elaziğ is limited by labor, startup of new equipment, supply of chromite, and weather conditions in the winter. High-

carbon ferrochromium comes in two grades, one 62% chromium and the other 57% chromium. Etibank's petition for duty-free treatment of low- and high-carbon ferrochromium was granted by the U.S. Trade Representative.

United Arab Emirates.—The Department of Industry and Economy (Al Fujayrah emirate), Derwent Mining (Ireland), and Portman Mining (Australia) agreed to exploit chromite deposits in Al Fujayrah. About 200,000 tons of chromite ore was found grading at 48% Cr₂O₃ with a chromium-to-iron ratio of 3:1. Annual mine production capacity was to be 20,000 to 30,000 tons.

United Kingdom.—Murex Ltd., an aluminothermic chromium metal producer in Rainham, Essex County, ceased production. Cedar Iron opened a new ferrochromium plant at Hatton. The plant was to produce high-carbon ferrochromium for the foundry industry.

Zimbabwe.—Drought in Zimbabwe resulted in reduced power supply by about 20% and some blackouts. Electrical energy cost had risen by 130%. The national utility planned to raise electrical power prices by an additional 48% in 1993.

Two ferrochromium producers operated in Zimbabwe, Zimbabwe Mining and Smelting and Zimbabwe Alloys. Zimbabwe Mining and Smelting is a subsidiary of Union Carbide (United It produces high-carbon States). ferrochromium at Kwekwe with an annual capacity of about 178,000 tons from six electric furnaces. Zimbabwe Alloys is a subsidiary of Anglo American (Republic of South Africa). It produces low-carbon ferrochromium with an annual capacity of about 22,000 tons and ferrochromiumsilicon at Gweru. Both companies experienced reduced demand and prices, leading them to plan reduced production rates by furnace closures and layoffs in 1993.

Current Research

Mineral Processing and Industrial utilizing a graphite lance to inject Applications.—U.S. Bureau of Mines reductant and carrier gas into molten

research provides fundamental scientific and technical information essential for advancing mineral science, processing conserving and and technology. developing domestic mineral resources. This research is conducted in support of the Strategic and Critical Materials Stock Piling Act of 1946 as amended, the Defense Production Act of 1950 as amended, the Mining and Minerals Policy Act of 1970, and the National Materials and Minerals Policy, Research and Development Act of 1980. Recent research related to chromium includes the study of chromium-containing corrosion and wear-resistant steels.

The U.S. Bureau of Mines studied the repassivation of Type 304 stainless steel. Analysis of electrical signals acquired during scratching showed that maximum current density and charge density were linearly dependent on the area fraction of bare surface. Regrowth of the passive film on Type 304 stainless steel was investigated by measuring the current that resulted from forming a scratch. Neither scratch hardness nor wear were affected by the presence or absence of the passive The passive layer remained film. adherent to the surface of the stainless steel during the rubbing mode of wear; i.e., where the surface is plastically deformed and no debris is formed.²⁶ The Bureau also studied the oxidation and corrosion resistance of two Bureaudeveloped low-chromium stainless steels²⁷ and quantitatively analyzed the complex morphologies of metal carbides within high-chromium white cast irons.28

The Council for Mineral Technology (Mintek) of the Republic of South Africa conducts Government-sponsored and commercially sponsored and cosponsored research and development on chromite ore and ferrochromium. Recent Mintek chromite has included research beneficiation, agglomeration, and Mintek reported on the smelting. development of an injection process, a fluidized bed process, a transferred plasma arc smelting process, and a variety of stainless steel studies. Mintek developed a solid injection system utilizing a graphite lance to inject

metal or slag. The system was used to inject coal into slag and nitrogen into molten metal for stirring. Mintek is optimizing the system with expectation that it will be used to improve the productivity and competitiveness of the South African ferrochromium industry.²⁹ Mintek studied fluidized bed preheating of chromite fines as an energy conserving process to produce ferrochromium. Bench-scale tests found the fluidized bed process capable of saving a substantial fraction of electrical energy requirements. Mintek is scaling up the tests.30 Mintek reported successfully applying transferred plasma arc technology to recover ferrochromium from submerged arc furnace slag and to melt metallized fines from chromium direct reduction process.31

Mintek reported the development and implementation of an integrated approach to the metallurgical optimization and computer-based control of submerged arc furnaces for the production of ferrochromium. Mintek developed a computer-based system to control raw material and electrical energy supply for stable furnace operation. Implementation of the system at ferrochromium smelters resulted in more efficient data acquisition, better furnace operation understanding and control, and better electrode control. As a result of these improvements, productivity increased.32

A variety of aspects of chromite reduction were studied. The gaseous residuals from a ferrochromium smelting operation were used in an effort to prereduce chromite ore. It was found that the presence of solid carbon is essential to the reduction process because it promptly restores the reducing potential of the gaseous phase by carbon gasification. The technologic feasibility of prereducing composite chromite-reductant pellets in an externally heated shaft furnace was established.³³

Kinetic aspects of chromite ore reduction were studied in relation to the CODIR ferrochromium production process. United States and South African chromite ore mixed with anthracite coal and silica were studied thermogravimetrically. Metallization was found complete after 2 hours at 1,550° C.34

Carbothermic prereduction of South African chromite from the lower group-6 seam was studied at the laboratory scale. Results showed that at 1,500° C, silica flux enhances the chromite-reduction reaction. Slag composition was characterized.³⁵

The development of low-grade chromite fine pretreatment to achieve efficient and competitive ferrochromium production was reported. Production processes were studied under commercial scale, pilot plant, and laboratory conditions to minimize high energy cost and meet demanding environmental regulations applied in Arctic conditions. A variety of processes applied to Kemi chromite ore were discussed. 36

The melting behavior and slag formation of a variety of chromite ores studied in the high-carbon ferrochromium production process. was found that chromium losses to slag occur mainly in the form of metal drops and small particles of ore. Chromium reduction was found to be an autocatalytic process in which early slag formation can inhibit the reduction process. To improve chromium recovery, it was recommended that the melting rate of the chromite ore correspond to its reduction rate.37

The development and operation of a direct-current, transferred-arc, open-bath, closed, 1.5-megawatt plasma furnace was described. Ore of Russian or Turkish origin and of less than 6-millimeter size from the NDS was used as feed material. Ore, flux, and reductant were fed both through a hollow cathode and through drop points in the furnace roof. The information obtained from trial operation of the 1.2-megawatt furnace was being used to design a 12-megawatt furnace.³⁸

Using chromite from seam 6 of the lower group in the Bushveld Complex, the kinetics of chromium in an iron-chromium-carbon alloy melt were studied using a rotating cylinder with rotation rates between 100 and 800 revolutions per minute and at a temperature of 1,600° C in an argon atmosphere. It was found that chromium recovery was significantly improved by the presence of

silicon in the melt.39

Private industry researched more economic production and utilization processes. Industry studied the application of hollow cathode technology to the production of ferrochromium from chromite ore fines. Hollow cathode use permits the direct use of fine ore, avoiding the need for agglomeration. Several process and product improvements were achieved.

Chromium recovery from slag resulting from ferrochromium production was studied to improve competitiveness. The slag contained about 3% to 4% ferrochromium. Jigging, magnetic separation, flotation, tabling, spiraling, and dense-media separation methods were the recovery evaluated for ferrochromium following for slag crushing. Only jigging was found to yield a directly salable product alloy in all size ranges, so it was the only method recommended for reclamation of chromium from ferrochromium slags.40

The commissioning and operation of a 6.4-ton induction furnace used for ferrochromium reclamation was reported. The 3.5-megawatt furnace was used to remelt ferrochromium fines (less than 1 millimeter in size) generated in the process of crushing and screening ferrochromium ingots. The otherwise unsalable ferrochromium fines were reclaimed in an electric arc furnace as part of the ferrochromium production However, fines were being process. produced at a rate greater than they could be reclaimed in the electric arc furnaces. Thus, an induction melting furnace was introduced to reclaim ferrochromium fines and, thereby, improve operation's competitiveness.⁴¹

The production of and marketing results for intermediate carbon (carbon between 1.5% and 5%) produced by the decarburization of high-carbon ferrochromium was reported. A Cruesot-Loire-Uddholm converter of 50,000-ton-per-year production capacity was satisfactorily used to decarburize high-carbon ferrochromium. End-use markets included foundries (23%), specialty steels (48%), stainless steels (23%), and carbon steels (6%). Most material was used in

Europe with the United States taking about 18% of production. 42

A wide variety of subjects related to chromium alloys, including novel production technologies, characteristics of certain chromium-iron alloys, and uses were reported. Smelting of chromite ore in an oxygen converter⁴³ and in a coke bed were reported.⁴⁴

The chromium industry of Finland was reviewed. Outokumpu Steel Oy operated one of the few chromium industries integrated from chromite ore production through ferrochromium, stainless steel, steel products stainless manufacturing. Chromite ore is mined at Kemi where reserves are about 150 million tons at an average grade of 26% Ore is mined by open pit Cr₂O₂. Extraction, dressing, and methods. smelting are closely integrated. Annual ferrochromium production capacity in 1992 was about 210,000 tons of highcarbon ferrochromium graded at 52% chromium and 7% to 8% carbon.45

Environmental.—Environmental concerns about chromium have resulted in a wide variety of studies to determine chemical characteristics, the natural background levels, sources of environmental emissions, movement of chromium in the environment, interaction of chromium with plants and animals, effect of chromium on plants and animals, measurement methods, and recovery technology. A broad review of many environmental factors and the role of chromium, among other metals, in the environment was published.

The National Technical Information Service published a literature search on chromium toxicity.⁴⁶

An in situ remediation process for chromium contaminated soil was reported under development. An electrokinetic process to remove chromate in unsaturated soils was demonstrated. The electrokinetic technique was experimentally applied to partially saturated soil common to the arid southwestern United States as an alternative to digging up the soil and chemically washing it to remover chromium. Field tests were planned.⁴⁷

Chromium contained in spent ore was

identified as an important pathway for chromium mobilization into the environment, suggesting the necessity of accurate analysis of chromium in the environment. An EPA analysis was compared with an alternate method and found to be lacking. Modification of the EPA method for total chromium in chromite ore was recommended. 48

EPA identified opportunities for chromium source release reduction. EPA regulation focused on treatment and disposal of pollutants until the Pollution Prevention Act of 1990, when it started looking at source reduction. presented interesting and stimulating challenges for research development of new methods for source reduction and recovery/recycling in the hard chromium plating; plating for appearance; surface etching, preparation, and cleaning; refractories; alloying; catalysts; wood treatment; pigments and oxides; and leather tanning industries.49 EPA also reported on waste minimization opportunities in the orthopedic implant⁵⁰ and metal cutting wheel⁵¹ industries.

The development of a process to eliminate hexavalent chromium disposal problems associated with the combined production of chromium metal and ferrochromium was reported. A process was developed wherein the leach residue resulting from chromium chemical production was used as a furnace feed in production of high-carbon ferrochromium. A calcium-free roastleach chemical process was developed for which several advantages were noted. The process resulted in a calcium-free leach residue containing 43% Cr₂O₃ and having a chromium-to-iron ratio exceeding 3:1 that was used as an electric arc furnace feed material. The new process was found to both eliminate the hexavalent chromium disposal problem and improve the economics of smelting.52

The leather tanning industry was studied with the objective of reducing water effluent pollution and odor. A substantial fraction of leather production has relocated from developed to developing countries over the 1960-80 time period. Several specific process modifications to reduce waste were

identified, as were economic, social, legislative, and industry barriers to changes.⁵³

The concentration of chromium in water runoff from municipal and industrial sites in Finland was measured. Median chromium value was found to be 15 micrograms per liter and was compared with another study of landfill leachates for Finland at 9 micrograms per liter, Germany at 97 micrograms, and the United States at 93 to 780 micrograms per liter.⁵⁴

Ion exchange technology was applied to the treatment of chromium-containing ground and storm waters from a wood treatment facility. The ion exchange system design and operation was described. The treatment process recovered hexavalent chromium in a condition suitable for reuse. 55

Wastewater treatment methods were designed for the recovery of chromium in salable form from industrial wastewater. Typical methods make a sludge which must be disposed of as a toxic waste. The proposed method uses ion exchange to remove chromic acid. 56

A method was developed for the removal of chromium from ground waters polluted as a result of uncontrolled solid Ground water was waste disposal. pumped into a tank where the iron-tochromium ratio could be controlled. compounds Chromium removed with the aid of iron sulfate. Subsequently, formed hydroxides were flocculated and separated by settling. Chromium concentration was reduced from milligrams per liter to less than 100 micrograms per liter under a pH range from neutral to alkaline.⁵⁷

OUTLOOK

On average in the United States, about 70% of chromium is consumed by the metallurgical industry and about 70% of metallurgical industry chromium consumption is for stainless steel production. Stainless steel, by definition, contains at least 11% chromium but may contain up to 36% chromium. Thus, stainless steel production accounts for about one-half of the chromium consumed

in the United States. The remainder is consumed in the production of other ferrous and nonferrous alloys, chemicals, and refractories. Some of the chemical and refractory products are consumed in the steel production process.

On average internationally, about 79% of chromium is consumed by the metallurgical industry, 13% by the chemical industry, and 8% by the refractory industry. Of the chromium consumed in the metallurgical industry, about 60% is consumed in stainless steel. Thus, stainless steel production accounts for about one-half of the chromium consumed internationally. Stainless steel production accounts for about one-half of the chromium consumed internationally.

The outlook for chromium consumption in the United States and internationally is the same as that for stainless steel. Stainless steel is estimated to be the major end use for chromium worldwide. Thus, stainless steel industry performance determines chromium industry demand worldwide. (See next section and table 24.)

The trend to supply chromium in the form of ferrochromium by chromite mining countries is expected to continue. The rate at which new ferrochromium plants come into production is expected to diminish now that all major chromite producers have such facilities. new, efficient ferrochromium production facilities and excess capacity in chromiteproducing countries, both production and capacity are expected to diminish in traditional ferrochromium-producing countries. except where domestic industries are protected by quotas and tariffs. Further upward integration of the chromium industry is expected as chromite-producing countries expand current capacity or develop new stainless steel production capacity.

Since the dissolution of the U.S.S.R. in 1991, the industries of the former U.S.S.R. have been reorganizing and integrating into the rest of the world economy. This process is expected to continue, at different rates for different C.I.S. republics depending on the rate of political, legal, and economic structure within those countries and the conditions of the world economy to accommodate changes. The first impact of this

integration has been on the globalized minerals markets. The low cost of chromite ore and ferrochromium from the former U.S.S.R. has resulted in that material displacing former suppliers to western markets. New stable relationships are expected to develop as cost-based pricing is introduced in former U.S.S.R. countries and as those countries complete the process of legal, political, and economic reform that they have begun. It is anticipated that industrial renovation and unfulfilled consumer demand in the former U.S.S.R. could stimulate recovery in those countries and add to world demand for chromiumcontaining products.

China is emerging as a potential major factor in the world chromium market. China is primarily a chromium processing and consuming country. Chromite ore production in China is minor. Continued industrial growth in China could result in increased demand for stainless steel in China because stainless steel use is characteristic of the larger and more technologically developed economies.

Stainless Steel

As pointed out before, chromium demand is driven by stainless steel demand. Stainless steel demand is price sensitive, and an important part of stainless steel cost is nickel cost (about 70% of stainless steel requires nickel). One factor that could affect chromium demand is the availability of inexpensive nickel. Nickel availability is adequate to meet current demand and anticipated stainless steel demand until about 1995, at which time new nickel production capacity may be needed to meet demand. Projected cost of new nickel production capacity could be substantially higher than that of currently available material.59 After 1995, the increasing cost of nickel may result in increased stainless steel cost, which could result in reduced demand for stainless steel. Thus, just when stainless steel demand chromium is anticipated to come into equilibrium with ferrochromium production capacity, demand may decline. reducing chromium industry growth after

1995. Several factors could modify this scenario. Nickel supply and stainless steel demand from the previously centrally planned economy countries is uncertain. Reduction in cost of stainless steel, owing to greater production rates, may offset some nickel cost increases. Stainless steel producers could substitute manganese for nickel in some cases, thereby reducing the impact of nickel cost increases. Short-term fluctuations in demand could exceed these longer term average projections.

Chromium Chemicals⁶⁰

Chromium chemical markets were reviewed in 1991. U.S. demand for sodium bichromate was reported to have been 130,200 tons in 1990 and was projected to be 130,800 tons in 1991 and 133,400 tons in 1995. The domestic chromium chemicals market showed -0.7% growth from 1981 through 1990 and was expected to show a positive 1% growth from 1991 through 1995. Reported price in 1991 for sodium bichromate crystals was \$0.60 per pound sodium bichromate dihydrate equivalent content (for pricing purposes, sodium bichromate dihydrate equivalent content of crystals is 100%) and for sodium bichromate liquor was \$0.55 per pound of sodium bichromate dihydrate equivalent content (typically the sodium bichromate dihydrate equivalent content of liquor ranges from 69% to 70%). Sodium bichromate was used as follows: chromic acid, 55%; chromium oxide, 10%; leather tanning, 8%; pigments, 7%; wood preservatives, 2%; drilling mud additives, 2%; other uses (including metal finishing, water treatment, textiles, and catalysts), 3%; and export, 13%. Environmental concerns were seen as driving the chromium chemicals markets.

Demand for chromic acid was expected to continue to grow at an annual rate of about 2% to 3% through 1995. Domestic chromic acid producers, American Chrome and Chemicals and Occidental Chemicals, increased their chromic acid production capacity to the current annual rate of 71,000 tons to meet increasing demand. Chromic acid prices

were about \$1.10 to \$1.15 per pound in 400-pound drums. Chromic acid was consumed for the production of wood preservatives, metal finishing, and chromium dioxide. Wood preservation currently accounts for about 70% of chromic acid demand and was expected to increase even though chromium chemicals account for about 70% of the U.S. wood Environmental treatment market. restrictions on the use of creosote (in marine pilings) and pentachlorophenol (in utility poles) are expected to result in greater use of chromic acid for wood The most widely used preservation. chromium-containing wood preservative is chromium copper arsenate (CCA). CCA-treated wood is resistant to decay and termite attack, and wood treated with CCA is easier to paint than wood treated with oil-based formulations. CCA-treated wood thus finds use in roofing, outdoor decks, and house foundations. Metal finishing accounts for about 27% of chromium oxide demand. Metal finishing includes chromium plating, aluminum anodizing, and other metal treatments. No growth was anticipated for metal finishing. The remaining 3% of chromic acid consumption included the production of chromium dioxide, a growth market that included the production of magnetic particles for use in magnetic recording media (audiotapes and videotapes and computer disks).

EPA regulations limiting chromium releases have encouraged recycling of chromium chemicals and the use of substitutes to reduce releases. As a result, demand is expected to be reduced for many end uses.

Preliminary. Revised.

¹Customs value per ton of chromium contained in imported material.

NOTE.—Constant dollar value is actual value multiplied by gross domestic product (GDP) ratio. GDP ratio is 1987 GDP divided by annual GDP index. GDP ratio calculated as the ratio of GDP indices reported in Economic Report of the President, U.S. Government, Feb. 1992, available from Superintendent of Documents, U.S. Government Printing Office.

TABLE 4

Preliminary. Revised. NA Not available.

NOTE.—Constant dollar value is actual value multiplied by gross domestic product (GDP) ratio. GDP ratio is 1987 GDP divided by annual GDP index. GDP ratio calculated as the ratio of GDP indices reported in Economic Report of the President, U.S. Government, Feb. 1992, available from Superintendent of Documents, U.S. Government Office.

¹Customs value per ton of chromium contained in imported material.

²Carbon not more than 4%.

³More than 4% carbon.

TABLE 5
AVAILABILITY OF CHROMITE AND CHROMIUM FERROALLOYS
FROM 10 MARKET ECONOMY COUNTRIES

Chromium materials	Quantity available (million metric tons,		Cost ¹ er metric ton)
Chiomani hadrais	gross weight)	Weighted average	Range
Chromite:			
Chemical grade	64.3	53	\$35 - \$174
Foundry sand grade	16.4	49	39 - 83
Metallurgical grade:			
Primary product	145.4	101	42 - 705
Secondary product	35.6	54	33 - 117
Subtotal	181.0	92	33 - 705

'Revised. W Withheld to avoid disclosing company proprietary data; included with "Miscellaneous and unspecified."

¹Low-carbon ferrochromium contains less than 3 % carbon.

²High-carbon ferrochromium contains 3% or more carbon.

³Data may not add to totals shown because of independent rounding.

Includes structural and hard-facing welding material.

⁵Includes cutting materials and magnetic, aluminum, copper, nickel, and other alloys.

⁶Revised to zero.

⁷Withheld to avoid disclosing company proprietary data.

⁸Includes estimates.

Includes 3,585 tons of chromium metal.

¹⁰Includes 433 tons of chromium metal.

¹¹Withheld to avoid disclosing company proprietary data; included with "Other."

¹²Includes 2,979 tons of chromium metal.

¹³Includes 426 tons of chromium metal.

Estimated. Revised.

In addition to the countries listed, Bulgaria and North Korea also may produce chromite, but output is not reported quantitatively and available general information is inadequate for formulation of reliable estimates of output levels. Figures for all countries represent marketable output unless otherwise noted.

⁵Average Cr₂O₃ content was as follows: 1988—39.0%; 1989—39.5%; 1990—38.9%; 1991—42.0%; and 1992—42.0% (estimated). Brazil also reports run-of-mine crude ore production and Cr₂O₃ content in metric tons as follows: 1988—410,256 (160,000) (revised); 1989-91—1,082,949 (432,900) (revised); and 1992—340,000 (142,800) (estimated).

¹Table includes data through May 26, 1993.

⁴Direct-shipping lump ore plus concentrate.

⁵Exports of direct-shipping ore plus production of concentrates.

Formerly part of the U.S.S.R.

⁷Reported figure.

^{*}Formerly part of Yugoslavia.

⁹All production in Yugoslavia from 1988-91 came from Macedonia.

⁵⁹Includes production by Bophuthatswana, which was as follows, in metric tons: 1988—536,500; 1989—676,154; 1990—468,262; 1991—484,000 (revised); and 1992—350,000 (estimated).

¹¹Dissolved in Dec. 1991.

¹²Dissolved in Apr. 1992.

Estimated. Revised.

¹Table includes data available through May 26, 1993.

²Estimated production is included in the ferroalloys table under "Other."

³Formerly part of Yugoslavia; data were not reported separately until 1992.

⁴Reported figure.

Includes ferrochromium-silicon and ferronickel, if any was produced.

Includes high- and low-carbon ferrochromium and ferrochromium-silicon.

⁷Formerly part of the U.S.S.R.; data were not reported separately until 1992.

Includes production from Bophuthatswana.

⁹Dissolved in Dec. 1991.

¹⁶U.S. output of ferrochromium includes high- and low-carbon ferrochromium, ferrochromium-silicon, chromium metal, and other chromium materials.

¹¹Dissolved in Apr. 1992.

CLAYS

By Robert L. Virta

Mr. Virta, a physical scientist with 17 years of U.S. Bureau of Mines experience, has been the commodity specialist for clays since 1992. Domestic survey data were prepared by Maria Arguelles, statistical assistant. The international tables were prepared by Ron Hatch, Douglas Rhoten, and Ted Spittal, international data coordinators.

The amount of clay sold or used by domestic producers decreased slightly in tonnage to 40.7 million metric tons and increased slightly in value to \$1.5 billion. Production of ball clay, bentonite, common clay, fire clay, and fuller's earth increased in 1992. Kaolin production decreased. Common clays accounted for 61% of the tonnage. Kaolin accounted for 63% of the value of clays produced in 1992. Imports increased 17% in tonnage to 41,200 tons and 17% in value to \$15.5 million. Exports increased 4% in tonnage to 4.2 million tons and increased 12% in value to \$663.5 million. (See table 1.)

Clays were produced in 44 States and Puerto Rico. The 10 leading producer States, in descending order, were Georgia, Wyoming, Alabama, Ohio, Texas, North Carolina, California, South Carolina, Michigan, and Missouri. (See table 2.)

DOMESTIC DATA COVERAGE

Domestic production data for clays are developed by the U.S. Bureau of Mines from one voluntary survey of U.S. operations. Of the 649 operations covered by the survey, 480 responded, representing 73% of the total clay and shale production sold or used shown in table 1. (See table 1.)

With the downsizing of the Federal Government, the U.S. Bureau of Mines has experienced reductions in both budget and personnel. As a result, greater emphasis is being placed on reducing the size of commodity chapters (and the workload associated with their preparation) while providing information

useful to industry. This year several tables were eliminated. The information in these tables was either available from other sources such as the Bureau of the Census or was duplicative of other tables. Users of this report are encouraged to contact the commodity specialist and indicate the information that is most crucial to their needs.

BACKGROUND

Definitions, Grades, and Specifications

Clays are categorized into six groups by the U.S. Bureau of Mines. The categories are ball clay, bentonite, common clay and shale, fire clay, fuller's earth, and kaolin. The definitions listed in this work for ball clay, fire clay, highalumina clays, and kaolin are similar to those in U.S. Bureau of Mines Information Circular 8335.1

Ball clay is a plastic, white-firing clay used mainly for bonding in ceramicware. The clays are of sedimentary origin and consist mainly of the kaolinite, sericite mica, and organic matter. Ball clays usually are much finer grained than kaolins and are renowned for their plasticity. They are classified according to the method of preparation (crude, shredded, air-floated, water-washed, or slurry) and specific physical and chemical properties.

Bentonite is a clay composed primarily of smectite minerals. The primary smectite mineral is usually montmorillonite. Swelling-type bentonite has a high-sodium ion concentration. Its volume increases 15 to 20 times its dry volume when wetted with water.

Nonswelling bentonites usually are high in calcium. Bentonite is classified according to its physical and chemical properties, with particular emphasis on particle size and swelling index.

Common clay is defined as a clay or claylike material that is plastic enough to mold easily. Its vitrification point is usually below 1,100° C. Shale is a laminated sedimentary rock that is formed by the consolidation of clay, mud, or silt. The common clays and shales are composed mainly of illite or chlorite. They also may contain kaolin and montmorillonite. Common clays and shales usually contain more alkali, alkaline earth, and ferruginous minerals and less aluminum than high-quality kaolins, fire clays, and ball clays. Iron present in the clay usually imparts a reddish color to the final product after firing. There is no formal classification of common clays and shales, although a clay may sometimes be referred to as common, brick, sewer pipe, or tile clay. Clay and shale are used in the manufacture of structural clay products such as brick, drain tile, portland cement clinker, and expanded lightweight aggregates.

Fire clay is defined as detrital material, either plastic or rocklike, that commonly occurs as underclay below coal seams. Low concentrations of iron oxide, lime, magnesia, and alkalies in fire clay enable the material to withstand temperatures of 1,500° C or higher. It is composed mainly of kaolinite. Fire clays also contain other clays such as ball clay, bauxitic clay and shale, burley, burley-flint, and diaspore. Fire clays generally are used for refractories or to raise

vitrification temperatures in heavy clay products. The fired colors of fire clays range from buffs to grays. Fire clays are classified according to their physical and chemical properties and the characteristics of the products made from them.

The term "fuller's earth" is derived from the first major use of the material, which was for cleaning textiles by fullers. Fuller's earth does not refer to a clay with a specific composition or mineralogy. It is defined as a nonplastic clay or claylike material, usually high in magnesia, that is suitable for decolorizing and purifying mineral and vegetable oils. They are composed mainly of the needleand/or lath-shaped clay mineral attapulgite or varieties of montmorillonite. Fuller's earths containing opal or other forms of colloidal silica also are produced. Fuller's earths are classified according to their physical and chemical properties. Sepiolite-type clays are grouped with fuller's earths under the Bureau classification system.

Kaolin, or china clay, is defined as a white, claylike material composed mainly of kaolinite and other kaolin-group minerals, such as halloysite and dickite. Kaolin has a specific gravity of 2.6 and a fusion point of 1,785° C. Kaolin is classified according to the method of preparation (crude, air-separated, waterwashed, delaminated, air-dried, calcined, slip, pulp, slurry, or water suspension) and on specific physical and chemical properties.

The American Society for Testing and American Foundrymen's Materials. Association, American Oil Chemists' Society, American Petroleum Institute, Technical Association of the Pulp and Paper Industry, and other national organizations have developed tests and set standards for some applications. Many producers and consumers, however, use nonstandardized tests that are applicable to their specific needs. Individual companies often set the acceptable limits of mineralogical composition, particle size, and other physical and chemical properties. Detailed data specifications have been published by the U.S. Bureau of Mines.²

Products for Trade and Industry

Because of the many types of clay and different qualities within each type, the consumption pattern and the products for trade and industry are constantly Consumption of kaolin in changing. refractories has been growing since 1970 because of the increasing popularity of castable, ramming, gunning, and plastic mixes that use calcined kaolin aggregates (grog) in their formulations.³ consumption of calcined kaolin grogs also has increased in refractory replacing imported manufacturing, calcined refractory-grade bauxite grogs. Bentonite products for waterproofing and sealing in construction and reservoir uses have gained in popularity. also Attapulgite-type fuller's earth production, like bentonite, is finding increasing applications in the premium drilling mud industry.

Industry Structure

An estimated 385 companies operating 1,139 clays pits or mines reported production in 1992; of these, 85 companies, most with multiple operations, accounted for approximately 41% of the tonnage and 62% of the value for all types of clay produced and sold or used. Clay production was reported in all States and Puerto Rico except Alaska, Delaware, Hawaii, Rhode Island, Vermont, Wisconsin, and the District of Columbia.

The leading clay-producing States were Georgia, 9.0 million tons; Wyoming, 2.5 million tons; Alabama, 2.4 million tons; Ohio, 2.3 million tons; Texas, 2.2 million tons; North Carolina, 2.1 million tons; California, 1.9 million tons; South Carolina, 1.6 million tons; Michigan, 1.3 million tons: and Missouri, 1.2 million tons. (See table 2.) Most of the clay is mined by open pit methods. Less than 1% of U.S. clay output was from underground mines in 1992. Most of the underground production was Pennsylvania, Ohio, and West Virginia, where the clays are mainly underclays associated with coal and suitable for refractory uses.

The ball clay industry was small, with 6 producers operating 36 mines in 5 States in 1992. Three of the producers were large, diversified firms with widespread foreign and domestic mineral interests. Tennessee ball clay production represented about 76% of the total output.

Firms producing bentonite operated 144 mines in 13 States. Four producers were large, diversified firms with international mineral operations; three of the firms had interests in other types of clay in the United States. Wyoming was the leading State, accounting for 76% of the total output. Swelling-type bentonite was produced mainly in Wyoming and Montana and nonswelling-type bentonite was produced in Mississippi and Texas. The United States was the world's largest producer and exporter of bentonitic clays.

Firms producing common clay and shale in 1992 were manufacturers of structural clay products, clay pipe, lightweight aggregates, and cement. Most companies mined the clays used in making their products. Less than 10% of the total output is usually sold. Private mining contractors and haulers were employed in many of the operations. Some producers were diversified firms having interests in metals and other nonclay products. Some companies owned and operated several clay pits and plants to cover a large market area. The economic radius for shipment of common clay or shale products was usually 320 kilometers or less. The high cost of transport promotes the development of local ownership companies, or in the case of a large firm, the ownership and operation of several strategically located pits and associated fabricating plants.

Fireclay producers were mostly refractories manufacturers that used the clays in firebrick and other refractories. Seventy-eight mines were operated in 1992 by 19 firms in 9 States.

Nineteen companies produced fuller's earth from 37 mines in 11 States. Eleven of the mines were in the attapulgite-fuller's earth areas of Florida and Georgia. These two States accounted for most of the domestic attapulgite production. Most producers were small, independent firms, but three were large,

diversified corporations with international mineral interests. The world's fuller's earth needs are supplied from relatively few areas. The United States is the world's largest producer and user of fuller's earth.

Forty-two firms operated 141 kaolin mines in 11 States. In 1992, three large, diversified firms accounted for about 60% of total domestic kaolin output. Most large kaolin producers have operations in Georgia, which accounted for 85% of the kaolin production.

Geology-Resources

Clay is formed by the mechanical and chemical breakdown (weathering) of rocks. The weathering products consist of mineral grains and rock fragments of different size and different physical and chemical properties. The nonplastic portion consists of altered and unaltered rock fragments (grit), which are usually feldspar, iron oxides, micas, and quartz. The plastic portion usually is composed of clays and is low in grit.

Clays may be classified as residual or sedimentary. Residual clays are deposited in the same location in which they were formed. Sedimentary clays are those that have been transported, usually by water, and deposited elsewhere.4 Sedimentary clays often undergo further alteration and classification during transport. Kaolin deposits in Georgia and South Carolina are sedimentary. Kaolin deposits in North Carolina and English china or kaolin clay deposits are residual.⁵ The Kentucky and Tennessee ball clays and the Missouri fire clays are sedimentary deposits. Most bentonites, montmorillonites, and fuller's earths were formed in place through the weathering of volcanic ash or tuff. The attapulgitetype fuller's earth deposits of Florida and Georgia were probably not formed from volcanic ash or tuff. Geologists have never found any evidence of volcanic materials associated with these deposits.6

The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals." Reserves are the part of an

ore body that can be economically extracted at the time of evaluation. Reserve base is the part of an ore body that meets specified minimum physical and chemical criteria related to current mining and production practices. Reserve base includes reserves, marginal reserves, and subeconomic resources.

Common clays and shale deposits are found throughout the United States. Clays and shale were mined commercially in 43 States and Puerto Rico. Domestic resources are almost unlimited. Not all deposits, however, are near potential markets, and most deposits are not suitable for all applications. example, most common clay or shale deposits can be used to manufacture common brick, but the color or strength of the final product may not meet the requirements of the local market. Relatively few deposits are suitable for manufacture of lightweight aggregate. Even with these limitations of location and use, resources of common clay and shale are "virtually unlimited."

U.S. reserves of other types of clays that are owned or controlled by domestic producers are estimated to be about 700 million tons. U.S. reserves of kaolin are estimated to be 400 million tons; ball clay, 30 million tons; fire clay, 100 million tons; bentonite, 120 million tons; and fuller's earth, 60 million tons.

Large quantities of high-quality kaolin suitable for paper-coating and paper-filler are found in Georgia. A small area in Georgia and Florida contains sizable reserves of attapulgite-type fuller's earth. Most bentonite for iron ore pelletizing and oil-well-drilling muds is mined in Wyoming. Fire clay deposits, such as those found in Missouri, are widespread. Deposits of high-quality fire clay are nearing depletion. Kentucky and Tennessee are two of only a few States that have sizable deposits of ball clay.

Technology

Exploration.—Exploration begins with an understanding of the geological occurrence of the clays of interest. With this knowledge, potential economic deposits can be located. Auger or core

drills are then made to delineate the size and shape of the deposit and to obtain material for testing.

Kaolins usually are evaluated for filler and ceramic applications. The grit, particle size, brightness, and leachability are determined. Air-floated clays normally require only grit and brightness determinations. Kaolin, ball clay, and fire clay for ceramic and/or refractory applications are analyzed for grit, brightness, green and dry strengths, fired color, and iron and alumina contents. The common clays and shales usually are tested according to the intended end use, such as brick, structural-drain tile, or lightweight aggregate. Usually, prepared specimens are tested for plasticity, green strength, shrinkage, vitrification temperature range, etc. For lightweight aggregates, the bloating range is determined. Bentonites and fuller's earth clays are difficult to evaluate because there are no standard testing procedures or specifications. Generally, they are processed to meet the purchaser's specifications.

Mining.—Most clays are mined from open pits using modern surface mining equipment such as draglines, power shovels, front-end loaders, backhoes, scraper-loaders, and shale planers. Some kaolin is extracted by hydraulic mining and dredging. A few clay pits are operated using crude hand-mining methods. A small number of clay mines, principally in underclays in coal mining areas, are mined underground using room-and-pillar methods. Clays usually are transported by truck from the pit or blending areas to the processing plants. Rail, conveyor belt, and in the case of kaolin, pipelines also are used.

About 100% of the clay is recovered from the minable beds in most open pit operations. Approximately 75% is recovered in underground operations. The waste-to-clay ratio is highest for kaolin, about 7:1, and lowest for common clay and shale, about 0.25:1.

Processing.—Clays are used in a large number of products, so they must be

treated in different ways. Processing can consist of very simple and inexpensive grinding or shredding and screening for some common clays. Very complex and expensive grinding or shredding, sizing, leaching, delamination, etc., may be required for paper-coating clays and high-quality filler clays for use in rubber, paint, plastic, and other products. In general, processing does not appreciably alter the chemical or mineralogical characteristics of the clays. The two exceptions are calcining and cation exchange.

Significant processing losses occur with kaolin and fuller's earth. About 40% of the kaolin and 30% of the fuller's earth delivered to the processing plants is discarded. Waste material from processing consists mostly of off-grade clays and small quantities of feldspar, iron-bearing minerals, mica, and quartz.

Ball Clay.—Processing involves drying, shredding, pulverizing, air floating, and slurrying.

Bentonite.—Processing involves weathering, drying, grinding, sizing, granulation, and the use of additives for cation exchange.

Common Clay and Shale.— Processing involves shredding, blunging, extruding, and drying. Common bricks, tile, lightweight aggregate, etc., require firing in a kiln. The kiln firing or drying operation produces a finished manufactured product.

Fire Clay.—Processing involves shredding, calcining, and blending.

Fuller's Earth.—Processing involves blunging, extruding, drying, crushing, grinding, sizing, and dispersing.

Kaolin.—Processing involves one or more of the following: shredding, blunging with dispersant, degritting, water fractionation, magnetic separation, ultraflotation, acid treatment, calcination, air floating, attrition grinding, slurrying, and delaminating. Kaolins used for paper coating applications may be leached and further delaminated by grinding, deflocculation, and centrifugation to special sizes. Ultraflotation or wet magnetic separation treatment may be used to remove iron- or titanium-bearing minerals to obtain a whiter product.

Processing costs for clays range from a few cents per ton for some common clays to more than \$400 per ton for some special paper-coating clays and highquality clays that require very elaborate and expensive treatments.

Price schedules, although not complete, are available and are published regularly in trade journals such as the American Paint and Coatings Journal, Chemical Marketing Reporter, and Industrial Minerals (London).

Federal tax laws allow clay producers a depletion allowance on both domestic and foreign gross income not to exceed 50% of net income with depletion deduction. Depletion allowances are as follows: ball clay, bentonite, kaolin or china clay, sagger clay, and clay used or sold for purposes dependent on its refractory properties, 14% domestic and 14% foreign: fuller's earth, 14% domestic and 14% foreign; clay used for extraction of alumina or aluminum compounds, 22% domestic; clay used or sold for use in manufacturing drainage and roofing tile, flower pots, and kindred products, 5% domestic and 5% foreign; and clay and shale used for making brick, tile, and lightweight aggregate, 7.5% domestic and 7.5% foreign. Severance taxes are levied by some producing States.

Byproducts and Coproducts

Firms in California, Florida, and Texas produce silica glass sand as a coproduct of its kaolin production. Flake mica is a byproduct in one kaolin operation in North Carolina. Bauxite is a coproduct in clay operations in Alabama and Georgia. Clay and limestone for cement manufacture are often produced from the same property and reported as coproducts or byproducts even though they are usually mined separately from different formations or beds. Sand, gravel, and stone aggregates are

occasionally produced together with common clays.

Economic Factors

Economic factors affecting clays vary in importance with type, quality, and intended end use. The cost of transportation is an important factor for the common clay and fire clay industries: mines must be close to consumers to be cost competitive. Other types of clavs are less abundant and have higher unit values. They can be shipped greater distances from the mines and still be cost competitive. For example, paper-coating clay from Georgia and attapulgite-type fuller's earth from Florida and Georgia can be shipped nationwide. Bentonite for iron ore pelletizing from Montana and Wyoming can be shipped a considerable distance to the iron ore centers. In some of these cases, the shipping costs exceed the value of the clays at the mine or processing plant.

Because most clays are relatively low-cost materials in the crude state, mining costs must be kept as low as possible. Cost of the crude clays ranges from less than \$3 per ton for some common clays to more than \$20 per ton for some of the higher quality materials.

Very little clay is imported because transportation costs would make the clays noncompetitive in price. Consequently, import duties have little impact on the amount of clays imported.

Operating Factors

To manufacture finished clay products, producers require equipment to mine and process the crude clay and a kiln for firing or drying their products. Mining, processing, and manufacturing are all energy-intensive operations. Many clay producers converted to coal from oil firing and gas firing. However, the conversion to coal and/or wood as a kiln fuel is gaining in popularity where feasible in heavy clay and refractory products manufacturing and in bentonite processing.

and, Losses in mining are extremely small, are except in underground mining where

recovery will average about 75%. Processing losses for material receiving, crushing, grinding, mixing, shredding, blending, and drying also are insignificant. Losses from washing, sizing, etc., reach 30% or 40%.

Clay mining lacks many of the hazards associated with other types of mining because only a few deposits require the use of explosives and most mines are open pit earth-moving operations. Domestic mine employment in 1992 was estimated to be 2,000 workers. Domestic mill employment was estimated to be 9,100 workers.

ANNUAL REVIEW

Issues

Clay mining has an environmental impact because of the disturbance to the land. Overburden is moved and clays are removed, leaving a depression or pit. State laws usually require leveling or recontouring of the disturbed area and planting trees or grasses to prevent or minimize erosion. For processing, the impoundment of slimes and dust control are usually required. The rules for disposal of coarse tailings are similar to or included with those laws governing reclamation of the mined area.

Many local governments are enacting stricter regulations. In some cases, they change the land use zoning. New regulations and land use changes sometimes force a mine to close or relocate to a more distant deposit, increasing costs to the community because of increased transportation charges.

An issue that continues to interest a segment of the clay industry is the classification of crystalline silica as a probable human carcinogen. Mineral products containing 0.1% or more crystalline silica must be labeled in accordance to the Occupational Safety and Health Administration's Hazard Communication Standard (HCS), and employers must comply with the terms of HCS with regard to worker training. The Mine Health and Safety Administration has proposed enacting a similar HCS.

Although domestic clay resources are more than adequate, the prices for clays are expected to rise. The increase reflects the demand for higher quality specialty clay by consumers and increased costs associated with land acquisition, severance taxes, land rehabilitation, energy requirements, and environmental factors.

Production

Ball Clay.—Production of domestic ball clay increased 9% to 853,828 tons valued at about \$36 million. Tennessee supplied 67% of the Nation's output, followed by, in descending order of production, Kentucky, Texas, Mississippi, and Indiana. Production increased in Tennessee and Texas, was unchanged in Indiana and Mississippi, and decreased slightly in Kentucky. (See table 3.)

United Clays of Texas Inc., a subsidiary of Watts Blake Bearne and Co. PLC, purchased the ceramics division of Southern Clay Products Inc. Included in the purchase were the ball clay and soapstone mining and processing facilities.⁷

Bentonite.—The quantity and value of bentonite sold or used increased slightly to 3.35 million tons and \$125.4 million, respectively. Wyoming was the largest bentonite producer, accounting for 76% of the total bentonite production and 90% of the swelling bentonite production. Mines in Alabama and Mississippi accounted for more than 61% of the nonswelling calcium or bentonite production. Production of swelling bentonites increased in Wyoming and Montana. Increases in production of nonswelling bentonite were reported in Arizona and Mississippi. Decreases were reported in other producing States. (See table 5.)

Bentonite Corp. began construction of a new processing plant. The plant will manufacture two products that contain between 50% to 99% bentonite for the metal casting industry. The plant will have a capacity of 127,000 tons and will consume 90,000 tons of bentonite per year.8

Common Clay and Shale.—Domestic sales or use of common clay and shale increased slightly in tonnage to 25.0 million tons and increased 4% in value to \$136.7 million. The 10 major producing States were Texas, Ohio, North Carolina, Alabama, California, Georgia, Michigan, South Carolina, Missouri, and Indiana, in descending order of tonnage. Of these States, production increased in Georgia, Michigan, Missouri, North Carolina, Ohio, and Texas. Common clay and shale represented about 61% of the quantity but only 9% of the value of total domestic clay production. (See table 7.)

Fire Clay.—Fire clay sold or used by domestic producers increased significantly in tonnage and value to 1.1 million tons and \$15.8 million, respectively. large increase resulted from reclassification of a kaolin producer with mines in Alabama and Georgia to the fire clay category, based on the mineralogy of the deposits and the end-use applications for the clay. Georgia was the leading producing State, followed by Alabama, Missouri, Ohio, Arkansas, Colorado, New Mexico, New Jersey, Washington. (See table 9.)

Fuller's Earth.—Production of fuller's earth increased 4% to 2.4 million tons valued at \$242 million. Production was reported in 11 States. Production from the region that includes Attapulgus, Decatur County, GA, and Quincy, Gadsden County, FL, was composed predominantly of the lath-shaped amphibolelike clay mineral attapulgite. Florida and Georgia accounted for most of the domestic attapulgite production. Most of the fuller's earth produced in other areas of the United States contains varieties of montmorillonite and/or other clays. Illinois, Mississippi, and Missouri accounted for more than one-half of the domestic montmorillonite-fuller's earth production. (See table 11.)

Kaolin.—Domestic production of kaolin decreased 16% to 8.1 million tons. The value of production increased slightly

to \$926.6 million. The decline resulted from the reclassification of a kaolin producer with mines in Alabama and Georgia to the fire clay category based on the mineralogy of the deposits, end-use applications, and unit value for the clay. Kaolin was produced in 14 States. Georgia was the largest kaolin producer with 85% of U.S. production, followed by South Carolina with 6% of production. Georgia accounted for 95% of the total production value of kaolin. (See table 13.)

More than 50% of the kaolin produced was water-washed; followed by delaminated, 16%; air-floated, 14%; calcined, 9%; and unprocessed, 9%. (See table 14.) Delaminated kaolin was produced exclusively in Georgia. Georgia also accounted for 99% of the production of water-washed kaolin and 78% of the calcined kaolin. Georgia and South Carolina accounted for 94% of the air-floated kaolin and 48% of the unprocessed grades. (See tables 14, 15, 16, and 18.)

ECC International began expanding the production capacity of its kaolin operations in Georgia. Capacity will be increased by 650,000 tons per year upon completion of the expansion. ECC began the project in anticipation of increasing demand in Europe, the Far East, and the United States.⁹

Albion Kaolin Co. completed its new kaolin slurry plant. The company constructed the new plant because of rising demand for slurried products. 10 Albion Kaolin also formed a joint venture with Old Hickory Clay Co. to provide kaolin and ball clay products to the ceramic and refractory industries. 11

Kemira Inc. announced its intention to acquire 20% of Nord Kaolin Co. Nord Kaolin produces approximately 300,000 tons of kaolin per year from mines near Jeffersonville, GA. The company markets kaolin for the paper industry.¹²

Consumption and Uses

Ball Clay.—Ball clays are extremely refractory, and their use, largely in whitewares, imparts a high green strength as well as plasticity to the bodies.

Although white-firing ball clays are preferable, fired products that range to cream or buff colors do not generally impair the quality of the whiteware products.

The principal ball clay markets were dinnerware, floor and wall tile, and sanitaryware with 15%, 22%, and 15%, respectively, of the domestic consumption. Consumption of ball clay for dinnerware, floor and wall tile, and refractories increased in 1992. (See table 4.)

Bentonite.—The swelling sodium bentonites were used largely in drilling muds, in foundry sands, and in pelletizing taconite iron ores. The nonswelling or calcium bentonites were used mostly in conjunction with the swelling bentonites in foundry sand mixes in which the sodium bentonites provide dry strength and the calcium bentonites provide high green strength.

Bentonite also was used for foundry casting by the steel, iron, and nonferrous casting. The bentonite provided good green strength and desirable dry strength characteristics. Sodium bentonites were used in steel casting. Ion-exchanged bentonites were used for iron and nonferrous casting. There has been an increased use of mixtures of ionexchanged and sodium bentonites to meet the more stringent demands of the casting industry. Calcium bentonite produced in Alabama and Mississippi was suitable for the production of absorbent, acidactivated, and foundry products.

The three major end uses were drilling mud, foundry sand, and iron ore pelletizing with 22%, 17%, and 23%, respectively, of total domestic sales. Sales of bentonite for foundry sand applications increased 4%. Sales of bentonite for drilling and pelletizing applications each decreased 7% and 6%, respectively. Producers that sold bentonite for pelletizing iron ore did not separate domestic and foreign shipments, in all cases. An estimated 100,000 to 130,000 tons was exported for pelletizing, making U.S. markets about 540,000 to 570,000 tons. Increases in consumption were reported for animal feed, foundry

sand, and water proofing and sealing. (See table 6.)

Common Clay and Shale.—Common clay was used most frequently in the manufacture of heavy clay products, including (1) building brick; flue linings, sewer pipe, drain tile, structural tile, and terra cotta: (2) portland cement clinker: and (3) lightweight aggregate, accounting for 51%, 31%, and 14%, respectively, of total domestic consumption. Consumption increased 4% for heavy clay products and decreased 6% and 2% for lightweight weight aggregates and portland cement clinker, respectively. A large increase in consumption reported for floor and wall tile does not correspond to construction trends. possibly represents a better accounting of end-use consumption as shown by the smaller tonnages reported under the "Other" category. (See table 8.)

Fire Clay.—Fire clays were used mostly in commercial refractory products such as firebrick and block, grogs and calcines, high-alumina brick and specialties, saggers, refractory mortars and mixes, and ramming and gunning mixes. Fire clays also were used to produce lightweight aggregates, portland cement, pottery, and common brick. Fire clay was used to increase the vitrification range of sewer pipes and bricks.

Consumption of fire clay for firebrick declined sharply in 1992 yet still accounted for 16% of consumption. There was a large increase in calcine use in 1992. This resulted from the reclassification of a kaolin producer to the fire clay category based on mineralogy and end-use applications. Grogs, calcines, high-alumina brick, and specialties accounted for 71% of fire clay use. (See table 10.)

Fuller's Earth.—Fuller's earth and calcium bentonite were used for decolorizing and purifying mineral, vegetable, and animal oils. Clays activated by acid treatment were used to process animal or vegetable oils. Acid treatment produced a highly absorbent sievelike structure. Attapulgite is used in

drilling muds instead of sodium bentonites for drilling saltwater formations. Sodium bentonite flocculates in brine, thereby destroying the gel-like colloidal suspension required for drilling. The major uses for attapulgite and montmorillonite types of the fuller's earths were in pet waste and oil and grease absorbents because of their absorbent properties.

Attapulgite, a fuller's earth-type clay, found wide application in both absorbent and gelling and/or thickening areas. The thixotropic properties of attapulgite clays provided important thickening and viscosity controls necessary for suspending solids. Mineral thickeners were used in such diverse markets as paint, joint compound cement, and saltwater drilling mud.

The major use for fuller's earths was in pet waste absorbents, which accounted for 59% of the fuller's earth consumption. Other major domestic uses were oil and grease absorbents (19%) and pesticide carriers (7%). The use of montmorillonite for oil and grease absorbent applications increased in 1992. Consumption of fuller's earth did not change significantly for other applications. (See table 12.)

Kaolin.—Kaolin had many industrial applications, and many grades were specifically designed for use as a filler in paper, paint, rubber, plastics, 13 and ceramics.¹⁴ New uses are constantly being developed. Kaolin is a unique industrial mineral because it is chemically inert over a relatively wide pH range, is white in color, and has good covering or hiding power when used as a pigment or extender in coated films and filling It also is soft and applications. nonabrasive, has low conductivity of heat and electricity, and costs less than most materials with which it competes. Fillers and extenders must meet very rigid specifications such as particle size, color, brightness, and viscosity. 15

Kaolin producers reported major domestic end uses as paper coating, 43%; paper filling, 18%; fiberglass, 6%; paint, 4%; rubber, 3%; brick, 3%; portland cements, 3%; and grogs and calcines, 3%. (See table 20.) There was a large apparent decrease in calcines and grog production in 1992. The decline resulted from the reclassification of a kaolin producer with mines in Alabama and Georgia to the fire clay category, based on the mineralogy of the deposit, end-use applications, and unit value.

There were distinct differences in markets for kaolin from Georgia and South Carolina. Major domestic markets for kaolin from Georgia were paper coating (52%), paper filling (21%), fiberglass (5%), and paint (4%). Major markets for kaolin from South Carolina were rubber, fiberglass, catalyst, and adhesives, in decreasing order of consumption. (See tables 17 and 19.)

Absorbent Uses.—Absorbent uses for clays accounted for about 2.2 million tons or 5% of total clay consumption. Consumption was for oil and grease absorbents, 21%; pet waste absorbents, 65%; and miscellaneous absorbent applications, 14%. Demand for absorbents increased 5% in 1992. Fuller's earth was the principal clay used for absorbent purposes (1.9 million tons), followed by bentonite (299,000 tons). (See tables 6 and 12.) Small amounts of ball clay and kaolin also were used for absorbent applications.

Ceramics.—Pottery and related products required good ceramic qualities, including plastic formation, desirable firing temperatures, color, etc. principal clays meeting these and other specifications were ball clay, common clay, and kaolin. Total demand for clay in the manufacture of pottery, sanitaryware, china and dinnerware, and related products (excluding clay flower pots) exceeded 871,000 tons. Common clay and shale, ball clay, and kaolin, in order of volume, were used in manufacturing floor, wall, and quarry tile. Demand in floor, wall, and quarry tile applications increased to 619,000 tons in 1992. (See tables 4, 8, 10, and 20.)

Construction.—Common clays and shales were used to manufacture a wide variety of construction materials such as

expanded aggregates, hydraulic cement, and structural clay products.

Expanded Clay and Shale.—Materials with specific bloating properties and strength are required for this use. Lightweight concrete blocks, floors, walls, and other products made from expanded clay and shale have a lower overall weight and better insulating qualities than equivalent products made with sand and gravel and crushed stone aggregates.

Consumption of common clay and shale in the production of lightweight aggregate decreased 6% to 3.4 million tons. Concrete block, which accounted for 62% of total lightweight aggregate production, decreased 13%. Structural concrete, which accounted for 21% of the market, decreased 2%. Highway surfacing, with 8% of lightweight aggregate production, declined slightly. (See tables 8, 10, and 21.)

Neutralysis Industries Development Co. announced plans to develop a lightweight aggregate plant that utilizes municipal waste in the process. Pulverized waste will be mixed with milled clay and liquid wastes and pelletized. The pellets will be fed into a multiple kiln plant. The waste in the pellets will be gasified and oxidized in the first and second kilns, respectively. A third will be used to vitrify the expanded clay. 16

Hydraulic Cement.—Clays provide the alumina and silica required to manufacture hydraulic cements. Common clays, kaolin, fuller's earth, fire clay, and bentonite, in decreasing order of consumption, were used in cement products. Approximately 97% of the clay consumed by the cement industry was common clay. (See tables 8, 12, and 20.)

Structural Clay Products.— Structural clay products include such items as building brick, drain tile, flue linings, roofing tile, sewer pipe, and terra cotta. Clays for structural applications must be plastic and easily shaped, must not warp during firing, and must produce a product with adequate strength. Common clay is most commonly used in these applications (99% of clay consumption for structural clay products). Other clays, such as ball clay, bentonite, fire clay, and kaolin, are not used in large tonnages because of their higher cost.

Slightly more than 12.9 million tons of clay was consumed for structural clay products. Common and face brick accounted for 94% of this total or 12.1 million tons. Other markets, in decreasing order of consumption, were sewer pipe, flue linings, structural tile, terra cotta, drain tile, and roofing tile. (See tables 8, 10, 20, and 22.)

The value reported by the Bureau of the Census for shipments of building and face brick was 5.8 billion bricks valued at \$885 million, an increase from that of 1991. Shipments of clay floor and wall tile increased to almost 44 million square meters of tile valued at \$638 million. Shipments of vitrified clay and sewer pipe fittings decreased to 138,000 tons valued at \$35 million.

Drilling Mud.—Drilling mud is a scientifically designed mixture of several items. The clays are used to adjust the viscosity and gel strength of the drilling fluid and to coat the drill-hole walls to prevent fluid loss. Drilling muds contain, in addition to bentonite or attapulgite. ground barite for its high specific gravity.17 Demand for clays in rotarydrilling muds decreased to about 663,000 tons. Swelling-type bentonite remained the principal clay used in drilling mud mixes, although fuller's earth, used mostly in saltwater drilling techniques. and nonswelling sodium-activated bentonites also were used to a limited extent. (See tables 6 and 12.)

Filler.—Clays are used as binders, extenders, and fillers in a wide variety of products, ranging from adhesives to flooring products to paint to rubber. They are added to products for widely varying reasons. For example, clays displace more expensive product components in paint, paper, and plastics; improve the ink retention and opacity in

paper; prevent pigment settling in paints; act as carriers for fertilizers and pesticides; and increase the strength of plastics.

More than 4.4 million tons of clavs was used as fillers and extenders. Kaolin accounted for approximately 90% of this amount, followed by fuller's earth, bentonite, ball clay, and common clay, in decreasing order of consumption. (See tables 4, 6, 8, 12, and 20.) Slightly less than 80% of the kaolin was used for paper-coating and paper-filling applications. Kaolin also was used in the manufacture of products such as adhesives, cosmetics, fertilizer, ink. linoleum, paint, pesticides, plastics, and rubber. (See table 20.) Fuller's earth was used mainly in pesticides, fertilizers, and animal feed. Lesser amounts were used in adhesives, asphalt emulsion, and paint, in decreasing order consumption. (See table 12.) Bentonite was used mainly in animal feed with smaller amounts used for the manufacture of adhesives, asphalt emulsions, cosmetics, paint, and pesticides. (See table 6.) Major ball clay uses were in animal feed, asphalt emulsion, asphalt tile, paper, and wall board. Common clay was used mainly in animal feed and asphalt emulsions. Small amounts of fire clay were used in animal feeds.

Glass.—Exacting chemical and physical specifications are required for clay used in glass manufacturing. More than 379,000 tons of kaolin, or 99% of all clay used for glass manufacture, was used in fiberglass. Small amounts of kaolin and bentonite were used as a raw material feed in formulating bottle and plate glass batches and mineral wool. (See table 20.)

Iron Ore Pelletizing.—Demand for bentonite in iron and steel production is based on its ability to form strong iron ore pellets from fine-grained taconite concentrates. Easily handled hard pellets are essential for efficient blast furnace operation. Demand decreased from 717,000 tons in 1991 to 675,000 tons in 1992. (See table 6.) Small amounts of common clay also were used for iron ore

pelletizing. (See table 8.)

Paper Products.—Demand for clays for use as filler and coater in paper has followed the rapid increase in demand for paper. Kaolin is the principal clay used. It serves to provide a smooth coating to paper, improves its ink retention and brightness, increases the paper density. fills interstices in the paper, and improves opacity. Kaolin accounted for essentially all of the clay used for paper coating (2.7 million tons) and 99% of the clay used for paper filling (1.1 million tons). (See table 20.) Small amounts of ball clay and fuller's earth were used in paper-filling applications and a small amount of bentonite was used for paper coating.

Clays also were important for newspaper recycling. During recycling, either washing or flotation is used to remove the ink from the newspaper stock. In the flotation process, clay was added to the pulp slurry. The clay absorbed ink on its surface and floated to the surface, where it was skimmed off, leaving clean, ink-free pulp.¹⁸

Refractories.—Refractories require strength at high temperatures, resistance to corrosion. low coefficient expansion, and many other physical and chemical properties, depending on Clays with physical application. properties most suitable for general refractory use have been classified as fire The current trend is for refractories designed for a specific use and castable mixes containing refractory and calcium aluminate aggregates cements. 19 Bentonite, both swelling and nonswelling, was used as a bonding agent in proprietary foundry formulations imparting both hot- and green-strength to the sand.

More than 1.7 million tons of clays was used for the manufacture of refractories. Ball clay, bentonite, common clay, fire clay, and kaolin accounted for 3%, 27%, 6%, 52%, 12%, respectively, of the refractories markets. Major uses were firebrick for ball clay and common clay; foundry sand for bentonite; grogs, calcines, and firebrick for fire clay; and grogs and calcines for

kaolin. (See tables 6, 10, and 20.)

Markets and Prices

Ball Clay.—The average unit value for ball clay reported by domestic producers was \$42.42 per ton. The unit value of imported ball clay was \$329.04. The unit value of exported ball clay was \$63.67 per ton.

Bentonite.—The unit value reported by domestic producers for nonswelling bentonite was \$47.84 per ton. The unit value for swelling bentonite was \$35.39 per ton. The unit value for all bentonite was \$37.38 per ton. The unit value of imported bentonite was \$497.43 per ton. The unit value of exported bentonite was \$90.78 per ton.

Common Clay and Shale.—The average unit value for all common clay and shale produced in the United States and Puerto Rico was \$5.44 per ton. The unit value of clay and shale used in lightweight aggregate was \$8.34 per ton.

Fire Clay.—The unit value for fire clay reported by domestic producers was \$15.02 per ton. The unit of imported fire clay was \$115.84 per ton. The unit value of exported fire clay was \$103.23 per ton.

Fuller's Earth.—The unit value of attapulgite-fuller's earth reported by domestic producers was \$137.46 per ton. The unit value of montmorillonite-fuller's earth was \$77.81 per ton. The average unit value of all types of fuller's earth was \$100.14 per ton. The unit value of imported fuller's earth was \$193.75 per ton. The unit value of exported fuller's earth decreased to \$148.96 per ton.

Kaolin.—The unit value of kaolin increased to \$114.91 per ton for all kaolin grades. The unit value for airfloat kaolin was \$53.10 per ton; for calcined kaolin, \$313.51 per ton; for delaminated, \$113.79 per ton; for waterwashed kaolin, \$112.38 per ton; and for unprocessed kaolin, \$19.56 per ton. The unit value of the imported kaolin was

\$502.72 per ton. The unit value of exported kaolin was \$163.62 per ton.

Foreign Trade

Ball Clay.-Ball clay exports decreased 16% to 49,000 tons valued at \$3.1 million, according to the Bureau of the Census. Shipments were made to 19 countries. The major importer was Mexico, with 71% of the exports. (See table 23.) Domestic ball clay producers reported that 99,678 tons of ball clay was exported in 1992. The exports were used mainly for floor and wall tile production and sanitaryware production. Other uses asphalt emulsions (4%), miscellaneous filler and extender applications, wallboard, and miscellaneous ceramics applications. (See table 4.)

The discrepancy between the Bureau of the Census and the tonnage producers reported as exports probably resulted because some shipments of clays may be classified under a nonspecific mineral category by the Bureau of the Census. Shipments classified under the nonspecific mineral category would not appear in the Bureau of the Census' ball clay export statistics.

Ball clay was imported only from the United Kingdom. Imports decreased 7% to 699 tons valued at \$230,000. (See table 24.)

Bentonite.—Bentonite exports decreased 10% to 591,000 tons valued at \$53.7 million. Bentonite was exported to 58 countries with Japan and Canada accounting for 55% of the exports. Domestic bentonite producers reported exports of 471,916 tons. This is 120,000 tons less than the Bureau of the Census data show but is accounted for by the inclusion of 100,000 to 130,000 tons of bentonite for Canadian iron pelletizing under domestic sales. Estimated markets for exported bentonite were foundry sand (49%), drilling mud (20%), and iron ore pelletizing (20%). Bentonite also was exported for absorbents, decolorizing and clarifying animal oils, desiccants, fertilizer carriers, ink, cosmetics, paint, and waterproofing.

(See tables 6 and 23.)

Bentonite imports consisted mainly of untreated bentonite clay and chemically or artificially activated materials. Imports of untreated bentonite increased 14% to 2,527 tons valued at \$1.3 million. Most of this material was imported from Canada (47%). Imports of chemically activated material increased 5% to 15,070 tons valued at \$9.8 million. Mexico supplied 83% of the chemically activated bentonite imported into the United States. (See table 24.)

Fire Clay.—Exports of fire clay increased 15% to 228,000 tons valued at \$23.5 million. Fire clay was exported to 33 countries. The major importers were the Netherlands, Mexico, and Japan. These countries accounted for 71% of the exports. According to the Bureau of the Census, 8,089 tons of fire clay valued at \$937,000 was imported in 1992. Most of the fire clay was imported from China (94%). Fire clay also was imported from Spain, Canada, the United Kingdom, and Japan. (See tables 23 and 24.)

Fuller's Earth.—Exports of fuller's earth were 27,000 tons valued at \$4 million. Fuller's earth was exported to 27 countries. The major importers were Canada (30%) and the Netherlands (26%). Domestic producers reported more than 82,000 tons of bentonite exports in 1992. (See table 12.) with ball clay, the discrepancy between the producers' and the Bureau of the Census' statistics is probably one of clay classification (see discussion under Ball Clay). The major market for exported fuller's earth was pet waste absorbents. Other markets were ceramic tile, foundry cosmetics. oil and absorbents, paint, and pesticide carriers. Small amounts of decolorizing fuller's earth were imported from Canada and Germany. (See tables 12, 23, and 24.)

Kaolin.—Exports of kaolin reported by the Bureau of the Census increased 5% to 3 million tons valued at \$491 million. Kaolin was exported to 69 countries. Major importers were Japan, Canada, Finland, the Netherlands, and Italy. Major end-use markets reported by producers were paper coating (75%) and paper filling (11%). (See tables 20 and 23.) Other markets included catalysts, fiberglass, paint, rubber, and sanitaryware production.

Kaolin imports for consumption increased 25% to 4,221 tons valued at \$2.1 million. The United Kingdom supplied 75% of the kaolin imports. (See table 24.)

World Review

World production of kaolin decreased 10%, bentonite production decreased 5%, and fuller's earth production decreased 8% from productions of 1991. (See tables 25, 26, and 27, respectively.)

Brazil.—Rio Capim Quimica Companhia Vale do Rio Doce and Caemi Mineracao e Metalurgia SA began planning for a kaolin mining operation in northern Brazil. The kaolin deposit has measured reserves of 40 million tons and estimated reserves of 150 million tons. The companies will focus sales on the papermaking markets in Europe and Asia.²⁰

Caulim da Amazonia S.A. awarded a contract for the installation of a high-gradient magnetic separator (HGMS). The HGMS, which can process 20 to 40 tons of kaolin per day, will be installed at the plant in Porto de Munguba.²¹

Eucatex Mineral Ltda. and Elf-Atochem initiated a joint venture to produce activated clay for bleaching markets. The plant will be built in Maua and will use clays from Eucatex's Paraiba Valley Mine. The clay will be used for filtration and clarification of mineral and vegetable oils, fats, waxes, and margarines.²²

Finland.—Engelhard Corp. began operating its kaolin production plant at Mussalo, near Kotka.²³

South Africa, Republic of.—Serina Kaolin Ltd. received permission to mine kaolin at Nordhoek. The deposit contains 3.2 million tons of kaolin. The company will operate a processing plant at the site.

The kaolin will be sold for ceramics, paint, and paper applications.²⁴

United Kingdom.—Laporte Absorbents PLC announced plans to build a 750-ton-per-year plant to manufacture synthetic smectite clays similar to hectorite. The plant will cost \$9.4 million and will increase Laporte's production capacity to 2,000 tons of synthetic smectite clay per year. Markets for the synthetic smectite range from cosmetics to toothpaste to gellants to thickeners.²⁵

OUTLOOK

U.S. clay demand between 1982 and 1992 has rebounded slowly from 32 million tons to 44 millon tons. This is well below the levels of the early 1970's. In general, there has been a decrease in construction activity in the public, private, and commercial sectors due to a slow economy. Demand for common clay and shale, which are strongly tied to the construction industry, has declined over the past 10 years. Kaolin, ball clay, and fuller's earth have fared better than their common clay and shale counterparts because they are used in more diversified applications and industries. Domestic demand for specialty clays should remain strong in the near future.

Estimated. Revised.

¹Table includes data available through July 26, 1993.

²In addition to the countries listed, China, Lebanon, Morocco, and Suriname also may have produced kaolin, but information is inadequate to make reliable estimates of output

⁵May include ball clay and other clays grouped for statistical purposes as kaolin.

⁴Reported figure.

⁵Data for year ending June 30 of that stated.

⁶Formerly part of Yugoslavia; data were not reported separately until 1992.

Until 1988, series included beneficiated kaolin, direct sales, and direct use. Beginning in 1989, series refers to beneficiated kaolin only. Direct sales and direct use in 1988 totaled 144,626 metric tons.

²Data for year ending July 6 of that stated.

Includes kaolinitic clay.

¹⁰Includes crude and washed kaolin and refractory clays not further described.

¹¹Dissolved in Dec. 1991. This commodity is believed to be produced mainly in Uzbekistan and Ukraine; however, information is inadequate to formulate reliable estimates of individual country production.

¹² Kaolin sold or used by producers.

¹³Dissolved in Apr. 1992.

Estimated. Revised.

¹Excludes centrally planned economy countries and former such countries, some of which presumably produce fuller's earth, but for which no information is available. Table includes data available through July 17, 1993.

²In addition to the market economy countries listed, France, India, Iran, Japan, and Turkey have reportedly produced fuller's earth in the past and may continue to do so, but output is not reported, and available information is inadequate to make reliable estimates of output levels.

³Reported figure.

⁴Sold or used by producers.

COBALT

By Kim B. Shedd

Ms. Shedd is a physical scientist (geologist) with more than 13 years of combined experience working for the U.S. Bureau of Mines (USBM) in research and mineral commodities. She has been the commodity specialist for cobalt since 1988. Domestic survey data were prepared by Jo-Ann S. Sterling and trade data were prepared by Dwayne E. Penn, statistical assistants. International production data were prepared by Amy Burk and Ronald Hatch, international statistical assistants, in coordination with USBM country specialists.

Cobalt is a strategic and critical metal used in many diverse industrial and military applications. The largest use of cobalt is in superallovs, which are allovs designed to resist stress and corrosion at high temperatures. The main use for superallovs is in jet engine parts. Another important use of cobalt is to make permanent magnets, which are used in a wide range of electrical devices. Cobalt acts as a binder in cemented carbides and diamond tools, which are used for metal cutting and forming, mining, and oil and gas drilling. Cobalt chemicals have diverse uses, including catalysts for the petroleum and chemical industries; drying agents for paints, varnishes, and inks; additives to ground coats for porcelain enamels; pigments for ceramics, paints, and plastics; rubber additives for steel-belted radial tires; and additives to iron oxide particles in magnetic recording media.

The United States is the world's largest consumer of cobalt, but has no domestic production, so it relies on imports to meet its primary cobalt needs. The United States stocks significant quantities of cobalt metal in the National Defense Stockpile (NDS) for military, industrial, and essential civilian use during a national emergency.

Demand for cobalt fell in 1992 owing to recessionary economic conditions, cutbacks in defense spending, and a drawdown of stocks by cobalt users. Where possible, consumers adapted their processes to use less expensive lower grade Russian cobalt. Free market prices steadily decreased during the year from the high levels set in late 1991/early

1992. The decrease in prices occurred despite ongoing concerns over supplies from Zaire and to a lesser extent from Russia, and strong demand from China early in the year. The African producers maintained their producer price at \$25 per pound for most of the year, resulting in a growing differential between the producer price and market price, a loss of sales, and subsequent buildup of producer stocks. In November, the African producers lowered their price to \$18 per pound to bring it closer to market prices.

DOMESTIC DATA COVERAGE

Domestic data on cobalt processing and consumption are developed by the USBM from three separate, voluntary surveys of U.S. operations. In the cobalt processors survey, all eight companies canvassed responded. Most of the data on cobalt chemical use were obtained from this survey. The second survey covers a broad range of metal-consuming companies, such as superalloy producers. magnetic alloy producers, and tungsten carbide producers. For this survey, more 100 cobalt consumers were canvassed on a monthly or annual basis. The USBM also canvasses 13 superallov recyclers to determine the consumption of secondary cobalt in superalloy production. The data in tables 3 through 6 contain estimates to account for nonrespondents.

BACKGROUND

Definitions, Grades, and Specifications

Cobalt is a metallic element. It is

silvery gray in color, hard, ductile, somewhat malleable, and magnetic. Other properties include atomic number, 27; atomic weight, 58.93; melting point, 1,493° C; boiling point, 3,100° C; and Curie temperature, 1,121° C. Cobalt-60 (60°Co) is produced by irradiating cobalt metal in a nuclear reactor. This radioactive isotope is used in radiation therapy, for the sterilization of medical supplies, and more recently, to treat fresh foods (see Consumption and Uses section of this report).

Currently, there are no internationally recognized specifications for cobalt metal. The two leading Western World producers. La Générale des Carrières et des Mines du Zaire (Gécamines) and Zambia Consolidated Copper Mines Ltd. (ZCCM), have proposed specifications for five grades of cobalt.¹ The U.S. Government has purchase specifications for NDS cobalt. The current NDS specification, P-13-R6, provides physical and chemical requirements for three grades of refined cobalt metal. Grades A and B must be in the form of electrolytic cathode; grade C can be either cathode or granules. Chemical requirements specify the weight percentage, in order of abundance, of cobalt, nickel, iron, and manganese, as well as maximum levels of 26 impurities.

Products for Trade and Industry

Less than one-half of the cobalt used in the United States was consumed as primary cobalt metal. Most of this metal is in the form of electrolytic cobalt (cathode or rounds), granules (shot), or metal powder of various grades (particle size ranges.) Some of the Russian cobalt metal is in ingot form and some of the Zambian cobalt is produced as crushed bar. About one-fourth of U.S. reported consumption in 1992 was from purchased Cobalt-bearing scrap originates from alloy processing, manufacturing, and used cobalt-containing products. The remainder of the cobalt used in the United States, about one-third of total consumption, was in the form of cobalt chemical compounds. includes cobalt oxide, which can be either gray oxide, with 75% to 78% cobalt content, or black oxide, with 70% to 74% cobalt content. The cobalt content of the oxides depends on the relative amounts of cobalt(II)oxide, CoO, and cobalt(II)dicobalt(III)tetroxide, Co₃O₄, available Commercially present. inorganic cobalt compounds include carbonate, chloride, hydroxide, nitrate, and sulfate (either as heptohydrate or monohydrate). Most of the inorganic compounds are sold in crystalline form, but some are also available in solution. A variety of organic cobalt compounds are also available.

Industry Structure

Cobalt mining and refining are limited to a few countries. The United States is not currently a cobalt producer. U.S. mine production of cobalt ceased at the end of 1971, and the sole U.S. cobalt refinery discontinued processing imported nickel-cobalt matte in late 1985. 1992, Zaire was the world's leading producer of refined cobalt, followed by Zambia, Russia, Norway, Canada, and Finland. These six countries represented 94% of world cobalt refinery production. Zairian and Zambian production was from domestic ores. Canada and Russia produced cobalt from both domestic and imported raw materials. All of the cobalt produced in Norway and most of the cobalt produced in Finland was from World imported raw materials. producers of refined cobalt and producers of intermediate cobalt-containing products are listed in tables 1 and 2. (See tables 1 and 2.)

Cobalt processors represent an

important source of supply for various | Processors differ from industries. producers in the feed materials they use and the products they make, although some overlap exists. Producers refine cobalt primarily from materials originating from mining or refining operations-ores, concentrates, mattes, or residues-although some refineries supplement their feedstock with cobaltbearing scrap. In contrast, processors use refined cobalt metal or cobalt-bearing scrap as feed materials. In terms of products, both producers and processors can make cobalt metal powders, oxides, and salts (acetate, carbonate, chloride, hydroxide, nitrate, and sulfates.) However, other metal forms, such as cathode and granules, are only made by producers, and organic cobalt compounds such as cobalt carboxylates are only made by processors. The world's largest cobalt processor is Union Minière S.A. in Belgium (formerly Metallurgie Hoboken-Overpelt S.A.) Other cobalt processors are in Africa, Asia, Europe, and North America (see Production section of this report).

Byproducts and Coproducts

Cobalt is rarely produced as the primary product from mining and refining operations. Nearly one-half of world cobalt supply is produced as a byproduct of copper in Zaire and Zambia. Cobalt production in most other countries is a byproduct of nickel. Exceptions are Morocco, where small amounts of cobalt are produced as a primary product, and the Republic of South Africa, where cobalt is produced as a byproduct of platinum.

Economic Factors

Most of cobalt's production costs are attributed to the primary metal produced at a given operation. The incremental costs applied to cobalt production include costs to separate cobalt from the primary metal, usually during the refining stage; transportation costs; and marketing costs.

Operating Factors

The U.S. Environmental Protection Agency (EPA) regulates releases of cobalt into the environment under various Workplace exposures are programs. regulated by the Occupational Safety and Health Administration (OSHA). addition to these regulatory agencies, the following groups issue guidelines or positions develop scientific consideration by government agencies American when making regulations: Conference of Governmental Industrial (ACGIH), International Hygienists Agency for Research on Cancer (IARC), and Agency for Toxic Substances and Disease Registry (ATSDR).

In April 1992, ACGIH published a review of cobalt and proposed that cobalt be given an "A3 Animal Carcinogen" classification. The A3 classification is defined as follows. "The agent is carcinogenic in experimental animals at a relatively high dose, by routes(s) of administration, at site(s), of histological type(s), or by mechanism(s) which are not considered relevant to worker Available epidemiologic exposure. studies do not confirm an increased risk of cancer in exposed humans. Available evidence suggests that the agent is not likely to cause cancer in humans except under uncommon or unlikely routes or levels of exposure."2 ACGIH also issued a notice of its intention to decrease its threshold limit value (TLV) for cobalt from an 8-hour time-weighted average of 0.05 milligram per cubic meter (mg/m³) to 0.02 mg/m³. ACGIH TLV's are used by regulatory agencies such as OSHA in setting permissible exposure levels. The proposed change in the TLV was still under consideration at yearend.

In July 1992, ATSDR published a toxicological profile of cobalt as required by section 110 of the Superfund Amendments and Reauthorization Act of 1986.³ The profile summarized toxicological and epidemiological literature on health effects from exposure to cobalt. The profile also presented information on the potential for human exposure to cobalt from data in EPA's Toxics Release Inventory (TRI).

The USBM completed an initial evaluation of the flow of cobalt-containing materials in the United States.⁴ The objective of the study was to characterize the inputs, outputs, and losses of cobalt at various stages in the life-cycle of cobalt-containing materials and products. The study addressed cobalt released during the mining and processing of other metals and minerals; scrap generation and subsequent recycling or cobalt recovery; and cobalt losses resulting from the generation of wastes, dissipative uses, and disposal of used products.

Even though the United States does not mine or refine cobalt, preliminary estimates from the study indicated that significant quantities of cobalt are released during the production of other metals and minerals. On an annual basis, an estimated 480 tons of cobalt is released from the burning of coal and at least 1,700 tons of cobalt is released from mining and processing lead and copper ores.

Industrial losses of cobalt from chemical and metal powder processing, alloy processing, and parts and product manufacturing were estimated to be 410 tons to 440 tons per year. This estimate is roughly equal to annual releases and transfers of cobalt and cobalt compounds reported by U.S. industries to the EPA for 1987 (441 tons contained cobalt), 1988 (462 tons), 1989 (591 tons), and 1990 (521 tons).⁵ The study determined that industrial losses are outweighed by the loss of cobalt in products discarded following use. An estimated 2,780 tons of cobalt is consumed in the United States each year to make products that will ultimately be discarded.

The superalloy. magnet allov. cemented carbide, tool steel. and hardfacing alloy industries have wellestablished recycling or cobalt recovery practices. These industries recycle home scrap, prompt scrap, and in some cases, obsolete scrap as well. Some metallic scrap is downgraded. Although this is a loss of usable cobalt, it is not an environmental loss. The petroleum industry has established recycling and metal-recovery practices for spent catalysts, and some chemical catalysts are also recycled.

Most cobalt uses are not dissipative in character. The annual amount of cobalt lost from the dissipation of agricultural products, the attrition of cemented carbides, and losses during the recycling of homogeneous catalysts is estimated to be about 120 tons.

ANNUAL REVIEW

Legislation and Government Programs

In February, the Department of Defense (DOD) presented its 1992 Report to the Congress on National Defense Stockpile Requirements. In the report, DOD proposed decreasing the quantities of materials held in the NDS to reflect a reduction in potential threats to U.S. national security. DOD proposed that the goal for cobalt be revised to 18,346 tons (40,446,597 pounds). Because the proposed goal was less than the existing cobalt inventory, adoption of the goal would result in excess cobalt available for disposal. In October, Congress passed and the President signed the Defense Authorization Act. The Act authorized the disposal of excess stockpile materials, including 5,897 tons (13,000,000 pounds) of cobalt. Before the Defense Logistics Agency (DLA) could begin cobalt sales, a revised Annual Materials Plan (AMP) outlining details of the disposals for fiscal year 1993 had to be approved by The revised AMP was Congress. submitted to Congress in late November. It listed 2,087 tons (4,600,000 pounds) as the maximum quantity of cobalt that could be sold during fiscal year 1993, although actual sales levels would depend on market conditions. In anticipation of congressional approval of the AMP, DLA prepared a draft Invitation for Bids (IFB) for NDS cobalt and invited industry to comment on the terms of the sale. The comments were used to prepare a final IFB, scheduled for release in early February 1993. At yearend, the cobalt inventory reported by the DLA was 24,070 tons, contained cobalt.

On June 17, 1992, the United States granted most-favored-nation (MFN) status

to the Russian Federation as part of a comprehensive trade agreement between the two countries. Russian products can now be imported into the United States under MFN duty rates, which are significantly lower than the rates for non-MFN countries. The change to MFN status will have the greatest impact on imports of cobalt chemicals, cobalt alloys, wrought cobalt, and cobalt articles. The change in status will not affect cobalt metal, cobalt ores and concentrates, or cobalt matte, waste, and scrap, which were already duty free.

Under the Emergency Planning and Community Right-to-Know Act, industries manufacturing, processing, or using certain chemicals in quantities above defined threshold limits must report estimates of emissions each year to the EPA. The data are compiled into EPA's TRI. In 1992, EPA published data on releases and transfers for the years 1987 through 1990.⁷ In 1990, U.S. industry released 36 tons of cobalt metal and 162 tons of cobalt compounds. Releases of cobalt metal were distributed as follows: 46% was released as air emissions, 11% was discharged to water, and 43% was released to land. Releases of cobalt compounds were distributed as follows: 15% was released as air emissions, 30% was discharged to water, and 55% was released to land. Transfers in 1990 included 124 tons of cobalt metal and 199 tons of cobalt compounds. Most of these transfers were to offsite treatment and/or disposal facilities other than municipal wastewater treatment plants.

Strategic Considerations

Cobalt is considered a strategic and critical metal because of its many industrial and defense-related uses and because the United States is highly dependent on imports for its supply. The United States is the world's largest consumer of cobalt. In 1992, the United States consumed about one-third of estimated world refinery production. There was no domestic production, so demand was met primarily from imports, with the exception of about 25% from purchased scrap.

To ensure an adequate supply for military, industrial, and essential civilian needs, cobalt metal is included in the NDS. Stockpile quantities are intended to sustain the United States for a period of not less than 3 years during a national emergency situation. Most of the cobalt in the stockpile was purchased prior to 1980 and does not meet current quality for vacuum-melted requirements · superallovs (see Legislation and Government Programs section of this report).

World cobalt production concentrated in a limited number of geographic areas. Political and economic conditions in these areas can impact cobalt production, transportation, and/or supply. Roughly one-half of the world's supply of refined cobalt originates in central Africa, primarily from Zaire and Zaire is the world's largest Zambia. producer. but its production has decreased significantly over the past few years as the result of a mine collapse, a continuing political stalemate, declining economic conditions, and periodic social unrest. Russia is also a significant cobalt producer and recently began exporting the metal to Western markets.

Production

There was no domestic mine or refinery production of cobalt in 1992. Blackbird Metals Inc. of New York continued to seek financing for the construction of a U.S. cobalt refinery.

The Knox Nickel Corp., a subsidiary of Black Hawk Mining Inc. of Toronto, Canada, continued with its plans to develop the Knox nickel-copper-cobalt deposit near Warren, ME. At midyear, residents of the town of Warren passed a local mining ordinance with more stringent regulations than those passed by the State of Maine in 1991. Knox Nickel decided to address the issues raised by the ordinance and continue with the permitting process.

U.S. cobalt supply included secondary cobalt from the recycling of superalloy and other forms of scrap. Cobalt was recovered from spent petroleum catalysts at the AMAX Metals Recovery plant in

Braithwaite, LA, and by Gulf Chemical and Metallurgical Corp. in Freeport, TX. Hecla Mining Co. of Coeur d'Alene, ID, began trial production of cobalt sulfate from secondary materials at its Apex Unit'shydrometallurgical processing plant in St. George, UT. The sulfate was used by the U.S. copper industry as an additive in the electrowinning process. Cobalt sulfate inhibits the corrosion of lead anodes, thereby reducing the level of lead contamination in electrowon copper.

Two cobalt processors produced extrafine cobalt metal powder in the United States. Carolmet, owned by Union Minière of Belgium, produced cobalt metal powder from imported primary metal at its Laurinburg, NC, plant. GTE Products Corp. produced cobalt metal powder from recycled materials in Towanda, PA. In August, GTE Corp. reached an agreement with OSRAM GmbH, a subsidiary of Siemens AG of Germany, for the sale of its Electrical Products Group. The Electrical Products Group is made up of six units, including the Chemical and Metallurgical Div., which includes GTE Products Corp.'s Production and Towanda plant. shipments of extra-fine cobalt metal powder are withheld to avoid disclosing company proprietary data.

Domestic cobalt processors produced 1,969 tons of cobalt oxide and hydroxide, inorganic cobalt compounds, and organic cobalt compounds in 1992. Because this figure includes production of intermediate forms, it does not represent net production. Shipments are defined as sales, transfers, or consumption to make end-use products such as paint driers or In 1992, shipments by catalysts. domestic cobalt processors included 1,838 tons of cobalt oxide and hydroxide, inorganic cobalt compounds, and organic Production and cobalt compounds. shipments each decreased about 3% in 1992 compared with production and shipments in 1991.

Consumption and Uses

Apparent consumption, as calculated from net imports, consumption from purchased scrap, and changes in

Government and industry stocks, decreased to 6,526 tons. U.S. reported consumption decreased 11% in 1992 compared with that of 1991. In 1992, the amount of cobalt consumed as metal decreased to 43% of all forms consumed, while cobalt consumed in scrap increased to 25% and cobalt consumed as chemicals increased to 33%. (See tables 3 and 5 and figure 1.)

As a whole, metallurgical industries (producers of cemented carbides. magnetic alloys, mill products, steels, superalloys, welding materials, etc.) consumed 15% less cobalt in 1992 as compared with consumption in 1991. Superallov melters' cobalt consumption continued to decrease from the recordhigh amount used in 1990, dropping just below the levels consumed in the late 1980's. Cutbacks in military programs, the economic recession and poor financial condition of commercial airlines, and the reduction of superalloy product inventories by jet engine manufacturers were cited as reasons for the continued decline. The steel industry used significantly less cobalt in 1992; producers of magnetic alloys and welding materials also used less cobalt than they had in 1991. In contrast, producers of cemented carbides used basically the same amounts of cobalt in both years.

Cobalt consumption by chemical industries as a whole was unchanged in 1992 as compared with that in 1991. However, only the catalyst industry showed an increase in cobalt use. Cobalt use in feeds, glass decolorizers, ground coat frits, paint driers, and pigments decreased.

The first plant in North America to use ⁶⁰Co for the irradiation of fresh foods began operations in 1992. The plant was built in Mulberry, FL, by Vindicator, Inc. In the plant, foods are treated with gamma rays from a ⁶⁰Co source to delay spoilage and kill organisms that cause illness. The first foods to be processed were fruits and vegetables. The company planned to eventually process poultry and seafood as well.

Stocks

Cobalt stocks held by U.S. processors and consumers decreased significantly during 1992. By yearend, total stocks of metal, scrap, and chemicals had decreased 45% from 1991 yearend stock levels. The largest decrease was in cobalt metal stocks, which dropped from more than 1,000 tons at yearend 1991 to 400 tons at yearend 1992. Yearend stocks of cobalt chemicals and scrap also decreased. (See table 6.)

In contrast, African producers' inventories accumulated during the second half of 1992 as the difference between the \$25 per pound producer price and declining free market prices widened. By November, African producer inventories were estimated to be in the 3,000- to 5,000-ton range.8

Markets and Prices

The producer price for cobalt was \$25 per pound for most of the year. When the 1992 price was first announced in December 1991, it was to be effective for 6 months, subject to review and a possible revision in June 1992. In early June, Gécamines and ZCCM announced that they would keep the price at \$25 per pound with the intention of maintaining confidence and stability in the market. On November 20, the African producers announced a new producer price of \$18 per pound, effective immediately, to be held for 12 months.

Prior to the announcement of the African producer price, a delegation from Gécamines visited Russian cobalt producers and Government officials to discuss the cobalt market. delegation, headed by the presidents of Gécamines Commerciale and Gécamines Exploitation, met with the heads of Severonickel, Norilsk Nickel, Yuzhural Nickel, and Ufaley Nickel, the Deputy Minister of Foreign Economic Relations of the Russian Federation, the Executive Ministry of Economy of the Russian Federation, Raznoimport (the Russian state trading organization), and the directors of the Government stockpile. Gécamines and Raznoimport issued the

following joint statement after the meeting. "It was recognized by all the parties of the necessity to cooperate, to regularly consult each other and to coordinate actions in order to stabilize the cobalt market, which will enable cobalt producers to obtain a realistic price for their products and to achieve a better return." The meeting and statement were an indication of the growing importance of Russian cobalt on Western markets. Estimates of the quantity of Russian cobalt entering Western markets during 1992 ranged from 2,500 to 6,000 tons. The Bureau of the Census reported that in 1992 439 tons, or 8% of U.S. cobalt imports, was from Russia.

The free market price for cobalt cathode steadily dropped from a high of more than \$30 per pound in January to about \$15 per pound in October. The decrease was attributed to reduced consumption because of recessionary economic conditions in the United States. Europe, and Japan; a drawdown of consumer stocks; and the availability of lower priced Russian cobalt in Western markets. These factors outweighed concerns over reduced production from Zaire and increased demand from China. By October, the differential between the African producer price and the free market price was about \$10 per pound. The free market price increased slightly in late October/early November, then stabilized at approximately \$16 per pound following the announcement of the \$18 producer price. The weighted average free market price for the year was \$22.93 per pound. (See tables 3 and 7 and figure 2.)

A third price series for cobalt developed during the year—prices at which Russian cobalt was sold. Metal Bulletin began reporting free market prices for 99.3% minimum cobalt from Russia in November. Prices for Russian cobalt were between \$10.80 and \$12.70 per pound during November and December, generally \$4 to \$5 per pound lower than Metal Bulletin's free market prices for higher grade minimum 99.8% cobalt.

Foreign Trade

U.S. imports of unwrought cobalt and cobalt in chemicals decreased 17% in 1992. Cobalt imports from Zaire decreased significantly to less than 600 tons. Zambia became the leading supplier of cobalt to the United States in 1992, providing 27% of cobalt imports; followed by Norway, supplying 16%; Canada, 15%; Zaire, 10%; Belgium, 8%; and Russia, 8%. In 1992, 37% of U.S. cobalt imports was from central Africa. In addition to the cobalt imported directly from Zaire and Zambia, some of the cobalt metal powders and oxides imported from Belgium were made from Zairian cobalt metal. Thirty-two percent of U.S. imports was from Canada and Norway. Some of the cobalt produced in Norway originates from ores mined in Canada. Imports of cobalt metal from Russia increased more than 50% to 439 tons. Russia is a major cobalt producer, but did not export cobalt to the United States before 1990. U.S. cobalt imports by source are presented in figure 3. (See figure 3 and tables 8 and 9.)

In 1992, the United States imported 90 tons, gross weight, of unwrought cobalt alloys valued at \$3.1 million. Five countries supplied 93% of these materials: France (37%), Sweden (20%), the United Kingdom (18%), Canada (12%), and Japan (6%). The United States imported 584 tons, gross weight, of cobalt matte, waste, and scrap, valued at \$7.5 million. Seven countries supplied 93% of these materials: the United Kingdom (38%), Japan (17%), Sweden and Germany (each 10%), Mexico (8%), and Canada and France (each 5%). The United States also imported 131 tons, gross weight, of wrought cobalt and cobalt articles valued at \$8.6 million. The leading suppliers of these materials were the United Kingdom (54%) and Japan (28%), followed by France (9%) and Canada (5%).

U.S. net import reliance as a percentage of apparent consumption was estimated to be 75% in 1992. The net import reliance would be 100% if no cobalt were recovered from secondary sources (scrap).

The import duty on cobalt acetates, carbonates, and chlorides was 4.2% ad valorem for MFN and 30% ad valorem for non-MFN. The duty on cobalt oxides and hydroxides was \$0.026 per kilogram for MFN and \$0.44 per kilogram for non-MFN. The duty on cobalt sulfates was 1.4% for MFN and 6.5% for non-Imports of unwrought cobalt MFN. metal: cobalt ores and concentrates; and cobalt matte, waste, and scrap were duty The duty on unwrought cobalt alloys and wrought cobalt and cobalt articles was 5.5% for MFN and 45% for non-MFN. Special rates of duty are applied to certain cobalt-containing materials under the following programs: Andean Trade Preference Act, Caribbean Basin Economic Recovery Act, Generalized System of Preferences. States-Canada Free-Trade United Agreement, and the United States-Israel Free Trade Area.9

In 1992, the United States exported an estimated 1,424 tons of unwrought cobalt and cobalt contained in chemicals valued at \$39.7 million. This represented a 7% decrease as compared with exports in 1991. More than one-half of this cobalt was shipped to four countries: Mexico (20%), Canada (18%), Guinea (12%), and Brazil (8%). The remainder was shipped to 42 other countries. (See table 10.)

Exports also included 405 tons, gross weight, of wrought metal and cobalt articles valued at \$13.2 million. More than three-fourths of these materials was sent to seven countries: the Netherlands (19%), Japan (15%), the United Kingdom (13%), Sweden (11%), Canada (7%), France (6%), and Hong Kong (5%). The remainder was shipped to 20 other countries. In addition, the United States exported 6 tons, gross weight, of material under the category entitled, "Cobalt ores and concentrates." The material, valued at \$82,632, was sent to Canada.

World Review

World cobalt production decreased for the second consecutive year in 1992. Refinery production reported by the seven Cobalt Development Institute (CDI)

member producers¹⁰—Falconbridge Ltd.; Gécamines: Inco Ltd.; OM Group, Inc.; Sherritt Gordon Ltd.; Sumitomo Metal Mining Co. Ltd.; and ZCCM—decreased 8% from 19,486 tons in 1991 to 17,891 The decrease was tons in 1992. primarily due to a significant decrease in production by Gécamines-the world's largest cobalt producer. If production by Gécamines is excluded, production by the remaining six CDI member producers shows an increase of 5% as compared with production in 1991. Two producers, Falconbridge and OM Group, reported record-high production levels in 1992. Production by Inco also increased, while production by Sherritt and Sumitomo decreased. The CDI estimated total 1992 world production at 22,780 tons, with nonmember production primarily from Russia (4,000 tons), the Republic of South Africa (500 tons), China (300 tons), and Brazil (100 tons.) additional 2,000 tons of cobalt was estimated to be available as nonconsumer stocks. The CDI estimate for 1992 demand was 21,500 tons, leaving approximately 3,000 tons of cobalt available as nonconsumer stocks.

Capacity.—The data in table 11 are rated capacity for refineries as of December 31, 1992. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable longterm operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and Capacity includes both maintenance. operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Because not all countries or producers make production capacity information available, historical reported or estimated cobalt production data have been used to estimate refinery capacity in some cases. Changes in refinery capacity can result from changes in facilities, changes in the grade of raw materials processed, and/or changes in knowledge about the facilities. (See table

11.)

Albania.—Mining of nickel-cobalt laterites was assumed to have largely ceased in late 1991. The last production at the Elbasan plant was reported to have been in 1990.

Australia.—The Queensland Nickel Joint Venture (QNJV) produced cobalt sulfide as a byproduct of lateritic nickel mining and refining. QNJV operates the nickel-cobalt refinery Yabulu Queensland, and the Townsville, Greenvale lateritic nickel mine, also in Oueensland. At the beginning of 1992, 72% of ONJV was controlled by a consortium of financial institutions and 28% was owned by the Queensland Government under Nickel Resources North Queensland (NRNQ), a limited partnership. The consortium continued with efforts begun in 1991 to sell the majority share. The share came under control of the consortium in July 1991 when former owner Dallhold Investments Pty. Ltd. went into receivership. Inco Ltd., the Canadian nickel and cobalt producer, held negotiations toward the purchase of the 72% share, but withdrew its bid when it could not reach the **Queensland** agreements with Government on future plans for expansion of the refinery and protection of QNJV's patented cobalt-recovery technology. Rather than sell the 72% interest to a single buyer, the consortium opted for a public float. In June, QNI Resources Pty. Ltd., wholly owned subsidiary of newly incorporated QNI Ltd., purchased the 72% share in QNJV. Subsequently, shares in QNI were offered to the public in August. In addition, QNI Resources entered into an agreement with the State of Oueensland whereby QNI Resources would acquire an additional 8% interest from NRNQ. In exchange, the State of Queensland would become a major shareholder in QNI through preference shares. Eventual ownership of the joint venture was to be 80% QNI Resources and 20% NRNQ.

QNI outlined the current and future ore sources for the Yabulu refinery. Mining at the company's Greenvale mine

was expected to end in October 1992, and the last stockpiled ore from Greenvale was expected to be delivered to Yabulu in March 1993. The company had contracts with various miners in Indonesia and New Caledonia to supply lateritic nickel ore through 1995 with options to extend the contracts through 1997. In addition, QNI received approval from the Queensland Government to develop the Brolga laterite deposit near Rockhampton in central Oueensland. Mining at Brolga was expected to last 4 years beginning about April 1993. The company anticipated that by June 30, 1993, 80% of its feed would be from imported ore.

QNI also presented a expenditure program. The company planned to spend A\$53 million over 2 years ending June 30, 1994. Included in the program were improvements to the Port of Townsville, extensions and improvements to the Yabulu refinery, and the construction of a cobalt pilot plant. The Yabulu refinery produces cobalt sulfide, which is further refined to cobalt metal powder, oxide, and salts by OM Group Inc.'s refinery in Kokkola, Finland.

Western Mining Corp. (WMC) produced nickel-cobalt sulfide as a byproduct of nickel mining and refining in Western Australia. WMC completed trial mining at the Bulong nickel-cobalt deposit east of Kalgoorlie in Western Australia. About 20,000 tons of lateritic nickel ore was produced, and a report on the mining and ore characteristics was initiated. In metallurgical tests on the ore, high-pressure acid leaching dissolved more than 90% of the nickel and cobalt. Solvent extraction of nickel and subsequent extraction of cobalt were also studied. WMC is studying the Bulong deposit under an agreement with owners Resolute Resources Ltd. and Energy Oil and Gas NL. Under the agreement, WMC will earn a 70% share in the property in exchange for a feasibility study on the project and the design, construction, and operation of a pilot plant.

MIM Holdings Ltd. continued work on a cobalt pilot plant. The company planned to use bioleaching technology to recover cobalt from its Mount Isa copper concentrates.

Belgium.—The merger between Acec-Union Minière, Metallurgie Hoboken-Overpelt (MHO), Vieille-Montagne, and Mechim was effectively completed in 1992. Shareholders voted to change the name of the resulting company from ACEC-Union Minière to Union Minière S.A. Union Minière produced extra-fine cobalt metal powder in Laurinburg, NC. and cobalt metal powders and oxides at Olen, Belgium. During 1992, the company compensated for problems with supplies of raw materials from Zaire by diversifying its sources of supply and operating its unit for recovery of cobalt from secondary materials at full capacity. Research and development efforts focused on the recovery of cobalt from various raw materials and the production of submicrometer cobalt metal powders. Union Minière's production capacity at Olen was 1,500 tons per year of extrafine cobalt metal powder, 1,000 tons per year of cobalt mesh powders, and 2,000 tons per year of cobalt oxides. capacity to produce extra-fine cobalt metal powders in Laurinburg was 550 tons per year. 11

Botswana.—BCL Ltd. mined nickel-copper ores from company mines in the Selebi-Phikwe district. Copper-nickel-cobalt matte produced by BCL Ltd. was sent to refineries in Norway and Zimbabwe to be refined.

Brazil.—Cia. Niquel Tocantins produced cobalt cathode at its nickel refinery in Sao Miguel Paulista, Sao Paulo State.

Canada.—Cobalt is produced as a byproduct of nickel by three Canadian companies, Falconbridge, Inco, and Sherritt-Gordon. In 1992, Falconbridge produced 800 tons of cobalt from nickel ores at its Sudbury, Ontario, operations and 900 tons of cobalt from custom-feed smelting. The company developed a pyrometallurgical process to remove unwanted elements from cobalt-bearing scrap prior to smelting. Cobalt-

containing nickel-copper matte from the Sudbury smelter was refined at the Falconbridge Nikkelverk refinery in Norway.

Inco produced cobalt oxide at its Thompson, Manitoba, refinery and cobalt cathode at its Port Colborne refinery. Feed materials for the two refineries originated from nickel mines in Thompson, Manitoba, and Sudbury, Ontario, respectively. Inco's production of refined cobalt increased 6% in 1992; the company produced 1,465 tons of cobalt in 1992 compared with 1,385 tons in 1991. Inco's 1992 cobalt deliveries, including cobalt contained in alloys and engineered products, were essentially unchanged from deliveries in 1991 at 1,402 tons. Incompany 14

Sherritt Gordon refined nickel-cobalt materials from Cuba, Canada, and elsewhere at its Fort Saskatchewan refinery in Alberta. During 1992, Sherritt completed the first phase of reconfiguring its refinery to improve processing of Cuban nickel-cobalt sulfides. The reconfiguration included a newly developed, more flexible cobaltnickel separation process. As a result of the reconfiguration, the refinery's annual cobalt capacity increased to about 1,350 tons (3 million pounds.) However, Sherritt's 1992 production of cobalt metal powder decreased 17% from production in 1991 to 685 tons.15 The decrease was partly a result of problems that occurred during integration of the new cobalt facilities with the nickel refinery. The second phase of the reconfiguration was to include construction of a new cobalt reduction plant in early 1993 and a gradual increase in annual cobalt capacity to about 2,000 tons (4.5 million pounds) by yearend 1993.

Sherritt introduced a new cobalt product in 1992—ultrafine cobalt metal powder. The ultrafine powder particles were between 0.6 micrometer (μ m) to 1.0 μ m, as compared with the 1.0- μ m to 1.6- μ m particles in the extra-fine cobalt metal powder introduced by Sherritt in 1991. Markets for the ultrafine cobalt powder included binders for sintered tungsten carbides and diamond tools.

China.—Cobalt was produced at various locations in China from both domestic and imported raw materials. At Jinchuan, Gansu Province, cobalt metal was produced as a byproduct of nickel from the refining of domestic nickel The Ganzhou cobalt sulfide ores. refinery in Jiangxi Province produced cobalt metal and salts from cobalt arsenide concentrates imported from Minor production sites Morocco. included the Zibo Cobalt Works in Shandong Province, where cobalt metal was produced from iron ore from Shandong Province and copper ore from Shanxi Province.

China is a net importer of cobalt. Official Chinese customs statistics indicated that 636 tons of cobalt was imported during 1992. More than threequarters of these imports was from the former U.S.S.R. Zaire and Zambia each supplied about 10% and Canada supplied the remaining 5%. Much of the cobalt that entered China was shipped through Hong Kong. In addition to the cobalt recorded in official Chinese statistics. approximately 400 tons of cobalt imported to Hong Kong and other Pacific Rim countries was believed to have been reexported to China. An additional 400 tons of cobalt was estimated to have been built up as stocks in Hong Kong during 1992. These stocks were expected to be drawn down during 1993.

Chinese cobalt consumption in 1992 was estimated to be about 1,500 tons. The cobalt was used to produce cemented carbides, cobalt oxide, samarium-cobalt powders and finished samarium-cobalt magnets, Alnico magnets, and superalloys for the aircraft industry. Following a short-term slowdown owing to overexpansion, cobalt consumption in China was expected to increase with the growing Chinese economy. 16

Cuba.—Cuba produces nickel-cobalt sulfides at its Moa Bay plant and nickel-cobalt oxide and oxide sinter at its Nicaro and Punta Gorda plants. All three plants use lateritic ore as their feedstock. The nickel-cobalt sulfides contain a greater percentage of cobalt than the oxide and sinter, roughly 5% as compared with

about 1%. Historically, all of the nickel-cobalt sulfides were refined at the Yuzhural Nickel refinery at Orsk in the southern Ural Mountains in Russia. Beginning in 1991, some of the sulfides were refined at Sherritt's Fort Saskatchewan nickel-cobalt facility in Canada under a long-term feed supply agreement. Reports indicate that a barter agreement established between Cuba and Russia at the end of 1992 included the export of some nickel-cobalt sulfides from Moa Bay to Orsk. 17

Czechoslovakia.—Production at the Niklovà Huta Sered nickel-cobalt plant near Bratislava was expected to end during the second half of 1992. The plant used lateritic ore from Albania to produce about 3,000 tons of nickel and 50 tons of cobalt per year. Disruptions in feed supplies and environmental problems were reported to be the reasons for the closure.

Finland.—Outokumpu Metals Resources Oy increased its ownership in OM Group, Inc. (OMG) to 96% by redeeming shares held by a consortium of and investment Finnish insurance OMG produced cobalt companies. products at three locations: the Kokkola Chemicals Oy refinery in Kokkola, Finland: the Vasset S.A. chemical plant in Ezanville, France; and the Moonev Chemicals, Inc. chemical plant in OMG companies' Franklin, PA. production of cobalt contained in metal inorganic salts. powders, carboxylates increased 23% in 1992 to 2,610 tons. 18 This production included a record 2,100 tons of cobalt in products refined at the Kokkola plant, a 40% increase from Kokkola's refinery production in 1991.19 In addition to extra-fine cobalt metal powders, cobalt oxides, and inorganic cobalt salts, the Kokkola plant recently began producing two new cobalt products-coarse-grade cobalt metal powder and 400-mesh cobalt metal powder. The coarse-grade powder is sold to chemical processors as feedstock for cobalt carboxylates and inorganic salts. The 400-mesh powder is sold to magnet producers.

During 1992, OMG completed a 2vear \$25 million capital expenditure program at its Kokkola refinery. The program included improvements in technology and plant processing equipment that would enable the plant to handle more diverse feedstocks, including slag and secondary cobalt-bearing In November, (recyclable) materials. OMG signed a contract with Gécamines to purchase cobalt slag from Zaire. OMG planned to begin processing the slag during the second quarter of 1993. The company expected the slag to represent up to one-half of Kokkola's total annual cobalt raw materials supply. The refinery has used cobalt sulfide from ONJV in Oueensland, Australia, as a raw material since 1987. Kokkola's contract to purchase QNJV's entire production of cobalt sulfide continues until yearend 1996.20

France.—Chempro, owned by Sassoon Metals & Chemicals AG of Switzerland, announced plans to increase the cobalt chemicals capacity at its Mirecourt plant in eastern France. Chempro produces organic cobalt compounds for use as adhesion promoters in the radial tire industry.

The French Government was reported to have offered 50 to 100 tons of stockpiled cobalt for sale in December.

India.—Hindustan Zinc Ltd. reportedly produced about 1 ton of cobalt metal at its newly commissioned pilot plant. The solvent extraction-electrowinning plant is installed at the Debari zinc smelter in Udaipur, Rajasthan State.

Indonesia.—State-owned PT Aneka Tambang (ANTAM) was under contract to supply 1 million wet tons of lateritic nickel ore to QNJV's Yabulu nickel-cobalt refinery in Queensland, Australia. The ore was to come from ANTAM's Oeboelie Mine on Gebe Island in eastern Indonesia.

Japan.—Sumitomo produced electrolytic cobalt, cobalt oxide, cobalt sulfate, and other cobalt salts as a

byproduct of nickel production at its Niihama Nickel Refinery in Ehime Prefecture.

According to Japan's Ministry of International Trade and Industry (MITI),²¹ 1992 Japanese cobalt consumption decreased 26% to 2.230 tons. Cobalt consumption decreased in each industry reported to MITI as follows: catalysts down 14% to 358 tons, hard metal tools down 19.5% to 294 tons, magnetic materials down 30% to 438 tons, special steels down 27% to 654 tons, and other uses down 36% to 451 tons. Demand for cobalt catalysts is tied to the petroleum and chemical industries. Demand for hard metal tools is tied to the Japanese automotive industry. The decrease in cobalt consumption in magnetic materials was attributed to the continued substitution of priced neodymium-iron-boron lower magnets for samarium-cobalt magnets. Japanese demand for cobalt was met primarily from imports, which decreased 37% in 1992 to 4,243 tons. Zaire, Zambia, and Belgium remained the three leading suppliers of cobalt imports to Japan, in order of abundance. However, 1992 imports from Zaire decreased 60% from the previous year, imports from Zambia decreased 20%, and imports from Belgium decreased more than 30%.

New Caledonia.—In 1992, three New Caledonian mining companies were under contract to supply lateritic nickel ore to QNJV's Yabulu nickel-cobalt refinery in Queensland, Australia. J.C. Berton Mines was to supply 500,000 wet tons of ore from its Bienvenue Mine, Nickel Mining Corp. was to supply 800,000 wet tons from its Kouaoua Mine, and Société des Mines de la Tontouta was to supply 555,000 wet tons from its Moneo and Nakety Mines.

Inco completed its purchase of Compagnie des Mines de Xere from Le Bureau de Récherches Geologiques et Minières (BRGM) of France. Compagnie des Mines de Xere (formerly called Société de Promotion de Mines) held mining titles to lateritic nickel-cobalt resources in southern New Caledonia. Inco formed a new company, Goro

Nickel S.A., to study the feasibility of mining and processing the laterites. Inco held 85% interest in Goro Nickel.

Norway.—The Falconbridge Nikkelverk refinery produced a record 2,293 tons of cobalt cathode in 1992, a 16% increase from the 1,983 tons produced in 1991. Feedstock for the refinery was in the form of matte from company operations in Sudbury, Canada; BCL Ltd. in Botswana; and Norilsk Nickel in Russia. The matte purchase contract with BCL was extended to the year 2006.

Philippines.—During the year, the Philippine Nickel Co. continued rehabilitation of the idled Nonoc Mining and Industrial Corp. nickel production facility and sought financing for the project.

Russia.—Most of the cobalt produced in the former U.S.S.R. was a byproduct of nickel mining and/or refining in Russia. Nickel and cobalt production in Russia involves a complex flow of ores. concentrates, and mattes between various production sites. Russian nickel-cobalt production is organized into two "Complexes" (also called Kombinats or Combinats). Norilsk Nickel Complex's production is from nickel sulfide ores mined, smelted, and refined at Norilsk in eastern Siberia and at various locations on the Kola Peninsula. Yuzhural Nickel Complex's smelters and refineries are in the Ural Mountains. Feedstock to Yuzhural Nickel's plants has included nickel laterites mined from the Ural region. cobalt-arsenide concentrates mined and beneficiated in the Tuva Autonomous Republic, and nickel-cobalt sulfides from Cuba. More recent reports²² suggest that Yuzhural Nickel is also toll-refining white alloy from Zaire.

In 1992, significant quantities of Russian cobalt continued to enter Western markets. (See Markets and Prices section of this report.) Much of the cobalt leaving Russia was smuggled out of the country in spite of attempts by the Russian Government to control metal exports.

South Africa, Republic of.—Cobalt was produced as a byproduct of the Republic of South Africa's platinum industry. Two companies produced refined cobalt: Rustenburg Base Metal Refiners Pty. Ltd. produced cobalt sulfate and Impala Platinum Ltd. produced cobalt metal powder. A third company, Western Platinum Ltd., produced nickel sulfate containing minor amounts of cobalt.

South Africa's Minerals Bureau reported cobalt production, domestic sales, and exports for the years 1982-91.²³ Cobalt production in 1991 decreased 16% from production in 1990, reportedly because of low recovery rates and labor disruptions at some of the mines. Production was expected to increase as a result of higher mill throughput at the platinum mines and improvements in recovery rates. Most of the cobalt produced in the Republic of South Africa was exported.

Taiwan.—Chempro, owned bv Sassoon Metals & Chemicals AG of Switzerland, and the Uranus Chemical Co. of Taiwan formed a joint-venture company to produce metal-based specialty chemicals. Chempro Uranus planned to produce cobalt acetate crystals and solutions at a plant constructed in 1992 in Hsinchu, Taiwan, Cobalt acetates are used as catalysts in the manufacture of terephthalic acid and dimethyl terephthalate, which are used in the production of polyester textile fibers and polyethylene terephthalate films and bottles.

Tanzania.—Sutton Resources Ltd. continued exploration and development work in northwestern Tanzania. Sutton subsidiary Kabanga Nickel Co. investigated the Kabanga deposit. Preliminary engineering studies predicted an annual production of 24,000 tons of nickel, 3,000 tons of copper, and 1,400 tons of cobalt. A second subsidiary, Kagera Mining Co., signed an exploration and development agreement with the Government of Tanzania for nickel, cobalt, copper, and other metals in the Kagera region of Tanzania.

During the year, Sutton and BHP Minerals International Exploration Inc. agreed to form a joint venture to develop the Tanzanian properties. Under the agreement, BHP would fund exploration costs to earn a majority interest in the properties.

Uganda.—The Ugandan Government signed an agreement with the French BRGM and United Government's Kingdom-based Barclays Metals to develop cobaltiferous pyrites stockpiled at the Kilembe copper mines. The detailed feasibility study included plans to build a pilot plant in Uganda. Results from the pilot plant would be used to plan a fullscale plant at Kasese in Western Uganda. The partners planned to use bioleaching followed by solvent extraction and electrowinning to produce up to 1,000 tons per year of cobalt cathode.

Zaire.—The political stalemate in Zaire persisted through 1992, causing sporadic periods of political and social unrest, the postponement of much-needed foreign investment, rampant inflation, and continued shortages of consumables and spare parts at state-owned Gécamines. Gécamines maintained its status as the world's largest cobalt producer in spite of a 38% decrease in production of cobalt metal. In 1992, the company produced 2,629 tons of high-quality cobalt cathode at its Luilu refinery (as compared with 2,989 tons in 1991), 1,837 tons of lower grade cobalt cathode at its Shituru refinery (2,439 tons in 1991), and 583 tons of cobalt granules at Shituru (2.686 tons in 1991.) In late 1992 and early 1993, Gécamines' production was only 150 to 200 tons of cobalt per month.

The cobalt content of ore milled by Gécamines in 1992 decreased 36% to 13,300 tons, from 20,900 tons in 1991. The cobalt content of concentrates produced decreased 42% to 5,700 tons from 9,900 tons in 1991. In addition to cobalt in concentrates, 1992 input to Gécamines' refineries included 4,106 tons of cobalt in hydrates (down from 5,483 tons in 1991) and 1,113 tons of cobalt in scrap (up from 517 tons in 1991.) Ore feed to the concentrators remained an

important concern for Gécamines. particularly as the stocks of cobalt hydrates are drawn down. The following mining projects were in progress to increase mine output: the rehabilitation Kamoto Mine. increasing of the overburden removal activities at the Kolwezi open pit, and the installation of two in-pit mobile crusher and conveyorbelt systems to transport ore from the KOV open pit mine. However, because of the lack of financing and shortages of spare parts and consumables it is unlikely Gécamines will be able to increase production from current levels in the near term.

Gécamines recently began selling cobalt-iron-copper "white alloy," cobalt-nickel matte, spillings, and cobalt-bearing slag, partially to offset the loss of income from lower sales of cobalt metal. In 1992, production of cobalt in white alloy and cobalt-nickel matte increased to 1,579 tons as compared with 506 tons in 1991. These materials require further refining before they can be used by cobalt consumers.

Zambia.—ZCCM produced 4,610 tons of refined cobalt metal between January and December 1992, a 4% decrease from the 4,817 tons produced in calendar year 1991.²⁴

Zimbabwe.—Minor amounts of impure cobalt oxide were produced in Zimbabwe as a byproduct of nickel mining and refining. The cobalt oxide was exported to be refined. (See tables 12 and 13.)

Current Research

The USBM researched the feasibility of upgrading NDS cobalt. The process under development involved three steps: direct electrodissolution of cobalt metal, solution purification using conventional hydrometallurgical techniques, then electrodeposition of high-purity cobalt. The dissolution and deposition steps used double membrane electrolytic cell (DMEC) technology previously developed by the Bureau to recover high-purity cobalt and nickel from superalloy scrap. Research focused on solution purification

procedures and electrolytic cell operating conditions to generate cobalt cathodes of high purity and good physical qualities, respectively.

The Bureau studied cobalt-manganese deposits in the Ouachita Mountains of west-central Arkansas. The study included field investigations, mineralogical characterization. beneficiation, and hydrometallurgical separation tests. Magnetic determined to be the most effective method for concentrating the cobaltbearing manganese oxides. Preliminary results gave recoveries in excess of 90% manganese and cobalt at grades of 41% and 0.22% cobalt. manganese Hydrometallurgical studies using an ammonia-reduction leach process were initiated. Further research is necessary to evaluate the cobalt and manganese resource potential of the district.25

The Idaho National Engineering studied (INEL) the Laboratory bioextraction of cobalt from pyritic ores under contract from the USBM. INEL used Thiobacillus ferrooxidans to leach a flotation concentrate from the Blackbird Mine in Idaho. INEL determined that nearly 100% extraction of both cobalt and arsenic occurred at low pulp densities, but that dissolved metal extraction did not increase proportionally with increasing Results of the study pulp density. indicated that the leaching of cobaltite was by an indirect process. The bacteria oxidized pyrite in the concentrate to produce ferric iron; the ferric iron then oxidized the cobaltite. It was concluded that further research would be necessary to optimize conditions for bioleaching cobaltite concentrates.26

The CDI of Wickford, Essex, United Kingdom, published abstracts on cobalt research, articles on selected cobalt uses, and annual and semiannual data on cobalt production by institute members in quarterly issues of Cobalt News.

OUTLOOK

In 1992, weak demand, continued supplies of Russian cobalt, and increases in production by several Western refiners helped to compensate for a significant decrease in production by Gécamines, the world's largest cobalt producer. However, political and economic conditions in Zaire were not resolved and production levels are not anticipated to improve in the near term.

In terms of supply, both total cobalt supply and the supply of high-quality cobalt must be considered. Continued imports of Russian ingot to Western markets and steady offers of cobalt granules and rondelles from the NDS have the potential to contribute to total cobalt supply. However, these cobalt products are not of high quality. In the case of the Russian ingot, where possible consumers are adapting their processes to take advantage of its lower price. Future availability of Russian cobalt depends on export licenses and the success of the Russian Government to control illegal exports. In the case of NDS cobalt, actual quantities of cobalt sold will depend on the prices bid and market conditions at the time of the bids. Bids accepted by the DLA in March through July 1993 were at prices close to the market price of the Russian ingot. Chemical processors and trading firms showed the most interest in NDS cobalt.

Gradually declining prices into the summer of 1993 imply that there were ample supplies of all cobalt grades to meet demand. However, overall cobalt demand is expected to increase when the economies of the major consuming countries improve. Of particular importance to the cobalt market is the outlook for the aerospace industry because of the quantities and quality of cobalt required to make superalloy jet engine parts. Although there may be adequate quantities of cobalt available when demand improves, the question remains whether there will be a shortage of high-quality cobalt. Producer stocks that accumulated during 1992 will provide some security in the short-term.

Estimated. Revised.

¹Includes salts.

²Cobalt chloride.

³Includes an estimated standby capacity of 1,900 metric tons.

⁴Standby capacity.

¹Table includes data available through June 1, 1993. Figures represent recoverable cobalt content of ores, concentrates, or intermediate products from copper, nickel, platinum, or zinc operations. Morocco was the only country where cobalt was mined as a primary product.

²In addition to the countries listed, Bulgaria, China, Germany, Indonesia, and Poland are known to produce ores that contain cobalt, but information is inadequate for reliable estimates of output levels. Other copper-, nickel-, platinum-, or zinc-producing nations may also produce ores containing cobalt as a byproduct component, but recovery is small or nil.

³Calculated from reported and estimated weight of nickeliferous ore.

⁴Figures represent quantities of cobalt contained in intermediate metallurgical products (cobalt oxide, cobalt sulfide and nickel-cobalt sulfide). Cobalt content of lateritic nickel ore, nickel concentrate, and zinc concentrate was estimated as follows, in metric tons: 1988–2,574; 1989–2,270 (revised); 1990–1,770 (revised); 1991–1,470 (revised); and 1992–1,070.

⁵Reported cobalt content of pelletized nickel-copper matte.

⁶Figures represent total cobalt content of all products derived from ores of Canadian origin, including cobalt oxides shipped to the United Kingdom for further processing and nickel-copper-cobalt mattes shipped to Norway for further processing. Actual mine production, defined as the assay content of cobalt in concentrates of Canadian origin, was reported as follows, in metric tons: 1988–6,234; 1989–6,167; 1990–5,470; 1991–5,274 (revised); and 1992–5,087 (preliminary).

⁷Reported figure.

^{*}Determined from reported nickel-cobalt content of granular and powder oxide, oxide sinter, and sulfide production.

⁹Cobalt content of concentrates.

¹⁰Series represents estimated recoverable content of ores and intermediate metallurgical products exported from New Caledonia to France. The estimated cobalt content of total ores mined is as follows, in metric tons: 1988—6,000; 1989—6,000; 1990—6,000; 1991—6,000; and 1992—6,000.

¹¹Formerly part of the U.S.S.R.

¹²All production in the U.S.S.R. from 1988-91 came from Russia.

¹³Dissolved in Dec. 1991.

¹⁴In addition to concentrates, cobalt hydrates and scrap are used as feed to the refineries. Cobalt content of these materials was as follows, in metric tons: Hydrates: 1988—0; 1989—0; 1990—3,194; 1991—5,483; and 1992—4,106. Scrap: 1988—31; 1989—27; 1990—49; 1991—517 (revised); and 1992—1,113.

¹⁵Fiscal years beginning Apr. 1 of that stated. Cobalt content of ore milled was as follows, in metric tons: 1988—10,687; 1989—10,590; 1990—10,870; 1991—10,976 (revised); and 1992—10,800 (estimated).

¹⁶Estimated cobalt content of ore.

COLUMBIUM (NIOBIUM) AND TANTALUM

By Larry D. Cunningham

Mr. Cunningham, a physical scientist with 13 years of U.S. Bureau of Mines experience, has served as the commodity specialist for columbium and tantalum since 1983. Domestic survey and trade data were prepared by Mr. Dwayne Penn, statistical assistant; and columbium and tantalum world production data, by country, were prepared by Ms. Audrey D. Wilkes, international data coordinator.

Columbium (Cb) is vital as an alloying element in steels and in superalloys for aircraft turbine engines and is in greatest demand in industrialized countries. Columbium is critical to the United States because of its defense-related uses in the aerospace, energy, and transportation industries. Acceptable substitutes are available for some columbium applications, but in most cases they are less desirable.

Tantalum (Ta) is used mostly in the electronics industry, mainly in capacitors, and in aerospace and transportation applications. Tantalum is also critical to the United States because of its defense-related applications in aircraft, missiles, and radio communications. Substitution for tantalum is made at either a performance or economic penalty in most applications.

Domestic columbium and tantalum resources are of low grade and are not commercially recoverable. The last significant mining of columbium and tantalum was during the Korean conflict when increased military demand resulted in columbium and tantalum ore shortages.

The United States continued to be dependent on imports of columbium and tantalum materials, with Brazil being the major source for columbium imports and Australia the major source for tantalum imports. Columbium and tantalum price quotations remained relatively stable.

National Defense Stockpile (NDS) inventoried stocks for columbium and tantalum remained the same. However, the Defense Logistics Agency (DLA) awarded contracts for the

conversion/upgrade of Governmentowned columbium-tantalum concentrates (minerals) and columbium and tantalum metal powders into vacuum-grade columbium and tantalum metal ingot pieces. The DLA also awarded contracts for the purchase of superalloy-grade ferrocolumbium and vacuum-grade tantalum metal ingot pieces for the NDS.

There was an overall increase in reported consumption of columbium in the form of ferrocolumbium and nickel columbium. However, demand for columbium in superalloys was down, owing to a decline in demand from the military sector. Demand for tantalum was flat, with the consumption of capacitor-grade powder continuing to decline.

DOMESTIC DATA COVERAGE

Domestic production data for ferrocolumbium are developed by the U.S. Bureau of Mines from the annual voluntary domestic survey for ferroalloys. Of the four operations to which a survey request was sent, two responded. Thus, ferrocolumbium production data for 1992 were incomplete at the time this report was prepared.

BACKGROUND—COLUMBIUM

Columbium and niobium are synonymous names for the chemical element with atomic number 41; columbium was the first name given, and niobium was the name officially designated by the International Union of

Pure and Applied Chemistry in 1950. The metal conducts heat and electricity relatively well, has a high melting point (2,480° C), is readily fabricated, and is highly resistant to many chemical environments. Columbium exhibits superconductivity at about 9° K, a temperature still too low for most commercial applications. (Superconductivity is the virtual loss of electrical resistance that occurs at a specific material-dependent temperature and results in energy conservation and more rapid operation of electrical circuits.)

Definitions, Grades, and Specifications

Columbium pentoxide (oxide) is a stable, white- to buff-colored compound that is produced in metallurgical, ceramic, and optical grades. Purity of oxide generally exceeds 99%.

Ferrocolumbium is categorized into three grades by American Society for Testing and Materials (ASTM) Specification A550: low-alloy steel grade. alloy and stainless steel grade, and highpurity grade. For all grades, the composition is approximately 65% columbium, with the balance iron: principal impurities are aluminum. silicon, and tantalum. Nickel columbium typically contains 63% columbium, with the balance nickel. Aluminum, iron, silicon, and tantalum are the principal impurities.

Columbium carbide is available as a powder containing about 87% columbium and the balance carbon.

Columbium metal is available in many forms and shapes. Purity of unalloyed metal is usually more than 99%, with attention mainly given to iron, tantalum, and zirconium as metallic impurities and carbon, hydrogen, nitrogen, and oxygen as interstitial impurities. Alloys with hafnium, tantalum, titanium, tungsten, and zirconium are of the most commercial importance. Chemical and physical standards for columbium and columbium alloy mill shapes are given in ASTM Specifications B391-B394, B652, and B654-B655.

Products for Trade and Industry

of in the form Columbium, ferrocolumbium, is used worldwide, principally as an additive to improve the strength and corrosion resistance of steel. Columbium-containing, high-strength corrosion-resistant steel is used in applications such as high-strength linepipe, structural members, lightweight components in cars and trucks, and Because of its exhaust manifolds. refractory nature, appreciable amounts of columbium in the form of high-purity ferrocolumbium and nickel columbium are used in nickel-, cobalt-, and iron-base superalloys for applications such as jet engine components, rocket subassemblies, and combustion and heat-resisting equipment. Columbium-base alloys are also used in aerospace applications such as rocket nozzles. Columbium carbide is used in cemented carbides to modify the properties of the cobalt-bonded tungsten carbide-base material. It is usually used with carbides of metals such as tantalum and titanium. Columbium oxide is the intermediate product used in the manufacture of high-purity nickel columbium, ferrocolumbium. columbium columbium metal, and carbide.

Geology-Resources

Columbium is almost always found in nature as an oxide in association with other minerals but not in elemental form or as a sulfide. Columbium has an overall crustal abundance estimated as 20

parts per million and a strong geochemical coherence with tantalum. Pyrochlore and bariopyrochlore (also known as pandaite), its barium analog, have become the main sources of columbium. The minerals contain little tantalum, having a columbium oxide-totantalum oxide ratio of 200:1 or greater. Pyrochlore and bariopyrochlore are commonly found in the interior parts of alkalic rock complexes, frequently in association with minerals of such other elements as thorium, titanium, uranium, and those of the rare earths. Columbite. the columbium-rich member of the columbite-tantalite isomorphous series, is normally found in intrusive pegmatites and in biotite and alkalic granites. However, because most such deposits relatively high in columbium content are small and erratically distributed, most columbite has been obtained as a for other byproduct of mining commodities, mainly tin.

Reserve and reserve base data for columbium are shown in table 1 and are based on a judgmental appraisal of current information. Reserve base is defined as the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. reserve base may encompass those parts of the resources that have a reasonable potential for becoming economically available within planning horizons beyond those that assume proven technology and current economics. Reserves are defined as that part of the reserve base that could be economically extracted or produced at the time of determination.

Technology

Exploration.—Columbium deposits of economic interest are most likely to be found in alkalic rock complexes and associated carbonatites. Aerial photography and geological mapping can be used to reveal alkalic complexes, which frequently occur with circular geometry and concentric rock arrangement. Test pitting and panning can be used to explore placer deposits for columbium by virtue of the high specific gravity of columbium minerals. The

columbium content of samples can be determined rapidly by means of truck-mounted spectrographic equipment and X-ray fluorescence spectroscopy.

Mining.—Pyrochlore has been mined mainly by mechanized open pit, underground stoping methods, or a combination of both. Currently, all mining for pyrochlore in Brazil is open pit, whereas in Canada underground mining is being done via a large-diameter blasthole method. Ore, with host rock, is usually dislodged from a working face with explosives. Beneficiation of the ore, after it has been finely ground, is achieved primarily by various flotation procedures combined with magnetic separation to remove iron minerals. A chloridizing and leaching process also can be employed to lower barium, lead, and sulfur contents. phosphorus. Methods used to mine columbite have ranged from simple hand operations in small pegmatite mines to hydraulic monitors and dredges at placer deposits.

Beneficiation. - Pyrochlore concentrates are used solely in the manufacture of ferrocolumbium for Aluminothermy is the steelmaking. process most widely being used for making steelmaking-grade ferrocolumbium from pyrochlore concentrates. Processes also have been developed for production of columbium oxide through treatment of produced from ferrocolumbium pyrochlore concentrates. This technology is being used to produce commercial quantities of columbium oxide suitable for manufacture of high-purity ferrocolumbium, nickel columbium, and columbium metal.

In the extraction of columbium from other mineral concentrates and tin slags, modern technology makes use mainly of digestion with hydrofluoric acid followed by liquid-liquid extraction with methyl isobutyl ketone (MIBK). This procedure efficiently recovers both columbium and tantalum in the form of separate streams that then can be further processed individually into oxides and metal.

Columbium oxide is precipitated from the columbium stream by ammonia and then purified and calcined.

Columbium oxide is aluminothermically reduced batchwise to produce high-purity ferrocolumbium, nickel columbium, and columbium metal. Aluminothermically produced columbium metal is commonly purified to remove aluminum and other contaminants by remelting it in an electron-beam furnace. Several remelts may be required before the desired level of purity is reached and a ductile ingot has been produced. The basic method for production columbium carbide is reduction of columbium oxide by carbon at high temperature under vacuum or a protective atmosphere.

Recycling.—Columbium used in steelmaking and in superalloy manufacture is essentially a dissipative use, and little is reclaimed. However, when strict scrap segregation practices are followed, small quantities of columbium-bearing superalloy scrap are recycled. Aside from sales to alloy melters, columbium metal scrap has not been recycled to any extent other than inhouse as home scrap by processors.

Byproducts and Coproducts

In Africa, Australia, Brazil, Malaysia, and Thailand, columbium, as well as tantalum, is produced as a byproduct and/or coproduct of tin mining. Columbium and tantalum also can be recovered economically from some tin slags, which constitute an important raw source for high-purity material columbium and tantalum. Other elements frequently associated with columbium deposits include rare earths, thorium, titanium, and uranium; some of these have been recovered along with columbium in the past and may be coextracted in the future.

Substitutes

For established applications of both columbium-bearing steels and superalloys, substitution of some

alternative steel or alloy requiring less columbium ordinarily lowers performance and/or cost-effectiveness. In some high-strength low-alloy (HSLA) steels, use of columbium as a microalloying element competes with use of such elements as molybdenum, titanium, and vanadium. In other HSLA steels, it may be desirable to use one or more of these elements along with columbium in complementary fashion. Tantalum is a costly potential substitute for columbium in superalloys. Titanium can be used instead of columbium in stainless steel to improve corrosion resistance.

Economic Factors

Prices.—Time-price relationships for columbium contained in concentrates in terms of actual prices and in constant 1987 dollars are shown in table 2 and figure 1. Actual prices reported are based on historical price quotations or best available information from producers.

By the end of World War II, new columbium-bearing superalloys were being used in jet airplane engines. Subsequently, the involvement of the United States in the Korean conflict and the rapid expansion of jet engine production during this period resulted in columbium concentrate shortages and increased prices. Additionally, the demand for ore to produce ferrocolumbium had outstripped the available supply of columbium-bearing materials. However, a significant activity during this period was the U.S. Government-guaranteed worldwide 100% bonus purchase program under title III of the Defense Production Act. program was initiated to encourage increased production of columbiumtantalum ore and concentrates of both domestic and foreign origin.

In May 1952, the Defense Materials Procurement Agency (DMPA) announced its schedule for the purchase of columbium concentrates for the National Stockpile at an average price of \$3.40 per pound of combined columbium-tantalum oxides. The program was such a success in the expansion of supply that in only 3

years the stockpile had acquired 6.8 million tons of columbium and tantalum oxides contained in columbium concentrates.

Having achieved its basic objectives, the U.S. Government stopped buying foreign material under the program in May 1955. Small-lot purchases of domestically produced material continued until 1958. The DMPA purchase price had largely governed the market quotations for columbium concentrates, and termination of the program was followed by lower prices and reduced production worldwide.

With the trend of increasing columbium demand, concentrate prices began to escalate in the mid-1970's with the peak year occurring in 1977. The price increase was attributed to inflation, higher labor costs, and resulting higher raw material costs.

In 1980, an important change in the nature of columbium supply occurred with the commercialization both in Brazil and the United States of plants for producing columbium oxide from pyrochlore-base materials. This event resulted in the lowering of prices for columbium oxide and high-purity columbium products. Columbium prices were lowered during much of the 1980's, owing to the large quantities of pyrochlore produced in Brazil and Canada and the products produced from this feed material.

Depletion Provisions.—U.S. columbium-producing companies are granted a depletion allowance of 22% for domestic production of columbium minerals and 14% for foreign production.

BACKGROUND—TANTALUM

Tantalum is a refractory metal that is ductile, easily fabricated, has a high melting point (2,996° C), is highly resistant to corrosion by acids, and is a good conductor of heat and electricity. It combines readily with other refractory metals such as hafnium and tungsten to form alloys having high-temperature strength and stability. Tantalum forms highly stable anodic films and exhibits a

rectifying, or electronic valve, action in an electrolyte. Tantalum is twice as dense as steel with a specific gravity of 16.6.

Definitions, Grades, and Specifications

Metallic forms of tantalum are produced chiefly in unalloyed form or alloyed with up to about 10% tungsten. Unalloyed metal and alloys with tungsten are available as ingot, plate, sheet, strip, bar, rod, wire, and tubing in accordance with ASTM Specifications B364, B365. and B521. Allowable impurity levels do not exceed 0.3% in most cases; the main impurities are columbium and oxygen, plus tungsten in the case of unalloyed Purity of tantalum metal tantalum. powder is usually about 99.9%. Depending on powder usage, impurities that must be controlled consist mainly of calcium, carbon, columbium, iron, nickel, nitrogen, oxygen, silicon, and sodium. Commercial tantalum carbide usually contains about 93% tantalum and about 6.3% carbon.

Products for Trade and Industry

The major end use for tantalum, as tantalum metal powder, is in the production of electronic components, mainly tantalum capacitors. Applications for tantalum capacitors include computers, communication systems, and instruments and controls for aircraft, missiles, ships, and weapon systems. The tantalum capacitor exhibits reliable performance and combines compactness and high efficiency with good shelf-life. Because of its high melting point, good strength at elevated temperatures, and good corrosion resistance, tantalum is combined with cobalt, iron, and nickel to produce superalloys that are employed in aerospace structures and jet engine components. Tantalum carbide, used mostly in mixtures with carbides of such metals as columbium, titanium, and tungsten, is used in cemented-carbide cutting tools, wear-resistant parts, farm tools, and turning and boring tools. Because of its excellent corrosionresistant properties, tantalum mill and

fabricated products are used in the chemical industry in applications such as heat exchangers, evaporators, condensers, pumps, and liners for reactors and tanks.

Geology-Resources

The principal source of tantalum is an isomorphous series of minerals containing manganese, columbium, iron. and Tantalum and tantalum oxides. columbium have strong geochemical affinity and are found together in most rocks and minerals in which they occur. Tantalite-columbite occurs mainly as accessory minerals disseminated in granitic rocks or in pegmatites associated with granites. The microlite-pyrochlore mineral series is also a source of These minerals consist essentially of complex oxides of calcium, columbium, sodium, and tantalum in combination with hydroxyl ions and fluorides. Microlite occurs mainly in the albitized zones of granite pegmatites, often associated with tantalite or columbite. Struverite is a low-grade source of tantalum recoverable from tinmining wastes in Southeast Asia. Struverite is a variation of the titanium mineral rutile. Tantalum also is obtained through byproduct recovery tantalum-bearing tin slags, principally from smelters in Brazil and Southeast Asia.

Reserve and reserve base data for tantalum are shown in table 3 and are based on a judgmental appraisal of current information. Reserve base is defined as the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. reserve base may encompass those parts of the resources that have a reasonable potential for becoming economically available within planning horizons beyond those that assume proven technology and current economics. Reserves are defined as that part of the reserve base that could be economically extracted or produced at the time of determination.

Technology

Exploration.—Exploration for tan-

talum is generally pursued on the basis of its known frequent association with tin and certain other elements in pegmatite environments, some features of which can be distinguished by aerial photography. Application of X-ray fluorescence analysis techniques has been helpful in tantalum at the low measuring concentrations at which it occurs. The high specific gravity of tantalum minerals makes it possible to reveal their presence in placer deposits by test pitting and panning.

Mining.—Most tantalum-related mining developments in the past generally were small, relatively high-cost intermittent operations that depended on the recovery of byproduct or coproduct minerals for economic viability. Future mine development will shift more to primary tantalum sources, notably operations in Australia.

Both alluvial and residual tantalum and tantalum-containing tin deposits are normally mined by hand, by hydraulic monitors, by dredges, or by mechanized The mining of open pit mining. pegmatite deposits, which may be either open pit or underground, is carried out by blasting, transporting, and crushing the rock to free the tantalum and associated coproduct minerals. The materials are then concentrated by wet gravity methods (sluices, jigs, spirals, and tables) and finally separated from associated minerals electrostatic and by gravity and electromagnetic processes.

Tantalum is recovered from slags produced at tin smelters throughout the world. Tantalum content varies in tin slag depending on ore and smelting practice.

Beneficiation.—Tantalum mineral concentrates and tin slags are the predominant feed materials for preparation of tantalum metal and compounds. Both raw materials usually contain recoverable amounts of columbium as well. Depending on circumstances, tin slags may be used directly for extraction of tantalum or they may be first upgraded. Upgrading is typically performed by means of an

electric furnace process that yields a synthetic concentrate.

In the extraction of tantalum from these source materials, technology makes use mainly of digestion with hydrofluoric acid followed by liquid-liquid extraction with MIBK. This procedure efficiently recovers both tantalum and columbium in the form of separate streams that then can be further processed individually into salts, oxides, and metal. The two streams are produced by a series of countercurrent extractions that also remove impurities. The tantalum product stream is a fluotantalic acid solution from which either potassium fluotantalate (Ksalt), by addition of potassium chloride or fluoride, or tantalum pentoxide, by addition of ammonia, can be precipitated. Reducing K-salt by sodium is the standard commercial method for making tantalum metal. The product of sodium reduction is a powder that is consolidated by a pressing, vacuum sintering, and melting sequence.

Tantalum carbide can be manufactured by several methods, the most common being solid-state reaction between tantalum oxide and carbon. Tantalum carbide also can be made by reacting metallic tantalum directly with carbon.

Recycling.—Recycling of tantalum largely takes place within the processing and product-producing industry and is mostly runaround or home scrap that is consumed internally. In addition, quantities of tantalum are recycled indirectly in the form of used tantalumbearing cutting tools and high-temperature alloy melting scrap.

Byproducts and Coproducts

Economic exploitation of tantalum minerals often is dependent on the price of associated recoverable byproduct or coproduct minerals, principally tin and columbium. Tantalite-columbite minerals occur in deposits associated with beryllium, lithium. rare-earth, tin. titanium, tungsten, uranium, and zirconium minerals. Minerals associated with tantalum in pegmatite deposits include beryl, feldspar, lepidolite, mica, pollucite, and spodumene. Tantalum and columbium also can be recovered economically from some tin slags, which constitute an important raw material source for tantalum and high-purity columbium. Tantalum is usually extracted in conjunction with columbium with much the same type of equipment.

Substitutes

Substitution for tantalum is usually made at a performance or economic penalty for most uses. Also, substitution requires both investment experimentation and does not necessarily occur quickly. Aluminum and ceramics compete strongly with tantalum for use in electronic capacitors. In cemented columbium carbides. carbide columbium-hafnium carbide can take the place of tantalum carbide in some cutting Replacements for tantalum in corrosion-resistant equipment are columbium, glass, platinum, titanium, and zirconium. Columbium, hafnium, molybdenum, tungsten, and platinum-group metals can be substituted for tantalum in high-temperature applications.

Economic Factors

Prices.—Time-price relationships for tantalum contained in concentrates in terms of actual prices and in constant 1987 dollars are shown in table 4 and figure 2. Actual prices reported are based on historical price quotations or best available information from producers. The prices show large swings between the high and low in response to market conditions.

The Korean conflict in 1950 increased demand for tantalum in military requirements. Thus, consumption rose sharply with resulting ore shortages. During this period, the U.S. Government-guaranteed worldwide 100% bonus purchase program was initiated to increase production of columbium-tantalum ore and concentrates of both domestic and foreign origin. In May 1952, a schedule was announced for the purchase of 15 million pounds of the

combined columbium-tantalum oxides at prices about double prevailing world prices. The program had the effect of increasing tantalum ore prices to a high of \$8 per pound of oxide.

Having achieved its basic procurement objectives, the purchase of foreign material was stopped in May 1955. Small-lot purchases of domestically produced material continued until December 1958. When Government purchase of domestic ore stopped, the immediate effect was a confused market in which production and prices of ore began to drift downward. By 1959, prices for tantalum ore had dropped to about \$4 per pound of oxide.

By 1960, tantalum demand for use in capacitors, high-temperature alloys, corrosion-resistant chemical applications, machine cutting tools, and aerospace applications had increased substantially. During the 1960's, the variations in supply and demand resulted in a repetition of 2 or 3 years of oversupply with lower prices followed by 2 or 3 years of high demand with higher prices. Price peaks in 1961 and 1966 were occasioned by a sudden increase in demand for tantalum, which outstripped the supply, driving prices up. This cyclical trend continued into the 1970's.

The 1970's can be characterized as a decade of increasing tantalum demand, ore shortages, escalating prices, and substitution. A 7-year trend of declining price, 1967-73, was followed by a trend of rapid price increase that was sustained through midyear 1980. The record price levels during this period were attributed in part to a state of panic buying influenced by anticipated greater tantalum demand amidst concerns at the time of a shrinking world tantalum supply. The high prices brought about substitution for tantalum and more widespread search for and development of new tantalum However, prices began sources. declining by yearend 1980 and by midyear 1986 were the lowest since first quarter 1977, hastened by a weak tantalum demand and an increase in tantalum material stockpiles. Subsequently, prices rebounded through yearend 1988 and were at the highest level since the third quarter of 1981, responding to increased demand for feed materials along with the drawdown of stockpiles. The price of tantalum continued its cyclic pattern, and the 1992 average price quote was about \$28 per pound of oxide.

Depletion Provisions.—U.S. tantalumproducing companies are granted a depletion allowance of 22% for domestic production of tantalum minerals and 14% for foreign production.

ANNUAL REVIEW— COLUMBIUM AND TANTALUM

Legislation and Government Programs

At yearend, Government stocks of columbium and tantalum in the NDS were the same as those in 1991 (table 7). As of October 23, 1992, the overall goal for the columbium group was 5.047 million kilograms, and the overall goal for the tantalum group was 3.959 million kilograms.

In September, the DLA contracted with two companies to provide columbium and tantalum materials for the NDS.

Cabot Performance Materials. Boyertown, PA, will convert Government-owned columbium-tantalum concentrates (minerals) into vacuumgrade columbium and tantalum metal ingot pieces for \$10.7 million and upgrade Government-owned columbium metal powder to vacuum-grade columbium metal ingot pieces for \$462,483. Cabot also will provide 113,400 kilograms of contained columbium in superalloy-grade (highpurity) ferrocolumbium for \$4.4 million.

NRC Inc., Newton, MA, will provide 28,600 kilograms of vacuum-grade tantalum metal ingot pieces for \$4.62 million and upgrade Government-owned tantalum metal powder to vacuum-grade tantalum metal ingot pieces for \$2.2 million.

DLA planned to make payment with excess stockpile material (commodities). Cabot and NRC appointed Sogem-

Afrimet Inc., New York, NY, as their agent for receiving payment commodities from DLA.

During the year, the United States officially entered into agreements on trade relations with 5 of the 12 independent states that succeeded the former U.S.S.R. Most-favored-nation (MFN) status was extended to the Republic of Armenia, April 7: the Russian Federation, June 17; Ukraine, June 23; the Republic of Moldova, July 2; and the Republic of Kyrgyzstan, August 21. In addition, the United States officially extended nondiscriminatory treatment to products of the Republic of Albania, effective MFN status means November 2. significantly lower U.S. import duties for columbium and tantalum products from these states. MFN tariffs for columbium and tantalum products range from duty free to 5.5% ad valorem, whereas non-MFN tariffs for columbium and tantalum products range from duty free to 45% ad valorem.

Strategic Considerations

The high degree of import reliance for columbium and tantalum continues to be the principal strategic problem faced by the United States. Summaries of important columbium and tantalum statistics are shown in tables 5 and 6, In the case of both respectively. columbium and tantalum, there has been no significant mining since the 1950's. Domestic columbium and tantalum resources are of low grade, some mineralogically complex, and most are not currently commercially recoverable. To ensure a supply of columbium and tantalum during an emergency, goals for both materials have been established for the NDS. However, inventories for both materials are substantially under set Consequently, a degree of goals. vulnerability still remains.

The NDS goals and inventory for both columbium and tantalum are mostly for source materials (feedstocks). However, the United States has become more reliant on the processing capability of foreign sources and the availability of intermediate products from those sources.

At the start of the 1980's, there were four major processors of columbium- and tantalum-bearing source materials. One of the operations was shut down in 1985, and another shut down its processing operation at yearend 1989. Of the remaining two companies, one is dedicated solely to the processing of columbium materials, and the other company processes both columbium and tantalum materials. Thus, there is concern whether the United States would have on hand in an emergency adequate processing capacity for conversion of the stockpile materials to an upgraded form and quality required by the critical end uses.

Production

In 1992, there were two processors of columbium- and tantalum-bearing source materials that were integrated from raw material processing to columbium and tantalum end products: Cabot Corp. for columbium and tantalum processing and Corp., Shieldalloy Metallurgical dedicated solely to columbium processing. NRC Inc., a major supplier, and Thai Tantalum Inc. produced tantalum products. Reading Alloys Inc. and Teledyne Wah Chang Albany were producers of high-purity maior columbium products. Kennametal Inc. was the major producer of columbium and tantalum carbides.

Consumption and Uses

Overall reported consumption of columbium as ferrocolumbium and nickel columbium rose by 6% compared with that of 1991 (see table 8). Consumption of columbium by the steelmaking industry increased by 10%, in line with a 6% increase in raw steel production and a 4% increase in the percentage of columbium usage per ton of steel produced. Columbium consumption in carbon steel increased by almost 40%, while columbium consumption in HSLA steel was down by 4%. Demand for columbium in superalloys was down 11%, owing to a decline in demand for superalloys from the military sector. That portion used in the form of nickel columbium decreased to about 148,000 kilograms.

Overall consumption of tantalum remained flat. Factory sales of tantalum capacitors were up by 23% to an alltime high, as reported by the Electronic Industries Association. However, the impact on tantalum demand by the record sales was offset by the continuing decline in the amount of tantalum capacitor-grade powder consumed per capacitor.

Markets and Prices

A published price for pyrochlore concentrates produced in Brazil and Canada was not available. A price for Brazilian pyrochlore has not been available since 1981, and the published price for Canadian pyrochlore was suspended in early 1989. The Metals Week published price for regular-grade ferrocolumbium, produced from pyrochlore concentrates, was unchanged throughout the year at \$6.58 per pound of contained columbium, f.o.b. shipping port.

The Metal Bulletin published price for columbite ore, on the basis of a minimum 65% contained Cb₂O₅ and Ta₂O₅, remained unchanged at a range of \$2.60 to \$3.05 per pound. For the year, the Metals Week published price for columbium oxide was quoted at \$8.17 per pound of oxide; the published price for high-purity ferrocolumbium containing 62% to 68% columbium was quoted at \$18.50 per pound of contained columbium, f.o.b. shipping point; and the published price for nickel columbium was quoted at \$20.50 per pound of contained columbium. The Metals Week published price for columbium metal was at a range of \$30 to \$50.

The Metals Week published spot price for tantalite ore, on the basis of contained Cb_2O_5 and Ta_2O_5 , c.i.f. U.S. ports, rose from a range of \$27.50 to \$29.00 to a range of \$28.00 to \$30.00 in early August, where it remained through December. The Metal Bulletin published price for tantalite quoted since July 1990 at a range of \$34 to \$37 per pound of contained Ta_2O_5 fell to a range of \$30 to

\$33 in mid-June where it remained through December. The Metal Bulletin published price for tantalite produced by Greenbushes Ltd. of Australia, on the basis of 40% contained Ta₂O₅, remained unchanged at \$40 per pound. A published price for tantalite from the Canadian producer, Tantalum Mining Corp. of Canada Ltd. (Tanco), was not available. Industry sources indicated that tantalum mill products sold at an average of \$170 per pound, depending on specification, and that tantalum capacitorgrade powder sold at an average of \$145 per pound.

Foreign Trade

Net trade for columbium and tantalum continued at a deficit and was more than double the level in 1991. Overall trade value for exports was down by 10%, with total volume up by 7%. For imports, trade value was up by more than 20%, with total volume up by 12%, owing in part to a significant increase in imports of tantalum concentrates from Australia. Data for exports and imports are summarized in table 9.

Imports for consumption of columbium mineral concentrates were down slightly from those of 1991 (see table 10). Canada continued as the leading supplier, providing more than 90% of total quantity and 86% of total value. Imports at an average grade of approximately 60% Cb₂O₅ and 1% Ta₂O₅ were estimated to contain 1.01 million kilograms of columbium and 25,000 kilograms of tantalum.

Imports for consumption of tantalum mineral concentrates increased substantially, with the average unit value for overall imports increasing by more than 20% (see table 11). Imports from Australia increased threefold and accounted for 35% of total quantity and 50% of total value. Imports at an average grade of approximately 35% Ta₂O₅ and 23% Cb₂O₅ were estimated to contain 395,000 kilograms of tantalum and 220,000 kilograms of columbium.

There were no imports for consumption of synthetic tantalum-columbium concentrates, compared with

63,000 kilograms valued at \$741,000 in 1991. These figures are not included in the salient statistics data.

Brazil continued as the major source for U.S. columbium imports, accounting for about 70% of the total, and Australia was the major source for U.S. tantalum imports, accounting for more than 30% of the total (see figures 3 and 4). The schedule of applied tariffs during 1992 to U.S. imports of selected columbium and tantalum materials is given in table 12.

World Review

Industry Structure.—Principal world columbium and tantalum raw material and product producers are shown in tables 13 and 14, respectively. Brazil and Canada remained the major producers of columbium raw materials feedstock, while tantalum raw materials continued to be produced mainly in Australia, Brazil, and Canada and in Thailand in the form of high-grade tantalum-bearing tin slags. Synthetic concentrates, produced from low-grade tin slags from Germany, were an additional source of columbium and tantalum raw material supply. Annual world production of columbium and tantalum mineral concentrates, country, is given in table 15. World tantalum supply in 1981-92 is shown in figure 5.

Australia.—For its fiscal year ending June 30, 1992, Gwalia Consolidated Ltd. reported that ore treated at its Greenbushes Mine, southwest Western Australia, was about 2 million tons, with tantalum oxide production in tantalum concentrates (tantalite) about 197 tons compared with 146 tons the previous year. 1 During 1992, construction of the new \$24 million tantalum processing plant at the Greenbushes Mine was completed on schedule and within budget. Commissioning of the plant had commenced using hard-rock ore from the new tantalum open pit where prestripping and preliminary development had been The plant had an initial completed. annual ore throughput capacity of about 850,000 tons with provision for expansion to 1 million tons. The plant's initial annual tantalum capacity was to be about 180 tons of Ta₂O₅ contained in tantalum concentrates.

As reported by Pancontinental Mining Ltd. for its fiscal year ending June 30, 1992, tantalum production at the Wodgina Mine was about 107 tons of Ta₂O₅ contained in concentrate compared with 127 tons the previous year. A total of 89.049 tons of ore grading 0.1536% Ta₂O₅ was processed in the treatment plant yielding 234.8 tons of concentrate grading 45% Ta₂O₅, with a metallurgical recovery of 77%. Wodgina is a 50-50 joint venture between Pancontinental and Goldrim Mining Australia Ltd. Pan West Tantalum Pty. Ltd., a wholly owned subsidiary of Pancontinental, is the operator of the joint venture. February, a 200-ton parcel of ore from the joint venture's Tabba Tabba tantalum deposit, 50 kilometers southeast of Port Hedland, was reported to be successfully processed through the Wodgina plant yielding 400 kilograms of concentrate grading 47.4% Ta₂O₅. The ore was trucked 65 kilometers to the Wodgina treatment plant.²

Canada.—As reported by Teck Corp., production of Cb₂O₅ at the Niobec Mine at St. Honoré, Quebec, decreased to about 3.28 million kilograms. Niobec is a 50-50 joint venture between Teck, operator, and Cambior Inc., product Ore milled increased to marketing. 815,000 tons, as the mill operated on the average of 2,234 tons of ore per day. Average recovery was down to 59.3% with Cb₂O₅ grade of concentrate at 68%. For the year, operating changes at the mine included installation of a computerized ventilation control system. replacement of flotation components in the carbonate circuit, and construction of a tailing water settling pond. Teck reported that ore reserve life, at the current rate of production, is 13 years.³

Japan.—According to the Tex Report, Japan's production of ferrocolumbium was 1,002 tons, up significantly from the 767 tons produced in 1991. Columbium ore imported for ferrocolumbium production declined by 13% to 1,169 tons, with Canada accounting for 68% of the total. Ferrocolumbium imports fell to 4,187 tons from the 4,526 tons reported in 1991. Brazil accounted for more than 90% of ferrocolumbium imports. Japan's demand for ferrocolumbium for steelmaking totaled 4,412 tons compared with 4,398 tons in 1991.

Roskill's Letter from Japan reported that Japan's demand for tantalum powder and compounds was 164 tons compared with 209 tons in 1991.

OUTLOOK

Columbium

Columbium is used principally as an additive in steelmaking, which annually accounts for about 80% of U.S. reported consumption. No significant change to this trend is expected in the near term because there are few other significant growth markets and/or uses for Thus, future columbium columbium. demand growth will continue to be directly related to the worldwide performance of the steel industry. U.S. apparent consumption of columbium has been in the range of 3,200 to 3,600 tons of contained columbium for the period 1987-92, and any major future variations from this trend will depend on future activities of the domestic steel industry. The outlook for steel is discussed in the annual report for iron and steel. The outlook for columbium will also be dependent to a lesser degree on the performance of the aerospace industry. Reported domestic consumption columbium in the production superalloys continues to be no more than 20% of total demand. Future growth for this end use will be affected mainly by the demand for columbium-containing superalloys by the aircraft industry. However, continued reduction in military spending is expected to lead to reduced aerospace shipments throughout the decade. The major components of U.S. supply-demand relationships for columbium in 1982-92 are given in table

Tantalum

For the past decade, more than 60% of the tantalum consumed in the United States was used to produce electronic components, mainly tantalum capacitors, with major markets in recent years being computer and communication systems. However, overall tantalum demand growth in this sector has been slowed owing to the industry's continued emphasis on higher capacitance powders and the miniaturization of electronic components resulting in less tantalum used per unit. Also, tantalum demand in the cemented carbide sector continues to be affected by the growing use of mixed carbides, coated cutting tools, improved tool life, and the downsizing of components. Thus, annual U.S. apparent consumption of tantalum is anticipated to be less than 400 tons through most of the 1990's. The major components of U.S. supply-demand relationships for tantalum in 1982-92 are given in table 17.

Estimated. 'Revised. NA Not available.

Excludes columbium- and tantalum-bearing tin ores and slags. Production of tantalum contained in tin slags was, in thousand kilograms: 1988—519; 1989—342; 1990—343; 1991—244; and 1992—160 according to data from the Tantalum-Niobium International Study Center. Table includes data available through July 2, 1993.

Data on gross weight generally have been presented as reported in official sources of the respective countries, divided into concentrates of columbite, tantalite, and pyrochlore where information is available to do so, and reported in In addition to the countries listed, Bolivia, China, and the former U.S.S.R. also produce, or are believed to produce, columbium and tantalum mineral concentrates, but available information is inadequate to make reliable estimates of output levels.

Unless otherwise specified, data presented for metal content are U.S. Bureau of Mines estimates based on, in most part, reported gross weight and/or pentoxide content. groups such as columbite and tantalite where it is not.

Less than 1/2 unit.

Reported in and/or by official country sources.

COPPER

By Daniel L. Edelstein

Mr. Edelstein is a physical scientist with more than 18 years of combined experience working for the U.S. Bureau of Mines in mineral processing research, process evaluation, and mineral commodities. He has been a copper commodity specialist for 9 years as well as a specialist for the byproduct metals arsenic, selenium, and tellurium.

Nineteen ninety-two was a year of | transition for the world copper industry. Despite record mine production in Chile, Indonesia, and the United States, world supplies of copper were tight and inventories declined during the first half of the year as a result of decreasing ore grades at some mines, strikes, political disruptions, and smelter bottlenecks. Prices, which had declined during the last quarter of 1991, rose steadily during the first half of 1992. The U.S. producer price peaked in July, averaging 118.65 cents per pound for the month, the highest level in more than 2 years. Coincidentally, stocks held on the world metal exchanges fell by about 75,000 metric tons during the first half of the year, to below 300,000 tons, after having risen almost continuously over a 2-year period. In the United States, both refined copper and scrap were reported to be in tight supply.

During the second half of the year the world copper balance turned from one of deficit to one of surplus. Copper inventories held on the world exchanges resumed the upward trend of the previous 2 years and by yearend had risen to more than 430,000 tons, the highest level since 1984. The bottleneck in smelting capacity began to ease as concentrates were shunted to underutilized smelters in Kazakhstan, Poland, Russia, and Zambia for processing. This redirection of concentrates led to lower smeltingrefining charges and increased availability of copper at a time of weakening global demand.

DOMESTIC DATA COVERAGE

Domestic production data for copper

were developed by the U.S. Bureau of Mines from seven separate surveys of U.S. operations. Typical of these surveys is the lode mine production survey. Of the 117 operations to which this survey was sent in 1992, 91% responded and 67 reported copper production, representing an estimated 99.7% of the mine production shown in tables 1, 3, and 5. Production for the remainder was estimated using other surveys.

ANNUAL REVIEW

Production

Domestic mine production increased during 1992 as a result of incremental expansions of existing mines and startup of several leach operations. In 1992, 67 mines in 13 States produced copper in the United States; 14 mines and 5 States accounted for more than 95% and 91%. respectively, of the national total. Domestic copper mines employed 13,600 workers during 1992, down slightly from the number employed in the previous year. Productivity at domestic mines increased significantly, from 17.7 worker hours per ton of copper produced in 1991 to 15.9 worker hours in 1992. Most domestic companies reported significant reductions in operating costs through productivity gains. In response to the global tightness in smelting capacity, all domestic smelters were undergoing modification to increase or better utilize existing capacity.

Arimetco International Inc. began production from its Emerald Isle Mine in Arizona with the completion of an 8,000-pound-per-day solvent extraction-

electrowinning (SX-EW) plant. Arimetco, which also operated the Johnson Camp, AZ, and Yerington, NV, SX-EW facilities, announced its 50% acquisition of the McArthur oxide copper property from Holcorp Mines Ltd., of Toronto, Canada. Located near its Yerington Mine, McArthur reportedly contains 40,000 tons of recoverable copper.

By the end of 1992, ASARCO Incorporated had nearly completed a 7-year, \$1.3 billion program to become a fully integrated copper and lead mining company. Asarco's copper reserves were expanded eightfold during that period. According to the company's 1992 Annual Report, mine production of copper rose 24% in 1992, to 280,000 tons, owing to completion of expansion projects at its Mission complex late in 1991 and its Ray Mine early in 1992 that increased capacity to 100,000 tons and 165,000 tons, respectively. Costs for expansion of the Ray Mine, which included a new concentrator and in-pit crusher, and the Mission complex were estimated at \$224 million and \$100 million, respectively.

Asarco's smelter production rose by 9%, reflecting the second year of record production at the Hayden smelter. Construction of the new CONTOP furnace at its El Paso, TX, smelter began in May. Startup of the furnace was expected during the first half of 1993.

Arizona Copper Co. (AZCO) began development of its Sanchez Project, in Arizona, with construction of a 25,000-ton-per-year SX-EW plant expected to begin early in 1993 and production startup scheduled for 1994. Exploration by previous owners had established oxide reserves in excess of 110 million tons

grading 0.37% copper.

According to its 1992 Annual Report, Cyprus Minerals Co. produced 300,000 tons of copper (including 8,000 tons from its Selwyn Mine in Australia) at an average cost of 78 cents per pound, down from 80 cents the previous year. Using updated cost and geological information, Cyprus reported a 60% increase in its proved and probable reserves to 6.5 billion tons having an average grade of 0.35% copper.

According to its Annual Report, Cyprus set a goal to reduce production costs to about 60 cents per pound, 25% below 1992 costs, and to become a fully integrated producer. In 1992, Cyprus processed only 60% of its concentrates in its own facilities. To achieve these goals, Cyprus initiated an investment program in 1992 that could approach \$350 million In 1992, it reported over 3 years. spending \$14 million on truck fleet modernization and anticipated spending an additional \$61 million in 1993. Other aspects of its cost reduction investment included \$83 million for expansion of its Miami, AZ, refinery; \$54 million for mill improvements and power cogeneration at its Bagdad Mine; and \$21 million at Sierrita/Twin Buttes for mill and leach improvements. An additional \$115 million expenditure was planned for incremental capacity expansion.

Installation of a new ISAMELT furnace at Cyprus' Miami smelter was completed during 1992. Capacity was expected to increase by 200,000 tons to 650,000 tons of concentrate per year by mid-1993. The smelter operated at reduced capacity during the year owing to shutdown for repair and maintenance.

Mine production at Kennecott's Bingham Canyon Mine rose to a record level in 1992 of 288,700 tons, up by more than 50,000 tons from the previous year (The RTZ Corp. PLC, Form 20-F, 1992). The increase was the result of having completed in January a \$219 million expansion of mill facilities begun in 1990. This was the second major investment in mine modernization at Bingham Canyon undertaken since 1985. In March, Kennecott announced plans to invest \$880 million to construct a new

on-site smelter and to expand refining capacity. The new smelter, with a projected capacity of 272,000 tons of copper per year, would make Kennecott a fully integrated producer. As a result of required environmental curtailments, Kennecott had been exporting about one-half of its concentrate production.

After several years of delay, Kennecott received the necessary environmental clearances to begin development of its Flambeau high-grade copper-gold deposit in Wisconsin. Startup of the 28,000-ton-per-year mine was scheduled for June 1993. In April, Kennecott and the U.S. Environmental Protection Agency signed a nonbinding "Agreement in Principal" for the remediation of ground water contamination resulting from its Utah operations.

In its 1992 Annual Report, Magma Copper Co. reported producing 251,000 tons of copper from its own operations, up 13,000 tons from the previous year. Nearly all of the increase came from its SX-EW production. Magma reported a record year for production and earnings, having reduced net operating costs in 1992 by 5 cents per pound, to 66 cents per pound, and improved productivity by 12%. During the 5-year period 1988 through 1992, Magma reduced net operating costs by 12 cents per pound and increased productivity by 61%. Total cathode production rose by 9% in 1992 on the strength of increased electrowon production (70,000) tons, and a 7% increase in custom smelting and refining. In July, Magma began the engineering phase for development of its newly acquired (1991) Robinson project, which was expected to be producing about 57,000 tons of copper per year by the end of 1994. Capital costs for the mine and mill were projected at \$250 million. In 1992, Magma increased its reserves with the acquisition of a major deposit near Florence, AZ, having combined oxide and sulfide reserves of more than 725 million tons. Early in 1993, Magma announced that it had approved the development of the Kalamazoo ore body, thus extending underground mining at San Manuel by 12 years to the year 2009. It also announced plans to expand smelting

and refining capacity by 20% through the construction of a third acid plant. The \$100 million project was slated for completion in 1994.

Copper production by Phelps Dodge Corp., according to its 1992 Annual Report, was at the same level as that in 1991 and amounted to 586,000 tons (including about 99,000 tons of its minority participant's share and 22,000 tons from its Ojos del Salbo Mine in Chile). Phelps Dodge was the largest U.S. and the world's second largest mine producer of copper. In January, Phelps Dodge ceased production of concentrate ore at its Tyrone Mine in New Mexico with the exhaustion of sulfide reserves. Production of copper in concentrate declined from 93,000 tons in 1990, to 57,000 and 8,000 tons, respectively, in 1991 and 1992. The loss of concentrate production was balanced by increases in SX-EW production at its Tyrone and In 1992, SX-EW Morenci Mines. accounted for 263,000 tons or 45% of Phelps Dodge's total production. In Phelps Dodge completed May, construction of its Northwest extension project at Morenci, raising SX-EW production capacity at Morenci by 64,000 tons per year to a total of 155,000 tons from the three adjacent pits at Morenci. Phelps Dodge's smelter production increased marginally despite a 60-day shutdown of its Hidalgo smelter for In October, Phelps refurbishment. Dodge began construction at its La Candaleria copper-gold project in Chile, which contained reserves in excess of 360 million tons grading 1.1% copper. In September, it sold a 20% interest in the project to Sumitomo Corp. of Japan for \$40 million. Production of more than 100,000 tons of copper per year was slated to begin in 1995.

Copper Range Co. produced about 50,000 tons of copper at its White Pine Mine in Michigan, according to its 1992 Annual Report. The company took advantage of high treatment and refining charges and tightness in world smelter capacity to double its purchases of outside concentrates to almost 14,000 tons of recoverable copper. The increased purchases allowed the company to more

fully utilize capacity and reduce purchases of pyritic flux ores. The cash cost, excluding depreciation, at White Pine was reduced by 13% compared to 1991 and averaged 82 cents per pound of copper.

Consumption

As noted previously, domestic demand for refined copper rose by 6% from its depressed 1991 level. According to data supplied by the Copper Development Association, shipments of copper and copper alloy products to U.S. markets rose by 5.3% in 1992, to 2.98 million tons. Building and construction was the largest market segment, accounting for 42% of demand, followed by electric and electronic uses, 24%; industrial machinery, 13%; transportation equipment, 11%; and consumer and general products, 10%. According to U.S. Bureau of Mines estimates, electrical uses of copper in all market segments accounted for about 72% of apparent consumption, followed by nonelectrical use in construction, 14%; machinery, 5%, transportation, 5%; ordnance, 2%; and other 2%.

World Review

Despite the aforementioned constraints, increased mine production in Chile, Indonesia, and the United States led world copper mine production to a record-high level. World mine production capacity increased to 11.2 million tons. In the United States, mine capacity reached 2.04 million tons, an increase of about 100,000 tons, while increased capacity utilization resulted in a 134,000-ton increase in mine production. Capacity and production in Chile rose by 130,000 tons and 96,000 tons. respectively. Production at the Escondida Mine in Chile rose by 40,000 tons to 337,000 tons, making it the second largest copper mine in Chile and the world. A \$440 million expansion of the Los Bronces Mine, owned by Exxon Minerals Chile, Inc., was completed in 1992, tripling capacity to 130,000 tons. An \$18 million expansion project at

Phelps Dodge's Ojos del Salado Mine, completed in November 1991, helped boost production by more than 4,000 tons. In Indonesia, mine production rose by almost 70,000 tons as a result of expansions at Freeport-McMoRan Inc.'s Grasberg Mine and mill. Significant increases also were noted in China (a new mill at the Dexing Mine was completed in 1991), Poland, and to a lesser extent in Australia. Production increases were partially offset by significant declines in the Philippines and Zaire and modest declines in other countries. Philippines, production at Atlas Mining, the largest producer continued to decline. falling by about 22,000 tons. Political turmoil in Zaire led to severe shortages of materials and fuel and a disruption of transportation routes.

Though U.S. demand for refined copper rose by 6% from its depressed 1991 level, spreading recession during the second half of the year in the rest of the world led to only a modest 2.8% growth in Western European demand and a marked 12.5% decline in Japanese consumption. Japanese consumption was partially offset by increases in Indonesia. North Korea, Taiwan, and other Asian countries. A large increase in western country exports of refined copper to China more than offset increased imports from Eastern European countries and helped to modify what would have been an even larger Western World surplus of refined copper.

Revised.

¹Includes primary copper produced from foreign ores, matte, etc., to avoid disclosing company proprietary data.

²Data may not add to totals shown because of independent rounding.

Includes copper content of alloy scrap. Copper content of alloy scrap imported and exported in 1989 and 1990 was estimated from gross weight.

XX Not applicable.

In 1992, 603,769 ounces of gold and 15,182,176 ounces of silver were recovered from concentrated ore. The average value of gold and silver per metric ton of ore concentrated was \$1.01.

In 1992, 603,769 ounces of gold and 15,182,176 ounces of silver were recovered from concentrates roast-leached.

Includes electrowon from concentrates roast-leached.

Includes gold ore, gold-silver ore, lead ore, lead-zinc ore, molybdenum ore, silver ore, tangeten ore, fluorapar, flux ores, cleanup, ore shipped directly to smelters, and tailings. *Data may not add to totals shown because of independent rounding.

Estimated. Revised.

¹Data represent copper content by analysis of concentrates produced except where otherwise noted. Table includes data available through June 30, 1993.

²Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁵Reported figure.

⁴Less than 50 tons.

⁵Copper content of pelletized nickel-copper matte produced in smelter.

⁶Reported by Comision Chilena del Cobre (COCHILCO). Includes recoverable copper content of nonduplicative mine and metal products produced from domestic ores and concentrates, and leach production for electrowinning. Mine production data reported by Servicio Nacional de Geologia y Mineria (SERNAGEOMIN) were as follows, in thousand metric tons: 1988—1,472.0;1989—1,628.3;1990—1,616.3;1991—1,840.0 (estimated); and 1992—1,935.0 (estimated).

⁷Copper content of cement copper. Includes copper content of pyrite for 1989.

Recoverable content.

⁹Formerly part of Yugoslavia; data were not reported separately until 1992.

¹⁰Recoverable copper content by analysis of concentrates for export plus nonduplicative total of copper content of all metal and metal products produced indigenously from domestic ores and concentrates; includes leach production for electrowinning in Portugal.

¹¹Includes copper content of pyrite.

¹²Dissolved in Dec. 1991.

¹⁵Includes electrowon from concentrates roast-leached.

¹⁴Dissolved in Apr. 1992.

¹⁵Copper content by analysis of ore mined.

¹⁶Data are for fiscal years beginning Apr. 1 of year stated. Zambian-mined copper reported recovered during smelting and electrowinning.

¹⁷Data may not add to totals shown because of independent rounding.

^{&#}x27;This table includes total production of copper metal at the unrefined stage, including low-grade cathode produced by electrowinning methods. The smelter feed may be derived from ore, concentrates, copper precipitate or matte (primary), and/or scrap (secondary). To the extent possible, primary and secondary output of each country is shown separately. In some cases, total smelter production is officially reported, but the distribution between primary and secondary has been estimated. Table includes data available through June 30, 1993.

²Argentina presumably produces some smelter copper utilizing its own small mine output together with domestically produced cement copper, and possibly using other raw materials including scrap, but the levels of such output cannot be reliably estimated.

³Reported figure.

Data include electrowon production; estimated to be 35,000 to 45,000 tons per year that is fire-refined and cast into wirebars; detailed data are not available.

Data may be for year beginning Mar. 21 of year stated. Only estimated production data are available. Secondary production is estimated to be about 5% of total.

Formerly part of the U.S.S.R.; data were not reported separately until 1992.

Formerly part of Yugoslavia; data were not reported separately until 1992.

Figures for U.S. primary smelter production may include a small amount of copper derived from precipitates shipped directly to the smelter for further processing; production derived from electrowinning and fire refining is not included. Copper content of precipitates shipped directly to smelter are as follows, in metric tons: 1988-49,299; 1989-34,485; 1990-22,997 (revised); 1991-27,684 (revised); and 1992-27,402.

¹⁰Dissolved in Apr. 1992.

[&]quot;For fiscal year beginning Apr. 1 of year stated. Electrowon is total electrowon production reported, less the quantity reported as "finished production, leach cathodes." (See table 18).

¹²Includes impure cathodes produced by electrowinning in nickel processing.

¹³Totals may not add to detail shown because of independent rounding.

Estimated. Revised.

¹This table includes total production of refined copper, whether produced by pyrometallurgical or electrolytic refining methods and whether derived from primary unrefined copper or from scrap. Copper cathode derived from electrowinning processing is also included. Table includes data available through June 30, 1993.

²Reported figure.

³Data may not add to totals shown because of independent rounding.

⁴Includes leach cathode from Zaire, which is processed.

⁵May include secondary.

⁶Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁷Formerly part of Yugoslavia; data were not reported separately until 1992.

⁸Dissolved in Dec. 1991.

⁹Dissolved in Apr. 1992.

¹⁰Excludes leach cathode exported for reprocessing in Belgium.

¹¹Data are for fiscal year beginning Apr. 1 of that stated. Electrowon covers only presumably high-grade cathodes reported as "finished production leach cathodes." Other, in addition to electrorefined cathodes, includes a smaller amount of "finished product shapes" presumably cast from electrorefined cathodes, high-grade electrowon cathodes, or any blister-anodes and low-grade electrowon cathodes that were furnace- or fire-refined.

¹²May not include copper-nickel matte (copper content more than 6,000 tons per year) imported from Botswana for toll refining.

FLUORSPAR

By M. Michael Miller

Mr. Miller, a physical scientist with 15 years of mineral experience with the Department of the Interior, has been the commodity specialist for fluorspar since 1989. Domestic survey data were prepared by Tonya Hardin, statistical assistant; and international data tables were prepared by Harold Willis, international coordinator. All units are in metric tons, unless otherwise noted.

In the United States, one major producer supplied about 11% of the Nation's fluorspar requirements. Supplementing fluorspar as a domestic source of fluorine was byproduct fluorosilicic acid production from some phosphoric acid producers. According to the Bureau of the Census, imports of fluorspar decreased by about 7% compared with the 1991 revised figures. Hydrofluoric acid (HF) imports were about 19% lower than those reported in the previous year.

DOMESTIC DATA COVERAGE

Domestic production and consumption data for fluorspar were developed by the U.S. Bureau of Mines from voluntary surveys of U.S. operations. Surveys were conducted to obtain fluorspar mine production and shipments and fluorosilicic acid production. The latter was formerly termed fluosilicic acid, but as a result of an international effort to standardize nomenclature, its name has been changed to fluorosilicic acid. Of the four fluorspar mining operations to which a survey request was sent, three responded, representing 100% of known domestic shipments. Production statistics in table 1 are withheld to protect company proprietary data. Of the eight fluorosilicic acid producers surveyed, seven respondents reported production, representing 100% of the quantity reported. The consumption survey was sent to 91 operations quarterly and to 40 additional operations annually. Of the operations surveyed quarterly, 74%

responded. Of the operations surveyed on an annual basis, 80% responded. (See table 1.)

BACKGROUND

Definitions, Grades, and Specifications

Technically, pure fluorspar, or the mineral fluorite, contains 51.1% calcium and 48.9% fluorine. Natural fluorite is commonly associated with other minerals such as barite, calcite, galena, quartz, and sphalerite. It occurs in well-formed isometric crystals, in massive and earthy forms, and as crusts or globular aggregates with radial fibrous texture. In crystalline form, it can be colorless or may exhibit a wide range of colors, including yellow, blue, purple, green, rose, red, bluish and purplish black, and brown. It has a hardness of 4 on the Mohs scale, a specific gravity of 3.18, and a melting point of 1,378° C.

Three principal grades of fluorspar are available commercially: acid, ceramic, and metallurgical. Although the specifications for individual grades are generally well defined, some variation is permitted to satisfy the requirements of individual consumers.

In the United States, acid-grade fluorspar (acidspar) contains in excess of 97% CaF₂. Some manufacturers of hydrofluoric acid in the United States and Europe can use 96% CaF₂ or slightly lower if the remaining impurities are acceptable. User specifications may impose limits on arsenic, beryllium, calcium carbonate, lead, phosphates,

silica, sulfide or free sulfur, and other constituents. Moisture content of the dried material is preferably 0.1% or less. Particle size and distribution are sometimes specified for proper control of the rate of chemical reaction and stack losses. Very few reserves in the world can be used to produce acid-grade fluorspar without flotation processing.

Ceramic-grade fluorspar is generally marketed as No. 1 ceramic, containing 95% to 96% CaF₂, and No. 2 ceramic, containing 85% to 90% CaF₂. An intermediate grade of about 93% to 94% CaF₂ is also available. Specifications on impurities vary, but may allow a maximum of 2.5% to 3.0% silica, 1.0% to 1.5% calcite, 0.12% ferric oxide, and trace quantities of lead and zinc. Shipments of ceramic-spar are usually tailored to the specific need of individual consumers.

Traditionally, metallurgical-grade fluorspar (metspar) has contained a minimum of 60% effective CaF2, with effective CaF₂ units calculated by subtracting 2.5 times the silica content of the metspar from its total CaF₂ content. More recently, there has been much less emphasis on effective CaF, units and more emphasis simply on total CaF, content. Today, the term "metspar" is usually used to refer to material with a minimum content of 85%, but is sometimes used for material as high as 96%, which includes what is technically ceramic grade. Metspar is often traded as lump or gravel that must meet physical requirements similar to those of the following National Defense Stockpile

(NDS) purchase specifications.

According to the current NDS purchase specifications (P-69b-R3), which were determined by the Federal Interagency Committee for Stockpile Purchase Specifications and Special Instructions in consultation with U.S. metallurgical-grade steel producers, fluorspar must contain a minimum of by weight effective CaF₂. Specifications for maximum allowable impurities are as follows: sulfur = 0.10%, lead = 0.25%, arsenic = 0.01%, barium = 0.01%, zinc = 0.01%, phosphorus = 0.25%, tin = 0.02%, antimony = 0.02%, and copper = 0.10%. Physical requirements are that all metallurgical-grade fluorspar shall be in the form of gravel and, after washing, shall pass a 75-millimeter sieve (3-inch sieve), and not more than 10% by weight shall pass a 9.5-millimeter sieve (3/8-inch sieve).

In the domestic steel industry, various shapes and sizes of briquets or pellets are being used. Generally made to consumer specifications, briquets contain varying quantities of fluorspar mixed with binders, fillers, and fluxing agents. Typically made on roll presses and ranging in size from that of a peach seed to a 5-centimeter square, briquets contain 25% to 90% CaF, and steel mill waste ingredients, such as mill scale, flue dust, shredded scrap, iron ore fines, and manganese ore fines. The most popular binders are molasses and lime, which do **Imported** not require baking ovens. briquets are often made from fines accumulated during metspar preparation and from flotation concentrates. Pellets have been made on balling machines using sodium silicate binder.

Geology-Resources1

Fluorspar occurs in a wide variety of geological environments, which indicates that deposition takes place in a number of different ways. From an economic standpoint, seven of the most important modes of occurrence are as follows:

1. Fissure vein deposits commonly occur along faults or shear zones and are the most readily recognized form of

fluorspar occurrence in the world. Although the vein structure may be persistent, the fluorspar mineralization commonly occurs as lenses or ore shoots separated by barren zones. Fissure veins occur in igneous, metamorphic, and sedimentary rocks.

- 2. Stratiform, manto, or bedded deposits occur as replacements in carbonate rocks. Some beds are replaced adjacent to structural features such as joints and faults. Frequently, there is a capping of sandstone, shale, or clay.
- 3. Replacement deposits in carbonate rocks along the contact with acidic igneous intrusives are another common type of deposit. Deposits do not have to be the result of contact metamorphism, but may be introduced later, following the contact zone as a conduit and replacing the limestone.
- 4. Stockworks and fillings in shear and breccia zones are another form in which fluorspar occurs. The Buffalo deposit in the Transvaal consists of a network of fluorspar veinlets in sill-like bodies that are inclusions in the granite of the Bushveld complex.
- 5. Carbonatite and alkalic rock complexes may have fluorspar at their margins. Fluorspar grades are not usually sufficient to be economic, but the Okorusu deposit in Namibia is made up of a number of bodies of fluorspar in limestones, quartzites, and related rocks that have been intruded and metamorphosed by an alkaline igneous rock complex.
- 6. Residual deposits of fluorspar are formed in clayey and sandy residuum that results from surficial weathering of fluorspar veins and replacement deposits. These deposits may be the sources of metallurgical-grade fluorspar. They include detrital deposits blanketing the apex of veins and the upper portions of the veins themselves that have been weathered to depths of 30 meters or more.
- 7. Fluorspar may also occur as a major gangue mineral in lead and zinc vein deposits. Two operations in the Parral area of Mexico have treated the tailings of lead-zinc mines to recover fluorspar from previously discarded

gangue minerals.

Technology

Mining.²—Mining methods according to geologic conditions at individual deposits around the world. usually require Deep deposits underground techniques, while wide, shallow deposits employ open pit methods. If the ground is unable to support underground mining, open pit methods may be used even though overburden removal might be substantial. In some cases, open pit methods are used until the mining reaches a practical production limit because of excessive waste removal. Mining operations then move underground.

Narrow vein mining is often done by shrinkage stoping and open stoping where strong walls occur, while stratiform or bedded deposits use room-and-pillar patterns. Replacement and fissure vein deposits are mined with shrinkage stoping or cut-and-fill methods if they are deep, narrow occurrences. They may also be mined by open pit or strip-mining techniques when they occur near the surface and have competent sidewalls. The replacement and stockwork deposits in the Republic of South Africa, the carbonatite deposit in Namibia, and most of the fissure veins in Thailand are mined However. with open pit methods. replacement deposits in Mexico are extracted by stoping or cut-and-fill methods.

Beneficiation.—Most fluorspar must be upgraded for marketing. Metspar is often produced by hand sorting of high-grade lump crude ore, followed by crushing and screening to remove most of the fines. In the case of fluorspar ores of lower grade and/or ores with relatively coarse interlocking of minerals, gravity concentration processes are used based on the specific gravity above 3.0 for spar and below 2.8 for most gangue minerals.

Heavy-media cone and drum separators are particularly effective in the 37.5- by 4.75-millimeter (1 1/2- by 3/16-inch) size range, either for producing

metallurgical gravel or for | preconcentrating crude ore for flotation feed. For the finer sizes, the heavymedia cyclone process is frequently used. The high capacity and low operating cost of heavy-media methods give very satisfactory results. Ores as low as 14% CaF, can be preconcentrated to yield a flotation feed of 40% CaF2 or more. In the process, lead and zinc sulfides and barite concentrate with the fluorspar. which enriches the flotation feed with these valuable minerals. In some cases. washing plants are used prior to flotation to remove clay or manganese oxides (wad).

Ceramic and acid grades of fluorspar are produced by multistage froth flotation. Ore from the mine is crushed and ground to proper size; care is taken not to overgrind and cause fluorspar to be lost in the slimes. If lead and zinc sulfides are present, thev preferentially floated off with xanthate collector. After this process is completed, all the easy floating fluorspar is removed in a quick pass through a flotation circuit and sent on to the cleaner circuit. The tailings are discarded. The middling product is reground to separate the more finely interlocked grains of fluorspar and gangue and passed through one or more cleaner circuits. The final products generally comprise an acid-grade concentrate and, in some cases, one or more concentrates of lower grade, which are sold as ceramic grade, or pelletized and sold as metallurgical grade. Fatty acids are used as collectors for the fluorspar. Quebracho or tannin is used to depress calcite and dolomite; sodium silicate is used to depress iron oxides and silica; and chromates, starch, and dextrin are used to depress barite. Cyanide is used to depress any remaining sulfides. Lime, caustic, or soda ash can be used acidity control. Flotation temperatures range from ambient to 80°

Economic Factors

Depletion allowances against Federal taxes of 22% and 14%, respectively, remained in effect for domestic and

foreign production by U.S. companies.

Operating Factors

The United States is import dependent for the majority of its fluorspar supplies. Fluorspar products are transported to customers by truck, rail, barge, and ship. Most acid-grade fluorspar is shipped in the form of damp filter cake containing 7% to 10% moisture to facilitate handling and reduce dust.

Most acid-grade imports come from China, the Republic of South Africa, and occasionally other overseas suppliers. Fluorspar is shipped by ocean freight utilizing the "Tramp" market for ships. Bulk carriers of 10,000 to 50,000 tons deadweight normally are utilized. Participants negotiate freight level, terms, and conditions. The main participants are charterers-generally the buyers or sellers, ship owners-who either own vessels or have them time chartered. operators—traders normally positions on either cargo or ships, and brokers—generally represent ship owners or charterers and act as go-betweens. Ships are primarily owned by the privately held shipping following: companies, publicly held shipping companies. Government-controlled companies, and groups of professionally managed fleets under varying ownership. The total number of ships in the 10,000to 50,000-ton range is about 2,000, of which more than 60% is at least 15 years old. The rate of new ship construction is very low; less than 2% of the total fleet is on order. Factors or concerns currently affecting the shipping market are the age of the fleet, environmental safety and quality assurance, insurance rates, rising operating costs due to inflation, increasing port expenses. increased tax or tariffs relating to ship costs, and anticipated volatility due to changing world conditions.3

ANNUAL REVIEW

Legislation and Government Programs

The Defense Logistics Agency,
Defense National Stockpile Center (DLA-

DNSC), measures the fluorspar stockpile in standard dry tons (sdt). In 1992, it was authorized to sell 20,000 sdt (18,144 metric tons) of metallurgical-grade fluorspar during fiscal year 1992 (October 1, 1991 to September 30, 1992). The DLA-DNSC sold 4,000 short wet tons (3,629 metric tons) in fiscal year 1992 from the stockpile in Marietta, PA. According to the fiscal year 1993 annual materials plan of the DLA-DNSC, there is an existing authority for the disposal of 20,000 sdt (18,144 metric tons) of metallurgical-grade material.

Major changes in the fluorspar stockpile were initiated. Based on revised national security needs dictated by new post-cold war planning assumptions. the Department of Defense has been authorized to dispose of the entire fluorspar stockpile. The overall mechanism for this disposal would be the National Defense Authorization Act for Fiscal Year 1993 (Public Law 102-484). which authorized the disposal of obsolete and excess materials contained in the NDS. To prevent undue disruption of markets, advisory and impact committees were to be established. Both committees were to have representatives from the Departments of Commerce, Energy, Interior, State, and Treasury. In addition, the advisory committee was required to have representatives from the mining and processing industries and their customers. The impact committee is required to "consult from time to time" with industry to determine how disposals could affect domestic and foreign markets.4

On November 15, 1990, the Clean Air Act Amendments of 1990 (CAAA) were enacted into law. Title VI covered stratospheric ozone protection and was directed primarily at chlorofluorocarbon hydrochlorofluorocarbon (CFC) and (HCFC) chemicals. Section 608 of title VI required the Environmental Protection Agency (EPA) to establish comprehensive program to limit emissions of ozone depleting substances during their use and disposal. As a result, in December 1992, **EPA** proposed regulations to establish a recycling program for ozone depleting refrigerants recovered during the servicing and disposal of air-conditioning refrigeration equipment. The proposed regulations would require persons servicing air-conditioning or refrigeration equipment to observe certain service practices that reduce refrigerant emissions and would establish equipment and offsite reclaimer certification programs. addition. EPA would require that ozonedepleting compounds contained "in bulk" in appliances be removed prior to disposal of the appliances, and that all air-conditioning and refrigeration equipment, except for small appliances and room air conditioners, be provided with a servicing aperture that would facilitate recovery of the refrigerant.5 The CFC's recycled in this program are exempt from the excise tax on ozonedepleting chemicals.

As part of energy legislation passed by Congress in 1992, the tax on those CFC's with the highest ozone depletion potential will rise to \$3.35 per pound (about \$7.39 per kilogram) in 1993, to \$4.35 per pound (\$9.59 per kilogram) in 1994, to \$5.35 per pound (about \$11.79 per kilogram) in 1995, and will increase by \$0.45 per pound (about \$0.99 per kilogram) each year thereafter. The new excise taxes are higher than those in the previous tax schedule, which was included as part of a deficit reduction bill in 1989.

Delegates representing signatories to the Montreal Protocol met in Copenhagen, Denmark, and agreed to speed up the phaseout of CFC's. The adjustments bring the worldwide production phaseout in line with European and U.S. plans announced earlier in the year. Under the new timetable, CFC-11, -12, -113, -114, and -115 production will be reduced 75% from 1986 production levels by January 1, 1994. It also calls for a complete production phaseout as of January 1, 1996. Amendments, which must be ratified, included a phaseout schedule for HCFC's and control of hydrobromofluorocarbons. Essentially, the HCFC schedule would begin in 1996 by freezing HCFC production at 1989 levels, then reduce that allowance by 35% in 2004, 65% in 2010, 90% in 2015, and 99.5% in 2020.

As part of a project initiated in 1991, the U.S. Bureau of Mines is continuing to collect information on the fluorspar and HF industries for the purpose of addressing impacts on production costs and supply and demand resulting from regulatory requirements on the industries or new technologies to produce replacements for banned CFC's. Network Flow Model and Supply Analysis Model will be developed for the fluorspar and HF industries to address material flow from the production of acid-grade fluorspar to HF plants and on to CFC consumers. Operating costs and transportation costs for each stage will be incorporated. During 1992, information on U.S. HF plants was collected and detailed engineering cost studies for the two types of HF plants currently in operation in the United States were During 1993, economic obtained. analysis of fluorspar operations and North American HF operations will be completed. During 1994, data will be collected on European HF industries and a final project report completed. funding becomes available, data on HF industries in South America and Asia will be added to the models in the future.

Issues

As required by Section 612 of Title VI of the CAAA, EPA is required to publish a list of safe alternative CFC's for specific uses. The list had not been published by the end of 1992. This delay is causing uncertainty in the consumer markets, in particular the foam blowing, refrigeration, and air conditioning markets. Equipment manufacturers and consumers are faced with the very real uncertainty of redesigning equipment and selecting replacement compounds without knowing if the replacement compounds will be on the "approved list" or not. This uncertainty is further complicated by the alternatives offered by the CFC Each CFC producer is producers. offering different products, usually blends designed to replace traditional products such as R-502. Because the pace of

research and development of replacements has been dictated by the phaseout schedule, there is a resulting lack of product standardization in the industry. Thus the consumer is being forced to choose a single supplier of replacement compounds, because the other CFC producers' products are likely to be incompatible with the consumers new equipment.

Production

Illinois was the only State reporting production in 1992 and accounted for nearly all reported U.S. shipments. Data on shipments of fluorspar by State and grade are withheld to avoid disclosing company proprietary data.

Ozark-Mahoning Co., the Nation's largest fluorspar producer and subsidiary of Elf Atochem North America Inc., operated three mines and a flotation plant in Pope and Hardin Counties, IL. Ozark-Mahoning also dried imported fluorspar and processed some material from the NDS to supplement its production. Seaforth Mineral & Ore Co. Inc. dried imported fluorspar at its facilities at Cave-In-Rock, IL, and East Liverpool, OH, for sale primarily to consumers in the ceramic industry. J. Irving Crowell, Jr., & Son shipped a small amount of fluorspar from stocks, but the Crowell-Daisy Mine in Nye County, NV, remained closed.

Two Canadian firms have been active in the exploration and acquisition of fluorspar properties in North America. Silverspar Minerals Inc. has explored prospects in Arizona and has negotiated the acquisition of fluorspar properties in Kentucky, New Mexico, and Tennessee. In Arizona, its property is called the Silver District Property, which is on the Arizona-California border north of Martinez Lake, AZ. In New Mexico, there is the Salado Property, west of Truth or Consequences, NM, and the Hidalgo Property, in southern New Mexico. In Tennessee, there is the Sweetwater Property, in south-central Tennessee. In Kentucky, Silverspar Minerals has been negotiating an option to purchase the fluorspar mining assets of USX Corp., which are in the Kentucky fluorspar district of western Kentucky. Verdstone Gold Corp. announced the acquisition of two fluorspar properties in British Columbia, Canada, and two properties in Nevada. The properties in Nevada were the Blazer fluorspar deposit in Lander County and the Baxter (Kaiser) Mine in Mineral County.

Nine plants processing phosphate rock for the production of phosphoric acid sold a reported 64,408 tons of byproduct fluorosilicic acid at a value of about \$8.6 million. This was equal to 111,600 tons of 92% fluorspar equivalent. The fertilizer industry is operating at a relatively high rate, and the supply and demand of fluorosilicic acid is at present reasonably balanced. Because fluorosilicic acid is a byproduct and not manufactured for itself alone, shortages can occur when fertilizer demand goes down.

Consumption and Uses

Acid-grade fluorspar, containing greater than 97% calcium fluoride (CaF2), was used primarily as a feedstock in the manufacture of HF. Ceramic-grade fluorspar, containing 85% to 95% CaF₂, was used for the production of glass and enamel, to make welding rod coatings, and as a flux in the steel industry. Metallurgical-grade fluorspar, containing 60% to 85% or more CaF₂, was used primarily as a fluxing agent by the steel industry. Fluorspar is added to the slag to make it more reactive. It increases the fluidity of the slag (by reducing its melting point) and thus increases the chemical reactivity of the slag. Reducing the melting point of the slag brings lime and other fluxes into solution to allow the absorption of impurities.

Reported domestic consumption by the HF industry in 1992 increased by about 5%. Reported consumption by the steel industry decreased by about 7%, despite a 4% increase in U.S. raw steel production.

In the ceramic industry, fluorspar was used as a flux and as an opacifier in the production of flint glass, white or opal glass, and enamels. Fluorspar was used in the manufacture of aluminum, brick, cement, and glass fibers and also was used in the melt shop by the foundry industry.

Three companies reported fluorspar consumption for the production of HF. The U.S. Department of Commerce, Bureau of the Census, reported that, based on its monthly survey, anhydrous, technical, and aqueous HF, 100% basis, "produced and withdrawn from the system," was 137,792 tons for 1992 compared with the 1991 quantity of 146,643 tons.

The largest use of HF was for the production of a wide range of fluorocarbon chemicals, including fluoropolymers and CFC's. CFC's were produced by five companies: Allied-Signal Corp., Ausimont USA Inc., E. I. du Pont de Nemours & Company Inc., Elf Atochem North America Inc., and La Roche Chemicals Inc. According to preliminary data from the U.S. International Trade Commission, production of trichlorofluoromethane (CFC-11) increased slightly to 45,451 tons and dichlorodifluoromethane (CFC-12) increased by 4.5% to 72,428 tons compared with 1991 figures. Data on production of chlorodifluoromethane (HCFC-22) was unavailable. information is currently collected on production of the HCFC and HFC replacement compounds.

The chemical industry continued construction on commercial plants to manufacture replacement HCFC's and HFC's. Eight new plants went on-line worldwide during 1992, four in the United States, two in Japan, and two in France. A reported 11 additional plants are under construction or are in the planning stage.

Some of the new plants will be producing HCFC's 22, 123, 124, 141b, and 142b. These HCFC substitutes have ozone-depletion potentials much lower than that of CFC-11, CFC-12, and CFC-113, which in total have accounted for more than 90% of CFC consumption. The most likely HCFC candidates to replace controlled CFC's are HCFC-22, for use in home air conditioning (already

in commercial use); HCFC-123, to replace CFC-11 as a blowing agent in polyurethane foams and refrigeration; HCFC-141b, to replace CFC-11 in blowing plastic foams; and HCFC-142b, to replace CFC-11 as a blowing agent for polystyrene and polyethylene foams. Unfortunately, because of the recently agreed upon phaseout schedule for HCFC's and the likelihood that the schedule will be accelerated, the market for HCFC's will exist for only a finite Industry expects amount of time. HCFC's to be produced and utilized at least through the end of this decade.

The HFC replacements have no ozonedepletion potential because they contain no chlorine atoms. The most promising HFC candidates are HFC-134a, to replace CFC-12 in refrigeration and auto air conditioners, and HFC's 32, 125, 141b, 143a, and 152a. The latter five HFC's hold potential for use by themselves or more likely as blends in mid- to lowtemperature refrigeration and automobile air conditioners. In addition, some interim replacements may be mixtures of compounds and HCFC's. Inhalation and toxicity tests continued on the various replacements. EPA has proposed additional HFC compounds for additional study, such as HFC's 227ca, 227ea, 236cb, 236ea, 236fa, 245cb, and 245fa.

The manufacture of synthetic cryolite and aluminum fluoride for use in aluminum reduction cells was a major use of HF. In the Hall-Héroult process. alumina is dissolved in a bath of molten cryolite, aluminum fluoride, and fluorspar to allow electrolytic recovery of aluminum. An estimated 20 to 30 kilograms of fluorine was consumed for each ton of aluminum produced. Aluminum fluoride was used by the ceramic industry for some body and glaze mixtures and in the production of specialty refractory products. It was used in the manufacture of aluminum silicates and in the glass industry as a filler.

HF was consumed in the manufacture of uranium tetrafluoride that was used in the process of concentrating uranium isotope 235 for use as nuclear fuel and in fission explosives. It also was used in

stainless steel pickling, petroleum alkylation, glass etching, oil and gas well treatment, and as a cleaner and etcher in the electronics industry. It was used as the feedstock in the manufacture of a host of fluorine chemicals used in dielectrics, metallurgy, wood preservatives, herbicides, mouthwashes, decaypreventing dentifrices, plastics, and water fluoridation.

Fluorosilicic acid was used primarily to make aluminum fluoride for the aluminum industry and in water fluoridation, either directly or after processing to sodium silicofluoride. (See table 2.)

Stocks

Consumer stocks at yearend were 47,699 tons, a decrease of nearly 31% from the level reported in 1991. At yearend, the NDS fluorspar inventory was essentially unchanged from yearend 1991 and contained 892,000 sdt (809,000 metric tons) of acid-grade material, 310,000 sdt (281,000 metric tons) of metallurgical-grade material, 899 sdt (816 metric tons) of nonstockpile, acid-grade material, and about 112,777 sdt (105,938 metric tons) of nonstockpile, metallurgical-grade material. The latter category was reduced by a sale of 4,000 short wet tons (3,629 metric tons) in September. The fluorspar stockpiles are at 22 sites across the country. largest acid-grade stockpiles are in Wilmington, DE; Memphis, TN; and Gate, CO. The largest North metallurgical-grade stockpiles are in Large, PA; Warren, OH; and Pine Bluff, AR.

Prices

According to prices published by Industrial Minerals (Metal Bulletin PLC), the price of domestic acid-grade fluorspar was unchanged compared with 1991 prices. Published yearend producer prices for Mexico were unchanged. South African and Chinese prices decreased compared with 1991 prices.

Yearend price quotations from the Chemical Marketing Reporter (CMR)

were unchanged at \$0.6875 per pound for anhydrous HF and were unchanged at \$52.00 per 100 pounds for aqueous HF, 70%, in tanks. These quotations were equivalent to about \$1.52 per kilogram for anhydrous HF and \$114.64 per 100 kilograms for aqueous HF, 70%, in tanks. The CMR yearend price quotation for fluosilicic acid, 100% basis, in tanks, was unchanged at \$340 per short ton (about \$375 per metric ton). The price quotation for synthetic cryolite also remained unchanged at \$510 to \$550 per short ton (about \$562 to \$606 per metric ton). (See table 3.)

Foreign Trade

According to the Bureau of the Census, U.S. exports of fluorspar decreased by about 82%. Because Ozark-Mahoning reported no foreign sales, all U.S. exports were reexports of material imported into the United States. (See table 4.)

Imports for consumption of fluorspar decreased by about 7% compared with those of the previous year, according to Bureau of the Census data and revisions made to 1991 data. It is believed that there were some Chinese shipments unreported in the official 1991 trade data, and an estimate of this tonnage was included in Chinese acid-grade imports. In 1992, China was the largest supplier of fluorspar to the United States, followed by, in descending order, the Republic of South Africa, Mexico, and Namibia. The average c.i.f. unit value, in dollars per metric ton, was about \$112 for acid grade and about \$85 for subacid grade. (See table 5.)

The suspension of the 13.5% ad valorem tariff on subacid-grade fluorspar imports expired December 31, 1992. The temporary suspension was part of the Customs and Trade Act of 1990, signed into law on August 20, 1990. The 13.5% ad valorem tariff went back into effect on January 1, 1993, and applies to both most-favored-nation (MFN) and non-MFN countries. The tariff on acid grade for MFN countries is \$2.10 per long ton (\$2.07 per metric ton) and for non-MFN countries \$5.60 per long ton (\$5.51 per

metric ton).

Imports for consumption of HF decreased 19% to a quantity equivalent to approximately 101,000 tons of fluorspar. Imports of synthetic and natural cryolite increased 21% to a quantity equivalent to approximately 4,880 tons of fluorspar. Imports of aluminum fluoride decreased by 3% to a quantity equivalent to approximately 48,400 tons of fluorspar. (See tables 6, 7, and 8.)

World Review

World fluorspar consumption and production decreased compared with 1991 levels. In order of rank, China, Mexico, the former U.S.S.R., Mongolia, and the Republic of South Africa were the major producers. The international fluorspar industry experienced the continuing effects of major changes in traditional markets, such as fluorochemicals and steel. World production has decreased by 25% in the past 2 years, despite major revisions downward of world production totals for prior years. China's pricing practices continued to cause difficulties for other fluorspar producers. the European Community proposed an import duty on Chinese acidspar of 10.9 ecu per ton (about \$13 per ton) with a floor price under consideration. The Mexican Government also was considering an import duty on Chinese imports.

Brazil.—The Brazilian fluorspar industry continued to be adversely impacted by low international fluorspar prices. Brazilian producers have abandoned the export market, relying strictly on domestic markets. Production comes from the mines and operations of the following companies: Mineracao del Rey Ltda., Mineracao Nossa Senhora do Carmo Ltda., Mineracao Floral Ltda., and Companhia Brasiliera Alumina.

In 1992, Mineracao Santa Catarina was acquired by Companhia Brasiliera Alumina, which already owned a fluorspar mining operation in Santa Catarina State to supply its aluminum production operations. Mineracao del Rey Ltda. and Mineracao Nossa Senhora

do Carmo Ltda., in cooperation, started the country's first fluorspar briquetting plant. The plant has a capacity of 66,000 tons per year.⁶

The Brazilian mining company Paranapanema announced plans develop a cryolite deposit in the State of Amazonas. The cryolite deposit was discovered in 1991 in the company's Pitinga tin mine, near the town of Joao Figueiredo. The cryolite occurs below the cassiterite ore body at a total depth of about 150 meters. The mine will produce about 25,000 to 30,000 tons per year and has total estimated reserves of 3 million tons. Development costs are estimated at \$15 to \$17 million with startup projected in 30 to 36 months. A company representative stated that the mine will be developed with a Danish partner.

China.7—Although fluorspar exports from China continued at high levels, the number of operating mines probably decreased in 1992. The central Government changed its method of funding fluorspar operations to emphasize actual sales rather than production. As a result, many of the smaller and more remote mines apparently ceased production. Large producer stocks, reportedly built up in recent years, have been sold. Whether these two factor will generate any upward pressure on international prices is uncertain.

Italy.8—Nuova Mineraria Silius S.p.A. was formed in early 1992 to take over the assets and operations of the country's major acid-grade producer. Mineraria Silius, S.p.A. Nuova Mineraria was being run by an executive committee. with the Sardinian Regional Autonomous Government maintaining majority equity in the company. The takeover has resulted in a substantial work force reduction. Serious planning was underway for a new flotation mill to be located at the mine, with startup anticipated in 1994.

Mexico.—In 1991, Sesa Fluorspar Inc. purchased the Reynolds Metals processing

plant in Eagle Pass, TX, and had moved it to Mexico. This new operational phase was short lived, because in 1992, Sesa Fluorspar was forced to shut down operations. Fluorita de Rio Verde also shut down operations in 1992. The small producer, Silsea, ceased production and was attempting to sell off its stockpile. Cia Minera La Valenciana S.A. de C.V. started production in 1992 after a hiatus of some years. Output was intended for the company's new HF plant.⁹

The Mexican Chamber of Mines presented a request to the Secretary of Commerce and Industrial Development for a compensatory tax on imports of Chinese acidspar into Mexico. The Secretary issued a statement that investigations had been initiated to confirm the dumping of acidspar, to collect price data, and to determine impacts on the domestic fluorspar industry. No results had been announced by the end of 1992.

Mongolia. - Mongolia's fluorspar mining industry is dominated by two joint-venture companies-Mongolsovtsvetmet (Mongolia and Russia) and Mongolczechoslovakmetal (Mongolia and Czechoslovakia). The latter operated the Chulut Cagan Del Mine, which sold all of its production to Czechoslovakia. Sales were terminated in early 1992 and the mine shut down. The company is seeking new markets, so far unsuccessfully.10 Mongolsovtsvetmet operated Mongolia's largest fluorspar mine and only flotation mill at Bor-Ondor. The mine was closed temporarily in 1992 as a result of a dam failure that flooded the mine.11

Turkey.—Taneks Foreign Trade Inc. announced plans in late fall of 1992 to start production of fluorspar from a deposit at Malatya in central Anatolia. The deposit has fluorspar reserves of 0.5 million tons. The company's plans included construction of a mill with an annual capacity of 24,000 tons, divided between metallurgical grade and acid grade. The majority of its output was expected to be metallurgical grade

intended for export to European iron and steel markets. 12

Turkey's state-owned mining, metallurgy, and banking company, Etibank, announced the opening of a thorium-bearing barite-fluorspar-rare earths deposit to foreign participation. Etibank sought foreign technical expertise in the evaluation, development, and marketing of the mineral deposit, which is near the city of Eskisehir in the Sivrihisar district of midwestern Turkey. The deposit is characterized by lens and layer occurrences, and carbonitic dikes and veins. Reserves are estimated at 30 million tons at an average grade of 37.44% CaF₂. Run-of-mine samples tested at 37.3% CaF₂, with a product grade of 90% with 60% recovery.13

United Kingdom. 14—The United Kingdom's fluorspar production is concentrated in Derbyshire. In 1992. Swan Industrial Minerals Ltd. acquired the Derbyshire mineral rights of fluorspar producer Deepwood Mining Co. Ltd. and its wholly owned subsidiary Matlock Barytes Co. Ltd. At the same time, they acquired Horace Taylor Minerals Ltd.. which will process fluorspar from Swan's fluorspar deposits at a new fluorspar and barite processing facility scheduled for startup in February 1993. The facility, in Matlock, will be producing high-quality metspar for domestic markets and export preconcentrates for acidspar production. (See table 9.)

Current Research

Phosphate Engineering Construction Co. of Lakeland, FL, applied for a patent whereby byproduct fluorosilicic acid is reacted phosphate rock to produce phosphoric acid and calcium silicon hexafluoride (CaSiF₆). In the process the CaSiF₆ is hydrolyzed to produce silica and calcium fluoride, which are separated centrifuging and settling. The calcium fluoride is then reacted with sulfuric acid to produce HF. The company is negotiating with phosphate producers to construct a demonstration plant.

The U.S. Bureau of Mines initiated a cooperative testing effort with private industry to demonstrate and evaluate Bureau column flotation and rapid flotation technology integrating advanced electrochemical sensors and intelligent process control strategies. flotation technology has proven to be more efficient than conventional froth flotation for the development of lower grade ores. Commercial application of column flotation has resulted in economic improvements that enhance industry's position in mineral production and allow it to remain competitive in the international marketplace.

The U.S. Bureau of Mines is assisting EPA in development of treatment methods to decontaminate lead wastes at several Superfund sites. The cleaning process utilizes fluorosilicic acid and consists of the following: (1) carbonating the lead waste to convert lead sulfate into acid soluble lead carbonate; (2) leaching the carbonated material with fluorosilicic acid and hydrogen peroxide to dissolve lead carbonate, lead oxide, and lead metal; and (3) electrowinning the lead-loaded leachate to recover metallic lead and recycle the leachate.

OUTLOOK

Consumption of metallurgical-grade fluorspar by the U.S. steel industry decreased again in 1992, despite a small gain in raw steel production. The closure of the last open-hearth furnaces, which significant required quantities fluorspar, eliminated a traditional market for fluorspar. The decreasing level of consumption is mainly a result of continuing changes in technology, improvements in efficiencies, and tighter raw material specifications. factors indicate that U.S. consumption of metallurgical-grade fluorspar will continue to decrease through the 1990's.

The international market for metspar is still huge. Worldwide, the steel industry is still the largest consumer of fluorspar. However, with the spread of more efficient steelmaking processes, the unit consumption of fluorspar is expected to fall. This will probably offset overall

gains in steel production.

The aluminum industry consumes fluorine from different sources and in different forms. Although some acidgrade fluorspar is consumed directly, fluorine is also consumed in the form of aluminum fluoride and synthetic or natural cryolite. Aluminum fluoride is manufactured either directly from acidgrade fluorspar, from HF, or from fluorosilicic acid. A small amount of cryolite is imported for consumption, but most is recovered as a byproduct of waste fluorine recovery or, in the case of a new potline, by tapping an operating pot for molten electrolyte. This material, termed "molten crushed bath," is allowed to solidify and is then crushed for use in the startup of a new potline.

Consumption by the primary aluminum producers in the Western World is expected to increase at a gradual rate through most of this decade. Demand is subject to a number of industry changes in operating performance, environmental performance, and technology, plus capacity increases.

Consumption of acid-grade fluorspar by the chemical industry for the production of HF is the largest market for fluorspar. The largest use of HF is in the manufacture of fluorocarbons (CFC's, HCFC's, and HFC's); the remainder is used in chemical intermediates, glass and metal processing, petroleum alkylation, stainless steel pickling, uranium chemical production, and other small uses.

Although U.S. reported consumption of fluorspar for HF production increased in 1992, it is not known if this reflected an upturn in the replacement fluorocarbon (HCFC's and HFC's) market or increased consumption necessitated by mothballing of the Allied-Signal HF plant in Amherstburg, Ontario, Canada. The fluorocarbon producers continue to build new HCFC and HFC facilities. Allied-Signal expanded HF capacity at its plant in Geismar, LA, but the capacity increase from 104,000 tons per year to 120,000 tons per year is not sufficient to offset the lost capacity from the mothballed Amherstburg plant (52,000 tons per

There is some indication that demand

by the fluorochemical industry is increasing, but in 1992 it was insufficient to make up for decreases reported by the steel and aluminum industries. With capture and recycling now required by EPA, ongoing development of not-in-kind replacements for CFC's, and the continued decrease in demand by the steel industry, it is difficult to forecast when demand will increase. With the final phaseout of CFC's in 1995 and expected production increases by the aluminum industry, demand for acidspar should increase in the mid-1990's.

Estimated. Revised. W Withheld to avoid disclosing company proprietary data.

Does not include fluorosilicic acid (H2SiF6) or imports of hydrofluoric acid (HF) and cryolite.

²Includes 2,700 tons of nonstockpile-grade metspar from the National Defense Stockpile beneficiated by Ozark Mahoning Co.

³C.i.f. value at U.S. port.

U.S. primary and secondary production plus imports plus adjustments for Government and industry stock changes.

Apparent consumption figures were revised by deleting "minus exports" from the apparent consumption equation. All fluorspar exports are general imports that have been reexported. They do not show up in the imports for consumption, but when included in apparent consumption distort the resulting consumption figure.

⁶Includes 907 tons of nonstockpile-grade metspar from the National Defense Stockpile.

Estimated. Revised.

ⁱTable includes data available through June 1, 1993.

²In addition to the countries listed, Bulgaria is believed to have produced fluorspar in the past, but production is not officially reported, and available information is inadequate for the formulation of reliable estimates of output levels.

³An effort has been made to subdivide production of all countries by grade (acid, ceramic, and metallurgical). Where this information is not available in official reports of the subject country, the data have been entered without qualifying notes.

⁴Reported figure.

⁵Year beginning Mar. 21 of that stated.

⁶Data are reported by Consejo de Recursos Minerales.

 $^{^{7}} Principally \ submetal lurgical-grade\ material.$

⁸Data show estimated proportions of acid-grade, ceramic-grade, and metallurgical-grade fluorspar within the reported totals. Data may not add to totals shown because of rounded estimates.

⁹Dissolved in Dec. 1991. This commodity is believed to be produced in Kazakhstan, Kyrgyzstan, Russia, Uzbekistan, and possibly other former republics of the U.S.S.R.; however information is inadequate to formulate reliable estimates of individual country production.

GEMSTONES

By Gordon T. Austin

Mr. Austin, a physical scientist with more than 30 years of industry and Government experience, has been the gemstones commodity specialist since 1986. Ms. Kelly Dorney of the Branch of Data Collection and Coordination prepared the domestic production survey data.

Webster's dictionary defines a gem "as any jewel, whether stone, pearl or the like, having value and beauty that are intrinsic and not derived from its setting: a precious or, sometimes, a semiprecious stone cut and polished for ornament. A stone of value because it is carved or engraved, as a cameo or intaglio." Additionally, the dictionary states that gemstone or gem material is a stone or material from which a gem may be cut. In less formal or common terms a gem, gemstone, or gem material may be described as specimens of minerals or organic materials used for personal adornment, display, or to manufacture objects of art because they possess beauty, rarity, and durability.

In 1992, the value of natural gemstones from deposits in the United States was \$66.2 million, a decrease of 22% compared with that of 1991. Production of gemstones included faceting rough, lapidary rough, carving material, specimen material, natural and cultured freshwater pearls, mother of pearl, fossil ivory, amber, and coral.

Synthetic gemstones are grown in the laboratory but have essentially the same appearance and optical, physical, and chemical properties as the natural material that they represent. Synthetic gemstones produced in the United States include alexandrite, coral, diamond, emerald, garnet, lapis lazuli, quartz, ruby, sapphire, spinel, and turquoise. Simulants are laboratory grown gem materials that have an appearance similar to that of a natural gem material but have different optical, physical, and chemical properties. The gemstone simulants produced in the United States include coral, cubic zirconia, lapis lazuli, malachite, and turquoise. Additionally,

certain colors of synthetic sapphire and spinel, used to represent other gem stones, would be classed as simulants. Colored and colorless varieties of cubic zirconia are the major simulants produced. In 1992, the reported combined production value of U.S. synthetic and simulant materials was \$18.9 million, about a 6% increase from that of 1991.

Wholesale and retail outlets, gem and mineral shops, gem and mineral shows dealers, cutting factories, and jewelry manufacturers were the major purchasers of domestic gem materials.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines estimates U.S. production from the "Natural and Synthetic Gem Material Survey," a voluntary survey of U.S. operations, and from Bureau estimates of unreported production. Of the 380 operations surveyed, 94% responded, accounting for about 96% of the total production, 93% of the natural production, and 99% of the synthetic and simulant production.

The number of operations surveyed in 1992 was essentially the same as the number surveyed in 1991. The response rate was slightly better. The Bureau estimated the production nonresponding operations, by professional collectors, and by amateur or hobbyist collectors. The basis for these estimates were information from published data, conversations with gem and mineral dealers, analyses of gem and mineral shows and sales statistics, and from information informally supplied by collectors.

BACKGROUND

The history of production and preparation of gemstones begins with the wearing of items for personal adornment in prehistoric times; this preceded even the wearing of clothes. Amber was mined in the Baltic countries for use as a gem material before 25000 B.C. Later. the Phoenicians in their writings described their trade routes to the Baltic for amber and to areas in Asia and Africa for other gemstones. The voyages of Columbus brought increased interest in gemstone deposits, especially emerald, in South America. The discovery of diamond in Africa in 1859 focused major interest on Africa. More recently, the discovery of diamond in Western Australia in 1967 resulted in the development of the largest known diamond deposit in the world.

Commercial mining of gemstones is extensive in the United States but not as large-scale operations. More than 60 different gemstones have been produced commercially from relatively small domestic sources. In many instances, production rests in the hands of the numerous hobbyists and members of mineralogical and lapidary clubs. The Crater of Diamonds State Park near Murfreesboro, AR, is open to the public on a daily-fee basis, as are many other gemstone deposits throughout the United States. Many gem-quality stones are found at these locations each year.

Definitions, Grades, and Specifications

Select rocks, certain varieties of mineral specimens, and some organic materials, such as pearl, amber, jet, and coral, are included in gemstones data. Customarily, diamond, ruby, sapphire, and emerald are considered the major gems.

The most important qualities of gemstones are beauty, durability. uniqueness, and rarity. Beauty, indicated as splendor, purity, or attractiveness, is judged mainly according to the taste of the beholder and includes appearances as luster, transparency, brilliance, and color. Luster of a mineral or stone is independent of color and is the surface appearance in reflected light. Apart from materials that have a metallic luster, the chief contributors to luster are transparency and refractive index. In cut gems, the perfection of the polish Visible enhances the luster. imperfections impair the luster of transparent stones. However, defects, described as "jardens" or "inclusions," may enhance the beauty and value of natural rubies, emeralds, and other In some cases these gemstones. inclusions may be used to identify the country and even the mine from which the stone was recovered. Durability is measured by the resistance of a stone to abrasion, pitting, chipping, or splitting. Resistance to abrasion is correlated with relative hardness, but intrinsic brittleness and toughness indicate resistance to wear in other aspects. Rarity is an essential qualification and is more important for some stones in determining their value than their physical characteristics.

Of the approximate 2,700 mineral species, only about 100 possess all of the attributes required of a gem. Collectors of gems may not require that a gem be durable because the stone is destined for display and is not to be worn. Therefore, the number of species of gemstones may be greater than the 100 that meet all of the requirements. Silicates furnish the greatest number, including such minerals as beryl, topaz, tourmaline, and feldspar. Oxides such as corundum (ruby and sapphire) and quartz (amethyst, agate, etc.) comprise the second largest group. Sulfides, carbonates, and sulfates are of small importance: the phosphates yield primarily turquoise and variscite. An exception is pearl, essentially calcium carbonate, which is ranked high as a gem. Diamond, the best known gem, is an isometric crystalline form of the element carbon.

Gemstones are classified the same as minerals; that is, into group, species, and variety. Group refers to two or more gem materials that are similar in crystal structure and physical properties but have different chemical properties. Each individual member of the group is called a species. Varieties of species have similar crystal structure and chemical characteristics but differ in color. An example of this would be the hessonite variety of the grossular species of the garnet group.

Products for Trade and Industry

Cutting and polishing of gems from gemstones are done to obtain the most effective display of the material. No significant change is made in the fundamental properties, and the preparation is intended to enhance the desirable characteristics that are present initially. Gemstones are cut into gems in three main styles: faceted, cabochons, and baroque.

Facet cutting usually is employed on gemstones to increase transparent brilliancy and appearance. It generally is confined to the harder materials. Softer materials may be faceted, but extreme care must be exercised in cutting and polishing the stones and in their use in jewelry. Often the softer gems are used only for display and not for making jewelry. The "round brilliant" cut, most commonly used in faceting, has 58 facets, 33 above the circle "girdle" and 25 below it, arranged in eightfold symmetry. The "round brilliant" and some other common cuts are illustrated in figure 1. (See figure 1.)

Cabochons are cut in four operations: sawing, grinding, sanding, and polishing. Sawing, the initial step in cutting, is customarily done with a diamond saw to obtain a slab or slice of the desired size and thickness from the rough gemstone. The cabochon outline is scribed onto a flat surface, most often using a template for making a standard size for jewelry mountings. Rough grinding of the stone

may be by metal-bond diamond, electroplated diamond, silicon carbide, or aluminum oxide wheels or coated abrasive disks. In grinding, the hardness of the gemstone determines the grit and hardness of the abrasive used. Multiple grinding steps starting with 80- to 100mesh (grit) through 600-mesh abrasives are normally used. The scratches left by grinding are removed by progressively finer grinding and sanding. Disk or belt sanders use abrasives bonded to cloth, waterproof reinforced paper abrasives, or cloth charged with abrasive pastes. The final polish is obtained by using hard felt. wood, or leather laps, with various polishing agents such as fine diamond compound, tin oxide, tripoli, chromium oxide, cerium oxide, alumina, or rouge.

Polished irregular shapes are called baroque gems. An inexpensive method of polishing baroque gems is to tumble them in rubber-lined drums, using a grinding and polishing medium with or without water.

Industry Structure

The world market for rough diamonds is controlled to a high degree by De Beers Centenary AG's marketing arm, the Central Sales Organization (CSO). It is by far the most controlled of the world's commodity markets. estimated 80% of gem and natural industrial diamond is marketed by the The marketing is done through the CSO by the Diamond Trading Co. Ltd. and Industrial Distributors Ltd. The CSO sells uncut gem diamonds on behalf of De Beers and most other major producers at sights (approved bidder viewings) in London, England, and Lucerne, Switzerland. There are 10 such sights each year.

Diamonds reach the CSO sights through three channels—De Beers owned and operated mines, contract sales by mine owner and operators, and openmarket competitive sales.

The distribution of rough diamonds in the Republic of South Africa is determined by the South Africa Diamond Board. A new agreement was reached between De Beers Consolidated Mines Ltd., its customer, and the Government of South Africa on the method of domestic rough diamond distribution. In the past, all categories of rough diamonds that could be processed economically in South Africa must first be offered to local manufacturers. Rough could be exported duty free only if it had first been offered to the local market, otherwise a 15% duty is charged. Now, all rough will be shipped to London and mixed with diamonds from the other producers. Rough for South African cutters is then drawn from the world rough supply.

CSO has been extremely The successful at maintaining the rough diamond market for more than 50 years. In modern times there has never been a decrease in CSO's price of rough diamonds. Table 1 illustrates the timing and the amounts of the average CSO price increases for rough gem diamonds from 1949 until the present, while table 2 indicates the value of CSO's annual sales for the past 10 years. The compounded effect over 44 years of these increases is a price increase of about 1,800%. Thus, a piece of rough that sold for \$100 in August 1949 would sell for about \$1,800 in April 1991. (See tables 1 and 2.)

For more than 30 years, the major diamond cutting and polishing centers of the world were in Belgium and Israel, with a certain amount of the larger stones being cut in the United States. In the early 1980's, the development of a large cottage industry in India-today there is estimated to be more than 500,000 cutters-made a major impact on world diamond trade. India consumes most of the world's small-gem, cheap-gem, and near-gem rough material in manufacture of small stones, which resulted in annual cut-stone exports worth billions of dollars. These small stones averaged less than one-fifth of a carat (0.20 carat). The availability of small inexpensive stones resulted in substantial changes in the design of jewelry. The utilization of small cut diamond stones (usually 0.07 to 0.14 carats each, called melee) to create a pavè effect (set close together to conceal the metal base) is but one example.

It is estimated that the Russian's

diamond cutting industry employs about 16,000 workers. The eight Krystall factories at Moscow, Smolensk, Kiev, Barnaul, Vinnitsa, Yerevan, Kusa, and Gomel employ fewer than 8,000, with the Moscow plant having about 900 workers. The workers at the various factories may be paid by different methods.

The workers at the Moscow plant are paid by the piece according to its size and difficulty of the cut. At Kiev, those workers whose work is not subject to inspection receive a 50% higher salary. Some of the Krystall factories have an incentive program for workers producing stones of 0.3 carats and larger. The incentive is a bonus of 5% of the added value that is paid to each 20-worker team and is shared by the team.

Annual cut diamond production is a function of the number of workers in the industry and their productivity. If it is assumed that the industry has a production rate of 20 carats of finished goods per month per worker and that polished yields are less than 40%, then the industry's consumption of rough and yield of finished goods can be estimated. It is estimated that during a year, the Russian diamond cutting industry processes about 3.8 million carats of rough that yields about 1.6 million carats of polished goods. The polished goods would be worth between \$500 million and \$550 million on the world market.

During 1991, Leo and Schachter & Co. opened the United States' newest, largest, and most modern diamond polishing factory in New York. The factory is fully computerized to track every diamond from rough to finished stone. The computer predicts the cash return from each piece of rough based on estimates of the rough's color, clarity, yield, and make; estimates are reported to be within 2% of actuals. The factory employs 40 polishers.

Cutting and polishing of colored, synthetic, and simulant gemstones is centered in, listed according to importance, Thailand, India, Hong Kong, Republic of Korea, China, and Brazil, where cheap labor and favorable export laws ensure the lowest total costs for finished gems.

Geology-Resources

Gemstones are found in a large variety of igneous, metamorphic, and sedimentary deposits, usually as a small fraction of the total deposit. The origins are as varied as the deposits. Gemstones form primarily by precipitation from watery solutions, by crystallization from molten rock, and by metamorphic processes. Approximately one-third of gemstones is composed of silicate minerals, about one-fifth of aluminasilicates, and almost one-seventh of oxides. The remaining compositional groups include the sulfides, phosphates, borosilicates, carbonates, and, in the single case of diamond, an element. The composition of selected gem materials is included as one of the items in table 3. (See table 3.)

There are no large resources of major gem materials defined in the United States. Emerald deposits are known in North Carolina, as are ruby and sapphire. Historically, sapphires have been mined in Montana, and significant commercial mining once again is underway. Numerous other domestic deposits of gemstones are known and have been mined for many years. However, no systematic evaluations of the magnitude of these deposits have been made, and no positive statements can be made about their reserve or the size of the resource.

Occasional finds of diamond have been made, but no great diamond pipes or alluvial deposits similar to those of Africa have been reported. Several companies are involved in diamond exploration in the Colorado-Wyoming State line area, in Michigan, Minnesota, Wisconsin, and Arkansas. Diamond-bearing kimberlites have been located and bulk samples have been processed for diamond recovery. Results have not been made public.

World resources of gemstones are nearly all unevaluated. However, world gem diamond reserves are estimated to be about 300 million carats, including neargem and cheap-gem qualities. Nearly all of the reserves are in, listed in order of size, Australia, Africa, and Russia (Siberia). The estimates for diamond reserves are of limited value because data

needed for reliable estimates are not available from the producers. Reserve data on other gemstones are even less available than for diamond.

Technology

Synthetic Gems.—Synthetic gemstone production uses many different methods, but they can be grouped into one of three types of processes: melt growth, solution growth, or extremely high-temperature, high-pressure growth.

The year 1902 saw the first production of synthetic ruby using the Verneuil flame-fusion process. Later, sapphire, spinel, rutile, and strontium titanate were grown with this technique. In this process, a single crystal, called a boule, forms in the flame of a simple, downward-impinging oxygen-hydrogen blowtorch. Pure oxides of aluminum (in the cases of ruby, sapphire, and spinel) or titanium (rutile and strontium titanate) are poured into the top of a small furnace and melted. Other oxides are added as needed for process control and to obtain the specific color desired. The melted material solidifies as a boule on a rotating fire-clay peg as the peg is slowly withdrawn.

A boule has a very characteristic shape, with a rounded end, a long, cylindrical body, and a tapering end. It is usually about 13 to 25 millimeters in diameter, 50 to 100 millimeters long, and weighs 75 to 250 carats (a carat is 200 milligrams). Under controlled conditions, a boule about 5 millimeters in diameter and more than 890 millimeters for long can be produced manufacturing of jewel bearings.

Another melt technique is the Bridgman-Stockbarge solidification method, named for an American, P.W. Bridgman, and a German, D.C. Stockbarge, who, aided by three Russians, J. Obreimov, G. Tammann, and L. Shubnikov, discovered and perfected the process between 1924 and 1936. Currently, the method is used primarily for growing nongem halide, sulfide, and various metallic oxide crystals, one of the metallic oxides being aluminum oxide or sapphire.

The Bridgman-Stockbarge process uses a specially shaped crucible, which is a cylindrical tube open at one end and capped at the other by a small, pointed cone. The crucible is filled with the powdered chemicals necessary to grow a specific crystal and is lowered slowly through a furnace. The small, pointed end of the cone cools first because it is the first part of the crucible that moves from the hottest part of the furnace into cooler regions and it is the first part to emerge from the furnace. As the crucible cools, the molten materials solidify, hopefully in the structure of a single crystal, in the point of the crucible. The crystal then acts as a seed around which the remainder of the molten material solidifies until the entire melt has frozen. filling the container with a single crystal.

This process is simple, and crystals of various sizes can be grown. The crystals are typically about 51 millimeters in diameter and 15 millimeters in length, but large ones exceeding 890 millimeters diameter and weighing more than 1 metric ton have been grown. The crystals have the same shape as the crucible.

The Czochralshi pulled-growth method is used for ruby, sapphire, spinel, yttrium-aluminum-garnet (YAG), gadolinium-gallium-garnet (GGG), and alexandrite. Czochralshi developed his method about 1917 while working with crystals of metallic nutrients.

In the Czochralshi method, ingredient powders—nutrients—are melted in a platinum, iridium, graphite, or ceramic crucible. A seed crystal is attached to one end of a rotating rod, then the rod is lowered into the crucible until the seed just touches the melt. Then the rod is slowly withdrawn. The crystal grows as the seed pulls materials from the melt, and the material cools and solidifies. Yet, because of surface tension of the melt, the growing crystal stays in contact with the molten material and continues to grow until the melt is depleted of the desired material.

Typically, the seed is pulled from the melt at a rate of 1 to 100 millimeters per hour. Crystals grown using this method can be very large, more than 51

millimeters in diameter and 1 meter in length, and of very high purity. Each year this method grows millions of carats of crystals for use as gems, laser rods, windows for special scientific or technical applications, and for other industrial applications.

Certain gemstones pose unique problems with regard to attempts to grow them. The problems arise because certain materials are either so reactive that they cannot be melted even in unreactive platinum and iridium crucibles or they melt at much higher temperatures than the crucible materials can endure. Therefore, another melting system must be used, called the skull melting system. Cubic zirconia, because of its high melting point (2,700° C) must be grown using the skull melting method.

The "skull" is a hollow-walled copper Water is circulated through the hollow walls to cool the inside wall of the skull. The cup is filled with powdered ingredients and heated by radio frequency induction until the powders melt. Because the water cools the walls of the skull, the powdered materials next to the walls do not melt, and the molten material is contained within a shell of Therefore, the unmelted material. reactive or high-temperature melt is contained within itself. When the heat source is removed and the system is allowed to cool, crystals form by nucleation and grow until the entire melt solidifies. Crystals grown using this system vary in size, depending on the number of nucleations. In growing cubic zirconia, a single skull yields about 1 kilogram of material per cycle.

Solution techniques for making synthetic gems include flux methods for emerald, ruby, sapphire, spinel, YAG, GGG, and alexandrite. The other solution method is the hydrothermal method, often used for growing beryl (emerald, aquamarine, and morganite) and quartz.

Quartz crystals are grown in a hydrothermal solution in large pressure vessels known as autoclaves. Careful control of temperature and pressure in the different areas of the autoclave result in the feed material, known as lascas,

dissolving in the hotter portion. The material redeposits on seed crystals, located in the cooler portion, forming synthetic quartz crystals. The process usually takes 30 to 60 days for the crystals to reach the desired size. The process can also produce rock crystal, amethyst, or citrine.

The same system is used to grow beryl crystals. Beryl seed crystals are suspended in the cooler upper portion of an autoclave. Nutrient materials dissolve in the hotter, lower portion of the autoclave and, because of the temperature and pressure gradients, migrate to the cooler seeds and are deposited.

Other techniques involve solid- or liquid-state reactions and phase transformations for jade and lapis lazuli; vapor phase deposition for ruby and sapphire; ceramics for turquoise, lapis lazuli, and coral; and others for opal, glass, and plastics.

The Verneuil, Czochralshi, and skull melting processes are the melt techniques most often used for gem materials. The various synthetics and the method of production are shown in table 4. (See table 4.)

Enhancement of Gemstones.-Enhancement of all types of gemstones through chemical and physical means has become much more commonplace and in the past few years has included a wider variety of materials. Irradiation by electromagnetic spectrum (X-rays, gamma rays, etc.) and by energetic particles (neutrons, electrons, alphas, etc.) is being used to enhance or change the color of diamonds, topaz, tourmaline, quartz, beryl, sapphire, zircon, scapolite, and pearls. Blue topaz is normally irradiated, but this does not imply that all of these gem materials are regularly irradiated.1

Many gemstones can be enhanced by chemical treatment or impregnations. The treatments may alter the bulk of the gem material or only penetrate the surface. This includes bleaching, oiling, waxing, plastic impregnations, color impregnations, and dyeing. The treatments that alter only the surface of the material include surface coatings of

various types, interference filters, foil backings, surface decoration, and inscribing. Chemical treatment is more widespread than just the common dyeing of quartz, treatment of turquoise, and oiling of emeralds. Chemical treatment and impregnations have been used to enhance amber, beryl, chalcedony, coral, diamonds, emerald, ivory, jade, lapis lazuli, opal, pearl, quartz, ruby, sapphire, tiger's eye, and turquoise.²

Since about 1987, fractures, cleavages, and other void-type imperfections that reach the surface in diamonds have been filled using a process developed by Mr. Zvi Yehuda, of Ramat Gan, Israel. This treatment can enhance that apparent clarity of treated faceted diamonds; examples are available that show SI stones enhanced to VS and I₁ improved to SI₂. Yehuda also has developed a similar treatment for emeralds.

The oldest and most common method of gemstone enhancement is heat treating. Heat treatment of gem materials was used in Greece and Rome well before the Christian Era. Heat treatment can cause color change, structural change, and improve clarity. In the past, heat treatment was common for quartz and gem corundum. Today, materials that are heat treated to enhance their appearance include amber. bervl. diamond, quartz, ruby, sapphire, topaz, tourmaline, zircon, and zoisite.3

Recently, an additional type of treatment for sapphire has appeared diffusion treatment, a chemical-heat treatment. In this process a thin layer of color is diffused into the surface of the gem. The color may be diffused as little as 0.1 millimeter or as much as 0.4 millimeter into the gem. The treatment is a long process of heat treatment in a bath of chemicals containing the proper proportions of titanium and iron. The American Gem Trade Association (AGTA) adopted a policy for the disclosure of diffusion treated sapphires. The policy is "If the color of a gemstone is confined to an area near the surface so that the color of the stone would be affected by recutting repolishing then the following statement must also appear: Although the color induced in the diffusion treated sapphire is permanent, it remains confined to a shallow surface layer." Therefore, recutting or repolishing is not recommended.⁴

Mining.—Gemstone mining operations can range from the most primitive to the most sophisticated. In hard rock, at shallow depths, an operation by one, two, or three persons may be mined by prybar, pick, shovel, and buckets or baskets for carrying material; often drilling and blasting is employed. A larger operation includes drilling, blasting, and minimum timbering. Mechanized hauling and hoisting is done only at the larger mines.

Diamond mining in the kimberlite pipes of Africa and Russia and the lamproite pipes of Australia represent the ultimate in that huge quantities of ore must be mined to extract small quantities of diamond (20 to 30 carats per 100 tons of ore) produced at as low a cost as possible.

Placer mining for gemstones ranges from small-scale, simple procedures to huge, complicated operations. In some areas, digging is by hand, and sorting and recovery is by panning, screening, or sluicing. Diamond miners in the larger placer operations use bucket dredges and heavy-duty excavating equipment, as, for example, in Australia, Brazil, Namibia, the Republic of South Africa, and Russia.

Processing.—Most gemstone ores are broken or crushed where necessary and concentrated by various combinations of hand picking, washing, screening, or jigging. In large-scale operations. mineral beneficiation methods are mechanized and employ the latest technology in each step from primary crushing and screening to the final recovery processes. Diamond recovery. in particular, makes use of standard methods, gravity grease belts, electrostatic separation, skin-flotation, magnetic separation, separation by X-ray luminescence, and separation by optical sorting.

ANNUAL REVIEW

Production

In 1992, all 50 States produced at least \$1,000 worth of gem materials. States accounted for 83% of the total value of production of natural gemstones. The States, in order of declining value of production, were Tennessee, California, Arizona, Louisiana, Texas, Oregon, Oklahoma, Iowa, Arkansas, and North Carolina. Certain States were known best for the production of a single gem material (i.e., Tennessee for freshwater pearls and Arkansas for quartz). Other States produced a variety of gemstones. Arizona produced the greatest variety. Production included agate, amethyst, antlerite, azurite, chrysocolla, fire agate, garnets, jade, malachite, obsidian, onyx, peridot, petrified wood, precious opal, shattuchite, smithsonite, and turquoise. California, Idaho, Montana, and North Carolina also produced a variety of gemstones. Historically, North Carolina is the only State to have produced all four of the major gems: diamond, emerald, ruby, and sapphire.

The average production value of natural gem materials for the past 10 years was \$34.9 million per year, with a high of \$84.4 million in 1991 and a low of \$7.4 million in 1983. The value of production for the past 10 years must be separated into two trends. The first trend was the period between 1981 through 1985, during which time approximately 24 operations reported production. Production averaged \$7.4 million per year and was generally level. In the second trend, 1986 to the present, production averaged \$45.7 million and was the result of an increase of 1,567% in the number of producers surveyed.

The reported value of synthetic and simulant gemstone production was \$18.9 million in 1992, an increase of 6% over that of 1991. The average value of production of these gem materials for the past 7 years was \$16.9 million, with a high of \$20.5 million in 1990 and a low of \$10.3 million in 1986. Fourteen firms, four in California, four in

Arizona, and one each in Massachusetts, Michigan, New Jersey, North Carolina, Ohio, and Washington, produced synthetic and simulant gem material. The eight States, in order of declining value of production, were California, Massachusetts, Arizona, New Jersey, Washington, North Carolina, Michigan, and Ohio.

Arizona is well known for the widest variety of gemstones produced by any State. In 1992, these included agate, amethyst, antlerite, azurite, chrysocolla, fire agate, fluorite, garnet, jade, jasper, malachite, obsidian (Apache tears), onyx, peridot, petrified wood, precious opal, shattuchite, smithsonite, and turquoise. Yet, turquoise, peridot, petrified wood, and azurite-malachite accounted for more than 90% of the total value of gem material produced. Production from Arizona of these gemstones was the largest in terms of dollar value in the United States and the world's largest for Additionally, four the first two. manufacturers of synthetic or simulant gem materials were in Arizona and produced about \$1.8 million worth of material.

Arkansas is famous for the production of quartz crystals, but it appears that the fads that have supported the production of quartz crystals for the past few years has ended. It is second in value of production of freshwater pearls and shells and the only State in the United States that has had any sustained diamond production.

Since 1972, hobbyists have found from 300 to 1,500 diamonds per year at the Crater of Diamonds State Park. From 1906 to the present, it is estimated that production from the deposit is 100,000 to 150,000 carats; this amount of diamond production is insufficient to classify the United States as a diamond-producing country. Still, the potential to become a diamond producer may be there, and efforts were underway to evaluate this potential more fully. A four phased program to evaluate the diamond deposit was halted by legal actions after completing three exploratory drill holes in 1990. After a Federal appellate court cleared the way for the program to

continue, phase 1, the drilling of 26 core holes totaling 2,600 meters, was completed during 1992.

Gemstone production from California of materials. includes a variety Tourmaline production from the State is the largest in the Nation, and California has the only producer of benitoite. Additionally, agate, alabaster, beryl, dumortierite, fire agate, freshwater mussel shell and pearls, garnet, gem feldspar, jade, jasper, kunzite, lepidolite, obsidian, quartz, rhodonite, topaz, and turquoise are produced from deposits in the State. Yet, even with this long list of gemstones, most people think of California in terms of its State gem benitoite, its high-quality tourmalines, and its fine orange spessartine garnets.

The State also has a freshwater culture pearl farm at Marysville. The farm uses animals imported from Tennessee and other southeastern States. Production includes pearls, shell, and finished nucleus for cultured pearl implants.

California also has four manufacturers of synthetic or simulant gemstones. The value of production from the State is the largest of any State for synthetics and simulants.

Colorado is not known as a gemstone-producing State, but it does hold some gemstone honors. It has the only commercially mined deposit of lapis lazuli in the United States and one of the few fee-for-dig topaz deposits currently operating. Additionally, the State was the first to commercially produce turquoise and still has commercially operated turquoise mines. It also produced the United States' finest gem-quality rhodochrosite and a quantity of high-quality rhodonite.

Many different locations in the State produce aquamarine, the Colorado State gemstone. The best known locations and the locations with the longest history of continued production (since about 1884) are Mount Antero and White Mountain in Chaffee County. Mount Antero, at 4,349 meters, may be the highest gemstone location in the United States. White Mountain, separated from Antero by a small saddle, is only slightly lower at 4,237 meters.

Star garnet, the Idaho State gemstone, leads the list of gemstones produced in the State. Idaho is one of two places that produce significant amounts of star garnet; India is the other. These almandite garnets are translucent. purplish-red stones that show four- or sixray stars when cabochon cut or are transparent deep red stones that can be faceted. The primary sources of Idaho star garnet are the placer deposits on the East Fork of Emerald Creek and its tributary gulches in Benewah County. Additionally, the placers of Purdue Creek in Latah County yield star garnets. Currently, garnets that do not cut stars also are commercially mined from areas in Clearwater County. These garnets range from purplish rose-red to a highly prized "special pink." Gem-quality garnets are found at several other locations in Idaho and are mined periodically by hobbyists or professional collectors for the gemstone market.

Opal is the second largest contributor to the total value of gemstone production in Idaho. The varieties produced include precious, yellow, blue, pink, and common. The Spencer opal mine is the largest producer. At the Spencer Mine, precious opal occurs as one or more thin layers within common opal that have partially filled gas cavities within a rhyolite-obsidian flow. About 10% of the material is thick enough to cut into solid gems; the remainder is suitable for making doublets and triplets. Spencer Mine is also the source of the pink opal, which occurs as either pink common opal or pink bodied precious opal.

In the U.S. gemstone industry, Maine and tourmaline are almost synonymous. In 1822, Maine's Mount Mica was the site of the first gemstone production in the United States. In 1992, Plumbago Mining Corp. was actively mining the Mount Mica pegmatite for gem material and mineral specimens. Over the years, production from Mount Mica has included hundreds of kilograms of fine-quality gem and mineral specimen tourmaline.

Mount Mica is not the only large producer of high-quality tourmalines.

Dunton Mine of Newry Hill is the most prolific gem tourmaline producer in Maine. Since its discovery in 1898, the mine has produced tons of gem- and specimen-grade tourmaline. Other mines and quarries in a three county area produce gem- and mineral specimengrade tourmalines. These include the Bennett, BB #7, Emmons, Harvard, Tomminen, Waisenen, Black Mountain and Red Hill Quarries, and Nevel Mine in Oxford County. It also includes the Mount Apatite Quarries in Androscoggin County and the Fisher and Porcupine Hill Quarries in Sagadahoc County.

Production from Maine deposits also includes fine-quality beryls—aquamarine, heliodor, and morganite. Pegmatites in Oxford, Androscoggin, and Sagadahoc Counties regularly produce fine-quality blue and blue-green aquamarine, rich yellow- and gold-colored heliodor, and rose- and peach-colored morganite.

Montana produces many different gemstones, some suited for faceting, while others are better suited for the cutting of cabochons, carvings, or objects-of-art. Montana is noted for the production of sapphires, Montana moss agate, and Dryhead agates. Yet, amethyst, amazonite, azurite, covellite, cuprite, garnet, onyx, opal, petrified wood, rhodochrosite, rhodonite, smokey quartz, sphalerite, and wonderstone (banded rhyolite) also are produced or have been produced from deposit in the State for use as gemstones.

Sapphires have been produced from Montana deposits since 1865. In recent years, Montana sapphire has gained in popularity, and because of the improved popularity, production has increased significantly. Currently, commercial sapphire production is from deposits on the Missouri River in Lewis and Clark County, the Rock Creek area in Granite County, and from the Yogo Gulch area in Judith Basin County. Additionally, there are fee-for-dig sapphire operations on the Missouri River and Rock Creek.

Nevada has been a major producer of turquoise since the 1930's, and until the early 1980's, the State was the largest turquoise producer in the United States. Estimates indicate that over the years, 75

to 100 different mines and/or prospects have produced sizable quantities of turquoise. Production varied from a few thousand dollars worth of material at some properties to more than \$1 million at others. Estimates of total production to date are between \$40 to \$50 million.

Precious opal production from deposits in the Virgin Valley area began in about 1906. The opal from Virgin Valley is comparable to any in the world for its vivid play of color and is unsurpassed in terms of the size of material available. The material varies in color from deep pure black to brown to yellowish-white to white to colorless. The play of color includes all the colors common to precious opal-red, blue, green, yellow, orange, and so on. The opal is found primarily as replacement of wood, or sometimes, the replacement of cones of conifer trees. The use of the opal is greatly restricted because of a severe problem with crazing. Currently, two mines in Virgin Valley are open to individuals on a fee-for-dig basis during the summer months. The operators of these mines also mine the deposits for their own inventories.

North Carolina is the only State in the United States where all four major gem materials, diamond, ruby, sapphire, and emerald, have been found. During 1988 was the last time all four major gemstones were found in the same year. The diamond was found in a gold placer mine, rubies and sapphires were recovered from the Cowee Valley, and emeralds were found near Hiddenite and Little Switzerland.

Production of ruby and sapphire from deposits along the Cowee Valley in Macon County began in 1895 when the American Prospecting and Mining Co. systematically mined and washed the gravels of Cowee Creek. Today ruby, sapphire, and fee-for-dig operations are in the Cowee Valley. Many people pay to dig or purchase buckets of gravel to wash to recover gem corundum, garnets, and other gemstones.

Historically, Oregon has been known for the production of various picture and scenic jaspers, agates, thundereggs, petrified wood, and to a certain degree, gem labradorite. Oregon's State rock, the "thunderegg," may be the best known gem material from Oregon. Graveyard Point, Priday, and Polka Dot are names that are uniquely associated with beautiful Oregon agates. The same is true for the relationships between the names Biggs, Deschutes, and Sucker Creek and picture or scenic jasper. Yet, gem labradorite (sunstone) is currently the largest single contributor to the value of annual gemstone production in At least seven firms or Oregon. producing individuals currently are sunstone from three different geographic areas.

The other gemstone to contribute significantly to the value of production from Oregon is opal. During 1988, the first significant commercial mining and marketing of a variety of very fine quality opals from Opal Butte began. The varieties include hyalite, rainbow, contra luz, hydrophane, crystal, fire, blue, and dendritic. Exquisite stones as large as 315 carats have been cut from contra luz rough from this deposit.

Tennessee has the largest U.S. production of freshwater mussel shells and pearls of the 11 producing States. There has been an established U.S. freshwater mussel fishing industry since the mid-1850's. The mussels are from the family Unioidae, of which about 20 different species are commercially harvested. During 1992 the value of U.S. mussel shell exports was more than \$43 million.

To date, freshwater pearls from the United States have been a byproduct of the shell industry. With the coming of the freshwater cultured pearl farms in Tennessee and the increasing popularity of freshwater pearl jewelry with the U.S. consumer, this may change. Since the technology for culturing freshwater pearls was proven in the late 1970's, six freshwater pearl farms have been established. These farms are the beginning and heart of the U.S. pearl industry.

In Wisconsin and Michigan, 12 kimberlite pipes have been identified on exploration holdings, 7 have yielded microdiamonds, and 3 have not been

tested.

Utah topaz is not well suited for use as a gem, but it does make a fine mineral specimen. Topaz crystals have been collected from certain rhyolite flows in the Thomas Mountains and the Wah Wah The crystals from the Mountains. Thomas Mountains are predominately small, 10 to 20 millimeters long and 4 to 6 millimeters across, and crystals from the Wah Wah Mountains are even smaller. Occasionally, large gem-quality crystals are found. The color of the topaz varies from colorless, to light yellow, sherry brown, rose, or light pink. The light yellow to sherry brown color fades to colorless if exposed to sunlight or heat and rose or light pink colored crystals are rare. Because of the size of the crystals and problem with color fading, the material yields only small to very small colorless stones.

Another Utah gemstone is variscite, first produced in about 1893 near Fairfield. The latest recorded commercial production was from near Lucin during the summer of 1992. Variscite is found as fracture fillings or as nodules. The nodules may be solid, almost geode in nature, or fractured solid nodules that have undergone alteration. The color of the variscite varies from a shade of light to dark yellow-green, but can be a dark, nearly jade green and so pale as to appear almost white. It also can have black and brown spiderwebbing.

Another material from Utah is snowflake obsidian. Snowflake obsidian (also known as flower obsidian) earns its name from the bluish-white or grayish-white patterns of cristobalite included in the normally black obsidian. During 1992, two different firms produced this material commercially.

The red beryl from the Wah Wah Mountains is the most remarkable and desirable of Utah's gemstones. Bixbite, the variety name for red beryl, is found in rhyolites at several locations in the Thomas and Wah Wah Ranges. The beryl varies in color from a pink to bright red, with the bright red being what could be called strong raspberry-red. The material from most of the locations is not as spectacular, either in crystal size or

color, as the crystals from the Violet claims in the Wah Wah's.

The Violet claims in the Wah Wah's are the only known location for commercial production of red beryl. In recent years, the claims have furnished a small but steady supply of materials for both mineral specimens and a few finequality gems. The crystals average about 10 millimeters in length, and most are Because of the size of the flawed. crystals and flaws, finished stones only average about 0.40 carats with few more than 1 carat. The largest finished stone to date is only 4.46 carats. The material is expensive, but justifiably so, because of its beauty and rarity.

Certain other States that produce a single gem material of note are: Alaska with its two jade mines; Florida's agatized coral; Hawaii's black coral; Minnesota's thomsonite; New York's herkimer quartz; Ohio's flint; and South Dakota's rose quartz.

The value of 1992 production by individual gemstone can be reported for those materials that have three or more producers and if one of the three does not account for more than 75% of the total or two of the producers account for 95% or more of the production. (See table 5).

Consumption and Uses

Consumption of domestic gemstones was in the commercial and amateur manufacture of jewelry, for exhibit in gem and mineral collections, and for decorative purposes in statuettes, vases, other art objects, and certain industrial applications.

Frequently, tourmaline is used as a standard for calibrating piezoelectric manometers and testing devices. It is also a control substance in boron experiments because it is itself an inert boron-containing compound. Tourmaline is the standard used in tests to check possible effects of water-soluble boron in fertilizers.

Many scientific and industrial instruments use tourmaline. One such use is tourmaline tongs, a simple laboratory instrument that shows the polarization of light. Because tourmaline is both

pyroeletric and piezoelectric, meaning it generates electricity when heated or compressed, it is a component of instruments for measuring high pressures and fluid compressibility. Thermal dosimeters, which were early instruments that measured the intensity of radium emanations, depended upon tourmaline's pyroelectric properties.

Once the mark of a top-rated watch or timepiece was that it was Swissmade and had 18 or 21 ruby or sapphire jewel bearings. Originally, these jewel bearings were made from natural ruby and sapphire. Later, the availability of inexpensive synthetic gemstones allowed the natural materials to be replaced in the manufacture of jewel bearings.

Why are ruby and sapphire used as bearings? Because ruby and sapphire, color variations of the mineral corundum, are second only to diamond in hardness; they have no cleavage (cleavage being the tendency for a crystallized mineral to break in certain definite directions, indicating a minimum value of cohesion in the direction easy fracture) and thus they are very durable; they have a very low coefficient of friction when highly polished; they are chemically inert; and they can be cut and polished without great difficulty.

Watches were not the only instruments in which sapphire and ruby bearings were used. Most precision gauges in aircraft and boats depend upon jewel bearings, as do many gauges, meters, and other instruments in manufacturing and chemical plants. The military is still highly dependent on jewel bearings for many of its high-tech weapons systems. Recently, another use for one type of jewel bearing appeared—as connectors for optical fibers.

In recent years, technological advances allowed the growth of large, high-quality synthetic ruby crystals, called laser ruby, for the manufacture of laser rods. Several other synthetic gemstones also are being produced for lasers, including chromium-doped chrysoberyl (dope being an element added to the crystal growing nutrients to achieve a particular color), synthetic alexandrite, and varieties of doped yttrium-aluminum-garnet (YAG).

Lasers require high-purity, optically perfect crystals. The crystal must be large enough so that a laser rod can be cut from the raw crystal, and the mineral or material must have the correct physical properties to allow light amplification without the necessity of excessive energy. Synthetic ruby, sapphire, and YAG have all these characteristics.

Over the years, both natural and synthetic corundum has been ground and graded as an abrasive. Corundum was the major compound used in the polishing of eyeglass lenses. While industrial diamond has replaced much of the corundum used in the lens-polishing industry, some polishers still use corundum for specialized lenses.

Other gem materials have enjoyed limited uses in nongem applications. The abrasive and ceramic industries use topaz as a raw material because of its hardness and chemical features. Once, lenses for eyeglasses were made from gem-quality beryl—if the morganite variety of beryl were used, one would truly be looking at the world through rose-colored glasses. Mortar and pestle sets, knife edges for balances, textile rollers, and spatulas are some nongem uses of agate.

Some industrial applications requiring clean homogeneous stones used low-quality gem diamond. The quantity of natural and synthetic industrial-grade diamonds used in the United States each year is 12 to 15 times greater than the amount of diamonds consumed by the jewelry industry.

The 1992, estimated value of U.S. apparent consumption was \$3,226 million, down about 13% from 1989's record high. The average annual estimated consumption for the past 10 years was \$3,148 million, with a high of \$3,705 in 1988 and a low of \$2,132 in 1983. The trend for estimated consumption for the past 10 years was one of continued growth with some downward adjustments related to economic conditions.

In 1992, the value of U.S. estimated apparent consumption of diamonds increased about 8% to \$2.8 billion. The average annual value of apparent consumption of diamonds for the past 10

years was \$2.6 billion, with a high of \$3.1 billion in 1989 and a low of \$2.1 billion in 1983.

The 1992 estimated apparent consumption of colored stones, led by emerald, ruby, and sapphire, was valued at \$392.0 million, a decrease of 3%. The estimated apparent consumption of pearls—natural, cultured, and imitations was \$19.1 million, a slight decrease. The average annual consumption for the past 10 years was \$155.3 million, with a high of \$244.7 million in 1984 and a low of \$16.5 million in 1990. **Estimated** apparent consumption of synthetic and imitation gemstones increased about 464% to \$117.9 million. Average apparent consumption of these materials for the past 10 years was \$62.6 million per year, with a high of \$117.9 million in 1992 and a low of \$17.2 million in 1983. During 1992, sales in retail jewelry stores increased about 4% to \$14.4 billion. according to the U.S. Department of Commerce.

Prices

Demand, beauty, durability, rarity, freedom from defects, and perfection of cutting determine the value of a gem. In establishing the price of gem diamond, the CSO's control over output and prices of diamond rough also is a major factor.

The average U.S. wholesale asking price of the top 25 grades (D through H color and IF through VS2 clarity) of a 1-carat diamond fluctuated between \$7,208 and \$7,256, and was \$7,208 at yearend. The average value per carat of all grades, sizes, and types of gem-quality diamond imports was \$443, a 14% decrease compared to that of 1991. The average value of diamond imports for the past 10 years was \$408 per carat, with a high of \$525 in 1990 and a low of \$353 in 1984.

The average yearend wholesale purchase price of a fine-quality 1-carat ruby, paid by retail jewelers on a per stone or memo basis, was \$3,900, the same as that of 1991. The average value of ruby imports decreased slightly to \$29.53 per carat. The average annual value of ruby imports for the past 10 years was \$36.67 per carat, with a high

of \$48.71 in 1990 and a low of \$16.42 in 1984.

The average yearend wholesale purchase price of a fine-quality 1-carat sapphire, paid by retail jewelers on a per stone or memo basis, was \$1,400, the same as that of 1991. The average value of sapphire imports decreased 30% to \$16.29 per carat. The average annual value of sapphire imports for the past 10 years was \$22.40 per carat, with a high of \$27.97 in 1987 and a low of \$16.29 in 1992.

The average yearend wholesale purchase price of a fine-quality 1-carat emerald, paid by retail jewelers on a per stone or memo basis, was \$2,750, the same as for 1991. The average value of emerald imports increased 72% to \$72.23 per carat. The average annual value of emerald imports for the past 10 years was \$57.30 per carat, with a high of \$78.79 in 1988 and a low of \$35.06 in 1984. (See tables 6 and 7).

Foreign Trade

The value of diamond exports plus reexports decreased 5% to \$1.45 billion. The quantity of cut diamonds exported and reexported decreased 10% to 911,419 carats, and the value of diamond exported and reexported decreased slightly to \$1.32 billion.

The value of other precious stones, cut but unset or rough other than diamonds, pearls, and synthetics, exported and reexported increased from \$105.5 million to \$241.2 million. The value of synthetic gemstone exports plus reexports decreased slightly to \$21.2 million.

The value of natural, cultured, and imitation pearls, not set or strung, exports and reexports of pearls increased 62% to more than \$6.7 million.

The value of gems and gemstones imported increased 4% to \$4,839.4 million compared to those of 1991, but was still below the 1989 record high of \$5,115 million. The value of imported gem diamonds accounted for about 86% of the total. The average annual value of gems and gemstones imports for the past 10 years was \$4,272 million, with a high of \$5,115 million in 1989 and a low of

\$2,856 million in 1983.

The value of imported gem diamonds increased 4% to \$4,143.6 million, but was below the 1989 record high of \$4,358 million. The imports of cut diamonds increased 15% in quantity and 5% in value to 7.7 million carats and \$3,648.6 million, respectively. The average annual quantity of cut diamonds imported for the past 10 years was 7.3 million carats, with a high of 8.9 million in 1989 and a low of 5.2 million carats in 1983. The average annual value of cut diamond imports was \$3,130.0 million, with a high of \$3,805.5 in 1989 and a low of \$1,982.7 million in 1983.

The value of imports of other gem and gemstones, led by emerald, ruby, and sapphire, was \$668.2 million, a decrease of about 26% compared to that of 1991. Emerald imports increased 29% to \$213.5 million. The average annual value of emerald imports for the past 10 years was \$164.6 million, with a high of \$213.5 million in 1992 and a low of \$134.1 million in 1983.

The value of ruby imports increased 10% to \$77.8 million, but was less than the record-high value for the past 10 years of \$98.4 million in 1990. The average annual value of imports for the past 10 years was \$76.1 million, with a high of \$98.4 in 1990 and a low of \$58.7 in 1987. The value of sapphire imports was \$75.1, a decrease of 8% compared to those of 1991. The average annual value of sapphire imports for the past 10 years was \$82.9 million, with a high of \$100.0 million in 1989 and a low of \$70.8 million in 1985.

The value of imported gem materials other than diamond, emerald, ruby, and sapphire increased 35% to \$327.7 million. The average annual value of imports was \$338.9 million, with a high of \$429.5 in 1988 and a low of \$210.3 in 1990. (See tables 8, 9, 10, 11, and 12).

World Review

Diamond sales by De Beers Centenary AG was \$3.4 billion in 1992, a decrease of 13% compared with 1991 sales of \$3.94 billion. Sales during the second half of 1992 were only \$1.63 billion,

12% less than the \$1.84 billion sales for the second half of 1991. A De Beers official stated that the reduction in sales was the result of the world economic conditions. De Beers controls about 80% of the rough, uncut diamonds sold in the world. Sales of colored stones remained strong.

Natural diamond production occurs in Africa, Asia, Australia, and South America. The principal producing localities are as follows: in Africa—Angola, Botswana, Namibia, the Republic of South Africa, and Zaire; in Asia—Russia (northeastern Siberia and in the Yakutia); in Australia; and in South America—Venezuela and Brazil.

Foreign countries in which major gemstone deposits (other than diamond) occur are Afghanistan (beryl, kunzite, ruby, tourmaline); Australia (beryl, opal, sapphire); Brazil (agate, amethyst, beryl, kunzite, ruby, sapphire, tourmaline, topaz); Burma (beryl, jade, ruby. Colombia (beryl, sapphire, topaz); sapphire); Kenya (beryl, garnet, Madagascar (beryl, rose sapphire); quartz, sapphire, tourmaline); Mexico (agate, opal, topaz); Sri Lanka (beryl, Tanzania topaz); ruby, sapphire, garnet, ruby, sapphire, (tanzanite, tourmaline); and Zambia (amethyst, bervl).

Angola.—Odebrecht, a Brazilian company, purchased modular diamond recovery plants from Van Eck & Lurie for use on its diamond projects in Angola. Odebrecht is undertaking projects in Quango Province on behalf of Endiama, the Angolan state mining corporation.

Armenia.—The diamond cutting and polishing factory at Nur Adjen produced about \$60 million of income during the year, despite cutbacks of rough diamonds from Yakutia. The factory worked at full capacity even in the winter because of its priority for electricity and heat. The factory's 1,800 workers are not allowed to drink at lunch (unlike Russian and Ukrainian diamond factory workers), have high moral, and comparatively high

salaries; these factors resulted in highquality production.

Australia. - Argyle's diamond production of 39.0 million carats was a record for the mine. The Argyle partners stated that the installation of a new heavymedia separation circuit in the alluvial plant and the 2-million-ton expansion in the AK-1 treatment plant would increase production and efficiency. The largest gem-quality diamond recovered from the Argyle mine to date, a 41.7-carat elongated octahedron, was discovered in May. The peanut shell-sized diamond has not been evaluated to establish a price. However, it is not as valuable as the highly prized Argyle pink diamonds. Since the start of mining in 1983, more than 265 million carats of diamonds has been recovered from the AK 1 pipe and alluvial operations.

Ashton Mining Ltd. reported that the Australian Diamond Exploration Joint Venture had discovered 20 commercial-sized stones in the Northern Territory. The stones were from work on the Merlin anomaly.

Redfire Resources NL announced it appeared its opal mining would start in early 1993 on their Coocoran opal project in New South Wales 20 kilometers west of Lighting Ridge. Initial company estimations are that the deposit has potential for a bonanza of economic-grade opals from two separate zones.

Centenary International Mining is spending \$373,000 to earn a 70% interest in the Lila Springs Claims, a boulder opal deposit in New South Wales. The company plans to raise funds for the purchase of equipment to start recovering opal to quickly establish a cash-flow. Additionally, Centenary has claims that cover about 200 kilometers of strike length along the Giralia Fault. These claims cover a fossil beach sand deposit suspected to contain diamonds.

Canada.—Sudbury Contact Mines announced the discovery of six more microdiamonds from its Diamond Lake property east of Kirkland Lake, Ontario. This brings to 14 the number of diamonds recovered from cores from 3 holes drilled during the winter of 1991-92. Sudbury drilled eight additional targets during the summer. The targets were drilled to an average depth of 150 meters.

Dia Met Minerals announced additional results from the testing of its kimberlite discovery in the Lac De Gras area of the Northwest Territories. The most recent information disclosed the recovery of 101 carats of diamonds from a 160-ton bulk sample from core drilling. About 25% of the diamonds was gem quality, and some of the stones were in the 1- to 3-carat size range.

Thermal Exploration Co. of California acquired a 70% interest in about 390,000 hectares in the Lac de Gras area of the Northwest Territories. The claims are on the same trend as Dia Met Minerals' and BHP-Utah's holdings. Kennecott Canada Ltd. can earn a 70% interest in Thermal's holding by providing 100% of the exploration costs.

Sudbury Contact Mines, which continued to explore in the Kirkland Lake mining district of northern Ontario, they sampled a second kimberlite pipe and commenced drilling late in the year.

Celtic Gold and Claude Resources secured funding to continued exploration of their joint-venture diamond project at Sturgeon Lake in Saskatchewan. Drilling is underway to examine a ring structure.

China.—Everay Jewellery Ltd. opened its sixth diamond cutting factory in Guangdong Province. The new factory is the company's largest in China and has a capacity for 1,000 workers. The factory produced round brilliants of five points and less. Everay's production of finished goods from China is just over 100,000 pieces per month.

Russia.—The Siberian Republic of Sakha (formerly Yakutia), an autonomous republic with the Russian Federation, signed an agreement with De Beers Centenary AG to exclusively market diamonds through the CSO. Under the agreement, the Republic has the right to retain up to 10% of its rough diamonds for cutting or independent sales. Sakha is

responsible for 99.8% of the rough diamond production from the Commonwealth of Independent States. Additionally, De Beers agreed to furnish equipment and training to establish a cutting factory in Sakha. Called Polar Star, the plant will cut about 100,000 carats per year and produce jewelry for the domestic market.

Sakha also signed an agreement with Reichbart Arye, an Israeli firm, which will supply diamond cutting equipment, technology, and training. Diamonds will be cut in the town of Barnaul and in Israel. Additionally, Sakha entered into an agreement with Arda Co., a Japanese jewelry firm, for diamond cutting plants in Sakha. Arda plans to cut 50,000 to 100,000 carats per year for sale in Japan, the Republic of Korea, and Taiwan.

Smolensk Gems NV is a venture between Antwerp-based PHP Diamond, Smolensk Cutting Factory, the Antwerp office of Russalmaz, and Almazjuvelierexport in Moscow. The venture will cut Russian rough into fancy cuts, mainly triangles and princess cuts. The finished goods will be sold in Antwerp.

A recent government decree created the Severoalmaz joint stock company to mine the diamond deposits discovered in the 1980's at Lomonosov in the Archangel region. The decree provides for creating a production complex to mine, sort, and cut diamonds and to make diamond instruments. Severoalmaz will include the Russian corporation Almazzoloto, the Finance Ministry, Archangel Regional Administration, and the Arkhangelskgeologiya enterprise. It is expected that foreign firms will join in providing technical and economic expertise, and assistance in construction of the mining and recovery plants.

Sierra Leone.—The National Provisional Ruling Council of Sierra Leone (which overthrew the President in April 1992) rendered invalid all diamond export licenses issued by the former regime. All sales of diamonds after July were by tender.

Sunshine Mining settled a legal dispute with Boulle Group, its former partner,

and gained 100% control of the Koidu Kemberlite project, believed to contain reserves of 2.5 million carats of diamonds. Sunshine announced plans for a two phase approach to developing the project. Phase 1 would be an approximate 2-year bulk sampling project to substantiate the reserves. Phase 2 would be the construction of a full-scale mine and recovery plant at a cost of about \$37 million. The project is anticipated to have a 15-year life.

South Africa, Republic of.—De Beers Consolidated Mines Ltd. brought its new Venetia Mine to full production late in the year. It is reported that the mine will produce about 5.9 million carats per year. Venetia, located in the northern Transvaal near Messina, is a low-cost, high-grade (137 carats per 100 tons) open pit mine. Production from the mine is reported to be 50% to 60% gem-quality stones. Production from the mine is equal to 70% of the country's total production in 1991.

Agreement was reached between De Beers Consolidated Mines Ltd., its customers, and the Government of South Africa on the method of domestic rough diamond distribution. In the past, rough mined in South Africa was offered to domestic cutters before being exported. Now, all rough will be shipped to London and mixed with diamonds from the other producers. Rough for South African cutters is then drawn from the world rough supply.

Three Canadian partners, Stow Resources, Dryden Resources, Southerera Resources, commissioned the treatment plant for the Leicester diamond mine near Kimberly. A dozen clear gem-quality diamonds white recovered during startup, including two that are slightly more than 1 carat and one of about 6.5 carats. Previous production from the mine yielded 32,000 carats, with about 50% gem-quality and about 10% larger than 10 carats.

Tanzania.—De Beers' subsidiary Willcroft Co. Ltd. entered into a prospecting and mining agreement with the Ministry of Water, Energy and

Minerals. The agreement is for prospecting and mining rights on an area of more than 22,000 square kilometers in the Mwanza, Shinyanga, and Tabora regions. The Ministry also has signed diamond exploration agreements with Reunion Mining Plc. and RZT.

In May, the Tanzania Mineral Dealers Association and the Ministry of Water, Energy, and Minerals of Tanzania held the first gemstone auction in Arusha. Sixty dealers offered goods for sale at the auction attended by 28 buyers from 9 countries. About \$200,000 worth of mostly rough tanzanite, ruby, rhodolite garnet, green garnet, chrome tourmaline, and sapphire were sold.

Uruguay.—It is estimated that annual exports of amethyst are about 80 tons valued at more than \$500,000. The amethyst is used as mineral specimens, decorator pieces, and as gemstones.

Uzbekistan.—A deposit of industrial diamonds was opened in Tyan-Shan near Tashkent. The diamonds are up to 2 millimeters in diameter, but the deposit also may contain larger gem diamonds. It does allow the republic to enter the ranks of diamond-producing countries.

Zaire.—The volume and value of diamonds marketed through unofficial channels increased after the mutiny in September 1991. The value of diamonds marketed through these channels was estimated to be more than \$200 million in 1991, two to five times greater than before the mutiny. The problem seems to have abated somewhat during 1992.

Zimbabwe.—Australian-based Auridiam Consolidated Ltd. recovered about 5,000 carats of diamonds, including a 17-carat gem-quality stone, from the 3-month pilot plant testwork on its Rive Ranch concession. The concession, near the Limpopo River, in southern Zimbabwe, was acquired in the past year after De Beers Consolidated Mines Ltd. and the Government of Zimbabwe could not come to terms. Based on these encouraging results, Auridiam is planning

a 200,000-cubic-meter-per-year production plant that would produce about 500,000 carats per year for 10 to 15 years. The diamonds recovered to date were offered for tender in Antwerp.

Reunion Mining Plc. discovered two kimberlites on its concession near Lake Kariba, 300 kilometers west of Harare. Other anomalies in the same area lead the company to believe a group or cluster of pipes may be present. Reunion has 6 additional concessions for diamond exploration in Zimbabwe.

See table 13 for world diamond production by country. (See table 13.)

OUTLOOK

World demand for gem diamond can be expected to rise because of increasing effective personal incomes in the populations of the United States and other industrialized countries. Also, demand will increase because of highly effective promotional efforts. These promotions are changing social customs in many eastern countries, particularly in the use of diamond engagement rings. changes are resulting in significant growth in the diamond market. Demand for other precious gems will continue to grow as diamonds become more expensive and the popularity acceptance of colored gemstones increase. Demand for synthetic and simulant gemstones for both personal industrial consumption is expected to increase. The diversity of sizes, types, uses, and values of gems and gemstones precludes any meaningful forecasting of future demand.

Name	Composition	Color	Practical size ¹	Cost ²	Mohs	Specific gravity	Refraction	Refractive index	May be confused with-	Recog- nition charac- ters
Diamond	Carbon	White, blue-white, yellow, brown, green, pink, blue	Any	Very high	10.0	3.516-3.525	Single	2.42	Zircon, titania, cubic zirconia	High index, dispersion, single refraction, hardness, cut, luster.
Feldspar:										
Amazonite	Alkali alumi- num silicate	Green	Large	Low	6.0-6.5	2.56		1.52	Jade	Cleavage, sheen, vitreous to pearly, opaque, grid.
Labradorite	do.	Gray with blue and bronze sheen color play	do.	Low	6.0-6.5	2.56	_	1.56	do.	Cleavage, sheen, vitreous to pearly opaque, grid.
Moonstone	do.	White	do.	Low	6.0-6.5	2.77		1.52-1.54	Glass or white onyx	Blue sheen, opal- escent.
Garnet	Complex silicate	Brown, black, yellow, green, ruby red, or orange	Small to medium	Low to high	6.5-7.5	3.15-4.30	Single strained	1.79-1.98	Synthetics, spinel, glass	Single refrac- tion, anom- alous strain.
Jade:										
Jadeite	do.	Green, yellow, black, white, or mauve	Large	Low to very high	6.5-7.0	3.3-3.5	Cryptocry stalline	1.65-1.68	Onyx, bowenite, vesu vian- ite, grossu- larite	Luster, spec- trum, trans- lucent, to opaque.
Nephrite	Complex hydrous silicate	do.	do.	do.	6.0-6.5	2.96-3.10	do.	1.61-1.63	do.	Do.
Peridot	Iron magne- sium silicate	Yellow and/or green	Any	Medium	6.5-7.0	3.27-3.37	Double (strong)	1.65-1.69	Tourmaline chrysoberyl	Strong double refrac- tion, low dich- roism.
Opal	Hydrous silica	Colors flash in white gray, black, red, or yellow	Large	Low to high	5.5-6.5	1.9-2.3	Isotropic	1.45	Glass, synthetics, triplets	Play of color.

TABLE 3—Continued
GUIDE TO SELECTED GEMSTONES AND GEM MATERIALS USED IN JEWELRY

Name	Composition	Color	Practical size ¹	Cost ²	Mohs	Specific gravity	Refraction	Refractive index	May be confused with-	Recog nition charac ters
Pearl	Calcium carbonate	White, pink, or black	Small	do.	2.5-4.0	2.6-2.85	_	_	Cultured and imita- tion	Luster, struc- ture, X-ray.
Quartz: Agate	Silica	Any color	Large	Low	7.0	2.58-2.64	<u>-</u>	. –	Glass, plastic, Mexican onyx	Crypto- crystal- line, irr gularly banded, dendriti inclu- sions.
Amethyst	do.	Purple	do.	Medium	7.0	2.65-2.66	Double	1.55	do.	Refrac- tive index, double refrac- tion, trans- parent.
Cairngorm	do.	Smoky	do.	Low	7.0	2.65-2.66	do.	1.55	do.	Do.
Citrine	do.	Yellow	do.	Low	7.0	2.65-2.66	do.	1.55	do.	Do.
Crystal, rock	do.	Colorless	do.	Low	7.0	2.65-2.66	do.	1.55	do.	Do.
Jasper	do.	Uniform or spotted red, yellow, or green	do.	Low	7.0	2.58-2.66		_	do.	Opaque, vitreous
Onyx	do.	Many colors	do.	Low	7.0	2.58-2.64		_	do.	Uni- formly banded.
Rose	do.	Pink, rose red	do.	Low	7.0	2.65-2.66	do.	1.55	do.	Refrac- tive index, double refrac- tion, trans- lucent.
pinel	Magnesium aluminum oxide	Any	Small to medium	Medium	8.0	3.5-3.7	Single	1.72	Synthetic, garnet	Refrac- tive index, single refrac- tion, inclu- sions.
pinel, synthetic	do.	Any	Up to 40 carats	Low	8.0	3.5-3.7	Double	1.73	Spinel, corundum, beryl, topaz, alexandrite	Weak double refrac- tion, curved striae, bubbles.

TABLE 3—Continued GUIDE TO SELECTED GEMSTONES AND GEM MATERIALS USED IN JEWELRY

Name	Composition	Color	Practical size ¹	Cost ²	Mohs	Specific gravity	Refraction	Refractive index	May be confused with-	Recog- nition charac- ters
Spodumene: Kunzite	Lithium aluminum silicate	Pink to lilac	Medium	Medium	6.5-7.0	3.13-3.20	Double	1.66	Amethyst, morganite	Refrac- tive index.
Hiddenite	do.	Yellow to green	do.	do.	6.5-7.0	do.	do.		Synthetic spinel	Do.
Tanzanite	Complex silicate	Blue	Small	High	6.0-7.0	3.30	do.	1.69	Sapphire, synthetics.	Strong trich- roism.
Topaz	do.	White, blue, green	Medium	Low to medium	8.0	3.4-3.6	do.	1.62	Beryl, quartz	Refrac- tive index.
Tourmaline	do.	All, includ- ing mixed	do.	do.	7.0-7.5	2.98-3.20	do.	1.63	Peridot, beryl, corundum, glass	Double refraction, refractive index.
Turquoise	Copper aluminum phosphate	Blue to green phosphate	Large	Low	6.0	2.60-2.83	do.	1.63	Glass, plastics	Difficult if matrix not present, matrix usually limonitic
Zircon	Zirconium silicate	White, blue, or brown, yellow, or green	Small to medium	Low to medium	6.0-7.5	4.0-4.8	Double (strong)	1.79-1.98	Diamond, synthetics, topaz, aquamarine	Double refraction, strongly dichroic wear on facet edges.

¹Small—up to 5 carats; medium—up to 50 carats; large—more than 50 carats.

²Low—up to \$25 per carat; medium—up to \$200 per carat; high—more than \$200 per carat.

Alexandrite	Flux	Creative crystals	1970's
Do.	Melt pulling	Kyocera	1980's
Do.	Zone melt	Seiko	1980's
Cubic zirconia	Skull melt	Various producers	1970's

TABLE 5 VALUE OF 1992 U.S. GEMSTONE PRODUCTION, BY GEM MATERIALS

Gem materials	Value
Agate	\$548,000
Beryl	323,000
Coral (all types)	122,000
Garnet	108,000
Gem feldspar	1,042,000
Geode/nodules	260,000
Fire agate	45,000
Jasper	111,000
Obsidian	4,000
Opal	756,000
Peridot	1,306,000
Petrified wood	211,000
Quartz	638,000
Sapphire/ruby	895,000
Topaz	12,000
Tourmaline	82,000
Turquoise	1,994,000
Total	8,457,000

Estimated. Revised. W Withheld to avoid disclosing company proprietary data.

¹Table includes data available through May 25, 1993. Total natural diamond output (gem plus industrial) for each country actually is reported, except where indicated by a footnote to be estimated. In contrast, the detailed separate production data for gem diamond and industrial diamond are U.S. Bureau of Mines estimates except Brazil (1988-90), and Central African Republic (1988-90), for which source publications give details on grade as well as totals. The estimated distribution of total output between gem and industrial diamond is conjectural, and for most countries, is based on the best available data at time of publication.

²Includes near-gem and cheap-gem qualities.

⁵Reported figure.

³Natural gem and industrial data may not add to totals shown because of independant rounding.

⁴Includes all synthetic diamond production.

Figures are estimates based on reported exports and do not include smuggled diamonds.

⁷Figures do not include smuggled artisanal production.

^{*}Formerly part of the U.S.S.R..

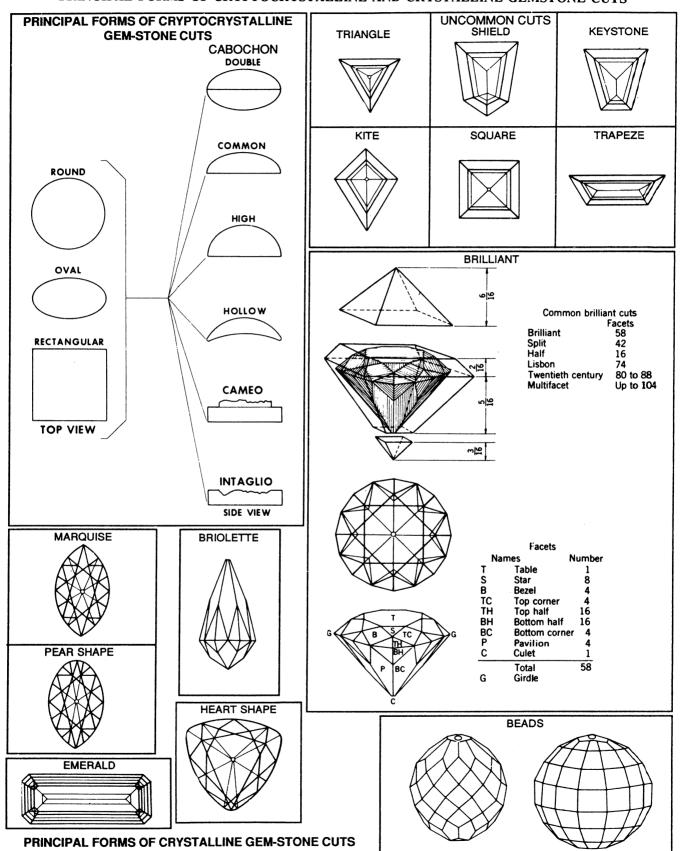

⁹All production in the U.S.S.R. from 1988-91 came from Russia.

¹⁰ Other De Beers' Group output from the Republic of South Africa includes Kimberley Pool, Koffiefontein Mine, and Namaqualand mines.

¹¹Dissolved in Dec. 1991.

¹²Dissolved in Apr. 1992; however, information is inadequate to formulate reliable estimates of individual country production.

FIGURE 1
PRINCIPAL FORMS OF CRYPTOCRYSTALLINE AND CRYSTALLINE GEMSTONE CUTS

GERMANIUM

By Thomas O. Llewellyn

Mr. Llewellyn, a physical scientist with more than 30 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for germanium since 1987. Domestic survey data were prepared by Tony E. Morris, lead statistical assistant.

The estimated domestic refinery production and consumption of germanium in 1992 were about 13% and 12%, respectively, below the levels of 1991. The lower production and consumption resulted mainly by a considerable reduction in defense infrared systems requirements.

DOMESTIC DATA COVERAGE

Domestic refinery production and consumption data for germanium are estimated by the U.S. Bureau of Mines based on discussions with domestic producers.

BACKGROUND

Germanium is recovered as a minor byproduct of the refining of base metal ores, and the potential supply of this metal, which is dependent on the level of zinc production, has historically exceeded demand.

Invention and development of the germanium transistor opened the path for the solid-state electronic field and, from 1950 through the early 1970's, provided an excellent market for germanium. Despite the continued growth of the electronics industry in the 1970's, germanium demand for transistors. diodes, and rectifiers declined because germanium was being replaced by electronic-grade silicon. However, the reduced demand for germanium in the electronics field was offset by a dramatic increase in demand for germanium in both infrared night vision systems and fiber-optic communication networks.

Definitions, Grades, and Specifications

Germanium has a metallic appearance and is grayish white in color and lustrous, hard, and very brittle. It is a semiconductor, with electrical properties between those of a metal and an insulator. The National Stockpile Purchase Specification P-114-R, December 16, 1989, for intrinsic germanium metal specifies an electrical resistivity of 50 ohm-centimeter at 20°C (40 ohm-centimeter at 25° C) over the entire ingot length.

Germanium is available commercially as a tetrachloride and high-purity oxide and in the form of zone-refined ingots, single-crystal bars, castings, doped semiconductors, optical materials, optical blanks, and other specialty products.

Industry Structure

Most germanium occurs as a minor constituent of certain base metal ores and coal deposits. Those producers that currently recover primary germanium for the most part depend on germanium-rich residues, mainly from zinc derived from past or present base metal smelting operations.

In the United States, Eagle-Picher Industries Inc.'s Quapaw, OK, Specialty Materials Div. has the capability of recovering primary germanium from zinc smelter residues. Eagle-Picher also reprocessed scrap. Kawecki Berylco Industries Inc., a division of Cabot Corp. in Revere, PA, and Atomergic Chemetals Corp., Plainview, NY, produced germanium from reprocessed scrap and semirefined foreign material.

The Jersey Miniere Zinc Co. in Clarksville, TN, continued to produce germanium-rich residues as a byproduct of processing zinc ores from its Elmwood-Gordonville Mines. These residues were shipped to Metallurgie Hoboken-Overpelt S.A. (MHO) in Belgium for germanium recovery and refining.

Little information was available on the financial structure of U.S. and world germanium industries. Germanium refiners usually were involved in the production and sale of many different metals and specialty products.

Geology-Resources

Minerals in which germanium is concentrated are germanite, sulfoarsenite of copper, germanium, and iron with an average content of 5% germanium; argyrodite, a double sulfide of germanium and silver containing 5% to 7% germanium; renierite, a complex sulfide of arsenic, copper, germanium, iron, tin, and zinc with 6% to 8% germanium; and several other minerals such as canfieldite, itoite, stottite, and ultrabasite. Primary germanium minerals are normally sulfide formed in mineralization processes аt low-to-intermediate temperatures, and secondary varieties may result from supergene alteration of sulfide ore deposits.1

Currently, there are two major reserves of germanium in the United States. The largest is the recoverable germanium that occurs as a minor constituent of zinc sulfide ores in the middle Tennessee zinc district. The other

major reserve of germanium is in | southern Utah. Here the germanium is found in the iron oxide ore zone of a depleted copper mine.

There are no reliable germanium assay data available for many areas of the world. The U.S. and world resources could be expanded if germanium were to be recovered from ash and flue dusts resulting from burning of certain coals for power generation.

Technology

Germanium is obtained commercially as a byproduct of base metal refining. Improvements have been made, but the basic processes have remained virtually unchanged.

Regardless of the source, germanium raw materials are reacted with concentrated hydrochloric acid to form germanium tetrachloride, which is then purified by fractional distillation. The purified germanium tetrachloride is hydrolyzed with water to produce germanium dioxide, which is removed by filtration and dried. Dried germanium dioxide is reduced with hydrogen at about 760° C to a germanium metal powder, which is then melted and cast into metal bars. These bars are then zone-refined to produce intrinsic-grade metal. high-purity metal is mainly used for electronic and infrared optics. Zone refining produces polycrystalline germanium.²

Certain applications of germanium, such as gamma-ray detectors, require single-crystal germanium. Single crystals are produced by two methods, the horizontal pulling process or the vertical pulling process, also known as the Czochralski method.

More than 50% of the metal used during the manufacture of most electronic and optical devices is recycled as new scrap. As a result of the low unit use of germanium in microelectronic devices, very little germanium returns as old scrap.

Substitutes

germanium in certain electronic Certain bimetallic applications. compounds of gallium, indium, selenium, and tellurium can also substitute for germanium. Germanium is more reliable in some high-frequency and high-power applications and more economical as a substrate for some light-emitting diode applications. In infrared guidance systems, zinc selenide or germanium glass substitutes for germanium metal, but at the expense of performance.

Economic Factors

Table 1 shows import duties for germanium products, which became effective on January 1, 1989, under the new Harmonized Tariff Schedule of the United States. Domestic producers are granted a depletion allowance of 14% on both domestic and foreign production of germanium. (See table 1.)

Operating Factors

Germanium has little or no effect upon the environment because it usually occurs only as a trace element in some ores and carbonaceous materials. The small quantities used in commercial applications also pose no threat to the environment. Germanium compounds generally have a low order of toxicity, except for germanium tetrahydride, which is considered toxic.

Based on a 1976 report, the energy requirements for the production of zone-refined germanium metal from zinc sulfide concentrates and scrap is 2,145 million British thermal units per net ton of germanium ingot.³

ANNUAL REVIEW

Strategic Considerations

The importance of germanium as a strategic and critical material was determined by the Federal Emergency Management Agency, and, on July 6, 1984, it was included in the National Defense Stockpile (NDS) with an initial goal of 30,000 kilograms of germanium Less expensive silicon substitutes for | metal. On July 24, 1987, a new NDS

146,000 kilograms goal of was established, based on the Army's estimates for actual emergency conditions of mobilization.

Under the 1992 Annual Material Plan, Public Law 102-484 of October 23, 1992, Department of Defense was authorized to sell about 713 kilograms of germanium. However, no inventory acquisitions or sales were made during the year, and, as of December 31, 1992, the stockpile inventory was 68,913 kilograms of germanium metal.

Production

The U.S. Bureau of Mines estimated domestic refinery production from both primary and secondary materials to be 13,000 kilograms, a decrease of about 13% compared with that of 1991. Germanium producers were forced to scale down their output to meet falling demand for the metal by the Department of Defense.

Consumption and Uses

The U.S. Bureau of Mines estimated that consumption of germanium decreased about 12% compared with the level of 1991 as a result of decreasing demand for the metal. The estimated consumption pattern by end use of germanium in 1992 was as follows: infrared systems, 42%; fiber optics, 34%; gamma-ray, X-ray, infrared detectors, semiconductors (including transistors, diodes, and rectifiers), 8%; and other phosphors, applications (catalysts, metallurgy, and chemotherapy), 6%.

Infrared systems and fiber optics continued to be the major end uses for germanium. Infrared optics were mainly used for military guidance and weaponsighting systems. Germanium-containing lenses and windows transmit thermal radiation similarly to visible light transmission by optical glass. Germanium glass was also used for nonmilitary surveillance and monitoring systems in fields such as satellite systems and fire alarms. Germanium is used as a dopant in the core of many optical fibers employed in telecommunications.

Martin Marietta Corp., Bethesda, MD, received a contract to provide an advanced infrared search and track (IRST) system to the Air Force by 1997. The IRST system detects and tracks aircraft through an advanced technology that senses the contrast between infrared energy from warm targets and their relatively cooler background. This technology enables the pilot to search for aircraft without having to radiate energy that could reveal the pilot's presence. The value of the contract was expected to be about \$50 million.⁴

Markets and Prices

Throughout 1992, domestic producer prices for germanium metal and dioxide, published by Metals Week, remained at the levels established in late 1981 (\$1,060 and \$660 per kilogram, respectively). However, discounting by producers was evident during 1992 because of competition from imported materials.

Free market prices, published by Metal Bulletin (London), remained at a low range of \$340 to \$350 per kilogram throughout 1992. Prices are likely to remain low for the near future owing to a continuing global oversupply of germanium materials together with low market demand.

Plenty of germanium products were available on the market, and the world's oversupply was further aggravated by Russia's entrance in the marketplace as an active supplier of germanium.

The Belgian producers' price for germanium metal, published by Metal Bulletin (London), remained throughout the year at about \$870 per kilogram.⁵

Foreign Trade

In 1992, the estimated germanium content of imports was approximately 12,600 kilograms. Total imports of germanium materials decreased dramatically compared with those of 1991. Germany, China, Spain, the United Kingdom, Russia, and Belgium, in descending order of shipments, accounted for approximately 85% of the total U.S. germanium imports for 1992. (See table

2.)

World Review

World refinery production was estimated at 65,000 kilograms, a decrease of about 19% compared with the 1991 level. The decline in world production was attributed to an oversupply and to a lower level of demand for the metal.

Capacity.—Rated capacity was defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable, long-term operating rate, based on the physical equipment of the plant and routine operating procedures for labor, energy, materials, maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author. can be brought into production within a short period of time with minimum capital expenditures. The total world germanium refinery capacity for 1992 was estimated at 270 metric tons.

Canada.—Cominco Ltd. restarted its germanium refinery plant at Trail, British Columbia, which was closed since December 31, 1990. The refinery produced germanium dioxide from Cominco's own feedstock material.

Germany.—Deutsche Bundespost Telekom, the state-owned network operator, will connect about 1.2 million homes and businesses in Germany to its current fiber-optic network by 1995. This photonic system will provide a wide range of services to the home and/or office, including high-definition television, multimedia computers, and videotelephony. The German officials expect that such a mass deployment of fiber in the local network will stimulate the production of fiber-optic products.⁶

Japan.—Germanium metal production was estimated at 2,700 kilograms, a decrease of about 21% compared with 1991 metal production levels.

Current Research

The U.S. Bureau of Mines investigated the recovery of gallium and germanium from a Tennessee zinc residue and a Utah ore. Leaching and solvent extraction techniques were studied that yielded about 95% gallium extraction and about 73% germanium extraction when the zinc residue sample was tested. Research results showed that about 96% of the gallium and 85% of the germanium content in the ore sample were extracted, using a two-stage countercurrent sulfuric acid leach circuit.⁷

OUTLOOK

In 1992, for the fourth consecutive year, the supply of germanium exceeded the demand for this specialty metal. Germanium supplies are likely to remain high for the next 4 years owing to a global increase in the availability of germanium products in the market. Producers for the third consecutive year were forced to lower prices to maintain their share of the market.

Market analysts agree that all primary germanium producers will probably continue facing difficult times in the near future. This assessment is based on a global oversupply of germanium materials together with a low market demand for the metal due to U.S. defense cutbacks and a world economic recession.

GOLD

By John M. Lucas

Mr. Lucas, a geologist with more than 30 years of experience in the mining industry, has been the U.S. Bureau of Mines commodity specialist for gold since 1980. While with private industry, Mr. Lucas was involved in exploring for a wide variety of commodities, including gold, in the United States as well as Australia, Brazil, and Canada. Domestic survey data were prepared by Dwayne E. Penn, and Lisa P. Conley, statistical assistants. International data tables were prepared by Audrey D. Wilkes, international data coordinator.

Throughout history, gold has been treasured for its beauty and permanence. Most of the gold that is fabricated today goes into the manufacture of jewelry. However, because of its superior electrical conductivity and resistance to corrosion and other desirable combinations of physical and chemical properties, gold also emerged in the late 20th century as an essential industrial metal. Gold performs critical functions in computers, communications equipment, spacecraft, jet aircraft engines, and a host of other products. Although gold is important to industry and the arts, it also retains a unique status among all commodities as a long-term store of value. It was, until recent times, considered essentially a monetary metal, and most of the bullion produced each year went into the vaults of government treasuries or central banks.

Domestic and international gold mining operations continued to produce gold at a record level during 1992. The U.S. gold mining industry produced 329,124 kilograms (kg) (10,581,581 troy ounces¹) of gold, an increase of 11% over production in the previous year. The State of Nevada was once again the Nation's dominant gold-producing State. Since the breakup of the former U.S.S.R., the United States has become the world's second largest gold-producing nation after the Republic of South Africa. For the fourth consecutive year the total demand for gold used in fabricated products in the market economy countries exceeded the record demand level set in Jewelry continued to be the dominant end-use sector.

The U.S. Bureau of Mines (USBM), in an effort to provide statistical data on gold that are consistent with international usage, reports gold data in kilograms (kg) and metric tons unless otherwise noted.

DOMESTIC DATA COVERAGE

Domestic mine production data for gold are developed by the USBM from two separate, voluntary surveys of U.S. operations. One of these surveys is the lode-mine production survey of copper, gold, lead, silver, and zinc mines. Of the lode gold producers in operation to which a survey request was sent, responded, representing 97% of the total lode-mine production of gold shown in tables 4 and 5. Production for the nonrespondents was estimated using reported prior-year production levels, adjusted by trends in employment, and other guidelines such as company annual reports, the news media, and State agency reports.

BACKGROUND

Gold lore and the use of gold predates written history. Gold has been considered a precious metal since ancient times, and the mystique and folklore associated with gold has been a part of the fabric of civilized society throughout history. Similarly, the search for gold has stimulated world exploration and trade for more than sixty centuries.

Gold mining in the United States began about 1800 in North Carolina, with Georgia joining in production in 1829 and Alabama in 1830; then Virginia, Tennessee, and later New Mexico became producers as prospectors moved west. The most important gold discovery, because of its influence on development in the Western United States and the amount of gold produced, was at Sutter's Mill in California in 1848. Later discoveries were made in most other Western States and territories.

Gold mining in Australia began about 1849 as an offshoot of the California gold rush. Russian gold mining had been expanding since the mid-18th century, and by the eve of the California gold rush, Russia was producing about two-thirds of the world's gold. Gold mining in the Republic of South Africa started in the 1870's. The last major gold rush began just prior to 1900 in Canada's Yukon and in Alaska.

Early mining was largely by placer methods, with a multitude of miners working stream deposits (placers) by hand mining techniques, a practice that continues to this day in many areas of the world. In the 1860's, the more difficult underground mining of lode deposits—the sources of the placers—became important. Cyanidation, a chemical process for gold extraction, was introduced about 1890, and the concentration of finely ground ores by selective adherence of mineral particles to rising bubbles, the flotation process, was first used for gold ores about 1900 and came into general use in the 1930's. Heap leaching, essentially a form of cyanidation, has come into general practice for treatment of lowgrade ores only during the past two

Cumulative world production to date is

estimated at about 112,000 metric tons (3.6 billion ounces), about two-thirds of it mined in the past 60 years. The total is equivalent in volume to a cube roughly 18 meters (58 feet) on a side. The Republic of South Africa has been the source of about 41% of that gold, but nearly all countries have reported at least some production of gold.

U.S. gold production from its beginning in the 18th century to date totals about 11,900 tons (383 million ounces). The principal producing States, in declining order of cumulative production, are California, Nevada, Colorado, South Dakota, Alaska, Utah, and Montana: the remainder came from 11 other States. To date, lode gold mining has supplied about 50% of U.S. production; placer mining, 35%; and base metal mining, 15%. The Homestake Mine at Lead, SD, has accounted for about 10% of all U.S. gold production. Other major sources of past production include the Mother Lode and Grass Valley areas of California, the Comstock Lode and Goldfield areas in Nevada, Cripple Creek in Colorado, and the Fairbanks and Nome, AK, areas.

Most domestic gold mines were closed by Limitation Order L-208 in the early months of World War II (October 8, 1942) so that scarce equipment, supplies, and skilled workers could be focused on mining essential base metals. L-208 was revoked July 1, 1945. Because of increased cost and rehabilitation problems, only a few mines reopened after the war. During the resurgence of gold exploration and mining over the past decade, many deposits affected by L-208 have been reexamined or returned to productive status.

Definitions, Grades, and Specifications

Fineness refers to the weight proportion of pure gold in an alloy, expressed in parts per thousand; 1,000 fine gold is 100% pure gold. Commercially traded gold bullion is usually 995 fine or higher. The term "fine gold" also may be used to designate the particle size of gold in its native state; for example, a placer deposit with gold

particles ranging from 0.38 millimeter (mm) to 0.76 mm (0.015 to 0.3 inch) in diameter contains fine gold, whereas a similar deposit with particles more than 1.5 mm (0.06 inch) in diameter contains coarse gold.

The term "karat," like fineness, refers to purity, but is expressed in 24ths; thus 24-karat (24k) gold is 1,000 fine or pure gold, and 10k gold is 10/24, or 41.7% Although there are many 10k gold. alloys, each 10k alloy contains 41.7% gold. Various 10k alloys, for example, differ from each other in the number, identity, and proportions of their other constituent metals. Gold alloys used in iewelry and certain other end uses are referred to as karat golds, whereas alloys used in dentistry and electrical devices are designated more precisely. Yellow, red, and green karat golds are essentially ternary alloys of gold, silver, and copper, often with additions of zinc and sometimes a little nickel. White karat golds are usually composed of gold, copper, nickel, and zinc, although platinum and palladium also have been used as components.

Having assumed the functions previously performed by the London Gold Market, the London Bullion Market Association (LBMA), established in 1987, sets standards for its members that are widely used in world gold trade. In 1991 the LBMA and the Bank of England successfully argued before the European Commission to retain the troy system of measurement for use in the gold and other precious-metals markets. Refined gold bullion bars are generally designated as "good delivery bars." A good delivery bar, as set forth by the requirements of the LBMA, must contain 350 to 430 troy ounces (10.9 to 13.4 kg) of gold with a minimum fineness of 995. The bar must bear the stamp of 1 of the world's 49 approved melters or assayers, have a good appearance, and be easy to handle and stack. Smaller bars are also commonly available on the commercial gold market.

U.S. trade practice rules for the jewelry industry, set by the Federal Trade Commission, require that any article labeled gold must contain at least 10k

gold, with a tolerance of three parts per thousand for most articles, or if soldered, seven parts per thousand. "Rolled gold plate" and "gold filled" are terms referring to articles made of base metal to which karat gold has been bonded by soldering, brazing, welding, or mechanical means. A marking such as "1/10 10-karat gold filled" means that one or more surfaces are covered with 10karat gold and the coating constitutes at least 10% of the weight of the entire article covered. No article may be marked "gold filled" if its karat gold surface constitutes less than 1/20 of the total weight. Thinner coatings are marked "rolled gold plate."

Gold has an atomic number of 79 and an atomic weight of 197, occurring naturally as a single stable isotope. Its melting point is 1,063 °C, and its specific gravity is 19.3. In addition to being highly resistant to corrosion, gold is also extremely malleable and ductile; 31 grams (1 troy ounce) can be beaten into about 23 square meters (250 square feet) of gold leaf about one-tenth of a micrometer (four-millionths of an inch) thick, while a similar quantity can be drawn into more than 80 kilometers (km) (50 miles) of wire.

As an illustration of gold's high specific gravity or density, 0.028 cubic meter (1 cubic foot) of pure metallic gold weighs a little more than 544 kg (1,200 pounds); 16.4 cubic centimeters (1 cubic inch) of pure gold weighs about 311 grams (10 troy ounces), a lump or nugget of gold the size of a navy bean weighs about 3 grams (0.1 troy ounce), and a flake of gold the size of a grain of rice weighs about 0.18 gram (0.006 troy ounce).

The troy system of weights is generally used in the United States for gold and other precious metals; however, to aid in harmonizing world data collection, Government practice now dictates the use of the metric system of measure. The troy weight system is based on the troy ounce of 480 grains or 20 pennyweight. One troy ounce is equivalent to 1.097 ounces avoirdupois. Many nations use the metric system; in this system, the weight of gold is

designated in standard metric units: gram, kilogram, or metric ton. The metric ton is equivalent to 32,150.7 troy ounces. In addition to the metric or troy systems, other units of weight applicable to precious metals also may be encountered. On the Indian subcontinent, for example, the weight of gold may be expressed in terms of tolas; 1 tola of 999 fine gold weighs 11.1 grams (0.375 troy ounce).

Uses and Products for Trade and Industry

In addition to its ages-old usage as a monetary metal as well as in jewelry, decorative applications, and dentistry, gold has a number of applications that are important to the functioning of domestic industry, modern high-technology, engineering, and defense systems. It is used extensively in a great variety of solid-state electronic devices, in industrial control and monitoring instruments, and in corrosion-resistant chemical process equipment.

Of the strategic and industrial uses of gold, the most important is its use in electronic devices, especially in printed circuit boards, connectors, keyboard contacts, miniaturized circuitry, and as a dopant in some semiconductors. Modern solid-state electronic devices such as computers employ very low voltages and currents, and thus require connectors, switch contacts, soldered joints, and certain other components that remain chemically and metallurgically stable for the life of the device. Increasingly complex civilian, military, and aerospace electronic systems use gold to ensure dependable operations under a wide range of operating conditions. For example, because of its ability to provide reliable electrical connections, gold is used extensively in spacecraft, such as the Hubble Space Telescope, that must function flawlessly in the harsh environment of outer space. A more down-to-earth example would be the common touchtone telephone that has up to 33 gold contact points; gold plating employed on the contact surfaces of the quick disconnect between the telephone and the line ensures static-free reception.

Gold alloys have long been used in electrical instruments: example, as wipers and windings in slidewire potentiometers, where long-term reproducibility is essential. palladium alloy wires are used in thermocouples, especially those used to measure high temperatures encountered in some industrial processes and aircraft engines. Gold-containing brazing alloys such as gold-nickel alloy are important to the aerospace industry, especially in the assembly of some military jet turbine engines and high-performance rocket engines. Gold is used as a reflector of infrared radiation in radiant heating and drving devices and heat-insulating windows for large buildings. It also is used in spacecraft such as the space shuttle, which relies upon gold to seal and protect its vital propulsion system from problems associated with hydrogen embrittlement. Gold-coated mirrors are the principal component of infrared jammers used on numerous military aircraft to confuse the guidance instruments of heat-seeking missiles.

Gold applied as organometallic liquids is used for the decoration of porcelain and glass dinnerware; gold leaf is used for the decoration of buildings, both inside and outside; and gold alloys are used in rupture discs in chemical-process equipment and in the perforated "spinnerets" through which cellulose acetate fibers are extruded. Since 1975, when Americans could again hold gold without a license, a small amount of gold has been used in the United States each year for medallions, small bars, and other similar items having high gold content, purchased primarily as investments.

Although gold compounds are used in substantial quantities in electroplating, most of the gold sold in the international marketplace for industrial usage is in the form of metal or metal alloys. Many standard metallic forms are available, such as bars, rods, sheets, foils, wires, powder, granules, and shot. Conductive pastes and inks prepared with gold powder are widely employed in the electronics industry. Much jewelry gold is supplied as granules of specified karat content. Semimanufactured items for

trade and industry may include gold jewelry findings or unassembled parts such as earring clamps, chain clasps, pins, etc.; dental findings; and inlaid, clad, and plated metals. Investment products such as bars, coins, and medallions are manufactured and sold by both industry and governments.

Industry Structure

In recent years in the United States about 90% of domestic gold production has been derived from gold ore, and most of the remainder was a byproduct of copper and other base metal production. Placer gold production has declined to about 1% of the reported total production in recent years. Ten mines accounted for about 50% of domestic output in 1992: 82% came from mines in California. Montana, Nevada, and South Dakota. The leading producer in most recent years, Newmont Gold Co., provided about 15% of domestic output from its surface operations near Carlin, NV. The Homestake Mine, a deep underground mine in South Dakota, has been a major producer for many years. The Utah Copper Div. of Kennecott, a major copper producer, has been a significant gold producer in many years since 1979, a year when it was the Nation's largest gold producer. Kennecott's gold is a byproduct of its extensive copper mining operations at Bingham Canvon, UT.

Attracted by the favorable U.S. business climate, foreign investment in domestic firms that produce gold as a principal product or as a byproduct has increased since 1980. This is especially true for mining interests acquired by multinational companies, some of which in turn may be directly linked to foreign governments. The general attractiveness of the United States as a country in which to conduct business has been a principal motive behind these acquisitions. Canadian mining companies have, throughout the history of North American mining, operated mines in the United States, as to a lesser extent have United Kingdom and other European companies.

An economic study published by the Nevada Bureau of Mines and Geology at

the University of Nevada,² in addressing the issue of foreign ownership of the U.S. precious metals industry, found that almost 60% of U.S. production is owned by American investors or institutions. Canadian and United Kingdom shareholders accounted for about 16% each while the remainder was held by Japanese, European, and other investors. The study also found that the vast majority of domestic ore reserves are largely U.S. owned and controlled.

The South African gold mining industry, accounting for about 27% of current world output, consists of about three dozen large underground operations and several dozen smaller mines. In a typical year, the Republic of South Africa's gold industry reportedly mills enough ore to cover 60 city blocks to a height of 20 stories; from this volume is recovered enough gold to fill a small bathroom. These mines are owned or controlled by six corporations that interlock through directorships and mutual shareholdings and have extensive mineral and industrial investments in many parts of the world. corporations are Anglo American Corp. of South Africa, Ltd.; Anglovaal Ltd.; Gencor Ltd.; Gold Fields of South Africa, Ltd.; Johannesburg Consolidated Investment Co. Ltd.; and Rand Mines Ltd.

Geology-Resources

The Earth's crust has been estimated to have an average gold content of about 0.0034 gram per metric ton (0.0001 ounce per short ton), or 3.5 parts per billion (ppb). Sedimentary rocks, especially sandstones, tend toward higherthan-average gold content. In igneous rocks, the content averages slightly higher in darkly colored "mafic" rocks than in lighter colored "felsic" rocks. Seawater typically contains about 0.011 ppb gold; however, content varies widely with location and may range from 0.001 to 44 ppb. Numerous attempts have been made over the years to recover gold from seawater: however, none have been commercially sustainable. The gold content in surface and ground waters lies within the range of analyses for seawater, but varies widely depending on source. For instance, waters from gold mines in the southern Yakutia-Sakha Republic of Russia contain an average of 0.7 to 0.9 ppb. In Colorado, waters draining from gold mining and other areas contain up to 0.15 ppb, but with no distinct differences between gold-enriched and gold-barren areas. Hot-spring waters generally contain more gold than other waters.

Gold deposits are found in many kinds of rock. Hydrothermal deposits appear to be somewhat more common in acidic and intermediate igneous rocks; in silty, laminated carbonate rocks; and in silicious or aluminous sedimentary or metamorphic rocks. The general deposit types include hydrothermal, hydrothermal-metamorphic, metamorphic, replacement (lode, massive, and disseminated), and cavity filling (fissures, stockworks, saddle, reefs, breccias, and conglomerates).

Gold occurs mainly as native metal, alloyed with silver and/or other metals, and as tellurides. A naturally occurring alloy of gold and silver is known as electrum. Other gold minerals are rare. Gold is commonly associated with the sulfides of antimony, arsenic, copper, iron, and silver.

Chemical and mechanical weathering and erosion cause gold in the free or metallic form to be released from lode or primary deposits and to accumulate as nuggets and grains in residual deposits or placer deposits. Although the richest lode gold deposits have been small fissure vein types with quartz gangue, the so-called bonanzas, much larger quantities of gold have been mined from large, mediumgrade deposits. U.S. gold ores average about 1.3 grams per metric ton (0.04 ounce per short ton) or less; however, the advent of chemical heap leaching now makes it possible for rock with suitable properties containing considerably less than the average to be considered ore.

Technology

Exploration.—Although a number of new techniques have come into use in the exploration for gold, the gold pan remains one of the simplest and most

efficient low-cost means of finding visible gold and tracing it to its source. Collecting, crushing, and panning quartz samples from geologically favorable areas is a common basic procedure employed in prospecting for bonanza-type deposits. Neutron activation analysis and atomic absorption spectroscopy permit relatively fast and reliable gold analyses and have had an important bearing on the ability of field geologists to do geochemical surveys of areas formerly of little interest because of sampling costs The longand lack of outcrops. established fire assaying technique, however, continues to be the most widely used method for determining the quantity of gold present in samples or market products where precision and accuracy of the results are important. Newmont Gold Co. recently initiated an automatic assay system whereby more than 4,900 laserread barcoded samples are directed daily through the various laboratory stages with the aid of computers. Geochemical studies have established relationships between gold and other elements, such as arsenic, copper, mercury, and tellurium, which can be useful trace elements in the search for gold. In recent years, computers have proven to be useful in determining the often subtle relationships between trace elements and gold Metallogenic studies mineralization. relating tectonic histories and regional and local geology have given better understanding of where important gold deposits may lie.

Wire-line core drilling and improved percussion drilling methods have reduced the costs and increased efficiencies of exploration and development. Research on sampling through statistical analysis techniques that take into account the distribution and size of gold particles in a sample has shown ways to effectively Computer reduce sampling costs. methods have been useful in defining the extent of pay zones in larger ore bodies, such as those in the Republic of South Africa, and have application to low-grade disseminated deposits. Improvements in mining machinery and procedures and the introduction of new gold leaching methods have combined to lower the economic cutoff limits for gold deposits, providing an impetus for extensive reevaluation of previously mined areas as well as the incentives necessary to encourage the exploration of new, heretofore unproductive, areas.

Mining.—The technology of gold mining is well established, having evolved largely over the past century. Much of the world's gold production has come from deep, narrow veins or from thin-bedded layers called reefs; these have been difficult to mine (in the Republic South Africa, for example) because of high underground temperature and humidity, and extreme rock pressure, which often causes dangerous rock bursts. Most domestic gold comes from surface lode mines.

Placer mining was once an important source of gold. Dredging offers the maximum efficiency in large alluvial or marine deposits; dragline, hydraulic, or bulldozing methods are commonly used in smaller, bouldery deposits such as those mined in some areas of Alaska. Most placer mining requires large quantities of water, but dry operation is also possible. using bellows or other air-blowing equipment for separation. However, recovery efficiency may be lower in dry processing. To illustrate the effort entailed in small-scale manual placer mining, such as that which has been and continues to be practiced in many areas of the world, including the United States, two persons feeding a sluice box can shovel about 4.6 cubic meters (6 cubic yards) of gravel per day. This is roughly equivalent to loading the beds of six 1-ton pickup trucks per day. Assuming that the gravel processed yields an average 0.49 gram per cubic meter (0.01 ounce per cubic yard) of gold, about 3 grams (0.06 ounce) of gold would be recovered per day. With a gold price of about \$380 per ounce, the gold recovered by two persons laboring all day would have an approximate value of \$23, a substantial sum in many areas of the world. Obviously, mechanization, even on a small scale, would vastly increase the amount of material that could be washed. Needless to say, mining a higher grade

deposit would be even more productive. Should the gold recovered be in the form of coarse nuggets, valued also for their use in jewelry or as specimens, the value of the day's production would be increased. For large-scale, open pit lode gold mining, computer models have been developed to analyze various production factors and establish optimum pit configurations and extraction efficiencies.

The South African mining industry, a leader in deep mining technology for many years, has evolved new methods of controlling problems relating to rock stress, dust, and virgin rock temperature. Both large and small water-powered rock drills, large-diameter raiseboring machines, and new types of rubber-tired transporters have been developed in recent years to increase the efficiency of mining operations. Also, South Africans have developed new techniques of shaft sinking, mineral processing, extraction that are critical to the success of deep mining. At the Vaal Reefs Mine, for example, part of the gold ore is transported to the surface from a depth of more than 2,100 meters (7,000 feet) by hydraulic pumps. Much of the Republic of South Africa's current production is now coming from depths of 2,000 to 3,000 meters (6,600 to 9,800 feet) below surface, with some as deep as 3,600 meters (11,800 feet). The new generation of ultradeep mines is intended eventually to be mined to 4,500 meters $(14,800 \text{ feet}).^3$

Beneficiation.—Milling technology for gold is highly developed, and normal mill recovery rates range from 92% to Gold is recovered by cyanide leaching of gold ore contained in tanks or heaped on impervious leaching pads; by amalgamation, flotation, gravity concentration, and smelting; or by a combination of these processes. Increased exploitation of gold-bearing sulfide ores in recent years has led to the development and application of several technologies designed to render sulfide and refractory ores amenable to cyanide leaching; thus, process steps such as autoclaving, biological preoxidation, or fluid-bed roasting have recently been incorporated at a number of milling operations.

Smelting-Refining.—Many gold mining operations recover the gold from cyanide leach solutions by precipitation with zinc dust, though, in recent years, carbon-in-pulp (CIP) recovery technology has been adopted at a number of new mining operations. With CIP, activated carbon made from coconut shells or other durable carbon sources collects gold from the cyanided pulp until it contains 10 to 12 kg (300 to 400 ounces) of gold per ton Gold with accompanying of carbon. silver is desorbed or stripped from the carbon with a strong alkaline cyanidealcohol solution. The precious metals are recovered from the strip solutions by electrodeposition on a stainless steel wool cathode. The cathode deposit is then refined into bullion or doré, a mixture of mostly gold and silver. The carbon is reused after being screen-sized and reactivated through controlled roasting. Generally, gold recoveries range from 92% to 97% of the feed content. Gold leaching processes in use or under development that do not employ cyanide as the principal lixiviant or dissolution medium include the application of thiourea, iodine, malonitrile, or various bioextraction techniques. Some of these alternate techniques, unlike the longestablished. well-understood cyanide process, may be accompanied by unacceptable cost or environmental burdens. When gold is associated with copper ores, it travels with the base metal through concentration and smelting to the refining stage. It is eventually separated from the anode slimes that accumulate in electrolytic copper refining cells and is recovered as gold bullion in the preciousmetals refinery. Gold losses in concentrating copper ores are about the same as for copper, but are negligible in smelting and refining.

Gold is refined by chlorination in the molten state (Miller process) and by electrolysis (Wohlwill process). Generally, gold bullion made by the Miller process is 996 to 997 fine, and bullion made by the Wohlwill process is 999.5 to 999.8 fine. (See figures 1 and 2.)

Recycling.—Because of its high intrinsic value, gold has been recycled throughout the ages. Thus, a modern article of jewelry containing recycled gold could conceivably contain atoms of gold from a golden earring worn by Helen of Troy or from a nugget of gold used in the year 4000 B.C. to barter for ingots of crude copper or other goods at a Mediterranean seaport.

Precious-metals refiners throughout the world recover gold from scrap. In the United States, about 60% to 80% of the scrap comes from current manufacturing operations, and the remainder comes from old scrap in the form of items such as discarded jewelry and dental materials, used plating solutions, junked electronic equipment, etc. Gold is so valuable that even the gloves, aprons, and dust masks worn by gold workers and the dust or "sweeps" from their shops may be processed to yield payable quantities of metal. Similarly, a specialized field of secondary gold recovery focuses on gleaning gold from defunct goldprocessing operations. Most domestic scrap processors are in the Northeastern States.

The general flow of gold in the secondary industry is shown in figure 3. Refiners receive scrap in a variety of forms and determine processing steps according to batch size, average gold content, and the impurities to be separated. Scrap dealers and semirefiners may process the scrap and then ship the upgraded product elsewhere, including overseas, for further treatment and refining. Scrap is either purchased outright or treated on a toll basis.

A considerable quantity of scrap is generated in manufacturing operations, but because of tight security controls over waste materials in precious-metals plants, nearly all of this new scrap or "homegenerated" scrap is recovered. Some old scrap, on the other hand, is lost because in practice gold cannot be economically recovered from all manufactured products; this is increasingly true as miniaturization of gold-bearing electronic products proceeds. The U.S. Department of Defense recovers a significant quantity of gold from military

scrap; other Federal Government agencies either participate in the Defense recovery program or have their own. (See figure 3.)

Economic Factors

On January 31, 1934, following provisions of the Gold Reserve Act of that year, the official price of gold was raised by the U.S. Government from \$20.67 per ounce to \$35 per ounce. The value of \$1 was thus established at 28.57 thousandths of a troy ounce, and gold flowed into the United States. By 1949, gold stocks held by the U.S. Department of the Treasury had risen to a peak of 21,708 tons (698 million ounces).

During the 1950's and 1960's, foreign central banks vigorously exchanged their large dollar holdings for U.S. gold. Consequently, U.S. stocks declined, with much of the gold accumulating in stocks owned by foreign governments. When the outflow of gold was finally stemmed in August 1971 by a Presidential order closing the so-called "gold window" or ending the convertibility of U.S. dollars into gold, U.S. stocks stood at 9,069 tons (291.6 million ounces). Thereafter, U.S. stocks declined somewhat, reflecting gold auctioned by the Department of the Treasury in 1975, 1978, and 1979 and later minting of gold coins and medallions for public sale. At yearend 1992, U.S. Treasury stocks stood at 8,144 tons (262 million ounces).

Because of increasingly severe pressures on official gold reserves stemming from attempts by monetary agencies to hold the price of gold down to \$35 per ounce, a seven-nation International Gold Pool established a twotier price system in March 1968. Under this system, there was an official price of \$35 on monetary transactions, thenceforth restricted to Government-owned gold, and an open market price for other transactions, which could fluctuate with supply and demand. Since then, the free market has flourished, and the price of gold has risen dramatically, while the monetary sector has evolved to the point where most nations conduct gold transactions and value their gold reserves

The United at market-related prices. States is the only remaining holder of large gold reserves to value them at the low official price of \$42.22 per ounce. The U.S. dollar was devalued twice in the 1970's, raising the dollar price of gold to \$38 an ounce on May 8, 1972, and then to \$42.22 on October 18, 1973, where it remains today. With the second devaluation, the President empowered to eliminate regulations on the private ownership of gold, which had been in force since 1934, and these were eventually removed on December 31, 1974. January 2, 1975, was the first day that the general public was allowed to resume holding gold without a licence issued by the U.S. Treasury's Office of Domestic Gold and Silver Operations; the office was closed on July 31, 1975.

Trading in gold futures began in New York and Chicago upon restitution of the right to private ownership of gold. Trading volume has increased nearly sixteenfold since 1975, peaking at about 43,000 tons (1,380 million ounces) in 1982; the volume in subsequent years has ranged from about 25,000 to about 35,000 tons. However, only a small percentage of the gold traded enters the physical market.

Because of gold's monetary role and the fixed \$35-per-ounce price from 1934 to 1968, domestic producers had difficulty maintaining production in the face of rising costs. Gold was particularly attractive as a commercial metal because its price was stable, and a dependable domestic supply was provided to industrial users by the U.S. Treasury until March 17, 1968.

In March 1982, the U.S. Gold Commission, which had earlier convened to consider a renewed role for gold in the U.S. economy, concluded that reintroduction of gold into the current monetary system would probably not serve to alleviate potential economic problems such as inflation. The prospects for a return to a gold standard in other countries also would seem to be uncertain. However, as a so-called "hard currency," gold may come to enjoy a greater role in world economics than it has in the recent past. This is especially

important as the world economic system adjusts to accommodate rapidly changing political, economic, and trade practices and to address the many issues associated with the rapid growth in world population, dwindling resources, and slower growth in industrial productivity. Small-scale bartering arrangements involving gold continue as they have for centuries, especially in frontier mining areas such as those in South America, Africa, the western Pacific, and remote areas of North America where raw gold dust and nuggets may be used directly to purchase goods and services.

Prices.—The price of gold is a topic of continuing concern and interest to the producer and the consumer of gold alike; where it has been, where it will go, and the reasons behind its wild fluctuations over the past decade or so have been studied from every angle by numerous observers. Apparent causes for the price changes have been presented and speculation on their future directions have been offered.

Unfortunately, many of these sophisticated econometric models. forecasting the price using combinations of economic, political, and social factors. that proliferated in the early 1980's had all but disappeared from the public domain by the end of the decade. The course of future events cannot, of course, be forecast with accuracy, nor can the price of gold. Forecasting gold's price is unusually complicated because gold occupies a unique position among the world's commodities. Gold is both an internationally traded commodity and, at the same time, a long-established, universally acceptable storehouse of value, considered by many people worldwide to be superior to fiat paper currencies with fleeting longevity or fluctuating, unpredictable value. Unlike many commodity prices that are more or less tied directly to supply and industrial demand, the price of gold cannot be viewed as one would view the price of other goods or services in a free market. Gold also cannot be viewed strictly from the standpoint of the U.S. market alone. for international, political, and economic

events that may impose a positive or negative influence on gold the commodity may be overshadowed by developments perceived to favor gold the medium of exchange. For example, citizens of nations that have been invaded by other countries during the course of their history tend to value the monetary and exchange aspects of gold more highly than countries such as the United States where this has not been the case. them, gold is money or the preferred substance of wealth, and the ownership of even a small amount of physical metal ensures escape or a new beginning. Therefore, many individuals worldwide, as a matter of tradition or simple prudence, continue to hold small quantities of gold in the form of jewelry, coins, nuggets, etc., legally or illegally, as a portable form of universally accepted capital: for some, especially developing countries, gold may constitute the only available and relatively risk-free form of old age or disaster insurance.

Although the average price of gold has declined from its record 1980 level of \$612 per ounce, it remains considerably higher than the prices of the early 1970's. This high price level, not generally enjoyed in recent years by many other commodities, continues to spark investor interest and lead to an overall sustained increase in the level of funding available to gold producers to invest in exploration and productive capacity. The heightened interest in gold has, as in the past, promoted exploration of those remote corners of the Earth where exploration for other less valuable minerals could not be justified but where their serendipitous discovery as a byproduct of exploration for gold will ultimately contribute to the needs of society.

In the fabrication of gold, particularly in the electronic and electrical industries, the cost of gold used per unit item is still such a small percentage of the total unit cost that the price of gold is often of small significance in pricing the product. Some industrial consumers of gold, however, confronted with unpredictable and potentially ruinous prices, have turned in recent years to the world futures markets to ensure that their future

gold requirements will be available at preselected prices.

Costs.—Costs of mining gold in the United States range upward from costs typical of low-cost placer mining, where dredging or hydraulic operations are conducted profitably on gravels containing less than 0.49 gram per cubic meter (0.01 ounce of gold per cubic yard). Surface lode mining, although considerably more expensive than placer mining, is profitable with some ores containing as little as 0.2 gram or less of gold per ton (0.006 ounce per ton), depending on the stripping ratio, size, and type of operation. Other important considerations include the characteristics of the ore processed and the mine's location, which determines the duration of the operational season and infrastructural requirements. Underground mining for gold is the most expensive mining, but costs vary greatly from mine to mine; nevertheless, some underground mines are able to produce an ounce of gold at costs below those of some surface operations.

Costs for processing gold ores can vary widely, depending on the treatment required. Recent advances in heap leaching and extraction with activated carbon may afford lower capital and operating costs than those associated with conventional cyanidation. One recent advance, for example, is particle agglomeration, a technique developed and patented by the USBM to increase the flow rate of leaching solutions through crushed ore. Fine particles of ore that would otherwise impede solution flow by blocking the spaces between coarser fragments are bound together or agglomerated through the addition of a water-soluble binder such as a cement or Other innovative techniques developed in recent years to improve the efficiency of the heap-leaching process include the use of ore conveyors and stackers, solution heaters, and improved solution distribution and recovery and leak detection systems. Other advantages of heap leaching over conventional milling include shorter plant construction time and greater adaptability to lower grade ores. A disadvantage of conventional heap leaching is lowered recovery, usually 60% to 80% of the gold present, compared with 88% to 92% or greater recovered by conventional mill treatment. The recovery efficiency of heap-leaching operations where agglomeration technology is employed approaches that of conventional methods.

Some producers, by forward selling their future gold production, are able to maintain economic production even during periods when their production costs may exceed the existing market price of gold.

Taxes.—Taxes may be levied on mining operations for gold and other minerals at the Federal, State, and local levels. In addition to the usual business, occupation, and property taxes and licence fees required of all business enterprises, mining operations in many States are subject to severance or extraction taxes imposed on the yield or proceeds received from the sale of newly mined products. In 1989, the State of Nevada, for example, increased the net profits tax on State mineral production from about 2% to 5%. In 1986, a new Federal tax, the Customs User Fee, was adopted: it places a 0.22% levy on all imports, including gold and gold-bearing products. The fee was reduced to 0.17% on September 30, 1987. During 1990, the enabling legislation was extended to September 30, 1995, but in late 1991, the percentage levy was changed to a flat transaction fee of \$400 per shipment.

Most major gold-producing nations impose taxes on domestic mining operations: taxation of the gold mining industry in some countries may be specifically tailored to accommodate a nation's stated economic and political objectives. For example, in the Republic of South Africa, gold mines are taxed in accordance with two basic formulas: one taxes the profits of mines opened before 1966, while the other formula applies to Many major goldnewer mines. producing nations have also provided tax subsidies. and other concessions. assistance to gold mining. The former U.S.S.R. supported gold mining through

administrative fiat. China encourages gold prospecting by both the civilian and military population. Australian mining companies have for decades been exempted from paying taxes on profits derived from gold mining. However, effective January 1, 1991, the Government of Australia eliminated its 6-decade-old tax exemption of income derived from gold production, including byproduct production from those copper operations where gold represents more than 40% of the total income.

Operating Factors

Environmental Issues.—The costs associated with meeting Federal, State, and local environmental requirements can vary considerably from one mine site to another. At mines utilizing cyanide recovery techniques in their milling or heap-leaching plants, special precautions, monitoring and leak detection procedures, and site design features are employed to avoid contamination of the surrounding environment and to reduce the exposure of wildlife to cyanide-laden process streams. For example, at the Mesquite Mine in California, two solution ponds with about 4 hectares (9 acres) of exposed area have been completely covered with plastic to minimize wildlife exposure as well as water loss by evaporation. Several processes have been developed in recent years to detoxify or neutralize spent ore prior to disposal or final site reclamation. New regulations pertaining to cyanide use on Federal lands were issued during 1990 and further clarified during 1991. In an emergency, chemical breakdown of cyanide can be induced quickly with chlorine gas.

Because of the danger of mercury pollution, the use of mercury amalgamation in domestic gold operations is now virtually nonexistent. Despite Government efforts to control the use of mercury, the amalgamation process continues to be used in environmentally detrimental manner in frontier unregulated operations in the Amazon Basin and in the Philippines. Mercury and arsenic can be natural contaminants of gold ores,

requiring troublesome or costly extraction processes. Other potential pollutants that may be byproducts from gold mining include antimony, bismuth, tellurium, and thallium. Two iron sulfides, pyrite and pyrrhotite, commonly occur in gold deposits and can be a source of stream pollution as they oxidize to sulfates and other soluble compounds. **Pollution** resulting from some placer operations may be reduced or eliminated through the use of properly designed settling ponds. mill tailings, Waste dumps, excavations are increasingly subject to public scrutiny, and environment control costs must be taken into account along with other operating factors. Expanded mine safety requirements in recent years are another important cost factor.

Employment.—According to annual data prepared by the U.S. Department of Labor, employment in the Nation's gold mines and mills, exclusive of office employees, increased from about 7,000 in 1985 to more than 16,000 in 1990. Employment at gold mines and mills declined to about 15,000 in 1992. The number of jobs available in both surface and underground mines and associated processing plants is not always directly proportional to mine production, instead variations reflecting development activity, the price of gold, weather, type of mining operation, etc. During 1989, citing employment studies for mining in Nevada and South Dakota, the Economics Institute of Boulder, CO,4 derived an employment multiplier of 19.4 jobs per \$1 million of gold production, giving an estimate for total direct, plus indirect employment attributable to domestic gold production, of about 51,000 persons. A companion study covering the period 1979-905 showed employment multipliers and the industry's contribution to gross State products and State personal income for 11 goldproducing States. The report noted that induced employment from preciousmetals production in Nevada, for example, accounted for between 14% and 20% of all new jobs created in Nevada from 1986 to 1989. An average employment multiplier of 20.3 jobs per \$1 million in output was calculated for the 11-State area.

ANNUAL REVIEW

Legislation and Government Programs

On May 13, the President signed legislation authorizing the minting of 10.4 million special coins to commemorate the 500th anniversary of the discovery of America by Christopher Columbus. The legislation, Public Law 102-281, known the Christopher Columbus Quincentenary Coin Act, called for the minting of up to 500,000 \$5 gold coins weighing 8.359 grams (0.268 troy ounce) each, up to 4 million \$1 silver coins weighing 26.73 grams (0.859 troy ounce) each, and up to 6 million half-dollar clad coins. Surcharges included in the price of each coin are paid to the Christopher Columbus Fellowship Fund to establish and endow the Christopher Columbus Fellowship Foundation. The foundation is authorized to award 2-year fellowships to outstanding individuals to encourage new discoveries in all fields of endeavor for the benefit of humankind.

Public Law 102-414, approved by the President on October 14, authorized the minting of up to 300,000 \$5 gold coins, 1.0 million silver coins, and 2.0 million half-dollar clad coins to commemorate the 50th anniversary of the involvement of the United States in World War II. As specified by the law, the gold coin is emblematic of the Allied victory and the silver coin is emblematic of the Battle of Normandy. Surcharges included on the price of each coin will be paid to the American Battle Monuments Commission to help fund a memorial in Washington, DC. to honor members of the Armed Forces of the United States who served in World War II and to the Battle of Normandy Foundation to create a U.S. D-Day and Battle of Normandy Memorial in Normandy, France. The metal content of the coins is the same as that specified for the Columbus coins.

Strategic Considerations

Gold is not a National Defense

Stockpile item; however, the Treasury had stocks of bullion amounting to about 8,144 tons (262 million ounces) at yearend 1992. Large quantities of gold were also held as commercial and private bullion stocks. Therefore, the availability of gold in a time of national emergency appears to be ensured.

One strategic aspect of the domestic gold mining industry that is infrequently considered is that the industry constitutes a valuable pool of experienced personnel, including chemists, geologists, engineers, and metallurgists as well as miners, machinists, and heavy equipment operators. In the event of a national emergency when time becomes a critical factor, these skills may be readily directed toward the discovery, development, and production of strategic materials.

Issues

An issue of continuing concern to domestic exploration companies, gold producers, and to producers of other minerals as well is that of mineral land availability. Because the geological forces that form mountains and unique physiographic features are commonly responsible for producing mineral deposits, exploration for gold and other minerals frequently focuses on these areas of disturbance. The same rugged features that make certain areas attractive to the minerals explorer also may make them less accessible for mining because these areas may presently be more valued for their undisturbed or wilderness qualities than for their mineral potential. In recent years, the trend toward preserving increasingly greater areas of unevaluated wilderness land, on which exploration is prohibited or severely restricted, may lead to a decline in new discoveries.

Another issue of concern to the mining industry as well as law enforcement authorities has been the growth in recent years in telemarketing fraud and investment swindles involving sales of gold bullion and investment in questionable mining ventures. The seriousness of the problem prompted the North American Securities Administrators

Association Inc. (NASAA) and the Council of Better Business Bureaus Inc. to issue, in late 1988, an Investor Alert entitled "Dirt Pile Gold Swindles." The alert was to educate the public regarding the organization, characteristics, and pitfalls of the class "dirt pile" or "goldin-the-ground" swindles. The NASAA is composed of representatives from the securities regulatory agencies of all 50 States plus Puerto Rico. enforcement authorities and various industry trade groups continue to police against other fraudulent practices, such as misrepresented gold quality marks on jewelry and bullion and fake collector coins.

Production

Of the 329 tons of gold (10.6 million ounces) produced in the Nation in 1992, 71% was attributable to the 25 leading producers. The average recoverable gold content of gold ores processed from lode mines was 1.27 grams per ton (0.037 ounce per short ton), while placer gravels yielded an average of 0.82 gram per cubic meter (0.02 ounce per cubic yard) of material washed.

The individual company production and performance data in this report were derived from published sources such as company annual reports.

Alaska.-Gold production in Alaska increased for the third consecutive year, according to a summary of 1992 mineral activity prepared by the Alaska State Division of Geology and Geophysical Surveys (DGGS).6 Gold production of about 5,000 kg (160,850 ounces) was reported to the USBM. However, an annual survey conducted informally by the DGGS suggests that a total of about 8,163 kg (262,500 ounces) of both lode and placer gold was produced; the comparable total for the previous year was 7,585 kg (243,900 ounces). Owing to the year's lower gold price, the value of the 1992 production was only slightly greater than that of the previous year but 1% less than the value of gold produced during 1990. Gold production during 1992 was derived from 2 lode mines and

197 placer mines. Two lode mines and 202 placer mines produced gold during the previous year. According to the DGGS, a late spring thaw and the early onset of winter in Alaska's interior region during 1992 caused many placer mining operations to lose up to 25% of their seasonal annual production. comparison of individual unit-cost data reported to the State showed a 10% to 25% improvement during 1992 when compared with those of the previous year. This comparison suggests that 1992 witnessed an improvement in overall placer mine productivity.

Greens Creek Mining Co.'s Greens Creek Mine, on Admiralty Island near Juneau, was the State's largest goldproducing lode mine. During 1992 the mine produced 103,241 tons (113,827 short tons) of sulfide concentrates bearing the principal values of zinc, lead, and silver plus 1,008 kg (32,400 ounces) of gold. In February 1993, as a result of continued depressed metal prices, the decision was made to curtail operations at Greens Creek. All operating and environmental permits will be maintained in anticipation of a resumption of operations once economic conditions improve.

Alaska's largest placer gold producer during 1992 was the Valdez Creek Placer Mine near Cantwell. The mine, owned by Cambior USA, Inc. (75%) and Camindex Resources Inc. (25%).produced about 2,672 kg (85,924 ounces) of gold during the year. This was twice the amount recovered during 1991 when work to temporarily divert Valdez Creek was finally completed. Production at the mine during 1992 as measured by the average daily gravel extraction rate reportedly improved 56% from that of 1991 to 25,740 cubic meters (33,670 cubic yards) per day.

Alaska Gold Co. continued to operate its two Yuba class bucketline stacker dredges on its property in the Nome area. In an attempt to overcome costs and problems association with the current mining process of stripping, thawing, and dredging, the company initiated a pilot project during the 1992 winter season aimed at excavating frozen payable

gravel, which is then stored in the wash plant area to be thawed naturally then processed during the 1993 summer season. During the year the company commenced a small-scale exploration project to define areas on its Nome holdings that might be suitable for open pit mining of frozen gold-bearing gravel. The company also operates a dredge at its properties along the Hogatza River. Large placer mining operations were also active near Circle, Fairbanks, Livengood, Ruby, and elsewhere.

Several large gold mines continued to developed during 1992. southeastern Alaska, Echo Bay Mines Ltd. continued its involvement in developing the Alaska Juneau (AJ) Mine, immediately behind the capital city of Juneau, and its Kensington joint-venture project, 115 km (72 miles) north of Juneau. Work at the wholly owned AJ Mine during the year focused on base and the reserve increasing completing a new feasibility study aimed at redesigning the planned underground mine and mill to accommodate a capacity of up to 27,200 tons (30,000 short tons) per day. The increased capacity would increase the expected yield to 14 tons (450,000 ounces) of gold per year. Echo Bay also owns the old Treadwell Mine on Douglas Island, across the Gastineau Channel from Juneau. The AJ. Treadwell, and Kensington are all former gold-producing mines.

Twenty-four km (15 miles) northeast of Fairbanks, Fairbanks Gold Ltd., an operating subsiding of Amax Gold Inc., continued engineering, permitting, and design work aimed at developing its Fort Knox Project into a large open pit gold mine. The project, located on 11,300 hectares (28,000 acres) of mostly State land with some private, is projected by the company to begin producing gold at a rate of 9,300 to 11,000 kg (300,000 to 350,000 ounces) per year by late 1995. In the Ester Dome area near Fairbanks, LaTeko Resources Ltd. and its wholly owned subsidiary, Citigold Alaska Inc., continued their evaluation of the Ryan Mine design work, Lode property. metallurgical testing, and delineation of ore reserves at the former gold producer

were continuing at yearend. Exploration also was conducted at Ester Dome by several other companies, including American Copper and Nickel, Inc.

Late in 1992, the Alaska Department of Natural Resources began to select its final 8 million hectares (20 million acres) of land from the Federal Government as part of the 1959 Alaska Statehood Act. When Alaska became a State it was awarded 42.6 million hectares (105 million acres) of land; in 1991 and 1992, State government diligently researched natural resource values to make its final decision by the January 1994 deadline. The USBM provided a computerized Mineral Availability System (MAS) data file and claim status information to the DGGS, the lead State agency determining mineral and energy potential data for the project. December 1992, initial land nominations were transmitted to the Bureau of Land Management. These nominations included 14 million hectares (35 million acres) selected for high mineral and Individuals and energy potential. companies holding Federal claims and wanting to convert to State ownership were being urged to do so by the DGGS before the 1994 deadline.

Arizona.—Arizona's largest gold mine was Cyprus Gold Co's. Copperstone Mine near Ouartzite in LaPaz County. Operated by Cyprus Copperstone Gold Corp., this open pit, milling, and heapleaching operation, opened in 1987, is on approximately 15 square km (9 square miles) of unpatented lode mining claims held by Cyprus under a long-term lease. During 1992, Copperstone processed ore at capacity and produced 3,614 kg (116,200 ounces) of gold. Economic ore reserves at the mine were depleted in December 1992, and mining ceased. The processing plant will continue in operation through about April 1993 processing mostly low-grade ore previously mined and stockpiled adjacent to the plant. Reclamation of the mine area in conformance with Federal and State permits was under way near vearend.

Gold production continued through the

summer at the Mystic gold mine, in Maricopa County, about 19 km (12 miles) north of Sun City. Fischer-Watt Gold Co., which holds a 100% operating interest in the property, ceased mining operations in the fall and placed the mine on standby status at yearend. Wickenburg, in Maricopa County, Pima Mining Co. filed an environmental assessment for its proposed Newsboy Mine. Pima, previously known as Wounded Bull Resources NL, has faced intense local opposition to the proposed open pit and milling operation, designed to produce about 840 kg (27,000 ounces) of gold annually.

In response to weak gold prices, mining operations at the underground Congress Mine in Yavapai County were discontinued in April. The mine's owner, Republic Goldfields Inc., formerly Mylartic Hygrade U.S. Inc., continued to operate the mill through September, processing stockpiled and custom ore at the millsite. Also in Yavapai County, mining continued at the McCabe Mine near Prescott by Magma Gold Ltd., a subsidiary of Magma Copper Co. Mining operations were discontinued in early 1993 owing to unsatisfactory ore grades. A substantial portion of Arizona gold production is also derived as a byproduct of copper mining.

A number of locations, mostly former gold-producing sites, continued to be explored for gold during the year. Properties under study included the Harquahala gold project of Manhattan Minerals Corp. in LaPaz County; Addwest Minerals Inc.'s Gold Road Mine near Oatman in Mohave County; Cambior Inc.'s Gold Basin property 80 km (50 miles) northeast of Kingman; and VLS Minerals Inc.'s Wilson placer project in the La Cholla placer district south of Quartzite, in LaPaz County.

California.—For the sixth consecutive year California was the Nation's second largest gold-producing State.

California's largest gold mine, Homestake's McLaughlin Mine, near Lower Lake, about 113 km (70 miles) north of San Francisco, produced 9,053 kg (291,094 ounces) or 11% more gold than in the previous year. McLaughlin was the site of the first successful commercial application of the autoclaveprocess technology for the extraction of This large surface mine has produced 54.4 tons (1.75 million ounces) of gold since operations began in 1985. The mine's new flotation circuit, used to treat lower grade refractory ores, was commissioned in late 1991 and became fully operational in 1992. During the mine received the national recognition from the Wildlife Habitat Enhancement Council for its voluntary wildlife enhancement and conservation

The State's second largest gold mine was the Mesquite Mine of Gold Fields Operating Co., near Brawley in the Chocolate Mountains of east-central Imperial County. Mesquite began open pit mining and heap leaching at the site in early 1986. To the east in Imperial County, Glamis Gold Ltd., through its subsidiary Chemgold Inc., continued open pit and heap-leaching operations at its Picacho Mine. During 1992, the company completed construction on its No. 5 heap-leaching pad and by November, more than 360,000 tons of ore grading 0.92 gram per ton (0.027 ounce per short ton) had been placed on the pad for leaching. Nearby, Glamis and a partner, Arizona Star Resources Corp., continued exploration on their Indian Rose and Octotillo projects. Glamis' Alto Mine, depleted and closed in 1991, yielded a small quantity of residual gold and, before yearend 1992, neutralization of the heaps, reclamation, and revegetation of the mine area had been completed. continued at the company's open pit and heap-leaching Yellow Aster Mine near Randsburg in Kern County where the operator, Rand Mining Co., a wholly owned subsidiary of Glamis, began construction at its nearby Baltic Mine Baltic is slated to begin production in late 1993 at a rate of about 1,200 kg (40,000 ounces) of gold per year. Also in Kern County, Cactus Gold Mines Co. completed open pit mining at the Cactus Mine in early 1992; heapleaching production is expected to

continue through mid-1994.

In February, following a 4-year hiatus for permitting, Viceroy Gold Corp. poured its first gold at its new Castle Mountain gold project in San Bernardino County. The new facility, an open pit and heap-leaching operation 150 km (65 miles) south of Las Vegas, NV, is expected to produce about 3,100 kg (100,000 ounces) of gold annually during the first 5 years of operation. Leaching solutions are applied to the heaps via drip irrigation. Pipes buried in the heap direct the resultant pregnant solution to closed solution storage tanks designed to provide both wildlife protection and water conservation. Under an agreement with Nature Conservancy, Viceroy established a 24,000-hectare (60,000acre) desert tortoise preserve at the adjoining Walking Box Ranch. Minerals Ltd.'s Colosseum Mine, in San Bernardino County, ceased mining activity in 1992. Leaching of stockpiled ore will continue into 1993.

In California's Sierra Nevada/Mother Lode Country, gold mining continued at Sonora Mining Corp.'s Jamestown Mine in Tuolumne County and FMC Gold's wholly owned Royal Mountain King Mine near Copperopolis, Calaveras County, where production at the FMC project rose to more than 2,200 kg (71,000 ounces) in 1992. In June, Brush Creek Mining and Development Co. Inc. officially opened its Ruby Mine. The newly reopened mine, an underground placer, is in Sierra County. Before its closure in 1942 by War Production Board Order L-208, the Ruby Mine had produced more than 5,600 kg (180,000 ounces) of gold. According to the company, the Ruby's coarse gold nuggets are sought after by fabricators of gold nugget jewelry and specimen collectors.

Also in Sierra County, operators of the Original Sixteen to One Mine near Allegheny conducted an unusual experiment that proved successful, according to newspaper accounts and company reports. In early 1992, the operators of the mine began using metal detectors as an underground gold locator tool. Early skepticism by the mine's management disappeared when, after 6

months of experimentation, more than \$1 million worth of gold had been detected and recovered. Before the experiment, the mine was having financial difficulty the company's liquidity significantly impaired, but the use of metal detectors made a big difference. In one 12-day period, miners reportedly detected and recovered 12 kg (400 troy ounces) of gold. Not surprisingly, the company used some of its new revenue to purchase eight additional detectors. The Original Sixteen to One Mine, developed in an unusually high-grade deposit and first opened in 1911, has reportedly produced more than 31.1 tons (1 million troy ounces) from ore with an average content exceeding 31 grams (1 troy ounce) of gold per ton.

In mid-June, Lassen Gold Mining Inc., a subsidiary of Amax Gold Inc., poured its first bar of production gold at its new Hayden Hill Mine, northwest of Susanville in Lassen County. The new open pit project employs both milling and heap-leaching recovery methods. The mine produced about 900 kg (28,815 ounces) during 1992 and is expected to yield more than 3,400 kg (110,000 ounces) in 1993.

Colorado.—Gold mining and exploration developments in Colorado during 1992 were summarized in a paper prepared by the Colorado Geological Survey (CGS).⁷

Gold production was reported by six Colorado operations during the year. The State's two major gold-producing mines were the San Luis Mine of Battle Mountain Gold Co. (BMG) and the operations of the Pikes Peak Mining Co. joint venture at Cripple Creek.

At the new San Luis Mine, near the town of San Luis, in Costilla County, production during the mine's first full year of production amounted to 1,710 kg (55,000 ounces), or 20% below company expectations. An operating problem with elevated cyanide levels in the tailings pond necessitated intermittent shutdowns until midyear, when the problem was finally resolved. BMG expects the San Luis, also known as El Plomo, to yield about 2,180 kg (70,000 ounces) in 1993.

At Cripple Creek, in Teller County, the Cripple Creek and Victor Gold Mining Co., a joint venture of Pikes Peak, a wholly owned NERCO Inc. subsidiary, and Golden Cycle Gold Co... produced 1.320 kg (42.451 ounces) of gold in 1992, establishing a new record but falling short of a 1992 goal of about 2,020 kg (65,000 ounces) projected earlier. The partner's Mine Dump program exceeded the goal of 311 kg (10,000 ounces), and mining, crushing, and heap leaching of ore from the Globe Hill and Ironclad open pits continued. However, the discovery of a solution leak in April necessarily delayed operations while repairs were made. The fluids reportedly almost completely contained on the pads, but action was taken to neutralize any fluids that might have escaped. The partners began permitting at their Cresson deposit in midyear; construction was scheduled for 1993 with initial gold production planned for 1994. Extensive exploration also was continued on lands held in the vicinity of Cripple Creek.
