Spraying of the heaps at Colorado's largest heap-leaching mine, Summitville Mine, near Del Norte in Rio Grande County, ceased in March and reclamation work was begun by the Consolidated operator. Summitville Mining Co., a subsidiary of Glamis Resources Ltd. About 9,330 kg (300,000 ounces) of gold was recovered during the 5 years of mine life. Reportedly. environmental problems and a failure in the mine's basic design led to substantial losses for the company, which filed for bankruptcy in December. The U.S. Environmental Protection Agency was expected to manage the cleanup efforts at the site.

Other gold producers in Colorado during the year included ASARCO Incorporated Black Cloud Mine at Leadville in Lake County and Franklin Consolidated Mining Co. Inc.'s Franklin Mine near Idaho Springs in Clear Creek County. Near Central City in Gilpin County, Solution Gold Ltd. recovered gold by reprocessing old mine tailings in the Central City mining district. Exploration for new gold deposits and of

known gold deposits was conducted at a number of sites throughout the State during the year.

Idaho.—Gold production in Idaho declined 5% from production achieved during the previous year. Idaho's largest gold mine, Pegasus Gold's Black Pine Mine in Cassia County, poured its first gold bar in January and proceeded to fulfill its first full year of production with a yield of about 1,500 kg (48,700 ounces) of gold and 460 kg (14,900 ounces) of silver. Ore mined from the new mine's Tallman and B pits is placed directly without crushing on the mine's unusual five-celled, valley fill leach pad, which incorporates a countercurrent leachate system. Pegasus has outlined three separate deposits at the Black Pine operation, which is near Bridge, 95 km (60 miles) southeast of Burley.

The State's second largest gold mine is NERCO's open pit DeLamar Mine, in Owyhee County, where about 1,180 kg (38,000 ounces) of gold and 57 tons (1.8 million ounces) of silver were recovered during 1992. During the year, NERCO its new \$7 million started up acidification, volatilization, reabsorption (AVR) plant to recycle cyanide used at the DeLamar site. The company also moved ahead with permitting for its Stone Cabin property 8 km (5 miles) from DeLamar. Permitting efforts, however, were reportedly slowed by wetland issues and changes in corporate priorities.

In Butte County, Idaho Gold Corp., an 85%-owned subsidiary of Bema Gold Corp., completed mining in early 1992 at its Champagne Mine, 32 km (20 miles) east of Arco. Gold and silver production through secondary and tertiary retreatment of the heaps will continue into 1993, and a heap neutralization program will begin during the first half of that year. Bema also has four gold deposits under evaluation and review in the Elk City area of Idaho County.

In Valley County, seasonal mining and heap-leaching operations were resumed at MinVen Gold Corp.'s Stibnite Mine near Yellow Pine. Production during the year was about 20% greater than that of 1991.

Also near Yellow Pine, at Hecla's Yellow Pine Unit, the company poured its final ounce of gold at the recently depleted facility where open pit mining and heapleaching operations began in 1988. A unique reclamation and neutralization process that uses naturally occurring. nonpathogenic bacteria has employed to neutralize the spent ore on the Yellow Pine leach heaps. During 1992, the Unit received the Pacific Northwest Pollution Control Association's Industrial Pollution Control Award for Idaho for innovative strides toward water quality improvement. Hecla and Barrick Gold Exploration Inc. signed a letter of intent to explore and develop the refractory sulfide deposit remaining on the property. However, Barrick withdrew from the agreement at the end of the year. Also in Valley County. Coeur d'Alene Mines Corp.'s closed Thunder Mountain Mine gained national recognition for voluntary wildlife enhancement and conservation efforts. Coeur-Thunder Mountain Inc. was 1 of only 21 companies nationally to be awarded a "highest habitat" certification under the corporate wildlife habitat program of the Wildlife Habitat Enhancement Council. The Thunder Mountain Mine had ceased operation in 1990 following exhaustion of the known ore reserves.

Atlanta Gold Corp. continued drilling evaluating its surface underground reserves at the Atlanta property in Elmore County. Forty-eight km (30 miles) southwest of Challis in Custer County, Hecla's Grouse Creek Mining Corp. conducted a major drilling project on land held around the Grouse Creek project. In early 1993, the company announced the discovery of a deeper, higher grade ore zone in the proposed pit area at the project. Selection of a target date to begin construction of the new mine was delayed by concerns relating to weak metal prices. Development of Meridian Gold Co.'s large beartrack property near Salmon, in Lemhi County, was further deferred pending an improvement in the price of gold. The 85-square-hectare (53-squaremile) property reportedly contains about 26 tons (839,000 ounces) of proved and probable heap leachable gold.

The Idaho Department of Parks and Recreation opened a new mining interpretive center in Custer County near Challis, at the intersection of U.S. 93 and State Highway 75; it includes interpretive displays and audiovisual programs on Idaho's mining history. A circle road tour was developed with a number of posted stops, including the historic Yankee Fork gold dredge that operated on the Yankee Fork of the Salmon River in the late 1940's.

Montana.—Mining and mineral developments in Montana during 1992 were summarized in a report prepared by the Montana Bureau of Mines and Geology.8 For yet another year, Pegasus Gold was Montana's leading goldproducing company, mining gold-bearing ore at four separate operations in Montana. The largest gold-producing mine in the State was Pegasus Gold's Zortman-Landusky Mine, in the Little Rocky Mountains of Phillips County, where about 3,515 kg (113,000 ounces) of gold was recovered during 1992. Operations at the Zortman-Landusky facility are focused on two separate surface mines several kilometers apart where gold is recovered using heapleaching methods. Mining during the year was confined to the Landusky side while work on the mine's Zortman Extension project was focused on metallurgical work and on obtaining State permits. In March 1992, Zortman Mining Inc., the operating company at the Zortman-Landusky operation, which began in 1979, celebrated the recovery of its millionth troy ounce of gold. Production at Pegasus Gold's Beal Mountain Mine, south of Butte in Silver Bow County, amounted to a record 1,624 kg (52,200 ounces) of gold, an increase of about 10% over that of the previous year. A new crushing circuit installed during the year aided in achieving improved gold recovery. In Jefferson County, Pegasus Gold's Montana Tunnels gold, lead, silver, and zinc mine also produced gold at record levels. The mine recovered 2,320 kg (74,700 ounces),

which was nearly 20% more than that in 1991. Tonnage of ore mined at Montana Tunnels increased by 7% during 1992. but the major factors leading to higher gold production were improved recoveries and higher than anticipated ore grades. About 15% of the gold was recovered by a new gravity circuit installed in 1991. and the remaining precious-metals values were recovered from lead concentrates that were processed at Asarco's smelter in East Helena, MT. Pegasus also continued leaching residual gold and conducting metallurgical tests at its Basin Creek Mine in Lewis and Clark County. Surface gold mining operations at Placer Dome's wholly owned Golden Sunlight Mine near Whitehall increased 30% in 1992 to 3,230 kg (103,870 ounces), mostly as a result of higher grades of ore mined. During the year the company completed constructing and lining a new tailings facility. Also, five environmental groups brought a suit contesting the issuance of the mine's operating permits. To the southeast, at Jardine, in Park County, equal partners Homestake and TVX Gold Inc. produced 1.320 kg (42,500 ounces) of gold at their Mineral Hill Mine. Mineral Hill, operated by TVX, is an underground facility accessed by three adits and operating as a zero discharge facility. The mine processed a record 159,000 tons (175,000 short tons) of ore during the year. **Exploration** conducted by the partners at nearby Crevice Mountain confirmed a new area Permitting was of mineralization. initiated for further work at the new find. In eastern Park County, near Cooke City, Crown Butte Resources Ltd. continued to pursue permitting and to evaluate its large New World gold, copper, and silver project. Responding to environmental concerns, the company reportedly revised its operating plans to eliminate open pit mining and the use of cyanide. The property is mostly on private land near the northeast corner of Yellowstone National Park.

To the north, in Fergus County, Canyon Resources Corp. produced 1,862 kg (59,857 ounces) of gold at its Kendall Mine, near Lewistown. Kendall, an open pit and heap-leaching facility, first began operation in 1988. Although the company essentially completed its exploration for additional ore reserves on the property during 1992, it is anticipated that known ore reserves will be sufficient to support 2 more years of active mining and gold production with 1 or 2 years of continued leaching after mining ceases. The company conducted extensive exploration drilling during the year on its 27.6%-held McDonald gold deposit near Lincoln in Lewis and Clark County. Canyon, together with its partner Phelps Dodge (72.75%), earlier formed the Seven-Up Pete Joint Venture to explore and develop the McDonald gold deposit, which, at the end of the year, was reported by the company to contain an estimated 255 tons (8.2 million ounces) of gold; this is a nearly 57% increase in estimated contained metal since the end of 1991. A preliminary feasibility study completed in 1992 indicated production at the McDonald could average approximately 9.3 tons (300,000 ounces) of gold per year. Extensive engineering, metallurgical, hydrologic, and biologic environmental baseline studies were initiated during 1992.

As in past years, many generally small, intermittent placer operations were active along favorable drainages in western Montana. Beginning in 1992, an estimate of the aggregate production derived from these operations has been appended as a footnote to table 2, Mine Production of Gold in the United States, by State.

Nevada.—For more than a dozen years Nevada has been the Nation's leading gold-producing State; if Nevada were a sovereign nation it would be ranked as the world's fourth largest gold producer. Thirteen of the Nation's leading 25 gold mines in 1992 were in the Silver State and yielded more than 60% of domestic gold production during the year. Gold is also the State's principal mineral commodity, accounting for about 87% of the total value of nonfuel minerals output during 1992.

Nevada and the Nation's dominant gold-producing company, Newmont Gold Co. (NGC), produced gold from its

extensive operations in Elko and Eureka Counties, near the town of Carlin. During 1992, NGC produced nearly 50 tons (1,587,900 ounces) of gold from five surface mines feeding five nearby mills and four heap-leaching facilities. NGC's total cash cost to produce 1 ounce of gold during 1992 amounted to \$207 compared with \$203 during the previous year. Overall, nearly 146 million tons of material was mined from the company's deposits in 1992. Proven and probable reserves at yearend 1992 on NGC's Elko and Eureka County properties amounted to 605.2 tons (19.5 million ounces) compared with 625.6 tons (20.1 million ounces) at the end of 1991. Of these reserves, NGC reported that 94% was located on private land. Gold Quarry, the largest mine operated by the company, produced 28.6 tons (927,800 ounces) in 1992 compared with 32.2 tons (1,034,500 ounces) in 1991. As the Gold Quarry pit has deepened in the nearsurface oxide ore, mining has begun to encounter refractory sulfide material interspersed with the oxidized ore reserves. Eventually all of the deeper ore mined at Gold Quarry will be refractory therefore, will need to be and. appropriately pretreated. In the meantime, refractory elements in the oxide material have had a negative effect on gold recovery. To counter this problem and still meet its production target of about 50 tons (1.6 million ounces), NGC increased the quantity tons treated in 1992 and initiated a roaster program for the treatment of higher grades of refractory ore. The company also continued the testing of its proprietary bioleaching process for lowgrade gold-bearing refractory materials. In December, NGC signed an agreement with Barrick Goldstrike Mine Inc., a wholly owned subsidiary of American Barrick Resources Corp., for the joint development of the Post ore body that extends across their common border in the northern region of the Carlin Trend. The lower and deep zones of the Post ore body, also known as the Deep Post Deposit, contain approximately 288 tons (9.25 million ounces) of gold. The two parties will share the cost of mining the

Post in proportion to their nearly equal interests in the contained gold. The agreement also allows NGC to process Barrick's low-grade refractory material, which is estimated to contain more than 31.1 tons (1.0 million ounces) of gold.

Gold production at Barrick Goldstrike Mines' Goldstrike Mine in Eureka County, at 34.5 tons (1.1 million ounces), was more than double the nearly 17 tons (546,146 ounces) produced in 1991. The sharp rise in production arising from the mining of higher grade ore served to reduce Goldstrike's production costs from \$318 per ounce (\$10.22 per gram) in 1991 to \$199 (\$6.40 per gram) in 1992. The company reported that its Betze Development Plan, begun in 1989 to access and develop its Betze deposit, was virtually completed and that the higher grade sulfide ore in the Betze pit had been exposed before yearend in concert with the timely commissioning of a second mill, the second and third autoclave units, and a new oxygen processing plant. company also reported that ore reserves had been increased during the year to 653 tons (21 million ounces) from the 574 tons (18.5 million ounces) reported at the end of 1991. Ultimately, as provided for in the December agreement with NGC, the Betze and Deep Post deposits will be accessed by one large open pit to be known as the Betze-Post pit. In early 1992, the company announced plans to develop its Meikle Mine, 1.6 km (1 mile) north of the Goldstrike Mine. Meikle deposit, formerly known as the Purple Vein Deposit, is scheduled to be brought into operation as an underground mine in 1996; average annual gold production is projected at about 12.5 tons During the year, (400,000 ounces). Barrick also maintained its 26.25% share in the Pinson Mine, northeast of Winnemucca in adjoining Humboldt Gold production at Pinson County. during 1992 amounted to about 1,584 kg (51,000 ounces).

Northwest of the Goldstrike operation, in Elko County, Dee Gold Mining continued milling and heap-leach production at its Dee Mine, where 1,207 kg (38,818 ounces) of gold was recovered

during the year. Nearby, at the Ivanhoe (Hollister) Mine, ore reserves from the first phase of the mining operations were essentially exhausted in early 1992. In midyear NGC acquired a 75% interest in the property, and leaching of residual gold in the existing heaps continued through yearend. NGC acquired the property because of its potential to add new reserves for future recovery.

In the Independence Mountain Range of Carlin, northeast partners Independence Mining Co. Inc. and FMC Gold Co. produced about 9,950 kg (320,000 ounces) of gold at their Jerritt Canyon Mine during 1992, down about 15% from the previous year because of lower ore grades processed. The mine moved a record 35 million tons of material during the year and increased mill throughput by 3% to about 7,400 tons per day. Exploration to discover new resources continued at a high rate, and during the peak season, up to 24 drill rigs and a team of 23 geologists drilled 921 holes, reportedly locating significant mineralization in 54% of the holes. Sixteen km (10 miles) north of Jerritt Canyon, Independence continued open pit operations at its wholly owned Big Springs Mine, where nearly 7,800 kg (250,000 ounces) of gold has been recovered since 1988.

Combined gold production at Santa Fe Pacific Gold Corp's, two surface mines, the Rabbit Creek Mine and the new Lone Tree Mine, both in eastern Humboldt County, amounted to about 9,200 kg (295,000 ounces). In mid-August, the Lone Tree operation completed its first full year of operation. Other large gold mines, all surface operations, in Humbolt County included Amax Gold Inc.'s Sleeper Mine, Granges Inc.'s Crofoot/Lewis Mine, Rayrock Mines Inc.'s Marigold Mine, Gold Fields Operating Co.'s Chimney Creek Mine, and FirstMiss Gold Inc.'s Getchell Mine. Aggregated gold production at these five operations amounted to about 25 tons (800,000 ounces) during the year. In late May, Gold Fields celebrated the pouring of the millionth ounce (31.1 tons) of gold recovered at its Chimney Creek Mine since the mine was opened in December

1987.

To the west in Washoe County, Amax Gold completed mining the known ore reserves at its Wind Mountain open pit and heap-leaching mine in early 1992. Leaching of stacked ore continued Similarly, Western through yearend. Hog Ranch Co. completed mining at its Hog Ranch Mine north of Gerlach. Leaching will continue until the existing heaps are depleted. In Story County, south of Reno, Miramar Mining Corp. began production at its Golden Eagle Mine near Virginia City. The new open pit and heap-leaching facility, formerly known as the Flowery Mine, is scheduled to produce at least 620 kg (20,000 ounces) of gold and 7 tons (225,000 ounces) of silver per year. In Lander County, St. George Metals Inc. poured its first bar of doré at its newly opened Dean Mine, 24 km (15 miles) south of the town of Battle Mountain. High-grade ore mined from the underground workings is processed by milling and heap-leaching facilities 16 km (10 miles) from the mine site. Nearby, Battle Mountain Gold Co. (BMG) produced about 5,530 kg (178,000 ounces) of gold and 13.2 tons (426,000 ounces) of silver at its Battle Mountain Complex. Owing to depletion of high-grade mill ore at BMG's Fortitude pit, milling operations at the complex were scheduled to end in early 1993. Milling may, however, be resumed later if a low-grade milling opportunity under evaluation at yearend proves feasible. By yearend, the company also had identified a large heapleachable deposit, designated the Reona project, within the complex area.

At the McCoy and Cove gold and silver property of Echo Bay Mines, 23 km (16 miles) south of the BMG complex, the company had another record-breaking year of operation, producing 9,377 kg (301,512 ounces) of gold and 246.4 tons (7,921,496 ounces) of silver from two separate gold deposits 1.6 km (1 mile) apart. During 1992, surface and underground mining at the Cove deposit moved ahead to the extent that the underground levels were overtaken by the open pit in early 1993. The 6% increase in gold production and

41% increase in silver production over 1991 were reportedly attributed to mining and milling the greater quantities of higher grade sulfide encountered at depth. Heap-leaching recovery methods are also employed at the McCoy/Cove operation to treat lower grade ore.

At the Cortez Mine, about 50 km (30 miles) southeast of McCoy/Cove along the Lander County/Eureka County line, improved grades and recoveries led to an increase in gold production to about 2,330 kg (75,000 ounces) in 1992. The company, Cortez Gold Mine Joint Venture, continued to explore its Pipeline and South Pipeline discoveries near the Cortez operation in Lander County. The planned surface mining project, called the Pipeline Project, is expected to be in production by early 1995. In White Pine County on the Alligator Ridge Trend, U.S.M.X. Inc. poured its first gold in mid-June at its new Yankee Mine. The new open pit and heap-leaching facility is U.S.M.X.'s third producing mine in the Alligator Ridge area. About 335 kg (10,800 ounces) of gold was reportedly recovered from the Yankee during 1992. The other two nearby U.S.M.X. mines are the Alligator Ridge and the Casino/Winrock.

At Round Mountain, about 100 km (60 miles) north of Tonopah in Nye County, Round Mountain Gold Corp. recovered about 11.5 tons (370,000 ounces) of gold and 9.8 tons (317,000 ounces) of silver at its Round Mountain Mine. production at Round Mountain, an open pit and heap-leaching operation, increased by 9% in 1992 owing primarily to the discovery of a high-grade vein from which more than 1,600 kg (52,000 ounces) of gold was recovered. company geologist reportedly recovered 50 kg (1,600 ounces) of gold in one afternoon using only a geologist's pick for a tool. Coarse gold of the sort contained in the high-grade discovery requires milling rather than heap leaching so the company installed a small mill and, gravity using separation methods, extracted the coarse-free milling gold from stockpiled high-grade vein material that contained nearly 2 ounces of gold per short ton. Near Beatty in southern Nye County, Lac Minerals Ltd. recovered 10.1 tons (323,825 ounces) of gold and about 9.7 tons (313,000 ounces) of silver at its Bullfrog Mine. Lower grade open pit ore reserves at Bullfrog have been nearly exhausted, and the transition to mining higher grade ore from the underground extension of the ore body was well under way by yearend.

Oregon.—There were no primary lode gold mines active in Oregon during the year. However, as in past years, several placer mines, including Bonanza Mining Co.'s mine on Pine Creek in Baker County, were in operation. Bonanza began reclamation at the site and extended its exploration to properties held nearby.

Formosa Resources Corp. resumed underground mining activities at its Silver Butte copper, gold, and zinc mine near Riddle, in Douglas County. Concentrates were trucked to Vancouver, WA, then shipped to Japan for further processing. Plexus Resources Corp. continued development and permitting work at its Bornite Project. Plans for the Bornite Project, to be an underground producer of copper, gold, and silver, called for mining 318,000 tons (350,000 short tons) of ore per year. The property is near Mill City in Marion County.

In September, the Oregon Environmental Quality Commission (EOC) granted final approval to new regulations governing chemical-process mining operations in Oregon. The new regulations focused primarily on new or future precious-metal mines using cyanide or other chemical recovery processes. In 1990, Atlas Precious Metals Co. had announced plans to spend \$80 million to develop its then recently discovered gold deposit known as Grassy Mountain, in Malheur County. The mine was to produce 3,100 kg (100,000 ounces) of gold annually and bring 190 jobs with a \$6 million payroll to Malheur County in eastern Oregon. Following announcement, citizen protests, largely in western Oregon, spurred the EQC to develop the new regulations and for Atlas to postpone development at Grassy Mountain. In October 1992, Newmont

Mining Corp. announced that it had acquired, through a lease, the exploration, development, and mining rights to the Grassy Mountain project from Atlas. Grassy Mountain reportedly has proven and probable reserves of 31 tons (1 million ounces) of gold and 77 tons (2.5 million ounces) of silver.

Gold exploration in Oregon continued but at a lower level than in past years. In Malheur County, ICAN Minerals continued drilling at its Racey "porphyry" gold deposit 65 km (40 miles) south of Baker. In Baker County, Cracker Creek Gold Mining Co. and Cable Cove Mining Co. continued small-scale exploration efforts at their respective properties, the Bourne and the Herculean projects.

South Carolina.—Commercial gold production began in South Carolina before 1830, and gold has been produced in that State discontinuously since that time. During 1992, gold was produced at four South Carolina mines and the State was the only gold-producing State east of the Mississippi River during the year. By yearend, however, mining operations at two of the four mines had been suspended pending improved gold market conditions.

The State's largest gold mine in 1992 was Kennecott Ridgeway Mining Co.'s Ridgeway Mine in Fairfield County. Ridgeway, an open pit and milling facility employing vat leaching recovery methods, produced 5,007 kg (161,000 ounces) during the year. In early 1992, the company, a subsidiary of RTZ's Kenncott Corp., acquired Galactic Resource's 48% interest in the property and thereby acquired sole proprietorship. McCormick County, near the Georgia-South Carolina border, Consolidated Nevada Goldfields Corp. had, by the end of its fiscal year on June 30, produced 489 kg (15,731 ounces) of gold and 587 kg (18,860 ounces) of silver at its Barite Hill Mine. Ore stacking at the open pit and heap-leaching mine's reusable leaching pad ended in early September, and leaching was terminated in late September. Concurrently, construction of a new permanent leach pad was completed and stacking and leaching of ore was begun in October. The new 1.4million-ton-per-year (1.5-million-shortton-per-year) leaching facility had, by yearend, yielded 146 kg (4,687 ounces) of gold, despite restraints on leaching and mining imposed by abnormally high Mining operations were rainfall. suspended at the Brewer Mine, near Jefferson in Chesterfield County, in early November. Processing ore on the leach pad was expected to continue at least through mid-1993. Brewer Gold Co., the operator, indicated near yearend that a decision to permanently close the mine was dependent on the outlook for mining costs and gold prices as well as the results of exploration under way on adjoining properties. Site reclamation at the surface and heap-leaching operation was expected to proceed, possibly into In September, the company's earlier request to transport ore from a deposit near Buford in adjoining Lancster County to the Brewer site was denied by Lancaster County authorities.

Gold mining had been suspended at the Haile Mine of Piedmont Mining Co. near Kershaw in mid-1991, but heap leaching and gold recovery continued into early 1992. In May, Amax exercised its 1991 option and acquired a 62.5% interest in the property and, effective July 1, Amax and Piedmont, through wholly owned subsidiaries, formed a joint venture, the Haile Mining Venture, to proceed with further development of the property. If warranted, the partners plan to develop a large-scale mining operation at the Haile property, which covers approximately 1,500 hectares (3,700 acres) of private or fee property in Lancaster County. Further drilling, evaluation, environmental studies, and permitting will continue in 1993 with the reported objective of completing a bankable feasibility study in early 1994.

South Dakota.—The Homestake Mine at Lead, the Nation's largest underground gold mine, increased its production 24% over that of the previous year to more than 12.3 tons (396,626 ounces). By implementing a new underground operating strategy, the company was able to reduce the total cost of producing 1 ounce of gold at the Lawrence County

facility from \$400 per ounce (\$12.86 per gram) in 1991 to \$337 per ounce (\$10.84 per gram) in 1992. Homestake's new strategy included withdrawing work force and equipment from uneconomic mining areas and transferring them to areas with higher grade ore. Following receipt of State approval, the company continued expanding its newly developed open pit, also known as the Open Cut, developed on the site of the original gold strike in 1876. Work was also continued on the new North Drift designed to connect the existing underground operations with a recently outlined ore body discovered earlier and located about 5 km (3 miles) to the north.

Gold production at South Dakota's second largest mine, Wharf Resources (USA) Inc.'s Wharf Mine, formerly known as the Annie Creek Mine, increased to 2,960 kg (95,186 ounces). During 1992, feed for the heap-leaching process was derived from several open pits, one of which, the Annie Creek pit, was mined out and undergoing backfilling with waste rock near yearend. Wharf Mine is 5 km (3 miles) west of Lead. In October, Wharf assumed management of the Golden Reward Mine. 13 km (8 miles) southeast of Lead. Gold production at Golden Reward, an open pit and heap-leaching facility, amounted to about 1,590 kg (51,000 ounces) compared with 1,262 kg (40,590 ounces) produced during the previous year. Ownership interests in the property were revised during the year giving, Wharf 60% and partner MinVen Gold 40%. Production at MinVen's wholly owned Gilt Edge Mine, 8 km (5 miles) southwest of Lead. amounted to about 840 kg (21,000 ounces). The decrease from the previous year's level reflected the gradual depletion of the mine's presently permitted oxide ore reserves. These were mined out by yearend, and mining operations were suspended at that time. MinVen received regulatory approvals in August to proceed with a bulk heap-leach test on Gilt Edge sulfide ores.

Bond Gold Richmond Hill Inc. produced 945 kg (30,373 ounces) of gold in 1992 at its Richmond Hill Mine. The company, a subsidiary of Lac Minerals,

announced plans to close the mine 6 to 9 months earlier than originally planned. The Richmond Hill property, 8 km (5 miles) northwest of Lead, is an open pit and heap-leaching operation. In midyear, acidic water draining from waste ore piles at the property led to a State order to cease most mining activity; however, leaching and metal production was not affected and continued into 1993.

On election day, November 3, voters in South Dakota passed a ballot initiative designed to impose new acreage and reclamation standards on the Black Hills gold mining industry. The initiative. which was approved by 59% of the voters, limits new mines to 130 hectares (320 acres) and allows existing mines to expand by 81 hectares (200 acres). After that, site reclamation is to be required on an hectare-for-hectare basis before any expansion is allowed. Underground mines, such as the Homestake gold mine at Lead, are exempt.

Utah.—The Bingham Canyon Mine of Kennecott Corp., one of the Nation's leading gold-producing mines for many years, produced 16 tons (515,000 ounces) of gold during 1992, a 12% increase in gold production over that of the previous year. The mine, owned by RTZ and operated by Kennecott, produces gold and silver as byproducts of its copper mining activities. In March, Kennecott announced plans to invest \$800 million to construct a new on-site smelter, expand the existing copper refinery, and construct a new precious-metals refinery. The new facility would employ the latest technology, enabling it to meet current and anticipated future environmental regulations, including air quality standards that will become effective in 1995.

Kennecott's Barney's Canyon gold mine, about 6.4 km (4 miles) north of the Bingham pit, produced 3,608 kg (116,000 ounces) of gold in 1992. Ore reserves at the open pit and heap-leaching facility, which began production in December 1988, are estimated to be sufficient for about 3 1/2 years; however, there may be potential for additional reserves to extend the mine life.

American Barrick's Mercur Mine in Tooele County produced 3,770 kg (121,239 ounces) of gold at an average operating cost of \$262 per ounce (\$8.42 per gram). Extremely hard, jasperoid ores mined throughout the year reduced the tonnage of ore milled; however, the higher gold content of the hard ore compensated for the reduced throughout.

In southwestern Utah, gold production continued at the Goldstrike Mine, an open pit and heap-leaching operation in Washington County about 65 km (40 miles) northwest of St. George. Negotiations to purchase the mine, operated by Tenneco Minerals Co., were begun by U.S.M.X. in early 1993. The mine produces about 1,180 kg (38,000 ounces) of gold annually.

American Consolidated Mining Co. and Goldstack Resources, Ltd. explored their copper and gold discoveries at the Gold Hill property in Tooele County, and Centurion Mines Corp. reported the discovery of a gold- and silver-bearing zone on properties held in the Tintic Mining District in western Utah. The company also identified a gold target on its property in the Dugway Mining District 145 km (90 miles) west of Salt Lake City.

Washington.—USBM data on aggregate gold production for the State of Washington have been largely withheld over the past decade to avoid disclosing company proprietary data: however, the Washington State Division of Geology and Earth Resources, in its annual review of Washington's mineral industry.9 indicated that gold production by the State's three major gold mining operations, the Cannon Mine. the Republic Unit, and the Kettle River Project, amounted to nearly 8,800 kg (283,000 ounces) during 1992.

Washington State's largest gold mine, the Cannon Mine at Wenatchee, Chelan County, produced 4,192 kg (134,786 ounces) of gold and 7,573 kg (243,498 ounces) of silver from nearly 450,000 tons (490,000 short tons) of ore. Cannon is a joint venture between Asamera Minerals (U.S.) Inc. and Breakwater Resources Ltd. Only about 2 more years

of ore reserves remain to be mined at the Cannon operation; in anticipation of the projected depletion date, some operations, such as the mill, began to be scaled back in 1992.

In Ferry County, near Republic. Hecla Mining's underground Republic Unit, where gold was first produced in 1896, recovered 1,815 kg (58,343 ounces) of gold and 9,329 kg (299,957 ounces) of silver in 1992. Although gold production was down 25% from that of the previous year because of lower ore grades, a record 93,400 tons (103,000 short tons) of ore was milled. In an attempt to replenish the mine's high-grade ore Hecla has intensified its reserves. exploration efforts over the past 2-years. Several promising targets in the Republic area have been identified, and 1993's exploration will focus on those areas. During 1992, construction was completed on a first-level on-site refinery to process concentrates from the mill. The mine now ships doré bars for parting into refined gold and silver bullion.

The only other Washington State mine producing gold in 1992 was Echo Bay's Kettle River project, west of Curlew in Ferry County. Production for the year amounted to 2,794 kg (89,848 ounces). At yearend, Echo Bay acquired the 30% interest of the joint-venture partner, Crown Resources Corp., thereby increasing Echo Bay's interest to 100%. The Kettle River project, scattered over 5.700 hectares (14,000 acres), has been developed around five separate deposits. The Kettle deposit was mined out in 1992, and ore from the Key West and Key East deposits was slated to replace the Kettle ore as soon as Kettle ore, stockpiled at the company's mill at the Overlook Mine, has been processed. Underground mining at the Overlook deposit was temporarily curtailed and milling operations were reduced pending improvement in gold market an Tunneling and other conditions. development work was continued at the Lamefoot deposit, about 5 km (3 miles) from the mill, to enable the Lamefoot to become the principal source of mill feed

To the west, near Chelan in Okanogan

County, work was continued on the development of the Crown Jewel deposit by owners Battle Mountain Gold Crown Resources. (operator) and Permitting for the new project was begun in 1992, the draft environmental impact statement is expected to be delivered in 1993, and gold production is expected to begin in early 1995 at a rate of 5,440 kg (175,000 ounces) per year. The Crown Jewel deposit is only a 40-hectare (100acre) part of holdings that exceed 3,200 hectares (8,000 acres), known as the Crown Jewel exploration project. As in recent past years, gold exploration in Washington generally was concentrated in Chelan, Ferry, Okanogan, and Stevens Counties.

Consumption and Uses

Reported data on gold consumed in the domestic industrial market, shown in table 8, account for only a part of the overall market for gold in commercial applications. An important segment of market demand is also satisfied by imported gold-bearing products in various forms ranging from unfinished jewelry products, such as gold chain and findings, to electronic equipment containing gold components.

The volume of gold futures traded on the Nation's gold futures exchanges during 1992 declined for the third consecutive year owing, in part, to continued apparent investor disinterest.

Contracts for gold futures traded during 1992 represented about 18,670 tons (600 million ounces) compared with those of the previous year, when the equivalent of more than 21,000 tons (680 million ounces) was traded. The New York-based Commodity Exchange Inc. (COMEX) was, as in the previous year, by far the Nation's dominant gold futures exchange.

Gold loans between commercial depository banks and gold producers continued to be an acceptable method of financing new mine development or expansion of existing facilities. Gold loan activity generally peaked in 1988, and many mines that benefitted earlier from gold loan programs have begun to

repay their original loans with newly mined gold.

Stocks

Stocks of refined bullion held by industrial users at yearend were substantially less than stocks on hand at Repeating a pattern vearend 1991. established in past years, when viewed on a quarterly basis, the greatest decline in industrial stocks was reported during the first quarter of the year; this may reflect a withdrawal by manufacturers to meet anticipated demand, especially for jewelry products destined for sale later in the year. Yearend stocks of gold certified for delivery by COMEX, were about 46.5 tons (about 1.5 million ounces), nearly 7% less than those held at the end of the previous year. Deliveries to the market during the fourth quarter of the year were substantial: this was reflected in a 23% decline from the year's level held at the end of the third quarter.

Markets and Prices

The Engelhard Industries/London daily final price of gold during the year was bound by highs of about \$360 per troy ounce in January and July and a low of about \$331 in November, its lowest level since January 1986. The average for the year was \$344.97 per troy ounce or about \$27 greater than the previous annual low of about \$318 per troy ounce established in 1985. Some factors contributing to the lackluster performance of the price during 1992 included periodic heavy bullion sales to the market by some central banks, producers, and investors: a unsettled world deteriorating and economic situation accompanied by fluctuating currency values and some apparent asset deflation; continuing conflict and uncertainty in eastern Europe: and the reluctance of many investors to seek the safe haven of gold for some of their assets while benefitting from the widespread availability of alternative investment vehicles.

Foreign Trade

For the third consecutive year, total U.S. exports of refined gold increased over those of the previous year. These refined exports registered an increase of 47% over those of 1991, and the rate of annual growth was the steepest recorded during the 4-year period. Exports of gold in ores and concentrates, and doré and precipitates, also increased. Exports of waste and scrap declined for the second consecutive year. Total exports during 1992 increased more than 36% over those of 1991. The principal recipient nations for gold in all classes of exports were Canada, Hong Kong, Switzerland, and the United Kingdom. Nearly 80% of the refined bullion exported during the year went to Hong Kong, Switzerland, Taiwan, and the United Kingdom.

Total imports of gold during the year were about 3% below those of 1991. Imports of refined bullion declined 4% during the same period. Brazil, Canada, and Chile were the principal sources of refined bullion imports in 1992. Imports of doré and precipitates, mostly of Canadian origin, registered a threefold increase over those of the previous year.

World Review

Nineteen ninety-two marked the 13th consecutive year of growth in world gold mine production. The rate of growth, however, failed to match the high rates of growth achieved during the late 1980's.

With the release of its annual statistical review of world gold supply and demand, Gold Fields Mineral Services Ltd. (GFMS)¹⁰ continued a comprehensive statistical series begun by its predecessor, Consolidated Gold Fields PLC, more than one-quarter of a century ago. To mark the occasion, GFMS included in the annual Gold Survey a brief summary of the data on gold supply and demand and gold price movements during the 25-year period up to 1992. For the first time in the history of the Gold Survey, which has always shown supply and demand in the Western World, the opportunity to expand the coverage to include data

previously unavailable from the Communist bloc nations has been afforded by the breakup of the former U.S.S.R. and the economic liberalization in China. Responding to these changes, GFMS was able to take the first steps toward expanding its supply and demand coverage on a global basis.

In its review of the gold market in 1992, GFMS observed that despite market problems associated with a steady decline in real gold prices over the past 5 years the strength of the demand for physical gold was undiminished. particularly the demand for gold used in the fabrication of jewelry products. It was the developing world that accounted for most of the increased jewelry output, with increased fabrication in many Southeast Asian nations responding to the market opportunities afforded by the rapid economic growth and increasing prosperity in China. Despite the increased level of demand the price continued to weaken. The principal reason for the lower prices, according to the review, was the net disposal to the market of nearly 600 tons (19.3 million ounces) by the central banks of several nations, notably Belgium, Canada, and the Netherlands, the highest level since 1968, and well in excess of the 544 tons (17.5 million ounces) sold into the market by the U.S. Treasury and the IMF during 1979.

Overall, the world gold market absorbed a record supply of 3,182 tons (102.3 million ounces) during 1992. On the demand side, despite a nearly 330-ton (10.6-million-ounce) increase in world jewelry fabrication over that of 1991, a new record for the fifth year running, most other components of fabrication showed only modest performance with dental and decorative growth in applications more than compensating for weakness in the electronic sector brought on by stagnation in the computer industry and weakness in the defense and consumer electronics sectors.

Data collected by GFMS on the hoarding of small bars for investment outside of Europe and North America showed a nearly 13% increase over 1991. Declines in hoarding in the Far East and

considerable dishoarding in Brazil and Indonesia were more than offset by substantial increases in many Middle Eastern nations and in India. The quantity of gold absorbed in official coin fabrication programs declined 40% from that of the previous year. The absence of special programs such as the Japanese Akihito coin issue in 1991 was largely to blame for the decline.

Australia.—Despite a 4% decline in gold production from 1990 to 1991, Australia's gold output in 1992 resumed the upward trend begun in 1981 as production during the year registered an increase of about 2.5% over that of the previous year. Many of the factors contributing to the reduced performance during 1991 persisted into 1992, exacerbated to a great extent by the continuing weakness in world gold prices, which, together with the removal of the income tax exemption in 1991, forced many smaller gold mines to close.

Accounting for a major percentage of Australia's production during 1992, the State of Western Australia maintained its long-held position as the nation's dominant gold-producing State, followed by the State of Queensland and the Northern Territory. The largest goldproducing mine complex in Western Australia during the year was the Super Pit operation in Kalgoorlie. The Super Pit was also the nation's largest open pit The Super Pit is operated by Kalgoorlie Consolidated Gold Pty. Ltd., which also operates the Mount Percy open pit and the Mount Charlotte and Fimiston underground operations, all along Kalgoorlie's famous Golden Mile. Homestake Gold of Australia Ltd. owns 50% of these Golden Mile producers while the remainder is held by Poseidon Gold Ltd. (PosGold). Production from the Super Pit during the year amounted to 14.8 tons (474,825 ounces). PosGold also maintained interests in a number of other Western Australian gold operations, including the Big Bell Mine, near Cue, and the Karonie and Jubilee Mines and Kaltails gold recovery project, all near Kalgoorlie. The open pit Big Bell, jointly owned with Placer Pacific Ltd., produced

GOLD—1992 553

a record 4,874 kg (156,708 ounces) of gold in 1992.

Gold production at the Telfer Mine near Nullagine, operated by Newcrest Mining Ltd. produced 11.8 tons (380,090 ounces) of gold by milling and heapleaching recovery methods during the year. Newcrest's other gold interests in Western Australia included the Ora Banda and the New Celebration Mines, both near Kalgoorlie; their 1992 gold production was, respectively, 4,753 kg (152,830 ounces) and 2,440 kg (78,472 ounces).

Western Mining Corp. (WMC) owned or managed four gold mines in Western Australia, which contributed 19.4 tons of gold to WMC's account during the company's fiscal year ending in June 1992. WMC's mines included several mines in the Kambalda-St. Ives area south of Kalgoorlie and multiple mine operations near the west Australian towns of Kalgoorlie, Lancefield, Leinster, Mount Magnet, and Norseman. WMC also holds a 48% interest in Alcoa of Australia's Hedges Gold Mine 97 km (60 miles) southeast of Perth. The Hedges property yielded 5,194 kg (167,005 ounces) of gold associated with bauxite. Elsewhere, WMC owns or participates in the operations of the Goodall Mine in the Northern Territory, which recovered 1,388 kg (44,642 ounces); the Stawell Mine in Victoria, which produced 1,802 kg (57,930 ounces); and the Roxby Downs or Olympic Dam Mine in South Australia; which, in addition to uranium and copper, produced 71 kg (22,851 ounces) in fiscal 1992.

Gold production at the Boddington Mine, near Alcoa's Hedges Mine, amounted to 10.9 tons (351,627 ounces). At both the Boddington and the Hedges Mines, the gold ore body underlies commercial bauxite deposits. Reynolds Metals Co., a 40% participant in the Boddington gold project, also owns the Marvel Loch gold mine and a 50% interest in the Mount Gibson gold project, both in Western Australia. Western Australia, production was begun at Resolute Resources Ltd.'s Marymia Mine 200 km (124 miles) north of Meekathara. Asarco Australia Ltd.

announced plans to build the world's largest bacterial oxidation plant to treat sulfide ores from its gold operation at Wiluna. Homestake placed its Fortnum Mine near Meekathara on care and maintenance owing to continued low ore grades and low gold prices.

In Queensland, production at Placer Pacific's 70%-held Kindston Mine, 200 km (124 miles) west of Cairns, amounted to 5,889 kg (189,359 ounces) during 1992. Battle Mountain Gold continued to experience good production at its Pajingo underground mine with 1,462 kg (47,000 ounces) recovered during the year. The deposit is expected to be depleted by mid-1993 with milling of stockpiled ore to cease by early 1994. Carpentaria Gold Pty. Ltd., a subsidiary of MIM Holdings Ltd., officially began production at its Tick Hill Mine in early 1992, at an annual rate of 3,110 kg (100,000 ounces) of gold. In northern Queensland, Ashton Mining poured its first gold bar at the Rishton Mine. The new open pit project is designed to recover 1,244 kg (40,000 ounces) of gold per year.

At Cobar in western New South Wales, CRA Ltd. began operations at its Peak Mine in October. The new, highly automated underground facility is designed to recover about 3,110 kg (100,000 ounces) of gold annually. Copper, lead, silver, and zinc also will be recovered as byproducts. The recovery plant, employing a column flotation recovery system to separate the base metal constituents, is reportedly the first of its kind in the world.

The Government of Australia decided during 1992 to end the restrictions that have long applied to foreign investment in mining (excluding uranium) by abolishing the requirement that foreign investment proposals have a minimum of 50% Australian equity and Australian control of the project's controlling body. Under the new provisions, by which foreign companies can now own up to 100% of such properties, all foreign investment proposals in the mining industry will be approved unless judged contrary to the national interest. U.S. companies have been major participants in Australian mining, especially for gold, for many

years.

In 1992, Australia's legal tender Kangaroo coins reportedly became the world's best selling gold coin, a position formerly occupied by the Canadian Maple Leaf coin. The Kangaroo was introduced in March 1991 and includes coins weighing 2 ounces, (62.2 grams), 10 ounces, (311 grams), and 1 kg (32.2 ounces). In April 1992, Gold Corp Australia, the seller of Australia's legal tender coins, announced the introduction of its new 1 kg (32.2 ounces) silver bullion coin, known as the Kookaburra, as well as a set of new 2-ounce (62.2 grams) and 10-ounce (311 grams) silver The new coins all have legal coins. tender status.

Canada.—The steady growth in Canadian gold production since 1981 was replaced in 1992 with a 10% decline from that of 1991 when a record 176,552 kg (5.7 million ounces) was produced. Continuing the previous year's trend toward the closure of marginal mines, there were 50 primary gold mines operating in Canada at the end of 1992 compared with 60 at the close of 1991. These 50 mines accounted for 88% of the gold produced during the year, according to an annual review of Canadian gold developments prepared by the Canadian Department of Energy, Mines and Resources. 11

The Province of Ontario was again the dominant gold-producing Canadian region. Of the 74 tons (2.38 million ounces) of gold produced in Ontario, more than 50% was derived from three major mines in the Hemlo area; these mines, all opened in 1985, were the Page-Williams Mine, the Golden Giant Mine, and the David Bell Mine. The Page-Williams and the nearby David Bell Mine are owned by Homestake Canada Inc. and the Teck Corp. Golden Giant is owned by Hemlo Gold Mines Inc. Homestake also owns 25% of another Hemlo area mine, the Quarter Claim property.

Gold production in Canada's second largest gold-producing Province, Quebec, declined from 51.9 tons (1.67 million ounces) in 1991 to 44.5 tons (1.43

million ounces) in 1992. The decline reflected the closure of seven mines and production decreases at several others. Of the seven closures, six were attributed to exhaustion of ore reserves. No mines were brought into productive status during 1992, but the Sleeping Giant Mine of Aurizon Mines Ltd., which closed in 1991, was expected to be reopened in early 1993 with Cambior Inc. as the operator. Operations at the Casa Berardi area Golden Pond East Mine of TVX Gold Inc. and Golden Knight Resources Ltd. 100 km (62 miles) north of LaSarre, were suspended in April following an inflow of overburden material into the upper level of the mine. Full production was expected to resume early in the new vear.

Near Couteau Bay on the southwest coast of New Foundland, Royal Oak Mines Inc. reopened its recently acquired Hope Brook Mine, which had been closed since the summer of 1991. Hope Brook, originally opened in 1987 as an open pit and heap-leaching operation, was later developed as an underground facility by a subsidiary of BM Resources Canada Inc. Royal Oak's production target for 1993 was reportedly 3,730 kg (120,000 ounces) of gold.

In the Northwest Territories, nine workers were killed in September by an explosion at Royal Oak's Giant Mine on the north shore of Great Slave Lake. At the time of the underground explosion the operation was in the midst of a bitter labor dispute. An investigation into the incident by the Royal Canadian Mounted Police was under way at yearend. The mine, which began production in 1948, produces about 3 tons of gold annually.

Near Smithers, in Canada's west coast Province of British Columbia, Timmins Nickel Inc. opened its Dome Mine. Production is estimated at about 350 kg (11,000 ounces) per year. In midyear Homestake, through its takeover of the Corona Corp., became the principal partner and operator at the rich Eskay Creek gold development property in northern British Columbia. A feasibility study was completed during 1992, and production could begin by late 1995. Homestake also had interests in three

other gold-producing mines in British Columbia: the Snip, Nickel Plate, and Golden Bear. In midyear Cheni Gold Mines Inc. exhausted the ore reserves at its Lawyers Mine in the Toodoggone River area north of Smithers, and development at Placer Dome's 70%-held Mount Milligan copper-gold property near Prince George was halted owing to low gold prices.

Ghana.—Gold production in the Republic of Ghana rose for the fifth consecutive year, increasing 18% during 1992 to 31,031 kg (997,670 ounces). Financing was completed in November for the expansion of Ashanti Goldfields Corp. (Ghana) Ltd.'s Ashanti Mine, near Obuasi. The expansion will increase the mine's gold production by about 50% to 31 tons (1 million troy ounces) per year by mid-decade. Part of the 3-year expansion includes the construction of a 220,000-ton-per-month bioleaching plant. When commissioned, the plant will be the world's largest bioleaching facility. The bioleaching process will be used to prepare the mine's gold-bearing sulfide ore reserves for conventional milling. The \$140 million financing includes \$40 million provided by the World Bank's International Finance Corp. (IFC). The loan, which may be drawn by the company in either dollars or gold, is the first such commodity-linked structured by the IFC. The loan package also carries two separate gold-hedging provisions advantageous to Ashanti. Ashanti Goldfields is a joint venture between the Government of Ghana (55%) and Lonrho Plc (45%).

In eastern Ghana, Sikamen Gold Resources Ltd. commissioned a new floating washplant at its Goldenrae placer mine near Kiki. The new plant, which replaced an earlier facility that failed to perform to specifications since the mine was opened in late 1990, is expected to produce 460 to 560 kg (15,000 to 18,000 ounces) of gold per year. An additional plant is scheduled to be in place and operating by mid-1993. In late 1992, Ghanian Australian Goldfields Ltd. (GAG) started production at its new Iduapriem Mine near Tarkwa in

southwestern Ghana. The new open pit mine, which is expected to produce about 3,110 kg (100,000 ounces) of gold per year, is operated by GAG, which is owned by Golden Shamrock Mines, the Government of Ghana, the IFC, and private investors.

Latin America.—Of the nearly 20 gold-producing nations of Latin America, more than one dozen registered an increase in production during 1992 relative to the previous year. Nations achieving the strongest rate of growth from 1991 were Bolivia, Chile. Colombia, French Guiana, Mexico, Peru, and Venezuela. As in recent years, the improved business, investment, and regulatory climates in many of these nations continued to attract exploration firms worldwide, especially North American companies.

Bolivian gold production registered a strong 34% increase over that of the previous year but failed to match the nearly 5,200 kg (167,000 ounces) of gold produced during 1990. Battle Mountain Gold Co. (BMG) continued development work at its Kori Kolo gold mine, and full operation was expected to begin by the end of the first quarter of 1993. The mine, in Bolivia's Altiplano near Oruro. 165 km (102 miles) southeast of La Paz. is owned by Empresa Mineral Inti Raymi S.A. (IRSA), which in turn is 85%owned by BMG and 15%-owned by Bolivian-based Zeland Mines. Kori Kolo was initially opened by IRSA in 1984 as a small heap-leaching operation treating oxide ore. BMG acquired an interest in the property in early 1989. The existing oxide operations yielded 1,680 kg (54,000 ounces) of gold during 1992. The expanded operations include new milling capacity designed to accommodate both the remaining oxide ores as well as the much larger underlying gold-bearing sulfide deposit developed in recent years. Annual production at the expanded facility is expected to be about 7,600 kg (245,000 ounces) of gold and 33 tons (1.06 million ounces) of silver. Gold and silver discoveries in the Santa Cruz Department of Eastern Bolivia reportedly sparked a classic gold rush into that

remote part of the nation. In mid-December, a mudslide buried more than 50, and possibly hundreds, of people in the small remote Bolivian placer mining camp of Llipi, about 130 km (80 miles) north of Bolivia's capital city of La Paz. Llipi, on the Tipuani River, reportedly was home to more than 1,200 miners and their families. Mudslides are just one of the many hazards accepted by the thousands of independent, unregulated placer miners working in remote frontier areas of Bolivia, Brazil, Peru, and elsewhere in Latin America.

Brazilian gold production, at 76 tons (2.4 million ounces), was essentially the same as production achieved during 1991. As gold production by Brazil's regulated or formal sector has risen over recent years, the amount of gold recovered by the nation's independent gold miners or "garimpeiros" has declined. For the most part, the formal sector has increasingly focused on mining relatively large, capital-intensive lode deposits while the garimpeiros fortunes continue to be generally dependent on mining small placer deposits along major rivers and streams in remote frontier areas of the country such as in the states of Roraima, Amazonas, and Pará. In these areas, portable, makeshift equipment and rugged living conditions are the norm. As the placer deposits of one area are deleted, garimpeiros migrate to other gold-bearing areas and reestablish their operations. During 1992, as the gold played out on the Brazilian side of the border between and Venezuela, migrating prospectors trespassed into Venezuela and were confronted by that nation's military A series of border clashes forces. between the two parties reportedly ended with the arrest of 350 gold miners. Much of the gold recovered by the garimpeiros escapes official accounting and instead is smuggled out of Brazil or may be used to barter for day-to-day necessities.

Brazil's regulated gold mining industry continues to expand with each passing year. The nation's largest gold mining company is Mineraçao Moro Velho (MMV), which operates gold mines in the State of Minas Gerais at Itajobi, Nova

Lima, Raposos, Sabará, and Pitanqui and in the States of Bahia and Goias at Jocobina and Sierra Grande, respectively. MMV produced about 12,300 kg (395,450 ounces) of gold in 1992. Companhia Vale de Rio Doce (CVRD). the second largest company, produced about 11,300 kg (363,300 ounces) from two mines in the State of Minas Gerais, two in the State of Bahiá, and one in the State of Pará. CVRD's new Igarapé Bahia Mine completed its first full year of production in September. Brazil's third largest gold producer in 1992 was Rio Paracatu Mineracao SA's Morro do Ouro Mine in Minas Gerais, where about 5,100 kg (164,600 ounces) of gold was recovered.

Chilean gold production increased 16% during 1992. Chile's largest gold mine, El Indio, near La Serena in the high Mountains close Andes Argentinean border, produced 7,100 kg (228,270 ounces) of gold plus values in silver and copper during 1992. The El Indio complex, consisting of the El Indio Mine and the nearby Tambo Mine, is 83%-held by LAC Minerals through a subsidiary, Compania Minera El Indio. The mine complex includes one open pit, underground mines on nine distinct vein systems, plant facilities, a heap-leach facility, and three camps. In April, Amax Gold acquired an indirect 90% interest in the small Guanaco heapleaching project, which had been in operation under the previous owners since the mid-1980's. At yearend, work was under way to more than triple the mine's capacity to 160,000 tons per month. The expansion was expected to result in an annual gold production rate of 1,870 to 2,500 kg (60,000 to 80,000 ounces). The recovery plant of the Guanaco facility had formerly been in operation at Sociedad Contractual Minera Vilacollo's Choquilimpie Mine, which was exhausted Also in and closed in November. November, Amax agreed to acquire a 50% interest in the Refugio Project, east of Copiapo, in the Maricunga Mining District of central Chile. Amax expects to bring Refugio into production in about 2 years. Also in the Maricunga District, Placer Dome and TVX Gold Inc.

completed their first full year of open pit and milling operations at their LaCoipa Mine, producing 61,000 kg (196,000 ounces) of gold and 500 tons (16.1 million ounces) of silver. Nearby to the north, gold production at Homestakes's wholly owned El Hueso Mine increased 8% to 2,190 kg (70,400 ounces). In mid-1992. BMG completed its first full year of production at its new San Cristobal Mine in the Atacama desert of northern Overcoming persistent startup problems, the new open pit and heapleaching operation recovered 1,800 kg (58,000 ounces) of gold during 1992. BMG owns a 56.52% interest in San Cristobal through its affiliate, Niugini Mining Ltd. Despite weaker world gold prices, Chile abounds with preciousmetals projects ranging from highly speculative ventures to highly advanced projects.

With 37 tons (1.2 million ounces) of gold produced in 1992, Colombia retained its position as Latin America's second largest gold-producing nation. Gold production is derived primarily from small to medium lode and placer mining operations in the Colombian divisions or Departments of Antioquia, Caldas, Chocó, and Tolima. Gold exploration and development, especially by foreign interests, in Colombia's many goldbearing districts continues to be hampered by inaccessibility and by terrorist activity. On January 17, 1991, the Government of Colombia lifted its restrictions on holding, marketing, and trading in gold by Colombian residents.

In Costa Rica, Minera Rayrock Inc. continued gold exploration on its Bellavista property, 112 km (69 miles) west of San Jose. In April, Newmont Mining Corp. (NMC) and Mallon Resources Corp. signed an agreement for NMC to explore Mallon's Rio Chiquito property in the Guanacaste Province of northern Costa Rica. Mallon operated a small gold and silver mine on part of the property until mid-1989. Several other companies, including Phelps Dodge, BMG, Greenstone Resources Ltd., and Minnova Inc., maintained exploration projects in Costa Rica during 1992.

Reserves of oxide ore, long the source

of gold production at Rosario Dominicana S.A.'s Pueblo Viejo Mine in the Republic, Dominican have been exhausted. In April, a new processing plant was inauguarated to process lower grade or "transitional" material. Later, the company received permits to begin mining the large gold-bearing sulfide ore body. Processing of the sulfide ore will require the construction of processing facilities projected to cost \$200 million. Canyon Resources Corp. and its partners, BMG, announced a gold discovery at the joint venture's EL Higo Exploration Concession in the Bonao area of the Dominican Republic.

In Western Guyana, construction was completed in late 1992 at the Omai Mine in Essequibo County. The new open pit mine, 160 km (100 miles) south of Georgetown, the capital, is reportedly expected to yield about 8.7 tons (260,000 ounces) of gold annually during the first 7 years of operation. The mine's new 12,000-ton-per-day mill began operation on December 15, milling ore with an approximate grade of 1.7 grams per ton. The mill is scheduled to reach full capacity by mid-1993. The mine is owned by Cambior Inc. (60%), Golden Star Resources Ltd. (35%), and the State of Guyana (5%). Elsewhere in Guyana, gold and diamonds continued to be recovered at the numerous placer mines operated by independant miners along many of Guyana's rivers and streams.

Mexican gold production increased 12% during 1992. During the year Mexico's new mining law become effective. The new law is designed to encourage increased foreign mineral investment and participation, as well as provide greater access to lands available for exploration; royalties previously imposed on new production were eliminated. Most of Mexico's gold is still produced as a byproduct of silver and base metal production; however, a number of new gold properties have been opened or were under development, especially in the Mexican State of Sonora. In November, Phelps Dodge Corp. and its partner, the Ariztequé Group, completed the first full year of heap-leach production at their new open

pit Santa Gertrudis Mine in Sonora. Also in Sonora, Hecla Mining Co. continued development on its La Choya project near Sonoita. When production begins in mid-1993, La Choya is expected to produce 1,600 to 1,800 kg (50,000 to 60,000 ounces) of gold per year. Magedalena, Sonora, Red Rock Mining Corp., and it Australian partner, Wahalla Mining Co., continued open pit and heapleaching development at the Amelia gold project. Similar activity was also reportedly under way at Campbell Resources Inc.'s. La Colorada property, a former producer, near Hermosillo in the La Colorada district of Sonora.

In mid-1992, Newmont Mining agreed with its partners to move ahead with production in mid-1993 at its Yanacocha gold project, 20 km (12 miles) north of Cajamarca in northern Peru. More than 3,100 kg (100,000 ounces) of gold will be recovered at Yanacocha annually using heap-leaching recovery methods. Liberalization of Peruvian gold laws in 1991 has reportedly ended problems associated with gold smuggling and led to an increase in the number of informal miners pursuing gold mining opportunities in Peru's numerous and remote lode and placer mining sites. An informal survey conducted in 1991 by U.S. Embassy personnel concluded that the approximately 25,000 miners pursuing placer gold in the Madre de Dios and Cuzco Departments, for example, were recovering about 1 gram (0.032 ounce) of gold per day-roughly equivalent in volume to about 5 grains of rice.

In Uruguay, American Resources Corp. (ARC), a publicly held copper and gold mining company based in San Francisco, CA, began operations near yearend at its Mahoma Mine and mill, about 100 km (62 miles) northwest of Montevideo. The mine, developed within the Florida Greenstone Belt north of Montevideo, is reportedly country's first gold mine utilizing carbonin-leach (CIL) recovery technology. The mine's transportable, 1,000-ton-per-day CIL plant, previously operated in Austraila, is expected by ARC to recover more than 1.2 tons (40,000 ounces) of gold in 1993 from ores mined by open pit methods at three separate gold deposits.

Exploration for gold, in addition to exploration that has long been conducted in gold fields throughout South America, also has been focusing in recent years on various islands of the Carribbean region where gold had formerly been mined or detected; this activity during 1992 included exploration or examination of the potential for gold on the islands of Aruba and Jamaica, the Republic of Cuba, and the Commonwealth of Puerto Rico.

Oceania.—Papua New Guinea's gold production, after declining to 14 tons (451,707 ounces) by 1980, had by 1992, increased nearly sixfold to 80.4 tons (2.6 million ounces). This increase was accomplished despite the forced closure in 1989 of CRA's 53.6%-held Bougainville copper mine on Bougainville Island, a major producer of byproduct gold. Papua New Guinea's largest gold mine, Placer Pacific Ltd.'s Porgera Mine, in the highlands of Enga Province, produced 46 tons (1,485,077 ounces) of gold from both surface and underground operations. The 22% increase in production over the previous year was reportedly attributed to increased mill throughput and improved recoveries, which were achieved through the operation of a new pressure oxidation circuit that came on-line in October 1991. CRA's Mount Kare alluvial project, also in Enga Province about 18 km (12 miles) southwest of Porgera, was attacked for a second time in less than 1 year by a group of 15 to 17 armed men in early January. The attack forced closure of the mine and resulted in more than \$2 million in damage. The Mount Kare deposit, developed by Mount Kare Alluvial Mining Pty. Ltd., was discovered in 1988 by CRA Minerals (PNG) Ltd. CRA retains a 51% interest in the mine and has granted more than 5,000 local landowners the remaining 49% share in the mine under a unique arrangement to avoid conflict over ownership of the mineral wealth. The attack, reportedly led by a disgruntled ex-employee, involved the systematic destruction of equipment, including buildings. earth-moving equipment, and a helicopter. Production was resumed at the mine in August. In late 1992, to resolve squabbles over the mine's ownership, CRA reportedly offered to relinquish its 51% interest in the property but only to the rightful landowners. Mount Kare is about 480 km northwest of the nation's capital of Port Moresby.

At the Misima Mine in Milne Bay Province, Misima Island Mines Pty. Ltd., wholly owned by Placer Dome, produced 11,642 kg (374,300 ounces) of gold during 1992. Higher ore grade and improved mine throughput were responsible for the 11% increase over 1991 production.

In the far west of Enga Province at Mount Fulbian, gold production at the OK Tedi copper-gold mine declined 29% from the previous year to 9.8 tons (313,862 ounces). Copper production, however, increased somewhat over that of 1991. Low water levels affected the shipment of gold-bearing copper concentrates from the remote mine site from time to time during the year. In 1982, during construction of the mine, the river ceased flowing completely, thus halting the movement of barges along the 1,290-km (800-mile) route between the mine and Port Moresby.

Development work was continued during the year at the giant Lihir Island gold deposit on a small island off the east coast of the Island of New Ireland. The which could begin Lihir project, production in 1993, is targeted to produce about 18.7 tons (600,000 ounces) of gold annually. The project is owned by partners RTZ Corp. (80%) and Niugini Mining Ltd. (20%). The mine is being developed on the coast and in the crater of an extinct volcano where control of high-temperature ground water has been one of the many problems tackled by the development team since the deposit was discovered more than 10 years ago.

Gold production in Fiji declined 7% from that of 1991, owing primarily to a slow recovery from an earlier labor dispute at the island's principal gold producer, the Emperor Mine at Vatukoula on the island of Viti Levu. Emperor first began gold and silver production in 1935. Both open pit and underground mining

has been employed at the Emperor; however, surface mining ceased in late 1992. Ore from the open pit had been stockpiled and will be processed during 1993. The Vatukoula tailing project, begun in 1991, ceased operations in late 1992 owing to metallurgical problems that led to unacceptably low metal recoveries. Some gold exploration was conducted in the Fiji Islands, including investigations by Placer Pacific at its Namosi copper and gold deposit on Viti Levu. CRA investigated gold targets on Viti Levu and Vanua Levu.

In West Irian on the Indonesian side of the island of New Guinea, Freeport Indonesia, Inc. produced 19.9 tons (641,000 ounces) of gold at its Grasberg/Ertsberg copper and gold deposit. Grasberg reportedly possesses the largest published gold reserves of any single operating mine in the world. Freeport is planning to increase annual gold production from the operation to more than 37 tons (1.2 million ounces) by 1996. The company continued exploration of the Big Gossan copper-gold prospect near the original Ertsberg mine site and began exploration on its newly acquired 2.6-million-hectare (6.5-million-acre) exploration area north of the Grasberg In January, Kelian Equatorial Mine. Mining, 90%-held by CRA, poured its first bar of production gold at the new open pit Kelian Mine. The new mine, in the Province of East Kalimantan, produced 14,535 kg (467,311 ounces) of gold and 15,333 kg (494,967 ounces) of silver during 1992. Gold exploration continued throughout the islands of Indonesia. Discoveries were reportedly made in the West Java Province and on Wetar Island. Newmont reported that drilling was in progress at its Minahasa prospect on the Island of Sulawesi and its Batu Hijau prospect on the Island of Sumbawa.

On New Zealand's North Island near Waihi, Cyprus Gold New Zealand Ltd. began commercial operations in February at its new Golden Cross project. The new surface and underground operation produced about 2,720 kg (87,400 ounces) of gold. At yearend, Cyprus was evaluating the possible sale of its 80%

interest in the project; the remaining 20% interest is held by the Todd Corp. Ltd., a private New Zealand company. Within the town of Waihi, Amax Gold Ltd. produced 2,368 kg (76,126 ounces) of gold at its 33.53%-held Waihi Mine. Amax's partners in the open pit mine, which began production in mid-1988, are ACM Gold Ltd. and Mineral Resources (NZ) Ltd. New Zealand's largest gold mine, the Macraes Mine, 60 km (37 miles) north of Dunedin in the Otago region of the South Island, produced 3,200 kg (103,000 ounces) of gold during 1992. The mine is owned by Macraes Mining Co. Ltd.

Other Asia.—Gold production in the Philippine Islands declined 4% from the previous year, reflecting cutbacks and closures at several Philippine mines. In late December, Benguet Corp. announced the shutdown of its underground Acupan and Balatoc gold mines near Baguio. The phaseout of mining operations, which followed an earlier announced round of closures and cutbacks at other companyowned mines in Benguet Province on the Island of Luzon, was reportedly attributed to continuing low gold prices and the improved value of the Philippine peso. Cutbacks also were initiated by several other Philippine gold mining companies. Gold production was begun in February at Benguet's Grand Antamoc gold mining project in the Antamoc Valley north of Manila in Benguet Province. The new open pit and milling operation reportedly vielded 2,749 kg (88,400 ounces) of gold during the year.

The Philippines' second largest gold mine, the Masbate Mine of Atlas Consolidated Mining and Development Co. in the Aroroy gold district of Masbate Island, reportedly produced about 2,500 kg (80,500 ounces) of gold or about the same as that in the previous year. Both open pit and underground mining methods are employed. Drilling and exploration were continued at CRA's 40%-held Far Southeast copper and gold project at Lapanto on the Island of Luzon. An underground drilling project was under way and will extend well into 1993. Philex Mining Corp. continued

development at its Bulawan gold project on Negros Island. Small-scale artisinal mining continued throughout the Philippines and especially on the southern island of Mindanao.

On Japan's northern Island of Hokkaido, a prospecting team fielded by the Nissho Iwai Corp., Australian Gold NL, and MIM Holdings Ltd. reportedly discovered a high-grade gold deposit at the Heisei Buho Mine west of Sapporo. One drill sample reportedly returned 72.8 grams per ton (2.1 ounces per short ton) of gold and 56 grams per ton (1.6 ounces per short ton) of silver. Further exploration will be needed to determine if this is a minable deposit.

In a move to liberalize its gold markets, an agreement in principle was reached during mid-January by the Government of Taiwan to abolish a ban imposed in 1949 on the trading and exporting of gold by private citizens. Currently, only certain Government agencies and firms are permitted to trade gold bullion. Finalization of the new regulations was expected to occur later in the year.

On February 5, the Government of Thailand reportedly removed its 5% import duty on gold. Before October 1991, when the 5% duty was established, the duty on imported gold stood at 35%. Removal of the duty will allow Thai jewelry manufacturers to purchase gold at international prices and was expected to spur domestic gold jewelry fabrication. Earlier in the year the Government introduced a 7% value added tax on consumer goods; gold is reportedly more or less exempt from the value added tax in that the tax is refunded when the gold is sold or exported.

Russia and the Former U.S.S.R.—Before the dissolution of the U.S.S.R., that country ranked as one of the world's largest gold-producing nations. In late 1991, the U.S.S.R. dissolved into 15 separate countries. The gold-producing countries in the former U.S.S.R., in declining order of production, are Russia, Uzbekistan, Kazakhstan, Kyrgyzstan, Tajikistan, Armenia, and Georgia. The Ukraine has significant potential gold

deposits, which it is trying to develop. From 1926 until the recent dissolution, all matters pertaining to gold, including all data on production, had been classified as state secrets. Beginning in mid-1992, production data for the various goldproducing states of the former U.S.S.R. became available (shown in table 11). In 1992, Russian secrecy laws were reportedly amended to permit access by the International Monetary Fund (IMF) to annual gold data for 1989 through 1991. The resolution to permit disclosure was passed in conjunction with Russia's induction into the IMF. Russia, by far the dominant gold-producing country in the former U.S.S.R., produced nearly 60% of the 252 tons (8.1 million ounces) of aggregate from former U.S.S.R. producers listed in table 11. More than one-half of Russia's gold is produced in the Magadan region of the far eastern region of Russia while other important gold-producing areas include the Yakutia region of northeastern Russia and the Lena River area further west.

The Russian gold mining industry is highly organized, with the chain of management beginning with the state and progressing downward through regional gold associations, then to large gold mining companies, and finally to independent gold prospecting companies called "artels." About 250 artels reportedly exist in the former U.S.S.R. and have been responsible for more than one-half of the gold produced in recent years. Artals may employ up to 1,000 people; they are highly independent, mobile, and better able to exploit unattractive gold deposits, especially alluvial deposits, than the larger corporations. At the end of 1991, Glavalmazzoloto of the U.S.S.R., the State Ministry presiding over all mining, refining, and manufacturing operations relating to precious metals, was taken over Russia by and renamed Rosalmazzoloto (the Russian word for gold is "zoloto"). Following longestablished practice, raw gold is delivered from the mines to state offices in Moscow for distribution to refineries in Moscow, Priosky, and elsewhere. The refined production is then directed

manufacturers and reserve depositories.

As in the previous year, there was considerable cautious interest on the part of U.S. and other companies regarding the apparent opportunities opening up for joint participation in Soviet gold mining. Some companies have been able to establish tentative ties with emerging Russian businesses. One U.S. company, for example, Newmont Mining Corp., announced in early 1992 that a jointventure agreement had been signed with the former Soviet Republic of Uzbekistan to produce gold for export. The joint project would employ Newmont's leaching technology to treat low-grade gold ore stockpiled at the Muruntau gold mine in Uzbekistan. The Muruntau Mine is the largest open pit gold mine in the world, producing 56 tons (1.8 million ounces) of gold annually. The stockpile contains an estimated 150 million tons of material with an average grade of 1.16 grams per ton (0.03 ounce per short ton). Construction of the project was expected to begin in 1992, with gold output slated to begin in late 1993. Newmont's success notwithstanding, many questions remained to be answered before foreign companies could proceed to establish firm, workable relationships. There is still considerable uncertainty regarding the status of existing mining laws, permitting procedures and legitimate lines of authority, disposition and repatriation of profits, regulations regarding foreign participation and partnerships, etc. By the same token, considerable uncertainty exists on the part of gold miners in the former U.S.S.R. as to exactly how to approach potential foreign investors and how to establish a workable and equitable relationship of the sort required to develop the apparently vast resources.

South Africa, Republic of.—The world's dominant gold-producing nation, the Republic of South Africa, increased production more than 2% during 1992 to 613,900 kg (19.1 million ounces). The increase could be attributed primilary to a more than 3% improvement in the average recovery grade of ore mined from 5.20 grams per ton (0.152 ounce per short ton) mined in 1991 to 5.37

grams per ton (0.157 ounce per short ton) mined during 1992. In terms of the tonnage of ore processed annually, 106 million tons (117 million short tons) was milled during 1992 by the nearly three dozen mines representing the membership of the Chamber of Mines of South Africa. This tonnage compares with 107 million tons (118 million short tons) milled by chamber members during the previous year and represents the third consecutive year in which the tons of ore milled has declined. This decline can be partially attributed to the industry's drive to maintain productivity and profitability by concentrating on the selective mining of higher grade reserves. Significant strides continued to be made in reducing the rate of increase in working costs per unit of gold produced; the rate of increase in average annual production costs slowed from 10% between 1989 and 1990 to 4% in 1991 and less than 1% by the end of 1992. This achievement was all the more remarkable considering that the average domestic inflation rate during 1992 was 14%.

Unlike many other major goldproducing nations where production is highly mechanized. South African gold mines are extremely labor intensive. Wages paid during 1992 amounted to more than one-half of the total production costs, and many mines not amenable to mechanization have been increasingly under pressure to maintain employment and to meet demands for increased wages during a difficult period of stagnant world prices. Some operations are approching a point at which further reductions in employment will become counter This, combined with the productive. continuing downward trend in capital expenditures in real terms on operating mines, implies reduced longevity as higher grade ore reserves become depleted. In addition to pursuing every possible cost savings in labor and processing, many mines continued their hedging activities on the world's futures markets. Expanded hedging activities by a number of mines since 1989 have reportedly raised the average price received in terms of South African rands by nearly 2%. Some industry observers have speculated that without an improvement in the economic conditions affecting the mines that some marginal operations will soon be forced to close and production will decline, possibly to below 500 tons by the year 2000.

The South African gold mining industry is denominated by six major corporate groups or "houses," including Anglo American Corp. of South Africa Ltd. (AAC), Gold Fields of South Africa Ltd. (GFSA), Johannesburg Consolidated Investment Co. Ltd. (JCI), Anglovaal Ltd., Gencor Ltd., and Rand Mines Ltd.

Gold production costs for chamber members ranged during 1992 from a low of \$169 per ounce (\$5.43 per gram) recovered at Gencor's Bracken Mine to a high of \$388 per ounce (\$12.48 per gram) at the Stilfontein Mine, also owned by Gencor. The average cost per troy ounce during 1992 was \$265.

The largest South African gold mines, in metric tons of gold produced, included AAC's Freegold Mine with 115.7; the Vaal Reef Mine, also owned by AAC, at 75.4; GFSA's Driofontein Mine with 57.3; AAC's Western Deep Levels Mine with 38.4; and JCI's Randfontein Mine with 31.7.

To reduce costs and streamline mining operations, Gengold, the gold mining division of Gencor, announced in mid-1992 a plan to merge its two largest Kinross Gold Mines and mines. Winkelhaak Mines, both in the Evander area of the Orange Free State (OFS). The main purpose behind the proposal reportedly was to have the Winkelhaak Mine operating under the tax shield of Kinross and thereby justify a capital expansion program required to access deeper ore via a new subvertical shaft In the fall of 1992, AAC project. announced that it had begun construction on a new high-grade deep level gold mine in the Moab area of the OFS. The new 2.149-hectare (5,300-acre) area to be developed is contiguous to AAC's Vaal Reefs Exploration and Mining Corp.'s Vaal Reefs Mine. Production is expected to begin in 1997 and, when fully operational, to produce 13 tons (418,000 ounces) of gold per year. The ore body at Moab will be accessed via a 2,500meter (8,200-foot) main shaft and two subshafts to a total depth of 3,700 meters (12,140 feet). AAC's 47.9%-held SA Land and Exploration (Sallies) operation, which had been recovering gold by treating rocks and mine dumps in the goldfields southeast of Johannesburg, ceased operations in August.

In an effort to conserve cash, several of the large gold mining companies placed exploration projects on hold and generally reduced their expenditures for Smaller companies. exploration. however, tended to forge ahead with spending on existing projects, which have been under way for several years. JCI's South Deep Exploration Co. continued exploration on the Ventersdorp Contact Reef adjacent to the company's Western Area Mine in the OFS. In the northern OFS, Anglovaal and its 53%-owned Witwatersrand, Middle subsidiary, continued exploration in the Bothaville Gap area of the OFS. One exploration project near Anglovaal's Lorain Mine reportedly uncovered results sufficient enough to justify continued support.

On January 1, 1992, South Africa's new Minerals Act came into effect. The new legislation, in addition to repealing or amending various existing statutes affecting mining in general, eliminates the state's exclusive right to mine precious metals and stones. The change also eliminated state-issued mining leases and the payment of royalties, and introduced strict environmental and reclamation requirements.

Current Research

The USBM maintains nine research centers throughout the Nation, and most conduct research into various aspects of mining and extractive metallurgy that may be directly or indirectly beneficial to the gold mining industry. Because gold mining is pursued in many nations, the results of the ongoing work may, like USBM's earlier work in heap leaching, ultimately benefit a broad segment of the industry worldwide. In recent years, the USBM's research relating to gold mining has generally focused on the use of cyanide in the recovery process. The

USBM addressed several questions regarding the use of cyanide, including such topics as the mass balance of cyanide in the leaching process, the mobility of metals in the heap during heap leaching, the persistence of cyanide in the environment, alternatives to cyanide, and reclamation of mining sites where cyanide was employed. The USBM was also investigating the leaching of metals from very low-grade ores with the aid of biotechnology. Bioleaching research for precious metals focused on a preleach treatment of precious-metal-bearing sulfide ores.

OUTLOOK

Gold is an internationally traded commodity but, unlike most commodities bound by the traditional laws of market supply and demand, gold also serves as a substance of wealth, a storehouse of value, held by investors and Governments alike.

Preparation of an outlook for normal supply and demand may first require consideration of the outlook for prices. Although the price of gold generally defies forecasting, consideration of the forces at work in the marketplace may aid in establishing the direction that the price may take. GFMS as well as other market observers generally forecasts for the gold price for more than the near term. The outlook for a sustained high rate of world gold demand, according to GFMS in its annual review,13 depends to a large extent on three key factors: maintenance of the consumption, growth in Chinese avoidance of full-scale recessions in Western Europe and Japan, and decisions that may be made in the future by the world's central banks regarding the future composition, disposition, and makeup of their gold reserve assets. The review notes that despite a net positive increase in Western gold investments since the second half of 1992, what the central banks ultimately may decide to do or not to do with their reserves remains a key factor in inhibiting renewed investor purchases. The threat of heavy disposals such as those seen during 1992 may be

seen by some potential investors as a deterrent to price stability. On the other hand, GFMS suggests that, were the official sales of last year to be repeated, there is every reason to believe that they could once again be absorbed without further damaging the market.

Because the fortunes of the domestic gold market as a component of the global market are inextricably tied international developments, especially those that influence the world market price for gold, those key influences cited by GFMS for the world market outlook also may be seen as key factors affecting the domestic outlook for gold demand. With regard to the domestic supply side and new mine production in particular, the continued viability of the domestic gold exploration and mining sector and maintenance of the United State's position the world's second-largest gold producer depends to a large extent on the outcome of the current debate over proposed changes to the General Mining Law and the extent to which other emerging regulatory initiatives affecting mining and rural enterprise in general progress.

Revised. W Withheld to avoid disclosing company proprietary data; included in "Total."

^{&#}x27;These figures, reported to the U.S. Bureau of Mines, probably understate production. Data collected by the State indicate production to have been as follows, in kilograms: 1988—8,258; 1989—8,852; 1990—7,206; 1991—7,585; and 1992—8,163.

²In addition to reported data shown in the table, placer production was estimated by the State to have been as follows, in kilograms: 1992—84.

TABLE 3 TWENTY-FIVE LEADING GOLD-PRODUCING MINES IN THE UNITED STATES IN 1992, IN ORDER OF OUTPUT

Revised.

¹May include small quantities recovered by leaching with noncyanide solutions and by proprietary processes.

²May include tailings and waste ore dumps.

³May include small quantities recovered by gravity methods.

⁴May include metal recovered by leaching of previously mined ore at some inactive mines.

¹Data do not add to total shown because of independent rounding.

¹Gold consumed in fabricated products only; does not include monetary bullion.

²Data may not add to totals shown because of independent rounding.

³Fabricated bars, medallions, coins, etc.

Because of the implementation of the Harmonized Tariff System in Jan. 1989, export data may not be comparable with previous years' data.

Bullion also moves in both directions between U.S. markets and foreign stocks on deposit in the Federal Reserve Bank. Monetary gold excluded.

Includes gold content of base metal ores, concentrates, and matte destined for refining.

Data may not add to totals shown because of independent rounding.

*Estimated. Revised.

¹Table contains data available through July 19, 1993.

²Gold is also produced in Burma, Cuba, Czechoslovakia, Norway, Senegal, Thailand, and several countries. However, available data are insufficient to make reliable output estimates. Poland annually mines and processes copper ore estimated to contain about 31,000 kilograms of gold. Disposition of the gold byproduct is unknown.

³Formerly part of the U.S.S.R.; data were not reported separately until 1992.

Only the combined total of gold and silver production is reported. For this table, based on the reported silver content of "about 2%" in 1987, gold content of the reported production figure is estimated to be 98% for 1988-92.

⁵Officially reported figures are as follows, in kilograms: Major companies: 1988—22,159 (revised); 1989—22,849 (revised); 1990—30,098; 1991—33,844; and 1992—34,000 (estimated). Garimpos 1988—34,288 (revised); 1989—29,678 (revised); 1990—71,815 (revised); 1991—55,525 (revised); and 1992—46,000 (estimated).
⁶Reported figure.

⁷Gold purchases by Banco Central from placer deposits and mines; actual production estimated to be at least twice this amount.

⁸Year ending June 30 of year stated.

⁹Does not include undocumented production from small artisanal production.

¹⁰Figures include reported mine production of 324 kilograms in 1988; 1,202 kilograms in 1989; 1,745 kilograms in 1990; 1,453 kilograms in 1991; and 1,113 kilograms in 1991 from the SAG mine. Remainder represents approximate reported sales to Government of artisanal production. Figures do not include artisanal production smuggled out of the country.

11Refinery output

¹²Excludes production from so-called people's mines, estimated at 15,000 kilograms per year during 1987-91, but includes gold recovered as byproduct of copper mining.

13 These figures are based on gold taxed for export and include gold entering Liberia undocumented from Guinea and Sierra Leone.

¹⁴Includes production from Kalana Mine and artisanal production. 1990 includes Syama Mine production.

¹⁵Data are based on official exports and do not reflect gold moved through undocumented channels.

¹⁶Dissolved in Dec. 1991.

¹⁷Year beginning Apr. 1 of year listed.

GRAPHITE

By Harold A. Taylor, Jr.

Mr. Taylor, a physical scientist with 26 years of industry, Federal Government, and U.S. Bureau of Mines experience, has been the commodity specialist for graphite since 1980. Domestic survey data were prepared by William Field, statistical assistant; and international data tables were prepared by Audrey Wilkes, international data coordinator.

Amorphous graphite was not mined domestically in 1992. Graphite supplies exceeded industrial demand to a major degree. Most prices of the major kinds of graphite dropped substantially from those of 1991. However, most quoted prices only began to reflect the oversupply at the end of the year. Production of manufactured graphite and graphite fibers increased 10% and 11%, respectively.

DOMESTIC DATA COVERAGE

Domestic production data for synthetic graphite are developed by the U.S. Bureau of Mines from a voluntary survey of domestic producers. Of the 32 operations polled, 100% responded. This represented 100% of the total production data shown in table 4. (See table 1.)

BACKGROUND

Definitions, Grades, and Specifications

Graphite, a soft crystalline form of carbon, has been called plumbago and black lead. It crystallizes in a lamellar hexagonal system, has a gray to black metallic luster, and is greasy to the feel. It is anisotropic in its physical properties and has a weak plane of cleavage parallel to the lamellae.

The term "amorphous" when applied to graphite is a misnomer. The term "microcrystalline" is more descriptive. The definition of amorphous, as applied to graphite, has been further complicated by longstanding industrial application of the term to very fine particles of crystalline flake graphite that can be sold only for low-value use such as foundry

facings. Fine-grained varieties of lump graphite that are easily reduced to fine particle size by grinding are called amorphous lump to distinguish them from the tough, platy and acicular varieties, known as crystalline lump, that can be reduced in particle size only with extreme difficulty.

Crystalline flake graphite is well defined in paragraph 214 of the Tariff Act of 1930 as follows:

"The term crystalline flake means graphite, or plumbago, which occurs disseminated as a relatively thin flake throughout its containing rock, decomposed or not, and which may or has been separated therefrom by ordinary crushing, pulverizing, screening, or mechanical concentration process, such flake being made up of a number of parallel laminae, which may be separated by mechanical means."

Under the foregoing definition, finely divided particles of crystalline flake graphite would be classified as crystalline graphite. The Court of Customs Appeals, however, has held that commercial designations and not scientific terms must govern classification, and when a commercial meaning differs from the technical meaning, the commercial designation must govern. Therefore, quantities of fine crystalline flake graphite are imported under the amorphous classification.

Sri Lankan lump graphite is classified as amorphous or crystalline. Each type is divided into a number of grades, depending on the size (such as lump, ranging from the size of walnuts to that of peas; chip, from that of peas to about that of wheat grains; and dust, finer than 60 mesh), graphitic carbon content, and

degree of consolidation.

Amorphous graphite is graded primarily on graphitic carbon content. Commercial ore contains about 75% to 93% carbon, depending on the source.

Crystalline flake graphite from Madagascar is divided into two main grades, "flake" (coarse flake) and "fines" (fine flake). Madagascan crucible flake must have a minimum of 85% graphitic carbon and be essentially all minus 20 plus 80 mesh in particle size. Other crystalline flake graphites are also graded according to graphitic carbon content and particle size.

Natural graphite is marketed in the form of crystalline graphite as flake, lump, chip, and dust and in the form of amorphous graphite in sizes from fine powder to lumps up to the size of walnuts. It is common practice to blend different graphite to obtain a product having certain desired physical and chemical properties. In many instances, the composition of these blends is retained as a trade secret.

Geology-Resources

The three principal types of natural graphite—lump, amorphous, and crystalline flake—are based on physical characteristics that are the result of major differences in geologic origin and occurrence. A variety of silicate minerals are generally associated with graphite in the ore.

Lump graphite occurs as fissure-filled veins. It is typically massive, ranging in particle size from extremely fine grains (amorphous) to coarse, platy intergrowths of fibrous to acicular aggregates (crystalline). The origin of vein-type

graphite deposits is believed to be hydrothermal.

Amorphous graphite is formed by metamorphism of coalbeds by nearby intrusives. Its purity depends on the purity of the original coalbeds. Amorphous graphite usually is associated with sandstones, shales, slates, and limestones.

Flake graphite commonly occurs disseminated in regionally metamorphosed sedimentary rocks, such as gneisses, schists, and marbles. It is believed that the graphite was formed under the same conditions that caused the metamorphism of the rocks—from carbon deposited with the sediments.

Although the flake graphite deposits of certain countries conform to this description, most of the commercial deposits that are exploited are the result of weathering of these metamorphic rocks, with the graphite being found in lateritic clays that have accumulated at the surface. Graphite, quartz, and other resistant minerals have been freed by weathering of the feldspars, thus lessening the amount of crushing necessary before beneficiation.

World graphite reserves totaled 21.0 million metric tons. Detailed breakouts are given in the 1988 Minerals Yearbook chapter. All tonnages are reported in metric tons, unless otherwise noted.

Technology

Mining.—In Sri Lanka, lump graphite is mined underground from narrow, steeply dipping veins. The ore is mined principally by overhand stoping and filling, using temporary stulls when necessary to support the walls. Hand drilling is used in most stoping to achieve selective mining and to avoid unwanted fines and product contamination. Drills are used in developing headings. The ore is hauled by truck to the sorting and classification yard.

Amorphous graphite beds are usually mined underground. However, the beds are much thicker than those of amorphous lump and crystalline lump. The ore is drilled, blasted, hand-loaded into cars, and hauled to the surface by conventional

methods.

Flake graphite deposits have been mined by underground and surface methods. Underground deposits are usually unweathered and require drilling and blasting. Most surface mining is confined to the weathered part of the deposit, and normal excavating equipment such as power shovels, bulldozers, and rippers is used with a minimum of drilling and blasting. The ore is usually trucked to the mill.

Milling.—Sri Lankan amorphous lump graphite and crystalline lump graphite are refined by hand cobbing and hand sorting and wiping lumps on wet burlap to remove fines. Light hand sorting and cleaning operations are done by women, while the heavier duties are performed by men.

Most amorphous graphite that requires beneficiation is not worth mining. Preparation for most uses requires grinding only, and coarse impurities are removed by screening or air separation methods.

Flake graphite from disseminated deposits must be concentrated to meet Virtually every market requirements. known concentrating device combination of separating principles have been tried. The mineral has gained a reputation of being difficult to concentrate, and probably in no other industry has such a large proportion of the mills failed to make commercial recoveries. Graphite actually is one of the easiest minerals to segregate into a rough concentrate, but one of the most difficult to refine.

Because of the premium placed on the mesh size of flake graphite, the problem in milling is one of grinding to free the graphite without reducing the flake size excessively. This is difficult because, during grinding, the graphite flakes are cut by quartz and other angular gangue minerals, thus reducing flake size rapidly. However, if most of the quartz and other angular minerals are removed, subsequent grinding will usually reduce the size of the remaining gangue, with little further reduction in the size of the flake.

Because graphite floats readily and

does not require a collector froth, flotation has become the accepted method for beneficiating disseminated ores. The chief problem lies with depressing the gangue minerals. Relatively pure grains of quartz, mica, and other gangue minerals inadvertently become smeared with the soft, fine graphite, making them floatable and resulting in the necessity for repeated cleaning of the concentrates to attain high-grade products.

Substitutes

Some interchange of the various types and grades of natural graphite and between manufactured and natural graphite takes place, but the degree is Manufactured difficult to determine. graphite does not compete with natural graphite in most uses because of its greater cost. Manufactured graphite is not substitutable for natural flake graphite in clay-bonded graphite crucibles, although some crucibles are machined from manufactured graphite for special uses. Calcined coke and other carbons are satisfactory substitutes for graphite for certain foundry core and mold washes and are used when they can compete in terms of price and supply. Other carbons with high purity can be used in batteries.

Economic Factors

The price structure of graphite is quite complex because of the wide variety of products and the lack of standard market quotations. Prices quoted in trade journals are only a range negotiated between buyer and seller and sometimes do not reflect the real market. Quotations are available in Industrial Minerals, Chemical Marketing Reporter, and the U.S. Bureau of Mines Annual Report. However, average declared import values per ton for amorphous and crystalline graphite have been available for years from U.S. Bureau of the Census data.

The cost for domestically produced graphite from new mines would be much higher than that for graphite from the major foreign sources for the same type and purity. The high cost of production results from high labor costs and the low

graphite content of the ore.

Taxes.—Graphite producers are granted a 22% depletion allowance for tax purposes on domestic lump and amorphous and 14% on domestic flake and on foreign operations.

Tariffs.—Duties on graphite items imported from most favored nations (MFN) are minimal. Graphite from a few former Soviet republics (not Ukraine or Russia) and certain other nations are subject to a higher duty.

Operating Factors

Environmental Issues.—Because there was no mining of graphite this year, there were no environment-related issues. Future mining of graphite is highly improbable; there are no domestic reserves and resources are low grade and expensive to recover. Natural graphite is an inert nontoxic substance, and environmental requirements are limited to dust control and certain organic vapors arising from ingredients blended with it to manufacture products.

Postconsumer waste mostly returns to the environment in simple and nonpolluting ways. Graphite products that have contact with molten iron and steel slowly dissolve in it during use. This applies to refractories crucibles, foundry facings, and electrodes, plus a few less important uses, which combine to account for about 75% of total usage. Other important products such as pencils and brake linings slowly dissipate as they are used, almost on an atom-by-atom basis.

Employment.—Production and marketable natural graphite requires little hand labor, except for the graphite mined in Sri Lanka. Even in areas of low-cost labor, mechanical methods are used to mine and concentrate flake graphite.

Because of the very small size of the domestic natural graphite industry, no publishable employment data are available. Because there is only one small mine open intermittently and the

product is beneficiated and processed to a minimal extent, employment probably does not exceed 50. Much of the imported graphite requires grinding, perhaps further refining, mixing with other grades to meet consumer specifications, bagging, and shipping. The total number of persons engaged in these operation, including marketing, probably does not exceed 500.

ANNUAL REVIEW

Legislation and Government Programs

No acquisitions of graphite for the strategic and critical materials stockpile occurred in 1992. Sales of Madagascar crystalline flake from the stockpile totaled 454 tons in 1992 compared with 106 tons in 1991. (See table 2.)

Production

United Minerals Co. continued its suspension of production of its amorphous graphitic material from its Montana mine in 1992. Output of manufactured graphite increased 10% to about 252,000 tons, at 29 plants, with a likelihood of some unreported production for in-house use. Production of all kinds of graphite fiber and cloth increased 11% to 3,600 tons.

In March, BASF Corp. decided to leave the graphite fiber industry and put up for sale its graphite fiber production plant at Rock Hill, SC, and its graphite fiber composite-intermediate plant at Anaheim, CA. In November, Toho Rayon Co. announced that is would take over the sales end of the business and supply the fiber from Japan. BASF will close the Rock Hill plant in mid-1993. This will at least help ameliorate the severe oversupply of graphite fiber around the world. One hopeful sign was the Toray Industries Inc. announcement that it would build a graphite fiber composite-intermediate plant at Frederickson, WA, to supply nearby Boeing operations. Another hopeful sign the General Motors Corp. announcement that it would build a pilot plant to test its in-house research

discovery of some years ago that has lead to a cheap new fiber production process. Some of the fiber, actually a carbon filament fiber, is being tested in composites.

A review article put the events of the past few years in perspective; to summarize, fiber producers will continue to have hard times until there is improvement in their major aerospace markets, which can presently not be foreseen. (See tables 3 and 4.)

Consumption and Uses

Reported consumption of natural graphite increased 15% to about 41,780 tons, according to a survey of more than 230 users. The three major uses of natural graphite were refractories, brake linings, and in packings, which together accounted for 58% of reported consumption. (See table 5.)

Nonclay refractories are represented by two important use categories of graphite. Standard refractory products, particularly gunning and ramming mixes, accounted for a sizable part of the demand in the past 5 years, mainly as amorphous graphite. Crucibles, shrouds, nozzles, stopper heads, and retorts, used in hot-metal processing operations such as the continuous casting of steel, use significant amounts of crystalline flake. Coarse flake graphite is preferred for crucibles and refractory associated items, but generally it is mixed with some fine crystalline material of lower value. The newest important refractory use for graphite in steelmaking is in carbon magnesite brick, where large amounts of crystalline flake are now used.

Graphite is used in brake and clutch linings. More graphite is being used as the brake and clutch producers change over from asbestos. The graphite lubricates, transfers the heat of friction away from the part, and leads to a lower rate of wear. Graphite is more commonly in heavier dutv used nonautomobile lining. Low-quality crystalline flake and amorphous graphite are suitable for foundry facing use. The graphite is mixed with a small amount of clay, suspended in an adhesive material, and applied as a thin coating to mold surfaces to provide for clean and easy mold release of the metal castings.

Graphite is important as a lubricant; when used as a lubricant, it can be a dry powder or mixed with oil or water. It is used with materials that must withstand extreme conditions, such as very high temperatures. Material for this use must be free of abrasive-type impurities.

Graphite used in packings, which includes expanded graphite and graphite foil, has been broken out again this year. While this new category includes uses in ammunition and seed coatings, in addition to packings, most of the tonnage was used to make expanded graphite and graphite foil and final products resulting from them.

Prices

Natural graphite prices are often negotiated between the buyer and seller and are based on purity and other Therefore, published price criteria. quotations such as those in Industrial Minerals are given as a range of prices. Another source of information for graphite prices is the average customs value per ton of the different imported These mainly represent classes. shipments of unprocessed graphite. A third source for natural graphite prices is the amount paid per ton at the point of consumption.

The price for crystalline graphite at the point of consumption—mostly crystalline flake, some crystalline dust, and a little lump graphite-dropped slightly to \$1,481 per ton from \$1,524 (revised). The price for amorphous graphite (including small amounts of amorphous-synthetic graphite mixtures) dropped slightly to \$677 per ton from \$707 (revised).

The index of unit value for high-modulus fiber produced in the U.S. (1973=100) was 44 in 1992, compared with 38 the previous year. (See table 6.)

Foreign Trade

The United States changed its tariff classification to the Harmonized Code on January 1, 1989. This has made the

1988 and 1990-92 import and export statistics somewhat noncomparable.

Total exports of natural graphite increased 4%. Exports of graphite electrodes totaled 76,000 tons valued at \$178.4 million, of which 29,784 tons (\$75.0 million) went to Canada, 6,650 tons (\$13.9 million) to Venezuela, 5,919 tons (\$15.7 million) to Japan, and the balance to other destinations.

Imports of natural graphite increased 48% from those of 1991. Imports of natural graphite from Canada increased dramatically. (See tables 7, 8, and 9.)

World Review

Graphite markets in the world were generally in difficulty; Japan was a prominent example. However, the U.S. market did show some improvement. Ouoted graphite prices finally began to reflect reality and had sizeable drops in Present several categories. prospective sales of U.S. stockpile graphite overhung the market, as did worries about the production of synthetic crystalline graphite from kish, a The worries are steelmaking waste. clearly premature because the pilot plant in Chicago did not produce anything in When successful, pilot plant 1992. production will be negligible and allow only test marketing. Full commercial production from kish on a significant scale is at least several years away. Production and export of Canadian graphite increased significantly this year, particularly from Cal Graphite Corp.

Canada.—Cal Graphite Corp. expanded its sales quite significantly this year. The mill was operating at slightly less than one-half capacity and is alleged to make a product from its refinery at Huntsville, Ontario. Stratmin Inc. brought its mill much closer to full capacity; according to published sources, it sold 6,800 tons of product in 1991 and 16,000 tons in 1992; it expects to sell 20,000 tons in 1993.

Canadian graphite activity has significantly lessened as the market has gotten poorer. Mart Mining & Exploration Ltd. did some drilling on its

micaceous graphitic schist deposit near Labrador City. Quinto Mining Corp. is evaluating byproduct graphite production at a gold prospect near Lumby, British Columbia.

A comprehensive article on the beneficiation of graphite ores, primarily Canadian, appeared this year. Emphasizing flotation, it gives a summary of process data and of analytical data.²

Japan.—Imports of all kinds of natural graphite in 1992 totaled 73,258 tons, compared with 122,650 tons in 1991 and Imports of 126,527 tons in 1990. graphite by kind in 1992 were 28,496 tons of crystalline powder or flakes, 75% or more of which can pass through a 105micron sieve (92% by ton from China), 24,805 tons of amorphous other than powder or flake (66% from China). 16,578 tons of amorphous powder or flakes (sic) other than that 75% or more of which can pass through a 105-micron sieve (51% from China), and a small balance of two other kinds.

Madagascar.—Societe Miniere de la Grande Ile is looking for a partner to help it expand its Ambatonitamba operation. Recent discoveries have increased mine reserves to 1 million tons. Installation of new flotation equipment has improved the product quality so much that it seldom drops below 90% carbon content.

Norway.—Elkem Skaland A/S completed the reconstruction of its mill and produced graphite from January to June, suspended operations, and started up again in November.

Sweden.—Anro Graphite AB has investigated a number of graphite prospects near its Kringelgruvan deposit. The firm is thinking of opening a mine and plant.

Tanzania.—Samax Ltd. and its partners are planning to open an operation 14 kilometers south of Kilimanjaro Airport. Feasibility studies are complete, and some equipment has been purchased. The beneficiation plant

is planned to have a capacity of 15,000 tons per year of predominantly coarse crystalline flake of a good carbon content and is targeted to come on-stream at the end of 1993. Reserves assay 7% carbon, exceed 20 million tons, and are not covered with overburden. Tanzanite and tsavorite, two gemstones, are also said to be found at the same location and may be extracted as coproducts or byproducts.

Current Research

A revised and updated graphite chapter emphasizing science and technology was published in the Kirk-Othmer Encyclopedia of Chemical Technology (Fourth Edition). Major sections cover physical and chemical properties, geographical occurrence, and end use.³

Late in the year, an announcement from Pennsylvania State University of a cheap process to convert graphite to diamond at low pressure initiated a multisided controversy. The new process was said to cut costs by a factor of 10 and involves subjecting a solid piece of graphite mixed with diamond dust, which acts as a seed, to a temperature of 800° to 900° C in the presence of hydrogen. Two firms made counterclaims and everyone is now racing to patent.

Fullerenes have been discovered in nature—in rocks on Earth and in outer space. Fullerenes, compounds with 60 to 70 carbons arranged in a soccerball structure sometimes with noncarbon atoms, have been found as films lining cracks in a shiny black rock called shungite from the Karelia area of Russia. Fullerenes also were discovered in the microscopic debris from a meteorite that had collided with a satellite. In both instances, painstaking precautions were taken in the examination and analysis leading to identification.

A simple method of producing fullerene tubes has been discovered, making them a viable substitute for graphite fibers. The method involves running electricity between two graphite rods in a helium-filled reaction vessel. The tubes conduct electricity and should be stiffer than graphite fiber; they may even be semiconductors. The fullerene

tubes can suck up gases and a variety of small molecules. The sucking strength gets stronger as the tube radius gets smaller.

OUTLOOK

Projected demand for crystalline flake graphite totaled 23,000 tons for 1995 and 25,000 tons for the year 2000. Demand for other graphite, mostly amorphous, totaled 15,000 tons for 1995 and 13,000 tons for the year 2000. This very slow growth rate reflects the maturity of the market, mostly in refractories, and particularly in carbon-magnesite brick. Production capacity is unlikely to increase from the present level while the overcapacity exists.

²For both 1991 and 1992, data for countries reflecting less than 500 metric tons each for yearly imports have been combined under the "Other" category in the "Country" list.

³Customs values.

¹Table includes data available through May 10, 1993.

²Does not include the following quantities sold directly without beneficiation, in metric tons: 1988–18,200 (revised); 1989–14,250; 1990–13,000; 1991–13,500; and 1992–14,400 (estimated).

³Indian marketable production is 10% to 20% of mine production.

⁴Reported figure.

⁵Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁶Dissolved in Dec. 1991.

GYPSUM

By Lawrence L. Davis

Mr. Davis, a physical scientist with 37 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for gypsum since 1985. Domestic survey data were prepared by R. Jean Jones, statistical assistant; and international data tables were prepared by Amy Burk, Section of International Data.

Demand for gypsum products increased in 1992, a result of increased construction activity, especially in new housing starts that increased 19% to 1.2 million units. The quantity of crude gypsum mined, calcined gypsum produced, and wallboard products shipped was greater than in 1991.

Sales of gypsum products increased 13% to 25 million short tons, but value remained about the same at \$1.3 billion. Increased competition caused lower prices for gypsum products. Imports for consumption of crude gypsum increased 4% to about 7.9 million tons. Total value of gypsum product exports increased 13% to \$97 million.

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on gypsum that are in compliance with Public Law 100-418, will begin to report data in metric units.

DOMESTIC DATA COVERAGE

Domestic production data for gypsum are developed by the U.S. Bureau of Mines from a survey of U.S. gypsum operations. Of the 116 operations to which the annual survey request was sent, 114 responded, representing 98% of the total crude gypsum production shown in tables 1 and 2. Nonrespondents were estimated from monthly and quarterly canvasses or from previous years' data. (See table 1.)

BACKGROUND

Definitions, Grades, and Specifications

Gypsum has a composition of 79% calcium sulfate and 21% water, CaSO₄•2H₂O, and is used as a commercial and generic term for all calcium sulfate materials. The wellformed transparent crystalline variety is called selenite. The massive variety is called alabaster and can be easily carved. The fibrous, silky variety is called satin spar. Gypsite is a mixture of clay and gypsum crystals.

Anhydrite is calcium sulfate, CaSO₄, with no water of crystallization. It is a naturally occurring mineral commonly associated with gypsum. When gypsum is calcined at high temperatures, it is converted to anhydrite.

Commercially calcined gypsum, CaSO₄•1/2H₂O, is a manufactured hemihydrate product produced by partial calcination of gypsum. It is produced by heating gypsum at temperatures to 350° F. The hemihydrate product, commonly called plaster of paris, is called stucco by the wallboard manufacturers. When water is added to form a paste, the calcined material reabsorbs water and it quickly sets and hardens to form gypsum again.

Byproduct gypsum is a chemical product of manufacturing processes such as phosphoric acid, hydrofluoric acid, citric acid, and titanium dioxide from ilmenite, consisting essentially of CaSO₄•2H₂O. The sludge produced from scrubbers in the desulfurization of stack gas in thermal powerplants is also byproduct gypsum.

Keene's cement is anhydrous gypsum

plaster with certain accelerator additives. It is produced by special high-temperature calcining. All of these minerals and materials, including the articles molded from the plaster, are commonly called gypsum or plaster.

Industry Structure

The domestic gypsum industry is large and is dominated by a few large vertically integrated companies that mine and calcine gypsum and manufacture plaster and wallboard products. These companies also sell crude gypsum for use in cement and agriculture. The large wallboard producers, through foreign subsidiaries, produce most of the crude gypsum that is imported to feed coastal wallboard plants. Plants on the east coast import mostly from Canada's Maritime Provinces, while plants on the west coast import gypsum from Mexico. gypsum from Spain, the other major source of U.S. imports, is used mainly by cement plants.

Gypsum production is worldwide, with at least 80 countries known to produce. Because of its wide distribution and plentiful supply, most of the world's production is consumed domestically. Exceptions include Canada and Mexico, which export significant portions of their production to the United States; Thailand and Australia, which export to much of the Southeast Asia market; and Spain, which exports to the United States, Scandinavia, and other countries. In the United States and other industrialized nations, the major use of gypsum is in the manufacture of gypsum wallboard products. Most crude gypsum is mined in rural areas and shipped to urban areas

for manufacture into wallboard and ultimate consumption. In developing countries, most gypsum is consumed by local cement plants.

Geology-Resources

Gypsum deposits may be found in any geologic era, but they are most common in the Permian. They are commonly found in association with the source rocks for petroleum. Most massive gypsum and anhydrite deposits occur as large, lenticular, stratified bodies that were formed by evaporation of seawater in basins that have one or more restricted openings to the sea. The basins range in diameter from a few miles to many hundreds of miles.

Classic evaporite formation involves the deposition of anhydrite, with later hydration of the anhydrite by meteoric waters to gypsum at depths ranging from 0 to 1,000 feet. The depth of hydration is generally related to topography, structure, and climate because these factors affect the depth of ground water and surface water penetration.

Technology

Gypsum deposits are explored to determine their physical and chemical properties and to determine a minable thickness and the ratio of gypsum to anhydrite. The depth of hydration is important in mining because the presence of only a few percent anhydrite is sufficient to render gypsum unusable for making plaster. Adequate samples may be obtained from outcrops or drill cores.

Deposits near the surface are developed by stripping the overburden, developing either single- or multiple-bench open pits, and constructing access and transportation routes. Underground ore bodies are developed by sinking shafts or driving adits, with mining development and production by the roomand-pillar system.

Most domestic gypsum is produced from surface mines using standard open pit mining methods. In a typical domestic mine, the gypsum is drilled and blasted as needed, usually every week or two. Broken gypsum rock, loaded with hydraulic shovel or front-end loader, is hauled to the primary crusher by a fleet of three or four 35-ton haultrucks. All material removed from the mines is crude gypsum. All waste is left in the mine.

The processing of crude gypsum depends on the end use. Gypsum for use in cement is crushed to minus 11/2 inch plus 3/8 inch. For agricultural or filler use, the gypsum is pulverized to 100 mesh or finer.

To produce plaster and wallboard products, minus-100-mesh gypsum is heated in batch kettles to remove threequarters of the water of crystallization, converting gypsum, CaSO₄ • 2H₂O, to the hemihydrate product, CaSO₄ • 1/2H₂O. A few rotary kilns are also used, in which case a coarse feed with fines removed is During the commercial calcined. calcining process, gypsum is heated to 250° F for about 2 hours, then the temperature rapidly rises to 300° to 350° F, at which time the calcine, called stucco, is dumped into a hot pit. The calcine is then mixed with various additives, including a retarder or accelerator, and manufactured into prefabricated wallboard products and other plaster and cement products.

Plaster is generally reground calcine, modified with retarders or accelerators and containing various binders such as hair, sisal, fiberglass, aggregates, or colored pigments. Retarders, usually glue, starch, or slaughterhouse byproducts, can increase the setting time to as much as 6 hours. Accelerators, such as metal salts, set plaster, or anhydrite, can reduce the setting time to less than 5 minutes. The plaster is packed in bags and sold under various trade names.

Prefabricated products include lath, veneer base, sheathing, and wallboard. These board products are manufactured by continuous methods on automatic machines that can be adjusted to any of the standard products. A slurry of wet plaster with additives and an accelerator is spread between two moving sheets of paper. Moving through the shaping rolls, the edges are molded and sealed. The green board is run out on a traveling belt

until the plaster has set. The board is then cut with a revolving knife into appropriate lengths and slowly passed through a drying kiln.

ANNUAL REVIEW

Production

The United States remained the world's leading producer of gypsum, accounting for 15% of the total world output. Crude gypsum was mined by 31 companies at 58 mines in 19 States. Production increased 5%. Leading producing States, in descending order, were Oklahoma, Iowa, Texas, Michigan, Nevada, California, and Indiana. These seven States produced more than 1 million tons each and together accounted for 76% of total domestic production.

Leading companies were USG Corp., 11 mines; National Gypsum Co., 7 mines; Georgia-Pacific Corp., 7 mines; Harrison Gypsum Inc., 2 mines; and Temple-Inland Forest Products Corp., 1 mine. These 5 companies, operating 28 mines, produced 69% of the total crude gypsum.

Leading individual mines, in descending order of production, were USG's Plaster City Mine, Imperial County, CA; USG's Sweetwater Mine, Nolan County, TX; USG's Sperry Mine, Des Moines County, IA; Harrison's Cement Mine, Caddo County, OK; USG's Shoals Mine, Martin County, IN; National's Tawas Mine, Iosco County, MI; USG's Alabaster Mine, Iosco County, MI; Temple-Inland's Fletcher Mine, Comanche County, OK; National's Sun City Mine, Barber County, KS; and Briar's Briar Mine, Howard County, AR. These 10 mines accounted for 42% of the national total. Average output for the 58 active mines increased 11% to 280,000

Gypsum was calcined by 13 companies at 70 plants in 28 States, principally for the manufacture of gypsum wallboard and plaster. Calcined output increased 8% in tonnage and 4% in value. Leading States, in descending order, were California, Iowa, Texas, Florida, Nevada, and New York. These 6 States,

with 27 plants, accounted for 47% of the national output.

Leading companies were USG, 20 plants; National Gypsum, 18 plants; Georgia-Pacific, 10 plants; Domtar, 7 plants; and Celotex, 4 plants. These 5 companies, operating 59 plants, accounted for 83% of the national output.

Leading individual plants were, in descending order of production, USG's Plaster City plant, Imperial County, CA; USG's Jacksonville plant, Duval County. FL; USG's Sweetwater plant, Nolan County, TX; USG's Sperry plant, Des Moines County, IA; USG's Shoals plant, Martin County, IN; Briar's Briar plant, Howard County, AR; USG's Baltimore plant, Baltimore County, MD; National's Tampa plant, Hillsborough County, FL; USG's Stony Point plant, Rockland County, NY; and James Hardie Gypsum Inc.'s Las Vegas plant, Clark County, NV. These 10 plants counted for 30% of the national production. Average calcine production for the 70 U.S. plants was 237,000 tons, a 10% increase.

A total of 695,000 tons of byproduct gypsum, valued at \$4.2 million, was used, principally in agriculture but some for gypsum wallboard manufacturing. Approximately 90% was nonphosphogypsum origin compared with 78% in 1990.

According to the Gypsum Association, yearend gypsum wallboard plant capacity for producing 1/2-inch regular wallboard increased slightly to 24.19 billion square feet per year. Total wallboard shipments were 19.2 billion square feet, 79% of capacity. Continued weakness in the wallboard market caused many plants to operate well below capacity level. Domtar's plants at Florence, CO, and at Sweetwater, remained closed TX. throughout the year. (See tables 2 and 3.) (See figure 1.)

Consumption and Uses

Apparent consumption, defined as production plus net imports plus industry stock changes, of crude gypsum, including byproduct gypsum, increased 6% to 24.6 million tons. Net imports consumed. Apparent consumption of calcined gypsum increased 8% to 16.5 million tons.

Yearend stocks of crude gypsum at mines and calcining plants were 2.6 million tons. Of this, 43% was at calcining plants in coastal States.

Of the total gypsum products sold or used, about 25% was uncalcined. gypsum, Uncalcined crushed screened to specifications, is marketed for use in portland cement manufacture, agriculture, and fillers. The cement industry uses gypsum to retard the setting time of concrete.

Finely ground gypsum rock is used in agriculture to neutralize alkaline and saline soils, improve the permeability of argillaceous materials, and provide sulfur and catalytic support for maximum fertilizer utilization and leguminous productivity. Small amounts of very pure gypsum are used as fillers and in glassmaking, papermaking, pharmaceutical applications. In 1992, 53% of the uncalcined gypsum was used in portland cement, and the remainder was used mainly for agricultural purposes.

Of the total calcined gypsum products, most went into prefabricated products. A small percentage was used in industrial and building plasters. Of prefabricated products, based on surface square feet, 64% was regular wallboard; 26% was fire-resistant type X wallboard; 4% was 5/16-inch mobile home board: and 3% was water- and/or moistureresistant board. Lath, veneer base, sheathing, predecorated, and other types made up the balance. Of the regular wallboard, 82% was 1/2-inch and 10% was 5/8-inch.

In descending order, the leading sales regions for prefabricated products were the South Atlantic, East North-Central, Pacific, and Middle Atlantic. Together these regions accounted for 62% of the total. (See tables 4 and 5.) (See figure

Markets and Prices

On an average value-per-ton basis, provided 32% of the crude gypsum | f.o.b. mine or plant, crude gypsum | gypsum remained at 108 million tons.

increased slightly to \$6.18, calcined gypsum decreased slightly to \$15.04, and byproduct gypsum increased 34% to Prefabricated products were \$6.01. valued at \$70.05 per ton, plasters at \$132.90 per ton, and uncalcined products at \$10.33 per ton.

Quoted prices for gypsum wallboard products were published monthly in Engineering News-Record. Spot prices in December, based on truck lots delivered to the job, showed a wide range. Regular 1/2-inch wallboard prices ranged from \$93 per thousand square feet at Cincinnati to \$160 at Detroit and Minneapolis. The average price in December for 20 cities was \$124 per thousand square feet, with some minor discounts for prompt payment. represented a 7% increase compared with that of December 1991.1

Although demand for gypsum products increased compared with 1991, the value of sales remained about the same at \$1.3 billion, well below the record high \$2.5 billion in sales achieved in 1986. The overall low level of prices for gypsum products continued to cause problems for the industry. At yearend, National Gypsum, the second largest gypsum company, remained under chapter 11 bankruptcy protection, and USG, the Nation's largest, was preparing a restructuring of debt plan in anticipation of filing for bankruptcy protection.

Foreign Trade

Imports for consumption of crude gypsum increased 4% to 7.9 million tons. Net imports represented 32% of apparent consumption. Crude gypsum from Canada and Mexico was used mainly to feed wallboard plants in coastal cities. Imports from Spain, the other major source of imported gypsum, were used mostly for portland cement manufacture. Gypsum wallboard imports, principally from Canada, increased 23% to 133 million square feet. (See tables 6 and 7.)

World Review

Estimated world production of crude

Total world production figures are probably low because, in some countries, significant production was consumed captively and not reported. Also, production from small deposits in developing countries was intermittent and often unreported. The United States remained the world's largest producer of crude gypsum with 15% of the world total. (See table 8.)

Canada.—Acting on complaints that U.S. gypsum wallboard was being dumped on the Canadian market, Canada's Customs Department issued a preliminary determination that dumping had occurred. The final determination was to be made within 90 days, and within 120 days the Canadian International Eastern Tribunal was to rule on whether dumping injured Canadian production. At yearend, those determinations were still pending.²

The Gypsum Association in the United States, of which all Canadian wallboard producers were members, reported that yearend capacity of 1/2-inch regular wallboard in Canada was 3.40 billion square feet, a slight increase compared with that of the previous year.

Denmark.—Knauf AG, a German construction materials firm, purchased Danogips, Europe's fourth largest gypsum wallboard producer. The purchase included two wallboard plants in Denmark and one in Sweden with a combined capacity of about 600 million square feet per year.³

Qatar.—A contract was awarded to construct a gypsum wallboard plant for Qatar Saudi Gypsum Industries, a joint venture of Qatar Industrial Manufacturing Co., Saudi Arabia's National Gypsum Co., and the Qatar National Cement Co. Construction was to begin by yearend.⁴

Saudi Arabia.—National Gypsum Co. announced plans to double the capacity of its Yanbu plant.⁵

Thailand.—Thai Gypsum Product Co. Ltd. opened its Laem Chabang gypsum wallboard facility at Chon Buri. Advanced technology and equipment developed by United States Gypsum Co. was utilized under an agreement between the two companies. The facility is the first in Thailand to use a computer-aided wallboard manufacturing system.⁶

Turkmenistan.—A new gypsum operation began production in Gaurdak, Chardzhou Oblast.⁷

United Kingdom.—British Gypsum, a subsidiary of BPB Industries PLC, was building a new 660,000-ton-per-year gypsum processing plant at Barrow Upon Soar, near Loughborough. Completion was expected in mid-1992. A new mine at the site was already in production using a continuous mining machine for excavation.

Redland PLC was working to double the capacity of its wallboard plant at Portbury, near Bristol. Construction was to be completed by yearend with production starting in 1993.

Knauf UK announced plans to build a 55,000-ton-per-year plaster plant at its wallboard facility at Immingham in Humberside.⁸

OUTLOOK

More than 90% of the gypsum consumed annually in the United States is used in construction, mainly in gypsum wallboard products, building plasters, and the manufacture of portland cement. The decline in construction activity that depressed demand for gypsum products over the past several years appears to have ended. Gypsum product demand increased in 1992, and a slow, but steady, recovery is expected to continue over the next few years.

Estimated. Revised.

¹Table includes data available through July 12, 1993.

²Reported figure.

³Includes anhydrite.

⁴Less than 1/2 unit.

⁵Formerly part of Yugoslavia; data were not reported separately until 1992.

⁶Data are for years beginning Apr. 1 of that stated.

⁷Data are for years ending July 7 of that stated. Reported in cubic meters and estimated at mean weight of 1.8 tons per cubic meter.

^aProbably does not include production for cement manufacture (normally 3% to 5% of finished cement, equivalent of an additional 12,000 to 15,000 metric tons per year).

⁹Data are for years beginning Mar. 21 of that stated.

¹⁰For cement production only. Information is insufficient to formulate reliable estimates for output for other uses (plaster, mortar, etc.)

¹¹Dissolved in Dec. 1991; however, information is inadequate to formulate reliable estimates for individual countries.

¹²Excludes byproduct gypsum.

¹³Dissolved in Apr. 1992.

FIGURE 1
SUPPLY OF CRUDE GYPSUM IN THE UNITED STATES

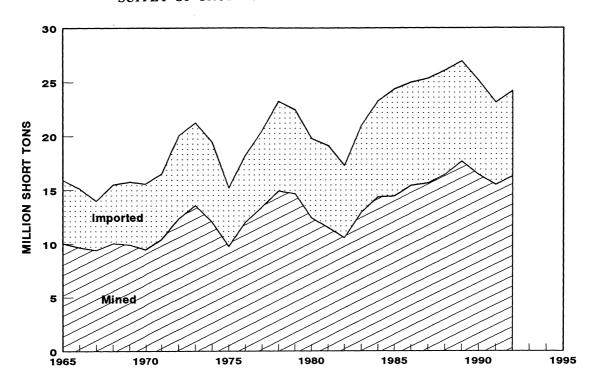

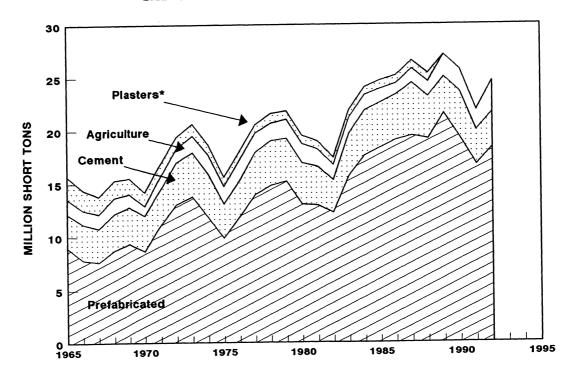

FIGURE 2
SALES OF GYPSUM PRODUCTS, BY USE

HELIUM

By William D. Leachman

Mr. Leachman, a chemical engineer with 39 years of U.S. Bureau of Mines experience, has been the commodity specialist for helium since 1983. He also prepared the domestic survey and international data tables.

Grade-A helium (99.995% or better) sales volume in the United States by private industry and the U.S. Bureau of Mines was 63.7 million cubic meters [2.297 million cubic feet (MMcf)] in 1992.1 Grade-A helium exports by private producers were 30.7 million cubic meters (1,106 MMcf), for total sales of 94.4 million cubic meters (3,403 MMcf) of U.S. helium. The Bureau's price for Grade-A helium, f.o.b. plant, was \$1.983 per cubic meter [\$55.00 per thousand cubic feet (Mcf)] and bulk liquid helium was \$2.253 per cubic meter (\$62.50 per Mcf) on January 1, 1992, with additional costs for container services and rent. On November 1, 1992, the bulk liquid helium price was raised to \$2.379 per cubic meter (\$66.00 per Mcf). Private industry also increased its helium prices last year, but the prices are lower than the Bureau's.

DOMESTIC DATA COVERAGE

Domestic production data for helium are developed by the U.S. Bureau of Mines from records of its own operations as well as the High Purity Helium Survey, a single, voluntary canvass of private U.S. operations. Of the eight operations to which a survey request was sent, 100% responded, and those data plus data from the Bureau's operations represent 100% of the total helium sales and recovery shown in table 2.

BACKGROUND

The U.S. Bureau of Mines role in helium matters dates back to the First World War when the Army and Navy became interested in using helium as an inert lifting gas and contacted the Bureau for assistance because of its natural gas expertise. In 1925, the Government's Helium Program was officially placed under Bureau control by Congress (Helium Act of 1925). In 1929, the Bureau's Amarillo, TX, large-scale helium extraction and purification facility was built and began operation. During World War II, demand increased significantly, and four more small Government helium plants were built.

New technology increased helium demand in the 1950's and led to the construction of the Keyes, OK, plant in 1959. Dwindling Hugoton-Panhandle Field natural gas supplies aroused concerns that no economic source of helium would exist by the turn of the century.

In 1960, Congress replaced the 1925 Act with new legislation (Helium Act Amendments of 1960). The purposes of the act were to provide for conservation of helium for essential Government activities and to supply the current and foreseeable future helium needs of the Federal agencies. The act directed the Secretary of the Interior to purchase and store helium for future Government use and to operate and maintain helium production and purification plants and related helium storage, transmission, and shipping facilities.

Purchases for helium conservation were made under 22-year contracts with private natural gas companies, which added crude helium extraction capabilities to their existing gas processing facilities. Four companies built five crude helium plants. The Bureau constructed a high-pressure pipeline to transport the helium from Bushton, KS, and intermediate

points to the Bureau-owned Cliffside Field near Amarillo, TX, for storage.

Helium needs of the Federal agencies, particularly the U.S. Department of Defense (DOD), the National Aeronautics and Space Administration (NASA), and the U.S. Department of Energy (DOE), have been met, and there is enough helium in storage to meet their foreseeable needs for up to 100 years. The present Federal helium demand is supplied solely by the Bureau's Exell Helium Plant, 56 kilometers (35 miles) north of Amarillo.

In the mid-1970's, the Bureau began accepting privately owned crude helium for storage in Cliffside under long-term contracts. Private industry currently has an 8-month supply of helium in Government storage, assuming all private market requirements would be supplied from storage.

Geology-Resources

Domestic measured and indicated helium resources as of January 1, 1992, the latest figures available, are estimated to be 13.0 billion cubic meters [467 billion cubic feet (Bcf)1. The total identified helium resources are about 0.1 billion cubic meters (4 Bcf) more than those reported in 1991. The resources include measured reserves and indicated resources estimated at 6.9 billion cubic meters (248 Bcf) and 0.9 billion cubic meters (32 Bcf), respectively, in natural gas with a minimum helium content of 0.3%. A slight increase in the measured reserves of helium is reported due to ongoing evaluations of the Nation's depleting helium resources. The measured reserves included 1.0 billion

cubic meters (34 Bcf) stored by the Bureau in the helium conservation storage system. Measured helium resources in natural gas with a helium content of less than 0.3% are estimated to be 1.2 billion cubic meters (44 Bcf). Indicated helium resources in natural gas with a helium content of less than 0.3% are estimated to be 4.0 billion cubic meters (143 Bcf). Approximately 4.5 billion cubic meters (163 Bcf) or 92% of the domestic helium resources under Federal ownership are in the Riley Ridge area and the Church Buttes Field in Wyoming and in the Cliffside Field in Texas.

Most of the domestic helium resources are in the midcontinent and Rockv Mountain regions of the United States. The measured helium reserves are in approximately 98 gasfields in 11 States. About 85% of these reserves are contained in the Hugoton Field in Kansas, Oklahoma, and Texas; the Keyes Field in Oklahoma; the Panhandle and Cliffside Fields in Texas; and the Riley Ridge area in Wyoming. The U.S. Bureau of Mines analyzed a total of 206 natural gas samples from 20 States and 5 foreign countries during 1992 in conjunction with its program to survey and identify possible new sources of helium.

Technology

Technology that uses liquid helium to produce superconducting temperatures continues to be developed and utilized. Liquid helium continues to be used at Fermi National Accelerator Laboratory for Tevatron/Tevatron 1, which was the world's first superconducting particle The liquid helium-cooled accelerator. superconducting magnets used in this accelerator provide an intense and extremely steady magnetic field using only a fraction of the energy required by conventional electromagnets. Tevatron is presently the second most energetic particle accelerator in the world (1.6 trillion electron volts). In addition, the DOE has already selected the magnets it proposes to use in the Superconducting Supercollider (SSC). The SSC magnets will be similar to the magnets used at Fermi, which have been proven and

tested in operation. When completed, the SSC will have about 20 times the energy of the Tevatron (40 trillion electron volts). The Texas site for the SSC was selected by DOE in January 1989.

Argonne National Laboratory is developing a marine magnetohydrodynamic (MHD) propulsion system for military and commercial use. system has no moving parts, but uses magnetic fields and electricity to pump water through a tube. This method of propulsion was illustrated in the film "Hunt for Red October." Researchers at Argonne used the world's largest heliumcooled superconducting dipole magnet to study this propulsion Development of this technology could lead to a new generation of water transportation vessels that would travel more quickly, quietly, and efficiently than present ships.

Liquid helium use in magnetic resonance imaging (MRI) continues to increase as the medical profession accepts and develops new uses for this equipment. MRI equipment is providing accurate diagnoses of medical problems where exploratory surgery was previously required. Another medical application being developed uses MRI to determine by blood analysis if a patient has any form of cancer. Most researchers seem to think it will be at least 5 to 10 years before uses of the new high-temperature -300 (about -184 °C or superconducting materials affect liquid helium demand.

Lifting gas applications are increasing. The U.S. Navv and U.S. Air Force are investigating the use of airships to provide early warning systems to detect low-flying cruise missiles. The Drug Enforcement Administration has installed six tethered radar blimps along the southern border of the United States to detect drug smugglers. In addition, NASA is now using helium-filled balloons to sample the atmosphere in Antarctica to determine what is depleting the ozone layer that protects the Earth from harmful ultraviolet radiation. Similar work is also underway in the Arctic. A stealth blimp is being tested by the Army's Intelligence and Electronic Warfare Center in New Jersey. In the commercial market, several companies in addition to Goodyear are now using "blimps" for advertising.

The development of Strategic Defense Initiative (SDI) weapons such as the antisatellite (ASAT) rocket, chemical laser, and rail gun has slowed with the decline of the "cold war." The ASAT rocket uses liquid helium-cooled infrared sensors for target location and guidance. Gaseous helium is used in the lasing gas mixture of the chemical laser, and liquid helium is used to cool the tracking telescope used to locate the target and aim the laser beam. High-pressure gaseous helium provides the initial push that inserts the projectile into the bore of the rail gun at a velocity of about 1,770 kilometers per hour (1,100 miles per hour). Electromagnetic energy applied along the bore accelerates the projectile to a final velocity of about 14,500 kilometers per hour (9,000 miles per hour). Superconducting magnetic energy storage (SMES) is also being investigated to provide power for DOD laser systems and electric power peak shaving in commercial applications. SMES allows the accumulation and storage of electrical energy over the long term (hours) when excess capacity is available discharges it in minutes or as needed to provide for peak demands.

Other evolving technologies that require the unique properties of helium are (1) metastable helium for energy storage, which involves raising helium electrons to an excited energy state and then stabilizing the atom there; (2) fiberoptic production, where an ultrapure inert atmosphere is required; (3) helium-filled plastic pillows, where low density is required to simulate a precursor wave from a nuclear blast; (4) helium ion tumor treatment, where large inert particles are required; (5) liquid heliumcooled superconducting microswitches, called Josephson junctions, which are conventional than much faster semiconductors and use less power; (6) "Aneutronic" nuclear fusion, where nuclear energy is produced by fusion of deuterium and helium-3, results in few or no neutrons; and (7) helium-hydrogen breathing mixtures that enable deep-sea divers to reach depths below 580 meters (1,700 feet).

ANNUAL REVIEW

Legislation and Government Programs

The Administration proposed legislation to amend the Helium Act of 1960 to remove the requirement that all Federal agencies buy their major helium requirements exclusively from the Secretary of the Interior. No action was taken on this legislation.

The Federal Helium Program is designed to provide all Federal agencies with their current and foreseeable-future helium needs to carry out other Government programs authorized and funded by Congress. The Bureau's major helium customers are DOD, NASA, and DOE.

Production

In 1992, 13 privately owned domestic helium plants were operated by 10 companies. Eight of the privately owned plants and the U.S. Bureau of Mines plant extracted helium from natural gas. All extraction plants except one use cryogenic extraction processes. The volume of helium recovered from natural gas increased 6.7%, while sales increased about 7.0% in 1992. A shortage of private helium production was prevented by purifying crude helium that had been stored in the Bureau's Cliffside Field. All natural gas processed for helium recovery came from gasfields in Colorado, Kansas, Oklahoma, Texas, and Wyoming. Seven private plants and the Bureau's plant purified helium this year. Pressure-swing adsorption is used for helium purification at all seven of the private helium plants and at the Bureau's plant. The Bureau also uses cryogenic purification for backup. The Bureau and six private plants that produce Grade-A helium also liquefy helium. The plant operators and locations are Air Products and Chemicals Inc., Hansford County, TX, and Liberal, KS; Exxon Co., U.S.A., Shute Creek, WY; Kansas Refined Helium Co., Otis, KS; and Praxair, Inc., Bushton and Ulysses, KS. Nitrotec's helium plant near Burlington, CO, produces Grade-A helium but does not liquefy it. (See tables 1, 2, and 3, and figures 1 and 2.)

Consumption and Uses

The major domestic end uses of helium were cryogenics, welding, and pressurizing and purging. Minor uses included synthetic breathing mixtures, chromatography, leak detection, lifting gas, heat transfer, and controlled atmospheres. (See figure 3.) The Pacific and Gulf Coast States were the principal areas of helium consumption.

Bureau sales to Federal agencies and their contractors totaled 8.626 million cubic meters (311 MMcf) in 1992, a decrease of about 8% when compared with last year's sales. This decrease was largely due to the helium price increases implemented during 1991 and reduced SDI purchases as the cold war declined. Sales to DOE also continue to decline.

The Federal agencies purchase their major helium requirements from the U.S. Bureau of Mines. Direct helium purchases by DOD, NASA, DOE, and the National Weather Service constituted most of the Bureau's Grade-A helium sales. Most remaining helium sales to Federal agencies were made through Bureau contract distributors. purchased equivalent volumes of Bureau helium under contracts described in the Code of Federal Regulations (30 CFR 602). Some of the contract distributors also have General Services Administration helium supply contracts. These contracts make relatively small volumes of helium readily available to Federal installations at lower freight charges by using the contractors' existing distribution systems.

Stocks

The volume of helium stored in the U.S. Bureau of Mines helium conservation storage system, including the conservation pipeline network and Cliffside Field, totaled 0.94 billion cubic

meters (33.8 Bcf) at yearend. The storage system contains crude helium purchased under contract by the Bureau from 1962 to 1973 and privately owned helium stored under contract. Excess private helium is extracted from natural gas supplying fuel markets in the winter and stored by the Bureau under contract. This privately owned crude helium is returned to the owners as needed for purification to supply private demand. During 1992, 25.3 million cubic meters (913 MMcf) of private helium was delivered to the Bureau's helium conservation storage system and 18.4 million cubic meters (663 MMcf) was withdrawn for a net increase of 6.9 million cubic meters (250 MMcf) of private helium in storage. (See table 4.)

Transportation

All Grade-A gaseous helium sold by the Bureau was shipped in cylinders, modules (large gas cylinders), special railway tankcars, or highway tube semitrailers. Small gas cylinders are filled at the Amarillo plant, and railway tankcars are filled at the Exell plant. Other shipping containers for gaseous helium can be filled at either plant. Bureau liquid helium was shipped in dewars and semitrailers from the Exell plant. Private producers and/or distributors shipped helium predominantly as a liquid in semitrailers. These semitrailers delivered the liquid helium to distribution centers where some of it was gasified and compressed into trailers and small cylinders for delivery to the end user. The remaining liquid helium was sold as bulk liquid or repackaged in dewars of various sizes for delivery.

Prices

The Bureau price for Grade-A helium, f.o.b. plant, was \$1.983 per cubic meter (\$55.00 per Mcf) and bulk liquid helium was \$2.253 per cubic meter (\$62.50 per Mcf) on January 1, 1992, with additional costs for container services and rent. On November 1, 1992, the bulk liquid helium price was raised to \$2.379 per cubic meter (\$66.00 per Mcf). Private

industry also increased its helium prices last year, but lagged behind the Bureau's.

Foreign Trade

Exports of Grade-A helium, all by private industry, increased by 13% in 1992 to 30.7 million cubic meters (1,106 MMcf). (See table 3). About 47% of the exported helium was shipped to Europe. Belgium-Luxembourg, France, and the United Kingdom, collectively, received about 88% of the European helium imports. About 37% of the U.S. helium exports went to Asia, with Japan receiving about 87%. Other exports were as follows: about 7% to North America; about 2% each to Australia-New Zealand. the Middle East, and South America; 1% to Central America: and less than 1% each to Africa and the Caribbean. The shipments of large volumes of helium to Western Europe were attributed to helium uses in cryogenic research superconducting applications. Significant volumes were also used in breathing mixtures for diving, welding, and as a lifting gas. Although no helium was imported by the United States in 1992, import tariffs on helium remained at the 3.7% rate for most favored nations established on January 1, 1987. non-most-favored-nation tariff also remained unchanged at 25%. changes in import tariffs are scheduled at this time.

World Review

World production of helium, excluding the United States, was estimated to be 11 billion cubic meters (400 MMcf), most of which was extracted in Poland and Russia. The remainder was produced in small plants in China and India. (See table 5.)

OUTLOOK

Until recently, all superconductors required liquid helium (-269 °C or -452 °F) to reach superconducting temperatures. Current research on superconductors has resulted in the discovery of superconducting materials

that operate above liquid nitrogen temperatures (-196 °C or -320 °F). These new superconductors have physical limitations, such as brittleness and poor current-carrying capacities, which have precluded their use in most superconducting applications. If these physical problems are solved, the new materials could replace liquid helium-cooled superconductors.

Since 1988, the market for U.S.-produced helium has grown at an average annual rate of 7.2%. Private industry's market has been growing at 8.2% per year, while the Federal market has dropped 23% since prices were increased in 1991. In 1992, private industry supplied about 86% of the domestic demand while the Bureau supplied the remaining 14%. Private industry supplies all of the U.S. helium exports. The foreign market made up about 33% of U.S. helium sales in 1992 and has grown at an average rate of almost 14% per year since 1988.

The outlook for helium looks good with growth continuing in new technologies that use helium. An adverse impact from high-temperature superconductors, if any, is not expected for several years.

IODINE

By Phyllis A. Lyday

Mrs. Lyday, a physical scientist with the U.S. Bureau of Mines, has been the commodity specialist for iodine for 14 years. Domestic survey data were prepared by Tonya Hardin, statistical assistant; and international data tables were prepared by Jeremy Tidwell, international data coordinator.

Three producers of crude iodine supplied approximately 62% of domestic demand; the remainder was imported. Because some exports and imports are in product categories rather than crude products, net imports are not clearly developed. The major world producer, Japan, produced iodine from brines associated with gas production. The second largest producer, Chile, produced iodine as a coproduct of sodium nitrate.

DOMESTIC DATA COVERAGE

Domestic production data for iodine are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the four operations to which a survey request was sent, four responded, representing an estimated 100% of the total production shown in tables 1 and 6. (See tables 1 and 6.)

BACKGROUND

Definitions, Grades, and Specifications

Commercial crude iodine normally has a minimum purity of 99.5%. Resublimed iodine is usually 99.9% pure. Most iodine is converted for industrial use to potassium iodide, sodium iodide, and other inorganic compounds, as well as numerous organic compounds.

Geology-Resources

Iodine occurs in rocks and soils, surface and underground brines, and caliche ores. Michigan brines contain about 30 parts per million (ppm) of iodine in the Sylvania Formation of

Devonian age. California brines contain 30 to 70 ppm of iodine in brines associated with oilfields in the middle Miocene age, Monterey Formation, and lower Pliocene age Repetto Formation. Louisiana brines contain about 35 ppm of iodine. In Oklahoma, iodine concentrations associated with oil and gas range between 150 and 1,200 ppm. In Woodward County, OK, iodine occurs in the Morrowan Formation of Pennsylvania age. The iodine concentration averages about 300 to 350 milligrams per liter; 22 barrels of brines are required for each kilogram of iodine.

Extensive iodine-bearing nitrate ores occur in caliche deposits in a belt several hundred kilometers long in the Atacama Desert of northern Chile. The ore layers are 1 to 3 meters thick, usually flat or gently dipping and near the surface. Evaporate minerals such as lautarite (CaI₂O₆) and dietzeite (2CaO•I₂O₅•CrO₃) occur as cementing material in unconsolidated surface material or as veins and impregnations in bedrock.

Japanese brines contain 50 to 135 ppm of iodine in the Kiwada, Otadai, and Umegase Formations of the Kazusa Group of Pliocene age. The major iodine-producing area was the southern Kanto Gasfield, which extends over Chiba. Tokyo, and Kanagawa Prefectures. Iodine was produced in the Niigata and Nakojo Gasfields in Niigata Prefecture, on the Sea of Japan side of central Japan, and the Sadowara Gasfield in Miyazaki Prefecture, southern Kyushu.

In Indonesia, iodine occurs with trace amounts of bromine in brines associated with oil. The most important iodineproducing area is the Gujangon anticline of sandstone and diatomaceous marls of the Upper Pliocene, Kailiberg Formation.

On Okinawa, iodine occurs in concentrations of about 85 ppm in the Tomigusuku Formation of the Shimajiri Group of late Miocene-early Pleistocene age.

Technology

Processing.—In Japan and the United States, iodine is removed from brines by processes that separate the brines from any associated hydrocarbons. In the blowing-out process, brine is acidified and iodine is liberated by reducing the pH to about 3. A countercurrent stream of air transports the liberated iodine to a second tower where the iodine is absorbed by a solution of hydriodic acid. The iodine settles, is filtered, and is melted under concentrated acid. Brine stripped of iodine is treated and then reinjected into its subsurface formation of origin.

In the absorption process, brine is passed through an absorber, and the waste brine is neutralized and sent to a disposal well. The absorbent laden with iodine is treated with an alkaline solution to regenerate the absorbent and eludes iodine as sodium iodide. Iodide is precipitated under acid.

Japanese plants also use an ionexchange resin. Upon saturation, the iodine is eluted using a caustic solution that regenerates the resin. Iodine is then processed with a sodium chloride solution and melted under acid.

Chilean caliche deposits are mined by open pit methods. The ore is leached with an alkaline solution to dissolve the iodine as sodium iodate, which is converted to sodium iodide. Iodine is precipitated by reacting with additional alkaline solution. The precipitated iodine is filtered in bag filters, and the iodine free-leach solution is returned to the nitrate-leaching cycle.

Recycling.—The removal of ionic silver from photographic processing solutions, such as developer, fixer, bleach fixers. and washwaters. can accomplished with halogens such as iodine and an adsorbent. Photographic silver is commonly recovered by electrolytic methods if the concentration is greater than 500 ppm. Adsorbents such as natural and synthetic zeolites, activated alumina, activated silica, Fuller's earth, and ion exchange resins are used to recover low concentrations of silver from a stream.

Economic Factors

Prices.—Changes in the official price of crude iodine have in the past been initiated during shortages. Because iodine cannot be substituted readily in radiopaque media, animal feeds, catalysts, and stabilizers, shortages tend to cause the accumulation of inventories to ensure an adequate supply. An adequate supply tends to lower and stabilize the price.

Costs.—One typical iodine brine well costs about \$2 million to complete and is between 1,800 and 3,000 meters deep. Electrical costs for maintaining the pumps to bring the brine to the surface, for airblowing the iodine, and for reinjecting the brine are major components of maintenance costs. Capital costs have been estimated at \$20 per pound of annual iodine production. These costs include high-quality stainless steels because iodine is highly corrosive. In addition, the brine must be leased from private landowners over large acreage for many years. The principal material cost is for chlorine because 1 pound is required for every 1.4 to 1.8 pounds of iodine produced.

Tariffs.—Crude and resublimed iodine enters the United States duty free. Calcium and cuprous iodine has a 25% ad valorem duty for non-most-favored-nation (MFN) status. Potassium iodide has duties of 2.8% ad valorem for MFN status and 7.5% ad valorem for non-MFN status.

Depletion Provisions.—The domestic and foreign depletion allowances for mined iodine are 14% of gross income, and they may not exceed 50% of net income without the depletion deduction. The domestic and foreign depletion allowances for minerals from brine wells are 5%.

Operating Factors

Environmental Requirements.—The reinjection of waste brine is a limiting factor to the production of iodine. During 1982, the Environmental Protection Agency reclassified disposal wells for spent brine after halogen extraction as Class 5 wells. All of the reinjection wells for iodine in Oklahoma were drilled for the reinjection of waste associated with brine production or oil and gas effluent.

Toxicity.—Iodine is absorbed by the body and concentrated in the thyroid. Iodine is essential to higher animals and humans. A normal person requires about 75 milligrams of iodine per year, which is usually consumed as iodized salt that contains one part sodium or potassium iodide to 100,000 parts of sodium chloride. Iodine deficiency is a major cause of goiter.

The maximum safe concentration for short-term air environment exposure of up to 1 hour is 1.0 ppm. Exposure of the lungs and eyes can be irritating at concentrations of 0.1 ppm and should be avoided. Greater exposure can cause severe irritations to the eyes and the respiratory tract and may lead to pulmonary edema.

In 1979 and 1986, nuclear accidents caused the release of radioactive iodine, I¹³¹, into the atmosphere. A dosage of

potassium iodide (KI) administered before or shortly after exposure to radioactive iodine can block the intake of radiation to the thyroid. The dosage must be repeated if exposure continues. Replenishing the thyroid with KI prevents the thyroid from using radioactive I¹³¹ for normal metabolic needs.

ANNUAL REVIEW

Legislation and Government Programs

The U.S. Department of Labor, Occupational Safety and Health Administration (OSHA), proposed in the Federal Register June 12 to amend its existing air contaminant standards that set permissible exposure limits (PEL's) for the maritime. construction, and sectors. Only agriculture industry employees of farms with more than 10 employees are covered under OSHA standards. Included in the proposed PEL's are iodoform and methyl iodide.

South Carolina and Virginia were granted exemptions for the use of iprodione on apples. The provisions included a maximum application area of 809 hectares (2,000 acres) a maximum of three applications made at 2- to 3- week intervals, a preharvest interval of 30 days, and an expiration date of January 1, 1993.¹

Strategic Considerations

The National Defense Stockpile contained 6.1 million pounds of crude iodine. The stockpile goal for iodine was reduced to zero with the passage of Public Law 102-484 on October 23, 1992. The Defense Logistics Agency (DLA) of the U.S. Department of Defense sold 11,340 kilograms (kg) of excess iodine valued at \$83,500 (\$3.34 per pound) during fiscal year 1991, and no iodine was disposed during fiscal year 1992, although Congress authorized 102,058 kg. The DLA sought to barter surplus metals and minerals, including iodine, but no exchanges were reported.

Production

IoChem Corp. began production in 1987, 2 miles east of Vici, Dewey County, OK, by the blowing-out process. The majority of production was shipped to Schering AG, Germany, under a long-term contract. IoChem was reported to have nine production wells and four injection wells with a total production capacity of 1,400 kg per year.

North American Brine Resources began operation of a miniplant at Dover in Kingfisher County, OK, in 1983. The plant is at an oilfield reinjection disposal site that obtains brines from about 50 wells in the Oswego Formation. Iodine concentrations ranged up to 1,200 ppm. The company also operated a plant at the border of Woodward and Harper Counties, OK, that began operating in 1991.

Woodward Iodine Corp. began production in 1977 and was purchased by Asahi Glass Co. of Japan in 1984. Woodward operated a plant in Woodward County that produced iodine from 14 brine wells using the blowing-out process. Nameplate capacity was reported at 900,000 kg per year.

Consumption and Uses

Iodine was used primarily in animal feed supplements, catalysts, inks and colorants, pharmaceuticals, photographic equipment, sanitary and industrial disinfectants, stabilizers, and radiopaque medium. Other smaller uses included production of batteries, high-purity metals, motor fuels, iodized salt, and lubricants.

In the mid-1980's, drug companies developed a new form of the iodine dye that is injected into patients so doctors can view the functioning of coronary arteries or kidneys on an X-ray screen. Fewer patients get adverse reactions from the new dye, but the price is 10 to 15 times higher. Some health plans, pressured to hold down premium increases, approved a guideline strongly encouraging use of the old, less expensive version, except for high-risk patients. The high-risk group of patients would

experience severe but nonfatal reactions, such as vomiting. It was estimated that 40 additional bad reactions per year among the southern California region's 2.3 million members would save an estimated \$3.5 million annually.²

The lithium-iodine battery was the first commercially successful lithium battery and is unusual because of its in situ growth of electrolytes. Superior charge transfer is achieved using an iodine compound with powdered iodine. Layers of lithium iodide act as both electrolyte and separator and are self-sealing in the event of a crack. Thus, the batteries are intrinsically reliable and withstand abuse.

Tall oil capacity increased as capacity was expanded to 920,000 metric tons per vear of fractionation capacity. Westvaco boosted capacity at Charleston Heights. SC, by 10,000 tons in 1990 and at De Ridder, LA, by 25,000 tons in 1991. Iodine is used to stabilize the tall oil for use in various tall oil fatty acids and tall oil rosin that compete against other types of oils for use in polymers. The supply of crude tall oil is increasing due to additional pine pulp production. Demand through the 1990's for tall oil rosin derivatives is expected to increase 3% per year, while supply will increase 1% or less. The adhesives, ink, and paper sizing markets make up 80% of the demand. Tall oil rosins will not be used for low-value applications.³

Deepwater Iodides announced plans for the construction of a \$3.7 million manufacturing and distribution facility at Woodward, OK. Two separate buildings will be constructed. One will be the production plant and the other the office, warehouse, and laboratory. The plant will make high-purity organic iodine derivatives for the pharmaceutical industry. The facility will occupy a 6-hectares site at Woodward Industrial Airpark. The company changed its name from Deepwater Inc. last year to more accurately reflect its business.

Producers sold \$86.9 million of iodophors for medical, veterinary, and food-processing applications. The two main classes of iodophors are povidone iodine, manufactured from polyvinylpyrrolidone and utilized in

human skin disinfectants, and the nonionic detergent-iodine combinations, utilizing primarily nonoxynol and the poloxamers. Iodophors are highly self-stable, substantially free of the corrosive effects of noncomplexed-iodine concentrations, and relatively nonirritating to human skin. One of the world's largest producers of nonionic detergent iodines is West Agro, Inc.⁴

Angus Chemical Co. was the only producer of diiodomethyl-p-tolylsulfone, a biocide, used in the control of fungi, mildew, and algae. Added in the pigment-dispersion operation, the preservative provides superior protection against mildew formation of latex paint films. Typical applications include products for the lumber, construction, home improvement, textile, and automotive industries. (See table 2.)

Prices

The average declared c.i.f. value for imported crude iodine was \$9.03 per kg (\$4.09 per pound). The average declared c.i.f. value for imported crude iodine from Japan averaged \$9.58 per kg (\$4.35 per pound). The average declared c.i.f. value for iodine imported from Chile was \$8.52 per kg (\$3.86 per pound). Quoted yearend U.S. prices for iodine and its primary compounds are shown in table 3. (See table 3.)

Foreign Trade

The U.S. Government adopted the Harmonized Commodity Description and Coding System (Harmonized System) as the basis for its export and import tariff and statistical classification systems. The system is intended for multinational use as a basis for classifying commodities in international trade for tariff, statistical, and transportation purposes. The Harmonized System as proposed includes resublimed and crude iodine under the same code, and the duty rate is free. Values that differ significantly could be a result of items being placed in the wrong category.

Calabrian Corp. and Mitsubishi International Corp. formed a joint venture

for the domestic sale of crude iodine produced by Ise Chemicals Corp. of Tokyo. The new company, called Mical Specialty Chemicals Inc., will be located in New Jersey. (See tables 4 and 5.)

World Review

Canada.—Brines with iodine enrichment are confined mainly to shallow formations of Cretaceous age. Contents generally are in the range of 40 to 50 ppm. These compositions are below current commercial production limits.⁵

Chile. - Sociedad Química y Minera de Chile (SOM, formerly known as SOQUIMICH) was the largest producer of iodine in Chile. During 1991, SQM formed two independent operating divisions, SQM Fertilizer and SQM-Iodine. SQM-Iodine will be responsible for marketing crude iodine and also iodine salts that SQM recently began manufacturing. Installed capacity was reported at 6,000 tons per year, although current production was about 4,000 tons per year. SQM operates 10 iodine plants in Chile: one at Maria Elena, two at Cova Sur, and three at Pedro de Valdiva with satellite plants at Araucamna, Ossa, and Puelma. SOM also announced plans to be certified under the International Organization for Standardization 9000 program or ISO 9000 program, which calls for third-party quality-assurance registration of a manufacturer's facility. process, and product lines. It places particular emphasis on documentation and uniformity of process. During 1991 SOM sales were \$140 million, but its new profits slumped to \$4.0 million compared with \$14 million during 1990. The slump in earning had been attributed to a halving of iodine prices over the past 3 years from \$18 per kg to less than \$9 per kg. As a result of the poor performance, the work force agreed to a 5% pay reduction. During 1992, iodine shipments rose, but the price dropped again.6

Cominac S.A., a subsidiary of Inversiones Errazuriz S.A. Enterprises,

began production at two of three reserve areas of the Pozo Almonte Project. The site is in a valley where the natural gravity flow is utilized to collect the iodine-rich solutions. A third reserve area was undergoing a third step in a civil process to determine ownership. The two areas under development are not involved in the civil processing and are under development by a subsidiary company, Compania de Salitre y Yodo de Chile (Cosayach). Cosayach has a plant to recover 600 tons of iodine per year by heap leaching. Plans to expand capacity were being developed.

ACF Minera Ltda. is a Chilean company with 50% joint venture with DSM of the Netherlands. The company maintains three production facilities that have a nameplate capacity of 1,200 tons and are located in the first region of Chile at La Granja, Lagunas, and Iris. The facilities are about 100 miles southeast of the port city of Iquique. The production capacity was reported to be 810 tons of 99.5% to 100.5% iodine, with mineral reserves of 48,000 tons of iodine in situ. The company also owns mineral rights at other locations in the first and second regions of Chile.

Mineral Yolanda was seeking a \$60 million investment to finance the Yolanda Project, also known as the Taltal Project. The project is wholly owned by Kap Resources Ltd., Vancouver, Canada. The project planned to produce 930 tons per year of iodine and 300,000 tons per year of sodium nitrate. The mineral salts or caliche will be leached with seawater to dissolve the salts. The solution will be processed to extract the iodine. The remaining solution will be evaporated in solar ponds to concentrate the nitrate salts. Production was expected to commence by 1994.⁷

Indonesia.—The only producer of crude iodine was the state-owned pharmaceutical firm, P. T. Kimia Farma, that operated a plant at Watudakon near Mojokerto, East Java.

Japan.—Production of iodine was from underground brines associated with

natural gas. Japan was the world's leading producer of iodine in 1992. Six companies operated 17 plants with a total production capacity of 9 million kg per year.

Mallinckrodt announced a 10-year exclusive agreement with Yamanouchi Pharmaceutical for distribution of Optiray in Japan. (See table 6.)

Current Research

An experimental transparent panel using negatively charged iodine could one day transform ordinary windows into seethrough solar cells. The panels are made with titanium and tin conductors with an electrolyte solution of iodine. The conversion of light to electricity ranges from 10% to 15%, which is more efficient than the amorphous silicon solar cells commonly found in calculators. The panels are projected to cost about one-fifth of amorphous solar cells.⁸

Researchers have used soluble conducting polymers doped with iodine to make a flexible light-emitting diode that works when bent. This is a significant step forward to semiconductor technology based on organic materials, which are easier to process and fabricate into different shapes and offer mechanical properties that inorganic semiconductors cannot match.⁹

OUTLOOK

Iodine production capacity in the United States and Chile has doubled during the past decade, ensuring an adequate world supply. Uses for iodine in specialty chemicals have remained stable. Recent developments in digital images using computers can produce electronic prints and overhead transparencies without using processing. Using a digital camera, or scanning and film and converting to digital, images are produced using pixels or numerical by position and color and stored on hard drives, disks, tape, or optical storage. Future use of iodine in films and processing could be limited to specialty imaging in the next decade.

²Dissolved in Dec. 1991. This commodity is believed to be produced in Azerbaijan and Turkmenistan; however, information is inadequate to formulate reliable estimates of individual country production.

³Reported figure.

IRON ORE

By William S. Kirk

Mr. Kirk became the commodity specialist for iron ore in 1992 and was previously responsible for cobalt, depleted uranium, hafnium, nickel, radium, thorium, and zirconium. The domestic survey data were compiled by Robin C. Kaiser, statistical assistant, Branch of Data Collection and Coordination. The world production table was prepared by Douglas R. Rhoten, International Data Section.

Iron ore is essential to the economy and national security of the United States. As the basic raw material from which iron and steel is made, its supply is critical to any industrial country. Scrap is used as a supplement in steelmaking, but is limited as a major feed material because there is a limited quantity of high-quality scrap.

In 1992, China became the world's largest producer and consumer of iron ore. Iron ore production fell in all major producing countries and regions with the exception of China. World pig iron production, the best indicator of iron ore consumption, fell slightly during the year. Production in the United States posted a moderate gain, while production in China rose by 15%. Pig iron production in China slightly exceeded that of Japan to make China the world's largest iron ore consumer. Australia and Brazil continued to be the leading exporters of iron ore with a combined total of close to 60% of the world total.

Domestic iron ore production and shipments fell slightly from 1991 levels. Total reported consumption, however, increased by 16% and stocks fell accordingly. The increase in consumption was the result of a 6% increase in raw steel production.

DOMESTIC DATA COVERAGE

U.S. production data for iron ore are developed by the U.S. Bureau of Mines from two separate, voluntary surveys of domestic operations. The annual "Iron Ore" survey (1066-A) provides the

basic data used in this report. Of 47 addressees to whom the 1066-A form was sent, 25 responded, representing 100% of total production shown in tables 1 through 4. In past years, production for nonrespondents to the annual survey was estimated from monthly surveys (1066-M), from railroad reports, or from reported production levels in prior years. This information may be supplemented by employment data, mine inspection reports, and information from consumers.

Data on consumption and stocks of iron ore and agglomerates at iron and steel plants were provided by the American Iron Ore Association (AIOA). AIOA also provided data on ore shipments from loading docks on the upper Great Lakes as well as receipts at transfer docks and furnace yards nationwide. The dock and steel plant data were compiled jointly by AIOA and the American Iron and Steel Institute (AISI). Data on consumption of iron ore for nonsteel end uses were compiled from information gathered from other Bureau surveys.

BACKGROUND

Industry Structure

History.—The history of iron mining in early America has already been reviewed in several other publications of the U.S. Bureau of Mines and its predecessor. For additional information on the economic history of the entire U.S. iron and steel sector, the reader should refer to the comprehensive works

of Father Hogan of Fordham University.²

The history of the iron ore industry as it currently exists began in 1844 with the discovery of "hard" magnetite-hematite ores on the Marquette Range of Michigan and the subsequent founding of the Jackson Mining Co.³ Initially, lack of transportation facilities prevented rapid development. However, completion of a shipping canal at Sault Ste. Marie in 1855 opened the way for further development of mining in the Lake Superior region. By 1885, ore had been discovered in the Gogebic and Menominee Ranges of Michigan and Wisconsin, and annual production of ore had climbed to more than 2 million metric tons (Mmt), 20 times the volume in 1860. The high grade of these ores, combined with the low cost of water transportation, made them increasingly competitive at eastern furnaces and forced many small mines in New York, Tennessee, and the Mid-Atlantic States to close. This trend was accelerated in the 1880's by production from the Vermilion Range and the discovery of the great Mesabi ore bodies in the 1890's. By the turn of the century, most of the eastern mines had closed. In Alabama, production of iron increased nearly tenfold between 1880 1890, and Birmingham established as a major ironmaking center. During this period, many steel companies acquired iron ore properties in the Lake Superior District, and the production of many smaller mines was consolidated by the formation of large mining companies. The mergers that took place in the steel industry between 1893 and

organized the iron ore industry into the structure that exists today.

Hundreds of mines closed during the 1950's because of the depletion of higher grade ores, rapidly rising imports, and costs of underground mining. By 1981, 15 mines accounted for 90% of the Nation's production of iron ore. By 1986, the 15 mines had been reduced to 10 because of increased imports of steel and 2 deep recessions from which the iron ore and steel industries have not yet fully recovered.

Size and Organization.—In 1992, iron ore was produced by 20 companies operating 20 mines, 16 concentration plants, and 10 pelletizing plants. The mines included 19 open pits and 1 underground operation. Virtually all ore was concentrated before shipment, and about 98% was pelletized.

Since the mid-1950's, quasi-symbiotic relationships have existed between several iron ore operations in Canada and the United States because of ownership ties. In 1992, 80% of domestic production came from mines owned by U.S. steel companies. In 1982, U.S. companies owned about 70% of Canadian production capacity for iron ore and held significant minority interests in iron ore mines in Australia, Brazil, Liberia, and New Zealand. Since then, Japanese interests have acquired part of the Canadian and overseas holdings previously owned by companies in the U.S. iron and steel sector.

The iron ore industry of Canada and the United States has been undergoing a major restructuring since 1985 aimed at lowering pellet costs and improving financial health. The bulk of this restructuring occurred in the summer of 1986, when the industry was experiencing one of its worst years since the Great Depression. Most of the pellet producers had already streamlined their operations by late 1987, when overall demand for steel began to grow. The modest recovery accelerated in 1988, only to level off in 1989.

The breadth and intensity of the restructuring is illustrated by USX Corp., the largest steel producer in the United

States. The company was formed after U.S. Steel Corp. acquired the Texas Oil and Gas Corp. USX is now a more diversified company with interests in energy, steel, mineral resources, real estate, and engineering services. Its energy segment includes the Marathon Oil Co. in addition to Texas Oil and Gas Corp. U.S. Steel paid \$6.5 billion for Marathon. The former U.S. Steel Corp. had been a leader in domestic steelmaking and iron ore mining for about 85 years prior to the 1986 restructuring.

USX owns and operates the Minntac Mine at Mountain Iron, MN. Minntac is the largest iron mine in the United States and supplies fluxed pellets to USX's blast furnaces at Gary, IN, and Dravosburg, PA. At the end of 1988, USX and the Blackstone Group formed a joint venture known as Transtar Inc., which manages variety of bulk transportation subsidiaries. USX sold 56% of its extensive transportation holdings to Transtar for about \$600 million. number of USX railroad lines were involved, including the Duluth, Missabe, and Iron Range Railway Co. (DM&IR). The new transportation company also acquired USX's lake shipping and river barging operations. In 1989, USX sold its 100% equity in the Quebec Cartier Mining Co. (QCM) to Dofasco Inc. The giant Canadian iron ore operation is currently owned by Dofasco (50% equity), Mitsui & Co. Ltd. of Japan (25%), and Companhia Auxiliar de Empresas de Mineracao (CAEMI) of Brazil (25%).

Recent technological advances have affected not only day-to-day operations, but also the structure of the industry. An increasing number of integrated steelworks in North America are using fluxed pellets. This newer, more easily reducible type of pellet is created by adding limestone (CaCO₃) and/or dolomite [(Ca,Mg)CO₃] to the iron ore concentrate during the balling stage. Sufficient fluxstone is added to raise the ratio of (CaO+MgO)/(SiO₂+ Al₂O₃) in the pellet to above 0.6. The most common ratio is about 1. Fluxed pellets comprised 56.6% of total U.S. pellet production in 1992 compared with 56.3 in 1991. Idle capacity was brought onstream at three mining complexes on the Mesabi Range during 1989 to meet increased pellet demand. The idled complex of Reserve Mining Co. at Silver Bay, MN, was renovated by Cyprus during the last quarter of 1989. Cyprus shipped a trial batch of fluxed pellets in April 1990.

Combined United States and Canadian production represented only about 11% of the world output of usable ore in 1992. At least 45 other countries mined crude ore during the year. The leading producer was Brazil, which accounted for about 19% of world output in terms of metal content, followed by Australia with 14% and China with 13%. Trends in world mine production since 1988 are shown on a country basis in table 19.

Geology-Resources

Iron is the fourth most abundant rockforming element, comprising about 5% of the Earth's crust. Astrophysical and seismic evidence suggest that the element also has combined with nickel to make up the bulk of the Earth's core. A small part of the crustal iron has been concentrated by sedimentary, igneous, or metamorphic processes into deposits containing up to 70% of the element.

The largest concentrations of iron are found in banded sedimentary iron formations of Precambrian age. These formations currently supply most of the world's iron ore and constitute the bulk of the world's iron resources. Precambrian ores are mined extensively in Africa, Australia, Canada, China, India, South America, the United States, and the former U.S.S.R. Individual banded iron formations (BIF's) can vary from less than 30 to 600 meters (m) in thickness. Some are relatively flat-lying, while others are steeply dipping or have been complexly folded. Some BIF's are exposed almost continuously along the margins of geosynclines and commonly underlie basin areas of hundreds or thousands of square kilometers (km²). Most consist of fine-grained iron oxides and quartz, with accessory iron silicates and in some places iron-bearing carbonates, and contain 20% to 40% iron. These rocks comprise ores of the taconite type mined in Canada, China, Norway, the United States, and the former U.S.S.R.

Locally, the BIF's have been concentrated by natural processes to form high-grade deposits of hematite or goethite by leaching of silica and oxidation of ferrous minerals. The highgrade ores are classed as residual or replacement deposits, depending on whether silica was removal of accompanied by introduction of additional iron oxide. The residual ores are usually earthy, porous, and contain 50% to 60% iron in their natural state. Examples are the soft ores of the Lake Superior District, the Schefferville District of Labrador, and the Krivoy Rog District of the Ukraine. Some soft ores appear to be merely decomposed bodies of BIF, containing 20% to 40% iron in the form of martite, hematite, or goethite. Examples of the latter are bodies of "wash ore" in the western Mesabi Range, which are highly siliceous but easily concentrated by gravity methods.

Replacement ores in the Precambrian BIF's are usually dense, massive, and contain 64% to 68% iron. Often, the ores retain banded structures of the original sedimentary rock. Examples are the hard ores of the Vermilion Range, MN; Steep Rock and Michipicoten Districts of Ontario; Minas Gerais, Brazil; Fort Gouraud, Mauritania; and Sishen, Republic of South Africa.

Another class of sedimentary iron deposits, of regional importance in the southeastern United States and Western Europe, is oolitic ironstone of Paleozoic to Cretaceous age. The formations are extensive laterally and contain 20% to 40% iron, but they differ from the Precambrian BIF's in several important respects. They are usually less than 15 m thick, and minable layers are commonly less than 6 m thick. The deposits rarely contain more than 48% iron, and most contain only 25% to 35% The ore consists of very finegrained hematite, quartz, chamosite,4 and siderite in varying proportions; sometimes enough calcite is present to make selffluxing ore. The ore is usually high in phosphorus and difficult to beneficiate. Oolitic ironstones were mined until recently in Alabama, Newfoundland, and the United Kingdom and are still mined extensively in France and to a lesser extent in central Europe. They also are mined in Egypt and comprise most of the iron resources of Pakistan.

A third type of sedimentary ore, consisting of siderite or limonite in flatlying lenses up to 6 m thick, is mined in east Texas from the Weches Formation of Eocene age. The ore is associated with glauconitic sand and clay and contains up to 35% iron.

Massive deposits of magnetite. sometimes with hematite, thought to be of igneous origin, are important sources of iron ore in many parts of the world. These deposits can contain as much as 65% iron and are often rich in titanium and vanadium, as at Lake Sanford, NY. There are two principal types of these igneous deposits: magmatic segregations and pyrometasomatic replacements. The first type is represented by irregular or layered masses that appear to have formed by segregation of magnetite crystals in magma, or as tabular, sheetlike bodies formed by injection of an iron-rich fluid into surrounding rocks. The Precambrian Bushveld Igneous Complex of the Republic of South Africa with its layers of magnetite and chromite is frequently cited as an example of magmatic segregation and crystal settling. The sill-like ore bodies at Kiruna, Sweden, and Pea Ridge, MO, represent the injection version of the process. The magnetite ores in these last two deposits contain significant amounts fluorapatite, which must be removed during beneficiation.

Pyrometasomatic deposits are concentrations of magnetite that have replaced portions of the limestone or igneous country rock at or near the contact of an igneous intrusion. These deposits may be partly altered to hematite and contain up to 65% iron, depending on the extent of replacement. Garnet, epidote, and wollastonite are commonly formed along with the magnetite during the thermal metamorphism of the country

rock. Deposits of this type are commonly associated with Jurassic or younger intrusives in the Western United States, Mexico, and western South America; they are also found in Pennsylvania. Examples include Iron Springs, UT; Eagle Mountain, CA; Hanover, NM; Cornwall and Morgantown, PA; El Romeral, Chile; and Marcona, Peru.

Technology

The construction of a plant to determine the technical and economic feasibility of the HIsmelt Direct Smelting Process was about 75% complete at yearend. The project was to be managed by HIsmelt Corp. Ptv. Ltd., a 50-50 joint venture between CRA Ltd., Australia's largest mining company, and Midrex Corp., based in Charlotte, NC. facility, at Kwinana, 40 kilometers (km) south of Perth, Western Australia, was expected to cost more than US\$100 million. The HIsmelt process converts iron ore fines directly into metal using coal rather than coke, as is used in conventional blast furnace technology. The purpose of the plant was to confirm that the process would (1) produce hot metal suitable for making high-quality steel from a wide range of iron ore fines, (2) use a variety of coals with an energy consumption comparable to that of an efficient blast furnace, (3) be capable of being scaled up to be competitive at a capacity of 0.5 to 1.0 million metric tons per year (Mmt/yr), and (4) meet future emission standards.

The heart of the new complex will be a 0.1-Mmt/yr prototype smelt reduction vessel (SRV), which is scheduled to startup in mid-1993. The capacity of a commercial-sized plant is considered to be 0.5 to 1.0 Mmt/yr. The process is a single-stage process that involves the direct smelting of iron ore in a closed molten bath reactor. Coal is injected into the iron bath to maximize recovery of the carbon and to generate bath turbulence. The ore is preheated and prereduced in a circulating fluidized bed prior to injection into the horizontal SRV. Hot air is supplied to the top of the SRV to post combust the generated CO. The hot metal and slag tapped from the SRV are transported to the pig caster and the slag pens. If the full-scale pilot plant tests at Kwinana are successful, several U.S. companies may follow suit.

Economic Factors

The United States has exhausted the reserves of high-grade direct-shipping ore it once had in Michigan and Minnesota. Almost all of the ore being mined now is low-grade taconite, which requires costly beneficiation and pelletizing. Moreover, the taconite mining and pelletizing complexes are deep in the interior of the country, far from any saltwater harbor. Because of the advantages of Great Lakes shipping, U.S. pellets are currently competitive at Gary, Cleveland, and Detroit. However, high rail costs put U.S. pellets at a disadvantage in the mid-Atlantic States and Alabama. Imported ores and agglomerates from Brazil, Canada, and Venezuela constitute the bulk of the iron units consumed at these coastal steelworks.

The St. Lawrence Seaway is a mixed blessing for the mining industry, being a bottleneck for ore carriers as well as an inexpensive means of transport in the Great Lakes region. The eight locks in the Welland Canal and the seven locks in the St. Lawrence River are all similar in size and have a gate-to-gate length of 262 m. The relatively short length of each lock prevents oceangoing ore carriers longer than 222 m from entering the Great Lakes. At the same time, domestic "1,000 footers" cannot leave the Lakes. Foreign ore bound for Indiana or Ohio either has to be offloaded onto smaller vessels in the gulf of the St. Lawrence or transferred to rail cars at Baltimore or Philadelphia. In some cases, ore is barged from the Port of New Orleans up the Mississippi River to steelworks in the Ohio River Valley and western Pennsylvania. The high rail costs that keep domestic ores from going to the coastal steelworks also keep foreign ores out of the inland steelmaking regions.

Operating Factors

Employment.—Statistics on employment and productivity in the U.S. iron ore industry in 1992, shown in table 2, were derived from quarterly employment data supplied by the Mine Safety and Health Administration (MSHA) and from production data derived from U.S. Bureau of Mines surveys. Both sets of data were obtained from producers' reports.

The statistics include production workers employed at mines, concentrators, and pelletizing plants and in repair and maintenance shops, but do not include 827 persons engaged in management, research, or officework at mines and plants. Employees engaged in ore preparation, such as sintering, at blast furnace sites are not included.

Because employment data reported to MSHA are primarily for safety analysis, hours spent by salaried employees in mines or plants may be included by operators in the total number of hours worked at individual mines or plants. This has resulted in understatement of calculated productivity by 10% to 25% for some operations, but its affect on If company others is not known. reporting practice is consistent, however, comparison of productivity from one year to the next should be reasonably valid. Average quarterly employment was 3.2% higher than that of 1991.

Transportation.—In 1990, the U.S. Army Corps of Engineers published a Notice of Proposed Rulemaking to set the closing for the Soo locks at Sault Ste. Marie, MI, at January 15, rather than the variable closing time that previously had been in effect. The Corps had studied the environmental impacts of an extended navigation season through the St. Marys River for a decade and could find no significant adverse effects. After a period of public comment, which produced no evidence to the contrary, the January 15 closing date became official as of the 1992 navigation season.

Transportation of iron ore on the U.S. Great Lakes has changed considerably since 1971, when the first self-unloading

"super-carrier," capable of carrying 45,000 tons of iron ore, was placed in service. Since then, 12 similar vessels have been built, each about 300 m (1,000 feet) long and capable of carrying about 60,000 tons of iron ore pellets. Each of these carriers replaced about four older vessels and can deliver about 2.5 Mmt of ore to lower lake ports during an 8-month shipping season. The last of this group of ships was completed in 1981.6 While these vessels were being built, a similar number of older ships were lengthened to increase their carrying capacity and were also fitted with self-unloading equipment. The average cargo capacity of the lake vessels has thus increased since 1971, while the total number of vessels has been reduced by more than 60%.

To accommodate the "1,000 footers," new loading facilities and materials handling systems were built at four of the seven upper lake ports, the last of which was completed in 1983, and three new receiving terminals were completed on Lake Erie. The self-unloading vessels have all but eliminated the use of Hulett clamshell unloaders at lower lake ports. The "1,000 footers" have unloading capacities of up to 10,000 metric tons per hour (mt/hr), while loading capacities at upper lake ports are of similar capacity. Details on individual port facilities are given in Greenwood's Guide to Great Lakes Shipping.⁷

Cargo capacities of vessels traveling the St. Lawrence Seaway between Montreal and Lake Erie are still limited to about 26,000 tons. On the north shore of Lake Erie, Stelco Inc., which has equity in several U.S. taconite mines, completed an unloading facility in 1979 that can accommodate 1,000-foot carriers. The Nanticoke facility can handle up to 6,000 mt/hr of pellets and has a stockpiling capacity of 860,000 tons of pellets and 1.06 Mmt of coal.8

U.S. coastal ports are still limited to incoming cargoes of 65,000 tons or less. Hunterston, Rotterdam, Taranto, and several other ports in Western Europe can now accommodate iron ore cargoes of 150,000 to 300,000 tons. The Ertsoverslagbedrijf Europoort terminal west of Rotterdam currently holds the

world record for the largest single cargo of iron ore ever unloaded. On August 22, 1989, 356,541 tons of Carajas sinter feed and natural pellet ore was delivered to the terminal by the world's largest ore carrier, the 365,000-deadweight-ton (dwt) Berge Stahl. The Berge Stahl and the Docefiord, another vessel capable of carrying more than 300,000 tons of ore. were built in 1986, primarily for trade between Brazil and Japan. In Japan, cargoes of 200,000 to 260,000 tons can accommodated at Fukuyama. Kakogawa, Keihin, and Oita. size cargoes are also routinely delivered to the island of Mindanao in the Philippines for sintering. The 351-mlong main berth of the Philippine Sinter Corp. has a depth of 23 m and can handle all but the very largest vessels that load at Ponta da Madeira. The three major loading ports in Western Australia (Dampier, Port Hedland, and Port Walcott) have all been modernized and have had their berths deepened to permit loading of ore carriers of the 250,000-dwt class.

Two major pipelines for transport of iron ore slurries were completed in northern Mexico in 1983, connecting the La Perla and Hercules Mines with a pelletizing plant in Monclova. A 20centimeter (cm) (8-inch), 87-km line from La Perla is connected to a 36-cm (14inch), 295-km line that runs from the Hercules Mine to Monclova. pipeline system can transport up to 4.5 Mmt of iron ore concentrates. A second system is operating in the Pacific Cordillera of Mexico. Two parallel lines transport concentrates 45 km from the Pena Colorada Mine in the mountains of northwestern Colima down pelletizing plant on the coast near Manzanillo. The 900-m drop in elevation permits the lines to be gravity operated. Major pipelines also have been built in Brazil and India since 1977, and others are operating in Argentina, Australia, New Zealand, and Peru.

ANNUAL REVIEW

Legislation and Government Programs

Voluntary Restraint Agreements (VRA's) on steel imports expired on March 31. Under the VRA's, steelproducing nations had agreed to limit steel exports to the United States in return for withdrawal of charges by U.S steel companies that the imports were a cause of injury to the U.S. steel industry. In June, U.S. steelmakers filed new complaints with the International Trade Commission (ITC) against 21 nations. alleging injury to the U.S. industry as a result of illegal subsidies and sales at less than face value. The ITC issued an initial decision affirming the claims of injury against a number of these nations. Effective December 7, importers were required to provide funds or bonds to cover countervailing duties, pending a final decision in 1993.

Production

Domestic iron ore production showed a 2% drop in 1992, down from 56.8 Mmt in 1991 to 55.6 Mmt. Productivity for usable ore in the Lake Superior District was greater than that of 1991.

Iron ore was produced by 19 open pit mines and 1 underground mine. Sixteen mines produced ore for the iron and steel industry, while the remainder shipped ore mainly to cement plants. Installed domestic production capacity for usable ore on December 31, 1992, was estimated at 82 Mmt/yr, of which 81 Mmt was pellets. Total output of usable ore was equivalent to about 68% of installed production capacity, down from 69% in 1991. An average of 3.3 tons of crude ore was mined in 1992 for each ton of usable ore produced, a slight increase from that of 1991. This ratio does not take into account the tonnage of waste rock or overburden removed. The ratio of total materials mined to usable ore produced was probably greater than 5:1. Low-grade ores of the taconite type mined in Michigan and Minnesota accounted for 99% of total crude ore

production. U.S. production of pellets totaled 54.2 Mmt, 98% of usable ore output. The average iron content of usable ore produced was 63.4%. Shipments from U.S. loading docks on the upper Great Lakes totaled 58.3 Mmt in 1992 compared with 55.9 Mmt in 1991.

Michigan.—Michigan accounted for 25% of the national output of usable ore in 1992. Ninety-nine percent of the State's production consisted of pellets produced at the Empire and Tilden Mines near Ishpeming in Marquette County. Both mining ventures are managed by Cleveland Cliffs Inc.'s (CCI) Cleveland-Cliffs Iron subsidiary. Empire shipped 6.8 Mmt of pellets produced from magnetite concentrate. Tilden shipped 2.2 Mmt of magnetite pellets and 2.3 Mmt of hematite pellets, for a total of 4.5 Mmt. Production of usable ore was up 10% from the 1991 figure of 12.6 Mmt. Production of pellets totaled 12.2 Mmt, of which 6.8 Mmt was produced at the Empire plant and 5.4 Mmt was produced at Tilden.

On March 19, the Marquette Range produced its 300 millionth long ton of iron ore pellets. Five mines contributed to the overall total since pellets were first produced in 1956.

Minnesota.—Minnesota produced 74% of the national output of usable ore in 1992. All of the State's production came from open pit mines on the Mesabi Range. Production of pellets totaled 40.4 Mmt, equivalent to about 84% of installed production capacity of the State's seven taconite plants.

The year 1992 marked the centennial of the iron ore shipments from the Mesabi iron range. In October 1892, ore shipments commenced from the Mountain Iron Mine, the first mine on the range. Shipments have totaled about 3.7 billion tons.

CCI ceased iron ore shipments to Sharon Steel Corp. after the steelmaker idled its blast furnace in November because of financial problems. Shipments to Sharon accounted for about 11% of CCI's operating revenues. Sharon Steel

remained closed at yearend.

Cyprus Northshore Mining Corp. closed its Babbitt Mine and Silver Bay processing plant in early June as the result of a weak market. The shutdown, which resulted in the laying off of 328 employees, was expected to last for 23 weeks. However, even though the iron ore market remained soft, a small increase in sales enabled Cyprus to restart its operations in September rather than later in the year.

LTV Steel Mining Co. resumed operations on August 23, after a 6-week shutdown to reduce pellet inventories. Of the company's 1,600 employees, 1,450 were affected.

Effective January 1, 1992, Wheeling-Pittsburgh Steel Corp. increased its ownership interest in the Empire Iron Mining Partnership to 12.5% by acquiring 2.5% from CCI.

In September, Armco Steel Co. LP reduced its requirements for iron ore pellets from Eveleth Mines at Eveleth, MN, for the balance of the year. Following tests run with 100% fluxed pellets in a blast furnace at its Ashland, KY, plant, Armco determined that its feed mix could be changed. company began receiving fluxed pellets from Northshore Mining Co. at Silver Bay, MN, and from Cia. Vale do Rio Doce (CVRD), in Brazil. The Cyprus Northshore pellets were delivered in selfunloaders to the Torco dock in Toledo, OH, with rail delivery to the Ashland and Middletown, OH, steel plants. CVRD pellets were loaded onto barges at New Orleans for shipment up the Mississippi and Ohio Rivers. As the reduction. Eveleth result of the announced that its 1992 production schedule was reduced by 9% to 3.6 Mmt. Armco decided to obtain its remaining 1992 iron ore requirements from sources other than Eveleth because of Eveleth's high costs.

At Mountain Iron, the Minntac Mine closed its No. 3 pelletizing line, the smallest of five, as the result of a weak market. The line closed in early October and remained closed through yearend. The plant, which is the largest of the Iron Range's seven taconite companies,

produced taconite pellets for USX | Corp.'s U.S Steel Group and others.

Missouri.—The Pea Ridge Iron Ore Co. produced iron oxide powder at its mining complex near Sullivan, MO. The company has the only active underground iron mine in the country. In January 1991, the company ceased pellet production and began concentrating on specialty iron oxide products, which had formerly been coproducts.

Utah.—Geneva Steel of Utah operated two open pit mines in the Pinto District of Iron County. The district, 32 km west of Cedar City, has provided magnetite and hematite ores for blast furnaces in the Rocky Mountain region on an intermittent basis since 1923.

Other States.—Two California mines produced iron ore during the year—the Baxter and the Beck. The bulk of the shipments went to cement plants in the Los Angeles basin.

In South Dakota, Pete Lien & Sons Inc. mined low-grade hematite at the CF&I pit near Nemo in Lawrence County. The mine was reopened in 1988 after a hiatus of 9 years, but operated only during part of 1992.

Consumption and Uses

The U.S. steel industry accounted for 98.6% of domestic iron ore consumption in 1992. The steel industry experienced a slight increase over the previous year as production and shipments of steel products declined along with the recessionary economy. Production of raw steel in the United States fell more than 6%.

Another factor affecting the consumption of iron ore is that electric arc furnaces, used in steelmaking primarily by minimills, do not use iron ore. Electric arc furnace steelmaking accounted for 38.0% of total steelmaking in 1992. This was the largest share for electric arc furnace steelmaking in the United States.

Consumption of iron ore was 7.7% higher than the figure for 1991.

Consumption for ironmaking and steelmaking totaled 68.9 Mmt. Monthly consumption of pellets, direct-shipping ore, and merchant sinter by the industry averaged 5.71 Mmt compared with 5.31 Mmt in 1991. Reported consumption of iron ore for manufacture of cement, heavy-medium materials, animal feed, ballast, ferrites, pigments, and other nonsteel products was 976,000 tons.

U.S. production of hot metal and pig iron totaled 47.0 Mmt, a 6.5% increase from that of 1991. During 1992, the number of blast furnaces in operation ranged from 41 to 44.

Consumption of iron ore and all types of agglomerates reported to the AISI by integrated producers of iron and steel totaled 73.7 Mmt. This included 60.2 Mmt of pellets; 11.4 Mmt of sinter, briquettes, etc.; and 2.1 Mmt of natural Of the primary ore coarse ore. consumed, 79% was of domestic origin, 10% came from Canada, and 11% came from other countries. Other materials consumed in sintering plants included mill scale, flue dust, limestone and dolomite, slag and slag scrap, and coke breeze. Other iron-bearing materials charged to blast furnaces included steel-furnace slag, mill scale, and slag scrap. According to AISI, 2.4 Mmt of ferrous scrap was consumed in blast furnaces in 1992.

Stocks

Stocks of iron ore and agglomerates reported at U.S. mines, docks, and consuming plants have been gradually dropping for more than 30 years. This trend temporarily reversed itself in 1988 and 1991, but has since continued downward. At yearend, total industry stocks were 21.3 Mmt. Furnace yard stocks stood at 16.1 Mmt and included 11.9 Mmt of domestic ores, 1.9 Mmt of Canadian ores, and 2.2 Mmt of foreign ores. Mine stocks at yearend were 35% lower than those of 1991.

Stocks of unagglomerated concentrates reported at pelletizing plants totaled 1.9 Mmt at yearend, an increase of 3% from that of 1991. This material is not included in mine stocks of usable ore reported in the accompanying tables because it is

considered an intermediate product. Stocks of byproduct ore also have been excluded since 1983 from the mine stock data to avoid disclosing company proprietary information.

Transportation

Great Lakes shipping continued to play a key role in the competitiveness of the U.S. iron ore industry. The Corps of Engineers kept the Soo locks open until January 10, 1993. Ore shipments from Escanaba on Lake Michigan began on March 11. The 1992 navigation season lasted 315 days. Iron ore shipments on the Great Lakes totaled 60.9 Mmt compared with 58.3 Mmt in 1991.

The fleet operated 57 of its 66 serviceable vessels, with the 57 vessels accounting for 94% of carrying capacity. Since 1980, the number of U.S.-flag vessels on the Great Lakes has dropped from about 140 to 61. At the same time, the average carrying capacity has risen from 20,900 tons to 25,900 tons. Of the 66 vessels, 6 were cement carriers and 3 were self-propelled tankers.

Prices

Internationally, price reductions were forced on iron ore producers for the second consecutive year. Steelmakers insisted on lower prices because steel prices were down for the fourth According to the consecutive year. Bureau of Labor Statistics, the Producer Price Index for Steel Mill Products fell from 114.52 in 1989 to 106.38 in 1992. a decline of 7%. The decreases of the past 2 years followed several years of increases that progress had been made in reversing a long trend of declines in iron ore prices, particularly in terms of inflation adjustment.

Most iron ore prices are negotiated between buyer and seller. About 80% of domestic ore is produced by captive mines (mines producing for company smelters) and therefore does not reach the open market. The average f.o.b. mine value of usable ore shipped in 1992 was \$31.18 per ton, 5.7% higher than 1991. This average value was based primarily

on producers' statements and should approximate the average commercial selling price less the cost of mine-to-market transportation.

In Japan, prices for lump ore were down about 6%; fines, about 5%. Very few published prices for domestically produced pellets changed in 1992. Oglebay Norton was both still quoting a price of \$0.7245 per long ton unit (Itu) of iron, natural, for its standard grades of Lake Superior pellets. An Itu is equivalent to 0.01 long ton or 22.4 pounds. The quotation included delivery to rail-of-vessel at lower lake ports. The price for Minntac acid pellets was left at \$0.3744 per dry Itu of iron, delivered into railcars at the Minnesota mine.

Published f.o.b. prices for direct-reduced iron (DRI) were also unchanged from those quoted in 1991 and were as follows, per ton: at Georgetown, SC, \$125.00 to \$135.00; at Contrecoeur, Quebec, \$115.00; and at Point Lisas, Trinidad and Tobago, \$120.00.

Foreign Trade

U.S. exports of iron ore were 25% higher than those of 1991. Virtually all exports consisted of pellets and concentrates shipped via the Great Lakes to Canadian steel companies that are partners in U.S. taconite projects in Michigan and Minnesota. U.S. imports of iron ore fell 6% to 12.5 Mmt.

Net imports for 1992 were 44% below the average of the previous 4 years and were equivalent to 10% of U.S. ore consumption. Canada's share of net imports was 55%; Brazil's share was 20%.

World Review

At least 55 countries mined iron ore during the year, producing a total of 929.8 Mmt. China was the largest producer, with an output of 194 Mmt. World production of pig iron, which directly reflects ore consumption, decreased by 1.7% to 498 Mmt. World DRI production rose by 7.9% to 20.9 tons.

For the second consecutive year

Australia was the leading exporter of iron ore, shipping 106.6 Mmt to world markets, followed closely by Brazil, which exported 106.0 Mmt. Together, the two countries accounted for 57.8% of exports in 1992. The next largest exporter was India, at 7.8%. Total exports were 367.5 Mmt, down from 398.8 Mmt in 1991. Australia's principal customer, Japan, accounted for about one-half of its exports. Brazil's primary customers were the European Community (EC) and Japan.

Integrated iron ore operations have become extremely complex and are so large as to resemble medium-sized towns in some cases. The production capacity of an operation of this magnitude is determined by equipment limitations at several stages of recovery. To simplify analysis and make comparisons of individual mines easier, data were collected that represent the rated or design capacity at three key points in the recovery process: crusher-screen output, concentrator output, and pelletizing furnace output. These three points were chosen because they serve to readily separate the mining, beneficiating, and agglomerating stages of the operation. At the first two points, the iron ore is already in a marketable form and can be diverted for sale or tolling if bottlenecks occur either downstream at the operation or upstream at competitors' facilities.

Changes in the economics of the process also could make diversion feasible. Table 21 shows world pelletizing capability at the close of 1992. The data represent the rated capacities of 82 plants in 26 countries. A significant part of the data was published by the Trust Fund Project on Iron Ore Information in 1992. The table excludes plants that have not produced since 1982. Four of these idled plants are identified in the table footnotes because they could be reactivated in some realistic scenarios. Table 21 also excludes sintering plants.

Australia.—BHP Iron Ore Ltd. opened its Yandi Mine in March with an initial production capacity of 5 Mmt/yr. Capacity was being doubled to 10 Mmt/yr through the installation of additional

crushing and screening equipment, which began in 1992 and was expected to be completed in 1993.

Robe River Iron Associates produced and shipped more than 20 Mmt of ore for the third consecutive year, but failed to achieve the record breaking levels of 1991. The company began mining the Mesa J deposit at Pannawonica at This event, combined with midyear. infrastructure improvements completed during the year, raised Robe River's nominal production capacity to 35 Mmt/yr. In the long term, the company intended to increase output to 50 Mmt/yr. Proven reserves at the J deposit were estimated at 600 Mmt and were likely to be closer to 800 Mmt.

Hamersley Iron Pty. Ltd. reached record production levels for the fourth consecutive year. Shipments for the year, on the other hand, declined as the result of drop in demand and a monthlong strike during which the company declared a force majeure. Fourth quarter shipments dropped by 16% from the same period in 1991. Production from the Brockman No. 2 Detritals Mine, which began operating in June, contributed to the record result. Brockman. 55 km northwest of Hamersley's main mine at Tom Price, was a small deposit, with only 20 Mmt of salable ore and expected life of 5 years. Like the Paraburdoo and Channar Mines and the Marandoo deposit, the Brockman was to be used to extend the life of the Tom Price Mine. After more than 27 months of negotiations, Hamersley gained approval in October from the Western Australian Ministry for the Environment for the development of the Marandoo deposit. The project was delayed because of environmental concerns and a dispute with Aboriginal interests regarding sacred sites. Development work on the deposit began late in the year with commissioning expected in 1995. The deposit was estimated to contain about 400 Mmt of high-grade ore. The Marandoo, 35 km east of Mount Tom Price, was expected to produce between 10 and 15 Mmt/yr beginning in early 1994.

Brazil.—Samarco Mineracao S.A.

signed a contract for a \$15 million loan from a group of Japanese companies to help finance its expansion plans. The group was led by Kobe Steel, one of the primary consumers of Samarco ore. Under the terms of the agreement, Samarco was to double its sales to Kobe to about 1 Mmt/yr. The projects included the construction of a pipeline and expansion of the company's pellet plant and was expected to increase Samarco's production capacity from 8.5 to 10 Mmt/yr.

Canada.—The two largest producers, Iron Ore Co. of Canada and Quebec Cartier Mining Co., experienced a drop in sales as the result of declining steel production in Europe, their primary market.

China.—In recent years, China's economy and industrial base have grown at a very rapid rate. To support this growth China has made enormous strides in increasing its iron ore production and consumption, and in 1992, became the world's largest producer and consumer of In terms of Fe content. iron ore. however, China was the world's third Over the 10-year largest producer. period 1983-92, China increased its iron ore production by 71% compared with a production growth rate of 7% for the rest of the world. For the same period, China's pig iron production rate grew 96%, compared with 3% for the rest of the world.

During 1992, China was planning the construction of at least three steel mills, each with a production capacity of 10 Mmt/yr. As a consequence, the country was seeking additional supplies of iron ore. As well as constructing eight new mines, China was considering expansions of the Nanfen Mine near Benxi, the Jian Chan near Taiyuan, and the Shuichang near Beijing. Late in the year, Anshan Steel signed a preliminary contract with United States and Canadian equipment manufacturers for large trucks, electric shovels, and slurry pipe machinery for the transport of concentrates. equipment was expected to be used in the

Oidashan Mine, which was to expand from a production capacity of 7 Mmt/yr to 15 Mmt/yr by 1995. Even with this level of effort. China was forced to look abroad for supplies of iron ore. Their imports of iron ore, primarily from Australia, have increased steadily, rising from 3.9 Mmt in 1983 to 25.2 Mmt in 1992. China was taking a number of steps to increase its imports. December, the Capital Steel Corp. of Beijing purchased an iron mine in Peru (see Peru section). Capital Steel, also known by its Chinese name of Shougang Corp., was China's fourth largest steel producer. Most of China's efforts in seeking iron ore abroad centered on Australia. China was a partner with the Western Australia Government in the Western Australia-China Economy and Research Fund, which provided money for studying the feasibility of construction of a DRI plant in Western Australia. China also owned 40% of the Channar Mine in Western Australia.

France.—Lormines, the Usinor Sacilor iron mining subsidiary, reached an agreement with unions on closing the group's three iron mines in Lorraine. The Mairy-Maiville closed in June, while the other two, Moyeuvre and Roncourt, were scheduled to close before the end of 1994. The reasons for the closures were metallurgical more than economic. The ore was low grade, at 32% Fe, and low quality because of its high arsenic and phosphorus contents. After the mines close, French iron ore production will have fallen to less than 3 Mmt/yr, all from Arbed S.A.'s two mines in Lorraine.

India.—The Indian Government was intent on increasing domestic steel production. To this end, the Government removed restrictions on licenses and prices and announced that it would not allow any new contracts for increased exports of iron ore. The State-owned steel producer, Steel Authority of India Ltd. (SAIL), set a target of investing \$11 billion over 15 years to expand production from existing plants. Its plan

calls for increasing production from 9.9 Mmt in 1991-92 to 18.9 Mmt in the year 2004-05. The Indian Steel Ministry set a goal of expanding overall steel production to 67 Mmt/yr by the year 2010 compared with 17 Mmt/yr in 1992. To supply part of the additional iron ore that will be needed, plans were made to double production to 18 Mmt/yr at the Bailadila Mine in Madhya Pradesh.

Iran.—Three 640,000-mt/yr Midrex Direct Reduction Corp. DRI modules became operational at the National Iranian Steel Corp.'s. (Nisco) facility in Mobarakeh. Two more were scheduled to come on-line in 1993, which would bring the complex's total DRI capacity to 3.2 Mmt/yr. Nisco, with technical help from Kobe Steel of Japan, was developing a large iron deposit at Chador Nalu in central Iran. The mine was expected to begin operation in 1995, with production of 5 Mmt/vr. Reserves at the deposit were estimated at 330 Mmt, grading 58% Fe. Kobe Steel was also involved in conducting a feasibility study to construct a DRI plant on Oeshm Island in the Strait of Hormuz.

Korea, Republic of.—Pohang Iron and Steel Co. (Posco) signed a contract to buy a Corex ironmaking unit from Voest-Alpine Industrieanlagenbau (VIA). The plant was expected to produce 600,000 to 700,000 mt/yr. Posco was the first customer to order the Corex technology after the Republic of South Africa.

Mauritania.—Five iron and steel companies, two each from Egypt and Algeria and one from Mauritania, signed an agreement to build an iron ore pelletizing plant in the country. Pending the results of a feasibility study, a deposit at Aouj Centere, 30 km north of F'Derik, was to be developed to feed the plant. Reserves at the deposit were estimated at 220 Mmt.

Peru.—The Peruvian Government succeeded in privatizing its state-owned iron ore producer. On December 1, 1992, Empresa Minera del Hierro del

Peru (Hierro Peru) was sold to the Capital Steel Corp. of Beijing. Hierro Peru owned and operated the Marcona Mine. Capital Steel was China's fourth largest steel producer.

Under the contract, Capital Steel agreed to pay \$120 million in cash, invest \$150 over the next 3 years, and assume \$42 million of Hierro's debt for a total of \$312 million.

Sweden.—State-owned producer Luossavaara-Kiirunavaara A.B. (LKAB) planned to increase pellet production capacity at Kiruna, its principal mine. The 4-Mmt/yr plant was expected to come on-stream early in 1995 and was expected to make LKAB the world's largest pellet producer, with a total capacity of 15 Mmt/yr.

Trinidad and Tobago.—Nucor Steel Corp., a minimill operator, announced plans to build a plant in Trinidad and Tobago to produce iron carbide, a form of DRI. The Charlotte, NC, based company was to build a 320,000-mt/yr plant at a cost of \$60 million; the plant's size could be quadrupled if it proved to be successful. Nucor was to use the process developed by Iron Carbide Holdings Ltd. and anticipated beginning construction of the plant early in 1993; production was expected to begin in late Feed for the plant was to be 500,000 mt/yr of Brazilian fines, which was expected to give them a cost advantage over pellets. Initially, the iron carbide was to be used in Nucor's flatrolled sheet mills in Crawfordsville, IN, and Hickman, AR.

Ukraine.—Prospects for finishing the large, joint-venture iron ore beneficiation plant project at Dolinska appeared to be dead. The joint-venture partners and their respective shares of the project were the former U.S.S.R., about 50%; Romania, 27%; Czechoslovakia, 14%; with the balance going to the former German Democratic Republic and Bulgaria. Plans for the project were to construct a 13-Mmt/yr pelletizing plant at Dolinska, about 60 km from Krivoy Rog

in the southern part of the country. Work on the joint venture began in 1986 and was scheduled for completion in 1992, but, at the end of the year was no more than one-half finished. With the dissolution of the U.S.S.R. and the unification of Germany, attitudes toward the project began to change. Germany, Russia, and the Czech and Slovak Republics indicated that they were not interested in completing the facility for various reasons, including changes in national priorities, escalating construction costs, and doubts about the quality of the ore.

Venezuela.—CVG Ferrominera del Orinoco CA (Ferrominera) launched an ambitious expansion program that, among other things, could nearly double its production capacity from 23 Mmt/yr to 40 Mmt/yr by the year 2000. As part of this program, the state-owned company began construction on a 3.3-Mmt/yr pellet plant at Peurto Ordaz, which was expected to begin operation at the end of 1994. Kobe Steel, a Japanese steelmaker, was also considering putting a pellet plant at the site in a joint project with Ferrominera, with construction beginning in 1993. Ferrominera and Kobe were also studying the possibilities of locating an 8-Mmt/yr concentrates plant at the mine site. Laboratory studies took place in Canada, Japan, and the United States, and a pilot plant was expected to begin operating in early 1993, to run for 2 years. The concentrates were expected to contain 68% iron. The cost of the project was projected to be \$1.3 billion. Ferrominera reportedly had proven reserves estimated at 1,900 Mmt grading 60% iron. Probable and possible reserves were estimated to be 11,700 Mmt grading 44% iron.

OUTLOOK

The domestic iron ore industry is totally dependent on the steel industry for sales. This dependence is not expected to change in the near future. Because of this relationship, the reader is referred to the outlook sections in the Iron and Steel chapter. Only 9% of the iron ore shipped

in 1992 was exported, with virtually all of it being pellets going to steelworks in Ontario. It is difficult for the United States to compete in the world iron ore market because of the country's declining ore grades, the inland location of its mines, and high labor and fuel costs.

For the near term, growth of the U.S. iron ore industry is tied to the growth of the integrated steelworks along the Great The U.S. steel industry is Lakes. concentrating on making high-value, quality steels, not increasing output. Domestic blast furnace production in the year 2000 is expected to be no more than 50 Mmt. The U.S. iron ore industry has no choice but to focus on making higher quality agglomerates, such as fluxed pellets, that meet much tighter chemical and physical specifications than have been required in the past. The hope for the domestic iron ore industry is that one or more of the new direct processes, COREX, DIOS, AISI, HIsmelt, carbide, etc., will prove to be economic for lake producers.

Electric arc furnaces currently account for more than one-third of total crude steel production. Because of advances in steelmaking, steel products now require lower residual alloy content than can be readily achieved with scrap. indicates a role for imported DRI in the coastal regions of the United States. The growth of gas-based DRI production capacity outside North America has been spectacular in recent years. Although a large part of this growth has occurred in Venezuela, the bulk of the construction has been spread evenly through a variety of countries that have surplus natural gas. It is too early to tell whether coal-based DRI production will be economically feasible in the United States. No matter how spectacular DRI growth is over the next decade, it will not be able to replace more than a fraction of the world's blast furnace production because technological restrictions. The blast furnace is expected to remain the mainstay of the iron and steel industries in most developed countries over the next 25 years.

In 1992, China became the world's largest producer and consumer of iron

ore. Iron ore production fell in all major producing countries and regions with the exception of China. World pig iron production, the best indicator of iron ore consumption, fell slightly during the year. Production in the United States posted a moderate gain, while production in China rose by 15%. Pig iron production in China slightly exceeded that of Japan to make China the world's largest iron ore consumer. Australia and Brazil continued to be the leading exporters of iron ore with a combined total of close to 60% of the world total.

In contrast to the United States, demand for iron ore in other parts of the world is expected to escalate, particularly China became the world's in Asia. largest producer and consumer of iron ore in 1992 (see section on China). From 1983 through 1992, pig iron production in China increased 96%, while in the rest of the world, the growth was 3%. Looking at Asia as a whole, production grew at 43% during the same period, whereas production in the rest of the world fell by 3%. India's growth was 65% and that of Taiwan was 55%. The most spectacular increase, at 140%, occurred in the Republic of Korea. The situation in Japan means greater consumption of iron ore elsewhere. The growth rate in that country has been flat and that is expected to continue, but Japan has been using more steel domestically. In the years from 1981 through 1991, in terms of its share of the world market, Japan's imports of semifinished and finished steel products rose from 1% to 6%. For the same period, its exports of these steel products fell from 20% to 10%, while apparent consumption rose from 11% to 15%. Given these data, it seems unlikely that Japanese steel exports will increase in the near term. The shortfall will have to be made up by higher steel production elsewhere and, consequently, higher iron ore consumption.

Steelworks in the EC have become more competitive in recent years and should benefit from the growth in steel consumption that is forecasted to occur in Western Europe after the single market takes effect and internal trade barriers are removed.

The increase in consumption in Asia is expected to benefit Australia, primarily. Australia and Brazil are the two leading exporters of iron ore; each accounts for about 30% of the world total, and no other exporter comes close to that level. Of the two, Australia seems to be better placed to take advantage of growth of iron ore consumption in Asia because of Australia's proximity and the consequent lower freight rates.

⁴Chamosite is a yellow-green to greenish-gray iron-rich alumino-silicate that forms ooliths in sedimentary ironstones. Fine-grained varieties of the alumino-silicate are also found in the groundmass of the ironstone, together with siderite and kaolinite. The mineral, which contains about 30% Fe, is closely related chemically to the chlorites, but has a layered structure more akin to serpentine [Mg₆Si₄O₁₀(OH)₈]. Chamosite is a major constituent of the Jurassic ironstones of the English Midlands.

Revised.

²Less than 1/2 unit.

³Data may not add to totals shown because of independent rounding.

¹Less than 1/2 unit.

²Sinter made from raw materials supplied by Australia, Brazil, and other countries.

³Excludes 28,923 metric tons of crude iron sulfate crystals valued at \$318,651, originally reported as iron ore from the Federal Republic of Germany.

Excludes 12 metric tons of iron oxide-based coloring preparations valued at \$7,542, originally reported as fine ores from China. The 1 ton of material from Namibia that was reported in October was part of a meteorite and was valued at \$10,881.

⁵Data may not add to totals shown because of independent rounding.

Estimated. Revised.

⁷Reported figure.

¹Table includes data available through July 20, 1993.

²In addition to the countries listed, Cuba and Vietnam may also produce iron ore, but definitive information on output levels, if any, is not available.

Insofar as availability of sources permits, gross weight data in this table represent the nonduplicative sum of marketable direct-shipping iron ores, iron ore concentrates, and iron ore agglomerates produced by each of the listed countries. Concentrates and agglomerates produced from imported iron ores have been excluded under the assumption that the ore from which such materials are produced has been credited as marketable ore in the country where it was mined.

Data represent actual reported weight of contained metal or are calculated from reported metal content. Estimated figures are based on latest available iron content reported, except for the following countries for which grades are U.S. Bureau of Mines estimates: Albania and North Korea.

⁵Nickeliferous iron ore.

⁶Data on gross weight presented for this country are taken from the Trust Fund Project on Iron Ore Information, United Nations Conference on Trade and Development (UNCTAD) publication.

^{*}Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁹Less than 1/2 unit.

¹⁰Formerly part of Yugoslavia; data were not reported separately until 1992.

¹¹ Series represent gross weight and metal content of usable iron ore (including byproduct ore) actually produced, natural weight.

¹²Includes magnetite concentrate, pelletized iron oxide (from roasted pyrite), and roasted pyrite (purple ore).

¹³Data are for year beginning Mar. 21 of that stated.

¹⁴Gross weight calculated from reported iron content based on grade of 66% Fe.

¹⁵Concentrates from titaniferous magnetite beach sands.

¹⁶Includes manganiferous iron ore.

¹⁷Includes magnetite ore as follows, in thousand metric tons: 1988-5,492; 1989-6,594; 1990-5,613; 1991-5,658; and 1992-4,647.

¹⁸Includes byproduct ore.

¹⁹Dissolved Dec. 1991.

²⁰Dissolved Apr. 1992.

¹Staged additions are treated at some mining complexes as if they were separate plants. Site data excludes plants that have had no production since 1982. Plants that produced after 1979, but have been continuously idle since 1982, are cited in the footnotes because they could be reactivated at some reasonable cost.

²The total for the United States includes the newer part of the E. W. Davis Works at Silver Bay, MN, but not the idled plant owned by Cleveland-Cliffs Inc. at Republic, MI. Cyprus Minerals Co. acquired the cannibalized Silver Bay facility in Aug. 1989 and resumed production in Jan. 1990. Cleveland-Cliffs has been considering reopening its 1.3-Mmt/yr Republic plant, which has been on care and maintenance since 1981.

³Pellets produced from imported direct-shipping ores and/or concentrates.

The older of the two plants, operated by A/S Sydvaranger at Kirkenes, has been idle since 1986. In addition, the 0.50-Mmt/yr plant operated by Norsk Jernverk at Mo-i-Rana was shut down in Jan. 1987 for an indefinite period, leaving only one plant in Norway on-line.

⁵In early 1988, the capacity of the Svappavaara plant was upgraded from 2.8 to 3.5 Mmt/yr. The 0.3-Mmt/yr steel belt plant at Malmberget is used for both research and development purposes as well as ordinary production. ⁶Based on incomplete information.

⁷The Skopje plant operated by Rudnici i Zelezara was recently idled.

*Excludes the No. 1 pelletizing plant (capacity of 2.4 Mmt/yr) of the Bong Mining Co. The No. 1 plant has been idle since 1980.

The Nador plant operated by Societe d'Exploitation des Mines du Rif (SEFERIF) has been idle for several years.

¹⁰There is an additional plant with a capacity of 1.8 - Mmt/yr at Mandovi in Goa, but it has been closed since 1982. The owner was planning to reopen the facility using high-grade blue dust from the Bellary Hospet area of Karnataka as feed.

¹¹There is an additional plant with a capacity of 3.0 Mmt/yr at Dampier in Western Australia, but it has been closed since 1980.

FIGURE 5 COMPARISON OF U.S. IRON ORE PRODUCTION WITH TOTAL PRODUCTION FOR THE WORLD

IRON AND STEEL

By Gerald W. Houck

Mr. Houck, a physical scientist with 36 years of industry and U.S. Bureau of Mines experience, is the commodity specialist for iron and steel. International data tables were prepared by Harold Willis, international data coordinator, and Ted Spittal, Orkand Corporation. Ferroalloys survey data were prepared by Jo-Ann Sterling, statistical assistant, and David Kulha, management analyst.

Iron and steel are vital to the United States for both national security and economic well-being. They are the basic metals of an industrial society. Although there are many acceptable substitutes for many of their uses, in the short term, there are no practical substitutes on a large scale because of the cost and lack of availability of alternative materials. Ferroalloys are alloys of iron that contain a sufficient amount of one or more other chemical elements to be useful as an agent to introduce these other elements into a molten metal, usually steel.

Data tables on ferroalloys production and consumption are contained in this chapter. The reader is referred to the Annual Reports dealing with specific elements, especially those for chromium, manganese, and silicon, for analysis and detail with respect to the ferroalloys industry.

Consistent with international usage, the U.S. Bureau of Mines is reporting all data on iron and steel in metric units, unless otherwise noted.

This was another poor year for the U.S. steel industry, despite strong increases in both production and shipments of steel. Production of raw steel in the United States increased 5.7%, to 84.3 million metric tons, from 79.7 million tons produced in 1991. Net shipments of steel mill products by U.S. companies increased about 4%, to 74.6 million tons, from 71.5 million tons in 1991.

Imports of steel mill products increased about 8%, to 15.5 million tons, from 14.3 million tons in 1991. Imports

captured 18.0% of the apparent consumption of steel mill products, up from 17.8% in 1991. Imports of fabricated steel products, such as fasteners, wire, and fabricated structural steel, totaled 1.8 million tons, representing another 2% of the U.S. steel market.

Exports of steel mill products declined to 3.9 million tons, from 5.8 million tons in 1991. This decline ended a 5-year period of increasing exports and marked a return to about the same level of exports that was recorded in 1989 and 1990.

Prices of steel mill products declined once more in 1992. The Bureau of Labor Statistics' Producer Price Index for steel mill products declined 2.8%, to 106.4 (1982 base = 100.0).

Despite the improvement in volume, lower prices prevented the U.S. steel industry from achieving profitable operations. The American Iron and Steel Institute (AISI), reporting on the aggregated financial results of companies that produced about 66% of the Nation's raw steel in 1992, announced that losses in 1992 were \$3,838 million on steel sales of \$26,838 million. These companies have reported cumulative losses of \$15,348 million over the 11-year period of 1982-92.

World production of raw steel in 1992 was 721.3 million tons, down 2% from that of 1991. Production in Eastern Europe and the former U.S.S.R. fell dramatically—more than 15% in 1992, adding to an 18% decline in 1991. Production in Japan was down more than

10%, and production in Western Europe declined about 4%. In China and in the other developing nations of Asia, Africa, and the Middle East, however, growth continued at a vigorous pace; production in China increased 13%.

DOMESTIC DATA COVERAGE

Data regarding U.S. production of iron and steel, and shipments of steel mill products are those reported by the AISI. These data can be regarded as representing 100% of the raw steel producers in the United States.

BACKGROUND

Definitions, Grades, and Specifications

Iron is the most useful and most abundant, as well as the cheapest of the metallic elements. It is also the most versatile and most widely studied and understood. Its many uses are based on the properties of its alloys; iron is never used by itself. Some of its useful alloys include the word "iron"; viz., pig iron, wrought iron, gray iron, malleable iron, ductile iron; others are known as "steel." The term "steel" was originally applied to an alloy of iron that would become very hard if cooled rapidly from a high temperature. Early steelmakers did not know that a carbon content from about 0.3% to about 1% is required for producing these properties, but by trial and error they developed empirical methods to produce metals of the proper carbon content.

Today, iron refers to alloys that contain too much carbon to be formable by forging or rolling. "Pig iron" contains about 4.5% carbon and is useful only for steelmaking or for remelting into cast iron products. Gray iron, malleable iron, and ductile iron are categories of cast iron and are produced by the foundry industry.

In modern terminology, steel refers to an alloy of iron that is malleable at some temperature that contains carbon. manganese, and often other alloying elements. Steel containing only carbon and manganese is called "carbon steel"; steel containing metallic elements such as chromium, molybdenum, or nickel is termed "alloy steel"; steel containing sufficient chromium to confer a superior corrosion resistance is called "stainless steel." Hundreds of individual alloy specifications have been developed to produce combinations of strength, ductility, hardness, toughness, magnetic permeability, and corrosion resistance to meet the needs of modern consumers. These alloy specifications are called "grades."

The malleability property of steel allows it to be produced by rolling or forging into a variety of product forms. Examples of forms include structural shapes (such as beams and angles), rails (such as railroad rails), round bars, wire, various types of pipe and tubular products, and flat-rolled products. In every case, the product is produced on specialized equipment in a range of sizes to suit intended applications.

For some products, metallic or nonmetallic coatings are applied to the product by the steel producer. Additionally, various thermal treatments may be used to meet the customer's requirements.

"Steel mill products" refers to products produced by a steel mill, either by forging or rolling, in the form normally delivered for fabrication or use. Some companies purchase semifinished steel mill products from other steel companies and use these semifinished products to produce steel mill products. To avoid double counting steel mill product shipments under these circumstances,

steel mills identify any shipments of steel mill products to other companies that are reporters of steel mill product shipments. The accumulated shipments of all companies, less the shipments to other reporting companies, are identified as "net" shipments.

Regarding the reporting of imports and exports, "fabricated steel products" are products produced from steel mill products, but not including products that incorporate steel products along with other materials. Examples of fabricated steel products are fabricated structural steel and steel fasteners. "Other iron and steel products" refers to products that are not produced from steel mill products. Examples of other iron and steel products include iron or steel castings and direct-reduced iron (DRI).

Industry Structure

Integrated Steel Producers.—Integrated steel producers are those that smelt iron ores to crude liquid iron in blast furnaces and refine the iron, with some scrap, in basic oxygen furnaces, producing liquid steel. The liquid steel is mostly cast into semifinished products in continuous casting machines, although 21% of U.S. production in 1992 was cast in ingot form and subsequently rolled into semifinished form. The integrated steel industry in the United States in 1992 consisted of 16 companies operating ironmaking and steelmaking facilities at 23 locations. Several of these companies also operated nonintegrated plants and/or other steelmaking facilities at the same locations.

The product mix of the integrated producers consists predominantly of flat products: sheet and strip, some of which is galvanized or tin-plated. Some integrated producers made structural shapes and bar products as well, but, for the most part, these products are produced by nonintegrated mills.

Nonintegrated Steel Producers.— Nonintegrated steel producers melt raw materials, primarily scrap, in electric

furnaces. Broadly speaking, there are two subcategories of nonintegrated mills: minimills and specialty mills. "Minimills" is a term used to describe steel producers that utilize modern technology in a plant built to produce a limited product line with maximum efficiency. These plants always incorporate electric melting of low-cost raw materials, continuous casting, and a hot-rolling mill, often closely coupled to the casting operation. It was once accepted that minimills produced only simple bar products such as reinforcing bars, wire rods, and small structural shapes. Today, however, minimills have become dominant in all long products, including special quality bars and large structural shapes. One company has successfully applied the minimill concept to the production of flat-rolled steel with the successful operation of thin-slab (50mm), continuous casting machines, closely coupled to a hot-strip mill, producing commercial quality hot bands. Several companies operate multiple minimills with cumulative steelmaking capability greater than that of the smaller integrated mills.

The second category of nonintegrated mills, specialty mills, is less well defined. Specialty mills definitely include the producers of stainless steel, alloy electrical steel, tool steel, and high-temperature alloys. In addition, this category includes producers of forging ingots and a variety of steel plants that, although not producing a large quantity of steel, are a significant part of what is called "the steel industry."

Overall, the nonintegrated sector of the industry consisted of about 68 companies with 96 raw-steelmaking locations.

Substitutes

Iron, as steel or cast iron, is the most widely used metal in the world because of its high strength-to-cost ratio. In applications where strength is not the major requirement, iron competes with less expensive nonmetallic materials or more expensive materials having some property advantage. Where weight reduction is required, aluminum, plastics,

and occasionally magnesium or titanium may be substituted; motor vehicles and airplanes are obvious examples. In construction, concrete, usually reinforced with steel, and wood are frequently substituted for steel. In packaging, steel cans, pails, and household goods were largely replaced with aluminum, glass, plastics, and paper, but drums and other containers used for more severe applications are almost invariably made of steel.

ANNUAL REVIEW

Legislation and Government Programs

Trade Agreements.—From October 1, 1984, until March 31, 1992, the import of steel products into the United States was limited by a program of "Voluntary Restraint Agreements (VRA's)," which were negotiated following an investigation conducted by the U.S. International Trade Commission (ITC) in which imports of certain steel products were found to be a substantial cause of serious injury, or threat thereof, to certain domestic industries. The President determined that imposing countervailing duties under the Trade Act of 1974 was not in the national economic interest and directed the U.S. Trade Representative to negotiate VRA's with countries whose exports to the United States had increased significantly in previous years due to an unfair surge in imports.

Agreements were negotiated with the European Community and 16 individual nations. Although the structure of the agreements varied from one country to another, each involved an agreement by the foreign Government to limit exports of certain steel products to the United States. To bring the agreements into effect, U.S. steel producers withdrew pending unfair trade petitions, and the U.S. Government suspended antidumping and countervailing duties that were in effect on the products covered by the agreements. The VRA's initially covered a 5-year period ending September 30, In July 1989, the President announced a "Steel Trade Liberalization Program" extending the VRA program for 2½ years, to terminate March 31, 1992. Negotiations resulted in new agreements with the European Community and the 16 other countries.

Anticipating the expiration of the VRA's, the United States, along with more than 30 other countries, has negotiated in an effort to reach a "Multilateral Steel Agreement." The principal U.S. objectives multilateral agreement include prohibitions against most subsidies, the elimination of tariff and nontariff barriers to trade, and the establishment of an effective mechanism to resolve disputes. Agreement on the Multilateral Steel Agreement was not reached before the expiration of the VRA's March 31, 1992.

Following the expiration of the VRA's, some U.S. steel companies filed new countervailing duty and antidumping suits, claiming injury to the domestic steel industry as a result of governmentsubsidized or unfairly traded steel imported into the United States from numerous countries, including those that have been the source of most of the imported steel in the U.S. market. The most important of these suits were filed on June 30, 1992, dealing with hotrolled, cold-rolled, and galvanized carbon steel sheets and hot-rolled carbon steel Claims of subsidization were plates. made against imported steel from 13 countries, and claims of unfair trade were made against 20 countries. The countries against whom the charges were filed had imported more than 5.8 million tons of the covered products during 1991. The products involved are the most important products of the integrated steel companies and represent more than one-half of all steel products shipped in this country.

To dispose of unfair trade cases such as these, the U.S. Department of Commerce (DOC) is responsible for determining whether there was subsidization or unfair trade, and if so, the value of it in relation to the value of the products imported. This determination establishes the percentage amount of a countervailing duty or antidumping duty that may be assessed. The ITC is responsible for determining

whether the subsidization or unfair trade resulted in injury to the U.S. industry.

In this case, the DOC made preliminary determinations that there was indeed illegal subsidization and unfair and the ITC determined preliminarily that there was injury to the U.S. industry in most of the cases. As a result, effective December 7, 1992, in the subsidy cases, and effective February 6, 1993, in the antidumping cases, importers of the covered products were required to make cash deposits or to post bond equal to the amount of the estimated dumping Recovery of the deposit or margins. bond is subject to final calculation of the duties and to a final determination of injury by the ITC. The duties are determined and applied on a companyspecific basis and differ widely. For example, the duties for hot-rolled plate range from 1.47% to 109.22%. Final determination of injury was expected from the ITC on July 27, 1993.

In addition to cases involving the major flat-rolled steel products, several other cases were processed during the year. Imports of steel rails from Japan, Luxembourg, and the United Kingdom were determined not to have been a cause of injury to the U.S. steel industry. Imports of special quality steel bars from Brazil also were determined not to have been a cause of injury. Imports from Brazil, France, Germany, and the United Kingdom of bars containing bismuth or lead to improve machinability were determined to have been a cause of injury, and duties were imposed on these particular steel products. Imports of standard and structural steel pipes and tubes from Brazil, the Republic of Korea, Mexico, Taiwan, and Venezuela also were determined to be a cause of injury, and dumping duties were assessed.

Research Programs.—The U.S. Department of Energy continued its research and development efforts under the Steel and Aluminum Energy Conservation and Technology Competitiveness Act of 1988, commonly known as the Metals Initiative. Work continued on five projects in steel processing carried over from prior years, and a sixth

project was selected for inclusion in the program. A requirement of the program is that industry sponsors provide cost-sharing contributions equal to a minimum of 30% of the total cost of any project.

The most notable of the steel projects was the Direct Steel Making Project, managed and jointly sponsored by the AISI. The objective of the project was to develop an energy efficient, economically competitive direct steelmaking process. The advantages of such a process would be: (1) more effective use of domestic raw materials; (2) continuous, rather than batch operations; (3) elimination of coke and the environmental impacts related to coke; (4) ease of startup and shutdown; and (5) facilitation of incremental capacity increases and adaptation to market conditions by modular design.

The process being investigated was an in-bath smelting process, coupled to continuous refining. Coal is injected into a molten bath of partially reduced iron ore, and the key to the success of the process is the efficient use of the energy of the gases generated. The carbon in the coal is a reductant for the iron ore and a source of thermal energy. Carbon monoxide is released, which must be partially combusted within the vessel to provide heat for the process. partially combusted smelter off-gas also must serve as the fuel and the reductant for a prereduction furnace to produce hot wustite pellets from hematite. Based on successes achieved with the process, AISI has decided that the best approach to advance the program is to install and operate a modified smelter to demonstrate sustained. continuous pilot-scale ironmaking during 1993. Success with this phase of the project was expected to lead to demonstration of the direct ironmaking process at a steel plant.

The AISI direct ironmaking process had many features in common with other programs under investigation in other countries. See discussion under Technology in this report.

Four other projects that were studied within the Metals Initiative included (1) Development of an ultrahigh carbon steel and a steel processing sequence to produce superplastic steel on a production

scale, managed by Lawrence Livermore National Laboratory, with cost-sharing by Caterpillar, Inc. and North Star Steel Co.; (2) Electrochemical Dezincing of Steel Scrap, by Argonne National Laboratory, with cost-sharing by Metal Recovery Industries (U.S.), Inc. (a pilot plant was under construction demonstrate a two-step process to electrolytically dissolve zinc from the surface of steel scrap and recover the zinc for purification and sale); (3) Direct Strip Casting, under investigation by Armco Inc. with additional sponsorship by Westinghouse Electric Corp. and North American Refractories; and (4) Rapid Analysis of Molten Metal Using Laser Produced Plasma, at Lehigh University, with sponsorship by the AISI, the Electric Power Research Institute, and an industrial consortium of nine companies. The objective of this program was to develop a probe that can be immersed in molten steel to produce an elemental analysis in less than 1 minute. Current practice requires removal of a molten sample, which must be frozen and analyzed in a laboratory, a sequence that requires a minimum of 4 to 8 minutes.

During 1992, approval was given to begin negotiation on a sixth steel project within the Metals Initiative. This was to be a multiyear project to improve quality, lower production cost, and conserve energy by focusing on the development of real-time measurement and control of product properties, reduction of waste material, and elimination of off-line testing. This program was to be managed by AISI and will include six individual projects involving different sensors and control systems needed for steel processing.

A second Department of Energy program, the Clean Coal Technology Program, provided funding to demonstrate new technologies for the environmentally sound and efficient use of coal. At the Bethlehem Steel Corp. plant at Burns Harbor Indiana, support was given for the installation of a system to inject pulverized coal into existing ironmaking blast furnaces and to demonstrate sustained operation with a variety of coal particle sizes and coal

types and to assess the interactive nature of these parameters. DOE is providing about \$31 million, 22% of the project cost

Bureau of Mines The U.S. demonstrated the feasibility of recovering a high-quality graphite product from kish, a waste product of iron blast furnaces that is currently disposed of in landfills. The process is being demonstrated on a pilot scale at a site in Indiana, in cooperation with members of the steel and graphite user industry. The amount of flake graphite that could be recovered from kish was estimated to be more than adequate for supplying all the flake graphite needs of the United States. There are currently no domestic resources for flake graphite, which is used in refractories and crucibles for steelmaking, in lubricants, and in electric motor brushes and batteries.

Production

Production of raw steel in the United States increased 5.7% to 84.3 million tons, from 79.7 million tons produced in 1991. Raw steel production capability was estimated by AISI as 102.6 million tons, down from 106.7 million tons in 1991. Production in 1992 represented 82.2% of estimated capability, compared with 74.7% in 1991.

Net shipments of steel mill products by U.S. companies increased about 4% to 74.6 million tons, from 71.5 million tons in 1991.

Electric arc furnace steelmaking was utilized for 32.0 million tons, 38.0% of total steelmaking in 1992. This is only slightly less than the record percentage for electric arc steelmaking of 38.4% set in 1991.

Basic oxygen steelmaking was utilized for 52.3 million tons, 61.6% of raw steel production, compared with 47.8 million tons and 60.0% of production in 1991.

For the first time since the open-hearth process was invented in the 19th century, there was no production of open-hearth steel reported in the United States for 1992. In 1991, open-hearth production was 1.3 million tons and 1.6% of production.

648 IRON AND STEEL—1992

The trend toward the use of continuous casting continued. Continuous casting production was 66.9 million tons, 79.3% of production, compared with 60.5 million tons, 75.8% in 1991.

Nucor Corp., operator of the first minimill to produce flat-rolled steel at its plant in Crawfordsville, IN, started up a similar minimill, at Hickman, AR. Each of the two Nucor flat-roll minimills has a capacity of about 1 million tons, and Nucor has announced its intention to expand each of the plants to about 2 million tons. Nucor's eventual goal is to have four plants with a total capacity of 8 million tons.

Florida Steel Corp., one of the largest of the U.S. minimill companies with five steelmaking plants in Florida and Tennessee, was purchased by Kyoei Steel, a Japanese minimill. Florida steel will operate as a wholly owned subsidiary of the Japanese firm, which also owns minority interests in two other U.S. minimill steelmaking companies.

Two significant mergers took place in the U.S. specialty steel industry. In the first merger, Armco Inc. acquired Cyclops Industries, Inc. Both were major producers of stainless flat-rolled steel and long products, with a total of five locations producing stainless steel. Armco announced that it would consolidate production of steel for its long products operations in the Bridgeville, PA, plant, formerly part of Cyclops. Steelmaking at Armco's Baltimore, MD, Specialty Steel Div. was discontinued.

The second important merger was the purchase by Lukens Inc., a Pennsylvania steel producer, of Washington Steel Co., Washington, PA, producer of stainless flat-rolled steel. Lukens had a strong position as a processor of stainless steel into plate products for other steelmakers, but itself had not been a melter of stainless steel.

Bethlehem Steel Corp. closed its Bar, Rod and Wire Div., including its steelmaking plant in Johnstown, PA.

Sharon Steel Corp., a small integrated company with blast furnaces and a steelmaking plant located in Farrell, PA, shut down in November 1992. Sharon had been attempting to develop a plan to emerge from bankruptcy proceedings.

Consumption and Uses

Shipments of steel mill products by U.S. companies were up 4.3%, to 74.6 million tons, but export shipments were down 41% from their record-setting level. Shipments to domestic customers were up more than 7%. Automotive shipments were up 11%, appliances were up 8%, and shipments to service centers and distributors were up 10%. Construction products were up about 7%.

Shipments of steel for containers, packaging, and shipping materials declined 7% in addition to a 5% decline in 1991.

Shipments for oil and gas drilling, mining, quarrying, and lumbering were about the same as the 1991 level, as were shipments for industrial and agricultural machinery, equipment, and tools.

Markets and Prices

Prices for steel mill products continued under severe pressure during the entire year. The Bureau of Labor Statistics' Producer Price Index for steel mill products was down by 2.8% at 106.4 (1982 base=100). Numerous efforts by steel companies to increase their prices were reported, but vigorous competition prevented prices from being increased.

Foreign Trade

Exports of steel mill products declined to 3.9 million tons, from 5.8 million tons in 1991. Canada was again the nation receiving the largest amount of U.S. exported steel, 1.3 million tons, with Mexico again in second place, also receiving 1.3 million tons. Declines in exports to Japan, the Republic of Korea, and Taiwan accounted for most of the year-to-year decrease in exports from those in 1991.

Imports of steel mill products increased about 8% from those of 1991. The European Community, Canada, and Japan were major sources for steel mill product imports. Increased imports from

Canada accounted for almost all of the year-to-year increase. Brazil and the Republic of Korea also were major importers, with much of the steel from these countries being imported in semifinished form for conversion in the United States into other steel mill products.

World Review

World production of pig iron and DRI in 1992 totaled 518.6 million tons, down 1% from that of 1991. Production dropped about 9% in Japan and almost 4% in the European Community. The collapse of economies in Eastern Europe and the former U.S.S.R. resulted in a 12% drop in that region. Steel production in these countries was down 32% compared with that of 1988.

Production in China increased about 9% to an estimated 73 million tons. With the breakup of the former U.S.S.R. into independent republics, China now rivals Japan for status as the top pig iron-producing nation in the world. India and the Republic of Korea are other major iron-producing nations that achieved continued growth in 1992.

Direct-Reduced Iron.—Although pig iron production dropped, world production of DRI increased to almost 21 million tons in 1992, with an 8% increase in the latest year and 52% over the past 5 years. Direct reduction of iron ore has proved to be a cost-effective way for developing countries, especially those with an abundance of natural gas, to encourage economic growth.

World capacity for DRI production was estimated to be 30 million tons, with an additional 8 million tons under construction. In India, one large gasbased direct reduction plant and several small coal-based plants were started up, bringing India's capacity for DRI to 2.2 million tons. An additional 2.7 million tons of capacity is under construction, with completion planned from 1993 through 1995.

Iran's program to develop DRI facilities was interrupted by its war with Iraq. With that conflict over,

construction of these facilities was resumed in 1989. About 1.3 million tons of capacity was started up in 1992; an additional 3.0 million tons was scheduled for 1993-94, which would bring Iran's total capacity for DRI to 5.8 million tons.

A gas-based direct reduction plant with a capacity of 0.65 million tons was started up in Saudi Arabia, and gas-based plants were under construction in Malaysia (1.2 million tons scheduled for 1993) and Indonesia (1.35 million tons scheduled for 1993).

Steel.—World production of steel was 721.3 million tons, down 2% from that of 1991. With the world economy in a recession, production in Japan was down more than 10% and in the European Community down 4%. The former U.S.S.R., which had been the leading steelmaking nation of the world, was dissolved into 14 independent republics. The combined production in the republics was down 12% from that of the former U.S.S.R. in 1991. Two of the republics, Russia and Ukraine, were fourth and fifth, respectively, among the steelmaking nations in 1992. Japan replaced the former U.S.S.R. in first place, followed by the United States and China.

Production of steel continued to increase in China, the Republic of Korea, India, and the Middle East.

OUTLOOK

The outlook for 1993 is for further declines in pig iron and steel production in the Eastern European nations and the former Soviet republics. Strong growth will continue in China, the Republic of Korea, the Far East, and the Middle East. The major economies of the European Community are suffering through a recession, and European steel production will decline again. In Japan, production will recover from the depressed levels of 1992.

For the long term, little growth of steel consumption is expected in the United States or countries with highly developed economies. Steel consumption tends to expand much more slowly than overall economic growth and to contract when economic growth is weak. The outlook for the U.S. steel industry is more uncertain. Imports have tended to capture an increasing share of the U.S. market, except when restrained by such devices as the VRA's. Even though U.S. companies have made great progress in modernizing their mills, adopting efficient technology, and reducing their costs, they have been unable to achieve profitability due to persistently low prices caused by intense competition by the foreign and domestic producers.

An important part of the competition to the integrated U.S. steel industry is that posed by minimills producing flatrolled steel. As described above, one steel company, Nucor Corp., has demonstrated that flat-rolled steel can be produced in a minimill at lower cost than that attainable by the integrated process. Buoyed by the success of its first plant, in Crawfordsville, IN, Nucor started up a second flat-roll minimill, in Hickman, AR, in 1992. Based on further success with the new processes, Nucor has announced its intention to double the capacity of the two plants, to a total of 4 million tons, and to build 2 more plants, either alone or in joint venture with others, increasing its capacity to 8 million tons. Other companies, noting Nucor's and optimism about the success possibilities of minimill production of flat-rolled steel, have announced similar intentions.

Some observers of the industry predict that as much as 20 million tons of capacity will be built by about the year 2000. With little or no growth in the market, any new capacity will have to displace either imports or integrated production from the U.S. market.

The supply of raw material for increased minimill production may become a problem in the United States. Although the United States traditionally has an excess supply of scrap and is a net exporter of about 9 million tons per year, the supply of low residual scrap necessary to produce flat-rolled steel and some other products may not be adequate. As noted in the section on DRI, imports of

DRI are increasing. In early 1993, Nucor announced that it will construct a plant in Trinidad to produce iron carbide, a form of DRI, for use in its U.S. plants. The plant will have a capacity of about 300,000 tons per year. Other minimill operators and iron ore producers are reported to be considering direct reduction plants to provide the necessary supply of low residual raw materials for the growing flat-roll minimill sector of the industry.

¹Includes furnace and merchant coke plants.

Source: Energy Information Administration, Quarterly Coal Report (DOE/EIA-0121).

¹Data do not add to total shown because of independent rounding.

²Coke production and consumption do not include breeze.

Direct reduced iron	 *14,417	¹ 16,555	r18,205	^r 19,413	20,946

Estimated. Revised.

¹Production is pig iron unless otherwise specified.

²Direct-reduced iron is obtained from ore by reduction of oxides to metal without melting.

³Table excludes ferroalloy production except where otherwise noted. Table includes data available through July 6, 1993.

In addition to the countries listed, Vietnam has facilities to produce pig iron and may have produced limited quantities during 1988-92, but output is not reported and available information is inadequate to make reliable estimates of output levels.

⁵Reported figure.

⁶Formerly part of Yugoslavia; data were not reported separately until 1992.

⁷Less than 500 tons.

^{*}Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁹Includes blast furnace ferroalloys.

¹⁰All production in the U.S.S.R. from 1988-91 came from Russia.

¹¹Dissolved in Dec. 1991.

¹²Dissolved in Apr. 1992.

Ferrotungsten (kilograms contained tungsten)	385,404	532,732	918,136
Silicomanganese	12,149	_	12,149

Steel formed in first solid state after melting, suitable for further processing or sale; for some countries, includes material reported as "liquid steel," presumably measured in the molten state prior to cooling in any specific form.

²Table includes data available through July 6, 1993.

³In addition to the countries listed, Burma, Ghana, and Mozambique are known to have steelmaking plants, but available information is inadequate to make reliable estimates of output levels.

⁴Reported figure.

⁵Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁶Data are for year ending June 30 of that stated.

⁷Formerly part of Yugoslavia; data were not reported separately until 1992.

⁸Dissolved in Dec. 1991.

⁹Includes steel castings.

¹⁰Dissolved in Apr. 1992.

Revised. W Withheld to avoid disclosing company proprietary data; included with "Miscellaneous and unspecified."

²Gross sales (including exports) minus purchases.

³Includes all regular and specialty grades of ferrosilicon, excluding silvery pig iron.

^{*}Includes ferroaluminum, ferroboron and other complex boron additive alloys, all chromium-containing ferroalloys and chromium metal, ferrocolumbium, all manganese-containing ferroalloys and manganese metal, ferromolybdenum, ferronickel, ferrotitanium, ferrovanadium, and silvery pig iron.

⁵Data may not add to totals shown because of independent rounding.

¹FeMn, ferromanganese, including spiegeleisen and manganese metal; SiMn, silicomanganese; FeSi, ferrosilicon, including silicon metal, silvery pig iron, and inoculant alloys; FeTi, ferrottanium, including other titanium material; FeP, ferrophosphorus, including other phosphorus materials; FeB, ferroboron including other boron materials.

²Part included with "Steel: Unspecified."

³Included with "Steel: Unspecified."

⁴Data may not add to totals shown because of independent rounding.

⁵Included with "Alloys (excluding alloy steels and superalloys)."

⁶Part included with "Alloys (excluding alloy steels and superalloys)."

⁷Part included with "Miscellaneous and unspecified."

[&]quot;Included with "Cast irons."

⁹Includes some producer stocks.

¹⁰Part withheld to avoid disclosing company proprietary data.

IRON AND STEEL—1992 677

Estimated. Revised. W Withheld to avoid disclosing company proprietary data; included with "Other."

¹Table includes data available through July 6, 1993.

²To the extent possible, ferroalloy production of each country has been separated according to the furnace type from which production is obtained; production derived from metallothermic operations is included with electric furnace production.

To the extent possible, ferroalloy production of each country has been separated so as to show individually the following major types of ferroalloys: spiegeleisen, ferromanganese, silicomanganese, ferrosilicon, silicon metal, ferrochromium, ferrochromium-silicon, and ferronickel. Ferroalloys other than those listed that have been identified specifically in sources, as well as those ferroalloys not identified specifically but which definitely exclude those listed previously in this footnote have been reported as "Other." Countries for which one or more of the individual ferroalloys listed separately in this footnote have been inseparable from some other ferroalloys owing to the nation's reporting system, such deviations are indicated by individual footnotes.

⁴Reported figure.

Formerly part of Yugoslavia; data were not reported separately until 1992. Imports of ferronickel originating in Macedonia were reported in 1992, but information on the output of the Kavadarci operation was not available.

⁶Includes silicomanganese.

⁷Included with other.

Includes ferrochromium-silicon and ferronickel, if any was produced.

⁹Includes silicospiegeleisen.

¹⁰Includes ferronickel if any was produced.

¹¹Formerly part of the U.S.S.R.; data were not reported separately until 1992.

¹²Series excludes calcium silicide.

¹³Includes ferrochromium-silicon.

¹⁴Includes calcium-silicon, ferrotungsten, ferromolybdenum, ferrovanadium, ferrocolumbium, and other ferroalloys.

¹⁵Estimated figures based on reported exports and an allowance for domestic use.

16 Includes production from Bophuthatswana. Includes net production of ferrochromium-silicon, if there was any.

¹⁷Dissolved in Dec. 1991.

¹⁸Soviet production of electric furnace ferralloys is not reported; estimates provided are based on crude source material production and availability for consumption (including estimates) and upon reported ferroalloy trade, including data from trading partner countries.

¹⁹U.S. output of ferromanganese includes silicomanganese and manganese metal.

²⁰U.S. output of ferrochromium includes high- and low-carbon ferrochromium, ferochromium-silicon, chromium metal, and other chromium materials.

²¹Dissolved in Apr. 1992.

²²Spiegeleisen for the Western states of Germany is included with blast furnace ferromanganese.

²³Ferromanganese includes silicomanganese (if any was produced) for countries carrying footnote 6 on "Ferromanganese" data line.

²⁴U.S. production under "Other" for 1988-92.

²⁵Includes silicospiegeleisen for France.

²⁶Ferrochromium includes ferrochromium-silicon (if any was produced) for Japan, Republic of South Africa, and United States.

IRON AND STEEL SCRAP

By Raymond E. Brown

Mr. Brown, a physical scientist with 37 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for iron and steel scrap since 1986. Domestic survey data were prepared by Henry F. Sattlethight and Cindy S. Liu, Section of Metals Data.

Use of iron and steel scrap to produce new steel and ferrous castings, vital to the United States for both national and economic well-being. represented significant energy, environmental, economic, and resource conservation benefits. Recycling of ferrous scrap also reduced the burden on limited landfill capacity. Direct-reduced iron (DRI), pig iron, and iron carbide could be substituted for iron and steel scrap but were usually considered more expensive than scrap. Also, availability of these substitutes on a large scale was limited, and there were certain technical problems associated with the use of some of these substitute materials. However, these scrap alternatives had certain advantages, which included providing iron free of residual elements, such as copper, for use in producing higher castings quality steel and ferrous products.

Brokers, dealers, and other outside sources supplied domestic consumers in 1992 with 41.8 million metric tons1 of all types of ferrous scrap at a delivered value of approximately \$3.90 billion, while exporting 9.26 million tons (excluding used rails for rerolling and other uses and ships, boats, and other vessels for scrapping) valued at \$1.10 billion. In 1991, domestic consumers received 41.4 million tons (revised) at a delivered value of approximately \$4.21 billion (revised); exports totaled 9.35 million tons valued at \$1.23 billion. This represented a tonnage increase of about 1% for received quantities and a tonnage decrease of about 1% for exported quantities. The total value of these received and exported scrap grades decreased by 8% and 11%,

respectively.

DOMESTIC DATA COVERAGE

Domestic production data for ferrous scrap were developed by the U.S. Bureau of Mines from voluntary monthly or annual surveys of U.S. operations. Of the operations to which a survey request was sent, 58% responded, representing an estimated 81% of the total consumption shown in table 2 for the three types of scrap consumers indicated. Consumption for nonrespondents was estimated using prior reports adjusted by industry trends. An estimation error was also contained in the difference between the reported total consumption of purchased and home scrap and the sum of scrap receipts plus home scrap production, less scrap shipments and adjustments for stock changes. For scrap consumption data shown in table 2, this difference amounted to 1% for manufacturers of pig iron and raw steel and castings, 1% for manufacturers of steel castings, 6% for iron foundries and miscellaneous users, and 2% average for all types of manufacturers combined. (See table 1.)

ANNUAL REVIEW

Legislation and Government Programs

According to the U.S. Nuclear Regulatory Commission, radioactivity in scrap metal will be a problem for the foreseeable future. There have been at least 11 reported smeltings of discrete radioactive sources in the United States since 1983. Cleanups have cost, on the average, more than \$1 million for each

event. Accidental smeltings of radioactive scrap was an international problem as well as a domestic one.²

Recycling old landfills, an unusual approach taken by the Lancaster County Solid Waste Management Authority in Lancaster County, PA, had paid significant dividends. Excavating the landfill and sending it to Lancaster County's waste-to-energy facility enabled the county to extract four elements of value from the waste stream. These included landfill space, energy, ferrous metals, and soil.³

On September 1, Westchester County officials in Westchester County, NY, made recycling mandatory for residents and businesses in this suburban area.⁴

The Environmental Protection Agency (EPA) published its proposed rule for coke oven emissions in December. The proposed national emission standards for hazardous air pollutants would amend section 112 of the Clean Air Act Amendments of 1990. The proposed rule, which was based on a series of negotiations among government, industry, and environmental groups, provided two methods of compliance for coke producers and steel companies with coke ovens.⁵

The Steel Manufacturers Association (SMA) urged Congress to consider a long-term solution to the national budget deficit by adopting a value added tax, rather than an energy tax, as a major alternative to personal and corporate income taxes. The American Iron and Steel Institute (AISI) stated that a Btu energy tax would hit energy intensive industries hardest and undermine the international competitiveness of the

United States.

On November 10, the U.S. Bureau of Mines and the American Metal Market (AMM) cosponsored a conference, "Challenges Facing Materials Recycling," in Washington, DC. The conference provided an opportunity to exchange information, to generate ideas on reducing waste as a means of conserving natural resources, and to explore new avenues by which the Bureau could contribute in this effort. Dr. Herschel Cutler, Executive Director of the Institute of Scrap Recycling Industries, Inc. (ISRI), presented the keynote address. Dr. Cutler provided an overview of the challenges facing materials recycling and methods that could be implemented for increased materials recycling. Dr. Cutler stated that environmental laws like the Resource Conservation and Recovery Act (RCRA) were equating recyclable materials with garbage and were doing little to stimulate markets for these materials.

The luncheon speaker at the U.S. Bureau of Mines-AMM conference, a congressional representative from Indiana, said that the metals industries could see a "greener" **RCRA** reauthorization bill in the upcoming session of Congress.⁶ A special report, "Iron and Steel Scrap Prices in the United States Through 1991," was prepared for and distributed to attendees at the November 10 forum by the Bureau's iron and steel scrap specialist. The U.S. Bureau of Mines scrap prices study revealed that, based on constant 1987 dollar terms, the selling price of No. 1 heavy melting steel scrap in 1991 was about one-half of that in 1909. summary of this report also had been published by AMM on October 29, 1992.7

In December, a representative of the Association of Home Appliance Manufactures (AHAM) stated that AHAM supported the EPA's proposed regulations governing service and disposal of equipment using chlorofluorocarbons (CFC's) and hydrofluorocarbons. However, an official of ISRI opposed the proposed rule on refrigerant recycling. According to ISRI, the EPA-proposed

rule improperly placed the ultimate responsibility for CFC removal on the recycler.

ISRI complained of "unnecessary and burdensome regulations" that, in its opinion, could be cut or curtailed. First on the ISRI list was the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA or Superfund), which, according to ISRI, made no distinction between materials headed for recycling and those headed for disposal. ISRI also asked the EPA to make a distinction within the current RCRA law between items considered waste and those considered secondary materials. §

Available Supply, Consumption, and Stocks

Overall domestic demand for ferrous scrap in 1992 by the iron and steel and the ferrous castings industries, the major consumers of this raw material, increased about 4% compared with that of 1991. Because of continued weak demand worldwide for ferrous scrap in 1992, average annual prices for most scrap grades declined.

According to the Steel Can Recyling Institute (SCRI), Pittsburgh, PA, the recycling rate for steel cans jumped from 34% in 1991 to nearly 41% in 1992. More than 1 million tons of steel cans (about 14 billion containers) was recycled in 1992. SCRI had set a recycling goal for steel cans of 66% by 1995. When SCRI was established in late 1988, only 15% of the steel cans produced was being recycled. The Can Manufacturers Institute (CMI), Washington, DC, reported that about 35.1 billion steel cans were shipped in the United States in 1992, down slightly from 35.3 billion in 1991.

Three of the Keep America Beautiful, Inc. (KAB) affiliates that had worked to educate citizens about recycling as well as increase the volume of metals and materials recovered were honored with the 1992 Steel Recycling Award at KAB's annual meeting in Washington, DC. The winners were Keep San Antonio, TX, Beautiful; Indianapolis, IN, Clean City

Committee; and Pitt County, NC, Clean Sweep. The award was jointly sponsored by KAB, Stamford, CT; the SCRI, Pittsburgh, PA; and the AISI, Washington, DC.

In September, German automaker BMW AG was awarded "Best Recycling Innovation In 1992" at the National Recycling Coalitions (NRC) annual conference in Boston, MA. One reason for the company being chosen as the winner was because of its two-step approach to recycling.

Proler International Corp. sold its Houston, TX, ferrous and nonferrous scrapyard to the U.S. subsidiary of Compagnie Française des Ferrailles (CFF), a large French scrap processor. Proler International had been experiencing financial problems for about 2 years since the shutdown of its Houston detinning plant and writeoff of the operation. The sale to CFF included only the 18-hectare (44-acre) Wallisville Road facility and not the other two wholly owned shredder processing facilities in El Paso, TX, and Kansas City, KS, that Proler had been trying to sell. The sale of the Houston operation indicated that Proler would be moving its corporate headquarters to another location.9

Nucor Corp., headquarted Charlotte, NC, commissioned in August a second minimill equipped with a thinslab caster and hot-strip mill for the production of steel sheets. The new \$300 million steel mill complex, in Hickman, AR, had a production capability of about 1 million tons per year. The capacity of the new steel mill in Hickman, AR, combined with that of the Crawfordsville. IN, plant provided Nucor with an overall capacity of approximately 2 million tons per year of hot-rolled steel sheets at yearend 1992. Also, Nucor and Oregon Steel Mills, Inc., planned to build a 1million-ton-per-year thin-slab sheet minimill in the Western United States. Both companies signed a letter of intent at yearend for the construction and operation of the \$350 million jointventure plant, which would be 60% owned by Nucor. The new mill could start producing by late 1995. partners were also assessing the addition of virgin ironmaking facilities to feed the new minimill, including DRI and iron carbide. By the end of the 1990's, Nucor envisioned operating four flat-rolled minimill steel plants with a combined annual capacity of about 8 million tons. Each plant would have an annual capacity of about 2 million tons.

USX Corp., headquartered in Pittsburgh, PA, ceased producing structural and piling products when its Southworks in Chicago, IL, was closed in April 1992. The permanent closure brought an end to the plant's 112 years of steelmaking operations. The three electric furnaces at Southworks had been major consumers of ferrous scrap.

Co-Steel Inc., Toronto, Ontario, Canada, was also considering building a 0.8- to 1-million-ton-per-year thin-slab, flat-rolled minimill in the United States. Construction of the proposed U.S.-based facility could start in 1993. Thin-slab technology also was being assessed by some integrated steel producers.

Stafford Railsteel Corp., Charlotte, NC, a newly formed company, would construct a 450,000-ton-per-year greenfield plant to produce rails. A startup date of mid-1994 for the \$105 million investment was targeted.¹⁰

There was no raw steel produced in U.S. open-hearth furnaces in 1992. The last open-hearth shop, owned by Geneva Steel Co., Provo, UT, switched from open-hearth to basic oxygen steelmaking in 1991.

Japanese minimill steel producer Kyoei Steel Ltd., Osaka, planned to acquire Florida Steel Corp.'s parent company, FLS Holdings, Inc., in a stock purchase deal valued at \$53.5 million. Completion of the transaction was conditional, which included the purchase by Kyoei of 90% of Florida Steel's debentures.¹¹

By the end of fiscal year 1993, Birmingham Steel Corp., headquartered in Birmingham, AL, planned to complete a \$79 million program to modernize and upgrade four minimill steel plants in Birmingham, AL, Jackson, MS, Kankakee, IL, and Seattle, WA (Salmon Bay). Birmingham continued to evaluate new minimill technologies such as thin-slab and strip casting.

As part of a \$42 million upgrade, New Jersey Steel Corp., Sayreville, NJ, decided to retrofit its existing electric arc furnace (EAF) with a Consteel continuous feeding and preheating system. The Consteel system used furnace offgas to preheat the scrap, which should save an estimated \$10 per ton on steel production. Startup was scheduled for February 1994. Other modernizations planned for the Sayreville plant included buying a new caster, melt shop, and pollution control system and renovating the melt shop's infrastructure.

North Star Steel Co., headquartered in Minneapolis, MN, was considering building a 300,000- to 500,000-ton-per-year minimill in the Western United States for the production of rebar and wire rods. A decision to enter into a joint venture with Cleveland Cliffs Inc. was pending.

BMW of North America named three auto dismantlers that would participate in its pilot automobile recycling program in the United States. The recycling program was a cooperative effort between BMW and the Automotive Dismantlers and Recyclers Association (ADRA). Also, the Big Three domestic automakers combined their efforts and formed the Vehicle Recycling Partnership (VRP) to research and promote the recovery and reuse of materials from junked cars. Similar automotive recycling programs were active in Europe. Applications for stainless steel in North American-built cars and trucks were expected to increase again in the 1993 model year as a result of the automobile industry's strategy to improve the performance, durability, and fuel efficiency of its vehicles.

The Chicago Board of Trade (CBOT), Chicago, IL, still hoped to offer futures contracts for two grades of ferrous scrap and was reexamining the financial and bonding requirements that were said to pose the biggest hurdles to the trading scheme. The futures contracts for shredded scrap and No. 1 dealer bundles were to be a part of CBOT's Project A, an electronic trading system that began operating in October 1992. The CBOT board might offer a revised version of the scrap futures trading scheme by late

February 1993.

Imports of metallurgical-grade coke increased 58% in 1992 to 1,578,000 tons compared with those of 1991. Metallurgical coke imports represented 7% of domestic apparent consumption in 1992 compared with 5% in 1991. The United States continued as a net importer of metallurgical coke. Domestic coal consumption in coke plants decreased 4% in 1992 to 29.4 million tons. Domestic metallurgical coal exports decreased 8% in 1992 to 53.9 million tons compared with those of 1991.

Raw steel production was 84.3 million tons in 1992 compared with 79.7 million tons in 1991. The shares of raw steel produced by electric, basic oxygen, and open-hearth furnaces were, respectively, 38%, 62%, and 0% in 1992 and 38%, 60%, and 2% in 1991. Continuous cast steel production represented 79% of total raw steel production in 1992 compared with 76% in 1991. Raw steel capacity utilization was 82% in 1992 and 75% in 1991. Raw steel production capability was 102.6 million tons in 1992 compared with 106.7 million tons in 1991.

Net shipments of all grades of steel mill products were 74.6 million tons in 1992 and 71.5 million tons in 1991. Imports of steel mill products increased from 14.4 million tons in 1991 to 15.5 million tons in 1992. Exports of steel mill products decreased from 5.76 million tons in 1991 to 3.89 million tons in 1992. The U.S. apparent supply of steel mill products increased from 80.1 million tons in 1991 to 86.2 million tons in 1992. Imports of steel mill products, as a share of the U.S. market, were 18% in both 1991 and 1992. Estimated steel mill processing yields [(total net shipments of steel mill products/total raw steel production) (100)] decreased from 90% in 1991 to 88% in 1992. Pig iron production increased from 44.1 million tons in 1991 to 47.4 million tons in 1992.

Iron castings shipments totaled 7.34 million tons in 1992 compared with 6.95 million tons (revised) in 1991. Steel castings shipments (including investment castings) totaled 0.93 million tons in 1992 compared with 0.90 million tons (revised)

in 1991.

In 1992, steel mills accounted for 76% of all scrap received from brokers, dealers, and other outside sources; steel foundries received 5%; and iron castings producers and miscellaneous users The apparent total received 19%. domestic consumption of ferrous scrap in 1992, in million tons, was composed of 41.6 net receipts (total receipts minus shipments), 22.0 home scrap, and 0.4 withdrawals from stocks. The 1992 total was 64.0 million tons; the apparent total domestic consumption was 62.4 million tons (revised) in 1991. The total market for U.S. scrap (net receipts plus exports minus imports) was 49.6 million tons in 1992 compared with 48.7 million tons (revised) in 1991. Stocks of ferrous scrap at yearend 1992 held by both steel mills and iron foundries decreased while those held by steel foundries increased. (See figure 1.)

Prices

Based on average composite delivered prices per long ton quoted weekly and monthly by the American Metal Market (AMM), converted to metric tons, No. 1 heavy melting steel scrap cost \$84.67 in 1992, ranging from a low of \$82.67 in November to a high of \$87.24 in April. Based on Iron Age data, also converted to metric tons, No. 1 heavy melting steel scrap cost \$83.88 in 1992, ranging from \$82.21 in November to \$86.65 in December. The average composite price for No. 1 heavy melting steel scrap in 1992 was lower compared with that of 1991, by 8% based on AMM data and by 9% based on Iron Age data. Based on prices quoted weekly by Iron Age for tonnages of 18-8-grade stainless steel scrap (bundles and solids) delivered to consumers in the Pittsburgh, PA, area, the average price of nickel-bearing stainless steel scrap decreased 14%, from \$861.28 per ton in 1991 to \$742.56 per ton in 1992.

In 1992, the average price for total ferrous scrap exports (excluding used rails for rerolling and other uses and ships, boats, and other vessels for scrapping) decreased 10% to \$118.74 per

ton compared with that of 1991, while that of total imports decreased 16% to \$112.20 per ton.

Foreign Trade

Foreign trade tables were based on the Harmonized Tariff Schedule (HTS), which became effective January 1, 1989. Additionally, valuation continued to be reported on an f.a.s. basis for exports and on a customs value basis for imports.

The trade surplus in 1992 for all classes of ferrous scrap (including used rails for rerolling and other uses and ships, boats, and other vessels for scrapping) was \$950 million in value and 8.0 million tons in quantity. This represented a decrease of 13% in value and 4% in quantity compared with the 1991 surplus of \$1.09 billion in value and 8.3 million tons in quantity. The balance of trade for all U.S. merchandise [exports (f.a.s.) less imports (customs value)] showed a deficit of \$84.3 billion in 1992, up from a deficit of \$65.4 billion in 1991.

The quantity and value of total exports in 1992 declined by 1% and 11%, respectively, compared with those of 1991. In contrast, the quantity and value of total imports in 1992 increased by 19% and 3%, respectively, compared with those of 1991.

Total U.S. exports of ferrous scrap (excluding used rails for rerolling and other uses; ships, boats, and other vessels for scrapping; stainless steel; and alloy steel) in 1992 went to 52 countries and totaled 8,709,768 tons valued \$881,952,004 for an average of \$101.26 per ton. Six countries received 83% of the total quantity. The largest tonnages went to Turkey, 2,018,666 tons; the Republic of Korea, 2,000,927 tons; India, 1,235,968 tons; Canada, 1,012,893 tons; Mexico, 533,015 tons; and Taiwan. 456,600 tons. The value of scrap exports to these six countries was \$711,099,299, 81% of the total value.

Total U.S. exports of stainless steel scrap in 1992 went to 34 countries and consisted of 223,200 tons valued at \$153,701,762 averaging \$688.63 per ton. Six countries received 90% of the total

quantity. The largest tonnages went to the Republic of Korea, 64,588 tons; Japan, 56,787 tons; Spain, 41,406 tons; Canada, 22,420 tons; Italy, 7,913 tons; and Taiwan, 7,449 tons. The value of stainless steel scrap exports to these six countries was \$137,695,695, 90% of the total value.

U.S. exports of alloy steel scrap (excluding stainless steel) in 1992 were shipped to 40 countries. The total comprised 328,984 tons valued at \$64,148,317, for an average of \$194.99 per ton. Six countries received 86% of the total quantity. The largest tonnages went to Canada, 127,370 tons; Hong Kong, 71,007 tons; Mexico, 32,031 tons; China, 30,778 tons; Republic of South Africa, 11,683 tons; and Japan, 10,750 tons. The value of alloy steel scrap to these six countries was \$49,149,355, which was 77% of the total value.

In 1992, based on tonnage of iron and steel scrap by customs district, Los Angeles, CA, was the leading customs district for exports, accounting for 16% of the total exports. New York, NY, followed with 15%, and San Francisco, CA, with 11%. Laredo, TX, was the leading customs district for reexports, accounting for 68% of the total reexports. New York, NY, followed with 10%, and Los Angeles, CA, with 10%. Detroit, MI, was the leading customs district for imports, accounting for 29% of the total Seattle, WA, followed with imports. 25%, and Buffalo, NY, with 9%. For more details on customs districts, including tonnages and values, refer to published data in U.S. Bureau of Mines Mineral Industry Surveys on iron and steel scrap. 12

Total U.S. imports for consumption of iron and steel scrap, which were supplied by 37 countries in 1992, contained 28,494 tons of tinplate waste or scrap valued at \$7,062,603.

World Review

World demand for iron and steel scrap in 1992 was estimated to have decreased by 2% compared with that of 1991. However, demand for ferrous scrap in 1992 increased in certain major steel-

producing countries. These included industrialized countries such as Australia, Canada, Finland, the Netherlands, Sweden, Turkey, and the United States; Asian countries, such as China, India, Indonesia, and the Republic of Korea; Latin American countries, such as Brazil, Mexico, and Venezuela; and Middle Eastern countries, such as Iran and Saudi Arabia.

The United States continued to be the leading exporting country of iron and steel scrap. France, Germany, the Netherlands, Russia, and the United Kingdom were also major exporters of ferrous scrap.

European Community (EC) member states would be given 10 years to raise the EC packaging recovery rate from about 18% to 90% under a plan proposed by the EC. Details of the proposal, which must win approval by the EC's Council of Ministers, showed individual EC countries would have wide latitude in determining how the goal would be met on a national level. The aim was to cut a large share of the 50 million tons of packaging waste generated annually in the EC that was burned or sent untreated to landfills.¹³

The Bureau International de la Recuperation (BIR), Brussels, Belgium, supported various events such as roundtable discussions of policies governing the recycling of cars, packaging, and agricultural products in Europe. The BIR had encouraged more emphasis on the recycling of industrial waste and less on municipal waste.

The BIR and Greenpeace International, Washington, DC, continued not to agree on an accord on what constitutes hazardous waste. In a letter made available to the press, the BIR reiterated the scrap industry's support for the socalled red-yellow-green system that was devised by the Organization for Economic Cooperation and Development (OECD), Paris, France. The OECD defined scrap and waste products and outlined plans for monitoring or controlling cross-border shipments of the most hazardous of these materials. The system was devised as a means of complying with the Basel Convention, an international treaty

designed to limit the shipments of hazardous wastes from the industrial countries to the world's less-developed nations. Greenpeace had opposed the OECD plan and instead had demanded that the definitions specified in the Basel Convention be applied by those who monitor trade in scrap and waste materials.

Officials of the International Iron and Steel Institute (IISI), Brussels, Belgium, invited executives of some of the largest electric furnace steel producers (minimills) to join IISI's organization. IISI's Secretary General disclosed during a report to delegates at the start of IISI's 26th annual meeting in Tokyo, Japan, that officials of the Institute had attempted to bring into the organization companies such as North Star Steel Co. and Birmingham Steel Corp., two of North America's biggest minimills. IISI projected that world steel usage would increase by about 32 million tons to 686 million tons by the year 2000.

According to the supplies director of the Gerdau minimill steel works group, Brazil's high port costs would have to be reduced before imported steel scrap could become a viable proposition for Brazilian electric steelmakers. Delegates at a seminar on scrap in Sao Paulo in October noted that the Government's port reform bill, which would deregulate the ports and clear the way for more competitive practices, was working its way through Congress and was expected to become law.¹⁴

Because of the success of a pilot project in three Ontario, Canada, communities. Ontario Hydro would expand its refrigerator recycling program provincewide at a cost of \$27 million. Ontario Hydro was targeting secondary, operating refrigerators. Some second refrigerators had been sitting basements, taking up space, and wasting Under the program, the electricity. electric utility would remove unwanted refrigerators and pay the owners \$50, regardless of the refrigerator's condition.

China's economy, one of the fastest growing in the world, expanded at a rate of about 13% in 1992, far exceeding Government targets designed to keep down inflation. Raw steel production in China was 80.0 million tons in 1992 compared with 71.0 million tons in 1991.

In December, France's environmental minister planned to call for new regulations that would require all major consumer appliances sold throughout the EC to be completely recyclable within 10 vears. The French Environmental Minister had announced plans earlier in the year to establish a system to process packaging waste similar to the programs Germany had pursed for the past 2 years. France's two major automakers, PSA Peugeot Citroen SA and state-owned Renault SA, had decided to work together to develop a system that would recycle up to 200 junked cars per day.

A joint venture between German steel and scrap group Klockner Kunstoff-und Automobilrecycling GmbH (KKA) and Kriesow, Germany's largest auto dismantler, to disassemble 25,000 cars annually was expected to begin in 1993. The joint venture was the first of KKA's overall plan for as many as 20 facilities around Germany in partnership with local dismantlers to process about one-half million autos per year. The first plant would be built in Hamburg, Germany, at a cost of about \$9.4 million, shared equally between KKA and Kriesow.15 Germany's Environmental Minister proposed a regulation that would require automakers to take back old cars that were no longer roadworthy. Metallgesellschaft AG, a German metals conglomerate, had formed a new unit for recycling in Australia and Southeast Asia. A German scrap recycler, a German aerospace company, and consortium of Russian defense companies had entered into a cooperative agreement to dismantle and recycle 1.6 million tons of Russian munitions.

The Indian steel ministry had taken a determined stand against the demands of DRI producers to increase the import duty on ferrous scrap. The duty on ferrous scrap imports had been cut from 35% to 10% about 1 year ago. 16 However, tariffs on Indian imports of ships for breaking were 15% in 1992, 5% higher than those for ferrous scrap imports.

Because increased volumes of ferrous scrap had been generated at home, Japan became a net exporter of ferrous scrap for the first time in 1992. Shipments of ferrous scrap to Japan had fallen off sharply during the second half of 1991 and throughout much of 1992. About 50% in volume of all steel cans produced in Japan had been recycled in 1991, up from about 45% in 1990.

An 800,000-ton-per-year directcurrent (DC) EAF thin-slab casting flat product mill complex was to be installed in Monterrey, Mexico, by Hojalata Lamina SA de CV (Hylsa). Startup of the \$400 million facility was scheduled for early 1995. The 150-ton DC furnace would be charged with DRI made from Hylsa's proprietary HYL technology.¹⁷ The privatization program, under which the Mexican Government had been selling some of its industrial interests, was completed for the Mexican steel industry in 1991.

Much of what the Soviet Army left behind in eastern European cities and towns where its troops once were garrisoned may end up in local scrap yards. According to a report from the Polish press agency, residents who lived near an abandoned base in western Poland sifted through what remained at the site and sold it. The cache included 40 tons of artillery shells, missiles, and bombs. 18

Pohang Iron and Steel Co. Ltd. (POSCO), headquartered in Pohang, the Republic of Korea, ordered a 600,000-to 700,000-ton-per-year Corex unit for its Pohang steelworks. The Corex hot-metal facility at Pohang would have doubled the capacity of the plant in operation at Iscor Ltd.'s works in the Republic of South Africa.

Russia was granted most-favorednation status for trade relations with the United States on June 17, 1992.¹⁹ The Russian metallurgical industry was characterized by a low share of advanced steelmaking methods. Of the total raw steel produced in Russia, basic oxygen furnaces and electric furnaces accounted for less than 50% and continuous casting amounted to only 18%.

Independent steel producers in Spain

asked the state-owned Ensidesa-AHV group to close down its long products operations as part of a restructing plan that was being discussed. The minimill federation Siderinsa had called for negotiations to eliminate the overlap in wire rod and heavy sections between Ensidesa and the private-sector producers.

A 77-ton shipload of scrap metals contaminated with radioactive material returned to Russia. Swedish customs officials had discovered the hot metal aboard a ship that had carried scrap exported from Estonia. The contaminated metals had originated within Russia.²⁰

Contaminated ferrous scrap imported into Taiwan in the early 1980's reportedly was the source of radiation found in three buildings in Taipei. Taiwan's Atomic Energy Council found contaminated steel reinforcing bars in the structure of an office building and two apartment buildings in the capital city.²¹

The United States continued to be Turkey's major supplier of ferrous scrap. However, the U.S. competitive position had eroded from providing Turkey with 70% of all iron and steel scrap imports in 1989 to just 45% in 1992. The United States was still the largest supplier of ferrous scrap to Turkey in 1992 but the Netherlands had rapidly become a serious competitor.

The United Kingdom's first dedicated car dismantling and recycling plant was opened by German automaker BMW AG and Bolney Motors, a British salvage company. The joint venture was the first of 15 similar partnerships that BMW hoped to make with British salvagers over the next 3 years, each capable of processing 2,500 vehicles. The BMW-Bolney plant would follow a reverse auto assembly line approach to dismantle vehicles, with as many components as possible resold through Bolney's established used-parts business. British steel mills consumed less scrap but more iron ore and pig iron in 1991 than in the The level of circulating scrap past. generated by the British steel industry had been declining since 1981 as a result of continuous casters taking a larger share of steel production capacity.

Current Research

Since 1985, EAF's had produced 36% to 38% of the nearly 80 to 90 million tons of raw steel produced annually in the A review of EAF United States. technologies, equipment, charge materials, and operating practices with respect to optimizing energy use was published by the Center for Materials Production (CMP), Pittsburgh, PA. The report was designed to provide operators and utility personnel with understanding of the factors that impacted the use of electrical energy. Such an understanding would be supportive of the continued upward trend of EAF steel production as a percentage of the domestic total.²² CMP also had sponsored a major symposium on EAF dust treatment technologies in Pittsburgh, PA, on January 28.

Cyprus Northshore Mining Co. planned to start building a 450,000-ton-per-year direct reduction iron plant at its Silver Bay, MN, taconite facility in 1993. Cyprus planned to use Midrex's Fastmet technology, which used coal as a reductant, for its initial \$50 million plant that would begin production in late 1995. Three additional 450,000-ton-per-year iron furnaces also had been on the drawing board.²³

Nucor would build the world's first commercial-scale iron carbide plant in Trinidad and Tobago and ship the iron units to the United States to feed its steel The U.S. minimill steelmaker mills. would spend \$60 million to build a 300,000-ton-per-year single-module facility that could be significantly expanded in future years. Construction was expected to begin by the end of March 1993 with startup anticipated in late 1994. Nucor would use the iron units to supplant a portion, about 15%, of the low residual scrap consumed at its sheet mills in Crawfordsville, IN, and Hickman, AR. With combined annual steelmaking capacity at those two plants at about 2 million tons, iron carbide requirements would be about 300,000 tons per year.

A new system for recovering nonferrous metals from shredder fluff

began operation at The David J. Joseph Co.'s, Tampa, FL, processing yard. The nonferrous metal recovery system, which employed eddy current magnets, would remove virtually all of the nonferrous metals from the residue left by auto shredders, according to the manufacturer of the system.²⁴

According to the Gas Research Institute, Chicago, IL, experiments conducted at Armco Steel Co., L.P.'s, Middletown, OH, Works No. 3 blast furnace showed natural gas could replace 25% or more of the coke burden and yield a net savings of about \$5 per ton of hot metal. The experiments, which had been done over a 2-year period, showed that charging natural gas at a rate of 97 kilograms per metric ton of hot metal yielded a savings of 25% of the coke normally charged and increased productivity by 10%.

OUTLOOK

The total market for U.S. ferrous scrap is affected by many factors. For example, major factors that impact the demand for domestic scrap include the quantities of domestic raw steel and ferrous castings produced, the level of scrap exports, and Government laws and regulations. To a lesser extent, other factors affecting the overall market for U.S. scrap include the production levels of U.S. industries that make ferroalloys, cement copper, and certain chemicals; the use of scrap substitutes; technological changes in steel mills and ferrous foundries; and the value of the U.S. dollar in relation to other world currencies. The health of the world's steel mills and ferrous foundries is of the utmost importance to the domestic scrap industry. The United States, the world's leading exporter of ferrous scrap, relies heavily on exports as a safety valve for the release of excess scrap when domestic demand slips.

The overall outlook for the total market for U.S. ferrous scrap through 1995 is expected to be one of continued growth. The total market for U.S. scrap is forecast to increase from 49.6 million tons in 1992 to approximately 53 million

tons in 1995, which represents an average annual growth rate of about 2%. This optimistic forecast is based on a combination of favorable factors affecting the market, which include continued world growth in the quantity of steel produced in scrap-based EAF's; an increase in the percentage of steel that is continuously cast; and an absence of excessive Government rules or restrictions on U.S. exports of scrap.

Revised.

Internal evaluation indicates that scrap consumption by manufacturers of pig iron and raw steel and castings is understated by the following approximated quantities: 4.7 million metric tons in electric furnaces and 0.2 million metric tons in open-hearth furnaces in 1988; 6.6 million metric tons in electric furnaces and 0.9 million metric tons in open-hearth furnaces in 1989; 2.9 million metric tons in electric furnaces in 1990; 2.8 million metric tons in electric furnaces in 1991; and 3.5 million metric tons in electric furnaces in 1992.

Internal evaluation indicates that pig iron consumption (for open-hearth furnaces) is understated by approximately 1.5 million metric tons in 1988 and 0.8 million metric tons in 1989.

³Excludes used rails for rerolling and other uses and ships, boats, and other vessels for scrapping.

¹Less than 1/2 unit.

²Data may not add to totals shown because of independent rounding.

Internal evaluation reveals that scrap consumption in electric furnaces operated by manufacturers of pig iron and raw steel and castings is understated by approximately 3.5 million metric tons.

TABLE 3

¹Includes molten pig iron used for ingot molds and direct castings.

²All data for 1991 have been revised.

³Data may not add to totals shown because of independent rounding.

⁴Less than 1/2 unit.

⁵Internal evaluation indicates that scrap consumption in electric furnaces operated by manufacturers of pig iron and raw steel and castings is understated by approximately 2.8 million metric tons.

LEAD

By William D. Woodbury

Mr. Woodbury, a physical scientist with the U.S. Bureau of Mines, Branch of Metals, had 25 years of mining and civil works geotechnical experience upon becoming the Bureau's lead specialist in 1982. Domestic survey data were prepared by Eraina Dixon and Lisa Conley, statistical assistants; and international data were prepared by Theodore Spittal and Virginia Woodson, international data coordinators.

Lead is a soft, heavy metal, the most corrosion resistant of the common metals. and one of the oldest metals used by man. Among the nonferrous metals, in terms of tonnage, demand for lead is surpassed only by demand for aluminum, copper, and zinc. Some historians have theorized that the downfall of the Roman Empire was expedited by the debilitating effects on its citizens of drinking water carried in lead pipes. Buildings built in Europe four centuries ago still stand under their original lead roofs. Today's major use of lead is in lead-acid storage batteries. The electrical systems of vehicles, ships, and aircraft depend on such batteries for startup, and in some cases, batteries provide the actual motive power. Other batteries provide standby electrical power for emergencies, and very large lead-acid systems are designed to provide "peaking" power in such applications as commercial networks and subway systems. increasing use is in the uninterruptible power supply systems necessary for voltage control and emergency power in critical computer storage systems. Lead in gasoline, once the second largest use of lead in the United States, has been virtually phased out to eliminate the health hazard it was found to present. Some nontransportation uses of lead include increasing use for soundproofing in office buildings, schools, and hotels and earthquake shock dampening in building foundations. It is widely used in hospitals to block X-ray and gamma radiation and is employed to shield against nuclear radiation both in permanent installations and when radioactive source material is being stored

and/or transported.

After 7 consecutive years with a growth of 700,000 metric tons, from 5.17 million tons in 1982 to the record 5.87 million tons (revised) in 1989, world demand for lead declined for 3 years by about 400,000 tons to an estimated 5.47 million tons in 1992, owing to the worldwide recession. For many years before 1983, primary metal demand represented about 60% of the total, but gradually declined to about 55% in 1988-92. This trend is expected to continue downward in the future as the overall end-use pattern becomes less dissipative. result of evolving worldwide environmental consciousness, leading also to stronger recycling efforts. Although total refinery production continued fairly strong in 1992, leading to record worldwide yearend metal stocks estimated at 760,000 tons (exclusive of the U.S. National Defense Stockpile), world mine production declined to the lowest level since 1968, the year before Viburnum Trend production in Missouri came fully on-stream. Only in Canada were significant gains reported; significant declines among major producers occurred in China, the United States, and the warravaged former Yugoslavia. World and North American average prices at yearend were \$0.04 and \$0.023 per pound below those at yearend 1991. There was no yearend rally, which is unusual, and prices were expected to continue downward owing to the large inventories. The record average spread between the two prices, \$0.106 per pound, forced domestic net metal imports, after 2 very low years, to soar back to the historic levels of recent

decades.

DOMESTIC DATA COVERAGE

Domestic data for lead are developed by the U.S. Bureau of Mines from five voluntary surveys. Typical of these are the combined secondary producer and consumer surveys, both monthly and annual. Of the 195 consuming companies to which a survey request was sent, 154 responded, representing 86% of the total U.S. lead consumption shown in tables 1. 6, 7, and 8. Of the 39 companies producing secondary lead, exclusive of copper base, to which a survey request was sent, 29 responded, representing 82% of the total refinery production of secondary lead, shown in tables 1, 5, and 9. Production and consumption for the nonrespondents were estimated using prior-year levels adjusted for general industry trends. (See table 1.)

ANNUAL REVIEW

Legislation and Government Programs

Although there was considerable legislative and regulatory investigative activity relative to lead in 1992, only the final drinking water regulations, promulgated under the Safe Drinking Water Act, of June 1991, became effective during the year (June 29). The rules seek to reduce lead levels from an average of 50 parts per billion (ppb) to 15 ppb in at least 90% of monitored households. In addition, water systems must meet a maximum contaminant level goal (MCLG) of "0" for lead under the source water requirements of the

regulation. The effective dates for meeting action levels and for replacing lead service lines are staggered, but the longer lead remains in pipes the less it leaches; thus, newer homes are deemed worst for systems monitoring. systems with more than 50,000 users must implement corrosion control, which involves simply altering the system chemistry to reduce lead solubility. Systems serving fewer than 500 persons are exempt. The Environmental Protection Agency (EPA) estimates that 95% of lead in drinking water can be reduced through corrosion control and estimates total capital costs to be \$630 million with annualized costs of \$210 million. All water systems that continue to exceed the lead action level after installing optimal corrosion control, and, if necessary, source water treatment, are required to replace all lead service lines where applicable. The full effect of the staggered corrosion control system mandates will not be achieved until the end of the century in some cases. Because EPA admits that there is limited quantitative information at present regarding the contribution from lead service lines to lead levels at the tap, where "first draw" samples are the standard in all cases, water companies have up to 15 years to replace service lines after completion of corrosion control. Therefore, some service line replacements probably would not begin until after the year 2010.

Water experts differ on how much of a factor lead service lines bear on contamination, but some older lines undoubtably have built up deposits that prevent leaching. However, this would probably not be true if the system had highly corrosive (acidic) water from excessive chlorination and/or fluoridation. That is why the regulations are tied to water quality control, but there are tradeoffs involved, benefits versus risks, in deleading water.

Numerous hearings were held concerning reauthorization of the Resource Conservation and Recovery Act. Other bills in various hearing stages dealt with labeling all lead products, premanufacture notification and approval

for any new lead products, comprehensive inventorying of lead products, leaching and content standards in plumbing fixtures, tightening of paint and packaging standards, and excise taxes on all lead produced or imported with the revenue to be applied to a comprehensive lead-base paint abatement program.

Issues

Source reduction is one of four "tiers" for integrated waste management of the EPA's Agenda for Action, published by its Office of Solid Waste (OSW) in February 1989. The other "tiers" are recycling, incinerating, and landfilling. Theoretically, not creating a waste in the first place would be the best option to control solid waste generation. However, in general, source reduction is the least studied, and in some ways the most complex, of the integrated waste management options, involving target reductions of both volume and toxicity, approached comprehensively. Therefore, in December 1992, EPA organized a forum on source reduction of heavy metals, specifically lead, cadmium, and mercury, in six products commonly found in municipal solid waste (MSW). The goal was to learn more about source reduction on a practical level, how it could be implemented, and what barriers (institutional, technical, economic, etc.) had to be overcome. The lead-containing products of concern were soldered circuit boards and cathode-ray tubes (CRT's).

The workshop for lead soldered circuit boards concluded that the two major uses. solder as an etch-resist in manufacture and as a component connect, must be analyzed separately. For the former, source reduction would entail changing the coating material, changing the manufacturing process (technology), and/or using alternative circuit boards. As a connecting medium the source reduction options are as follows: use adhesives, increase component density of the circuit board to decrease required connections, and implement totally new technologies. Lead-free joining systems currently are being researched. The same basic technology using antimony, bismuth,

copper, indium, or silver alloyed with tin would, at the least, require major changes in the manufacturing process, and performance data for decisionmaking at this time are virtually nonexistent.

In the CRT workshop, 11 source reduction options were identified. Evaluation by the panel of a matrix containing reductions achievable, technical feasibility, cost, environmental tradeoffs, and performance yielded only two short-term options and one long-term option that were ranked as having great potential. The two former are zirconium substitution in the faceplate of the CRT's and lower voltage CRT's. The long-term option would be the development of flat panel (liquid crystal) technology that would replace the CRT. Lower voltage with possible lower performance would require implementation of a new worldwide standard, which could result in consumer displeasure. The latter point raises the issue, advanced by many, of the appropriateness of focusing only on the disposal-related impacts associated with products at the expense of not fully recognizing the need for a life-cycle approach to source reduction analysis. All of the economic implications and perturbations over an extended period of time, especially where substitution of materials is concerned, can only be determined by independent, objective, individual life-cycle analyses for each subject material, either before or in parallel with, the source reduction analysis for any given product of concern.

Production

Primary.—The significant decrease in domestic mine production of lead in 1992, more than 50,000 tons in Missouri, was primarily the result of the announcement by The Doe Run Co. about continuing cutback to prevent stock buildup in the depressed market. However, Missouri's share of the total mined lead production remained at 75%, the same as that in 1991, owing mostly to a one-third cutback in Idaho, the result of even worse silver market conditions. Alaska, Idaho, Montana, and Colorado,

in order of output, produced all but 2,200 tons of the balance. The top 12 mines listed in table 3 produced more than 99% of the total, and ASARCO Incorporated, Doe Run, and Cominco (American/Alaska) accounted for almost 90% of the domestic mine production of lead in 1992. (See tables 2 and 3.)

Doe Run of St. Louis, the Nation's only fully integrated primary lead producer, operated five mines and four mills in southeast Missouri in 1992. Doe Run's primary smelter-refinery Herculaneum, MO, apparently produced about 119,000 tons of refined lead in 1992, 38,000 tons less than in 1991. Approximately 65% of Doe Run's ore was on properties under Federal mineral leases for terms of 10 to 20 years, renewable for 10 years, for which the company pays the Bureau of Land Management a royalty of 5% on the gross value of concentrates produced. November, Doe Run's parent company, Fluor Corp., classified Doe Run as a "discontinued operation" for purposes. That action resulted in a onetime \$79 million offset to net earnings in 1992 and included both the estimated loss on disposal and estimated operating losses through the disposal date. It was hoped that the divestiture would be completed within 1 year of the announcement, but there were no buyers by yearend. Doe Run's Missouri mines produced about 156,000 tons of contained lead in concentrates in 1992.

Asarco operated two mine and mill complexes in southern Missouri that produced slightly more than 97,000 tons of contained lead in 1992 compared with slightly less than 95,000 tons of contained lead in 1991, according to the company's annual report to the stockholders. This represented a gain of 5% for its smelterrefinery at Glover, MO, which had near capacity production of 118,000 tons for the second consecutive year. Asarco's Omaha, NE, refinery, which received the bullion output from its East Helena, MT, custom smelter, produced 68,000 tons of lead in 1992, down slightly from that in 1991 owing to mine closures in the region and in Mexico and Peru. Asarco also received, as operator, 52.5% of the production from the Leadville Mine in Colorado. At yearend, Asarco reported reserves in Missouri of 18.9 million tons grading 4.93% lead at Sweetwater and 6.6 million tons grading 5.65% lead at West Fork. In late 1992, Asarco announced that by May 1993 all of its lead, zinc, silver, and mineral operations would be organized under a single manager headquartered in New York. (See table 4.)

The Magmont Mine at Bixby, MO, a 50-50 joint-venture of Cominco American Inc., the operator, and Dresser Industries Inc., dropped a notch to become the third largest domestic lead-producing mine in According to parent company Cominco Ltd.'s (Canada) annual report to stockholders, the 20% decrease in production from that of 1991 was the result of a decline in average ore grade from 6.5% lead to 6.1% lead and less efficient pillar and salvage mining operations in preparation for final closure in the next 2 years. Surface drilling during the year revealed no new ore extensions. In 1992, Magmont milled 873,000 tons of ore, which yielded 66,000 tons of concentrate grading 7.7% lead (compared with 7.8% in 1991). The mine also produced 7,400 tons of zinc in concentrate from 1.0% ore and 1,500 tons of copper from 0.3% ore. At Cominco Alaska Inc.'s Red Dog Mine, near Kotzebue in northwest Alaska, difficulties were encountered in the mill recoveries in lead and bulk concentrates during the second full year of operations. At yearend, Cominco had published ore reserves (measured and indicated) of 5.2 million tons at Magmont grading 8.5% lead and 1.3% zinc and of 58.2 million tons at Red Dog grading 5.5% lead and 18.4% zinc. It also declared 14.1 million tons of inferred ore reserves grading 2.7% lead and 10.0% zinc for Red Dog.

Secondary.—Domestic secondary production in 1992 was estimated to have nearly achieved 1990's alltime record as capacity utilization for the year was an optimum 88%. This was mainly because a major battery recycler in Alabama was permanently closed by the EPA early in the year.

Operations were indefinitely suspended at a smaller battery recycler in midvear in Tennessee, but this was offset by Refined Metals Corp.'s Memphis plant, which had been shut down at the beginning of the year, coming back on-stream. During the year, several smaller nonbattery recyclers who mainly produced specialty alloys for such uses as solders, brass or bronze ingots, bearing metals, etc., closed permanently, a result of being overcome by very low to nonexistent enforced margins and increasingly environmental emissions and workplace standards.

A new, small, "just-in-time" battery recycler came partially on-stream in Ohio, but was not producing at yearend owing to financial and technical However, at yearend, the problems. secondary lead industry had an estimated production capacity of 1.04 million tons, 1.0 million tons of which resided with 15 battery recycling companies. These 15 companies operated 20 breakers and 22 smelter-refineries with capacities of 10,000 to more than 100,000 tons per year, although two in Ohio and Tennessee were still shut down at yearend and several had curtailed operations. Also operating were five midlevel, nonbattery smelters-refineries, including Asarco's Omaha, NE, refinery, with furnace and kettle capacities of 6,000 to 10,000 tons per year. In addition, 13 small specialty alloy producers were operating, 3 with capacities of 1,000 to 2,000 tons per year; the other 10 had considerably smaller capacities.

Total production from the nonbattery plants in 1992 was 38,000 tons, much of which was from copper-base scrap and/or new scrap. In the first full year of operation, the Doe Run's state-of-the-art secondary plant at Boss, MO, on the site of its former Buick primary smelter-refinery, produced at full capacity. For the year, though, the RSR Corp. of Dallas, TX, the Nation's largest secondary lead producer, out produced both Doe Run's and Asarco's individual total (primary and secondary) outputs of pig lead. (See table 5.)

Consumption and Uses

Reported consumption of lead declined only slightly in 1992 compared with that of 1991. Decreases totaling 26,000 tons of lead in gasoline additives (zero), batteries, cable, sheet, and solder were partially offset by 16,000 tons of total gains in bullets/shot, castings and extrusions, and CRT's for television and computer screens. Lead used in construction remained about level for the seventh consecutive year, at 34,000 tons, the same as in 1991 (revised). All other uses increased or decreased marginally.

The Battery Council International (BCI) reported a 1992 starting-lightingignition (SLI) battery production of 81.07 million units, compared with 77.81 million units in 1991 and 79.61 million units in 1990. The total includes both original equipment market (OEM) and replacement market automotive-type batteries. Using the BCI estimate of 20.9 pounds per unit, that sector's offtake was 768,600 tons. That total category includes batteries for buses and trucks. tractors, marine, golf carts, motorcycles, aircraft, mine equipment, floor care, and other miscellaneous equipment, including military uses but excluding motive power. The industrial (stationary)-traction (motive power) sector was estimated to have consumed 220,500 tons of lead, a record in quantity and percentage of the total (998,200 tons) battery industry offtake. Consumer batteries; i.e., small, sealed lead-acid cells (SLA) for flashlights, tovs. powertools, lawn mowers, floor polishers, etc., less than 25 pounds, were estimated to have consumed the balance of 9,100 tons.

The industrial and traction battery sector includes uninterruptible power supply (UPS) systems designed to ensure constant voltage for large computer systems at hospitals, banks, communication networks, etc., and standby power supply (SBS) systems for emergency lighting and some telenets. The whole sector exhibits great potential continued future growth networking of computers of all capacities expands, both externally and internally. and general purpose electric vehicles and electric power load-leveling loom closer to universal application; the latter especially for the customer side of the meter. In 1982, this sector consumed only 67,900 tons of lead and represented less than 10% of total battery lead, compared with more than 22% in 1992. Recently, consumer-type UPS batteries for home and individual office personal computers were introduced to the marketplace.

According to BCI statistics, critical inventories of SLI batteries at yearend stood at a record 9.65 million units, a 1.5-month supply, compared with 8.49 million units at yearend 1991 and 9.49 million units at yearend 1990. (See tables 6, 7, 8, 9, 12, 13, 14, and 15.

World Review

According to International Lead and Zinc Study Group (ILZSG) statistics, consumption of soft and antimonial lead in market economy countries (MEC) declined moderately in 1992 to 4.42 million tons compared with 4.47 million tons (revised) in 1991 and 4.48 million tons in 1990. Record MEC consumption of 4.58 million tons was established in 1989, according to ILZSG. Comparable world totals for those years, including about 2% other lead alloys, was estimated by the U.S. Bureau of Mines to be about 5.47, 5.57, 5.73, and 5.87 million tons, respectively. These revised obviously reflect the continuing general, worldwide recession of recent years. Although MEC consumption and refined metal production were in balance during 1989, MEC production of soft and antimonial lead in 1990, 1991, and 1992 combined was in deficit by more than 120,000 tons. However, during this same 4-year period, net imports of pig metal into the MEC from Eastern European and Asian socialist countries was about 280,000 tons, according to ILZSG, and stocks reached an alltime record. This was primarily attributed to MEC net imports of about 170,000 tons during 1992.1 Although the London Metal Exchange (LME) average cash price for lead, essentially the world price, was only \$0.08 less per pound in 1992

than in 1991 (\$0.245 versus \$0.253 cents), the price in the last 2 months of the year averaged only \$0.207 per pound. This was the result of the metal surplus and weak demand owing to very high Not only was there battery stocks. worldwide excess metal production capacity, but also apparently excess product (battery) manufacturing capacity at yearend. The LME price for the year peaked during the last week of August and first week of September, averaging \$0.297 per pound for that 2-week period. That was also the peak in the United States, where the weighted average producer price was \$0.388 per pound, delivered, for those 2 weeks. However, the LME price plummeted more than \$0.09 to \$0.206 per pound by yearend, while the yearend domestic price was \$0.324 per pound. That very wide spread encouraged greater importation into the United States in the last quarter than usual.

Mine Capacity.—There was statistically insignificant net gain of 10,000 tons in world mine capacity in 1992 for a yearend total of 4,010,000 tons. In Europe, the permanent closing of Germany's last two remaining lead mines, which had been producing since the middle of the last century, was offset by the opening of the new Louisa Mine at Lindesberg, Sweden. In the Western Hemisphere, small capacity increases at two large open pits plus the opening of a small new underground mine in Mexico were offset by the closures of the Real de Asientos Mine in Mexico and the Boquira Mine in Brazil. The capacity increase was the result of a new lead-producing gold mine coming on-stream at Cobar, New South Wales, Australia. In Canada, at Faro in the Yukon Territory, the Vangorda open pit started operations as one replacement for the phasing-down Faro Mine to maintain the 120,000-tonper-year output. In Morocco, the Haiar Mine near Marrakesh, opened in 1991, reached full capacity of more than 20,000 tons per year. World lead-producing mines operated at 81% of capacity in 1992, slightly less than that in 1991 (82%) owing to the 34,000- ton decline in production. Significant production decreases occurred in Spain, the United States, and the former Yugoslavia, which were not offset by the large increases reported by Canada and Sweden.

Late in the year, MIM Ltd. (72%) announced that it would proceed with development in 1993 of the large McArthur River project in the Northern Territory of Australia. MIM's partner is ANT Minerals, a consortium of Nippon Mining (15%), Mitsui (5%), Mitsubishi (5%), and Marubeni (3%), all of Japan. At a capacity of 1.2 million tons of ore 350,000 tons of bulk per year, concentrate containing 40,000 tons of lead would be produced by 1995 if market conditions warrant. (See table 10.)

Capacity.—World primary Metal smelting and refining capacity increased by less than 1% in 1992 (35,000 tons). A new conventional pyrometallurgical plant of 40,000-ton-per-year capacity came onstream in northern Iran at Zandjan and a new 80,000-ton QSL plant came onstream at Onsan in the Republic of Korea. Also in Asia, at Karnchanaburi. Thailand, the conventional smelterrefinery built in 1987 was expanded from 12,000 tons to 17,000 tons per year. At the 90,000-ton Cartegena, Spain, conventional smelter-refinery built in 1945 was permanently closed, the cost of upgrading apparently environmental prohibitive. At yearend, world primary smelting capacity stood at 4.6 million tons. In the secondary sector, three expansions and two new small plants totaling 60,000 tons of capacity were offset by the 50,000 tons closed in the United States (previously discussed) and the closure of Holland's largest plant (35,000 tons per year) at Arnhem. At yearend, world secondary capacity was about 3.1 million tons per year and capacity utilization for the year was about 82%. (See table 11.)

Reserves.—Worldwide reserves of lead contained in demonstrated resources from both producing and nonproducing deposits estimated to be economically viable at yearend were estimated at 60 million tons by the U.S. Bureau of Mines. For the largest producers among the MEC, Australia and the United States contained about 10 million tons each and Canada 6 million tons, compared to about 15 million tons for the countries of the former U.S.S.R. and China combined. Estimated average grades among major MEC producers ranged from about 6% in Australia to about 1% in Mexico and Spain, compared with a little less than 3% in the United States and about 2.5% for demonstrated resources of all of the MECs, including the United States. No definitive average grade data are available for the former U.S.S.R. or the Asian centrally planned economies. At current and extraction production levels efficiency, these data would indicate a recoverable metal supply of less than 20 However, marginal economic deposits, measured and indicated, would extend the "reserve base" to 123 million tons at somewhat less extraction efficiency on average, or about 40 years. In this category, Australia would clearly dominate at an estimated total of 35 million tons, followed by the United States at 22 million tons and Canada at 13 million tons.

In continuing exploration developments, Ibernia West Corp. (47.5%) and Chevron Mineral Corp. (52.5%) of Ireland completed drilling at Europe's second largest zinc-lead deposit at the Lisheen deposit in County Tipperary. resulted in announced proven and probable reserves of 18.4 million tons grading 13.4% zinc and 2.4% lead. A full feasibility study was then initiated during the year toward the objective of a mine being in production at Lisheen in the late 1990's. In Australia, CRA Ltd. secured a development license for its Century zinc-lead deposit in Queensland, but actual production mining cannot begin until acceptance by the Government of a yet-to-be completed environmental impact report. The resource is estimated to be about 120 million tons averaging 10.3% zinc and 1.5% lead. If an open pit mine were developed, production would be 55,000 tons per year of lead in concentrates, or 35,000 tons per year

from an underground mine. In Canada, Curragh Resources secured all required permits for development (18 to 24 months) of its Stronsay Mine in British Columbia. Reserves were estimated to be 50 million tons of more than 10% combined lead and zinc, with a planned production rate for lead of 30,000 tons per year.

Current Research

lead-acid storage batteries operation, energy efficiency is limited to about 50% of the theoretical value—even less at high discharge rates. One way to obtain high power levels at high discharge rates, a necessity in electromotive applications for example, would be to increase the porosity of the battery grid paste, conventionally 55% to 60%. However, above 60%, a traditional SLI battery pasted plate loses strength. In contract work performed by Johnson Controls Inc. for the Jet Propulsion Laboratory in 1992, an improved new paste formula for positive plates was developed that increased porosity to nearly 70%. This was accomplished by increasing the surface area significantly by creating a much larger fraction of small pores. This was done by utilizing pure tribasic lead sulfate (33% to 39%) and orthorhombic lead oxide (38% to 45%), instead of conventional bulk lead oxide, mixed with about 4% 325-mesh solid potassium persulfate or sodium persulfate, the key ingredient. pasted grid was conventionally cured and formed, and the resulting new plate had only about 20% surplus of theoretical The new plate delivered capacity. signficant improvements.2

A comprehensive coverage of lead-related investigations and an extensive review of current world literature on the extraction and uses of lead and its products were published in quarterly issues of "Leadscan" published by the Lead Development Association, London, United Kingdom.

OUTLOOK

Although domestic demand for lead

grew on average about 4% per year from 1985 to 1989, this rate cannot be sustained in the future because some end uses of lead will be curtailed or eliminated entirely by legislation and/or source reduction, one of the current pollution prevention regulatory strategies. Use of lead in solders, paints and coatings (already eliminated in interior house paints), ceramics, gasoline additives, containers or other packaging (including inks or dyes, especially where food is concerned), and cosmetics will certainly be affected. Some reduction of lead per battery unit also can be anticipated as the technology continues to As a result, U.S. annual advance. growth in lead demand will probably fall within a range of 0.5% to 1.5% per year in the decade of the nineties, averaging about 1%, as the storage battery sector becomes even more dominant. higher growth rate could be attained if the use of lead-acid batteries for peak-power, load-leveling applications becomes widely accepted for households and commercial facilities and/or there is moderate demand for private, general purpose electric cars. The latter two conditions will probably not prevail until the end of the century or early in the 21st century.

World demand for lead grew at an average rate of about 2% through 1989 from the low recession year of 1982. Lower growth in U.S. demand, which is about 20% of the total, will undoubtedly lower the overall world growth rate somewhat in the future. However. storage battery use in all applications will certainly grow faster in the rest of the world than in the United States as some poorer nations increase their living standards while they grow with the world economy. It is estimated that about 60% of world demand is currently for batteries, compared with about 80% in the United States, and is forecast to reach about 70% by the end of the decade as the rest of the world's supply-demand pattern changes in response environmental concerns. Therefore, the most probable world growth in lead use until the end of the century is forecast to average about 1.5% per year once the world's economy recovers from the

current downturn.

The attendant worldwide production outlook is interrelated with anticipated structural changes. Because of large capital demand and high costs associated with environmental concerns, large production surpluses in the future are not likely. High realized producer prices are critical to profitably amortizing the large improvement expenditures anticipated over the next 10 years. However, this will continue to be subjected to developing situations in zinc and silver markets because of the geologic relationships of the three metals in the primary production sector. The trend of increasing secondary share of production and consumption is expected to continue until optimum recycling is achieved. Complex multinational, multifaceted realignments and restructuring, including divestitures, among world lead producers and product manufacturers are expected to continue through the rest of the Most noticeable will be century. investment of primary producers, in many cases through acquisitions and mergers, in secondary lead production to protect existing market share.3

	Miscellaneous uses	⁸ 26,478	*13,009
	Grand total	r 31,246,344	1,236,571

Revised. W Withheld to avoid disclosing company proprietary data; included in appropriate totals.

¹Includes "Terne metal: Motor vehicles and equipment."

²Included with "Building construction" to avoid disclosing company proprietary data.

³Data do not add to total shown because of independent rounding.

Included with "Bearing metals: Motor vehicles and equipment."

⁵Included with "Other metal products" to avoid disclosing company proprietary data.

⁶Includes lead consumed in foil, collapsible tubes, annealing, galvanizing, plating, and fishing weights.

Included with "Miscellaneous uses" to avoid disclosing company proprietary data.

*Includes "Gasoline additives."

Estimated. Revised.

¹Table includes data available through July 6, 1993.

²In addition to the countries listed, Uganda may produce lead, but available information is inadequate to make reliable estimates of output levels.

³Reported figure.

⁴Formerly part of Yugoslavia; data were not reported separately until 1992.

⁵Less than 1/2 unit.

 $^{^6}$ Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁷Year beginning Mar. 21 of that stated.

⁸Reported for 1988 as galena (not further specified), assumed 78% Pb.

⁹Dissolved in Dec. 1991. ¹⁰Dissolved in Apr. 1992.

¹¹Pb content of ore milled in year beginning Apr. 1 of that stated.

¹²Data may not add to totals shown because of independent rounding.

LIME

By M. Michael Miller

Mr. Miller, a physical scientist with 15 years of minerals experience with the U.S. Department of the Interior, has been the commodity specialist for lime since 1989. Domestic survey data were prepared by Tonya Hardin, statistical assistant; and the world production table was prepared by Harold D. Willis, international data coordinator.

Lime is an important chemical with hundreds of chemical, industrial, and environmental uses in the United States. Its history probably dates back at least 4,000 to 6,000 years. The ancient Egyptians utilized lime as an ingredient in mortar and plaster. The Greeks, Romans, and Chinese utilized lime for construction, agriculture, bleaching, and tanning. Its uses began expanding with the advent of the industrial revolution, but it remained primarily a construction commodity until the rapid growth of the chemical process industries at the beginning of the 20th century. At the turn of the century, more than 80% of lime consumed in the United States was for construction uses, but now more than 90% of lime is consumed for chemical and industrial uses.

Lime is a basic chemical that ranked sixth in total production in the United States in 1992. It is produced in 32 States and Puerto Rico; its major markets are the steel industry, the utility power industry, the pulp and paper industry, the construction industry, and municipal water- and sewage-treatment facilities.

Total lime sold or used by domestic producers, excluding that from Puerto Rico, increased by about 587,000 short tons to nearly 17.9 million short tons in 1992. Production included commercial sale or captive consumption of quicklime, hydrated lime, and deadburned refractory dolomite. products were valued at more than \$949 million. Merchant sales increased by 504,000 tons to a record high of nearly 15.8 million tons, while captive consumption increased by 82,000 tons from 1991 levels. (See table 1.)

DOMESTIC DATA COVERAGE

To comply with Federal law and Executive Order 12770, the U.S. Bureau of Mines has decided on the following transition plan for the mandated conversion of the remaining commodity publications not currently being reported in metric units. It was decided that for the 1992 Commodity Annual Reports and 1993 Mineral Industry Surveys, all tables containing measures of weight will be published in English units with an additional total line showing metric units. For the 1993 Commodity Annual Reports and 1994 Mineral Industry Surveys, all data will be published in metric units with an additional total line showing English Beginning with the 1994 Commodity Annual Reports and the 1995 Mineral Industry Surveys, all data will be published in metric units only. As a result, the 1992 Lime Annual Report has been published in English units with an additional total line showing metric units. That will be reversed for the 1993 report, and the 1994 report will be entirely in metric units.

Domestic production data for lime are developed by the U.S. Bureau of Mines from two separate, voluntary surveys of U.S. operations. The survey used to prepare this report is the annual "Lime" survey. Of the 115 operations to which the annual survey request was sent, 101 responded, representing 80% of the total sold or used by producers shown in table 2. Production for 12 nonrespondents was provided based on the monthly lime survey. Production for nonrespondents was estimated using reported prior-year production figures. Three plants were idle or shut down.

BACKGROUND

Definitions and Specifications¹

Lime is a manufactured product made by calcining limestone (calcium carbonate or a combination of calcium and magnesium carbonate) or other calcium carbonate materials at temperatures ranging from 1,800° F to 2,400° F. It is never found in a natural state. calcination process drives off the carbon dioxide, forming calcium oxide (quicklime). The subsequent addition of water creates calcium hydroxide (hydrated or slaked lime). The term "lime" is a general term that includes the various chemical and physical forms of quicklime and hydrated lime. It may be high calcium, magnesian, or dolomitic. Quicklime is calcium oxide (CaO) with no water of crystallization. Hydrate is hydrated calcium oxide, or calcium hydroxide [Ca(OH)₂], and contains 24% combined water. Dead-burned refractory dolomite is dolomite that has been calcined at 2,800° F to 3,150° F. All of these products are called lime.

Quicklime is commercially available by the carload, in bulk, or in paper bags, in the following standard sizes:

- 1. Lump lime—the product exceeds 2.5 inches in diameter. Although sizes can vary, the typical size is 5 by 8 inches. This largest size of quicklime is strictly a product of vertical kilns.
- 2. Crushed or pebble lime—the product ranges in size from 0.25 inch to 2.25 inches, but the specific product size is more precise. This size has traditionally been a product of rotary kilns, but it is now available from vertical kilns as either a primary product or as a

result of crushing lump lime.

- 3. Ground lime—the product is generally ground from larger size material. A typical product size passes nearly 100% through a No. 8 sieve and 40% to 60% through a No. 100 sieve.
- 4. Pulverized lime—the product is the result of further grinding. A typical product size passes nearly 100% through a No. 20 sieve and 85% to 95% through a No. 100 sieve. This is usually a secondary product and is produced by intense grinding and classification.
- 5. Pelletized lime—the almond-shaped pellets or briquets are of uniform 1-inch size, molded from quicklime fines.

Hydrated lime is shipped in bulk tank trucks, railcars, and in 50-pound paper bags. As a result of the hydration process, it is of fine particle size. A typical product size passes 85% or more through a No. 200 sieve, and a few special applications may require a product passing 95% to 98% through a No. 325 sieve.

Because of the differences in limestones, a rigid standardization of lime material specifications is impossible. Few plants manufacture lime with exactly the same properties; as a result, lime specifications are by necessity quite general in their provisions.

Technology²

Lime manufacture involves three main processes: stone preparation, calcination, Stone preparation and hydration. involves quarrying or mining (including drilling, blasting, and conveying broken stone), crushing, and screening to provide the proper size kiln feed. Care is taken to avoid contamination with undesirable impurities, such as iron oxide, silica, and alumina. Although most lime manufacturers produce their own stone, some purchase the stone for kiln feed from commercial limestone producers.

Calcination is a simple chemical reaction. It is the addition of heat to limestone to cause thermal decomposition, in which the coproducts of CaO (quicklime) and CO₂ (carbon dioxide) are formed. This process is

performed in a kiln, of which there are a variety of systems in use. The two basic kiln designs are rotary and vertical (or shaft). There are a few other miscellaneous designs, but the majority of commercial kilns are of rotary or vertical design.

A rotary kiln is a long cylindrical kiln with a refractory lining, inclined at a slight angle, rotated at a slow speed, and fired by fuel at the lower end. The calcareous raw material (kiln feed) is fed into the upper end and calcined at about 2,000° F during its travel through the kiln to form quicklime, which is discharged at the lower end. The calcination temperature depends on size and composition of kiln feed and the type of desired product. The carbon dioxide is driven off as a gas and normally exits the system with the stack gas.

Vertical kilns are short, wide, vertical cylinders lined with refractory materials. They are usually circular in cross section, typically with a diameter of 9 to 14 feet and a height of 50 to 70 feet. They are the most widely employed type in the world, especially in Europe. A vertical kiln is divided into four distinct zones where specific parts of the manufacturing process take place. They are, from top to bottom, (1) stone storage zone, (2) preheating zone, (3) calcining zone, and (4) cooling and discharge zone.

Examples of other kiln designs are the rotary hearth kiln and the fluosolids kiln. The rotary hearth design consists of a preheater, circular hearth, and cooler, all refractory lined. Stone is placed on the hearth and rotated through a heating chamber. In the fluosolids kiln, fine-sized stone is densely suspended by air and hot gases in the preheating and calcining zone of a vertical heated chamber. It can be operated at lower temperatures because of the fine stone size. The quicklime product is the most highly reactive of any commercial lime.

Byproducts and Coproducts

Most lime companies mine their own limestone or dolomite for kiln feed. Some companies also produce a separate coproduct crushed and pulverized stone

production. If practical and if markets exist, byproduct fines from the kiln feed preparation process and kiln dust from the calcination process are also sold. Precipitated calcium carbonate (PCC) is produced as a coproduct at three commercial lime plants by combining quicklime with byproduct carbon dioxide recovered from the kiln. Byproduct carbon dioxide is also recovered for use in the carbonation step of sugar refining.

Substitutes

Limestone is a low-cost substitute for lime in many uses such as agriculture, fluxing, and flue gas desulfurization (FGD). Limestone contains less reactive material, is slower to react, and may have other disadvantages compared with lime, depending on the use. Calcined gypsum is an alternative material in industrial plasters and mortars. Cement, lime kiln dust, and fly ash are potential resources as substitutes for some construction uses of lime. Alkalis such as caustic soda. soda ash, sodium bicarbonate, sodium sulfate, and magnesium hydroxide are substitutes used in the neutralization stage of water treatment.

Economic Factors

Prices.—Traditionally, lime has been a low-priced commodity. Its average value, as reported to the U.S. Bureau of Mines on an f.o.b. plant basis, ranged from \$4 to \$15 per ton from 1910 to 1970. It was only in the 1970's, when energy prices escalated, that lime values showed a progressive and dramatic increase. This steady increase continued into the 1980's, although at a slower pace. In 1987, lime decreased in value for the first time since 1968. When comparing values over the past 20 years, based on constant 1992 dollars, two trends become evident. From 1973 to 1979, they increased every year and were up a total of 49%. From 1979 to 1991, they decreased every year and were down a total of 30%. This long downward spiral finally stopped in 1992, when the average value increased, albeit by only 0.4%, over that of 1991. (See figure 1.)

Costs.—Production costs in lime manufacture can be divided. descending order, into the following categories: energy (mainly fuel costs), kiln feed, dust collection, depreciation, direct labor, and miscellaneous. ranking may differ from plant to plant, and most of the categories display a great range in costs from one plant to another. The difference in ranking and the range in costs are accounted for by such variables as distance from fuel sources: thermal efficiency of individual kilns; whether kiln feed is quarried, mined underground, or purchased; electrical energy rates: and age of the plant.3

Tariffs.—In the Harmonized Tariff Schedule of the United States, quicklime, slaked lime (hydrate), and hydraulic lime under 2522.10.0000. are listed 2522.20.0000, and 2522.30.0000, respectively. Imports are free from countries with most-favored-nation (MFN) status and Canada. Non-MFN countries have tariffs of 0.2¢ per kilogram (about \$2.20 per short ton) for quicklime, 0.3¢ per kilogram (about \$3.31 per short ton) for slaked lime, and 0.2¢ per kilogram (about \$2.20 per short ton) for hydraulic lime. Mexican imports of lime are assessed a countervailing duty of 1.21%. This applies to all Mexican lime producers included in the scope of a countervailing duty investigation completed in 1984 and a changed circumstances administrative review completed in 1989.

ANNUAL REVIEW

Legislation and Government Programs

The Environmental Protection Agency (EPA) began testing the drinking water in 660 large public water systems for lead, in compliance with the Safe Drinking Water Act regulations. The initial sampling found excessive levels of lead in the drinking water of 130 cities. EPA's lead standard is 15 parts per billion (ppb), and they found samples in 10 cities with levels above 70 ppb. These levels do not represent average lead levels but

rather were taken from "high-risk" homes defined as those homes served by lead service lines or that contained lead piping or copper piping with lead solder.

All water systems serving more than 50,000 users must implement corrosion control, regardless of the test results. The 15 ppb standard will be utilized for systems serving fewer than 50,000 users. Corrosion control measures consist of treating the water with chemicals such as calcium phosphate, zinc orthophosphate, or lime. Corrosion control measures for large systems must be in place by January 1, 1997.

EPA. under a court-mandated deadline, finally released its rule on treatment standards for municipal sewage sludge (Part 503 of Clean Water Act) in December 1992. The final rule sets management standards for the use and disposal of municipal sewage sludge. The rule encourages recycling and reuse of sludge, rather than incineration or landfilling. Following removal of toxic contaminants, sludge can be recycled as soil compost or fertilizer. At present, approximately 30% of sewage sludge is being recycled; the rule encourages an increase in that level.

Lime stabilization is a recognized means of treating municipal sludge before land application. EPA had previously included lime stabilization in its list of "Processes to Significantly Reduce Pathogens." The standard lime stabilization process involves the addition of lime slurry to liquid sludge to meet the EPA standard of a pH \geq 12, 2 hours after treatment. A more cost-effective process for large treatment plants involves adding dry quicklime to the dewatered sludge.

The Department of Transportation regulations covering the transportation of hazardous materials (HMR-181), 49 CFR 171-180, were revised. The regulations were revised to comply with the U.N. Recommendations List of Dangerous Goods Most Commonly Carried. As a result, quicklime's listing was changed to "UN 1910 - Class 8, Packaging Group 3." Class 8 stands for corrosive material and Group 3 means minor danger. Based on these regulations, quicklime shipments

would have to be placarded and manifested as corrosive materials. However, it was judged that these revisions were in error, and the regulations were revised again. An "A" symbol was added to the quicklime listing, stipulating that the provisions of the regulation applied only to shipments by "air only." No placards or manifests are required for shipment by truck or rail; only the description "UN 1910, Quicklime, Calcium Oxide" is required on shipping documents.⁴

Production

The term "lime," as used throughout this chapter, refers primarily to six chemicals produced by the calcination of high-purity calcitic or dolomitic limestone followed by hydration where necessary. They are: (1) quicklime, calcium oxide (CaO); (2) hydrated lime, calcium hydroxide [Ca(OH)₂]; (3) dolomitic quicklime (CaO•MgO); two types of dolomitic hydrate, (4) type N $[Ca(OH)_2 \bullet MgO]$ and (5) type $[Ca(OH)_2 \bullet Mg(OH)_2]$; and (6) deaddolomite. **Nondolomitic** burned quicklime and hydrated lime are also called high-calcium lime. Lime can also be produced from a variety of calcareous materials such as aragonite, chalk, coral, marble, and shell. Lime is also regenerated that is, produced as a byproduct, by paper mills, carbide plants, and water-treatment plants; however, regenerated lime is beyond the scope of this report.

Total U.S. lime production from limestone, including that of Puerto Rico, increased by 3.4% compared with that of 1991. Merchant lime sales increased by 3.3%, and captive lime used by producers increased by 4%.

In 1992, 69 companies produced lime. Leading producing companies, in descending order, were Dravo Lime Co., with two plants in Kentucky and one plant in Alabama; Mississippi Lime Co. in Missouri; Marblehead Lime Co., with two plants in Illinois and one each in Indiana and Michigan; Chemstar Inc., with two plants each in Arizona, California, and Nevada and one each in

Idaho and Utah; Continental Lime Inc., with one plant each in Montana, Nevada, Utah, and Washington; APG Lime Co., with one plant each in Texas and Virginia; Allied Lime Co., with two plants in Alabama; Martin Marietta Corp. in Ohio; Chemical Lime Inc., with two plants in Texas; and Wimpey Minerals PA Inc., with two plants in Pennsylvania. These 10 companies operated 29 plants and accounted for 59% of total lime production.

Domestic lime plant capacity is based on 365 days minus the average number of days for maintenance times the average 24-hour capacity of quicklime production, including quicklime converted to hydrated lime, and reported in short tons per year. Specific plant capacity data were unavailable for all commercial lime plants. Based on the data available, the commercial lime industry operated at about 75% of capacity in 1992. (See tables 2 and 3.)

The industry reported some consolidation and new plant construction in 1992. Mississippi Lime Co. acquired Virginia Lime Co. (Ripplemead, VA) from Scottish Heritable Inc. and renamed the company Eastern Ridge Lime Co. LP. No capacity increases were planned. but equipment upgrades were planned to increase reliability. Continental Lime Inc. completed installation of a third rotary kiln at its plant at Delta, UT. The kiln was a used F. L. Smidth with a preheater of Continental design and went on-line in September 1992. Electric Power Cooperative's subsidiary Dakota Coal Co. completed construction of a lime plant near Frannie, WY, to operate as Wyoming Lime Producers. The plant will operate a 400-ton-per-day Kennedy Van Saun preheater rotary. Plant operations will be run by Pete Lien & Sons, Rapid City, SD. Operational start was scheduled for January 1993. Western Lime & Cement Co. started installation of a second preheater rotary kiln at its lime plant in Green Bay, WI. The new kiln was expected to go on-line during the summer of 1993.

Chemical Lime Co., Ft. Worth, TX, purchased the Texada Lime Division of

BP Resources Canada Ltd. The lime plant is at Fort Langley, British Columbia, and has two calcimatic (rotary hearth) kilns producing high-calcium quicklime. Texada will operate separately but will report to Chemstar. Chemical Lime Co. also acquired the idle M.E.R.R. Corp. lime plant located near Grantsville, UT. Chemstar's plans for a new lime plant at Cosgrave, NV, were put on hold while the company reviewed the markets. It applied for a permit extension and plans to do more drilling of the limestone reserves in the permit area.

Chemstar Lime Inc. completed construction of its Tenmile lime plant near Soda Springs, ID. The plant went on-line in September 1992. The quarry is operated under contract by Conda Mining Inc., which is responsible for supplying material to Chemstar's crushing plant. The operation is on Federal land, and a mining plan with concurrent reclamation was required. Chemstar constructed a 600-ton-per-day Maerz vertical shaft kiln on the site. A Maerz kiln is more energy efficient than straight rotary kilns or preheater rotary kilns. It consumes about 3.5 million Btu's per ton of lime compared with about 4.5 to 5.0 million Btu's for a preheater rotary and 6.0 million Btu's for a straight rotary. The selection of a Maerz kiln was made, in part, to facilitate permitting, as the kiln is more environmentally friendly than conventional rotary kilns.⁵ (See table 4.)

Consumption and Uses

Lime was consumed in every State. The breakdown of consumption by major end uses was as follows: 66% for chemical and industrial uses, 24% for environmental uses, 8% for construction uses, and 2% for refractory dolomite. Captive lime was used mainly in sugar refining and in the production of steel in basic oxygen furnaces.

In steel refining, quicklime was used as a flux to remove impurities such as phosphorus, silica, and sulfur. Dolomitic lime was often substituted for a fraction of the high-calcium lime to extend refractory life. Dead-burned dolomite, also called refractory lime, was used as a

component in tar-bonded refractory brick used in basic oxygen furnaces. Lime consumption for raw steel production (from basic oxygen and electric arc furnaces) was essentially unchanged at 5.1 million tons and accounted for about 29% of all lime consumed in the United States.

In nonferrous metallurgy, lime was used in the beneficiation of copper ores to neutralize the acidic effects of pyrite and other iron sulfides and thus maintain the proper pH in the flotation process. It was used to process alumina and magnesia, to extract uranium from gold slimes, and in the recovery of nickel by precipitation. It was used in gold and silver recovery operations to control the pH of the sodium cyanide solution used to leach the gold and silver from the ore. Such leaching processes are called dump leaching when large pieces of ore are involved, heap leaching when small pieces of ore are involved, and carbon-inpulp cyanidation when the ore is leached in agitated tanks. Dump and heap leaching involve crushing the ore, mixing it with lime for pH control and agglomeration, and stacking the ore in heaps for treatment with cyanide solution. Lime is used to maintain the pH of the cyanide solution at a pH level between 10 and 11 to maximize precious-metals recovery and to prevent the creation of dangerous hydrogen cyanide gas.

In the environmental sector, lime was used in the softening and clarification of municipal potable water. In sewage treatment, lime was used to control pH in the sludge digester, which removes dissolved and suspended solids that contain phosphates and nitrogen compounds. It also aided clarification and killing of bacteria. Lime was used to neutralize acid mine and industrial discharges. In FGD systems serving utility and industrial plants, lime was used to react with sulfur oxides in the flue gas. Lime was used to stabilize sludges from sewage and desulfurization plants before disposal.

The paper industry used lime as a coagulant aid in the clarification of plant process water. It was used, generally in conjunction with soda ash, for softening

738 LIME—1992

plant process water. This is a precipitation process to remove bivalent soluble calcium and magnesium cations (and to a lesser extent manganese, ferrous iron, zinc, and strontium), which contribute to the hardness of water. This process also reduces carbonate alkalinity and dissolved solids content.

In the basic Kraft pulping process, wood chips and an aqueous solution (called liquor) of sodium hydroxide and sodium sulfide are heated in a digester. The cooked wood chips (pulp) are discharged under pressure along with the spent liquor. The pulp is screened, washed, and sent directly to the paper machine or for bleaching. Lime is sometimes used to produce calcium hypochlorite bleach for bleaching the paper pulp. The spent liquor is processed through a recovery furnace where dissolved organics are burned to recover waste heat and where sodium sulfide and sodium carbonate are recovered. recovered sodium sulfide and sodium carbonate are diluted with water and then treated with slaked lime to recausticize the sodium carbonate into sodium hydroxide (caustic soda) for reuse.

Lime was used to make PCC, a specialty pigment used in premium-quality coated and uncoated papers. The most common PCC production process used in the United States is the carbonation process. Carbon dioxide is bubbled through milk-of-lime to form a precipitate of calcium carbonate and water. The reaction conditions determine the size and shape of the resulting PCC crystals.

The chemical industry used lime in the manufacture of alkalies. Quicklime was combined with coke to produce calcium carbide, which was used to make acetylene and calcium cyanide. Lime was used to make calcium hypochlorite, citric acid, petrochemicals, and other chemicals.

In sugar refining, milk-of-lime, a suspension of hydrated lime in water, was used to raise the pH of the product stream, precipitating colloidal impurities. The lime itself was then removed by reaction with carbon dioxide to precipitate calcium carbonate. The carbon dioxide

was obtained as a byproduct of lime production.

Dolomitic quicklime was used as a flux in the manufacture of glass. Quicklime was used to make calcium silicate building products such as sandlime brick; hydrated lime was used to produce silica refractory brick.

In construction, lime was used for soil stabilization to upgrade clay soils into satisfactory base and subbase materials. Common applications included construction of roads, airfields, building foundations, earthen dams, and parking areas. Hydrated lime was used with fly ash to make a base material, in asphalt mixes to act as an antistripping agent, and in plaster, stucco, and mortar to improve durability. Other applications of lime included agricultural uses. leather and tanning. plastics manufacture, pigments.

As a result of the expansion of certain markets and in an effort to disseminate as much data as possible, the end-use table has been expanded to include several end uses formerly included under "other." These newly listed end uses include petrochemicals, argon oxygen decarburization, ladle desulfurization, asphalt paving, industrial solid waste treatment, industrial wastewater treatment, and scubber sludge solidification. (See table 5.)

Prices

The average value of lime sold or used by producers, as reported to the U.S. Bureau of Mines on an f.o.b. plant basis, increased by \$1.57 per ton over the previous year to \$53.30 per ton. Average values were \$51.56 per ton for chemical and industrial lime, \$52.17 for environmental lime, \$63.11 for construction lime, \$65.28 for agriculture lime, and \$75.87 for refractory dolomite.

The average value of quicklime sold increased to \$50.33 per ton. Average values per ton were \$50.23 for chemical and industrial lime, \$49.34 for environmental lime, \$50.30 for construction lime, \$79.32 for agricultural lime, and \$74.62 for refractory dead-burned dolomite.

The average value of hydrated lime sold increased to \$65.45 per ton. Average values were \$60.49 for chemical lime, \$65.41 for environmental lime, \$68.29 for construction lime, and \$64.88 for agricultural lime.

Foreign Trade

According to the Bureau of the Census, exports of lime increased by 25% to 64,500 tons. Imports of lime increased by 22% to 212,520 tons. Most U.S. trade was with Canada and Mexico, which together accounted for nearly 100% of the U.S. imports and exports of lime. Canada was the major trading partner, receiving 80% of U.S. exports and shipping 90% of U.S. imports.

The import statistics were revised to include lime classified as "hydraulic lime." Almost all U.S. lime imports came from Canada, and because Canada did not produce hydraulic lime it is believed that the material was actually hydrated lime. (See tables 6 and 7.)

World Review

Australia.6—Dennis Mitchell Ltd. (DML) and Dennis Mitchell-Melcann Pty. Ltd. (DMMPL) own a number of limestone and lime operations across Australia. In the State of Tasmania, DML operated a 33,000-ton-per-year lime plant at Mole Creek. Its major market was the mining industry, which has been solid despite a poor local economy. DML's largest lime operation is located at Lilydale in the State of Victoria. The company produced limestone, quicklime, and hydrate for local markets. DML also operated lime plants in the State of Queensland at Calcium and Ootann, where markets include the sugar and gold industries. The Calcium plant added a hydrator as a result of strong demand for hydrated lime by the gold industry. DMMPL is a joint venture operating several operations in the States of New South Wales and Queensland. The jointventure company operated lime plants at Tamaree, Oueensland, and Attunga, New South Wales. DML took a 50% equity interest and management role in Loongana Lime Pty. Ltd., a producer in the State of Western Australia serving the gold industry.

Canada.—Shipments of lime were essentially unchanged from 1991 levels at 2.6 million tons valued at \$182.8 million, based on preliminary data. In 1992, the Canadian lime industry was composed of 13 companies that operated 19 plants. Capacity utilization was estimated at 60% in 1992. More than 90% of output was auicklime. which was consumed predominantly by the steel. environmental, and pulp and paper industries.

Although there was no new plant construction in 1992, there were a number of ownership changes. Canadian steel producer Dofasco Inc. sold its lime subsidiary, Beachvilime Ltd., Calcitherm Nederland BV of the Netherlands in August 1992. Beachvilime's lime plant is located at Ingersoll, Ontario, and had a reported annual capacity of about 518,000 tons of quicklime and 75,000 tons of hydrate. Calcitherm is a holding company for a number of limestone and lime producers in the Belgium, Italy, and United States. Canadian steel producer Stelco Inc. also sold its lime operation, Chemical Lime Works, to Global Stone Corp. of British Columbia. The Chemical Lime Works lime plant, located at Ingersoll, Ontario. had a reported annual capacity of 248,000 tons.7

BP Resources Canada Ltd. sold its Texada Lime Division (Fort Langley, British Columbia) to Chemical Lime Co. of the United States. Texada operated two calcimatic kilns and produced highcalcium quicklime. Texada Lime will operate as a separate company but will report to Chemical Lime Co.'s subsidiary, Chemstar Lime Inc. Chemstar operated lime plants in five Western states. Koch Minerals of Canada Ltd. purchased the Reiss Lime Co. at Spragge, Ontario.

Germany.—Bundesverband der Deutchen Kalkindustrie (German Lime Association) celebrated its 100th anniversary. It was formed in 1892 from a larger lime and cement association. The German Lime Association is currently host for the International Lime Association, which transfers between member nations periodically.

United Kingdom.—Redland, PLC, agreed to sell the manufacturing plants of its subsidiary Steetley Refractories, Ltd. to J. E. Baker Co. of the United States. Steetley has two facilities located in Dudley and Worksop, about 130 miles northwest of London. Steetley Refractories Ltd. is a well-known producer and supplier of refractory products, including magnesite-carbon brick, basic brick, slide grate refractories, and heat storage blocks. The additional product line will complement J. E. Baker's line and strengthen Baker's international business. (See table 8.)

Current Research

Chemstar Lime Inc. has been busy in the research and development of new lime-based products designed for specific markets. They patented a new lime-based agglomeration product designed to decrease leaching times and increase the recovery rate of gold from its ore. The product is intended for use in the heapleaching process for extracting gold from low-grade ores. The product is a combination of inorganic minerals that when agglomerated with fine particles create dendritic crystalline structures allowing greater contact of oxygen and cyanide with the ore. The material is utilized in the same fashion as lime and portland cement and provides the pH control necessary for maximum gold recovery. The company also patented a new lime-based dust-control agent. The material is a cost effective semipermanent and permeable sealant designed to last 6 months. It is combined with water and then sprayed over dust sources such as construction and landfill sites, tailing piles, and open-air transport vehicles. Chemstar is also conducting research on a lime product designed to compete with caustic soda in the water- and sewagetreatment market. Much of the potential

success of such a product depends on the development of a form with easier use and handling characteristics.⁸

OUTLOOK

Lime has dozens of end uses in the chemical, industrial, and construction industries. Steelmaking is still the largest single end use for lime; the steel industry's consumption of lime in basic oxygen and electric arc furnaces was essentially unchanged compared with 1991 levels. Consumption by the steel industry has been relatively flat in recent Steel output is expected to increase modestly in the short term. Demand should increase for steel for highway and transit construction resulting from the Intermodal Surface Transportation Efficiency Act (ISTEA), from improved auto sales resulting from an improved economy, and in general construction. If the economy continues to improve, these factors should translate into increased lime consumption for the next few years.

Construction markets, which showed a healthy increase in 1992, should continue a strong showing. The passage of ISTEA and the lime industry push to market more lime to the asphalt paving industry should be the driving forces in the construction markets. Unfortunately, the construction markets tend to be dependent on the weather, and prolonged periods of rainy weather can damage regional markets, as was the case in 1991.

Environmental markets as a whole should show growth, led by the FGD market. FGD consumption is expected to show significant growth, despite the small decrease reported in 1992. The deadline for phase 1 compliance with the Clean Air Act Amendments is January 1, 1995, which means utility companies will be forced to make decisions on their compliance strategies in the near future. Because individual utility powerplants are large consumers, often requiring hundreds of thousands of tons per year, even a small percentage of utilities installing new lime scrubbers would translate into significant long-term increases in demand for lime. Longer term increases could materialize from the use of lime in dry scrubbers used with small boilers.

Other environmental markets should be solid, with the greatest potential for growth in sewage sludge stabilization. Research continues into the use of lime combined with other reagents for the destruction of polychlorinated biphenyls and dioxins, and on the use of lime as a binder and desulfurizing additive in refuse-derived fuels. Lime's traditional use as a neutralizing agent should remain relatively stable. It could, however, lose some market share in the acid mine drainage market, as there is increasing research and development of cheaper alternative processes such as the use of anaerobic bacteria and wetlands or the use of fly ash.

Consumption by the pulp and paper industry decreased by 10% in 1992. Lime is used in the sulfate process pulp mills to recausticize sodium carbonate into caustic soda. Consumption of caustic soda for pulping and bleaching is expected to decline by about 5% in 1993, and then remain essentially flat through 1996. Consumption of lime by the pulp and paper industry is expected to follow a similar trend.

Total U.S. paper demand is projected to increase by 2.4% annually through the 1990's. The outlook depends on the health of the economy and the strength of the U.S. dollar against foreign currencies. Increased consumption of paper products, driven by a stronger U.S. economy, should translate into greater consumption of lime for precipitated calcium carbonate production. Increases in exports are expected, assuming there isn't substantial strengthening of the U.S. dollar against foreign currencies.

Regionally, gold production will continue to provide a solid market in the West for lime consumed in the cyanide heap-leaching process. The gold boom may be over owing to the changed political climate and growing antimining sentiments, but current mining and mines in development should fuel the lime market for decades.

When caustic soda prices escalated in recent years, Western soda ash producers

constructed facilities for the lime-soda production of caustic soda, termed chemical caustic. Chemical caustic was deemed a cost-attractive substitute to traditional "electrolytic" caustic soda, which at the time was priced between \$250 and \$290 per ton. Unfortunately, recent spot prices for caustic have been as low as \$100 per ton. This eliminates any cost value advantage the chemical caustic producers might have. The chemical caustic industry could still develop into a significant regional market for lime, but it will depend entirely on the price of caustic.

The price of caustic soda and availability of supply could delay or even eliminate a potential new regional market. A major manufacturer of propylene oxide was considering switching from the use of caustic soda to hydrated lime for the dehydrochlorination stage of the manufacturing process. If the manufacturer proceeded with the substitution, the company would consume about 500,000 tons of hydrated lime per year. The current caustic situation is likely to have put any plans for switching to hydrated lime on the back burner, at least until caustic supplies tighten and prices rise.

Estimated. Revised.

¹Table includes data available through June 21, 1993.

²Lime is produced in many other countries besides those listed. Argentina, Iraq, Pakistan, and Syria are among the more important countries for which official data are not available.

³Reported figure.

⁴Formerly part of Yugoslavia; data were not reported separately until 1992.

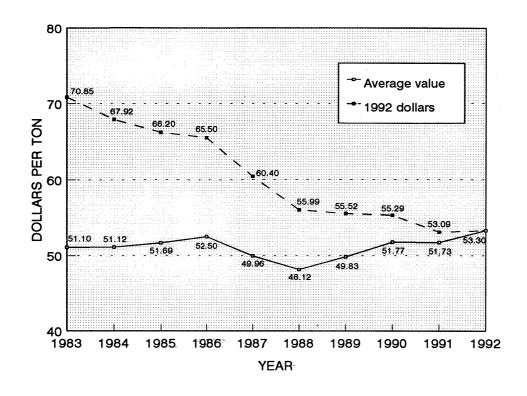

SLess than 1/2 unit.

⁶Includes hydraulic lime.

⁷Dissolved in Dec. 1991; however, information is inadequate to formulate reliable estimates for individual countries.

⁸Dissolved in Apr. 1992.

FIGURE 1
TIME-VALUE RELATIONSHIPS FOR LIME

LITHIUM

By Joyce A. Ober

Mrs. Ober, a physical scientist with 15 years industry and U.S. Bureau of Mines experience, has been the commodity specialist for lithium since 1986. Domestic survey data were prepared by Pamela G. Shorter, statistical assistant; and the world table was prepared by Theodore Spittal, international data coordinator.

The United States has been the leading producer and consumer of lithium and its compounds for many years. Chile, as a leading and low cost producer of lithium carbonate, is now challenging the United States; production in Chile is conducted by one of the two U.S. lithium companies, the world's largest producer of lithium carbonate. The other U.S. producer is vigorously pursuing opportunities to develop a similar low-cost operation in South America.

Because lithium is electrochemically reactive and has other unique properties, there are many commercial lithium products. Producers sold lithium as mineral concentrate, brine, compound, or metal depending on the end use. Most lithium compounds were consumed in the production of ceramics, glass, and primary aluminum.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines collects domestic production data for lithium from a voluntary survey of U.S. operations. The two U.S. companies responded to the survey, representing 100% of total production. Production and stock data were withheld from publication to avoid disclosing company proprietary data. (See table 1.)

ANNUAL REVIEW

Legislation and Government Programs

The Department of Energy (DOE) held a 36-million-kilogram stock of lithium hydroxide monohydrate that had been on the list for disposal for the past several years. DOE had planned to offer the lithium hydroxide in 1989, but delayed the disposal until an environmental impact study was complete. A final decision about disposal was delayed, and no material was offered for sale in 1992. DOE was planning to sell at least a portion of the material in 1993.

The DOE stocks were excess from a weapons program that used the lithium to make tritium, a compound necessary for nuclear fission reactions. The stockpile originally contained about 42,000 metric tons of material, from which about 75% of the lithium 6 isotope had been removed. This material possibly contained 8 to 9 parts per million of mercury, which could present an environmental hazard.

Production

The two companies that produced lithium in the United States in 1992 did so from two different types of deposits. Both firms mined spodumene, (a lithiumaluminum-silicate mineral) from large hard-rock deposits in North Carolina using open pit methods. Lithium was recovered from geothermal brine deposits in Nevada. Spodumene is the most common form of lithium ore, but petalite and lepidolite are other types of lithium ores that are mined in different parts of the world. These three types of ore are beneficiated to produce lithium ore concentrates that can be consumed directly in certain applications. Spodumene and brines are converted to lithium carbonate and then other compounds for consumption in other end uses.

Lithium carbonate is the most important lithium compound produced

from brine and ore deposits. Spodumene was a major raw material for the production of lithium carbonate in North Carolina, and small amounts of spodumene concentrate were produced for sale. Extracting lithium from spodumene entails an energy-intensive chemical recovery process.

After mining, spodumene is crushed and undergoes a flotation beneficiation process to produce concentrate. Concentrate is heated to 1.075° C to 1,100° C, changing the molecular structure of the mineral, making it more reactive to sulfuric acid. A mixture of finely ground converted spodumene and sulfuric acid is heated to 250° C, forming lithium sulfate. Water is added to the mixture to dissolve the lithium sulfate. Insoluble portions of ore are then removed by filtration. The purified lithium sulfate solution is treated with soda ash, forming insoluble lithium carbonate that precipitates from solution. The carbonate is separated and dried for sale or use by the producer as feedstock in the production of other lithium compounds.

Production of lithium carbonate from brine in Nevada is much less energy intensive than production from the spodumene. Brines enriched in lithium chloride—averaging about 300 parts per million when operation began in 1966—are pumped from the ground and progress through a series of evaporation ponds. Over the course of 1 year to 18 months, concentration of the brine increases to 6,000 parts per million lithium through solar evaporation. When the lithium chloride reaches optimum concentration, the liquid is pumped to a recovery plant and treated with soda ash,

precipitating lithium carbonate. The carbonate is then removed through filtration, dried, and shipped.

Cyprus Foote Mineral Co. produced lithium carbonate from its brine deposit in Silver Peak, NV, and spodumene concentrate at its mine in Kings Mountain, NC. It operated processing facilities for downstream lithium products and metal in Kings Mountain, Sunbright, VA, and New Johnsonville, TN. The company continued to maintain its lithium carbonate plant at Kings Mountain on a care-and-maintenance status as it had since mid-1986.

FMC Corp., Lithium Div., formerly Lithium Corp. of America (Lithco), mined spodumene from pegmatite dikes near Bessemer City, NC. The company produced lithium carbonate and a full range of downstream compounds, including lithium metal and some organic lithium compounds, at a chemical plant near the mine. The company also operated a butyllithium plant in Bayport, TX.

Consumption and Uses

The aluminum, ceramics and glass, lubricating grease, and synthetic rubber industries consumed most of the lithium minerals and chemicals. These markets were primarily related to transportation; aircraft and automotive i.e., the Industrial and consumer industries. applications also used ceramics and glass. consumption Estimated domestic decreased about 12% in 1992. Ceramics and glass production and aluminum smelters were the largest consumers of lithium and lithium carbonate concentrates in the United States. comprising 20% and 18% of the lithium market, respectively. Other consuming industries were synthetic rubber and pharmaceuticals, 13%; chemical miscellaneous manufacturing, 13%; 12%; lubricants, 11%: chemicals, batteries, 7%; and air treatment, 4%.1

Lithium carbonate and mineral concentrate additions in ceramics and glass manufacturing processes lower process melting points, reduce the coefficient of thermal expansion and the

viscosity, and eliminate the use of more The manufacture of toxic chemicals. thermal-shock-resistant cookware (pyroceramics) consumed the majority of lithium used in the ceramics and glass industry domestically. The manufacture of black and white television picture tubes consumed significant amounts of lithium Low-iron concentrates overseas. spodumene and petalite were a source of lithium used to improve the physical properties of container and bottle glass and as a source of alumina, another important component of the glass. Glass manufacturers used lithium in container and bottle glass, enabling them to produce lighter weight, thinner walled products.

Aluminum producers added lithium carbonate to cryolite baths in aluminum potlines. The chemistry of the potline converts it to lithium fluoride, lowering the melting point of the bath, allowing a lower operating temperature for the potline, and increasing the electrical conductivity of the bath. Operators used these factors to increase production or reduce power consumption.

The third largest end use for lithium compounds is as catalysts in the production of synthetic rubbers and plastics and pharmaceuticals. N-butyllithium initiates the reactions between styrene and butadiene that form abrasion-resistant synthetic rubber and thermoplastic rubbers that require no Other organic lithium vulcanization. catalysts for compounds are production of plastics like polyethylene. Lithium metal and compounds also are used by drug manufacturers in the production of a number of drugs, including Vitamin A, some steroids, an anticholesterol drug, an analgesic, tranquilizers, sleep antihistamines. contraceptives. inducers, and Pharmaceutical-grade lithium carbonate is approved directly for the treatment for manic-depressive psychosis. This is the only treatment approved by the U.S. Food and Drug Administration in which lithium is consumed by the patient.

The multipurpose grease industry was another of the important end uses for lithium in 1992. Lithium hydroxide

monohydrate was the compound used for the production of lithium lubricants. Lithium-base greases are favored for their retention of lubricating properties over a wide temperature range; good resistance to water, oxidation, and hardening; and formation of a stable grease on cooling after melting. These greases continued to be utilized in military, industrial, automotive, aircraft, and marine applications.

Almost all major battery manufacturers marketed some type of lithium batteries, and research and development continued for further substitution in applications that implement more conventional alkaline These batteries represent a batteries. growth area for lithium consumption, and new battery configurations continue to be Renewed interest in developed. electrically powered vehicles spurred additional interest in battery research and new, more efficient types of rechargeable (secondary) lithium batteries were developed and improved to meet the needs for this market. Special interest was shown for a lithium polymer battery developed in Japan.

Nonrechargeable (primary) lithium batteries offer improved performance over alkaline batteries at a slightly higher cost and have been commercially available for more than 10 years. They were used in watches, microcomputers, and cameras, and, more recently, in small appliances, electronic games, and toys. The military purchased large and small lithium batteries for a variety of The Galileo military applications. spacecraft, launched in October of 1989 for its 6-year trip to explore the atmosphere of Jupiter, contained lithium sulfur dioxide batteries to power its scientific instruments when it reaches its destination. Recent modifications to the lithium sulfur dioxide battery have extended the life of the batteries to at least 10 years with little or no reduction of performance.

Aircraft manufacturers in several countries have designed new aircraft using aluminum-lithium alloys for wing and fuselage skin or structural members.

Use of aluminum-lithium alloys can reduce the weight of the aircraft by more

than 10%, allowing significant fuel savings during the life of the aircraft. The alloys, which are 2% to 3% lithium by weight, are attractive to the aircraft and aerospace industry because of their reduced density and superior corrosion resistance compared to those of conventional aluminum alloys. These alloys face direct competition, however, from composite materials consisting of boron, graphite, or aramid fibers imbedded in polymers.

Small quantities of other lithium compounds were important to many industries. Lithium chloride and lithium bromide were used in industrial airconditioning systems. commercial dehumidification systems, and in the production of sophisticated textiles. Sanitizers for swimming pools, commercial glassware, and public restrooms contained lithium hypochlorite, as did dry bleach for commercial laundries. Lithium metal was used as a scavenger to remove impurities from copper and bronze, and anhydrous lithium chloride was used as a component in fluxes for hard-to-weld metals such as steel alloys and aluminum.

Prices

Both domestic companies increased prices for almost all lithium products for the sixth consecutive year. Prices averaged about 3% higher in 1992 than in the previous year. The close balance between supply and demand worldwide kept prices in step with inflation. Although installed production capacity remained in excess of demand, the chemical plant at Kings Mountain remained inactive, helping to keep supply and demand balanced sufficiently to maintain the trend. (See table 2.)

Foreign Trade

Total U.S. exports of lithium compounds were about 12% lower in 1992 than they were in 1991. The majority of U.S. exports of lithium compounds were to Germany, Japan, and the United Kingdom. Imports of lithium compounds reported by the Bureau of the

Census increased 31%. Cyprus Foote Mineral Co. owns a lithium brine operation in Chile; nearly 100% of all lithium carbonate imports was from this source. Lithium ore concentrates from Australia, Canada, and Zimbabwe were consumed in the United States, but no import statistics were available. (See tables 3 and 4.)

World Review

small number of countries throughout the world produced lithium ore and brine. The United States and Chile were the leading producers of lithium carbonate; significant quantities of lithium compounds and ore concentrates also were produced in Australia, Canada, Chile, China, Portugal, the former U.S.S.R. (probably Russia), Zimbabwe. Argentina, Brazil, and Namibia produced smaller quantities; production primarily consisted concentrates. Rwanda, the Republic of South Africa, and Zaire are past producers of concentrates. Pegmatites containing lithium minerals have been identified in Austria, France, India, Mozambique, Ireland. Spain. Sweden, but economic conditions have not favored development of the deposits. Lithium has been identified in subsurface brines in Argentina, Bolivia, China, and Israel. Companies in France, Germany, Japan, and the United Kingdom produced downstream lithium compounds from imported lithium carbonate.

Capacity.—Lithium presents special problems when compiling estimates of production capacities for different operations. Ore concentrate products are not comparable to lithium carbonate. Lithium carbonate was the primary compound produced at lithium chemical plants and the compound from which all other lithium chemicals were produced. Because even high-grade ore products usually contain less than 4% lithium and lithium carbonate contains almost 20% lithium, production capacities reported in tons per year represent large differences in the actual lithium content of the product. For that reason, capacities were reported based on the lithium content of the products also known as contained lithium.

Lithium carbonate production capacity has been established at about 6,300 tons contained lithium in the United States and Chile, the world's largest producers. Additional capacity at Cyprus Foote's Kings Mountain plant has been idle since mid-1986, and it is not expected to reopen in the near future. For this reason, 1,500 tons of lithium capacity was not included in U.S. figures. The plant has not been dismantled, and this capacity could be available if required.

An estimated 1,800 tons of lithium contained in lithium carbonate may be produced in China and the former U.S.S.R., but these estimates denote only an approximate order of magnitude. No basis for more exact estimates is available; output for China and the former U.S.S.R. has never been reported, but production in those countries is known to occur.

Worldwide production capacity for lithium ore concentrates, which are used directly in the ceramics and glass applications and are not converted to any other lithium compound, is estimated to be about 2,900 tons, contained lithium.

Argentina.—Small annual production occurred from pegmatite deposits in the Catamarca and San Luis Provinces. Spodumene reserves are estimated at 140,000 tons of 0.7% lithium.

Brine deposits have also been identified. FMC signed an agreement with the Argentine Government in 1986 to explore the Salar del Hombre Muerto in Catamarca Province. Estimates of geologic resources have been reported at 130,000 tons of lithium contained in brine ranging from 0.22 to 1.08 grams per liter. The Salar del Rincon also was identified as a lithium resource in the Salta Province.²

Australia.—The Gwalia Group mined high-grade, low-iron spodumene at its mine in Greenbushes, Western Australia. Gwalia produced two spodumene concentrate products through a flotation

process for sale to the ceramics and glass industry. The majority of the company's spodumene concentrate was used in the manufacture of black and white television picture tube glass and pyroceramics in the Pacific Rim countries and Europe. Glass-grade concentrate with lower lithium content was marketed in the same countries for consumption in container glass.

Bolivia.—A lithium brine deposit identified in Bolivia may be the world's largest salt flat. Preliminary studies of the Salar de Uyuni, which is more than 3,600 meters above sea level, indicated resources of 5.5 million tons of lithium, 110 million tons of potassium, and 3.2 million tons of boron.³

FMC had been negotiating for 4 years with the Government of Bolivia for the rights to develop a joint-venture operation in the Salar de Uyuni, a lithium brine deposit considered to be a national asset. FMC's plans included an exploration program and a plant for the recovery of lithium carbonate from the evaporated brines. Extreme political pressures in 1990 delayed the ratification of the contract that defined FMC's development of the project to produce 10,000 tons per year of lithium carbonate over 40 years at an investment of at least \$92 million.4 After FMC signed the contract, the Bolivian Congress changed four major conditions of the contract, including raising the value-added tax rate. FMC informed the Government of Bolivia that the company could not accept the changes to the contract, and it is unlikely that FMC will follow through with the project.5

Brazil.—Brazil has produced small quantities of lithium minerals for almost 30 years. Companhia Brasileira de Litio built a plant in Aquas Verhelhas, Minas Gerais, to produce 1,000 tons of lithium hydroxide and 200 tons of lithium carbonate.

Canada.—Tantalum Mining Corp. (Tanco) mined spodumene concentrate at its mine near Bernic Lake in southeastern

Manitoba. Since mining began in 1984, Tanco has grown to become the largest supplier of lithium concentrates to the U.S. ceramics and glass industry. The Canadian spodumene was similar to the material mined in Australia (high-grade spodumene with very low iron content), making the concentrates ideal for direct application in the ceramics and glass industry.

A number of other lithium deposits have been identified throughout Canada. A pegmatite deposit was operated in Quebec for about 10 years starting in 1955, but there has been no production since then. The largest demonstrated resources occur in the Yellowknife deposits in the Northwest Territories. Although large deposits, the location is too remote for production to be feasible in the foreseeable future.

Chile.—Cyprus Foote Mineral Co. is the sole owner of its lithium brine operation at the Salar de Atacama, Sociedad Chilena de Litio Ltda., having bought the remaining interest from the Chilean Government in 1989. Cyprus Foote produced lithium carbonate from the brines at this Salar, which has been The project worked since 1984. originated as a joint venture between Foote and Corporación de Fomento de la Producción (CORFO), a Chilean Government agency. Production capacity for lithium carbonate increased steadily from a 6,300-ton-per-year capacity to reach the current level of almost 12,000 tons per year.

The possibility of a second lithium operation at the Salar de Atacama has been under investigation. Minera Salar de Atacama Ltda. (MINSAL), the consortium formed by **AMAX** States). Exploration Inc. (United CORFO, and Molibdenos y Metales S.A. (Chile), completed studying the feasibility of developing another lithium operation on the Salar in 1988. Evaluations of the results were analyzed, and AMAX announced its decision to sell its portion of the project in 1990.7

Sociedad Quimica y Minera de Chile (SQM) bought AMAX's interest in the project in the second half of 1992. SQM

is a Chilean fertilizer producer, and its interest in the MINSAL project is for the potash that would be produced as a raw material for its potassium nitrate plant. For the project to be economically feasible as a potassium nitrate operation, production and sales of byproduct lithium carbonate are essential. Reports indicate that FMC would contribute to the development costs and receive the exclusive rights to the lithium that would be recovered, and in this way would acquire the low-cost lithium deposit for which the company has been seeking.⁸

China.—Lithium pegmatite and brine deposits are worked in China, but specific information about any of the deposits is not available. Lithium carbonate and hydroxide from China has been marketed in Germany, Japan, and the Netherlands.

France.—Lithium metal is produced by Metaux Speciaux SA in Plombieres St. Marcel, Savoie. The plant has the capacity to produce 25 tons per year of very high-purity metal for use in aluminum-lithium alloys. The company is a subsidiary of Pechiney.⁹

Germany.—Germany has been a major producer of lithium compounds, although no lithium ore is mined there. Chemetall GmbH, a member of the Metallgesellschaft Group AG, produced downstream lithium compounds and metal from lithium carbonate imported from the United States and other countries. The company's lithium operations are in Langelsheim.

Japan.—Japan is a major consumer of lithium compounds, some of which it produces from imported lithium carbonate. FMC and the Honjo Chemical Co. have a joint venture, Asia Lithium Corp., to market FMC's lithium products in Japan. Asia Lithium operated a 100-ton-per-year battery-grade lithium metal operation in Kagawa to meet the demands of the large lithium battery industry in Japan. Yahagi Iron Co. also produced lithium metal in Nagoya.

Namibia.—Southwest Africa (SWA) Lithium Mines produced petalite concentrate at its Rubicon Mine near Karibib. Low-grade ores beneficiated through a flotation process, while high-grade ores were hand picked. Small amounts of two other lithium minerals, lepidolite (lithia mica) and amblygonite (lithia alumina phosphate), were other products. Germany imported most of these concentrates. High-grade lepidolite was hand picked at the company's Helicon Mine for export to Western Europe and Japan. 10

Portugal.—Lithium has been produced inconsistently in Portugal. Recent reports indicate that production has gone up significantly in recent years, but details on the operations and markets are not available. Past lithium production had been lepidolite.

Former U.S.S.R.—Lithium ores, compounds, and metal were produced in the former U.S.S.R., but no details were available. The majority of lithium production is believed to be from the Kola Penninsula in Russia.

United Kingdom.—Lithium Corp. of Europe operates a facility in Bromborough, Mersyside, for the production of lithium metal and butyllithium. Lithium carbonate and lithium chloride are imported from its parent company, FMC.

Zimbabwe.—Bikita Minerals Ltd. mined petalite, another lithium mineral, near Masvingos. Although the ore reserves were becoming depleted, installation of a dense-media separator made it possible to recover lithium in the form of petalite averaging about 4.4% lithium oxide from a stockpile of previously rejected material. extended the estimated mine life by 30 years. Hand sorting, the method used since the mining began in 1916, amassed a stockpile of more than 1 million tons that could be recovered with a significant savings in mining costs after installation of the new device. Hand sorting

continued to be used only for special small orders of minerals other than petalite. (See table 5.)

OUTLOOK

The health of the lithium industry is closely tied to the performance of the primary aluminum industry. Reduced consumption of lithium in the aluminum industry has once again had a negative effect on lithium consumption. Demand for lithium compounds and minerals in the ceramics and glass industry continues to grow modestly. Similar increases are expected for the near future.

Demand for butyllithium is expected to continue to increase, and both domestic producers have increased production capacity to meet that demand. Demand for lithium metal for batteries and to some extent for alloys should increase. but total consumption of metal will remain small in comparison to the demand for lithium compounds for the short term. The fate of the lithium battery market will be largely dependant on the success of electric vehicles and whether the best type of battery for powering them finally is determined to be some form of lithium battery.

Other markets should remain relatively stable with slight growth. Lithium demand could increase dramatically if any of the new technology areas such as nuclear fusion were perfected. This is not expected to occur within the remainder of this century and probably not within the next 25 years.

The United States should remain the largest producer of lithium carbonate until FMC begins production of lithium carbonate from a brine deposit in South America. Although no official announcement concerning a formal agreement for actual production in any South American country has been announced, FMC's continued pursuit of such an operation is not in doubt, only the timing is in question. Chances are very good that FMC will be producing lithium carbonate at the Salar de Atacama within the next few years. At that time, Chile will become the leading producer of lithium compounds in the world.

Estimated. Revised. W Withheld to avoid disclosing company proprietary data.

¹Table includes data available through Apr. 23, 1993.

²In addition to the countries listed, other nations may produce small quantities of lithium minerals, but output is not reported and no valid basis is available for estimating production levels.

³Data are for year ending June 30 of that stated.

⁴Reported figure.

⁵Estimates based on imports by the United States.

These estimates denote only an approximate order of magnitude; no basis for more exact estimates is available.

⁷Formerly part of the U.S.S.R.

⁸All production in the former U.S.S.R. from 1988 through 1991 came from Russia.

Dissolved in Dec. 1991.

MAGNESIUM AND MAGNESIUM COMPOUNDS

By Deborah A. Kramer

Ms. Kramer is a physical scientist with the Branch of Industrial Minerals. She has covered magnesium and magnesium compounds for 9 years. Domestic survey data were prepared by Lillian Wood, statistical assistant, and Renaldo Summerset, management assistant; international data tables were prepared by Doug Rhoten, international data coordinator, and Ron Hatch, international data coordinator.

U.S. magnesium metal production increased slightly in 1992, but imports decreased, and producers drew down their inventories to meet demand. Partially as a result of the drop in inventories, U.S. transaction prices for primary magnesium trended up from midyear.

One of the areas that has continued growing is the use of magnesium diecastings in automobile components. Many U.S. automakers planned to add more magnesium components to future models, and as a result, several North American diecasters increased their production capacities or planned new facilities.

Antidumping and countervailing duties were assessed against the largest Canadian magnesium producer, and as a result, 1992 imports from Canada, which had been the largest U.S. import source since 1990, dropped dramatically. The newly independent States of the former U.S.S.R. were granted most-favored-nation status midyear, and Russia became the United States' largest import source for primary magnesium.

As in the United States, world magnesium inventories decreased as several companies in Italy, Japan, and the United States closed all or part of their plants. New capacity was planned for construction in Australia, Israel, and Saudi Arabia by the end of the decade. If all these plants are constructed, world production capacity would increase by

120,000 metric tons.

Total demand for magnesium compounds increased slightly in 1992. Refractory applications, although still the primary end use, remained at lower levels than in the past. Producers were investigating environmental applications. such as water treatment and flue gas desulfurization, as potential growth markets for magnesium compounds. Imports of magnesia increased, particularly dead-burned magnesia from China, which was the principal source of U.S. imports. Net import reliance for magnesium compounds increased to 23% for 1992 from 18% in 1991.

Mine and plant closures occurred in Canada, Germany, Greece, and the United Kingdom during the year. These closures were partially offset by additional magnesium compounds capacity that came on-stream in Australia, Israel, and Mexico.

DOMESTIC DATA COVERAGE

Data for magnesium metal are collected from two voluntary surveys of U.S. operations. Of the 115 companies canvassed for magnesium consumption data, 76% responded, representing 47% of the primary magnesium consumption shown in tables 4 and 6. Data for the 28 nonrespondents were estimated based on prior year consumption levels and other factors.

Data for magnesium compounds were

collected from one voluntary survey of U.S. operations. Of the 19 operations canvassed, 74% responded, representing 63% of the magnesium compounds shipped and used shown in table 13. Data for the five nonrespondents were estimated based on prior year consumption levels and other factors.

BACKGROUND

Definitions, Grades, and Specifications

Primary magnesium metal contains a minimum of 99.8% magnesium. Magnesium-base alloys are named by the composition of the two chief alloying elements, each designated by a letter, and the approximate percentage of each alloying element. For example, AZ91 contains about 9% aluminum (A) and 1% zinc (Z), and HK31 contains about 3% thorium (H) and 1% zirconium (K). Other letters used in specifying magnesium alloys are E for rare-earth metals and M for manganese.

Magnesite, or magnesium carbonate (MgCO₃), has a theoretical magnesium content of 47.6%. Dolomite is a calcium carbonate-magnesium carbonate mineral (CaCO₃•MgCO₃) that has a theoretical magnesium content of 22%. Brucite, magnesium hydroxide [Mg(OH)₂], contains up to 69% magnesium, and olivine (Mg₂Fe₂SiO₄) contains up to 19% magnesium. Of these minerals, magnesite and dolomite are the largest

sources of magnesium and magnesium compounds.

Seawater, brines, and bitterns represent vast sources of magnesium and magnesium compounds. In the United States, more than 60% of the magnesium compounds produced annually is recovered from seawater and brines, and 80% of the magnesium metal production capacity uses seawater or brines as a raw material.

Various magnesia products are made by calcining magnesium carbonate or magnesium hydroxide at different temperatures. Caustic-calcined magnesia, which is readily reactive with water, is calcined at temperatures up to 890° C. Dead-burned magnesia, also called refractory or sintered magnesia, is calcined at temperatures up to 1,450° C and is unreactive with water. Fused magnesia is produced at temperatures greater than 3,000° C. Magnesia produced from magnesite is generally called natural magnesia, and magnesia produced from seawater or brines is called synthetic magnesia.

Standards for magnesia, including chemical composition, bulk density, and particle size, generally are set by the consumer for a specific application. Refractory magnesia composition depends on the area of the furnace in which the material is to be used. Magnesia produced from magnesite can contain between 88% and 98% magnesia, with varying quantities of silica, iron, calcium, Synthetic and alumina impurities. magnesia normally is purer than natural magnesia, containing between 92% and 99.5% magnesia, with smaller quantities of the same impurities found in natural magnesia. Most fused magnesia contains greater than 94% magnesia.

Products for Trade and Industry

The principal use for magnesium metal, averaging greater than 50% of U.S. consumption annually, is as an alloying addition to aluminum. Magnesium improves the hardness and corrosion resistance of pure aluminum. Aluminum-magnesium alloys are used in a variety of applications, including

automobiles, trucks, aircraft, appliances, and home siding. Two-piece beverage cans, containing about 2% magnesium, are the largest single use for these aluminum-magnesium alloys.

Magnesium and its alloys are used as structural components on automobiles, trucks, aircraft, computers, and power tools. Many of these applications use magnesium because of its light weight and ease of machinability. Magnesium is used in the iron and steel industry for external hot-metal desulfurization and in the production of nodular Production of the nonferrous metals, beryllium, hafnium, titanium, uranium, and zirconium, involves the use of magnesium as a reducing agent. Anodes of magnesium are used for cathodic protection of underground pipe and water tanks. Small quantities of magnesium are used as a catalyst in producing organic compounds, as photoengraving plates, and in alloys other than aluminum.

Refractory magnesia represents the largest use of magnesium in compounds. Refractory magnesia is manufactured into bricks and other shapes principally for linings in furnaces and auxiliary equipment used to produce iron and steel. Magnesia-base refractories also are used in furnaces in the cement, glass, and nonferrous metals industries.

Caustic-calcined magnesia is used in a variety of applications in the agricultural, chemical, construction, and Causticmanufacturing industries. calcined magnesia is an important component of animal feed and fertilizer, providing essential nutrients for livestock and plant growth. In construction, caustic-calcined magnesia is used in special cements for industrial flooring and in lightweight insulating wallboard. In the chemical industry, it is used as a starting point for the manufacture of other Special grades of magnesium salts. caustic-calcined magnesia are used for including antacids, pharmaceuticals. toothpaste, milk of magnesia, and cosmetics. Magnesia is used to remove sulfur from flue gases and boiler fuels and is used for acid neutralization in process wastewater and in lubricating oils. Caustic-calcined magnesia is also

important in manufacturing paper, rayon, and rubber. 1

Other magnesium compounds are used in place of, or in addition to, caustic-calcined magnesia in many of the above applications. Magnesium hydroxide is used in the pulp and paper industry; magnesium sulfate is used for pharmaceuticals, animal feed, and fertilizers; and magnesium carbonate is used in the chemical, pharmaceutical, and rubber industries. Fused magnesia is used primarily for electrical insulation.

The principal use for olivine is as a foundry sand used in casting iron and steel components and some nonferrous metals. Olivine is used in smaller quantities for refractories, slag control in blast furnaces, and soil conditioning. In Europe, olivine is used instead of silica sand for blasting debris from bridges and buildings and in incinerators.²

Industry Structure

U.S. producers of magnesium and magnesium compounds are shown in tables 1 and 2. Olivine is produced by two companies in the United States—Applied Industrial Minerals Corp. (AIMCOR) and Olivine Corp. AIMCOR operates two mines in North Carolina and Washington, and processing plants in Indiana, North Carolina, and Washington; Olivine operates one mine and one processing plant in Washington.

Electrolytic plants in Canada, Kazakhstan, Norway, Russia, Ukraine, and the United States represent 68% of the world magnesium metal production capacity (excluding the capacity in Kazakhstan, Russia, and Ukraine that is used exclusively for titanium metal production). Smaller thermal plants are in Brazil, Canada, China, France, India, Italy, Japan, the United States, and Yugoslavia.

The largest magnesite production facilities in the world are in China, North Korea, and Russia. Together, these three countries account for 58% of the world magnesite production capacity. Japan and the United States account for 61% of the world's magnesium compounds production capacity from seawater or

brines. Fused magnesia is produced in Australia, Canada, France, Israel, Japan, Mexico, the United Kingdom, and the United States.

Norway is the world's principal producer of olivine, and in addition to supplying its domestic needs, Norway is a major world supplier of olivine. Countries with smaller output are Austria, Italy, Japan, Mexico, Spain, Sweden, and the United States. (See tables 1 and 2.)

Geology

Magnesium is the eighth most abundant element and constitutes about 2% of the Earth's crust. It is the third most plentiful element dissolved in seawater, with a concentration averaging 0.13%. Although many minerals contain magnesium, magnesite, dolomite, brucite, and olivine are the only minerals from which magnesium compounds are recovered commercially.

Dolomite is a sedimentary rock commonly interbedded with limestone, which extends over large areas of the United States. Most dolomite occurrences are likely the result of replacement of calcium by magnesium in preexisting limestone beds. Magnesite primarily is found in four types of deposits-sedimentary beds, alterations of serpentine, vein fillings, and replacements of limestone and dolomite. Brucite is found in crystalline limestone and as a decomposition product of magnesium silicates associated with serpentine, dolomite, magnesite, and chromite. Olivine generally occurs as granular masses or disseminated grains or crystals and is a common constituent of basic igneous rocks such as basalt and gabbro. Dunite is an olivine-rich rock.3

Technology

Processing—Metal.—Two thermal processes currently are in use to recover magnesium metal from dolomite—the Pidgeon process and the Magnetherm process. Both use the same basic chemistry, but the Pidgeon process uses an external heat source, and the

Magnetherm process uses heat generated by the electrical resistance of the reactants. In the Pidgeon process, dolomite and ferrosilicon are formed into briquettes and heated in a retort under a vacuum. Magnesium oxide in the dolomite reacts with the ferrosilicon to produce magnesium vapor, which is cooled and condensed in a separate section of the retort. Plants in Canada, Italy, and Japan use this process to recover magnesium.

In the Magnetherm process, calcined dolomite, ferrosilicon, and alumina are heated under a vacuum. Alumina reduces the melting point of the slag produced by the dolomite-ferrosilicon reaction to make resistance heating practical. Magnesium vapor is cooled and condensed in a condensing chamber. The Magnetherm process is used in plants in Brazil, France, Japan, the United States, and Yugoslavia.

Electrolytic recovery of magnesium requires a magnesium chloride feedstock that normally is prepared from seawater or brines. Two types of magnesium chloride can be made-hydrous and anhydrous. In the preparation of hydrous magnesium chloride, used by Dow Chemical Co., magnesium hydroxide is precipitated from seawater by the addition of dolomitic limestone. Adding hydrochloric acid to the magnesium hydroxide produces a neutralized magnesium chloride solution. This solution is dehydrated until it contains about 25% water and then is fed directly to electrolytic cells.

Magnesium Corp. of America (MagCorp) and Norsk Hydro A/S of Norway use an anhydrous magnesium chloride feed for their electrolytic cells. MagCorp uses solar evaporation initially to concentrate magnesium chloride brines from the Great Salt Lake. After adding calcium chloride to precipitate sulfate impurities and removing boron by solvent extraction, the brine is concentrated further and dehydrated in a spray dryer. The resulting powder is purified, concentrated, prilled, and dehydrated to produce anhydrous magnesium chloride.4 Norsk Hydro starts with concentrated magnesium chloride brine. The brine is

purified, concentrated, prilled, and dehydrated to produce anhydrous magnesium chloride.

Electrolytic cells used to recover magnesium from either hydrous or anhydrous magnesium chloride differ from company to company, and most information about cell design and operating conditions usually is not disclosed. Essentially, magnesium chloride fed to an electrolytic cell is broken down into magnesium metal and chlorine gas by direct current at 700° C. Magnesium is removed from the cell and cast into ingots, and the chlorine gas is recycled or sold.

Magnesium International Corp. developed a one-step process for producing anhydrous magnesium chloride that was demonstrated at Magnesium Co. of Canada Ltd.'s (MagCan) new plant that opened in 1990 and closed in 1991. Reacting magnesite with chlorine gas in the presence of carbon monoxide in a packed-bed reactor at 900° C produces magnesium chloride and carbon dioxide. Liquid magnesium chloride collects at the bottom of the reactor and is tapped periodically for transfer to electrolytic cells.5

Nonmetal.-Preparing either causticcalcined or dead-burned magnesia from magnesite involves crushing magnesite to various sizes, depending on the type of material to be produced. After crushing, magnesite is beneficiated; the degree of beneficiation depends on the quality of the ore and its ultimate end use. Lower quality ore often requires heavy-media separation, magnetic separation, and flotation to remove impurities. High-quality ore may require only screening and hand sorting to produce a material of acceptable quality. Caustic-calcined magnesia is produced in shaft kilns, multiple-hearth furnaces, or rotary kilns. Dead-burned magnesia is produced in rotary or shaft kilns.

In producing synthetic magnesia, seawater or brines are treated either with a small quantity of lime or sulfuric acid to remove dissolved carbon dioxide. Then calcium hydroxide, in the form of lime or dolime, is added to precipitate the

dissolved magnesium as magnesium hydroxide. The resulting slurry is thickened and vacuum-filtered to yield a filter cake containing about 50% magnesium hydroxide. The filter cake can be directly calcined to produce caustic-calcined or dead-burned magnesia, or it can be calcined and pelletized before dead-burning to give specific size and density characteristics.

Fused magnesia is produced by fusion of high-grade magnesite or caustic-calcined synthetic magnesia in an electric arc furnace. After fusion, the material is crushed, inspected to remove any unfused magnesia, and crushed further in a ball mill.

Recycling.—Magnesium scrap is in forms similar to those of other nonferrous metals. New scrap comes in forms such as castings, drippings, drosses, gates, runners, and turnings. Old scrap primarily comes from old aircraft parts and discarded consumer products, such as lawnmower decks, chainsaw housings, and hand tools. The diecasting industry traditionally is the largest source of scrap magnesium.

Sorted scrap is charged into a steel crucible, which is heated to 675° C. As the scrap at the bottom begins to melt, more scrap is added. The liquid magnesium on the bottom is covered with a flux to inhibit surface burning. After any alloying elements are added and melting is complete, molten magnesium is transferred to ingot molds by either hand ladling, pumping, or tilt pouring.⁶

Economic Factors

Costs to produce magnesium metal vary greatly, depending upon the feed material and the process used. Operating costs for magnesium production range from \$309 to \$2,283 per ton, with energy costs as the largest component of the total operating cost. A weighted average operating cost was estimated to be \$1,122 per ton. Total production costs from seawater sources were lower than from brines or dolomite sources. Magnesium compound operating costs also vary depending upon source material and

processing techniques. Operating costs range from \$24 to \$425 per ton for magnesium compound production, with seawater as the most costly source. The weighted average operating cost for magnesium compounds production from all sources was \$288 per ton. Energy costs also represent the largest component of total operating costs.⁷

Analysts at Commodities Research Unit (CRU) evaluated the direct operating costs of magnesium plants that operated during 1991. The operating cost curve showed that about one-half of the producers had direct operating costs less than \$1.00 per pound of magnesium, and about 20% of the production was at direct operating costs above \$1.25 per pound. In their cost estimates, CRU evaluated capital and operating costs for a 60,000ton-per-year greenfield magnesium plant constructed in Australia. Capital costs were estimated at \$470 million, with a 20% rate of return on investment over a 10-year life of the loan. In addition, operating costs were estimated to be \$1.76 per pound in constant 1990 dollars, with most of the costs being capital charges resulting from the rate of return on investment and loan life. If the rate of return was lowered to 10% and the life of the loan was extended to 20 years, capital change would drop by one-half.8

Tariffs for magnesium and magnesium compounds are shown in table 3. Depletion allowance for magnesium chloride from domestic or foreign sources is 5%. Magnesium carbonate and dolomite have depletion allowances of 14% from domestic and foreign ores. Depletion allowances for other ores are brucite, 10% (domestic and foreign), and olivine, 22% domestic and 14% foreign. (See table 3.)

ANNUAL REVIEW

Magnesium

Legislation and Government Programs.—On July 7, 1992, the International Trade Administration (ITA) made a final determination on countervailing and antidumping duties assessed on magnesium imported into the

United States from Canada. The final countervailing duty for primary and alloy magnesium was 21.61% ad valorem, and the final antidumping duty was 31.33% ad valorem for primary magnesium only. These duties affect Norsk Hydro Canada Inc., but do not affect material imported from either Norsk Hydro in Norway or Timminco Ltd. in Canada.9 These duties were affirmed by the International Trade Commission, which voted on the determinations on August 11. As a result, the U.S. Customs Service was required to collect both countervailing and antidumping duties on imports of magnesium from Norsk Hydro Canada.

On November 16, the Department of Commerce announced a final decision concerning Canadian Provincial government subsidies of Norsk Hydro Canada's electric power contract for its Becancour, Quebec, primary magnesium According to Commerce, the amended power contract between Norsk Hydro and Hydro Quebec, the power supplier, which was approved on August 5 and made retroactive effective to January 1, no longer conferred a subsidy. As a result of this determination, the countervailing duty for pure and alloy magnesium dropped from 21.61% ad valorem to 7.61% ad valorem. 10 The 14% difference in the margin is the quantity assigned to the power contract; in its original investigation, ITA found that Norsk Hydro received a 60% discount when compared to Hydro Ouebec's other customers. Antidumping duties, which were levied on pure magnesium only, were not affected.

In an effort to eliminate all countervailing and antidumping duties, Norsk Hydro filed a request for review with the United States Section of the Binational Secretariat of the United States-Canada Free Trade Agreement on September 25. When a request for review is made, a panel is formed to review the final determination and to determine whether it conforms to the antidumping or countervailing duty laws in the country that imposed the duty. The reviews were scheduled to take place in 1993.

With the signing of trade agreements

on June 17, the Russian Federation officially received most-favored-nation status. As a result, the tariff on U.S. primary magnesium imports from the former U.S.S.R. was reduced from 100% ad valorem to 8% ad valorem, making imports of the metal competitive in U.S. markets.

Production.—Total U.S. primary production increased by 4% from that in 1991. Producers operated at 86% of their rated capacity.

After resolving some furnace problems, Northwest Alloys Inc. reported that its primary magnesium plant in Addy, WA, was operating five out of nine furnaces at the end of August. After its announced cutback in December 1991, Northwest Alloys was operating only three furnaces because of the problems. The company planned to increase capacity while operating the same number of furnaces to satisfy some of Alcoa's magnesium requirements that had been met by Norsk Hydro Canada. (See table 4.)

Consumption and Uses.—Automobile manufacturers continue to magnesium in some of their new models. Ford Motor Co. began using magnesium in some radio components in the 1993 models of cars built in North America and overseas; this is part of a program that is expected to consume about 500 tons of magnesium annually. Ford's new radio applications involved two-piece amplifier housings. The magnesium was expected to be purchased in North America, and in addition to being used in North American plants, it will be used in vehicles manufactured in Portugal and perhaps in Brazil. In addition, Chrysler Corp. announced that it would use diecast magnesium steering column support brackets in the 1994 models of its standard-size T300 pickup trucks. This application could consume up to 250 tons of magnesium annually. Chrysler also planned to use magnesium valve covers on the largest engines in the T300 truck; this application was expected to consume more than 70 tons of magnesium

annually.

Significant quantities of magnesium also were to be used in new models of minivans, one of the most popular types of vehicles. General Motors Corp. (GM) was evaluating magnesium instrument panel support beams for two of its minivans, for introduction in 1996. Annual consumption of magnesium for this application was estimated to be 1,360 tons. Chrysler also planned to install magnesium steering column assemblies in a new model of its minivans, scheduled to be out in 1996. The company was considering magnesium steering column support brackets for use in these minivans. An article reviewed new applications for magnesium in the automotive industry and properties of magnesium that make it attractive for these uses.11

Although Ford's electric vehicle is still a concept vehicle, the company planned to use magnesium in some components, including the transmission housings. Magnesium, along with aluminum and plastic components, was expected to minimize the effect of the vehicle's heavy battery pack on performance.

A firm in the United Kingdom, Hawtal Whiting Holdings Plc, constructed an ultralight car door structure from aluminum and magnesium. The new door, weighing 12.3 pounds as compared with a steel door, which weighs between 35 and 50 pounds, was made to fit a Swedish-built Volvo 240. The main door structure and attached mirror bracket were made of magnesium alloy; the intrusion beam and window frame were aluminum. The door was said to meet U.S. Federal safety requirements for direct and side impacts, but the cost of a mass-produced door was not known.

GM was studying magnesium alloy AE42 for potential applications in transmission cases. Engineers at the company were studying the casting characteristics, performance, and machinability for transmission cases for rear-wheel-drive vehicles. The Chevrolet Corvette would be the first candidate for the new transmission cases, if tests prove successful.

Because of increased demand for large

die-cast magnesium components, Lunt Manufacturing planned to begin construction of a second 6,000-squaremeter magnesium casting facility near Chicago, IL, in 1993. The company currently operates an 7,900-square-meter facility with 12 diecasting machines. In addition, Magnesium Products Ltd., a subsidiary of Canada's Meridian Technologies Inc., announced that it would construct a new 6,000-squaremeter diecasting plant in Eaton Rapids, MI. Completion was scheduled for 1994.

Consumption of secondary magnesium was 7,515 tons. Of this consumption, 56% was from old scrap and 44% was from new scrap. (See tables 5 and 6.)

Stocks.—Producers' stocks of primary magnesium at yearend 1992 dropped to 5,863 tons, which was significantly lower than the yearend 1991 stocks of 21,294 tons. Although there was not a large increase in domestic demand, the sharp dropoff in imports required producers to draw down their stocks to replace demand that was met by imported material in 1991. Consumer stocks of secondary magnesium increased slightly to 356 tons at yearend 1992 from 337 tons at yearend 1991.

Markets and Prices.—Throughout most of the year, published U.S. producer prices of primary magnesium and diecasting alloy continued to be significantly higher than estimates of actual transaction prices. U.S. producers announced several price increases in the first half of 1992, but did not state what their actual prices were. Although both Dow and MagCorp had announced that they would increase primary magnesium prices by 10% in January 1992, the published list price of \$1.43 per pound did not change. Press reports estimated that the actual transaction price was about \$1.22 per pound. In mid-June, Dow and MagCorp announced price increases of \$0.10 per pound for primary magnesium, but neither company increased its published \$1.43-per-pound quotation. The estimated transaction price was \$1.32 per pound. In September, both

companies reported that they had increased the primary magnesium price to \$1.43 per pound, their published price quotations. By mid-December, Dow and MagCorp reportedly increased their primary magnesium price to \$1.53 per pound, but Dow announced a temporary voluntary allowance of \$0.07, which reduced its actual transaction price to \$1.46 per pound. At yearend, U.S. producers' price for magnesium was \$1.46 to \$1.53 per pound.

In April, both Dow and MagCorp announced increases in diecasting alloy prices. Dow increased its published price by \$0.06, from \$1.34 to \$1.40 per pound. MagCorp also announced a price increase of \$0.06 per pound, but its published price of diecasting alloy remained at \$1.43 per pound. In mid-November, both companies announced price increases for diecasting alloy to \$1.54 per pound; Dow increased its price by \$0.14 per pound, and MagCorp increased its price by \$0.10 per pound. At yearend the diecasting alloy AZ91D was quoted at \$1.54 per pound. This was the first time in many years that the price of diecasting alloy was higher than the primary metal price.

Two trade publications, Metals Week and Metal Bulletin, began publishing estimated transaction prices for primary magnesium. Metals Week began publishing a U.S. transaction price and a European free market price in May, and Metal Bulletin began quoting a free market price in February.

Metals Week's U.S. transaction price was quoted at \$1.22 per pound at the beginning of May. It rose steadily throughout the year and closed at \$1.46 to \$1.53 per pound by yearend. Metals Week's European free market price was quoted at \$1.02 to \$1.07 per pound at the beginning of May and rose to a high of \$1.27 to \$1.29 per pound by mid-June. This price generally trended down through the remainder of 1992 to end the year at \$1.16 to \$1.20 per pound. The free market price quoted in Metal Bulletin followed essentially the same pattern as the European free market price. The free market price was quoted at \$0.88 to \$0.93 per pound in February, rose to a

high of \$1.27 to \$1.29 per pound by the end of June, and decreased to \$1.18 to \$1.20 per pound by the end of 1992.

Norsk Hydro began publishing a European indicator price at the beginning of 1992. This price was quoted at 3.85 Deutchemarks per kilogram on January 1 and was raised on a quarterly basis to 5.35 Deutchemarks per kilogram by yearend.

Foreign Trade.—Exports of magnesium were 6% less than those in 1991. The Netherlands (31%), Japan (24%), and Canada (15%) were the principal destinations.

The effects of the antidumping and countervailing duty determinations against Norsk Hydro in Canada were reflected in the U.S. import statistics in 1992. Imports of primary magnesium from Canada fell from more than 21,000 tons in 1991 to about 500 tons in 1992. In addition, granting most-favored-nation status to the Russian Federation led to a significant quantity of primary magnesium imported from the former U.S.S.R.; Russia and Ukraine became the largest single sources of primary magnesium in 1992. Total U.S. imports in 1992 were 63% less than those in 1991. (See tables 7 and 8.)

World Review.-According to the International Magnesium Association, world inventories of magnesium at the end of 1992 were nearly one-half the level at yearend 1991. Total world inventories stood at 29,500 tons at the end of December 1992, compared with 55,100 tons at the end of 1991. Temporary and permanent closures of several facilities throughout the world led to a tight supply situation during 1992, down their drew and producers inventories to meet demand. (See tables 9, 10, and 11.)

Australia.—In Australia, the Commonwealth Scientific, Industrial and Research Organization (CSIRO), the Government research and development organization, and Japan's Ube Industries Ltd. signed an agreement with the owners

of the Kunwarara magnesite deposit to develop new electrolytic magnesium metal production technology that will be internationally competitive. Current plans were for Ube Industries, along with Queensland Metals Corp. and MIM Holdings Ltd., to construct a 700- to 1,000-ton-per-year pilot plant by 1994 or 1995. If the technology proves successful, the three companies plan to build a 60,000-ton-per-year plant in Australia using magnesite from the Kunwarara deposit as raw material.

Brazil.—Brasmag's parent company, Rima Group, announced in December that the two companies completed their debt repayment under the Brazilian law equivalent to the U.S. chapter 11 bankruptcy law. The companies had filed for bankruptcy in November 1990, citing high interest rates, shortage of credit lines, and the startup of Brasmag's capacity expansion as some of the reasons for the filing.

Canada.—At the end of May, Noranda Minerals reportedly signed an agreement with Benvest Capital (formerly Lavalintech) to purchase its 50% interest in the Magnola magnesium project in Canada. This purchase made Noranda the sole owner of the project, and the company said that it was seeking financing from additional partners before proceeding with project development. The Magnola project was designed to recover magnesium from asbestos mine tailings in Quebec.

Magnesium Products announced that it would expand its discasting facility in Strathroy, Ontario, in response to new business from North American automobile manufacturers. The 370-square-meter addition, with a 2,200-ton discasting machine, was expected to be completed by June 1993.

France.—Pechiney announced that it would shut down its 18,000-ton-per-year magnesium plant in Marignac, France, during January and February 1993. Because of energy costs, which are highest during these 2 months, Pechiney may decide to continue this practice

during the next few years.

Israel.—Dead Sea Works Ltd. (DSW), a subsidiary of Israel Chemicals Ltd., announced that it planned to construct a 50,000-ton-per-year magnesium production plant in Israel that could begin production as early as 1995. Construction and final financing decisions were expected in the fall. Initially, the company planned a two-stage construction; construction of a 25,000-ton-per-year facility by 1995 and an additional 25,000 tons of annual capacity by 1998. DSW planned to use technology that has been used in the former U.S.S.R. to recover magnesium from carnallite, which is said to be easier than magnesium chloride to dehydrate. DSW currently produces bromine, chlorine, magnesium compounds, potash, salt, and sodium hydroxide from brines in Israel.

Italy.—The primary magnesium producer in Italy announced in March that it would cease production at its plant in Bolzano for at least a few months. Because of inventories that have built up at the plant, the company had enough magnesium to meet the demands of its current contract customers, but would not renew the contracts when they expire. In addition, there were sufficient stocks to continue the current production levels for magnesium alloys for anode production. According to a company spokesperson, the low price of magnesium resulting from exports from the former U.S.S.R. influenced the company's decision to discontinue primary magnesium production. Approximately 220 to 230 of the plant's work force of 250 were expected to be laid off.

Japan.—Japan Metals and Chemicals Corp. temporarily stopped production of primary magnesium at its 5,000-ton-per-year plant, although the company planned to maintain its remelt production.

Canada-based Meridian Technologies reportedly signed an agreement with Kobe Steel Ltd. of Japan under which Kobe Steel will market Meridian's diecastings in Japan, mainly for the automotive industry. Kobe Steel currently produces magnesium sand castings, primarily for the aircraft industry. Magnesium diecasting in Japan has been limited to low volumes of small castings, and Kobe Steel does not have the equipment necessary to produce castings for the automotive industry. If demand increases sufficiently, Kobe Steel and Meridian plan to form a joint venture to produce magnesium diecastings in Japan.

Saudi Arabia.—British Aerospace International reportedly was evaluating construction of a magnesium metal plant in Saudi Arabia. The proposed plant initially would have an annual capacity of 10,000 tons, with a potential for expansion to 30,000 tons. Magnesium would be recovered from salt water by electrolysis, which would take advantage of low-cost electrical power available in Saudi Arabia. British Aerospace stated that the decision whether to go ahead with a feasibility study would not be made until mid-1993.

Current Research.—In Japan, Mitsui Mining & Smelting Co. Ltd. reportedly developed three new magnesium alloys with a wide range of potential applications. Two of the new alloys combine magnesium with rare-earth metals—one with terbium and one with gadolinium. These alloys are highly heatresistant, which make them candidates for applications in pistons of automobile engines. The third alloy is a magnesiumlithium alloy that possesses high specific strength and superplasticity. Potential applications for the magnesium-lithium alloy are in office automation equipment and other industrial products.

Researchers at Magnesium Elektron Ltd. in the United Kingdom announced the development of a process for making metal-matrix composites that blends liquid magnesium alloy with ceramic particles, such as alumina or silicon carbide. These magnesium metal-matrix composites were lightweight and demonstrated significant increases in modulus and tensile strength, compared to unreinforced material, at

both ambient and elevated temperatures. The process for making the magnesium metal-matrix composites was essentially a direct mixing process, and the company claimed that this was a cost-effective process to make metal-matrix composites for cast and wrought applications.¹²

Magnesium Compounds

Production.—Production of all magnesium compounds in 1992 dropped slightly from 1991 levels, except for magnesium sulfate production, which increased by about 9%. Martin Marietta Specialties Inc. announced plans to increase its merchant capacity for producing magnesium hydroxide at its Manistee, MI, facility in mid-1994. Annual production capacity was scheduled to increase to 50,000 to 70,000 tons from current levels of a few thousand tons. Martin Marietta has been a significant producer of magnesium hydroxide for internal use; the company calcined the magnesium hydroxide to magnesium oxide, which it marketed. (See table 12.)

Consumption and Uses.—Dead-burned magnesia refractories for use in metal, cement, and glass production furnaces continued to be the primary application for magnesium compounds in the United States, representing about 60% of the total U.S. demand for magnesium compounds. Harbison-Walker Refractories Inc. introduced magnesiaalumina spinel refractories for use in lime and cement kilns as replacements for magnesia-chrome refractories. According to the company, magnesia-alumina spinel bricks have demonstrated an improved service life in many plants and may reduce the need for hazardous waste disposal of bricks that contain traces of soluble chrome. 13

In 1992, agricultural applications (animal feed and fertilizer) were the dominant use for caustic-calcined magnesia, accounting for 32% of U.S. shipments. Chemical processing was the next largest segment, with 21% of total shipments. The following categories, with the individual components in

parentheses in declining order, were the other end-use sectors for caustic-calcined magnesia: metallurgical (refractories, water treatment, electrical, and stack-gas scrubbing), 16%; manufacturing (rayon, fuel additives, rubber, and pulp and paper), 14%; construction (oxychloride and oxysulfate cements and general construction), 5%; pharmaceuticals and nutrition (medicinal and pharmaceutical, sugar, and candy), 3%; and unspecified uses, 8%. A review of magnesium oxide compounds applications in neutralization was published, reflecting the growing interest in minerals for environmental applications.14

Magnesium carbonate was used principally as a chemical intermediate and in medicines and pharmaceuticals. Magnesium hydroxide was used mainly in pulp and paper, chemical industries, and in water treatment.

Magnesium sulfate was used mostly in pharmaceuticals and animal feed. According to a review article on agricultural applications of kieserite (MgSO₄•H₂O), using kieserite-containing fertilizers increases both the available magnesium and sulfur to crops. Depending on soil type, kieserite may be used in conjunction with magnesium carbonate in carbonate-deficient soils.¹⁵

Magnesium chloride was used mainly in oxychloride cements. Magnesium chloride brines were used principally for road dust and ice control.

Refractory and foundry uses were the largest applications for olivine in the United States, each accounting for 44% of consumption of domestically produced material. Sand blasting and other abrasive applications accounted for 7%, and slag control accounted for the remaining 5% of U.S. olivine consumption. (See table 13.)

Markets and Prices.—Yearend 1992 prices for most magnesium compounds did not change from those of 1991. The only exceptions were dead-burned magnesium, which decreased by \$62 per short ton, and synthetic magnesia, which increased by \$36 per short ton. (See table 14.)

Foreign Trade.—Trade data for olivine are not reported separately by the Bureau of the Census. Some data on olivine are available from a computer service, the Port Import/Export Reporting Service PIERS reports data on (PIERS). materials that are transported by ship. According to this source, the United States imported 123,249 tons of olivine from Norway in 1992. Exports of olivine from the United States totaled 2,744 tons. Chile, with 56% of the total, and Peru, with 25% of the total, were the principal recipients. Australia, Italy, the Republic of Korea, New Zealand, and Taiwan were the other destinations. (See tables 15. 16. 17. and 18.)

World Review.—A review article of the world magnesia industry discussed the status of all the principal world magnesia producers, including a review of magnesia products, changes in product quality, and development of new markets. ¹⁶ (See tables 19 and 20.)

Australia.—Devex Ltd. reportedly signed a Heads of Agreement with Toyota Tsushi Corp. and Mitsubishi Materials Corp. for further development of its mining and processing magnesite operations at Thuddungra, New South Wales. In the proposed joint-venture agreement. Devex will own 50% of the operations and Toyota Tsushi and Mitsubishi Materials together will own 50%. Expanding the mine's facilities will include installation of calcining equipment to produce 43,000 tons per year of calcined magnesia and electric arc furnaces to produce 13,000 tons per year of high-grade fused magnesia. construction schedule for the \$21 million facilities was expected to be set by early 1993.

The Queensland Magnesia Project Joint Venture (QMAG) commissioned additional furnaces at its magnesite processing operation in Queensland. A second 10-ton-per-hour, multiple-hearth Herreshoff furnace was installed in February for the initial magnesite calcination step; the first furnace was installed in October 1991. Calcined

magnesite from these furnaces was used as feed for QMAG's dead-burning and fusion operations. A second 50,000-ton-per-year shaft kiln was commissioned in the dead-burning plant in February 1992, and a third kiln is scheduled to be installed sometime in 1993.

In addition to dead-burned and fused magnesia. OMAG is in several joint ventures to market other products derived from magnesite. These joint ventures include one with ICI Australia to evaluate market potential and technical requirements for calcined magnesia and hydroxide to the magnesium environmental market (Enviromag); Cemag, with Queensland Cement Ltd.. to develop magnesia cements and building products; and Flamemag, a joint venture with CSIRO, to produce specially formulated flame-retardant fillers for plastics. The company is also in a joint venture with Japan's Ube Industries, MIM Holdings, and CSIRO to construct a 1,000-ton-per-year pilot plant to produce magnesium metal.¹⁷

Austria. — Radex-Heraclith Industriebeteilgungs AG announced a restructuring of its organization. This restructuring involved a noncash capital contribution of 70% of Radex Austria AG to Veitscher Magnesitwerke AG as part of a capital increase; acquisition of 30% Veitscher Austria by Radex from Österreichische Magnesitwerke Magnesit AG; renaming Veitscher Magnesitwerke to Veitsch-Radex AG für feuerfeste Erzeugnisse; and the dissolution of Österreichische Magnesit. As a result of this restructuring, Radex-Heraclith holds controlling interest in 610,000 tons per year of magnesia production capacity in Austria and has interests in magnesia operations in Australia, Greece, Italy, and Turkey.

Canada.—Canadian Refractories
Dresser Canada Inc., a subsidiary of
U.S.-based Harbison-Walker, announced
that it planned to close its underground
dolomitic magnesite operation in Kilmar,
Quebec, by May. After the mine was
closed, the company planned to rely on
accumulated aboveground stocks for 4 to

5 years of feed supply for its 15,000-tonper-year dead-burned magnesia plant.

China.—Construction of a 10,000-tonper-year magnesium sulfate plant reportedly was completed in Laizhou, Shandong, in 1992. The plant was expected to use locally produced magnesite and sulfuric acid as feedstock. This was reported to be the largest magnesium sulfate plant in China.

Germany.—Kali und Salz AG reportedly ceased production of magnesium chloride flake at its Salzdetfurth plant in March. According to a company spokesperson, magnesium chloride flake was no longer a profitable business. At one point, Kali und Salz was supplying Norsk Hydro with magnesium chloride flake as a feed for its magnesium metal plant in Norway, but Norsk Hydro had switched to a different supplier. Supplies of magnesium chloride that were lost from the closure of Kali und Salz's plant were expected to be replaced by production at DSW's new magnesium chloride plant in Israel, with a capacity of 100,000 tons per year, which began operating in early April. In addition to magnesium metal, magnesium chloride is used by the artificial seawater industry; in textiles. adhesives, and special oxychloride cements; and as an alternative deicer. 18

Greece.—Fimisco and its affiliated company Macedonian Magnesite SA reportedly will be sold through a public auction. The companies, which had a combined magnesia production capacity of 365,000 tons per year, cited depletion of ore reserves and falling prices and revenues as reasons for the liquidation. Fimisco stopped production at the end of November 1991 after several years of financial problems and went into liquidation in January 1992.

India.—Tamilnadu Magnesite Ltd. (Tanmag) announced plans to produce high-quality dead-burned magnesia at its plant in Salem by the end of 1993. Tanmag was expected to install technology based on Sulzer Brothers

Ltd.'s Sulmag process to produce 26,000 tons per year of dead-burned magnesia from domestically mined silica-rich cryptocrystalline magnesite. The company also planned to produce 10,000 tons per year of magnesia-chrome clinker.

Italy.—At the beginning of 1992, Cogema SpA, a subsidiary of Sardamag SpA with a 65,000-ton-per-year seawater magnesia plant in Sicily, was dissolved as a separate entity, and its plant was operated under the Sardamag name. Sardamag also operated a 65,000-ton-per-year plant in Sant Antioco. Because of depressed prices, the Sant Antioco plant was closed from November 1991 until April 1992, but the company supplied its customers from inventories.

Mexico.—In September, Industrias Peñoles SA de CV announced the opening of a 5,000-ton-per-year fused magnesia plant to be operated by a new subsidiary Magnelec SA de CV. The new \$5 million plant is in Ramos Arizpe, Coahuila, and its output is expected to be consumed primarily by the Mexican refractory industry. Feedstock for Magnelec's fusion process was supplied by dead-burned magnesia from Quimíca del Rey Sa de CV's brine operation, also in Coahuila.

United Kingdom.—Steetly Magnesia Products Ltd. reportedly closed its 35,000-ton-per-year facilities for the production of high-purity pelletized magnesia. Instead, the company planned to concentrate on production of magnesium-aluminum spinels and magnesium hydroxide for environmental applications. Spinel production capacity was estimated to be 12,000 tons per year, but Steetly planned to increase this to 30,000 tons per year.

A review of refractories consumption in the United Kingdom showed some of the same patterns occurring as in the United States. Overall refractories consumption has declined as open-hearth steel furnaces were replaced by electric arc furnaces, basic-oxygen steelmaking, and continuous casting. Refractories

consumption per ton of steel produced dropped from 250 kilograms to less than 5 kilograms just by changing production technologies. In addition, the refractories were being replaced less often as improved refractory products are developed.¹⁹

OUTLOOK

Growth areas for magnesium metal consumption in the United States in the next few years are likely to be in automotive components and iron and steel desulfurization, with the largest growth in automotive components. To meet more stringent requirements for fuel economy, manufacturers have essentially two choices-make the vehicles smaller or reduce weight. To satisfy consumer preferences for larger vehicles, automakers are using magnesium components to reduce the total weight. The average magnesium content of a typical U.S. vehicle has doubled from 1.1 kilograms in 1987 to 2.3 kilograms in 1991. Many auto manufacturers continue to specify new magnesium components in vehicles to be built throughout the rest of the decade.

Iron and steel desulfurization in the United States is expected to continue to grow, but at slower rates than in the past. Magnesium has already been substituted for calcium carbide; in the United States, almost all hot metal already is desulfurized with magnesium. Growth in the desulfurization market will come as additional metal requires desulfurization, not by replacing currently used desulfurization agents as was done in the past. This factor would lead to slower growth rates in this market.

Recent political changes in the former U.S.S.R. have begun to affect the world supply of magnesium metal. Normally, most of the magnesium produced in the former U.S.S.R. was used in the production of titanium for defense applications. With the shift of emphasis away from defense applications and because of the country's need for hard currency, this magnesium has begun to appear on the world market at prices less than prevailing world prices. This is

likely to continue to affect future supplies.

Production and demand for magnesium compounds in the United States was expected to remain relatively stable over the new few years, but the proportion of magnesia used as refractories was expected to continue to decrease. Technological changes in steel production have had a deleterious effect on the consumption of specific refractories. Open-hearth furnaces have disappeared in the United States and been replaced by electric arc furnaces and basic-oxygen Although the trend to steelmaking. electric arc furnaces has reduced the overall demand for refractories, highquality basic refractories (including magnesia-base refractories) are needed for the body of the furnace. In addition, the use of continuous casting has increased at the expense of ingot casting. At the same time, improvements in refractories technology resulted in increased longevity. As a result of these changes, in the past 15 years, there has been a threefold to fourfold decline in refractories consumption per ton of steel produced to about 14 to 15 kilograms of refractories per ton. This figure is projected to drop to 10 to 11 kilograms per ton by 2000.20 The decline in use of magnesia-base refractories, however, has not been as great as declines for other materials, such as firebrick. Although refractories are the principal use for magnesia, environmental applications, such as flue gas desulfurization and water treatment, are being investigated as growth areas for magnesia and other magnesium compounds. Any increase in demand for other magnesium compounds is expected to be offset by the decline in refractories demand, leading to a stagnant demand for magnesium compounds in the United States.

TABLE 1
U.S. MAGNESIUM METAL PRODUCERS, BY LOCATION, RAW
MATERIAL, AND PRODUCTION CAPACITY IN 1992

Company	Plant location	Raw material	Annual capacity (metric tons)
The Dow Chemical Co.	Freeport, TX	Seawater	90,000
Magnesium Corp. of America	Rowley, UT	Lake brines	35,000
Northwest Alloys Inc.	Addy, WA	Dolomite	35,000
Total			160,000

TABLE 2
U.S. MAGNESIUM COMPOUND PRODUCERS, BY RAW MATERIAL SOURCE, LOCATION, AND PRODUCTION CAPACITY IN 1992

Raw material source and producing company	Location	Capacity (metric tons of MgO equivalent)
Magnesite: Premier Services Inc.	Gabbs, NV	100,000
Lake brines:		
Great Salt Lake Minerals & Chemicals Corp.	Ogden, UT	90,000
Reilly Industries Inc.	Wendover, UT	45,000
Well brines:		
The Dow Chemical Co.	Ludington, MI	200,000
Martin Marietta Chemicals	Manistee, MI	275,000
Morton Chemical Co.	do.	10,000
Seawater:		
Barcroft Co.	Lewes, DE	5,000
The Dow Chemical Co.	Freeport, TX	20,000
Marine Magnesium Co.	South San Francisco, CA	15,000
National Refractories & Minerals Corp.	Moss Landing, CA	165,000
Premier Services Inc.	Port St. Joe, FL	50,000
Total		975,000

TABLE 3
U.S. IMPORT DUTIES

T-	HTS	Most favored nation (MFN)	Non-MFN
Item	No.	Jan. 1, 1992	Jan. 1, 1992
Magnesium:			
Unwrought magnesium	8104.11.0000	8.0% ad valorem	100% ad valorem.
Unwrought magnesium alloys	8104.19.0000	6.5% ad valorem	60.5% ad valorem.
Magnesium waste and scrap	8104.20.0000	Free	Free.
Wrought magnesium	8104.90.0000	14.8 cents per kilogram on Mg content + 3.5% ad valorem	88 cents per kilogram on Mg content + 20.0% ad valorem.
Magnesium compounds:	:		
Crude magnesite	2519.10.0000	Free	\$10.33 per ton.
Dead-burned and fused magnesia	2519.90.1000	0.4 cent per kilogram	1.7 cents per kilogram.
Caustic-calcined magnesia	2519.90.2000	\$2.07 per ton	\$20.70 per ton.
Other magnesia	2519.90.5000	Free	15.4 cents per kilogram.
Calcined dolomite	2518.20.0000	6% ad valorem	30% ad valorem.
Kieserite, natural	2530.20.1000	Free	Free.

Estimated. Revised.

¹Table includes data available through July 1, 1993.

²Reported figure.

³Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁴Formerly part of Yugoslavia.

⁵All production in Yugoslavia 1988-91 came from Serbia and Montenegro.

⁶Dissolved in Dec. 1991.

⁷Dissolved in Apr. 1992.

¹Table includes data available through July 1, 1993.

²Reported figure.

³Dissolved in Dec. 1991; however, information is inadequate to formulate reliable estimates for individual countries.

Estimated. Revised. W Withheld to avoid disclosing company proprietary data; not included in "Total."

Figures represent crude salable magnesite. In addition to the countries listed, Bulgaria produced magnesite, but output is not reported quantitatively, and available general information is inadequate for formulation of reliable estimates of output levels. Table includes data available through May 11, 1993.

²Reported figure.

Series reflects output of marketable concentrates. Production of crude ore was as follows, in metric tons: 1988—810,837; 1989—1,385,565; 1990—1,432,741; 1991—879,477 (revised), and 1992—880,000(estimated).

⁴Magnesitic dolomite and brucite. Figures are estimated on the basis of reported tonnage dollar value.

⁵Year beginning Mar. 21 of that stated.

⁶Includes 3,336 tons of huntite, (Mg₃Ca(CO₃)₄.)

⁷Formerly part of the U.S.S.R.

⁸All production in U.S.S.R. from 1988-91 came from Russia.

⁹Formerly part of Yugoslavia.

 $^{^{10}}$ All production in Yugoslavia from 1988-91 came from Serbia and Montenegro.

¹¹Dissolved in Dec. 1991.

¹²Dissolved in Apr. 1992.

MANGANESE

By Thomas S. Jones

Dr. Jones, a physical scientist with more than 30 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for manganese since 1982. Domestic survey data were prepared by Glenn Wallace, statistical assistant; and the international data table was prepared under the direction of Ivette Torres, Chief, Section of International Data.

Manganese (Mn) is essential to iron and steel production by virtue of its sulfur-fixing, deoxidizing, and alloying properties. Currently, no practical approaches exist for replacing it with other materials or for obtaining the bulk of U.S. requirements from domestic sources. The steel industries and economies of Japan and Western Europe are in much the same position relative to manganese as are those of the United States.

In the United States in 1992, ironmaking and steelmaking continued to account for about 90% of domestic manganese demand. Reported data indicated that the overall rate of usage of manganese in steelmaking was about 6% less than in 1991 because of a decline to a somewhat greater extent in the rate of usage of ferromanganese. Foreign trade in silicomanganese was relatively brisk. Imports of silicomanganese, which included a significant amount of material from Ukraine, were only slightly less than the 1991 record quantity, and exports were the greatest ever. Government's stockpile policy underwent a major change that implied that most holdings of manganese materials would gradually be eliminated. Government inventory of manganese, all forms, declined only marginally and at yearend still represented more than 2 years of apparent consumption.

Price trends were negative. On the international market, price decreases for metallurgical-grade manganese ore were in the range of 12% to 14%. In the United States, year-average prices for ferroalloys declined by about 15% for high-carbon ferromanganese and by more

than 8% for silicomanganese.

World manganese ore production as listed in table 1 was estimated to have decreased to somewhat less than two-thirds of estimated capacity. The decline in output of the Republic of South Africa was particularly significant among declines indicated for a number of major producing countries. Revival of production in Egypt and Panama made a small addition to supply.

The level and nature of manganese use by the United States is expected to remain much the same in the near future. The rate of adaptation of the manganese producing and consuming industries of the Republics of the former U.S.S.R. to their new political environments continued to have an important influence on the rate of stabilization of the global manganese industry.

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on manganese that are in compliance with Public Law 100-418, will begin to report data in metric units.

DOMESTIC DATA COVERAGE

Data on domestic consumption of manganese ore, exclusive of that consumed within the steel industry, are collected by means of the "Manganese Ore and Products" survey. By means of this survey, approximately 15 firms were canvassed that process ore by such methods as grinding and roasting or consume it in the manufacture of manganese ferroalloys, metal, and chemicals. In 1992, responses were

obtained from all firms canvassed, whose collective consumption is believed to represent that of the United States except for negligible quantities consumed by other firms, if any. The aggregated consumption data so obtained were incorporated into table 4 but only displayed within totals to avoid disclosing proprietary data.

BACKGROUND

Definitions, Grades, and Specifications

Ore.—The U.S. Bureau of Mines has compiled statistics on manganese-bearing ores, concentrates, nodules, and sinter. all referred to simply as "ore," by manganese content as follows: manganese ore. 35% or more manganese; manganiferous ore, less than 35% but not less than 5% manganese; and within the latter ferruginous manganese ore, 10% to 35% manganese: and manganiferous iron ore, 5% to 10% manganese.

Manganese ore may be considered as metallurgical, chemical, or battery grade. Metallurgical-grade material has an approximate manganese content range of 38% to 55% and may differ from chemical-grade ore only in physical form. Chemical- and battery-grade ores are often categorized by manganese dioxide (MnO₂) content, which typically is in the range of 70% to 85% (44% to 54% Mn). The U.S. Government maintains specifications for metallurgical, chemical, and battery grades of ore for stockpile purposes; industry has no corresponding standards.

Ferroalloys and Metal.-Ferromanganese is a manganese-ironcarbon alloy classified according to decreasing carbon content into standard or high-carbon grades, medium-carbon grades, and low-carbon grades. Silicon is also specified in silicomanganese (such as 18%) and ferromanganese-silicon (about For U.S. tariff purposes, 30%). ferroalloys are required to have an iron content of 4% or greater; a manganese material with less iron would be treated as manganese metal. The specifications the U.S. industry generally follows for manganese ferroalloys and metal are those of the American Society for Testing and Materials.

Products for Trade and Industry

Metallurgical-grade ore is used primarily in making ferroalloys, pig iron, and steel. In making ferroalloys, ore with a relatively high manganese and low phosphorus content is particularly desirable.

The sulfur-fixing, deoxidizing, and alloving attributes of manganese, whose atomic weight is 54.94, are obtained mostly through use of intermediate forms Manganese such as ferromanganese. ferroalloys for use in steelmaking are selected on the basis of cost per manganese unit, allowable steel carbon and silicon specifications, steelmaking practice. For 1992, with the cost of manganese in metallurgical ore 1.0, the corresponding taken as approximate costs per manganese unit were 2.0 for high-carbon ferromanganese, 1.8 for silicomanganese, 3.5 for mediumcarbon ferromanganese, and 7.1 for manganese metal. Metallic manganese is little used per se because it is typically brittle and unworkable.

Manganese is added to aluminum principally by use of briquets that typically contain 75% Mn, 25% Al and that are made by compacting manganese and aluminum powders. Electrolytic manganese metal and aluminum-manganese master alloys that typically contain 25% Mn are also used for this purpose.

Various manganese dioxide-types of

material, possibly ground, are used for batteries and other applications. These include natural mineral product (NMD) and synthetic dioxide produced either electrolytically (EMD) or chemically (CMD). If pure, these dioxides would contain 63.2% Mn.

Other manganese materials and some of their uses include manganese sulfate (MnSO₄) and manganous oxide (MnO) for animal feed and soil conditioners, ground manganese ore for brick coloring, and potassium permanganate (KMnO₄) for water treatment.

Industry Structure

Makeup of the world's manganese ore producers has been chiefly as follows: Australia, Groote Eylandt Mining Co. Ptv. Ltd. (GEMCO) plus, recently, Portman Mining Ltd.; Brazil, Cia. Vale do Rio Doce (CVRD) (including Urucum Mineração S.A.) and Indústria e Comércia de Minérios S.A. (ICOMI), plus a number of relatively small mines; China, apparently mostly small- to moderate-size operations in the eastern Provinces: Gabon, Compagnie Minière de l'Ogooué S.A. (COMILOG); Georgia, mining of the Chiatura Basin; Ghana, Ghana National Manganese Corp.; India, more than 200 mines, with Manganese Ore India Ltd. the most prominent company; Mexico, Cía. Minera Autlán de C.V. (Autlán); Republic of South Africa, The Associated Manganese Mines of South Africa Ltd. (AMMOSAL) and Samancor Ltd.; and Ukraine, mining of the Nikopol' Basin. Most ore produced goes into metallurgical applications. 1 Ore for nonmetallurgical uses generally is supplied by the large-scale producers mentioned plus smaller ones elsewhere.²

In recent years, the international ore market mainly has been supplied by a group of countries consisting of Australia (GEMCO), Brazil (ICOMI and CVRD), Gabon (COMILOG), and the Republic of South Africa (AMMOSAL and Samancor) acting in the manner of an oligopoly. In addition, Georgia and Ukraine in the former U.S.S.R. together had been supplying more than I million tons³ of ore annually to Eastern Europe.

However, the total of such exports was not much more than 700,000 tons in 1987 and dropped precipitously to average about 150,000 tons in 1990-91. The radical political changes that have taken place in Eastern Europe and the former U.S.S.R. cast considerable uncertainty on the pattern of manganese ore exports and imports in this region in the future.

Smelting of ore into manganese ferroalloys is much more diversified than Leading ferroalloy ore production. producers are as follows: Brazil, Cia. Paulista de Ferro-Ligas (a number of plants); China, about 10 main plants; France. Société du Ferromanganèse de Paris-Outreau (SFPO); Germany, Thyssen Stahl AG; Japan, Japan Metals & Chemicals Co. Ltd. and Mizushima Ferroalloy Co. Ltd.; Mexico, Autlán; Norway, Elkem A/S; Republic of South Africa. Metalloys Ltd., a subsidiary of and Ukraine. Samancor: Nikopol' As with ore Ferroallov Works. production, the output of Georgia the much larger combined with production from Ukraine had made the former U.S.S.R. by far the world's producer of manganese largest ferroallovs.

Four market economy countries (MEC's) currently produce metal, all electrolytically, in decreasing order of capacity: the Republic of South Africa, the United States, Japan, and, beginning in 1989, Brazil. China, Georgia, and Ukraine produced metal, including that obtained metallothermically in the former U.S.S.R. World productive capacity for metal was given as 76,000 tons annually as of 1985⁴ and would be approximately the same in 1992.

Annual world capacity for EMD was assessed as 198,000 tons in 1989, including capacities of 71,000 tons for Japan and 36,000 tons for the United States.⁵ The main change since has been the establishment of a new plant in Australia with an annual capacity of about 18,000 tons. The principal producer of CMD is Belgium's Sedema S.A., with an annual capacity of about 36,000 tons.

Geology-Resources

The world's major land-based economic resources of manganese are of two principal types: marine chemical sediments and secondary enrichment deposits.6 Marine chemical deposits represent a majority of known resources. In 1985, the Manganese Centre (name changed in 1989 to International Manganese Institute) estimated that known relatively high-grade deposits (those with a manganese content of at least 44%) contained about 330 million tons of manganese.⁷ As given in the World Review section of this chapter, the reserve base for manganese can be considered more than 10 times this size. In a recent study, the world total for manganese in land-based resources was assessed as about 9 billion tons each in actually minable manganese deposits and in potentially minable accumulations.8 The world's potential supply of manganese also includes extensive marine accumulations, such as oxide nodules on deep ocean floors and oxide crusts on midocean ridges, whose commercial future is indeterminate.

Among the more common minerals occurring in manganese ores are oxides including pyrolusite, a mineral form of manganese dioxide; the oxysilicate braunite; and rhodochrosite, a mineral manganese carbonate.

Technology

Exploration.—Highly selective methods of locating land manganese deposits do not exist, but interpretation of geologic environments can assist prospecting.9

Mining.—Most manganese ore is produced by mechanized operations. Standard earth-moving equipment is used in surface mining. Underground mining generally is by room-and-pillar techniques. Selective mining may be practiced in producing battery- and chemical-grade ores from a deposit being worked principally for metallurgical-grade ore.

Beneficiation.—Crushing, screening, washing, jigging, and tabling as well as flotation, heavy-medium, and high-intensity magnetic separation are being or have been used to upgrade raw manganese ore into usable concentrates. Carbonate ore may be calcined. Ore fines are sintered into bulkier shapes at some ferroalloy plants, a practice being adopted increasingly by ore producers as well.

Processing.—Electrothermy is the predominant method of manufacturing manganese ferroalloys, commonly by the submerged-arc furnace process. ¹⁰ Blast furnace-type operations are still used in a few foreign countries to make important quantities of high-carbon ferromanganese. Recovery of metallics other than iron from manganese-bearing ore is rare.

Manganese metal and EMD commonly are produced by electrolyzing a solution of manganese sulfate prepared from ore that has been reduction roasted. Production of the dioxide is especially sensitive to minor ore impurities. 11 CMD can be prepared by precipitating manganese carbonate from a sulfate solution and decomposing the carbonate to oxide. 12

Recycling.—Scrap recovery specifically for manganese is insignificant. Considerable manganese reenters processing as a minor component of steel scrap, steel slag, and nonferrous scrap. Such recycling of manganese tends not to lead to a progressive buildup in steelmaking but it does in aluminum processing.

Economic Factors

A study by the Minerals Availability Program (MAP) of the U.S. Bureau of Mines has identified transportation as the most significant cost element in the production of manganese concentrates.¹³ In a later MAP assessment of costs for most major mines in MEC's, transportation was found to account for about two-thirds of concentrate cost.¹⁴ Transportation costs were about equally

divided between transportation to the port and transportation to the market. Also according to this assessment, the major mines for metallurgical-grade ore of the MEC's are quite competitive as to ore production cost. Of the considerable resources evaluated, more than 80% had estimated production costs within 20% of the lowest cost.

Operating Factors

Environmental Issues.—Manganese is an essential element for people, animals, and plants. 15 For adults, a daily dietary intake in the range of 2 to 5 milligrams of manganese has been recommended. and it seems that normal diets satisfactorily meet human requirements.16 In excess, manganese can be harmful to the respiratory and nervous systems. 17 Thus, manganese can be an industrial poison, but normally is not a hazard. According to a review published in 1991. no environmental damage was known to be caused by manganese nor did manganese exposure pose a general risk to the environment.18

In 1988, the Environmental Protection Agency (EPA) imposed an annual requirement of reporting releases to the environment of manganese chemical compounds and metal (40 CFR 372). This initially applied to operations classifiable within Standard Industrial Classification codes 20 to 39 that annually manufacture or process at least 75,000 pounds of these materials, subject to a minimum concentration limitation. This threshold decreased to 25,000 pounds for 1989 and beyond. Also, a reporting threshold of 10,000 pounds established for annual use of these materials other than in their manufacturing and processing.

ANNUAL REVIEW

Legislation and Government Programs

On January 3, EPA denied Ethyl Corp.'s July 12, 1991, request for a waiver to permit sale of methylcyclopentadienyl manganese tricarbonyl (MMT, "HiTEC 3000") as an

additive for use in unleaded gasoline (57 FR 2535). In doing so, the Agency stated it was unable to conclude that Ethyl had established that MMT would not lead to the failure of a significant number of vehicles to meet emissions standards. Shortly thereafter, Ethyl filed an appeal of EPA's denial with the U.S. Court of Appeals for the District of Columbia Circuit; action on the appeal was still pending at the end of 1992. The 1991 request for a waiver for MMT, an octane enhancer, was the fourth such application by Ethyl. **Previous** applications had been submitted on March 17, 1978; May 26, 1981; and May 9, 1990.

Strategic Considerations

Security of Supply.- Manganese, for which there is no economical substitute, is essential to steelmaking. Steel producers in the United States, Japan, and Western Europe have shared a about lack common concern domestic economically minable manganese deposits. Also, the ore supply of these countries has come from relatively few sources, chiefly Australia, Brazil, Gabon, India, Mexico, and the Republic of South Africa, and from just one or two major ore mining companies in each of these countries. The United States has been additionally concerned about supply of manganese the The domestic manganese ferroallovs. ferroalloy industry has declined well below self-sufficiency, and its continued existence has been uncertain for some vears.

Stockpile.—The authority of the Defense Logistics Agency (DLA), U.S. Department of Defense, to dispose of excess manganese materials in the National Defense Stockpile was increased considerably on October 23 when the President approved the FY93 Defense Authorization Bill, which then became Public Law 102-484. As shown in table 2, the new levels of disposal authority corresponded at yearend to total inventories of synthetic manganese

dioxide and all varieties of ore and most inventory of high-carbon of the ferromanganese. Other provisions of the law were that dispositions previously authorized should be completed by September 30, 1997, unless doing so would cause an undue market disruption; and that before October 1, 1993, metallurgical-grade ore could be disposed of only for processing within the United States and no ferromanganese could be disposed of. DLA subsequently indicated it expected the overall program of disposals authorized for manganese and other stockpile materials would take place over 10 to 14 years.

On December 4, DLA released the Annual Materials Plan for FY93, which specified maximum amounts of materials available for sale but not necessarily to be offered for sale in FY93. For manganese materials, the quantities were, in tons, natural battery-grade ore, 27,216; synthetic manganese dioxide, 2,732; chemical-grade ore, 36,287; and metallurgical-grade ore, 67,132.

In 1992, cash disposals consisted of 20,775 tons of natural battery ore, nonstockpile-grade including any material. and 10,668 tons of nonstockpile-grade metallurgical ore. Payment-in-kind disposals toward the ferroalloy upgrading program consisted, in tons, of metallurgical ore, stockpilegrade, 43,908 and nonstockpile-grade, 11,449; high-carbon ferromanganese, 2.268; medium-carbon ferromanganese, 907; and silicomanganese, 10,597. At 1.7 million tons, the reserve of contained manganese being held by the Government was only marginally diminished from that at yearend 1991.

DLA contracted with Elkem Metals Co. on September 30 to continue the program of upgrading stockpile metallurgical-grade ore into high-carbon ferromanganese. In a contract valued at \$43.7 million, about 142,000 tons of ore was to be converted into 76,100 tons of ferromanganese by December 31, 1994. Upgrading of about 115,000 tons of ore into about 70,000 tons of ferromanganese in 1992 at a cost of \$45.4 million had been authorized on April 1, 1991, when DLA exercised an option on a then-existing contract. The

site of all conversions was Elkem Metals' Marietta, OH, plant.

Issues

The United States has been lacking in reserves and significant production of manganese almost since the start of Extensive domestic steel production. efforts to discover worthwhile ore deposits or effective methods of using low-grade resources, including steel slags, have resulted in little commercial promise. In a 1985 report, the U.S. Congressional Office of Technology Assessment (OTA) concluded that improvements in steel production technology offered the best prospect for manganese import U.S. reducing In so doing, OTA vulnerability.19 discounted ocean mining for the present, a view shared by most participants at a December 1989 conference on marine mining.20

The setting up and maintenance of a large stockpile has been the most tangible aspect of Government manganese programs. Management of the makeup, size, and disposition of this stockpile has been a key part of Government policy. Current law limits use of the stockpile to emergency situations, but its mere presence has had economic implications. Political developments during recent years and reappraisal of stockpile needs have led to the view that the size of the stockpile can be considerably reduced. DLA has signaled its intention to dispose of the large majority of the manganese items in the stockpile, an action deemed likely to require a decade or more.

Production

Ore and Concentrate.—Production and shipments continued to consist only of a small amount of manganiferous material for use in coloring brick. This material was mined in Cherokee County, SC, and had a natural manganese content in the range of 5% to 15%. Shipments data were not published to avoid disclosing proprietary data.

Ferroalloys, Metal, and Synthetic Dioxide.—Production statistics for these materials were not published to avoid disclosing proprietary data; plant sites and products are given in table 3. The only producer of manganese ferroalloys, Elkem Metals, suffered a major disruption early in December at its Marietta, OH, plant, when the electric furnace exploded that was being used to upgrade manganese ore into high-carbon ferromanganese for the Government stockpile. Four workers were injured, and the damaged furnace was put out of service indefinitely. Subsequent investigation indicated that zinc in the ore being smelted contributed to the cause of the accident.

In midyear, Chemetals Inc. announced that the annual capacity of its New Johnsonville, TN, plant for EMD was being increased by 4,500 tons. expansion, scheduled for completion by July 1993, would raise Chemetals' annual capacity for EMD to more than 16,000 tons. The expansion program was designed to allow for additional incremental expansion if warranted by demand. Kerr-McGee Chemical Corp., one of the two other domestic producers of EMD, reported that its plant at Henderson, NV, was operating at its capacity of 14,500 tons per year.

Consumption, Uses, and Stocks

Metallurgical applications accounted for most manganese consumption, almost 90% of the total for steelmaking. This can be deduced from the data relating to manganese end use that form the basis of tables 4 and 5 plus certain other information. Industry averages are presented in table 6 for kilograms of manganese used in ironmaking and steelmaking (including for castings) per ton of raw steel produced, on the basis of the reported data in tables 4 and 5. (Note: Multiply by 2.0 to convert data in terms of kilograms per metric ton to pounds per short ton, the unit previously used in manganese annual reports.) Although somewhat increased, unit consumption of manganese in ironmaking was still roughly at the comparatively low

level reached in 1991. Manganese unit consumption in steelmaking declined 6% overall because of a drop in the rate of usage of ferromanganese. Relatively small quantities of manganese were used for alloying with nonferrous metals, chiefly as manganese-aluminum briquets for alloying with aluminum.

Nonmetallurgical applications for manganese included animal feed, brick coloring, dry cell batteries, manganese chemicals, and plant fertilizers.²¹ One report raised the possibility that potassium permanganate, an oxidizer used in water treatment, could be used in the future to control water line blockages from zebra mussels now invading the Great Lakes.²²

Domestic companies engaged in the manufacture and marketing of manganese-containing dry cells reported that the key growth component was the alkaline type of battery based on use of synthetic manganese dioxide. One company observed that, in terms of units, the compound growth rate during the past 5 years was 3% for dry cells overall and 8% for alkaline cells.

The international affiliations of the Eveready Battery Co. were expanded in July through acquisition of Ever Ready Ltd. in the United Kingdom, a firm that Eveready Battery had been associated with before Ralston Purina Co.'s purchase of the battery business of Union Carbide Corp. in 1986. Further international battery activities of Ralston Purina included establishment of the Beijing Eveready Battery Co. in China and acquisition of a battery business in Portugal and Spain.

Attention continued to be focused on two environmentally related aspects of the dry battery industry, mercury elimination and recycling. According to one source, battery manufacturers in the United States, Europe, and Japan may have achieved by the end of 1992 the goal of adding no mercury in production of all dry cells commonly in household use. As of January 1992, the various battery recovery operations of Texas' Basalt Industries Inc. were made into a separate company, Recovery & Reclamation Inc. (R&R), located in Pecos. R&R was using physical methods to recover

materials in dry cell batteries in facilities having annual capacities of more than 2,000 tons for processing carbon-zinc cells and about 4,500 tons each for alkaline cells, with or without mercury. In Switzerland, Recytec S.A. (as of late 1991) and Batrec AG (as of mid-1992) were processing dry cells collected under a Swiss program in which recycling was being aided by taxes on batteries. Pyrolysis was a part of the processing sequence at both Swiss plants. According to technology developed by Japan's Sumitomo Heavy Industries Ltd., at Batrec the manganese content of batteries was being converted into low-grade ferromanganese that was to be used in steelmaking in Switzerland.

Markets and Prices

Manganese Ore.—For the second successive year, the price of metallurgical manganese ore decreased from the peak reached in 1990. Agreements between Japanese consumers and their traditional suppliers were reached comparatively early. For the benchmark of high-grade lumpy ore containing 48% manganese, Australia's Broken Hill Pty. Co. Ltd. (BHP) agreed as of mid-December 1991 to an f.o.b. price of \$2.95 per metric ton unit (mtu) for material from GEMCO, a decrease of 11.9% from the 1991 contract price. As of early February 1992, South African suppliers accepted a decrease of 14.4% to an f.o.b. price of \$2.85 per mtu for similar ore. In mid-January. Portman Mining Ltd. had settled for delivery at \$2.70 per mtu, f.o.b., for its lumpy ore containing 46% manganese from Western Australia, which has been a factor contributing to the downward trend in ore price. In May, Metal Bulletin of London revised downward by about 14% its c.i.f. price for delivery of ore to European ports.

The average price, c.i.f. U.S. ports, for metallurgical ore containing 48% manganese was assessed as \$3.25 per mtu, for a decline similar to that in other international ore markets. Contracts were made at prices both above and below this average, and significantly lower prices were available late in 1992. The metric

ton unit is 1% of a metric ton; that is, 10 kilograms of contained manganese. The price of manganese in ore in 1992 and 1991 thus can be expressed in cents per kilogram as 32.5 and 37.2, respectively. The price of a metric ton of ore is obtained by multiplying the metric ton unit price by the percentage of manganese content of the ore.

The ore market consists of a number of submarkets because of differences between ores according to the various end uses such as ferroalloy production, blast furnace ironmaking, and battery manufacture. The price trend for metallurgical ore during the past two decades is given in table 7, in which constant dollar prices were calculated using Implicit Price Deflators for GDP.

Manganese Ferroalloys.—Again as in 1991, price trends in the United States for manganese ferroalloys, as given by quotations for imports, were negative, both for average price in comparison with that for the prior year and for change during the year. Declines in price were more pronounced for high-carbon ferromanganese than for silicomanganese. The decrease in year-average price was more than 15% for high-carbon ferromanganese and somewhat more than half that for silicomanganese.

According to one study of trends in Western countries during 1985-90, fluctuations in the prices of high-carbon ferromanganese and silicomanganese approximately followed the crude steel production trend.23 For 1992, the influence on ferroalloy prices of an increase of about 4% in crude steel production in the United States apparently was overridden by a decrease in crude steel production in Western countries of only about 1%. However, crude steel production in Western countries was estimated as the least since 1988. English units continued to be used for price quotes in the United States as given in sources such as Metals Week. For high-carbon ferromanganese containing 78% manganese, the price range of imported material, f.o.b. Pittsburgh or Chicago warehouse, was \$555-\$560 per long ton of alloy at the start of 1992.

The level of the price range generally decreased throughout the year, most strongly in March. The yearend range of \$485-\$490 signified again as in 1991 a decrease for the year of about 13%.

The change in price range for imported silicomanganese with 2% carbon, in cents per pound of alloy, f.o.b. Pittsburgh or Chicago warehouse, from 23.8-24.25 at the start of 1992 to 23-23.25 at yearend represented a decrease that approached 4%. The price trend for silicomanganese was moderately downward at the beginning and end of the year and firmer in between.

Domestic producer prices given by Metals Week for high-carbon ferromanganese and silicomanganese remained unchanged from those previously listed in 1989. These prices, f.o.b. plant or warehouse, were \$695 for high-carbon ferromanganese and 35 cents for silicomanganese.

Manganese Metal.—Trade journal listings again remained the same throughout the year as those already published effective mid-November 1990: a price range of \$1.04-\$1.05 per pound according to Metals Week and \$1.05 per pound according to American Metal Market. These were for bulk shipments of domestic material, f.o.b. shipping point.

Foreign Trade

The total of manganese units exported in 1992 was about seven-tenths that in 1991 after adjusting for transshipments of ore from Gabon to Mexico that were included in the data for 1991. Ore exports in 1992 were almost 70% less than the adjusted total for 1991 and were the least since 1965. Ore reexports in 1992 were only 85 tons, all to Mexico, and appeared to have been transshipments.

Among exports of ferroalloys and metal, those of ferromanganese and metal decreased, by 8% overall and 5%, respectively. Exports of ferromanganese containing less than 2% carbon decreased by about one-eighth to 8,766 tons whereas the quantity remained about the same for those containing more than 2%

carbon. Exports of silicomanganese were principally to Canada and more than tripled to become the greatest since a reporting category separate silicomanganese was set up effective as of 1978. Reexports of ferromanganese and silicomanganese, all to Canada, consisted of 3,227 tons of ferromanganese and 1,432 tons of silicomanganese. Those of ferromanganese were about equally divided between higher and lower carbon Exports of 2,235 tons of spiegeleisen were reported, all to the Republic of Korea, but at a unit value so low as to put the data in question.

The total manganese units imported was about 2% less than that in 1991 and again the least since 1987. Within the content totals for 1992 imports, the ratio of the sum of ore plus dioxide to the sum of ferroalloy plus metal was 3.2, or about midway between values of this ratio for For ore and 1990 and 1991. overall. average ferromanganese manganese contents were nearly the same as in most years of the past decade, at 78.4% for ore and 48.8% ferromanganese. The apparent increase of about 5% in volume of ore imports was actually about 18% after adjusting the data for transshipments of Gabonese ore to Mexico in 1991. The increase in ore imports in 1992 came about mostly because of ore containing less than 47% manganese received from Brazil.

For most categories of ferroalloy and metal, quantities imported in 1992 were less than in 1991. The overall total for ferromanganese was about 5% lower and the least since 1983. However, imports of medium-carbon ferromanganese rose by about one-fifth to the third largest amount during at least the past two Imports of silicomanganese decades. declined only marginally from the record total set in 1991. Among these, the quantity from Brazil advanced to a new record, and material received from Ukraine was the first significant receipt of mineral-related manganese from countries that had been a part of the now restructured former U.S.S.R. For the two categories of metal exclusive of waste and scrap, although quantities imported decreased overall, the imports of unwrought metal from China increased for the fourth successive year to rise to about one-fifth of imports of unwrought metal. Imports of spiegeleisen were reported as 214 tons, all from Germany at a high unit value.

Among imports of manganese chemicals, those of manganese dioxide increased about 6% and were the third highest on record. All dioxide imports were synthetic material, evidently disregarding 38 tons that appears to have been misclassified. In rising about 7%, imports of potassium permanganate included for the former Czechoslovakia about seven times the 1991 quantity whereas those from China and Spain declined again. Imports from Mexico under the classification "Other sulfates" that includes manganese sulfate increased by almost one-fourth to 12,439 tons at a value of \$6.7 million.

The schedule of tariffs that applied during 1992 to U.S. imports of selected manganese materials is given in table 10. Most-favored-nation (MFN) trade status was granted in 1992 to a number of the newly independent states that formerly were a part of the U.S.S.R. Of such states having the potential to be a source of U.S. imports of manganese materials, the granting of MFN status was effective June 17 for the Russian Federation (Russia) (57 FR 27840) and June 23 for

For most former Yugoslav Republics, duty-free treatment under the Generalized System of Preferences (GSP) program was restored as of September 11, after having been suspended December 24, 1991. The change, effected by Presidential Proclamation 6465 (57 FR 39095), again made ferroalloy producers in Croatia and Macedonia eligible for GSP benefits. The principal manganese item exported to the United States has been silicomanganese.

Ukraine (57 FR 28771).

World Review

Capacity.—The rated capacity data in table 11 are as of December 31, 1992. Generally they differ only in minor respects from those for the previous year except for an increase in the figure for

China. The figure for the former U.S.S.R. reflects conditions before the formation of independent Republics. The capabilities of these Republics, largely concentrated in Georgia and Ukraine, may be overstated in view of the political and economic changes that have taken place. The data correspond to the manganese contents of ore and/or concentrates capable of being utilized, as in feed to a smelter. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable, longterm operating rate.

Reserves.—Only a few of the world's many manganese concentrations have enough economic significance to be classed as reserves;24 no domestic deposits qualify.25 World reserves of manganese, generally on the same basis as capacity, are given in table 12 with no distinction between ore type application. The data in table 12 are exclusive of perhaps 1% to 2% of total known reserves. These are in nonlisted countries having a similar proportion of world production, as can be seen from table 13.

Australia. - Manganese ore operations were producing at a substantially diminished rate at the Groote Eylandt Mine (Northern Territory) of the GEMCO subsidiary of BHP. Reflecting this, manganese ore production reported by BHP for the 1992 fiscal year ending May 31 was 970,000 tons, a reduction of about 30% from that in the prior fiscal year and an output less than one-half that of an annual capacity of about 2.3 million tons. Shipments of ore by GEMCO to foreign and domestic destinations during calendar 1992 were reported as only 952,000 tons.²⁶ This was a decline of about one-fifth from those in 1991.

In Western Australia, 1992 shipments of manganese ore by Portman Mining Ltd. from the Woodie Woodie area of the Pilbara Manganese Province were again in the range of 300,000 tons. In these operations, the Radio Hill and Lox deposits were worked out and mining

progressed to the Cracker deposit, for which a heavy-medium separation plant was installed for control of silica and overall product quality. In the Peak Hill Manganese Province to the southwest, ore production was reactivated at the Millidie deposit north of Meekatharra in the latter half of the year. Valiant Consolidated Ltd. and Sabminco NL, principals in this venture, projected an annual output in the vicinity of 100,000 tons within a year, with shipment for export to be via the port at Geraldton.

Brazil.—Shipments of manganese ore by ICOMI from operations at Serra do Navio, Amapá Territory, through Porto de Santana on the Amazon River, increased by more than one-fourth to 490,000 tons. Most of the increase was in domestic shipments, which more than doubled from 76,000 tons to 160,000 tons. Exports of ICOMI, a subsidiary of Cia. Auxiliar de Empresas de Mineração S.A., rose by 21,000 tons to 330,000 tons.²⁷

CVRD's production of manganese ore from its Azul Mine in the Carajás region was 372,000 tons, a decrease of almost 40% from the 601,000 tons produced in 1991. In 1992, CVRD's manganese ore sales were 322,000 tons to export, a 27% increase, and 79,000 tons to domestic customers, a 28% decrease. **CVRD** acquired a 35% interest in Société Européene d'Alliages pour la Sidérurgie (SEAS), a new producer of manganese ferroalloys whose coastal plant at Dunkirk, France, was completed near the end of 1991. CVRD previously had entered into a long-term contract to supply about two-thirds of the manganese ore feed for the SEAS plant, initially to come from the Azul Mine.

Also in the Carajás region, the endeavors of Prometal Produtos Metalúrgicos S.A. to begin manganese mining and/or smelting were scaled back to development of the Buritirama deposit acquired in 1986, subject to the making of financial arrangements within Brazil.

Output of manganese ore by Urucum Mineração in the State of Mato Grosso do Sul, 47% owned each by CVRD and the State, declined by 24%, to 203,000 tons

from 267,000 tons in 1991. In 1992, sales to the domestic market more than doubled, to 205,000 tons from 87,000 tons, whereas those to foreign markets decreased by 44% to 63,000 tons from 114,000 tons. Export destinations in recent years have included Romania. A further potential outlet developed for ore being produced by Urucum Mineração was a silicomanganese plant proposed to be set up in Paraguay, which would use a duplex smelting process to deal with the relatively high alkali and phosphorus contents of Urucum ore.

Canada.—In the latter half of the year, RAM Batteries Canada Inc. (RAM) completed, with governmental aid, the financing for a \$10 million dry cell battery plant. Initially, this plant would manufacture a popular consumer type of alkaline battery that would be mercury-free and rechargeable. The Nova Scotia Business Development Corp. provided a major loan for the plant, which was to be built in Amherst, Nova Scotia. The technology to be employed by RAM Batteries was under license from Battery Technologies Inc. of Ontario.

China.—Imports of manganese ore continued a growing trend, with quantities reported in thousand tons as 425, 357, 561, and 640 in 1989, 1990, 1991, and 1992, respectively.²⁸ Australia and Gabon were the leading sources of these imports.

An important factor in the magnitude of imports of high-grade ore has been the importing of ore into China for conversion into manganese ferroalloys that are subsequently exported for sale, particularly to other countries in the Far East. According to press reports, Hong Kong-based Eastern Century Holdings Ltd. has been a major participant in this activity via a subsidiary, Bogay Investment Ltd. Gabon has been the source of Eastern Century's manganese ore via France's SFPO, in which COMILOG has held a significant interest. In the latter part of 1992, Eastern Century invested in three of China's most important manganese ferroalloy

producers: Jiangxi Xinyu Iron and Steel Complex, Jilin Ferro Alloy plant, and Shanghai Ferro Alloy plant.

At the Jiangxi Xinyu Iron and Steel Complex, China's largest ferromanganese producer, a duplex blast furnace process has been developed for obtaining highcarbon ferromanganese from domestic ores whose contents are typically relatively low in manganese and high in phosphorus. Development of the process also reflected the relative abundance of coal but shortage of electric power in China. By this process, manganese ore was first smelted to segregate phosphorus and iron into a pig iron byproduct and a manganese-rich slag that was fed to a second blast furnace for production of Drawbacks of the ferromanganese. process were a high coke consumption and a manganese recovery of only 69 %.29

Egypt. - Manganese ore and ferromanganese production resumed on the Sinai Peninsula following lapses extending back to the late 1960's at the time of the Arab-Israeli War. At Abu Zenema in southwestern Sinai, a refurbished and modernized electric furnace facility with an annual capacity of about 40,000 tons for high-carbon ferromanganese was obtaining at least a portion of its feed from reactivated mines about 200 kilometers south of Suez in the Um Bogma region. The Um Bogma mines and the Abu Zenema plant were operated by the Sinai Manganese Co., one of the companies belonging to the public sector's Mining and Refractories Corp.

France.—Late in the year, Pechiney took actions that would end its participation in France in production of manganese ferroalloys. The plant of its Dunkerque Electrométallurgie subsidiary on the northernmost coast at Dunkirk was sold to SFPO, the operator of a blast furnace ferromanganese plant at Boulogne, also on the coast southwest from Dunkirk. Pechiney gave as a reason for the sale the need for a close connection with a manganese ore producer such as the relation between

SFPO and COMILOG. Pechiney also announced the intention to close by the end of 1993 its Le Giffre plant, a producer of specialty manganese alloys located in the alpine region of southeastern France. Pechiney ascribed this decision to a decline in demand for low-carbon ferroalloys and competition with material from China and the former U.S.S.R. Reported annual capacities were 60,000 tons of silicomanganese at Dunkirk and 20,000 tons of manganese in products at Le Giffre.

As mentioned above under Brazil, Brazil's CVRD acquired a 35% interest in SEAS, a new manganese ferroalloys subsidiary of the French steel producer Usinor-Sacilor S.A.

Gabon.—Production and exports of metallurgical-grade ore COMILOG's Moanda Mine decreased by 7% and 17%, respectively, whereas those of battery-grade ore rose substantially, by 84% and 65%, respectively. production total included 101,000 tons of battery-grade ore. The export total of 1,551,000 tons consisted of 1,458,000 tons of metallurgical-grade ore and 93,600 tons of battery-grade ore. it was reported that November COMILOG had ended export of manganese ore via the traditional route through neighboring Congo. This was the outcome of failure to resolve controversy arising from an accident in September 1991 on the rail portion of the route terminating at the Congolese port of All of COMILOG's Pointe-Noire. shipments henceforth would be via the Trans-Gabon Railroad and the Gabonese port of Owendo.

COMILOG's involvement in manganese ferroalloy production in China is discussed above under China.

Ghana.—Exports of ore from the Nsuta Mine of Ghana National Manganese Corp. through the Port of Takoradi were 284,000 tons, a decline of 11% from the 320,000 tons shipped in 1991. Destinations of the shipments were Japan and Europe (the former Czechoslovakia, Finland, France, Ireland, Norway,

Romania, and Spain).30

Japan.—Overall production of manganese ferroalloys decreased by about one-sixth to 458,000 tons. For ferromanganese, production decreases were about one-fifth each for total quantity, to 362,000 tons; for high-carbon, to 294,000 tons; and for low-carbon, to 68,000 tons. In each case, these outputs were the least since 1987. Production of silicomanganese increased by about one-tenth to 96,400 tons.

Imports of manganese ferroalloys declined 20% overall to 219,000 tons. Of this total, silicomanganese was imported in the largest quantity, 194,000 tons, a decrease also of almost 20%. Principal supplying countries silicomanganese were China, Republics of the former U.S.S.R., and Brazil, with 37%, 22% combined, and 19% of the total, respectively. On June 18, the Japanese Government announced that it would not impose provisional duties on imports of silicomanganese from China, Norway, and the Republic of South Africa before conclusion of antidumping investigations. Within 1 month, Japan Ferro the Allovs Association formally notified the Government of its dissatisfaction with this interim decision. Among other items of foreign trade in manganese ferroalloys, overall imports of ferromanganese decreased almost 22% to 25,500 tons. Exports of manganese ferroalloys were still relatively small. Those of ferromanganese rose by two-thirds to 8,400 tons overall and of silicomanganese by about one-third to 86 tons.

For EMD, production declined by 7% to 54,300 tons. Exports decreased 3% to 30,300 tons while remaining at roughly the same level as in 1989-91.

Imports of unwrought manganese metal, including scrap, increased 11% to 19,950 tons, of which 51% was from the Republic of South Africa and 46% was from China.

Mexico.—Ore output from the operations of Autlán in the Molango District of Hidalgo State rebounded from

the abnormally low levels of 1991. In that year, the rotary kiln used to produce oxide nodules from carbonate ore was shut down for 5 months for repairs and installation of pollution control equipment. Production in 1992 consisted of 525,000 tons of carbonate ore, of which 65,000 tons was sold without nodulizing; 316,000 tons of oxide nodules; and, from the Nonoalco Mine, 26,000 tons of battery ore. Autlán's production of manganese ferroalloys also advanced to total almost 189,000 tons, an increase of about 8%. The product mix consisted of 95,900 tons of high-carbon ferromanganese, 35,300 tons of low- and medium-carbon ferromanganese, 57,500 tons of silicomanganese, which represented increases of 1%, 12%, and 17%, respectively.

Autlán's increased ferroalloy output helped compensate for the domestic production lost from closure at the end of 1991 of the ferroalloy plant of Ferroaleaciones de México, S.A. (Ferromex). Ferromex, headquartered at Gómez Palacios, Durango State, had been principally a producer of ferromanganese and silicomanganese with a combined annual capacity for these ferroalloys in the range of 40,000 tons.

Norway.-Faced with losses and weak markets for its products, Elkem, the larger of the two Norwegian producers of manganese ferroalloys, strengthened its financial position by carrying out a refinancing plan late in the year. The plan involved a share issue for which there proved to be sufficient interest that a commitment made by the Norwegian state to serve as an underwriter was not needed. The refinancing was preceded at Elkem by economy moves and an internal reorganization. Elkem's plant at Sauda experienced an explosion in late March that put out of service for some weeks a newly installed unit for producing granulated silicomanganese. Because of market conditions, the Sauda plant was shut down the last 6 weeks of 1992.

Panama.—On August 5, Caribbean Mining Co. Inc. received a manganese

extraction concession from the Government of Panama. This concession had been preceded in June by an authorization for exchange of an exploration concession for an extraction concession and, before that, by the granting of an exploration concession in the Colón area. Caribbean Mining was reported to have plans to reopen a mine not far from the canal passing through central Panama. The ore output of the mine was expected to be in the range of 100,000 tons annually and targeted mainly at the U.S. market.

South Africa, Republic of.-Overall manganese ore production declined for the third successive year; the decline in 1992 was more than one-fifth. The bulk of production was metallurgical-grade ore, which totaled 2,375,000 tons. Of this quantity, the two largest components of the metallurgical-grade ore were material having a manganese content exceeding 48% and material with a manganese content between 30% and 40%. These two components accounted for 56% and 21%, respectively, of the output of metallurgical-grade ore. The relative magnitudes of these components in the South African statistics for metallurgical-grade ore have been about one-half or greater, and one-fifth, respectively, since Samancor, following its installation of a heavy-medium orebeneficiating plant, began producing in late 1989 a high-grade sinter containing a minimum of 48% manganese. In the statistics for the years just before that, the relative proportions by content had been almost 40% for ore containing 30% to 40% manganese and about 30% for ore containing more than 48% manganese.

Besides having added sintering capabilities, Samancor worked toward future production of high-quality mine and smelter products. One project involved extending the supply of high-grade ore from its underground Wessels Mine in the Kalahari Field in the northern Cape Province. Access to the western block of reserves at that mine was provided by excavation work and installation of crushing and ore-handling equipment. Another project involved

installing a casting machine at the North Plant of Samancor's Meyerton manganese ferroalloys operations. The purpose of this machine was to give more uniform sizing to products from the two large high-carbon ferromanganese furnaces at that plant.

Former U.S.S.R.—Manganese ore production continued to suffer from the economic disruption accompanying changeover to a Commonwealth of Independent States from the former Soviet state. Aggregated ore output for 1991 and as estimated for 1992 was at the lowest level since 1970.

Transition to a decentralized economy also required the establishment of new relationships between suppliers and consumers. This involved manganese ore and ferroalloys production that was concentrated in Georgia and Ukraine. particularly the latter, plus a minor amount of ore produced in Kazakhstan. Kazakhstan's production is estimated to have been typically of the order of 100,000 to 200,000 tons annually but was only a fraction of that in 1992. One of the more significant inter-Republic shipments of ore was that from Ukraine to Russia. This was from mines in the furnace blast Nikopol' Basin to ferromanganese operations at the Kosaya Gora Iron Works south of Moscow. Problems encountered in material flow to meet a manganese demand coming mostly from steel production centers in Russia and Ukraine included internal ones Shipments for related to payments. export were hampered somewhat by port realignments.

Ore exports had increased somewhat in 1991 from the total of only 128,000 tons in 1990, although quantities for both years were relatively small in comparison with quantities exported annually during the four previous decades. Destinations of Ukraine's 1991 ore exports were, in tons, Poland, 91; the Republics of the former Czechoslovakia, 72; and the former Yugoslavia, 3, for a total of 166.31

Current Research

Information on manganese mineral resources was significantly enlarged by issuance of several publications. The updated Mines Bureau of U.S. information on the principal manganese deposits of MEC's through the 1988-89 period, with emphasis on supply and This information, demand aspects.14 developed by the Bureau's Denver Minerals Availability Field Office, previously had been reported on in 1984. The August 1992 issue of Economic Geology contained a collection of 16 papers on manganese deposits. Five were and discussed relatively general geological conditions and environments associated with the deposits and their mineralogy. Eleven dealt mainly with specific deposits in Australia, Brazil, China, India, Japan, Mexico, Namibia, Nova Scotia, and Scotland.32 In one of a series of studies on small U.S. manganese deposits, the U.S. Geological Survey presented evidence for a submarine hydrothermal origin of the Bald Knob deposit in upper northwestern North Carolina. This deposit was found to have geological similarities with three other small metamorphosed manganese deposits in California.33

The U.S. Bureau of Mines, in the Minnesota cooperation with University Survey, Geological Minnesota Minnesota. and the Department of Natural Resources, has been exploring the potential for using in situ leach mining to extract manganese from manganiferous iron formations of the Cuyuna Range in central Minnesota. This work has resulted in publication of several studies addressing geological factors related to two potential sites, one in the Emily district and the other slightly to the south, and the need to make further investigations.34

In another project aimed at determining the potential for utilizing domestic resources, the U.S. Bureau of Mines conducted tests on manganese- and cobalt-bearing samples from former mines in a region of west central Arkansas having as yet undefined resource possibilities. Head samples with

contents of manganese ranging from 9.2% to 22.6% and of cobalt from 0.02% to 0.11% were subjected to mineralogical examination and tests of grinding, gravity and magnetic concentration, and hydrometallurgical response. Magnetic separation gave the highest recoveries, which were as great as 95% for manganese and 93% for cobalt at grades of 41% Mn and 0.22% Co.³⁵

The proceedings of the 6th International Ferroalloys Congress (INFACON 6), which was held in the Republic of South Africa in March, contained several technical papers dealing with pyrometallurgical processing of manganese materials.³⁶ On pp. 131-138, P. C. Pienaar and W. F. P. Smith of Samancor reviewed the steps taken that ultimately led to production of sinter containing 48% manganese from ore containing 38% manganese from the company's Mamatwan Mine and stated the improvements in productivity and product manganese content that resulted when this sinter was used in smelting high-carbon ferromanganese. S. Suzuki and M. Masukawa of Japan's Mizushima Ferroalloy Co. described, on pp. 149-154, how oil injection and accompanying oxygen enrichment of the blast was used to increase by about one-tenth the productivity of the company's shaft furnace for smelting ferromanganese. On pp. 145-147, Z. Jinhua (Univ. of Science and Technology, Beijing) and L. Zhizhong (Liaoyang Ferroalloy Plant) discussed development in China of silicothermic technology that entails use of a shaking ladle to produce low- and medium-carbon ferromanganese. Chinese ferroalloy producers have widely adopted this technology because of the high silica content of native manganese ores. Another application of silicothermic technology, in this case for producing silicomanganese from slag from ferromanganese smelting, was set forth on pp. 139-143 by R. Kamata, Y. Kizu, and H. Tsujimura of Japan's Nippon Denko Co. Ltd. Reduction conditions were enhanced by injection, using a gas such as nitrogen for stirring and a flux such as lime for adjusting slag basicity. The process was claimed to result in phosphorus and carbon contents lower than in silicomanganese conventionally obtained by electric furnace smelting.

Operational features and improvements of the Øye Smelteverk manganese ferroalloy plant of Norway's Tinfos Jernverk A/S were presented at a meeting held in the United States. During the plant's first 17 years of service, 1974-91, 2.3 million tons of high-carbon ferromanganese and silicomanganese was produced. In the past decade, mostly silicomanganese has been produced at near the annual capacity rate of 135,000 tons. Specific energy consumption for producing silicomanganese has been lowered from about 4,800 kW • h per ton to slightly more than 3,000 kW • h per ton, including the effect of electric energy recovery begun in the early 1980's.37

The U.S. Bureau of Mines carried out a laboratory investigation of the feasibility of recovering manganese from slag generated during basic oxygen steelmaking. With the use of an ammonium carbamate leach, manganese recoveries of more than 80% were obtained for a silicon steel slag containing 3% manganese. The investigators found that pretreatment of the slag with hydrogen gas at about 700° C was necessary to achieve a reasonable degree of recovery.³⁸

The potential effect of steel property requirements on steel manganese content was illustrated in a comparative study of steels for automotive wheels. Wheel design trends tending to increase wheel weight have been leading to a need for stronger but lighter formable steels. Improved properties obtained with a high-strength low-alloy steel or a dual-phase steel were associated with compositions requiring roughly twice as great a manganese content, 1.4% and 1.2%, respectively, as in a conventional mild steel containing 0.7% manganese.³⁹

The possibility of attaining superplasticity in Hadfield manganese steels and thereby overcoming difficulties in shaping such steels was investigated in the laboratory. Various thermomechanical processing techniques were applied to samples containing 1.2% to 1.7% carbon and 12.3% to 16.3%

manganese to develop the requisite ultrafine grain structures. In initial tests conducted at 750° C to 900° C, strain rate behavior indicative of superplasticity was observed.⁴⁰

Iron-base alloys capable of undergoing reversible martensitic transformations have the possibility of serving as shape memory alloys capable of reassuming a previous geometry upon heat treatment. containing Allovs 14% to 30% manganese and 2% to 7% silicon were among a number of compositions investigated for this possibility. Studies indicated that such ferrous alloys had promise, particularly for a one-time application, as an alternative to the more expensive nickel-titanium shape memory allovs.41

Thermodynamic assessments were performed of two binary systems, manganese-oxygen and aluminummanganese, by researchers at the Royal Institute of Technology in Stockholm, Sweden. For the Mn-O system, a calculated phase diagram was presented for the temperature range of 1,000° K to 2,500° K and an oxygen partial pressure of 0.21 atmospheres that applied to compositions ranging from manganese to those with oxygen mole fractions of up to 0.7.42 For the Al-Mn system, the "CALPHAD" computer technique was used to obtain a complete description of the system for all compositions between pure aluminum and pure manganese, based on which a phase diagram was presented for temperature range of 400° C to 1,400°

OUTLOOK

The trend of manganese demand, domestically and globally, will continue to closely follow that of steel production. Nonmetallurgical components of manganese demand, especially batteries, may experience higher growth rates than for steel production but will have only a minor effect on overall manganese demand.

For the past decade, U.S. apparent consumption of manganese has not varied from 635,000 tons of contained

manganese by much more than plus or minus 10%, as shown in table 14. This has largely been a consequence of similar variability in domestic steel production. Manganese demand as calculated in table 14 generally has corresponded to but not traced precisely the level of activity in the steel industry. Differences in the respective year-to-year variations are believed to show the influence of unmeasured changes in stocks of manganese materials, such as those of importers, the effect of which may outweigh changes in demand steelmakers.

The outlook for domestic steel production in 1993, as discussed in the Annual Report for Iron and Steel, includes a further improvement over that for 1992, from which a corresponding increase in manganese demand can be expected. Forecasts of the International Iron and Steel Institute (IISI) continue to suggest only slow growth in U.S. steel output through 1995. This indicates that U.S. apparent consumption of manganese in 1993-95 is unlikely to range far from 635,000 tons of contained manganese, on the assumption of insignificant change in manganese unit consumption in steelmaking. The majority of U.S. demand will be met by imports.

Global forecasts of IISI and others suggest that world manganese demand during the balance of the 1990's should increase only marginally. The IISI's late-1992 estimate of world steel consumption in 2000 is only 105% of consumption in 1990. IISI foresees for steel consumption a static condition for industrialized countries and an increase for developing countries and China that offsets the decrease expected for the former U.S.S.R. and Eastern Europe. Developments in the steel and manganese industries of China and the former U.S.S.R. can be expected to have a particularly significant influence on world manganese supply and demand in the coming years. Resurgence of ore production from localities such as Western Australia and potential new developments elsewhere could add to future supply for at least a limited number of years, depending on future ore

¹Data may not add to totals shown because of independent rounding.

²Includes quantities reserved for payment-in-kind disposal.

TABLE 3 DOMESTIC PRODUCERS OF MANGANESE PRODUCTS IN 1992

Company	Plant location		Product	s ¹			
	Train rocation	FeMn	SiMn	Mn	MnO ₂	Type of process	
Chemetals Inc.	Baltimore, MD	_	_	_	X	Chemical.	
Do.	New Johnsonville, TN	_	_	_	X	Electrolytic.	
Elkem Metals Co.	Marietta, OH	х	X	X		Electric furnace and electrolytic.	
Kerr-McGee Chemical Corp.	Hamilton, MS		_	X		Electrolytic.	
Do.	Henderson, NV	_	_	_	X	Do.	
Ralston Purina Co.:							
Eveready Battery Co.	Marietta, OH	_	_	_	х	Do.	

¹FeMn, ferromanganese; SiMn, silicomanganese; Mn, electrolytic manganese metal; MnO₂, synthetic manganese dioxide.

TABLE 4 U.S. CONSUMPTION AND INDUSTRY STOCKS OF MANGANESE ORE, 1 BY USE

(Metric tons, gross weight)

Use	Consu	mption	Stocks, Dec. 31		
	1991	1992	1991	1992	
Manganese alloys and metal	w	w	w	w	
Pig iron and steel	47,000	49,000	27,000	20,000	
Dry cells, chemicals, miscellaneous ²	w	w	w	W	
Total	473,000	438,000	275,000	276,000	

W Withheld to avoid disclosing company proprietary data; included in "Total."

¹Containing 35% or more manganese (natural).

²Natural ore, including that consumed in making synthetic manganese dioxide.

U.S. CONSUMPTION, BY END USE, AND INDUSTRY STOCKS OF MANGANESE FERROALLOYS AND METAL IN 1992

(Metric tons, gross weight)

	F	erromangane	se		
End use	High carbon	Medium and low carbon	Total ¹	Silico- manganese	Manganese metal
Steel:					
Carbon	190,839	72,657	263,496	76,589	2,450
Stainless and heat-resisting	13,679	(²)	13,679	5,169	1,768
Full alloy	20,942	5,283	26,225	15,728	464
High-strength, low-alloy	18,811	2,563	21,374	4,915	(²)
Unspecified ³	389	689	1,079	546	260
Total steel ¹	244,661	81,192	325,853	102,947	4,943
Cast irons	10,809	585	11,394	11,355	6
Superalloys	w		w		103
Alloys (excluding alloy steels and superalloys)	1,102	275	1,377	(4)	⁵ 19,659
Miscellaneous and unspecified	w	_	w	(*)	W
Total consumption ¹	256,572	82,052	338,624	⁶ 114,303	24,712
Total manganese content ⁷	200,000	66,000	266,000	75,000	25,000
Stocks, Dec. 31:					
Consumers and producers	22,370	6,059	28,429	7,106	(*)

W Withheld to avoid disclosing company proprietary data; included in "Alloys (excluding alloy steels and superalloys)."

¹Data may not add to totals shown because of independent rounding.

²Withheld to avoid disclosing company proprietary data; included in "Steel: Unspecified."

³Includes electric and tool steel, and items indicated by (2).

Withheld to avoid disclosing company proprietary data; included in "Cast irons."

⁵Approximately 85% of this combined total was for consumption in aluminum alloys.

⁶Internal evaluation indicates that silicomanganese consumption is considerably understated.

⁷Estimated based on typical percent manganese content (rounded).

⁸Withheld to avoid disclosing company proprietary data.

TABLE 6 U.S. UNIT CONSUMPTION OF MANGANESE IN IRONMAKING AND STEELMAKING

(Kilograms per metric ton of raw steel unless otherwise specified)

Form used	1991	1992
IRONMAKING		
Basis:		
Production of raw steel million tons	79.74	84.32
Ore ²	.24	.26
STEELMAKING		
Basis:		
Production of raw steel and steel castings million tons	80.65	° 85.27
Ore ²	_	<u> </u>
Ferromanganese	3.24	3.00
Silicomanganese	.80	.80
Manganese metal	.06	.06
Total, steelmaking	4.11	3.85

Estimated.

TABLE 7 TIME-PRICE RELATIONSHIPS FOR MANGANESE IN METALLURGICAL ORE

	Average annual U.S. price, dollars per metric ton unit							
	dollars per n							
Year	Actual price	Based on constant 1987 dollars ¹						
1972	0.59	1.52						
1973	.64	1.55						
1974	.89	1.97						
1975	1.36	2.76

^eEstimated. ^eRevised. XX Not applicable.

¹Table includes data available through July 12, 1993. Data pertain to concentrates or comparable shipping product, except in a few instances where the best data available appear to be for crude ore, possibly after some upgrading.

In addition to the countries listed, Colombia, Cuba, Panama, Peru, and Sudan may have produced manganese ore and/or manganiferous ore, but available information is inadequate to make reliable estimates of output levels. Low-grade ore not included in this table has been reported as follows, in thousand metric tons, gross weight: Argentina (19%-30% Mn), 1988—9 (revised); 1989—6; 1990—4 (estimated, revised); 1991—5 (revised), and 1992—4; and Czechoslovakia (about 17% Mn), an estimated 1 in each year.

³May be for average content of each year's production rather than for content of typical products.

⁴Metallurgical ore.

⁵Formerly part of Yugoslavia.

⁶All production in Yugoslavia from 1988-91 came from Bosnia and Herzegovina.

⁷Gross weight reported; metal content estimated. Estimated metal content figures have been revised as necessary.

For 1989-92, production of beneficiated ore as reported in Sumário Mineral (Brasilia); for 1988, the same plus direct-shipping manganese ore as reported in Anuário Mineral Brasileiro, the latest year for which such data were available.

⁹Includes manganiferous ore.

¹⁰Calculated metal content includes allowance for assumed moisture content.

¹¹Reported figure.

¹²Formerly part of the U.S.S.R.; data were not reported separately until 1992.

¹³Concentrate.

¹⁴Much of India's production grades below 35% Mn; average content was reported as 38% Mn in 1985.

¹⁵ Mostly oxide nodules; may include smaller quantities of direct-shipping carbonate and oxide ores for metallurgical and battery applications. Gross weight is calculated from reported metal content data.

¹⁶Dissolved in Dec. 1991.

¹⁷Dissolved in Apr. 1992.

¹⁸ Category represents the combined totals of Burma, Egypt, Greece, Indonesia, Italy (from wastes), Japan, the Philippines, Thailand, Turkey, and Zambia.

¹⁹Data may not add to totals shown because of independent rounding.

¹Where available, data for manganese dioxide included beginning in 1984.

²Including manganiferous ore.

³Data may not add to totals shown because of independent rounding.

⁴New series for steel-related end uses beginning in 1989.

⁵Includes miscellaneous nonmetallurgical uses of ore beginning in 1987.

⁶Not specifically based on reported data; includes processing losses. Through 1988, the distribution within this category is approximately the same as for end uses above exclusive of batteries and chemicals. Beginning in 1989, includes nonidentified uses of steel corresponding to about one-third of total steel shipments.

MATERIALS RECYCLING

By Arnold O. Tanner

Mr. Tanner is an industrial material specialist with 14 years of experience at the Department of the Interior, the first 7 years as a geologist at the U.S. Geological Survey. Since 1986 he has served at the U.S. Bureau of Mines as a physical scientist (commodity specialist), leading to his present position specializing in materials recycling. For the past 3 years he has conducted studies concerning materials recycling and solid waste management as a member of the Branch of Materials. Some of the data, tables, and graphs were prepared by Micheal George, material application assistant, and Vikas Parekh, material application clerk, both with the Branch of Materials.

INTRODUCTION

Modern society faces significant changes in the ways it makes use of and interacts with the physical world. With continued growth in population and increasing material consumption come related effects on the availability of material resources and on the natural environment from which they are extracted. Use of our raw and manufactured materials with increasing efficiency can partly offset these effects. The recycling of scrap and waste materials provide an alternative material source to that of virgin supplies. Fairly rapid growth has occurred in recent years in the recycling of a wide variety of physical structure materials and products that are used in our everyday lives. If a substance can be reused or recycled for part or all of its inherent value, it is a candidate for diversion from the solid waste stream. The longer a material's useful lifetime can be extended, the less Earth's virgin resources of that material must be consumed.

The greater the economic viability of a material's overall recycling process, the greater is its potential for continued recycling. Successful recycling provides opportunities for new businesses in the economy, thereby providing materials, services, and jobs. The recycling of the aluminum used beverage can (UBC) is a prime example of a profitable secondary/used material recovery operation. The reuse of UBC's requires significantly less energy resources than

the equivalent processing of virgin aluminum and reduces the quantity of waste that is overcrowding our landfills.

The shrinking availability of landfill space is a very visible and politically active issue. Along with associated water and air pollution at some existing landfills, the growing question of how best to manage our waste and other used materials is coming under increasing Increased interest in more efficient materials use and reduction of the impacts of waste on the environment are part of the sustainable development approach to economic activity and environmental protection. Sustainable development was defined in the Bruntland report as development that meets the needs of the present without compromising the ability of future generations to meet their own needs.1 Materials recycling, although far from a total solution for all our waste ills, is one avenue for managing our used, or otherwise rendered-useless, materials.

A large variety of materials are recycled by different sectors of our society. The materials recycling that is mainly addressed in this writing is from waste that is generated after manufacturing and use. Included is recycling that is generally more obvious to the public: the collection, reprocessing, and remanufacture of materials into new products from post-consumer UBC's, scrap metal, glass containers, paper goods, increasingly plastics, as well as rubber tires and other used goods. On the other hand, a variety of materials are

recycled within the individual operations by mineral and material processors, the chemical industry, product manufacturers, utility companies, etc. This latter solid and liquid reprocessing and recycling is done internally in many industries and is generally less visible to the general public than the recycling of materials from municipal solid waste. Recycled materials in the various industries are commonly liquid or chemical in form, but also include the clean excess scrap from paper, glass, and plastic manufacturers (often called "home," runaround, or flash scrap). A significant portion of pre-consumer scrap, sometimes called new scrap, is traded to industrial consumers of scrap materials to produce new products and is included in much of the data that follow. Most of the physical structure materials that are recycled back to the consumer as new products are solid materials. Other materials such as lubricating oils, solvents. and household hazardous increasingly, substances such as paints, home solvents, and cleaners, are currently categorized as "solid" waste, but are not addressed in this writing.

The U.S. Bureau of Mines (USBM) publishes several annual reports that address many of these recycled materials and products. For the most part these publications address metals that society has traditionally recycled. This chapter is the initial attempt to cover several of the basic materials and products that are not covered in other USBM writings. These materials are diverse in their makeup;

hence, the general title "Materials | Recycling" was used. However, one "characteristic" ties them together: if, following their initial intended use they are not: (1) reused relatively "as-is"; (2) recycled following material reprocessing; (3) incinerated in a waste-to-energy (WTE) facility; or (4) otherwise processed into usable material, such as through composting, then they become waste and are landfilled. Society may always produce some quantity of waste products that cannot be used again and must be disposed of. The important consideration here is how much must be Solid waste discarded at what rate. management, or resource management as some professionals more positively characterize it, is the overall theme surrounding the growing efforts to reuse and recycle our used materials. Of equal importance for future generations is the conservation of our natural resources, especially nonrenewable resources. This also has been a motivational force behind recent efforts to increase the recycling of materials.

DOMESTIC DATA COVERAGE

Data in this report are derived from a variety of published and unpublished sources that are mostly external to the USBM. Much of the solid waste data and some of the recycling data come from U.S. Environmental Protection Agency (EPA) studies. The other main data sources were various industry, trade association, and independent contractor studies and journal and media reports. At this Federal limited writing Government surveys existed concerning the quantities of post-consumer materials in the municipal solid waste stream or of those being recycled. Several Agencies, in particular the USBM, the Bureau of Census in the Department of Commerce (DOC), and the EPA, have been involved in early talks concerning the gathering of such data.

BACKGROUND

Definitions, Grades, and Specifications

Solid Waste Material Overall Flow.—Post-consumer materials become part of the solid waste stream unless otherwise diverted into secondary material use. Although commonly used by various industries to refer to preconsumer scrap, the term secondary also can be applied to used or post-consumer waste materials that are recovered for recycling. The most publicized waste is municipal solid waste (MSW), and much of the materials recycling that has become an important public issue in the past decade comes from MSW. Municipal solid waste, however, is an extremely small portion of the total solid waste stream. Estimates of solid waste from all sources vary greatly, and most are based on incomplete, mid-1980's data. from estimates of between 11 and 13 billion tons² of legally designated "solid" waste, only about 180 million tons is MSW, a little more than 1.5% of total solid waste, as shown in figure 1. Also note that these "solid" waste streams are perhaps 80% or more liquid, a common constituent being wastewaters as well as other liquid wastes. Much of these liquid-form "solid" wastes are contained in surface impoundments for treatment, storage, or disposal. True solid wastes that are not recycled, composted, or incinerated are generally managed by way of landfills, waste piles, or in other land disposal areas.

Municipal Solid Waste Material Flow.—Municipal solid waste, while being a small portion of our total solid waste stream, is mostly (about 95%) solid in nature when introduced into the wastestream. Two of the included categories of waste, yard waste and food waste, are mostly solid in form but have low to moderate liquid (commonly waterbased) contents. These liquid-containing wastes contribute liquid to landfill effluent as landfill wastes degrade. Together yard and food waste comprise about 25% of MSW.

Solid Waste Management Options.— The Hierarchy.—A hierarchy of solid waste management methods has been established by the EPA. Although a strong emphasis is often placed upon its first two levels, the solid waste hierarchy is a list of method preference rather than a rigid set of hard and fast rules. The hierarchy includes: (1) source reduction, (2) reuse, compost, or recycle, (3) wasteto-energy incineration, and (4) landfilling. A balanced approach in choosing the best methods for managing wastes in each particular situation is called integrated waste management (IWM). In IWM, the different methods are intended to be utilized, as appropriate, for the varied locales or States. Recycling is not always the answer because of such reasons as geography and sparse population, local economics, lack of accessible technology. Likewise, the next preference, incineration, also may be impractical. For example, an adequate future supply of solid waste "fuel" must be confidently anticipated to justify the high capital cost of building an incinerator. Landfilling in conjunction with minimal recycling activities may be the most workable and beneficial waste management choice for the solid wastes in a certain county. Local or regional economics can restrict the use of the other options, especially in sparsely populated areas.

Source Reduction.—The first preferred option is actually a "pre-option" called source reduction, sometimes referred to as waste reduction. Solid waste source reduction is the design, manufacture, purchase, or use of materials or products (including packages) to reduce their amount or toxicity before they enter the solid waste stream. Not creating the waste in the first place is better than having to deal with it later. Because it is intended to reduce pollution and conserve resources, source reduction should not increase the net amount or toxicity of wastes generated throughout the life of the product.³ Reduction of the quantity of materials in a particular packaging application is one example of source reduction. Another example is the design of a product, such as the

MATERIALS RECYCLING—1992

automobile or a home appliance, with recycling in mind. A more easily disassembled vehicle, refrigerator, or stove, made of readily recyclable materials, will reduce the amount of discarded material. One related design factor, the energy that will be needed to reprocess the materials, may either encourage or discourage a source reduction effort. The total energy expended, commonly derived from nonrenewable hydrocarbons. considered as well as the metals, plastics. and glass materials that may be kept out of the wastestream by recycling into new. qualitative hard goods and materials.

Recycling and Composting.—Direct reuse or the recycling, physical or chemical, of a product or other waste material is given second preference. The goal here is to recover materials from the wastestream and thereby minimize the use of virgin resources. Recycling is not 100% effective because there is always some waste that results during the recycling process. Some portion of the material either degrades too much to be reused or is lost in the process. But, recycling, while not being a perfect solution, does extend the lifespan of a material by keeping it in use. Recycling decreases the throughput of materials into the wastestream and thereby slows the filling up of valuable landfill space.

Composting is also included in this level of preference. It involves the chemical breakdown of materials into different, usually more basic, materials or chemical compounds. This contrasts with the physical breakdown of a material into smaller pieces that are chemically the same. The recycling of paper is a physical process in which the individual paper fibers may be reduced in size but remain chemically unchanged. composting of food and yard waste is increasingly becoming an integral part of the solid waste management efforts of many communities, especially where laws have been passed banning the landfilling of yard wastes. Composting provides an alternative to chemical fertilizers in a variety of applications. Municipal solid waste is also compostable after the removal of metals, plastics, rubber, and glass. Three factors that tend to limit its popularity are: (1) the concentration levels of some contaminates, especially metals such as lead and cadmium, (2) small pieces of glass, metals, and plastics that remain, and (3) competition from the other waste management methods, especially the recycling of paper.

Waste-to-Energy Incineration.—The next choice in the hierarchy is MSW incineration, especially when it is used to produce energy. WTE incineration. producing energy either in the form of steam or electricity, is often a viable waste handling option that makes use of the energy values contained in MSW rather than simply burying it. Incineration of MSW also reduces the volume of the waste that remains to be disposed of to as little as 15% of the combusted materials' original volume. Some components of MSW, such as plastics, are virtually reduced to zero, only a very minute portion of char remaining. This volume reduction is especially important in regard to plastics because, when compared to other MSW materials of like weight, plastics take up about twice as much space. Although volume reduction is a significant reason for incinerating MSW, incinerators without energy recovery have of late been on the decline and those with such recovery are becoming the norm. Plastic material (as well as rubber) is an important portion of MSW "fuel" in a WTE incinerator because it can provide higher energy values than the other components of MSW.

Sanitary Landfilling.—Although it is still the most common form of used/waste material management, landfilling is becoming the least preferred. Minimizing the quantity of discarded materials that are landfilled has been stressed during the past several years because of the shrinking availability, sometimes physical and sometimes political, of landfill space. The diversion of materials from landfills and the solid waste stream as a whole is the dominant force driving current material reuse and

recycling efforts.

Material Resources and Related Economic Issues.—Collection Material Processing.—Supplies of materials collected for recycling are relatively large in the United States. Old newspaper, mixed paper, green glass, and some plastics are examples of materials that have been collected in quantities beyond the markets' capacity to absorb them. Causes for the oversupply of some recovered materials include: (1) lack of a recycling industry infrastructure; (2) inadequately developed markets; (3) often, an uneven playing field of competition with competing virgin materials; (4) low prices for recovered materials; and (5) the recent weak state of the U.S. economy. Sometimes lacking are supplies of clean or uncontaminated materials. A load of an otherwise usable material can be rendered useless if it includes too high a level of other unlike materials. The processing of such loads can be limited for technological or economic reasons. Further development of collection practices and sorting procedures and technologies, such as those for sorting plastic containers of different types, may serve to increase supplies of more competitive, marketable materials.

A foreign example of collection that exceeds secondary markets is to be found in Germany. During 1992, the nationwide recycling collection organization, Duales System Deutschland, collected more than 4.5 times as much tonnage of scrap plastic as it had initially anticipated, and this 205 million kilograms of plastic was more than 3 times the amount that the country had the capacity to handle. One-third of the plastic was exported, and the rest was stockpiled awaiting future increases in capacity and better markets for the materials. This oversupply was felt beyond the German border. In at least one district in England, secondary raw materials from Germany could be purchased for less than it cost the district to collect its own. For 1993 Germany is predicting a doubling of plastics collection to about 410 million kilograms to be used

in about the same proportions as in 1992. Almost one-third, 135 million kilograms, will likely be added to the current stockpiles.

Economic Factors Within the Recycling Industry.—The basic economic structures for each commodity within the recycling industry are similar. Metal recycling, particularly of steel and aluminum, is the most established. The paper and glass recycled material markets also have been in place for a long time.

The market for recycled plastics is still in development and in most cases secondary plastic resin is more expensive than virgin material. Makers of plastic bottles buy the recycled material in spite of the price disadvantage because they have faced regulation against their products to keep them out of landfills and recycling of the material is economically more favorable to the industry than a ban or costly restrictions.

Plastics recycling businesses are not as integrated as those for other materials. A significant number of small firms perform only one or a few of the various steps involved in recycling and reproducing plastic materials and manufacturing new products that go to market. Companies in the other more established marketplaces commonly undertake many or even all of the steps. This allows for greater efficiency and leaves the companies less vulnerable to changes in markets and prices. For example, when several companies are involved in various steps of the recycling of a material, the transportation costs alone between sites can significantly add to overall processing costs compared to a more "integrated" company handling the entire process at a single site.

Another difficulty for materials recycling is that of classic supply and demand. Most recycled materials, with the exception of scrap metals, face similar basic economic problems: high supply, low demand, high cost, low quality (compared to virgin), and low, unsteady prices. The high supplies have been caused by somewhat enthusiastic collecting by the public, and in part by mandatory recycling without sufficient

building of the product marketplace. Low quality, commonly due to contamination by unlike materials, such as paper mixed in with a load of postconsumer plastics, limits the use and value of the materials. Contamination results in higher processing costs, or even rejection of the otherwise good material load. Virgin material is usually less expensive and quality is far more consistent and easier to control. Oversupply and unreliability of the material quality only adds to the standard costs of recycling, which are collection, transportation, sorting, further processing, and the specific technologies involved in reproducing a useful new material and final product. The recycled material marketplace can be made more stable through: (1) continued improvements in material quality, (2) the continuous reliability of that supply, and (3) emphasis on the demand for the final product to better match increasing quantities of collected materials.

The primary sources of pricing information for most recycled goods are weekly and monthly trade publications, which calculate the prices by polling traders. In recognition of the often low, changeable prices, the Chicago Board of (CBT) began an experimental Trade project to help develop the recycled material market. The CBT is creating the country's first recyclables cash exchange market as an electronic forum for buyers and sellers of recyclables. This is hoped to provide potential buyers with more accurate pricing information and standardized quality specifications. CBT believes that the unregulated and volatile nature of dealing recyclables has in part been responsible for the slow development of recycled material and product markets.4

The "Not-In-My-Back-Yard" Factor.—"NIMBYism," as it is often called, refers to resistance by citizens to the siting of certain nonresidential facilities near to where they live. Whether the resistance is based on legitimate concerns or is more an emotional reaction, it represents a real problem for both the solid waste and

The siting of a recycling industries. needed recycling facility, incinerator, or landfill can be a very difficult process. Most people do not want one "in their back yard," but reality dictates that they must be constructed somewhere. The public must be protected from unreasonable or harmful facility sitings and at the same time be served in their needs for solid waste management and materials recycling. Various facilities are needed to recycle the various used and waste materials. Some examples of these are materials recovery facilities (MRF's) where collected materials are sorted and made ready for shipment to recycled material processors and materials transfer stations that handle and process the materials that the public puts out at the curbside for collection. Location is not the only issue; general economic issues involved can prohibit the siting of a facility in a location even when most of the people concerned accept the site.

Legislation and Government Actions⁵

Issues surrounding the transportation of solid waste and hazardous waste across State lines received significant attention during 1992 at both the State and Federal levels. Representatives from garbage importing States attempted to write legislation that would provide State Governors with the authority to restrict the disposal of out-of-State wastes. Several State legislatures had attempted to restrict the importation of unwanted wastes through the enactment of bans or other restrictive measures.

On June 1, 1992, the U.S. Supreme Court ruled on two jurisdictional waste transportation cases: Chemical Waste Management, Inc. v. Hunt and Fort Gratiot Sanitary Landfill, Inc. v. Michigan Department of Natural The Court reaffirmed its Resources. original holding in the 1978 case of Philadelphia v. New Jersey that interstate waste transactions are subject to the Commerce Clause and that undue discrimination against out-of-State waste resulted in economic protectionism and was therefore unconstitutional. Chemical Waste Management, Inc. (a case in which the EPA participated as <u>amicus</u>, arguing against the State law), the State of Alabama had imposed a differential fee on all hazardous waste generated out of State that was disposed of at in-State facilities. This was deemed by the Court to be an undue burden on interstate commerce. In <u>Fort Gratiot</u>, a Michigan statute had prohibited out-of-county solid waste unless authorized by a State-approved county plan. Likewise, the Court ruled against the State, holding that the Michigan law violated the Commerce Clause.

In the context of these and other related factors, the 102d Congress set out to reauthorize the Resource Conservation and Recovery Act (RCRA), which had last been accomplished in 1984. furtherance of the reauthorization the Senate Environment committee produced a series of bills, the most noteworthy of which had three primary themes: that of (1) providing States greater latitude in restricting out-of-State municipal waste; (2) allowing ash from municipal incinerators to be treated as regular solid waste, thereby allowing easier disposal (environmental groups advocated treating this ash as hazardous waste, thereby necessitating potentially more onerous disposal procedures); and (3) the prohibition against discarding lead-acid batteries in municipal landfills or incinerators and a requirement that retailers, wholesalers, and manufacturers take back old batteries for safe disposal or recycling. The Energy and Commerce Committee proved unable to resolve the interstate waste shipment issue and the Senate bill was not passed.

In the House, under the combined work of the Energy and Commerce Committee and the Hazardous Materials Subcommittee, a narrowed down version of an initially broader-scoped and controversial solid waste bill was Primarily, passage of the attempted. House Rule would have amended Subtitle D of RCRA and provided the EPA with the authority to regulate nonhazardous solid wastes. In its narrowed down version the bill contained provisions relating to requirements for recycled paper and packaging, environmental marketing claims, and the recycling and disposal of scrap tires and batteries. But because of the large number and complexity of issues involved in this bill, it also was put on hold.

Efforts to again fully reauthorize RCRA are not expected in the 103d Congress because of a shift in focus to Superfund and related hazardous waste issues. Currently, Federal Circuit Courts of Appeal are applying the two 1992 U.S. Supreme Court holdings aforementioned to a variety of State and municipal law challenges. One 1993 holding of importance was rendered by the Eighth Circuit in the case of Waste Systems Corp. v. County of Martin, Minn. In Waste Systems, the county ordinance required all compostable solid waste to be delivered only to local facilities. The rationale for the county "exportation" restriction was that it required a longterm reliable waste supply for its economic security. Relying on the Supreme Court's Philadelphia decision, the Circuit Court held that unreasonable exportation restrictions, like importation restrictions, violated the Commerce Clause.

ANNUAL REVIEW

Paper Recycling

Paper and paperboard materials are initially produced almost exclusively from wood pulp, which is wood or "cellulose" fiber that is mainly processed from softwood timber and to a lesser degree from hardwood timber. Softwood fibers impart strength and tear resistance while hardwood fibers provide density and printability. The major categories of paper products include: paperboard; kraft paper, including that used for corrugated container board; cardboard; newsprint; printing and writing paper; and various utility papers, such as for bags, plates, tissues, and towel products. These products, as well as fiberboard used in construction and paper-based insulation materials, are potential markets for both pre-consumer and post-consumer recycled paper fibers to supplement virgin fiber content and reduce the quantity of paper in the solid waste stream.

Issues.—Two issues with potential to affect increases in paper recycling are the growing quantities of paper in municipal solid waste and environmental issues related to virgin material supply. Our society has become a heavy consumer of paper and paperboard products. The "paperless society" speculated by many in the past does not appear to be close at hand. We are using more and throwing away more with each passing year.

According to the EPA, the total generation of paper and paperboard products in MSW has grown steadily from 27 million tons in 1960 to almost 67 million tons in 1990. As a percentage of the total MSW generated, paper (by weight) represented about 34% in 1960. Although the percentage has varied over time, it has generally increased, to 37.5% of total MSW generated in 1990. Much of the paper that we use comes in the form of nondurable goods with relatively short lifespans. Waste from paper packaging materials and newspapers, having lifespans of less than 1 year (often only several days) have followed this same trend. When added together, they account for about 60% of total paper waste. However, the actual quantities going to landfills has shown small decreases of late. Based upon EPA data, the quantity of paper being landfilled dropped by about 5% between 1985 and 1990. During this time paper recovery for recycling and incineration (usually with energy recovery) has significantly increased.

Paper recycling, a common practice during the newspaper drives since the 1950's and 1960's, has greatly increased in the past two decades. The recycling of paper reduces the need for virgin wood fiber. The diversion of paper alone could significantly reduce the quantities of waste filling up our landfills.

Quantities of solid waste managed by incineration substantially declined from the mid-1970's through the mid-1980's, but rebounded to above 1970 levels by 1990. Since 1985, numerous new facilities—cleaner, more efficient, and almost exclusively with energy recovery

systems—have come into operation. This includes both mass burn and refuse-derived-fuel (RDF) plants. RDF is MSW that has had certain materials, especially metals, separated out, after which the remaining materials are processed into a fairly consistent, uniform-sized feed of combustible material.

Secondly, because paper materials are produced from wood fibers, production of paper and paperboard products promotes significant use of timber resources. About 25% of U.S. timber production goes into the making of woodpulp, of which about 95% is used in the production of paper. Increasing attention is being paid to a variety of environmental issues. Growing controversies over various endangered species. the loss of virgin forests with relatively untouched biological diversity, and the erosional effects of the clear-cutting of forests are several issues related to the harvesting of timberland. These factors have a potential to influence the increased use of recycled paper fibers in new paper products.

Currently at issue is establishing a generally acceptable standard or legal definition of "recycled paper." The use of pre-consumer scrap paper in paper production is a common practice of many manufacturers because it is a good alternate source of raw material. generally yields a high-quality product more easily, and most often at a lower cost than when post-consumer paper is used. Post-consumer paper tends to be "dirtier" with more contaminants than the more consistent and controlled quality of pre-consumer scrap that often has not left the factory. The need to divert more post-consumer paper from the Nation's landfills is becoming increasingly emphasized. Settling on ways to accomplish this while continuing to encourage the recycling of pre-consumer scrap has been difficult. **Proper** definitions are needed for government procurement procedures to be effective. The Federal Government is a significant potential market for recycled paper. It is not only the largest single consumer of paper, but additionally, it may serve to set an example for the voluntary efforts of other organizations. State agencies and private industry tend to follow its lead.

Annual Supply and Recycling Rates.—All recycling rates are not based on the same type of data. EPA and the American Forest and Paper Association (AFPA) report paper recycling from two different perspectives. EPA compares the total post-consumer paper recovered for recycling to the estimated total paper waste generated each year. **AFPA** compares the combined total of preconsumer and post-consumer paper recovered to the total "new supply" (apparent consumption) consumed by the paper industry during that year. Fabrication scrap is included in its preconsumer recycled scrap numbers as part of the recycling rate.

EPA estimated that 28.6% (19 million tons) of the paper waste generated (66.5 million tons) during 1990 was recovered. This was up from the 22% and 21% rates of the early and mid-1980's, respectively. By AFPA measures the paper recovery rate was 33.6% in 1990, up from 26.75% for both 1980 and 1985. During 1992, AFPA reported that 30.5 million tons (33.6 million short tons) of paper and paperboard were recovered out of a total supply of 79.4 million tons (87.5 million This translates into a short tons). recovery rate of 38.4%, as shown in figure 2. Also shown are the recovery rates for the two leading types of paper According to AFPA, old products. newspaper (ONP) recovery grew from almost 45% in 1990 to almost 56% in 1992. Old corrugated containers (OCC's) are the highest tonnage source of recovered paper, as shown in figure 3. The recovery of OCC's grew from almost 55% to 59% of the total supply of new OCC paper between 1990 and 1992.

The pattern of growth in the consumption of fiber used at U.S. paper and paperboard mills between 1980 and 1992 is shown in figure 4 and table 1. The quantities of primary (virgin) wood fibers have consistently grown during this time period, but its percentage of total consumption has remained fairly constant, and the use of other (virgin) plant fibers,

a relatively small quantity, has dropped by 1%. The greatest growth by percent, from 22.5% to 29.5%, has come from the increasing use of fiber from recovered paper. Quantities of wood residues and waste, also a recovered/recycled material, have fluctuated in small amounts since 1980, but have only minimally increased since 1980.

Consumption and Uses.—Although more than 70 different types, or grades, of paper exist, the paper industry uses 5 basic classifications: corrugated containers, newsprint, mixed, pulp substitutes (clean converting scrap), and high-grade deinking. A summary of the quantities of recovered paper and paperboard between 1982 and 1992, as reported by AFPA, is provided by category in table 2. These data include pre-consumer paper scrap. Consumption of growing supplies of collected waste paper is complicated by contamination by other waste materials, reduced secondary fiber quality (shorter fibers), economically viable markets for the secondary paper fibers. Though not without its own difficulties, a collection program can be set up in a rather short period of time. But creating costcompetitive, marketable products is the greater challenge.

Kraft paper can serve as an example of a paper material with a secondary market. Kraft paper is the brown paper used to make corrugated containers and paper bags. According to EPA, it makes up about 36% of the total generation of paper waste. The previously mentioned 38.4% paper recycling rate is possible because of a specific market for recycled kraft paper fiber. The outside sheets of corrugated board, called liner paper, often need to meet rigorous specifications for resistance to bursting, puncturing, and crushing. This is especially true for paper that is to be made into boxes for shipping fragile products such as electronics, appliances, and glassware.

Recycled paper has shorter fibers than does virgin paper and it is consequently, not as strong. As the recycled content of the liner paper increases, the paper's strength decreases. This limits the

potential use of recycled fibers in the liner paper of corrugated boxes. The specifications for the paper from which the inner fluting of the corrugated box is made are much less rigorous. The inner fluting is the curved middle paper material between the two paper liners that gives a box the structure and look that we think of as "corrugated." It provides the transported product protection from potential damage.

Another example where significant opportunity exists for using recycled paper in lower grade applications is that of used newsprint recycled to manufacture cellulose insulation and garden mulch. In such less demanding types of applications lie a significant potential for the use of large volumes of waste paper.

Technology.—Contamination make the recycling of post-consumer paper very expensive if not economically impractical. OCC's sometimes include wax coatings, plastics, food, wrappings, etc. The recycling of office paper is complicated by a large diversity of paper grades, as well as quantities of contained groundwood fiber, nonwaterglues, soluble paper clips, rubberbands. Although improved cleaning equipment and technological advances are minimizing these impacts, continual improvements in collection methods and an evolving education of the public concerning the problems caused by contamination are an important part of Probably the most the solutions. significant technological progress is occurring in the deinking industry, in which new methods and technologies are being developed and many new plants have been coming on-line or are in the planning stages.

Steam explosion deinking technology is a current state-of-the-art and increasingly utilized method to deink office paper, especially the lower and mixed grades of paper. The process can be used as well to process OCC's at roughly two-thirds the cost of a similarly sized plant using conventional technology. A number of new plant projects were begun in 1992, both in the United States

and in Canada. Steam explosion, a process used in the past to break apart wood chips and other biomass, deinks by "exploding" waste paper. This is accomplished by feeding the paper into a high-pressure chamber and then releasing it to atmospheric pressure. This process enables the recycling of even contaminated and low grades of waste The steam explosion system paper. results in more uniform pulp than other processing alternatives, requires no hazardous chemical deinking, and can process problem feedstocks, such as coated and waterproof stocks. Also it requires substantially less water and energy than the more commonly used technologies. When used for newsprint and writing paper-grade sheets, some further deinking by the more common methods of flotation and washing is needed to remove small quantities of ink that remain.6 In flotation methods ink and other contaminants are chemically induced to be hydrophobic (waterrepelling). Air is injected in the lower half of the flotation tank. contaminants attach to rising air bubbles because they are repelled by the water and the bubbles are the only way to get away from the water. Washing, the oldest deinking technology, involves chemically inducing ink particles to be hydrophilic (water-attracting) so that the ink is washed away with the water. A company in Virginia and another in Maryland were developing cogeneration plants to turn coal (VA) and natural gas (MD) into electricity and steam. New waste paper facilities were to be added, using the electricity generated to run the plants and provide the steam for the deinking processes.7

International Paper Co. announced a new recycling initiative for recovering milk and juice cartons into recycled-content copier and printing papers, and a variety of other recycled paper products. The company had completed a pilot project on the west coast and was planning to install a new carton processing plant in one of its existing mills in the Northeast. Recovered cartons there will be used to produce copier and printing papers. The initial

concern has been to establish an adequate flow of suitable materials. For this reason the company was holding ongoing discussions with several major metropolitan areas about adding cartons to their curbside collection programs.⁸

Markets and Prices.—Markets for recovered paper and reprocessed paper pulp vary with the type and grade of paper that is collected or processed. A large variety of paper products with recycled content is produced in the United States. But significant quantities of scrap and discarded paper, notably newsprint, OCC's, and office paper are exported as well. The third largest market for old newspapers in the United States is the export market. These ONP exports primarily go to Pacific Rim mills that use waste paper as a primary raw material. Almost 3 of the 14.5 million tons of OCC's that industry reported as recycled in 1991 were exported. And more than one-half of the office paper collected for recycling is generally exported, again primarily to Pacific Rim countries.9 Quantities of recovered paper being recycled have been continually increasing, but except for minor upswings in 1992, the prices paid for recycled pulp fiber remained relatively flat. The prices have been relatively low in part because of oversupplies of recovered paper in addition to the sluggish overall economy. At the same time, efforts continue to collect increasing quantities of post-Without significant consumer paper. improvements in the general economy, prices for secondary fiber were not expected to greatly improve.

Plastics Recycling

Plastics are long-chain polymer and resin materials that are synthetically produced almost entirely from nonrenewable hydrocarbon resources, most notably natural gas and petroleum. During the past three decades rapid growth has occurred in the use of plastics for a seemingly countless variety of purposes. Production in the United States has shown an average annual growth rate of 10% with continued growth expected

MATERIALS RECYCLING—1992 819

into the future. This growing flow of plastic materials has resulted in gradually accelerating increases in the quantity of plastic waste annually generated in the United States as shown in figure 5. The increasing use of plastics in packaging accounts for much of the waste. According to the EPA's municipal solid waste characterization study, containers and packaging accounted for almost 43% of all the plastic waste generated in the United States in 1990. Plastic packaging is a target for recycling because most packaging material has a relatively short period of use (less than 1 year) before discard. Packaging is usually a temporary "transportation" medium for another product and is not intended to have a long useful life. The typically more durable products it contains are generally not intended for such immediate discard, and the packaging material is quickly available for use in another product.

Other sources of waste plastic in MSW are appliances, furniture, carpets, and lead-acid batteries, in addition to a variety of nondurable goods such as plates and cups, trash bags, footwear, disposable diapers, and synthetic textiles. Textiles are in an industry separate from the plastics industry and are sometimes forgotten to be a source of waste resin. In 1990, approximately 62% of the fibers consumed in the U.S. textile industry were synthetic resin fibers. Textile resin fibers also become part of the municipal solid waste stream. However, only small quantities were actually recycled in 1990. Although not included in MSW data, significant quantities of waste plastic result from the discard of automobiles and from the construction and even more from demolition (C&D) of houses, buildings. and other human-made structures.

Issues.—Plastic products, especially as used in packaging and containers, are a low weight but high volume waste material that contributes to filling up our landfills. Although being about 9% by weight of our municipal solid waste that is landfilled each year, they account for possibly 20% or more of the volume, as

reported by the EPA. A recent estimate of the volume of plastics in landfills was reported by William Rathje of the University of Arizona. In archeological digs of landfills across North America, as part of his "The Garbage Project," he determined that plastics compact better in landfills than has generally been believed. In these excavations plastics took up about 16% of the space in the landfill. Although they may take up less space than previously believed, plastics by weight still take up more than their share of landfill space. Because they are a significant nonbiodegradable material, they are often a target for recycling or incineration. Some of the very qualities, such as durability and corrosion resistance, for which plastic materials are used are the same "qualities" for which they are criticized upon discard. The management of plastic products when they have outlived their usefulness is an ongoing issue. Some States and counties have chosen to manage certain plastics by banning their use.

Under the EPA's waste management hierarchy, recycling used or waste plastic products into new products is preferred to the incineration or landfilling of them. Plastics recycling is further encouraged by some advocates because plastic is derived from nonrenewable energy resources and cannot be grown as a tree can from a seed. But to be successful recycling must result in a product with (1) high enough quality, (2) low enough cost, and (3) be done with an efficient expenditure of energy and other natural resources. If not, incineration of waste plastic is a potentially valuable alternative. When its hydrocarbon origins are considered, plastic is, not surprisingly, a highly energy-intensive material. In the WTE incinerator it is a very valuable component of the mixed municipal solid waste. As well as having high energy values, the heat it gives off promotes better burning of the surrounding mixed wastes. Incineration is a final one time use of the material promoted by its advocates as more productive than simply burying it.

Although some degradable plastics have been produced and others are under

design, they are only a small part of the solution to related landfill and litter problems. These materials may be useful in specific applications; for example, for 6-pack beverage container rings, packing peanuts, compost bags, and possibly disposable diapers. But they are not practical for many uses of plastic. Also, the production of truly degradable plastics in the large scales necessary would currently be technologically and economically prohibitive. The large majority of "degradable" plastics at present are more accurately labeled as "bio-disintegratable" "photoor disintegratable" as the plastic itself does not truly degrade. Disintegratable plastics, such as our everyday plastic grocery bags, break down into a plastic sand or dust when the starch molecules that join them together truly degrade due either to biological agents or solar energy reactions. The polymer in these materials does not degrade—it is the same durable plastic in miniature. The environmental consequences of this plastic dust is unknown. For some applications the desired characteristics of plastics, such as durability and corrosion resistance, would be adversely affected by formulating the plastic to be degradable. Another issue is that of the recyclability of other plastic materials, for technological or economic reasons. can be limited when contaminated with quantities biodegradable plastics.

An ongoing, controversial issue for many recycled plastic material and product producers is that they conduct business on an uneven, unfairly competitive playing field with virgin plastic producers, resulting in unfairly stiff competition. Recyclers contend that virgin producers have the advantage of buying their raw materials from the oil and gas industry, which receives either subsidies or tax breaks, thereby reducing the expense of their raw materials. In efforts to encourage more recycling, a number of alternative approaches to this controversial problem was under discussion in the EPA and the U.S. Congress, as well as other government agencies and independent task forces.

The Recycling Advisory Council

(RAC), formed in 1989 in part under a grant from EPA, consists of representatives from business, industry, environmental organizations, and public interest groups. In a major effort to find ways to increase recycling in the United States, RAC's mission was to investigate the crucial issues concerning and surrounding materials recycling, not the least of which were barriers to the development of the various scrap commodity markets. During 1992 and to be completed in 1993, its market development committee conducted a study of the barriers to recycling and possible approaches to solve these problems. To encourage greater use of recycled materials, several of the alternatives proposed for consideration were: establish a variety of minimum content standards for recycled materials in products, (2) require that the manufacturer of a product be responsible for its recycling, (3) apply a tax on the production of virgin materials, and (4) establish a subsidylike "trust fund" for rebates to companies using recycled materials.

Supply and Recycling Annual Rates.—Most survey-based plastics recycling data came from trade groups and consulting groups who conducted studies of the relatively young plastics The American recycling industry. Plastics Council (APC), a major plastics recycling trade group, reported the results of its fourth annual post-consumer plastics recycling rate study, conducted by R. W. Beck and Associates. The study examined six resins commonly used in consumer packaging that also were recycled: polyethylene terephthalate high-density polyethylene (PET), (HDPE), polyvinyl chloride (PVC), low-/ linear low-density polyethylene (LDPE/LLDPE), polypropylene (PP), and polystyrene (PS). Various other plastics, such as polycarbonate and nylon, were included in the survey totals as they also were reported as recycled by some For a detailed of the companies. breakdown of the recycled plastics from the APC study for the years 1991 and 1992 see table 3.

The APC surveys, as well as the other more limited surveys, have consistently reported increases in plastics recycling each vear. APC reported that total plastics recycling during 1992, including both packaging and nonpackaging, grew 41% over that of 1991, while the recycling of packaging plastic was strongest with a 47% rise. More than 582,410 tons of post-consumer plastics was recycled in 1992, up from almost 413,680 tons in the previous year. Almost 75% of the recycled plastic was from packaging materials. The packaging component grew from 291,660 tons to 429,950 tons. As this survey has been refined each year, not only have newly formed companies been added, but also some companies missed in a previous year were picked up and added that Thus, some of the following year. recycled increase could reflect the absence of these companies from earlier This does, however, reporting years. also suggest that recycled quantities may have been better in earlier years than those surveys suggest. Nonetheless, it appears to be the most complete and accurate survey that has been conducted for the public record to date.

PET has become the most recycled of all post-consumer plastic in the United States. Recycling of PET has grown from 3,600 tons in 1979 to nearly 210,000 tons in 1992. Almost 83% of the 1992 total, 173,000 tons, resulted from the recycling of soda bottles alone. This quantity was almost 41 % as much as the virgin PET sales for soda bottle production for the year. Almost 26,500 tons of nonpackaging PET, 13% of total recycled PET, was recycled in 1992. Total HDPE recycled in 1992 was 201,000 tons, principally from the recovery of natural milk and water bottles, and less so from pigmented bottles and soft drink base cups.

PS is used in packaging applications in the form of PS foam. Both its very high volume-to-weight ratio and its common use with food products makes collection and some associated processing more difficult than other plastics. Nevertheless in 1992, more than 17,000 tons of PS, 53% more than the previous year, was recycled in the United States.

A nonpackaging application where significant plastic recycling growth occurred during 1992 was in the recycling of lead-acid vehicle battery casings made of PP plastic. Recycled quantities of PP from this source alone increased almost 41%, from 65,500 tons in 1991 to 92,200 tons in 1992. One major reason for this recycling growth is the regulations by State and local governments that (1) require lead-acid vehicle battery retailers to return spent batteries directly back to the manufacturer for recycling purposes, and/or (2) prohibit the flow of the same batteries into solid waste landfills. As of mid-1993, 35 States had enacted battery recycling legislation and 7 other States had banned the municipal solid waste disposal of lead-acid batteries.

Whereas the reported increases are an indication of positive movements in the industry, there is still a long way to go. Based on conservative estimates of plastic waste contained in the municipal solid waste that was generated in 1992, the total plastic recycled was, possibly at best, about 3.5% of the total. Although small, this does show progress from the roughly 2% achieved in previous years.

Consumption and Uses.—The two major types of plastic, thermosets and thermoplastics, have significantly different limitations and challenges in Thermosets are long-chain recycling. polymers that have been "set" chemically or "cured" in a crosslinked pattern. When heated to the proper temperature these molecules do not melt in the manner that thermoplastics do. crosslinked bonds remain intact and the degraded or charred material cannot be formed into a new and usable shape. To date, thermosets have very limited use in recycled products. They are limited to being crushed or cut up into small pieces and used as a filler or aggregate material certain product applications. Thermoplastics also are composed of long-chain polymers, but they have not been chemically linked together, allowing them to slide by each other when properly heated. They melt into a liquid or moldable form. When the temperature drops they resolidify or harden into the new product form.

Recovered and reprocessed plastic is consumed by a large number of industries, consequently resulting in a wide variety of new products. Consumption by individual industry is difficult to quantify. Recycled PET plastic is used in the manufacture of carpets, industrial strapping and pallets, fiberfill for sleeping bags and ski jackets, automobiles parts, nonfood containers, plastic lumber, and a continuing variety of other products. An important market for recycled PET is the synthetic fiber (textile) industry that uses the PET for carpet backing and other fiber products. HDPE is commonly formed into bottles, industrial and consumer containers, drums and oil storage containers, fuel and other tanks. tank liners, housewares, corrugated pipe, pipe for irrigation and oil, gas and mineral production, consumer bags, some food packaging, sheeting, wire, and cable. Some of the products manufactured from recycled polystyrene are: park benches, office equipment, videotape cartridges, pallets, the new compact disc "jewel" cases, and a variety of household products.

Most recycling of plastics is based on physical alteration or breakdown (crushing and shredding) and melting of the material to produce another product. Tertiary plastics recycling is a very small portion of plastics recycling and is fundamentally different. The old material chemically broken down into fundamental components or chemical substances. Recycling occurs when a new, "virginlike" polymer is then produced from the resin components into a new, marketable product. technology needed to chemically break down plastics into fuels and into the basic feedstock hydrocarbons has been known for decades. But, until recently, it was used principally within manufacturing plants where it was economically beneficial to do so. In part because of the limited one-time reuse, the chemical recycling of plastics into a fuel is generally not considered recycling in EPA's solid waste hierarchy; it is in effect comparable to WTE incineration.

Since late 1990, tertiary recycling by methanolysis, glycolysis, and pyrolysis has been used by three soft drink companies to recycle PET plastic. In these processes used PET bottles are chemically recycled back into new PET soda bottles that are usually composed of a mix of 25% of the recycled material and 75% virgin material. Bottles made of 100% chemically recycled PET are technologically possible but currently cost-prohibitive. The quantities recycled by this method are a very small portion of the PET bottle recycling data. Because of the associated economics, thus far apparently marginal at best, this practice is not flourishing. However, most, though not all, of the original projects are still ongoing. Although virgin PET supplies were sufficient, virgin PET material output was at times near capacity. This measure of uncertainty created a demand for raw materials from the tertiary recycling operations to more securely guarantee supplies of needed new bottle material.

A significantly higher portion of plastic was recovered for WTE incineration to produce energy via steam or more directly to produce electricity than was recycled. In 1990, an estimated 16% of the plastic waste portion of the generated MSW generated was combusted in WTE incineration plants. When the resin fibers in the textile portion of MSW is included, the total percent of plastic incinerated rises to about 19%.

Technology.—Possibly the greatest difficulty in processing post-consumer plastics, both technologically and more so economically, is that of sorting or separating the different types of plastics. A high-quality recycled plastic material of a particular type may be feasible, but many products demand that recovered materials be uncontaminated with glass, dirt, and other types of plastic. In some cases minute quantities of contamination greatly or even critically reduce the quality and usability of the recycled material. A good example of this is PVC-contaminated PET (polyethylene

terephthalate-soda bottle plastic). Their similar densities complicate the process of segregating the two before melting, and during melting PVC, which has a sufficiently lower melting point, contaminates the PET with a detrimental char product. Some materials and products demand very pure "recyclate" material, others such as some plastic lumber and park bench materials are more forgiving and can accommodate a combination of plastics.

Highly reliable separation technologies that demand little to no labor and also are cost-effective are needed for continued and accelerated growth of recycling in the plastics industry. The human sorter cannot recognize all the different variables of plastic categories and subtypes, as well as different colors, particularly at the speeds necessary to make the process economical. Numerous plastics sorting technologies have been invented and range from those achieving limited results to some very effective and sophisticated systems. Most of these are based on various spectroscopic and X-ray analyses, infrared recognition, and laser technologies. Other systems under development include a water surface tension technique, a selective "dissolution system," and a near infrared light system that incorporates specialized "neural networks" instead of conventional computers. Because of the problem of similar densities, in particular that of PET and PVC, one company is developing a flotation-type system to separate the two by means of their differing surface tensions.

The Rensselaer Polytechnic Institute (RPI) is currently testing and developing a selective dissolution system to separate individual resins. In the process, all plastic resins are commingled, shredded, and subjected to several solvent baths. Each bath is heated to the precise dissolving point of a certain resin and the resulting liquid is siphoned off into a holding tank. The temperature increases with each bath until all resins are removed. According to an associated consulting company. after processing by "flash devolitization," the remaining resin is nearly as pure as virgin plastic and may be sold at a discount of at least 2.25 cents per kilogram. RPI is currently awaiting approval from the U.S. Food and Drug Administration to use food packaging in a future pilot devolitization process.

The Sandia National Laboratories of the U.S. Department of Energy is developing a system that uses the near infrared light/neural network system. Modeled after the assimilatory abilities of human nerve cells, these networks will be capable of "learning" the characteristics of the resins—a process less arduous and time-consuming than preprogramming. In some test runs, once the networks have been trained through trial-and-error for all types of resins, accuracy levels of 100% have been reported in the lab. A prototype was under testing by a recycling equipment manufacturer. 10

With the increasing effectiveness and sophistication of sensing systems often comes a higher cost that limits their use by many companies because of the relatively low prices for scrap plastic. But, cost factors aside, some very accurate sensing systems are still hindered by mechanical difficulties encountered in separating the material. Two problems that researchers are working on are how to provide the automated systems with single plastic bottles or pieces and how most perfectly to mechanically segregate the different plastics.

Because of the bailing of plastics that is necessary for economical transport, used plastics become clumped together and a foolproof breaking of these clumps into the individual pieces is expensive and difficult. Several new technologies have been claimed to be virtually 100% effective in sensing the different plastics, but if the plastics are still stuck together then the sensor reads the clump as one object. If there is more than one resin or color in that clump, rather than jeopardize the rest of the stream the system rejects the clump. The more this happens, the larger the amount of material that has to be sent through the system a second time, proportionately reducing the efficiency and increasing the costs of the sorting and processing operation. If bottles are not completely separated into individual pieces, even perfect sensing and physical sorting technologies cannot finish the job as needed. Most, if not all, "singulation" systems are having these problems. The other mechanical difficulty is that of doing the physical sorting. This is generally done by air jet nozzle systems that are becoming increasingly accurate, although not foolproof. These systems balance the sensors recognition time with the speed of the conveyor belt to eject the different bottles via streams of air into the proper collection bins. Some systems use a negative sort in which a plastic is sorted by not being jettisoned, but merely dropping off the belt into another bin. The greater the variety of plastics being separated the more difficult the process Some of the most sophisticated is. systems can separate plastics into four main streams or types. One operation has combined two systems and is able to separate a mixed stream of baled or loose plastics into five categories: HDPE, natural HDPE, PVC, green PET, and clear PET.11

A major source of waste plastic is that of scrapped automobiles. **Following** shredding, the auto shredder residue (ASR) that remains, composed of plastics, fluids, glass, rubber, and various other mixed materials, including dirt, is most often landfilled. Plastics compose about one-third or more of the total. About 10 million automobiles are shredded each year. At an approximate average of 100 kilograms of plastic per car, this amounts to 1 million tons (1.1 million short tons) of plastic that could potentially be diverted from our landfills The Argonne National annually. Laboratory (ANL) is one of a number of and companies working on technologies to process ASR. Argonne's technique uses solvents in an effort to dissolve the residue into products that could be economically substituted for, or mixed with, virgin material without reduction in final product quality. According to ANL, this process reduces the residue to 50% reusable materials and 50% residue remaining for disposal. Argonne claims to have achieved a 92%

recovery of the processing solvents in its laboratory work with even higher anticipated percentages of recovery possible in commercial applications. These recycled plastics could potentially be used in products such as park benches. posts. traffic cones, construction materials. Under present economic conditions, these recycled materials have limited marketability because most impurities are not removed, and the cost of making the products can be as much as if virgin materials were used. 12

The Japan Recycle and Research Center, formed in association with the Japan Iron and Steel Scrap Association, is taking a different approach in attempting to deal with the 5 million automobiles that are annually scrapped in Japan. They have begun a new research program to design and construct a new type of WTE incineration plant for elimination of ASR. Remnant ashes are to be processed into concrete materials.¹³

Markets and Prices.—The marketing of recycled plastic products generally suffers because of high costs and insufficient demand for recycled materials. Materials for many products are very specialized and either need a quality that cannot be produced from recycled plastic, or when proper quality can be achieved, the cost would be noncompetitive with virgin resins. Other plastic products can be produced more easily with recycled plastic but are still simply too expensive as compared to the same product made from virgin plastic. An additional reason is true acceptance by The general public is the public. becoming increasingly enthusiastic about the idea of recycling and materials conservation. Municipalities want plastic materials and goods to be diverted from the solid waste stream. But both individuals and institutions have been slow to translate these notions into expressed demand for recycled material content used in lieu of virgin materials in the products that they buy off the shelves every day. The general public often is not readily confident that recycled products may be as good as the virgin

MATERIALS RECYCLING—1992 823

products sitting next to them on the same shelf. In addition, when the recycled products are more expensive, the incentive to purchase the recycled product is further reduced.

Thus far. PET and HDPE are the only plastics that have commanded high enough prices with sufficient demand to achieve a measure of consistency in the recycling industry. PET plastic has been the most cost-effective and consistently recycled of the two with many marketable products that can be made from clean, processed PET scrap. Its main challenge has been to be cost competitive with virgin PET, the price of which has been relatively low during the same period. Recyclers of HDPE, while experiencing a higher percentage increase in output in 1992 than recycled PET processors, had to endure greater competition in the marketplace. One major processor of recycled HDPE canceled its HDPE operations altogether to concentrate its efforts in the better market opportunities of recycled PET, although it planned to restart its HDPE operations when the market showed sufficient improvement and stability.

Rubber Recycling

Rubber recycling includes synthetic rubber and, to a lesser degree, natural rubber. Synthetic rubber (SR) is a major member of the family of materials called the elastomers. plastic, it is made up of long-chain polymers that are produced from hydrocarbon feedstocks. In addition, the SR polymers have been synthesized to consistently reproduce, at ambient temperatures, natural rubber's best properties, most notably its "rubberlike" elasticity. Sources of rubber waste products are discarded clothing, footwear, rubber tires, and a variety of miscellaneous durable and nondurable goods, such as gaskets on appliances. various automobile parts, furniture, floor coverings, and hot water bottles. But rubber tires are the predominant source of rubber in municipal solid waste. As many as 250 million waste tires (about 2.3 million tons) are generated annually in the United States. Of equal concern is the backlog of tires that have accumulated across the country, especially since the end of World War II. Both by illegal dumping and by legal stockpiling, an EPA-estimated 2 billion to possibly as many as 3 billion "units" (tires) have been thus "disposed" of in preference to being landfilled, incinerated, or recycled.

Issues.—Tires, about 85% of which come from automobiles, are a significant and problematic portion of our municipal solid waste. For decades they have been a growing problem because, landfilled or stockpiled, discarded tires can be a threat to human health and the environment. Landfills have traditionally been the method of disposal for scrap tires in the absence of a market. Today landfill bans are restricting this practice, especially the burial of whole tires. Their composition and shape do not allow easy compaction in the landfill, and they do not decompose, thus occupying significant amounts of valuable landfill space. Additionally, whole tires trap gases due to their round and hollow shape and over time "float" to the surface, breaking the landfill cover and allowing landfill gas to escape.¹⁴ Being exposed on the landfill's surface, they then become a breeding ground for insects, rodents, and birds.

Stockpiled tires have similar associated problems, which can be amplified because greater quantities are crowded into one place. Because of their shape tires hold water at any angle, which makes them a very attractive breeding site for mosquitoes and other insects, some of which can carry disease. North American varieties of mosquitoes can be of concern by themselves, but in recent years other strains of insects have been "imported" from other countries. For example, in 1985 the Asian Tiger Mosquito, which is known to carry some relatively dangerous sicknesses, arrived in Houston, TX, aboard a shipload of used tires from Japan. This same mosquito has since been located in other parts of the country.

Another danger is that of fire. A tire fire is extremely difficult to extinguish and can burn for a long time.

Uncontrolled tire combustion at the characteristically low temperatures at which these fires usually burn tends to release significant amounts of thick, black smoke. Both the air is fouled and the rubber melts into a toxic substance or "goo" that can adversely affect ground water. A few tire piles that have caught fire have been designated Superfund cleanup sites by the EPA.¹⁵

Currently, the overriding issue is of how to use or safely dispose of scrap tires and other rubber products: whether to incinerate them for their contained energy values or to stress the reuse and development of recycling uses for waste rubber and tires. Incineration of tires for their energy values is currently the leading method of use/disposal after that of landfilling or stockpiling. While markets for materials and products that include recycled rubber are increasing. the greatest potential to date is the use of ground rubber tires in the production of rubber-modified asphalt for our Nation's

Supply and Recycling Annual Rates.—EPA estimated that in 1990 about 181,400 tons (200,000 short tons) of rubber from tires was recovered for recycling. At an average of 9 kilograms (20 pounds) per tire, the average weight of a passenger car tire, this amounts to more than 20 million tires. More recent estimates have been projected by the Scrap Tire Management Council (STMC). For 1992, the council estimated the annual recovery at more than 68 million tires, 58 million of which was estimated to be used as fuel by several major industries. Of the remaining 10 million tires, nearly onehalf was used in rubberized asphalt. Other uses included civil engineering applications and the manufacture of recycled rubber products. A small portion was chemically broken down to more basic chemicals and materials by the process of pyrolysis. The apparent discrepancy between the two recovery estimates is not as great as it may appear because the EPA's estimate does not include tires that were combusted either as a fuel or for the production of energy.

According to an EPA study, an estimated 12 million used/waste tires were exported in 1990. If included with STMC's estimated 1992 recovered quantity of 68 million tires, an approximate 80 million tires were potentially recovered for the production of energy, recycled products, reuse, and export for similar purposes. Thus, about one-third of all waste tires in 1992 (presuming a similar exported quantity as reported for 1990) were potentially diverted from the Nation's landfills, stockpiles, and "illegal dumps." exports are not included, then the recovery rate was about 28% of total discards.

Retreaded tires usually are not included in recycling data as they are considered a reuse. But they are a valuable "recycling" of the tire body as a whole and their reuse also slows their introduction into the solid waste stream.

Consumption and Uses.—Pulp and paper mills are a major user of tires as a fuel. Tires, like coal, are used as a fuel supplemental to their traditional fuel of Consumption in this wood chips. industry has remained fairly constant in the past several years. The pulp and paper industry consumed between 12 and 13 million tires as a supplemental fuel in The industry has burned tirederived fuel (TDF) since the early 1980's. TDF is tire rubber that has been chipped into pieces 2 inches or less in size, called crumb rubber, and is processed to be clean of contaminants. including the steel belts. The steel belts are sold as scrap metal. The pulp and industry needs this clean, paper uncontaminated TDF if it is to use tires as a fuel. In conjunction with this need, the industry's major constraint is the cost of competing fuels, such as wood chips, petroleum coke, and coal. Lower prices for competing fuels can limit the use of TDF. Two other limiting factors are the remote location of many mills, which results in higher transportation costs and the reliability of TDF supply.

Tire recovery has substantially increased during the past 2 to 3 years as a fuel in electric utility boilers, cement

kilns, and in new, dedicated tire-to-In 1992, almost 17 energy plants. million tires were combusted in utility company boilers or in other boiler facilities, such as agricultural product processors and chemical companies. TDF is the common rubber fuel that is used in electric power companies' utility boilers, although requirements for clean TDF sometimes are less stringent than those of the pulp and paper industry. Some systems allow for the burning of whole tires. In parts of the Midwest and the East high-sulfur coal is burned in utility plants. At times when coal costs less than TDF, using TDF as a fuel can still be competitive because of its low sulfur content. Both TDF and whole tire combustion is reported to produce less ash than burning coal, emit less carbon dioxide, and produce lower sulfur-dioxide emissions when replacing a high-sulfur coal.16 Very significant growth has occurred in this sector in the past few years alone, and according to STMC, some of the major utilities are currently considering using scrap tires.

The cement industry has increased its use of waste tires from 3 million tires in 1990 to about 14 million in 1992. Cement kilns are rather heavy users of coal, making the use of the cleaner burning rubber an attractive option. As with some utility users, a growing number of cement kilns are able to burn whole tires, avoiding the associated costs of buying processed TDF. Tires offer these kilns other advantages. Tires have a higher energy value than coal, and a tire's steel belts and beads can replace the iron ore needed in the cement making process, thus reducing the manufacturer's raw material costs.

Only two major tire-to-energy facilities, both built by one company, were operational in 1992, but between them they consumed about 15 million tires. The same company was in the planning stages of building two more plants. The completion of one of these units by 1997 would more than double the current 15-million-unit capacity. Even though these operations have been successful, the use of this technology is usually only practical in regions with high

electric rates and high solid waste tipping fees. The capital costs per megawatt of generating capacity for these facilities runs between two and seven times more than coal-fired plants.

In 1992, about 5 million scrap tires recycled either through incorporation into asphalt binder material or as aggregate in rubber-modified asphalt. Rubberized asphalt costs about twice the price of conventional asphalt, but experience indicates that it can be applied in thinner layers and lasts much longer. A more widespread use of the basic technology as well as the end of a patent on one of the most frequently used processes should help to reduce costs of this rubber-modified product. Some questions as to the safety and durability of this product, as well as its recyclability in the construction of future roadways, has been raised, mostly due to a lack of long-term experience with it. But to date, roads made of this material appear to be more durable and longlasting as well as safe to travel on. According to a recent report to Congress jointly submitted by the EPA and Department of Transportation, the use of asphalt containing recycled rubber is not substantially different from conventional asphalt in terms of health and environmental effects, recyclability, or adequacy as a paving material.

Another 5 million tires were used mostly in civil engineering applications and to a lesser degree in recycled rubber products. Civil engineering applications include embankments, clean fill, leachate collection in lieu of sand or gravel, artificial reefs, breakwaters, sideslope stabilizers, crash barriers, sound barriers, and playground structures and protection. Other applications include use in products such as railroad crossing ties, dock bumpers, a variety of flooring materials and mats, carpet underlay, sound insulation in automobiles, truck and trailer liners, and drip irrigation pipes.

Possibly as many as 1 million tires were consumed by tire pyrolysis, the process of chemical and physical breakdown of the whole tire into oil, gas, and char (low-grade carbon black) byproducts, and steel from the steel

MATERIALS RECYCLING—1992 825

belting. This use has not flourished because of inconsistent markets for the oil and char byproducts.

Although making new tires out of old tires may seem like the most obvious choice, this is not possible. Tire rubber is a thermoset or "vulcanized" material. To date, no technology has been able to reverse or "devulcanize" this process. Because of this the new, strong chemical bonds necessary for new tire production cannot be achieved. Only a very minimal and inconsequential amount of rubbings, very fine crumb rubber, can be used as noncritical filler in the manufacture of some tires.

The only way that old tires are used in tire manufacture is as retreads. retreading of tires is a direct reuse of the basic tire and thus is not included in reported recycling amounts and rates. The American Retreaders Association (ARA) contends that it should be considered recycling because of fine lines of difference between retreading and some other recycling uses of used tires. The life of the tire is extended and consequently the annual quantity of tire waste that must be managed is reduced. Additionally, natural resources are conserved because annual demand is reduced for new, virgin tire material. The ARA reported that the retreading process gave new life to about 31 million tires in 1991. Of these, approximately 8 million were passenger car tires, another 8 million were light-truck tires, and 15 million were truck tires, whose high replacement cost makes retreading costeffective.

Technology.—A significant, source reduction-related technology has been the longer wearing vehicle tire. The development of the radial tire more than a decade ago increased the tread life expectancy from the range of 20,000 to 25,000 miles, for the standard bias-ply tire, to 40,000 miles and more for the then new radial-ply tire. An added advantage of the radial tire was that it delivered better fuel mileage. A trend to smaller cars began somewhat earlier, during the 1970's. Smaller cars usually use smaller tires. These factors caused a

reduction in the amount of rubber used in manufacture of tires consequently, in the quantities of tire waste generated. According to a World Rubber & Tire Report issued in 1992 by the Freedonia Group of Cleveland, OH, the amount of natural and synthetic rubber used in tires dropped from 45% of all rubber consumed in 1980 to 42% in The International Institute of Synthetic Rubber Producers in Houston, TX, recently estimated that almost 52% synthetic rubber of all currently consumed goes into tire production. Both of these percentages could change further during the next decade if the most recent advanced tire technology is successfully integrated into the tire marketplace. In 1991, the original producer of the radial tire introduced a new radial tire in the United States that it warranted for 80,000 miles. Although the new technology has not been fully revealed by the manufacturer, these tires include the use of a newly developed family elastomers.17

Also significantly important is the mix of raw materials used in the radial tire. Radial tire design produces higher operating temperatures than that of other types of tires, and this affects the composition of the tire material. higher temperatures perpetuated increase in the percent of natural rubber needed. Synthetic rubber helps tire tread last longer, but natural rubber is less heat sensitive. Radial-ply tires are composed of about 16% natural rubber as compared to their bias-ply predecessors that used 11% natural rubber. Thus a small yet significant portion of synthetic rubber, which is manufactured from nonrenewable hydrocarbon resources, is being replaced with natural rubber, a renewable resource.

Two companies have developed tire pyrolysis technologies that they claim are economically feasible. Up to now pyrolysis overall has not been viable. Too small a portion of the byproducts—pyrolytic oil, gas, char, and metal from the char—have been profitably marketable on a consistent basis. The gas is usually used to fuel the process, and the metal, approximately 1.1 kilograms

(2.5 pounds) of the typical 9-kilogram (20-pound) tire, is clean enough to market. But the grade of pyrolytic oil and char is often below market standards. Both companies claim that their more pyrolysis technologies sophisticated produce higher quality materials. One of the proposed processes operates at a relatively low temperature, 177° to 205° C (350° to 400° F) as opposed to the traditional operations at 925° to 980° C (1,700° to 1,800° F). The char or "carbon black" is sold to manufacturers of low-grade carbon products such as hoses and tires for lawn mowers and forklifts. Thus far, pyrolysis technologies have not been able to produce a carbon black of high enough grade to reuse in tire production.¹⁸ But even if low-temperature methods prove to be successful, widespread commercialization of them appears likely to be several years away.

Since 1990, the Scrap Tire Management Council reports that one significant technological change has occurred in the tire-to-energy industry. In the second of the two commercial facilities in the United States, certain innovations have allowed for whole tires, as well as processed TDF, to be combusted, thereby lowering everyday operational expenses.

Markets and Prices.—Continued growth is projected for most scrap rubber markets. But the two market areas that offer the most potential are incineration as a fuel and for the generation of energy and the use of crumb rubber in the maintenance and rebuilding of highways. Most of the current uses are expanding and some, such as cement kilns and utility plants, are limited principally by reliable tire supply. However, the expansion of these uses would require significant capital outlay for plant modifications needed to use TDF or whole tire fuel.

The use for scrap tires is likely to grow significantly through 1997 because of the Intermodal Surface Transportation Efficiency Act (ISTEA) in December 1991. The law mandates a recycled content of rubber material on federally

funded State roads. Beginning in 1994, 5% of all federally funded roads paved with asphalt must contain recycled scrap tire rubber at the approximate minimum rate of 9 kilograms of rubber per ton applied. The 5% is to increase another 5% each year through 1997 when 20% of federally funded roads will be so affected thereafter. Although rubber is likely to be the main component of the recycled materials that are mandated under the law, the use of other materials such as glass, asphalt pavement, or plastic may reduce the anticipated quantities of crumb tire rubber that is included in the mix. The final interpretation and the degree of implementation of the law will determine how much is actually used each year. Under the ISTEA legislation STMC estimates that up to 68 million tires could be used for this application by 1996.

OUTLOOK

Alternative Material/Waste Management Methods

The degree to which an integrated waste management system is instituted will greatly affect the future and the effectiveness of recycling, composting, incineration, and landfilling. Since 1988, the number of recycling collection programs and yard waste composting facilities have increased considerably. Curbside collection programs have risen from little more than 1,000 in 1988 to more than 5,400 by the end of 1992. Yard waste collection and disposal facilities during the same period have increased from 700 in 1988 to almost 3,000 in 1992. The number of incinerators during the same period also rose at a slower rate from more than 135 to more than 171 in 1991, and dropping slightly by two units to 169 units in 1992. Even with increasing quantities of municipal solid waste being landfilled, the number of landfills have dropped from nearly 10,000 in the early 1980's to about 8,000 in 1988 to nearly 5,400 in 1992. Closures of many smaller, less profitable sites and others no longer environmentally permissible account for the large drop. 19 Fewer in number, but much larger and better environmentally designed, new state-of-the-art sanitary landfill facilities, or expansions of existing operations, have replaced some of the reduced landfill capacity. Appropriate local ordinance, and State and Federal laws and regulations have mandated these changes, as concern over clean, freshwater supplies and a clean natural environment have risen. Recycling, composting, and probably WTE incineration is likely to increase, but landfilling will probably continue to decrease in comparison to the other alternatives in the foreseeable future.

Source reduction will continue to be stressed as we reduce the weight and size of the materials and products that we produce to levels that are still adequate for the task at hand. Efficiency and practicality will guide these efforts. A new material may make some forms of packaging lighter and thinner than its predecessor, but if it is not cost-effective or if it uses an excessive amount of energy to produce it, then it is neither efficient nor practical. The development of longer lasting materials is likely to be the target of many future research efforts.

"Design For Recycling" Programs²⁰

If designed with recycling in mind, some products could have significant impacts on reducing the generation of solid wastes and on increasing the quantities, as well as the quality, of recycled materials in the future. Automobiles, major appliances, and some packaging applications are just a few examples. This concept is becoming an integral part of the design and research efforts of some companies in the manufacturing and service industries. "Design For Recycling" is an official program and policy of the Institute of Scrap Recycling Industries (ISRI). Through its program, ISRI is seeking a national policy to promote the design and manufacture of goods that, at the end of their useful lives, can be recycled safely and efficiently. Major thrusts of their program are to motivate and assist the manufacturing industry to: (1) make consumer products and durable goods recyclable; (2) reduce environmental risks from consumer products; and (3) control any related special environmental problems.

The concept of design for recycling is relatively simple, but implementation will be a little more difficult to achieve, especially in a culture which, during the past two or more decades, has shifted its habits toward "disposability." U.S. manufacturers presently have no legal responsibilities or obligations to plan ahead for the obsolescence of their products. New products are designed to meet the increasingly complex needs of modern society. The needed materials sometimes become more complex and difficult to recycle and may even contain toxic materials unless attention is paid to recyclability in the product design stage. Toxic materials can be harmful to the environment and to the recycling worker if released during the recycling process. A current example is the sodium azide capsule in the automobile air bag inflation mechanisms. Being both explosive and toxic they have complicated automobile recycling processes. An example of a product that is not dangerous but is complicated to recycle is multilayered food packaging. Although this product is highly effective in protecting food from the environment, the many layers of different materials make it rather difficult to recycle. The scrap recycling industry is aware of these problems, and an objective of ISRI's program is to alert manufacturers.

The Automobile.—Such goals as weight reduction and lower emissions remain important, but increasingly, U.S. automobile manufacturers are instructing designers to give recyclability highpriority consideration. Currently, about 75% of each U.S. auto is recycled in the United States, and the domestic auto industry is striving to do better. Additionally, a number of foreign manufacturers have been in the forefront of recycling-conscious automobile design. One problem that is encountered in automobile design is that as weight reduction is achieved the use of nonmetallic components increases. This

MATERIALS RECYCLING—1992 827

is most of the 25% of the car that is difficult, or currently not possible, to recycle. Plastics are particularly difficult because of the numerous different types that are used and, generally speaking, the lack of compatibility between them.

General Motors (GM) has been using recyclable plastic for body panels on its Saturn²¹ automobile. Defective panels at the plants can be ground for immediate recycling into other molding parts. Used body panels can be recovered and recycled when Saturns are scrapped. Chrysler Corp. has developed an awardwinning prototype car, the Neon, which contains recyclable interior and exterior panels, wheels made from previously recycled aluminum, and is painted with water-based paint. In an attempt to maximize recycling potential, Chrysler vehicle lines were introduced in 1992 that were designed for 90% recyclability. E.I. du Pont de Nemours & Co. (DuPont) supplies the glass reinforced, PET-based plastic for the fenders on these cars. This material can be reground, remolded, and reformed. A methanolysis process, also developed by DuPont, can be used to return the material to its original feedstock components, which can be used again on applications, including new fenders.

While the phrases "design for recycling" and "design for disassembly" go hand in hand, they are different. Design for recycling aims not only at ease of disassembly but also minimum disassembly so that subassemblies may be removed and recycled without further separation. Several European carmakers have taken an early lead in establishing programs in these areas. In 1991. Bayerische Motoren Werke AG (Bayarian Motor Works, BMW) and Volkswagenwerk AG (Volkswagen, VW) started pilot disassembly plants to recover metals, plastics, glass, and other materials from old cars, and BMW announced plans to build a commercial plant. The German Automobile Club (ADAC) has a research dismantling facility at which its goal is the design of a 100% recyclable automobile. The French automaker Peugeot SA (Peugeot) has entered a joint venture with a leading French scrap metals processor and cement manufacturer to maximize recycling and to convert nonrecyclable components into fuel for the cement plants. They plan to recycle more than 7,000 Peugeot and Citroen cars by 1994. In the United Kingdom, the Rover Group has joined with the Bird Group, a leading scrap They plan to processor in Europe. develop rapid dismantling techniques and set up standards and procedures. Japan, similar efforts began with Toyota's collection of used plastic bumpers. The bumpers were sold to recyclers and manufactured into products such as pallets. This program was started with 26 dealers in Tokyo and was expanded to all dealers in the Tokyo area.

The U.S. big three automakers recently formed a consortium to research and promote the maximum recovery and reuse of materials from junked cars. The Vehicle Recycling Partnership also is expected to develop industry guidelines for new vehicle manufacturing in such areas as materials selection and compatibility and needed materials and techniques for joining, coating, etc.

The Automotive Group of the Durables Committee of the Society of the Plastics Industry has established a pilot study to develop economical environmentally sound methods recovering and recycling post-consumer automotive plastics and an industry infrastructure to support such processes. The use of as many as 40 different types of hard-to-identify plastics in automotive applications such as fan shrouds, fender liners, radiator end caps, windshield washer bottles, interior trim pieces, and grill panels has made auto plastic recycling difficult. GM and Ford Motor Company now require labels that identify the type of resin in each plastic part. Auto dismantlers, an auto shredder, a nonferrous metals separator, plastics recovery and reclamation facilities, and industry laboratories will participate in the project. The difficulties encountered and information learned during this project will be used to advise manufacturers in their design for recycling efforts in future cars.

BMW will be cooperating in a pilot

automobile recycling program with three U.S. recycling companies in California, Florida, and New York who are members of the Automotive Dismantlers and Recyclers Association (ADRA). They were chosen by meeting criteria that included outstanding adherence to the ADRA Code of Ethics and use of the ADRA Hazardous Waste Management Booklet as the basis for environmentally sound practices. Fluids will be drained and recycled and batteries will be removed and properly disposed of. If the car has air bags, they will be deployed per BMW specifications to eliminate the risk of sodium azide contamination. All economically salvagable components will be removed before the metal shell is shipped to an auto shredder. BMW will use a monetary incentive to encourage the return of old BMW cars for the project.

White Goods.—U.S. steelmakers have begun talks with scrap processors and home appliance designers to develop washing machines, refrigerators, freezers, and stoves that will result in more efficient disassembly and recycling. These discussions thus far have been bilateral rather than industrywide. Steelmakers are enthusiastic because they feel that their material has the advantages of significant recyclability and the potential for easy disassembly. Plastic materials hold the advantages of lower weight and component integration.

MICA

By Lawrence L. Davis

Mr. Davis, a physical scientist with 37 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for mica since 1983. Domestic survey data were prepared by Linder Roberts, statistical assistant; and international data tables were prepared by Audrey Wilkes, international data coordinator.

In 1992, about 85,000 metric tons of scrap and flake mica was produced in the United States, a decrease of 17% from 1991 production. Ground mica sales were 84,000 tons valued at \$22 million, an increase in tonnage of about 13%.

Almost all sheet mica supply continued to be imported. Consumption of muscovite block mica decreased 6% to 5.6 tons. Consumption of mica splittings decreased slightly to 836 tons. The value of sheet mica exports decreased 4% to \$7.5 million. The value of imports for consumption of sheet mica increased 31% to \$11.0 million. (See table 1.)

DOMESTIC DATA COVERAGE

Domestic production and consumption data for mica are developed by the U.S. Bureau of Mines by means of three separate, voluntary surveys and one mandatory survey. Of the 18 operations to which the crude scrap and flake mica production form was sent, 17 operations, or 94%, responded, representing 95% of the production shown in table 1. Of the 17 operations to which the ground mica sent. 16 responded. was representing 97% of the production in table 1. Of the five canvassed operations to which the mica block and film consumption form was sent, four, or 80%, responded, representing 96% of the consumption shown in table 1. Of the nine canvassed operations to which the mica splittings consumption form was seven operations, or 78%, responded, representing about 98% of the splittings consumption shown in table 1. Consumption for the nonrespondents was estimated using prior-year production data.

BACKGROUND

Definitions, Grades, and Specifications

Mica is a group name for a number of complex hydrous potassium silicate minerals with differing chemical compositions and physical properties. Crystals of mica have excellent basal cleavage and split easily into tough, flexible sheets. The important mica minerals are muscovite and phlogopite.

Commercial qualities of sheet mica are relatively free of defects and tough enough to be punched or stamped into specific shapes. Sheet mica is classified as block, film, or splittings. Block mica is not less than 0.018 centimeters thick and has a minimum usable area of 6.45 square centimeters. Film mica is split to specified thicknesses ranging from 0.0030 to 0.010 centimeters. Splittings are sheets with a maximum thickness of centimeters and a minimum usable area of 4.84 square centimeters. Punch mica, which includes circle and washer mica, is low-quality, handtrimmed mica up to about 5 centimeters in diameter. The American Society for Testing and Materials (ASTM) designates 13 quality groups for sheet mica, based on quantity of visible inclusions and structural imperfections, ranging from black- and red-stained to perfectly clear. ASTM also designates 12 grades based on the maximum usable rectangle. The sizes range from grade 6 (with 6.45 usable square centimeters) to grade OOEE special (with 645 usable square centimeters).¹

Block and film mica products are small flat pieces of uniformly thin mica cut or stamped to close tolerances into a variety of shapes and sizes, depending on the use. Shapes can vary from simple circles, squares, or rectangles to very intricate patterns. Fabricators make their own dies to be able to cut the mica into any pattern desired.

Built-up mica, or micanite, consists of partly overlapped and irregularly shaped and arranged splittings cemented together with either an organic or inorganic binder. Large sheets of built-up mica are made by alternating layers of splittings and binder. Sheets of any thickness are made by pressing the layers at high temperatures. Built-up mica is sold in large, uncut sheets or is cut or molded to any size and shape specified by the customer. It is often bonded to another material such as fiberglass cloth to form a composite sheet.

Reconstituted mica or mica paper is a paperlike material made by depositing fine flakes of scrap mica as a continuous mat, which is then dried. The mica paper is sometimes impregnated with an organic binder.

Scrap and flake mica is generally of a quality and size that is not suitable for use as sheet mica. Mine scrap varies greatly in quality but usually is a heterogeneous mixture that must be crushed, screened, and washed to yield the scrap mica in usable form. Mine scrap may be the sole product of mining a pegmatite or may be a byproduct of sheet mica production. Bench scrap or

shop scrap is the mica discarded during the processing of handcobbed mica into sheet. Factory scrap is the waste that results from cutting and stamping sheet mica into pieces of definite size and shape. Factory scrap is usually the highest grade and quality material. Scrap mica that is recovered from schists and from the beneficiation of feldspar, kaolin, and lithium pegmatites is often referred to as flake.²

Industry Structure

The sheet mica industry in the United States is small, consisting of processors and fabricators of imported mica. Worldwide. India dominates production of muscovite sheet mica. Madagascar is an important producer of phlogopite sheet mica. Sheet mica mining, trimming, and splitting are very labor intensive, and producing countries have the advantage of low wages and a large labor force that is usually trained at an early age. India's sheet mica industry is characterized by a large number of small operations, most of which sell to larger companies or the Government's Mica Trading Corp. of India Ltd. for further processing and export. India is putting more emphasis on exporting fabricated mica products. This is expected to reduce further the amount of mica that will be fabricated in the United States

The U.S. flake mica industry ranks first in world production. Most production comes from surface mining of mica schists and as a byproduct of feldspar, kaolin, and lithium beneficiation. Nearly all flake mica is ground to final specifications depending on the use. Other countries producing significant amounts of flake mica are Canada, China, India, the Republic of Korea, and the former U.S.S.R. Many other countries produce small amounts.

Geology-Resources

Sheet muscovite is obtained from coarse-grained igneous rocks called pegmatites. Pegmatites also contain feldspar, quartz, and various accessory

minerals. Pegmatite dikes and veins range from 1 kilometer or more long and 100 meters wide to thin veins and veinlets of approximately 2 centimeters in width.

The United States has no reserves of sheet mica. Small U.S. reserves were extensively worked in the past, and the high cost of labor has kept the mines shut down since the Government's purchase program ended in 1962. The primary sheet mica resources are in New England, the southeastern Piedmont from Virginia to Alabama, the Blue Ridge Mountains in North Carolina, the Black Hills of South Dakota, and northern New Mexico. Other States with some sheet mica resources are California, Colorado, Idaho, Montana, and Wyoming.

No formal evaluation of world resources of sheet mica has been made. mainly because of the occurrence of this mineral. The most productive sheet mica districts in the world are in the States of Bihar, Andhra Pradesh, and Rajasthan in India. India's large reserves and resources of sheet mica have been the primary world sources for many years. Large reserves of sheet mica also are found in Brazil and western Africa. In Russia, sheet mica reserves are known in the Lake Baikal and Sayan upland areas as well as in the South Eniessy Range. Smaller but substantial reserves occur in Argentina, Australia, and Zimbabwe.

Phlogopite deposits are in areas of metamorphosed sedimentary rocks intruded by masses of pegmatite-rich granitic rocks. The phlogopite is found as veins or pockets in pyroxenite interlayered with or intersecting marble or gneiss. Canada and Madagascar have the world's major reserves of phlogopite. Additional reserves are known in Mexico, Sri Lanka, and the Sludyanka River district and Alden area of Russia.

The primary domestic source of flake mica for grinding purposes is weathered alaskite bodies and pegmatites in North Carolina, where most domestic flake mica is produced. The mica is recovered as a coproduct of feldspar and kaolin beneficiation. Flake mica is also recovered from muscovite schists. These schists bodies range in size from 3 to

more than 100 meters thick and several kilometers long. The mica content ranges up to 90%. Another form of flake mica is fine-grained muscovite called sericite, which is an alteration product of various aluminosilicate minerals.

World reserves and resources of scrap and flake mica are not well known but are considered to be very large. All countries with sheet mica reserves or resources have even larger quantities of scrap mica because only a small fraction of the mica present is of sheet quality. Many other countries have reserves or resources of mica that, although not of sheet quality, are suitable for grinding.

ANNUAL REVIEW

Legislation and Government Programs

The Government inventory of stockpile-grade mica decreased slightly to 9,700 tons. The U.S. Department of Defense sold 157 tons of muscovite block, stained and better; 11 tons of muscovite film; 71 tons of muscovite splittings; and 25 tons of phlogopite splittings. (See table 2.)

Strategic Considerations

Sheet mica and high-quality scrap mica used for making mica paper are important in the electronic and electrical industries. The United States is not self-sufficient in these materials and imports all its supplies, mostly from India. The United States competes with the rest of the world for Indian mica, and availability is sometimes limited, particularly for high-quality mica. Long delivery times and quality inconsistency also adversely affect sheet mica availability.

In a short-supply situation during an emergency, the National Defense Stockpile would be able to meet short-term demand until substitutes could be made available. It is unlikely that domestic sheet mica production could replace or significantly reduce imports. Of the five strategic stockpile categories, only muscovite block mica has ever been produced domestically in significant quantities, and then only under the

stimulus of above-market prices paid by the Government. Domestic production in this century never provided more than a small fraction of domestic requirements.

The domestic supply of flake mica is adequate. Scrap and flake mica are not considered to be strategic materials. The United States is self-sufficient in flake mica but does rely on imports of high-quality scrap for the manufacture of mica paper.

Production

Scrap and Flake Mica.—Mica was mined by 9 companies with 12 mines in 5 States. Four mines that reported production in 1991 were idle during 1992. North Carolina remained the major producing State, with 60% of the total production. The remainder was produced in Georgia, New Mexico. South Carolina, and South Dakota. Most mica was recovered from mica schist, highquality sericite schist, and as a byproduct of feldspar, kaolin, and lithium beneficiation.³ The five largest producers were, in alphabetical order, The Feldspar Corp., Spruce Pine, NC: Franklin Mineral Products Co., Hartwell, GA: KMG Minerals Inc., Kings Mountain, NC; Lithium Corp. of America, Gastonia, NC; and MICA, Fairview, NM. These five companies produced 69% of the national total.

Low-quality sericite, used primarily in brick manufacturing, is excluded from tabulated data contained in this report. In 1992, three companies, one in North Carolina and two in South Carolina, mined low-quality sericite and reported an average value of \$5.52 per ton.

Ground Mica.—Ten companies operated 13 grinding plants in 6 States. Nine plants produced dry-ground and four produced wet-ground mica. The five largest producers accounted for 73% of the total. They were, in alphabetical order, KMG Minerals, Kings Mountain, NC; MICA, Fairview, NM; Spartan Minerals Corp., Pacolet, SC; Unimin Corp., Spruce Pine, NC; and USG Corp., Spruce Pine, NC. (See tables 3 and 4.)

Consumption and Uses

Sheet Mica.—Sheet mica is used principally in the electronic and electrical industries. Its usefulness in these applications stems from its unique electrical and thermal insulating properties and its mechanical properties, which allow it to be cut, punched, or stamped to close tolerances.

The largest use of block mica is as an electrical insulator in electronic equipment. High-quality block mica also is used to line the gauge glasses of highpressure steam boilers. Transparency, flexibility, and resistance to heat and chemical attack are the properties that make mica suitable for this use. Other uses include diaphragms for oxygenbreathing equipment, marker dials for navigation compasses, optical filters, retardation plates in helium-neon lasers. pyrometers, thermal regulators, and stove windows.

Muscovite film mica is used as a dielectric in capacitors. Only high-quality mica, at or near the top of the quality scale, is used. The highest quality goes into capacitors that are to be used as standards. The next highest qualities are used for transmitting capacitors. Receiving capacitors use slightly lower quality film.

Consumption of muscovite block (ruby and nonruby) totaled 5.6 tons, a 6% decrease from that of 1991. Stained and lower-than-stained quality remained in greatest demand accounting for 90% of consumption. About two-thirds of the muscovite consumed was grade No. 4 or larger. The decrease in consumption was a continuation of a long-term decrease in block mica use. Five companies continued to consume muscovite block and film in five plants in four States: two in North Carolina and one each in New Jersey, Ohio, and Virginia.

Splittings represent the largest part of the sheet mica industry in the United States. Muscovite and phlogopite splittings are used to make built-up mica. Consumption of mica splittings decreased slightly to 836 tons. Muscovite splittings from India accounted for nearly all of the consumption. The remainder was

phlogopite splittings from Madagascar. The splittings were fabricated into various built-up mica products by nine companies operating nine plants in seven States.

Built-up Mica.—The primary use of this mica-base product, made by mechanical or hand setting of overlapping splittings and alternate layers of binders and splittings, was as electrical insulation material. Principal built-up mica products are segment plate, molding plate, flexible plate, heater plate, and tape.

Segment plate acts as insulation between the copper commutator segments of direct-current universal motors and generators. Phlogopite built-up mica is preferred because it will wear at the same rate as the copper segments. Muscovite has a greater resistance to wear, causing uneven ridges that may interfere with the operation of the generator.

Molding plate is sheet from which V-rings are cut and stamped for use in insulating the copper segments from the steel shaft at the ends of a commutator. Molding plate also is fabricated into tubes and rings for insulation in transformers, armatures, and motor starters.

Flexible plate is used in electric motor and generator armatures, field coil insulation, and magnet and commutator core insulation. Heater plate is used where high-temperature insulation is required.

Some types of built-up mica have the bonded splittings reinforced with special paper, silk, linen, muslin, glass cloth, or plastic. These products are very flexible and are produced in wide, continuous sheets that either are shipped in rolls or cut into ribbons, tapes, or any desired dimensions.

Total production, sold or used, of built-up mica decreased slightly from that of 1991. Segment plates and molding plates were the major end products, accounting, respectively, for 31% and 25% of the total. Other end products included flexible plates, heater plates, and tapes.

Reconstituted Mica (Mica Paper).—
Primary end uses for mica paper are the

same as those for built-up mica. Three companies consumed scrap mica to produce mica paper. The principal source of this scrap mica was India. Manufacturing companies in 1992 were Corona Films Inc., West Townsend, MA; General Electric Co., Coshocton, OH; and US Samica Corp., Rutland, VT. (See tables 5, 6, and 7.)

Ground Mica.—The largest domestic use of ground mica was in gypsum plasterboard joint cement. The mica acts as a filler and extender, provides a smooth consistency, improves the workability of the cement, and imparts resistance to cracking.

In the paint industry, ground mica is used as a pigment extender that also facilitates suspension, reduces checking and chalking, prevents shrinking and shearing of the paint film, increases resistance of the paint film to water penetration and weathering, and brightens the tone of colored pigments.

Ground mica is used in the well-drilling industry as an additive to drilling muds. The coarsely ground mica flakes help prevent lost circulation by sealing porous sections of the drill hole.

The rubber industry uses ground mica as an inert filler and as a mold lubricant in the manufacture of molded rubber products such as tires. The plastics industry uses ground mica as an extender and also as a reinforcing agent.

Ground mica is used in the production of rolled roofing and asphalt shingles, where it serves as an inert filler and surface coating to prevent sticking of adjacent surfaces. The coating is not absorbed by freshly made roofing because mica has a platy structure and is not affected by the acid in the asphalt or by weathering. Other uses include decorative coatings on wallpaper and on concrete, stucco, and tile surfaces; as an ingredient in some special greases; as a coating for cores and molds in metal casting; and as a flux coating on welding rods.

In 1992, the major end uses were joint cement, 51%; paints, 19%; plastics, 4%; and well-drilling muds, 3%. (See table 4.)

Stocks

Reported yearend consumer stocks of sheet mica decreased 27% to 469 tons; of this, mica splittings represented 91%, and mica block and film represented 9%.

Markets and Prices

Prices for sheet mica vary with grade and quality and can range from less than \$1 per kilogram for low-quality mica to more than \$2,000 per kilogram for the highest quality. The average values of muscovite sheet mica consumed in the United States in 1992 compared with 1991 were as follows: Block decreased 8% to \$80 per kilogram, and splittings decreased slightly to \$1.53 per kilogram. The average value of phlogopite block remained at \$26 per kilogram, while the value of phlogopite splittings remained about the same at \$4.41 per kilogram. The changes in average value are more a reflection of the quality of mica consumed during the year than actual changes in price. The average value of crude flake mica, including high-quality sericite, was \$54 per ton. The average value per ton for North Carolina flake mica, predominantly a flotation product, was \$58.

Foreign Trade

The United States continued to rely on imports, mostly from India, for nearly all of its sheet mica and paper-quality scrap Imports for consumption of unmanufactured block, film, splittings were about 2,100 tons, 50% more than in 1991. Worked mica imports were about 1,400 tons, 56% more than in 1991. About 11,600 tons of ground mica was imported mostly from Canada, while about 4,000 tons was exported to 27 countries. The combined value of all mica imports increased 33% to \$19.5 million, while the combined value of all mica exports decreased 1% to \$9.7 million. (See tables 8, 9, 10, 11, 12, and 13.)

World Review

World production of mica decreased 12% to 186,000 tons. The United States continued to lead in the production of flake mica. India continued to lead in the production of sheet mica. (See table 14.)

OUTLOOK

Demand for sheet mica has decreased dramatically during the past 30 years. For block and film mica, the major cause of decreased demand was technological change, specifically the introduction of semiconductor technology in electronics to the detriment of vacuum tube electronics that used large quantities of mica. Although the major impact of the technology change was felt in the 1960's and 1970's, consumption of block and film mica continues to decrease, albeit more slowly. Substitute materials cause part of the decrease, and increased imports of finished electronic gear mean fewer mica parts are fabricated in the United States. Since 1979, consumption block mica has decreased at an average annual rate of about 20%. This decline is expected to continue, and, by 1995, consumption will decrease to 2,500 kilograms. Consumption of mica splittings, the major type of sheet mica consumed in the United States, also decreased sharply through the 1960's and 1970's. During the 1980's, consumption leveled off to between 900 and 1,000 tons per year. Decreases were due to the development of substitute electrical insulating materials, miniaturization of electrical equipment, and increased imports of foreign-built products. Consumption of splittings is expected to decrease very slightly in the near future, remaining between 800 and 1,000 tons through 1995.

Scrap and flake mica enters markets as ground mica, and demand tends to follow construction activity levels. With increased construction activity in 1992, ground mica consumption increased about 12%. In the near future, modest increases in construction activity are expected to continue, which will probably bring ground mica consumption to about

100,000 tons by 1995.

The major end use, as a filler in joint compounds, will continue to account for about one-half of the market. Consumption for other uses—in paints, well-drilling muds, and plastics—is expected to increase slightly by 1995.

¹American Society for Testing and Materials. Standard Specification for Natural Muscovite Block Mica and Thins Based on Visual Quality. D351-77 in 1984 Annual Book of ASTM Standards: V. 10.01, Electrical Insulation—Specifications: Solids, Liquids, and Gases; Test Methods: Liquids and Gases; Electrical Protective Equipment for Workers. Philadelphia, PA, 1984, pp. 136-143.

²Skow, M. L. Mica—A Materials Survey. BuMines IC 8125, 1962, 240 pp.

³Production of high-quality sericite is included in the totals; however, figures for low-quality sericite, used principally for brick manufacturing, are not included.

¹⁰Dissolved in Dec. 1991.

 $^{^{11}\}mbox{Excludes U.S.}$ production of low-quality sericite and sheet mica, if any.

¹²Dissolved in Apr. 1992.

MOLYBDENUM

By John W. Blossom

Mr. Blossom, a physical scientist/engineer with 45 years of industry and Government experience, has been the commodity specialist for molybdenum since 1982. Survey and trade data were prepared by Sherwood C. Jordan, statistical assistant; and the world production tables were prepared by Harold D. Willis, international data coordinator.

Molybdenum is a refractory metallic element used principally as an alloying agent in steels, cast irons, and superalloys to enhance hardenability, strength, toughness, and wear and corrosion resistance. Primarily added in the form of molybdic oxide or ferromolybdenum, it is frequently used in combination with chromium, columbium, manganese, nickel, tungsten, or other alloy metals to achieve desired metallurgical properties. The versatility of molybdenum has ensured it a significant role in contemporary technology and industry, which increasingly require materials that are serviceable under higher stresses, greater temperature ranges, and more corrosive environments. Moreover, molybdenum finds significant usage as a refractory metal in numerous chemical applications, including catalysts, lubricants, and pigments. The variety of uses for molybdenum materials, few of which afford acceptable substitutions, has resulted in a demand that is expected to grow at a greater rate than most other ferrous metals.

Distribution of molybdenum reserves and productive capacity is concentrated in a few countries of the world. World mine output was an estimated 112,000 metric tons (molybdenum contained in concentrate) in 1992, of which Canada, Chile, China, and the United States provided 80%. An estimated 13% of world output came from the former U.S.S.R. These five countries, led by the United States, are expected to continue as the principal mine producers for the rest of this century. These countries also possess about 90% of the estimated 11 million tons of molybdenum in world reserve base.

The metric system is the official sys-

tem of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on molybdenum that are consistent with international usage, will henceforth report data in kilograms and metric tons.

DOMESTIC DATA COVERAGE

Domestic production data for molybdenum are developed by the U.S. Bureau of Mines by means of three separate, voluntary surveys. These surveys are Molybdenum Ore and Concentrate, Molybdenum Concentrate and Molybdenum Products, and Molybdenum Concentrates. Surveys are sent to all operations that produce molybdenum ore and products. Out of 12 operations to which surveys were sent, all responded, representing 100% of the total United States production shown in table 1.

BACKGROUND

From the period of the Greek and Roman civilizations to the late 18th century, terms such as "molybdous" or "molybdaena" were applied to minerals that were soft and "leadlike" in character, probably including minerals now known as galena, graphite, and molybdenite. This confusion was resolved in 1778 when the Swedish chemist, Karl Scheele, demonstrated that molybdenite, the principal molybdenum mineral, was a discrete mineral sulfide. Four years later, P. J. Hielm of Sweden reduced the acid-forming oxide of the element by heating with charcoal, thereby producing an impure powder of the metal, which he named "molybdenum." Various properties of the element and its compounds were

determined during the 19th century, and in 1893, German chemists produced a 96%-pure metal by reducing calcium molybdate. The impure metal was reported to have been used experimentally as a substitute for tungsten in tool steels.

Molybdenum-bearing armorplate was produced in France in 1894; this was the first recorded use of the metal as an alloving element in steel. Soon thereafter, Henri Mossiam, a French chemist, succeeded in producing a 99.98%-pure metal by reduction of molybdenum in an electric furnace. Mossiam then conducted studies to establish the element's atomic weight and to determine its physical and chemical properties. These studies stimulated interest in the metal and its compounds and investigations of commercial applications. By the late 1890's, molybdenum was used in certain chemicals and dyes, and in 1898, a self-hardening molybdenum tool steel was marketed.

The first mine production of molybdenite was probably from the Knaben Mine in southern Norway in the late 18th or early 19th century. Because essentially no commercial use for the metal existed, output from the mine remained insignificant until about 1880. By the end of the century, molybdenum ore was also mined intermittently in Australia and the United States. Molybdenite and wulfenite concentrates were produced from ores in Arizona and New Mexico, but U.S. output was small and ceased entirely in 1906 owing to lack of demand.

World War I generated the first appreciable utilizations of molybdenum, when it was substituted for tungsten in high-speed steels and used as an alloying element in certain steels for military armament. From 1912 to 1920, small

output was recorded from several additional countries, and U.S. production was resumed. The flotation process for separating molybdenite from its ores was developed during these years. The Climax deposit in Colorado and the Questa deposit in New Mexico were initially exploited from 1917 to 1919. Development of the Climax deposit, the world's largest, later proved the viability of hightonnage extraction of relatively low-grade ore and established the United States as the leading producer of molybdenum.

Output terminated in 1920 in the United States and most other countries because nonmilitary consumption of molybdenum was insufficient to support continued production. However, industrial efforts to develop peacetime applications, primary as an alloy in steels and cast irons, were successful, and by the mid-1920's, demand exceeded that of the war years. Operations resumed at the Climax deposit in 1924. By 1930, world output of molybdenum totaled 4.2 million pounds, of which the United States and the Climax Mine accounted for about 89% and 73%, respectively.

In 1933, the Greene Cananea Copper Co., a Mexican subsidiary of the Anaconda Co., initiated the recovery of molybdenite as a byproduct of copper mining operations. Three years later, Kennecott Corp. began byproduct recovery at its Bingham open pit in Utah. Since that time, molybdenite recovery circuits have been installed at numerous copper concentrating plants, notably in Canada, Chile, and the United States. These sources have supplied 40% to 50% of the world molybdenum output in recent years.

Since the early 1930's, industrial research and marketing programs have considerably expanded the range of metallurgical materials in which molybdenum is a preferred or essential alloy ingredient. The use of molybdenum as a refractory metal and in a variety of chemical applications also has experienced significant growth.

Definitions, Grades, and Specifications

Molybdenum is a silver-white metallic

element with an atomic number of 42. atomic weight of 95.95, and a density of 10.2 grams per cubic centimeter. The chemistry of molybdenum is complex; molybdenum exhibits oxidation states from -2 to 6, coordination numbers from 4 to 8, and forms compounds with most inorganic and organic liquids. Molybdenum is a strong carbide-forming element, and much of its alloying effect in steel is imparted through the formation of carbides. It has a melting point of about 2,610° C; among the metallic elements. only osmium, rhenium, tantalum, and tungsten have higher melting points. Other significant physical properties of molybdenum metal are good thermal conductivity (about one-half that of copper), the lowest coefficient of thermal expansion of the pure metals, high strength at elevated temperatures, and resistance to corrosion in a wide variety of mediums. Molybdenum metal is stable in air or water at moderate temperatures, but above 500° C, it oxidizes readily.

Molybdenite is the principal mineral from which molybdenum is obtained. Crude ore containing molybdenite is beneficiated to produce molybdenite concentrate. The concentrate generally contains about 90% molybdenite; the grade may be somewhat lower, particularly if produced at copper byproduct concentrating plants. Technical-grade molybdic oxide is produced by the roasting of molybdenite concentrate. Typically, the oxide has a content of 85% to 90%, or a minimum of 57% contained molybdenum. Other raw materials, including ferromolybdenum, purified molybdic oxide, ammonium, and sodium molybdate, and molybdenum metal powder are produced from technical-grade oxide. The production of these materials is described in the section entitled "Products for Trade and Industry."

The American Society for Testing and Materials (ASTM) has developed standards for the chemical composition of molybdenum oxide products (Specification A 146-64, reapproved 1979) and ferromolybdenum (Specification A 132-74, reapproved 1979). These standards specify minimums for molybdenum content and maximums for impurity content

as an aid to producers and purchasers. Material marketed by the major domestic producers generally meet or exceed ASTM standards.

Products for Trade and Industry

Some commercial-grade molybdenite concentrate is treated in additional grinding and flotation steps to produce lubricant-grade molybdenum disulfide. Oil and water are volatilized by passing an upgraded concentrate through an inertgas-swept kiln. The oil-free product is about 99% molybdenum disulfide and suitable for use in lubricant applications.

Molybdenite concentrate is converted to technical-grade molybdic oxide, the major form of molybdenum used by industry and the base material for production of ferromolybdenum, chemicals, and molybdenum metal powder. The technical-grade oxide is produced by roasting molybdenite concentrate in the multiple-hearth furnace at temperatures of up to 650° C. Typically, the roasted product contains 90% molybdic oxide and a maximum of 0.1% sulfur. Technical-grade oxide is used to add molybdenum to steels, cast irons, and other alloys.

Ferromolybdenum is typically produced by reduction of technical-grade oxide and iron oxide with a conventional metallothermic process, using silicon and/or aluminum as the reductant. The molybdenum content ranges from 58% to 64%. Ferromolybdenum is used as a alternative additive in producing alloy steels, cast irons, and nonferrous alloys.

Ammonium molybdate is produced by reacting pure molybdic oxide with ammonium hydroxide and crystallizing out the pure molybdate. Sodium and calcium molybdate are made in a similar manner using sodium hydroxide and calcium chloride.

Molybdenum metal powder is manufactured by reducing pure molybdic oxide or ammonium molybdate with hydrogen. The purest metal powder (99.95% molybdenum minimum) is produced from ammonium molybdate. Metal powder is pressed and sintered into small metal ingots, which are converted into rod, wire, or sheet by hot rolling, swaging, or

forging. Large ingots are produced by arc-casting powder under a vacuum or inert gas atmosphere.

Industry Structure

Five countries, Canada, Chile, China, the former U.S.S.R., and the United States, mine 90% of world output of molybdenum ore. Plants to convert ore concentrates to technical-grade oxide and other molybdenum products are in Chile, China, the former U.S.S.R., the United States, and Western Europe.

Geology-Resources

Almost all molybdenum is recovered from low-grade deposits of the mineral molybdenite. Two types of deposits, primary and byproduct porphyry copper provided the U.S. and world output of molybdenite. Primary molybdenum deposits generally grade 0.2% to 0.5% molybdenite; copper ores from which byproduct molybdenum is recovered contain 0.02% to 0.08% molybdenite.

The average crustal abundance of molybdenum is 1 to 2 parts per million (ppm). The molybdenum content of igneous rocks tends to increase with increasing silica content. Molybdenum does not occur in nature in its free or native state, but is found only chemically combined with other elements. Small deposits of molybdenum-bearing minerals occur throughout the world, but the only molybdenum mineral of commercial importance is molybdenite. Wulfenite, powellite, and ferrimolybdite are common but have supplied very little molybdenum.

Molybdenite (MoS₂) is a lead-gray metallic mineral that characteristically occurs in thin, tabular, commonly hexagonal plates and also disseminated as fine specks. It has a specific gravity of 4.6 to 4.7, a hardness of 1 to 1.5, a greasy feel, and it soils the fingers. Superficially, it resembles graphite, for which it commonly has been mistaken.

Molybdenum deposits are of five geological types: (1) porphyry or disseminated deposits, including stockworks and breccia pipes in which metallic sulfides are dispersed through relatively large volumes of altered and fractured rock, (2) contact-metamorphic zones and tactite bodies of silicated limestone adjacent to intrusive granitic rocks, (3) quartz veins, (4) pegmatites and aplite dikes, and (5) bedded deposits in sedimentary rocks.

The first three genetic-type deposits are hydrothermal in origin and as such represent nearly all the known molybdenum resources currently mined in the world. The remaining types do not represent a great volume of molybdenum but are of certain economic importance only when molybdenum is associated with other minerals.

In the hydrothermal deposits, metallic minerals are precipitated from high-temperature aqueous solutions either by changes in temperature and pressure or by evaporation of the liquid. Minerals are deposited in the cavities, cracks, or interstices of the matrix rock.

Most of the porphyry coppers contain small quantities of molybdenite disseminated with the copper minerals through large bodies of granitic rock. The chief minerals are chalcopyrite and chalcocite, with pyrite and small amounts of other sulfides, including molybdenite.

Available information on world reserves and reserve base of molybdenum varies widely in reliability. For certain countries such as Canada, Chile, and the United States, company annual reports or other published materials enable inventorying minable ore reserves. For most other countries, reserves must be estimated from fragmentary or preliminary data on ore tonnage and grade of known or anticipated sources. In particular, the reserve figures for China and the former U.S.S.R. should be considered order-of-magnitude estimates.

It should be noted that the reserve data refer to molybdenum contained in ore. The recovery of molybdenum after milling approximates 75% to 90% of the inplace ore content at primary molybdenum sources. Recoveries achieved at byproduct sources vary markedly from mine to mine, but average an estimated 55% of the molybdenum in ore processed. Overall, an estimated 65% of the total world molybdenum reserves can be considered as recoverable.

Most of the world reserves of molybdenum occur in the western mountain regions of North and South America, extending from Alaska and British Columbia through the United States and Central America to the Andes Mountains of Chile. These regions, roughly bordering the eastern margin of the Pacific Basin, are also regarded as most promising for future discoveries and additions to reserves.

Technology

Exploration.—Prospecting and exploration for molybdenum is basically the same as that for deposits of other metals. Areas generally considered favorable for molybdenite mineralization are those metallogenic provinces that encompass known occurrences of molybdenum stockworked deposits and copper-molybdenum porphyry deposits. An understanding of regional geology, mineral associations, and known patterns of molybdenite mineralization is essential to identify potential sites for field investigation. Sites for detailed study may be selected on the basis of geologic mapping of rock units and structures, geochemical analyses of sediments and soils, and ground geophysical surveys. An intensive drilling and sampling program is then required to estimate the size, grade, and continuity of the discovery. Exploration drifts may be driven into the ore body to provide more specific geologic information and bulk samples for metallurgical testing.

The evaluation of a deposit may require 2 to 5 years from the time of discovery. During this time, the technical, economic, and environmental aspects of mine development must be evaluated. An additional 3 to 8 years may be required to prepare the deposit for production. Long development times are indicative of the complex planning and considerable capital needed to develop the large, low-grade stockwork and porphyry deposits that are expected to remain the significant sources of molybdenum. As a general rule, development of underground molybdenum deposits would require more time and capital than that of surface deposits.

MOLYBDENUM—1992 849

Mining.—Molybdenum ore is mined by underground and open pit methods, the choice of method determined by the size, configuration, grade, and depth of the ore body. Underground and surface operations accounted for about 40% and 60%, respectively, of the domestic molybdenum output.

Underground deposits of molybdenum ore are mined by block or panel caving methods modified to suit the characteristics of the particular ore body being worked. In these methods, large masses of ore are undercut and blasted at the base to induce the collapse and fragmentation of the ore under its own weight. The broken ore may be drawn off from the caved mass by gravity through finger raises into slusher drifts. The ore is then scraped to draw holes where it falls into ore cars on a haulage level beneath the slusher drifts. Alternatively, the broken ore may be funneled by gravity to crosscut drifts at intervals between production drifts. Ore is moved from the ends of the crosscuts along the production drifts to ore passes where it is dumped and collected in loading pockets on a deeper main haulage level. Ore is then transported from the main haulage level to the site of the initial milling operations. Caving methods are used to mine underground deposits of molybdenum because the low grade of the ore necessitates extraction of large tonnages of rock at a minimum of cost. However, caving of the ore must be carefully controlled to avoid ore dilution and excessive ground stresses to mine openings.

In open pit mining operations, the ore is exposed by removal of waste rock. The cut in the ore takes the form of benches, which vary in height and width from mine to mine. The cycle of open pit extraction consists of drilling, blasting, loading, and haulage. Primary drilling consists of driving a vertical blasting hole into the ore. Secondary drilling and blasting may be required to break large boulders. Ore is loaded by mechanical shovels into rail cars or trucks and hauled by large trucks for short distances or by train for long distances. Skipways and belt conveyors are used at some mines for transporting ore to the mill site.

Beneficiation.—Because of their low molybdenum content, all molybdenumbearing ores require beneficiation. After crushing and grinding to a suitable size. both primary molybdenite and copper sulfide ore containing molybdenite are beneficiated by flotation. With primary ores, a final concentrate of 90% to 95% molybdenite is produced by subjecting the ore to several stages of grinding and reflotation. Copper, iron, and lead minerals are generally the critical impurities that must be minimized in the final concentrate product. Overall recovery of molybdenite at primary-ore concentrating plants ranges from 75% to 90% of the inplace ore content.

Production of molybdenite concentrate from copper ores is more difficult, however, because molybdenite constitutes less than 0.1% of the ore. As a byproduct value, molybdenite recovery is generally given less priority than recovery of copper values. In some cases, improved molybdenite recovery may be attained only at the expense of reduced copper recovery or lower grade of copper concentrate produced.

Recovery from copper ores begins with the bulk flotation of copper minerals and molybdenite as the first separation from gangue materials. Molybdenite in the bulk flotation product is then separated from the copper minerals in a selective flotation process, which usually involves the flotation of molybdenite and depression of copper minerals. The separatory flotation requires close control of pH, reagent mix, and several flotation steps. Processing of copper-molybdenum ore varies from plant to plant depending on the grade of mineralization and impurities in the ore. Concentrate produced as a byproduct contains 70% to 90% molybdenite, although most approaches the higher end of the range in content.

Recycling.—Some secondary molybdenum is recovered in the production of alloy steels, superalloys, and the metal, but data on quantities are incomplete and inconclusive. Most of this recycled material is generated and reused directly at metal-forming or fabricating plants (runaround scrap) or shipped to plants that reclaim it (prompt industrial scrap). A small amount of molybdenum-containing obsolete scrap is processed for its molybdenum content. Although some molybdenum is recycled as a minor constituent of scrap alloy steels, the use of such scrap does not generally depend on its molybdenum content. An increasing quantity of molybdenum is being reclaimed from spent catalysts and chemical residues.

Byproducts and Coproducts

Tin, tungsten, and a very minor quantity of pyrite are recovered as byproducts from molybdenum ore at the Climax deposit in Colorado. Rhenium is extracted from flue gases and dust produced during the roasting of molybdenite concentrate that has been produced as a byproduct of copper mining.

Molybdenum is recovered as a byproduct primarily from copper ores. A very small amount is also obtained from tungsten and uranium ores. At the Sierrita Mine in Arizona, copper and molybdenum are considered coproduct values.

Substitutes

Historically, molybdenum has been a relatively inexpensive alloying agent used primarily in specialty steels and alloys, and in the United States, it has been readily available. As a result, metallurgical applications for molybdenum were broadened, and its utility as an alloy ingredient became well recognized. The substitution for molybdenum by other alloy metals has had little impetus.

Several factors mitigate the possible replacement of molybdenum to the degree that its overall demand would be significantly affected. First, there is no acceptable substitute in numerous metallurgical and chemical uses. Second, it is commonly added to steels and alloys to enhance several desired properties (such as hardenability, strength, corrosion resistance, etc.), often in synergistic effect with other alloy metals. In such cases, molybdenum could be replaced for particular effects, but at a sacrifice in overall

MOLYBDENUM—1992

performance. Moreover, the molybdenum content of alloy and specialty steels ranges from less than 1 to a few percent. Therefore, costs of molybdenum raw materials have to increase substantially to appreciably affect the cost of the finished product, thereby stimulating substitution. Finally, the United States is self-sufficient in molybdenum, a situation unlike that of many other ferrous metals. Significant replacement would entail increases in the imports of substituted metals.

Nevertheless, possible alternatives exist in most applications of molybdenum. Steels and alloys containing less or no molybdenum might be used in place of those with higher molybdenum content. In most cases, such substitution would result in lowered or unacceptable performance. Boron, chromium, and manganese can replace molybdenum in steels where hardenability is the only desired effect. In certain low-alloy steels, columbium, manganese, and vanadium act in similar fashion to molvbdenum. Chromium, nickel, and tungsten are possible substitutes in steels and other alloys. Molybdenum has substantially replaced tungsten in high-speed tool steels; a return to tungsten grades is possible, but with a reduction in economy and performance. Nonmetallurgical materials, such as plastics and ceramics, can replace steels and alloys containing molybdenum in certain applications.

Tungsten and tantalum can be substituted for molybdenum in certain refractory metal uses, but as a cost disadvantage. Molybdenum can be replaced by graphite for refractory elements in electric furnaces in the range of 1.000° to 1.600° C. but at the expense of slightly greater difficulty in operation and control. Chrome orange, cadmium red, and organic orange pigments are possible substitutes for molvbdenum orange. Acceptable substitutes for molybdenum are not found in most of its major catalytic applications. Graphite and other solid lubricants generally do not perform as well as molybdenum disulfide, especially under high-pressure and high-temperature conditions.

Economic Factors

The prices of molybdenum products are quoted on a contained-molybdenum basis and reflect, at least partially, the cost of conversion. Technical-grade oxide, the major form of molybdenum sold commercially, varies slightly in price depending on purity, type of packaging, and whether it is briquetted.

Price quotations generally fall under two groups, the producer-marketer and The producer-marketer the merchant. mines and concentrates the ore, converts the concentrates into consumer products, and markets these products, while a merchant buys and sells concentrates and may convert concentrates into products that are marketed. The source for the merchant to buy concentrates is the byproduct producer. The byproduct producer prices the byproduct as one that provides extra credit. Therefore, this type of a producer is not likely to hold back concentrates from sale. The producer-marketer tries to keep the market balanced by setting a price-based cost plus profit and varying the output to maintain a balance.

Operating Factors

Environmental Requirements.—The mining of molybdenum ore and disposal of ore tailings disturb land areas. Land reclamation is part of the ongoing mining operation. Development of new mining and milling complexes present local socioeconomic and land use problems. Because new, potentially economic sources are likely to be found in relatively unpopulated regions with little other industry, development of a major mine can have significant impact on established occupational patterns. Interaction between mining firms and local, State, and Federal agencies are required to ensure that mine development proceeds in as orderly and environmentally sound a manner as possible. The conversion of molybdenite concentrate to technicalgrade molybdic oxide involves roasting. Roasting facilities have been modified with sulfuric acid recovery equipment to reduce emissions and thereby comply with stringent environmental restrictions.

Toxicity.—Compared to other industrial metals, molybdenum exhibits very low, negligible toxicity. No significant toxic effects in human beings have been identified in mining or processing of molybdenum materials. As an environmental trace element, molybdenum is an essential micronutrient. Deficiencies of molybdenum can affect the normal growth and development of plant and animal species.

Employment.—Employment in the past decade has reduced by a factor of five with about the same tonnage of production. This improvement in productivity was due to changes in mining and milling equipment and methodologies.

ANNUAL REVIEW

Domestic and foreign molybdenum markets for concentrates did not change in 1992. Domestic stock levels increased 26%. U.S. mine output of molybdenum was about 45% of world production. Reported end-use consumption of molybdenum in raw materials remained about the same as that of the previous year. Exports of all forms of molybdenum from the United States decreased, while imports of molybdenum increased. Domestic producer stocks of molybdenum products decreased about 21% from that of the previous year. Domestic mine production of molybdenum concentrate decreased to a total of 50,000 tons of contained molybdenum compared with 53,000 tons in 1991. World mine production of molybdenum concentrate also decreased from a total of 118,000 tons in 1991 to 112,000 tons in 1992. Canada, Chile, China, the former U.S.S.R., and the United States accounted for more than 93% of the molybdenum produced worldwide. (See tables 1, 2, and 3.)

Consumption and Uses

Consumption of molybdenum concentrate decreased 5,500 tons in 1992. Domestic mine production of molybdenum concentrate was either roasted,

exported for conversion, or purified to lubrication-grade molybdenum disulfide. The consumption in 1992 of technicalgrade molybdic oxide remained about the same as that of the previous year. Oxide is the chief form of molybdenum utilized by industry, particularly in steel, cast iron, and superalloys. However, some of the material is also converted to other molybdenum products, such as ferromolybdenum, high-purity oxide, ammonium and sodium molybdate, and metal powder. Apparent U.S. consumption (defined as U.S. primary plus secondary production plus imports minus exports plus adjustments for Government and industry stock changes) was about 21,000 tons of molybdenum. (See table 4.)

Stocks

Total industry stocks, which include those of producers and consumers, increased about 4,600 tons of contained molvbdenum. Inventories of molvbdenum in concentrate at producer locations increased about 6,600 tons. Producer stocks of molybdenum in consumer products, such as oxide, ferromolybdenum, molybdate, metal powders, and other types, decreased about 2,000 tons. Compared with apparent consumption, yearend producer stocks of these materials represented about a 12-month supply. Domestic consumer inventories of about 2,500 tons, the same amount as at yearend 1991, represented approximately a 2month supply as measured by average monthly reported consumption. (See table 5.)

Prices

The average 1992 "Metals Week Dealer" (MWD) price of concentrate (per kilogram of contained molybdenum) was \$4.851. The average MWD price of oxide was \$4.851 and the average MWD price of ferromolybdenum was \$6.937.

Foreign Trade

Exports of molybdenum in concentrate and of oxide remained about the same when compared with those of 1991.

Molybdenum concentrate exports were about 67% of domestic mine production. Approximately 95% of reported shipments of concentrate and oxides were made to Belgium, Chile, France, Germany, Japan, the Netherlands, Sweden, and the United Kingdom. The calculated molybdenum content of all exports was about 35,000 tons in 1992. Total value of exports increased from \$154 million in 1991 to \$165 million in 1992.

Approximately 3,000 tons of molybdenum in various forms was imported into the United States, about 400 tons more than in 1991. Total value of all forms of molybdenum imported increased from \$26 million in 1991 to \$27 million in 1992. In terms of both value and quantity, the major form imported was ferromolybdenum. (See tables 6, 7, 8, and 9.)

World Review

Capacity.—The rated capacity for mines and mills as of December 31. 1992, was 150,000 tons per year of contained metal. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Mine capacity for molybdenum is based on published reports, production statistics, and estimates.

Reserves.—The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification For Minerals," which is reprinted in the U.S. Bureau of Mines "Mineral Commodity Summaries, 1991."

Estimated world reserves and reserve base of molybdenum appear in table 10. The United States, with a reserve base of molybdenum estimated at 11.8 million tons, has 45% of the world molybdenum reserve base. About 90% of U.S. reserves occur in large porphyry or disseminated deposits mined, or anticipated to be mined, primarily for molybdenum. These deposits are in Alaska, Colorado, Idaho, Nevada, New Mexico, and Utah. Other molybdenum sources contribute insignificantly to U.S. reserves.

Canadian reserves of primary molybdenum are in British Columbia, including 30% of the total in the Endako primary deposit. Other Canadian reserves are associated with molybdenum and coppermolybdenum porphyry deposits in British Columbia and in relatively minor sources in Ouebec and New Brunswick.

Molybdenum reserves in Central and South America are mainly in large copper porphyry deposits. Of several such deposits in Chile, the Chuquicamata and El Teniente deposits are among the world's largest and account for 85% of total molybdenum reserves in Chile. Mexico and Peru have substantial reserves. The La Caridad deposit in Mexico is a large producer. Numerous other copper porphyries that may contain recoverable quantities of molybdenum have been identified in Central and South America. Many of these deposits are actively being explored and evaluated and could add substantially to reserves in the future.

Reserves of molybdenum in China and the former U.S.S.R. are estimated to be substantial, but definitive information about the current sources of supply or prospects for future development in the two countries is lacking. Copper ores are being investigated on the islands of New Guinea and Bougainville in the southwest Pacific, but it is not known whether these contain economically recoverable molybdenum.

OUTLOOK

Capital expenditures are expected to decrease from that of the previous year to a more normal level over the next few years. Alloy and stainless steel demand is forecast to decline in 1993. Short-term molybdenum demand is expected to remain a little below that of 1992. Molybdenum production must be adjusted to

reduce inventories that have been built up during 1992. The long-term demand depends on events and the ability to meet the needs of capital expenditures for environmental controls and to expand the manufacturing capacity.

Estimated. Revised.

²Data may not add to totals shown because of independent rounding.

¹Table includes data available through June 18, 1993.

²In addition to the countries listed, North Korea, Romania, Turkey, and Yugoslavia are believed to produce molybdenum but output is not reported quantitatively, and available general information is inadequate to make reliable estimates of output levels.

³Reported figure.

⁴Dissolved in Dec. 1991. This commodity is believed to be produced in Armenia, Georgia, Kazakhstan, Russia, Tajikistan, and Uzbekistan; however, information is inadequate to formulate reliable estimates of individual country production.

NICKEL

By Peter H. Kuck

Dr. Kuck has been a physical scientist with the U.S. Bureau of Mines since 1979 and was previously responsible for iron ore, silicon, and vanadium. Domestic survey data were prepared by Barbara J. McNair, Metals Data Section. International data tables were prepared by Ivette E. Torres, Chief, Jeremy Tidwell, and Ronald Hatch, Section of International Data.

Nickel is vital to the stainless steel industry and has played a key role since the beginning of the 20th century in the development of the chemical and aerospace industries. The element (symbolized by Ni) is critical in a highly industrialized and technological society because of its myriad of applications. Nickel's greatest value is as an alloying agent with other metallic elements, adding strength and corrosion resistance over a wide range of temperatures.

Domestic and Western World nickel demand dropped slightly in 1992, as a result of the global recession. Demand for nickel in the Western World was about 635,000 metric tons, down 35,000 tons from the record high of 1990.1 Nickel prices continued to weaken because of oversupply and the stagnating economic situation in Japan and the United States. At the end of 1992, recessionary forces also began to take hold in Western Europe. The assimilation of eastern Germany into the European Community (EC) began running into roadblocks at a time when the entire economic structure of Western Europe was being overhauled upgraded.

The splintering of Yugoslavia and economic turmoil in the rest of Eastern Europe complicated midterm planning for French, German, and Scandinavian stainless steel producers. With the dissolution of the former U.S.S.R. and the creation of a market economy in the Russian Federation, large tonnages of primary nickel that would have been used by the Soviet military-industrial complex were made available to markets in

Western Europe, Japan, and the United States. This influx of Russian material accelerated in early 1992, exerting downward pressure on nickel prices in the second half of 1992. On December 31, 1992, the London Metal Exchange (LME) cash price was only \$7,001 per ton (\$3.176 per pound).

Prices recovered briefly during the first quarter of 1993, only to drop back below the \$2.50 per pound mark at midyear. In June 1993, North American producers began idling less profitable operations because of the poor price situation. Outokumpu Oy of Finland and Western Mining Corp., however, were more sanguine about the future of the nickel industry and proceeded to bring two new mines in Western Australia onstream.

The United States produced 1.27 million metric tons (Mmt) of nickelbearing stainless steel in 1992, an increase of 6% from that of the previous year.² In Japan, though, production of nickel-bearing stainless steel dropped, falling 8%.³ Japan has been the largest stainless steel producer in the Western World for more than a decade and produced 1.85 Mmt of hot-rolled, nickelbearing stainless in 1992.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines (USBM) tries to identify and canvass every nickel consumer who uses 2 tons or more per year. Most of the larger companies report on a monthly basis. Reports were received from 77 of the 84 facilities on the 1992 monthly canvass. An additional

176 facilities were canvassed at the end of the year. Of the 176 facilities, 123 responded, or about 70% of the second canvass. Estimates for nonrespondents were made by comparing data reported in prior years with current consumption trends. Reported primary consumption, based on data from monthly and annual canvass forms and estimates, was 80% of apparent primary consumption. Apparent consumption is defined as primary nickel produced from domestic ores plus scrap recovery plus imports minus exports plus adjustments for Government and industry stock changes. (See table 1.)

BACKGROUND4

Definitions, Grades, and Specifications

Primary nickel is normally marketed as either nickel metal, nickel oxide sinter, or ferronickel. Commercial nickel metal is more than 99.5% pure and may be in the form of square plates, powder, briquets, pellets, ingots, disks, or shot. The square plates are referred to as "cathode" because they are cut from an electrolytic cathode sheet at the end of the refining process. The ferronickel produced in the United States contains 48% to 52% Ni and has traditionally been sold in 28-pound ingots; that produced in other countries may contain anywhere from 20% to 50% Ni. In 1992, Glenbrook Nickel Co., the sole U.S. producer, began marketing ferronickel shot for the first time—again with a 48% to 52% Ni content. Several customers prefer the shot over the ingot because the shot is more amenable to computerized,

bulk loading systems than the ingot. Nickel oxide sinter contains either 77% or 90% + Ni. Almost all of the 90% + grade imported into the United States comes from the Yabulu refinery of the Queensland Nickel Joint Venture (QNJV) in Australia.

Most nickel compounds are divalent, although the oxidation state can vary from -1 to +4. The chloride, the sulfate hexahydrate, and the nitrate hexahydrate are used in electroplating. The sulfate is also used as a colorant and as a starting material for some catalysts. The nitrate, oxide, hydroxide, and peroxide are preferred for fuel cell and battery manufacturing.

Industry Structure

At least 22 countries mined some type of nickel ore in 1992. In almost every case, the nickel came from either a laterite deposit or a sulfide deposit. Seven other countries had active smelters and/or refineries. Most producing companies tend to favor one of the two deposit types at the expense of the other because of significant differences in how the ores are processed. Inco Ltd. is an exception owing to the global nature of its operations. Because laterites are formed by surface water percolating downward through ultramafic rock, most laterite deposits are either in the tropics or in subtropical to temperate coastal regions that have a long geologic history of heavy rainfall. Sulfide deposits, on the other hand, can occur almost anywhere, ranging from central Africa to the high Arctic.

The nickel in laterite ores is usually processed into ferronickel because (1) the ores have a high iron content and (2) the ores are more easily smelted than concentrated. Sulfide ores are more concentration amenable to and hydrometallurgical refining. Over the 5year period from 1988 through 1992, laterite operations accounted for about 37% of world mine production, with the balance coming from sulfide operations. The Norilsk Nickel Combine of Russia is currently the largest producing company in the world, followed by Inco Ltd. of Canada. For 1988 through 1992, the six largest producing countries and their share of world mine production were as follows: the former U.S.S.R. (27%), Canada (21%), New Caledonia (10%), Indonesia (7%), Australia (7%), and Cuba (4%).

The Sudbury district of Ontario continues to be one of the principal sources of nickel for the world. Falconbridge Ltd. and Inco operate most of the mines in the Sudbury Basin. Most of the nickel at Sudbury is tied up in iron sulfides, which are intergrown, in turn, with copper sulfides. Other important nickel mining regions are the Noril'sk district of central Siberia, the western half of the Kola Peninsula, and the Kambalda district of Western Australia. Like Sudbury, all three have numerous deposits of sulfide ores averaging more than 2% Ni and 1% copper (Cu).

Cuba and New Caledonia have the largest reserves of laterite. Laterites are also currently mined in Australia, Brazil, Colombia, the Dominican Republic, Greece, Macedonia, Indonesia, the Philippines, Russia, and the Ukraine. The only U.S. producer is Glenbrook Nickel, which operates a laterite mine and ferronickel smelter at Riddle, OR. Some nickel is also produced in the United States as a byproduct of copper refining and recycling. The Glogovac mining and smelting complex in Serbia reportedly closed in late 1992.

Geology-Resources

Nickel is the Earth's fifth most abundant element, but occurs in the Earth's crust only in the range of 0.008% to 0.02% by weight. The bulk of the nickel is believed to be concentrated in the Earth's core. Geologic studies indicate that most nickel deposits have been derived from ultramafic rocks, such as peridotite or serpentinite. These are igneous rocks that are low in quartz and feldspar, but high in ferromagnesian silicates. The nickel content of ultramafic rocks, although relatively high compared with that of other rocks, seldom exceeds 0.3% by weight. These values are too low to make them economically minable as nickel ore. Because nickel tends to follow iron and can be readily incorporated into either silicates or sulfides, the element is less likely to be concentrated in an economically viable deposit than some less abundant elements, such as copper and lead. To be rich enough to mine, some natural process must have concentrated the nickel. These processes result in the two very different types of nickel deposits mentioned earlier.

Nickel laterites are formed by the weathering of ultramafic rocks. As the rocks weather. nickel. iron. sometimes cobalt are taken into solution by descending meteoric water and redeposited at greater depth, producing a zone of enrichment. The water is initially acidic because of the presence of organic acids and dissolved carbon dioxide. As the metal-bearing water descends, it reacts with the bed rock and becomes more basic. The cobalt and iron tend to precipitate out first, forming a limonite zone that averages 0.8% to 1.5% Ni and is rich in nickeliferous goethite [(Fe,Ni)OOH]. Further down, a point is reached where the bulk of the nickel precipitates out, together with the accompanying magnesium and silica. This second zone of enrichment typically contains 1.8% to 3.5% Ni. Here, the principal ore mineral is garnierite, a hydrous nickel-magnesium silicate.

Nickel sulfide deposits, on the other hand, are formed by some type of igneous or metamorphic activity, such as the intrusion of molten ultramafic rock or the alteration of the host rock by hydrothermal solutions. The principal ore minerals are pentlandite [(Fe,Ni)₉S₈] and nickeliferous pyrrhotite (Fe_{1-x}S). Millerite (NiS) is regarded as a secondary, supergene mineral at Sudbury, but also can occur as a primary mineral in some lower temperature types of (Ni_3S_2) , deposits. Heazlewoodite niccolite/nickeline (NiAs), and the various linnaeite end members [(Fe,Co,Ni)₃S₄] are normally present in only minor amounts. At Sudbury, pentlandite and pyrrhotite are frequently associated with chalcopyrite (CuFeS₂) and, to a lesser degree, cubanite (CuFe₂S₃). As a result, copper is an important byproduct for both Falconbridge and Inco. Cobalt and platinum-group metals are also being recovered from the sulfide concentrate.

Nickel sulfide deposits are found in both volcanic and plutonic settings. The sulfides can occur as massive ore, disseminated blebs, breccia fillings, or vein fillings. Economic geologists have developed a variety of depositional models to explain these different features. One of the more popular plutonic concepts involves magmatic segregation and crystal settling, in which a molten magma slowly intrudes upward through the country rock. As the magma cools, the nickel and other metals combine with sulfur to form dense immiscible droplets that settle to the bottom of the magma chamber. This model can be used to explain some of the geologic phenomena observed at Sudbury and at the Bushveld Igneous Complex in the Republic of South Africa. However, the segregation model exhibits several inconsistencies and is far from perfect. Sudbury's origin remains controversial, with one group of geologists postulating that ore genesis was initiated by the impact of an asteroid or large meteorite.

Recycling

The International Metals Reclamation Co., Inc. (INMETCO), a subsidiary of Inco United States Inc., has been operating a recycling plant for chromium and nickel at Ellwood City, PA, since 1978. Baghouse dust, mill scale, grinding swarf, and other particulate waste from stainless steel plants are blended, pelletized, mixed with a reductant, reduced in a rotary hearth furnace, and then smelted in an electric furnace. The nickel and chromium are recovered as a remelt alloy and sold back to the stainless producers.

The Pennsylvania plant was modified several years ago so that a wider variety of waste materials could be treated. INMETCO now accepts spent pickling solutions, pickling and wastewater treatment filter cakes, and chromiumbearing refractories. Spent nickel-cadmium (Ni-Cd) batteries are also

processed on-site. The cadmium is recovered as a dust and sent across the State to a zinc recycling plant for further treatment.

A completely different type of plant is operated by the U.S. Filter Recovery Services, Inc. at Roseville, MN. The Minnesota plant uses a variety of hydrometallurgical and electrowinning processes to recover nickel, cadmium, and copper from scrap and ion exchange resins.

Substitutes

With few exceptions, substitutes for nickel would result in increased cost or some sacrifice in the performance of the product. For example, manufacturers can cut costs by substituting aluminum, coated steels, or even plastics for austenitic stainless steel in certain situations. However, substitution may not be desirable because of significant downstream tradeoffs. Most plastics are more susceptible to fatigue than stainless and can crack over long periods of time, raising the end user's maintenance costs and encouraging the end user to turn to another manufacturer. Other present and potential nickel substitutes include nickelfree specialty steels for the power generating, petrochemical, and petroleum industries; titanium and plastics for highly corrosive environments; and cobalt, copper, and platinum for catalysts.

Economic Factors

Prices.—Nickel prices traditionally have been quite volatile. The time-price relationship for the metal over a 150-year span is given in the metal prices handbook recently published by the USBM.⁵ In the early 1980's, excess production capacity caused nickel prices to drop. In terms of constant dollars, nickel prices in the mid-l980's were at their lowest levels since the end of World War II. Between 1984 and 1986, producers were forced to close at least six production facilities; some others were on the verge of failure and lost large amounts of money.

World consumption, driven by

stainless steel demand, rebounded dramatically in late 1987, reaching record levels that year and in each of the next 3 years. Prices soared along with demand. In mid-1992, the cycle began to repeat itself when demand for stainless weakened in Japan and parts of Europe. Nickel prices turned downward after large amounts of Russian cathode appeared in Western warehouses. (See table 1.)

Costs.—There are several significant factors that determine the cost of producing nickel. They include the type and nickel content of the ore, the mining method, transportation, infrastructure, energy prices, labor and materials, regulatory compliance, and credits from recoverable byproducts.

Generally, nickel can be recovered from sulfide ores at a lower cost than from laterite ores because sulfides are more readily concentrated using established mineral dressing methods. On the other hand, virtually all of the laterite deposits are open pit operations and, therefore, less costly to mine. Most sulfide deposits occur at depth and have to be mined from underground. Shaft sinking, timbering, roof bolting, lighting, ventilation, and pumping all drive up costs. The absence of massive, primary sulfide deposits at the surface is understandable. Many sulfide minerals readily oxidize to sulfates when exposed to air for an extended period of time. Sulfuric acid forms when copious amounts of water are present, accelerating the oxidation process.

Energy consumption is the most significant cost in recovering nickel from laterite ores. Estimates indicate that for every \$1 increase in the price of a barrel of crude oil, there is a corresponding increase of \$0.05 per pound of nickel produced at operations that are dependent on oil for both drying and smelting. It does not seem to matter much whether the laterite ore is converted to ferronickel or to matte. Sulfide ores, on the other hand, do not have to be dried, and, unlike laterite ores, are more amenable to concentration.

Byproduct revenues can significantly

reduce net production costs. Smelters that convert laterite ores to ferronickel produce only slag, iron, and occasionally electrical power as byproducts. Smelters that process laterite ores using a chemical leaching method sometimes recover cobalt as a byproduct. In contrast, sulfide operations generate revenues from the recovery of byproduct cobalt, copper, and precious metals. The Sudbury nickel deposits are an important source of both platinum and palladium. The principal platinum mineral is sperrylite, PtAs₂, while much of the palladium is tied up in bismuthides and bismuth tellurides. Some sulfide facilities also profit from the sale of byproduct liquid sulfur dioxide and sulfuric acid.

The costs of complying with air pollution control regulations can be significant. Dust generated in the processing of laterite ores can be controlled using relatively inexpensive equipment. In contrast, a large capital investment is required to reduce sulfur dioxide emissions from a smelter processing nickel-copper sulfide concentrates. During the past 10 years, Inco has allocated 12% of its total capital expenditures to attain compliance with Canadian regulations limiting sulfur dioxide emissions.

In 1991, the USBM published an information circular entitled "Availability of Primary Nickel in Market-Economy Countries."6 This report evaluated the availability of nickel from 36 deposits or districts in 16 market-economy countries, analyzing more than 95% of production capacity in those countries. The study determined the quantity of nickel available on the basis of net production costs and total costs with both a 0% and a 10% discounted cash-flow rate of return. Costs of production were expressed in dollars per pound of recovered nickel. The study also indicated sensitivities of the cost of production to energy, labor, and similar factors. The deposits and properties in the study contained approximately 33 Mmt of recoverable nickel. Sensitivity studies performed for both laterite and sulfide deposits indicated that the total cost of producing nickel from laterites was most sensitive to increases in energy costs and that the total cost of producing nickel from sulfide deposits was most sensitive to increases in labor costs; sulfides were also affected by changes in revenues from byproducts.

Operating Factors

Environmental Issues.—The principal environmental problem associated with nickel production is the emission of sulfur dioxide (SO₂) from smelters that process sulfide ores. The SO₂ emitted from smelter smokestacks combines with water in the atmosphere to form droplets of sulfuric acid (H₂SO₄), a major component of acid rain. The Provincial government of Ontario has ordered Inco to reduce SO₂ emissions at its Sudbury complex by two-thirds and has imposed a ceiling of 265,000 metric tons per year (mt/yr), starting in 1994. The company is spending \$530 million on state-of-the-art pollution control equipment to meet the new limit. The only alternative would have been to reduce production by twothirds from 1989 levels.

Nickel smelters have a much higher sulfur burden than their copper and zinc counterparts. As a rule of thumb, 1 ton of sulfur is generated for each ton of copper produced. In contrast, 8 tons of sulfur is generated for each ton of nickel.

Recent environmental legislation and other responses to environmental concerns are expected to significantly affect future nickel consumption. In some cases, the effect will be positive; in others, negative.

In November 1990, the Congress amended the Clean Air Act (CAA), updating Federal air pollution standards for the first time since 1977 and completely overhauling the hazardous air pollutants program. The amendments (Public Law 101-549), among other things, put controls on airborne emissions of nickel metal, its compounds, and alloys. Nickel compounds were specifically included in the new list of 189 hazardous air pollutants to be regulated.

The law also directed the U.S. Environmental Protection Agency (EPA)

to develop an initial list of pollution source categories that warranted regulation. It took EPA more than 1 year to develop the list because of the magnitude and complexity of the problem. EPA received more than 140 comments from public and private interests between June 1991 and July 16, 1992, when the list was finally published in the Federal Register.⁷ A number of nickel consumers appeared on the July list, including integrated steel mills, electric arc furnace operations, iron and steel foundries, and ferroalloy production facilities. Primary producers of aluminum, copper, and lead were also listed, together with their secondary counterparts. Additional categories were to be added at a later date. A draft schedule for promulgating emission standards for each of the initial 174 source categories was published in the Federal Register on September 24, 1992, as part of the 10-year phase-in of CAA regulations.

Because many facilities will need new pollution control equipment to comply with these standards, the enactment of the Clean Air Act Amendments is expected to increase demand for stainless steel and other alloys of nickel. Under the new law, 111 fossil fuel-fired powerplants must reduce their SO₂ emissions by 1995. This particular section of the law was enacted to help control acid rain. The 111 plants—a total of 251 generating units—were specifically targeted because each emits more than 2.5 pound of SO₂ per million British thermal units. Not all of the plants exceeding the 2.5-pound level, though, will necessarily have to reduce their emissions. It appears that the EPA will require compliance on a systemwide basis. Some utilities may be able to meet the overall compliance requirements by drastically reducing emission levels at a few of their heavier polluting facilities. Some plants can reduce SO₂ emissions by simply switching to fuels that contain lower levels of sulfur; others will be forced to install scrubbers (flue gas desulfurization units).

In any event, electric utilities will need increasing amounts of stainless steel over the next 20 years. Because so few

powerplants were built during the 1980's, construction programs soon may have to be accelerated if the projected demand for electricity is to be met. A significant amount of stainless will not only go into pollution control equipment, but also into turbines.

Under the CAA, few, if any, new plants will be permitted to emit more than 1.2 pounds per million British thermal units. Because it is far cheaper and easier to include scrubbers in the design of a new plant than to retrofit an existing facility, many, if not most, of the new plants will be equipped with some type of scrubbing system. About 100 tons of corrosion-resistant alloy will be required for each scrubber. Although it is not clear which alloy will be used, many of the most promising candidates contain significant amounts of nickel. Nickel is ideal in this situation because of the element's ability to improve the resistance of different metals to both corrosion and heat.

In July 1990, the EPA published proposed drinking water standards for nickel and other materials. The maximum contaminant level goal for nickel was set at 0.1 milligram per liter.

Data compiled by the EPA indicate that, of the 17 substances covered by the Agency's Industrial Toxics Project, nickel and its compounds showed the highest increase of reported releases from 1988 to 1989. This increase has heightened concerns in several areas.

The American Conference Governmental Industrial Hygienists (ACGIH) postponed action on a proposal to set more stringent recommended workplace limits for nickel and its compounds. The ACGIH had proposed reducing the workplace limits, or threshold limit values (TLV's), for nickel metal and all nickel compounds to 0.05 milligrams per cubic meter (mg/m³) and to designate nickel metal and all inorganic nickel compounds as confirmed human carcinogens. Action on the more stringent values was postponed until 1993 so that existing scientific evidence could be weighed more carefully and additional evidence, expected to become available in the interim, could be evaluated. ACGIH guidelines are important because the U.S. Occupational Safety and Health Administration (OSHA) and regulatory agencies in other countries weigh them carefully in determining mandatory permissible exposure limits for the workplace.

The Nickel Producers Environmental Research Association (NiPERA), among others, had urged the ACGIH not to reduce the current TLV's for nickel metal and all nickel compounds. The 8-hour TLV is currently set at 1.0 mg/m³ for insoluble forms of nickel (e.g., NiO) and 0.1 mg/m³ for soluble forms of nickel (e.g., NiSO₄). In comments to the ACGIH TLV committee, NiPERA argued that new epidemiological information suggests that there would not be a measurable increase in cancer incidence or mortality at the current threshold NiPERA felt that it was not values. necessary to reduce the current TLV to protect against adverse nonmalignant respiratory effects and recommended that ACGIH wait until the results of ongoing studies being sponsored by the U.S. National Toxicology Program and by NiPERA were released.

In 1990, the International Committee on Nickel Carcinogenesis in Man published a study intended to clarify the nature and extent of the risks that nickel and its compounds pose to humans.8 Called the Doll Committee, after its chairman, Sir Richard Doll of Oxford University, the committee's conclusions were based on an analysis of various epidemiological studies of individuals exposed to nickel in the workplace. The main conclusion was that workers exposed to very high concentrations of oxidic and/or sulfidic nickel did indeed have an increased risk of getting lung or nasal sinus cancer. The threshold concentration in air seemed to be about 1 mg/m³ in the case of soluble nickel compounds and more than 10 mg/m³ for less soluble ones. Exposure levels of this magnitude are no longer tolerated at North American smelters and refineries. There was no evidence to suggest that occupational exposure to metallic nickel increased the risk for any type of cancer. However, the metal can cause an allergic reaction in some individuals. The risk to the general population from exposure to extremely small concentrations of airborne nickel compounds (less than 1 microgram Ni/m³) was minute and, possibly, nonexistent. The study was sponsored by, among others, the EPA, NiPERA, and Energy, Mines, and Resources—Canada.

In 1991, the United Nations published indepth environmental health criteria for nickel, together with a companion health and safety guide on nickel metal, nickel carbonyl, and selected nickel compounds. The 383-page report was prepared as part of the International Program on Chemical Safety (IPCS), a joint venture of the UN Environmental Program, the International Labor Organization, and the World Health Organization. The principal conclusions are summarized below:

"Although some, and perhaps all, forms of nickel may carcinogenic, there is little or no detectable risk in most sectors of the nickel industry at current exposure levels; this includes some processes that were associated, in the past, with very high lung and nasal cancer risks. Long-term exposure to soluble nickel at concentrations of the order of 1 mg/m³ may cause a marked increase in the relative risk of lung cancer, but the relative risk among workers exposed to average metallic nickel levels of about 0.5 mg/m³ is approximately 1. cancer risk at a given exposure level may be slightly higher for soluble nickel compounds than for metallic nickel and, possibly, than for other forms as well. absence of any marked lung cancer risk among nickel platers is not surprising, as the average exposures to soluble nickel are very much lower than those in electrolytic refining or nickel salt processing."

Energy Requirements.—As mentioned earlier, energy costs are much more critical for laterite operations than for

NICKEL—1992 867

sulfide operations. Laterite ores are typically smelted in direct-arc furnaces having power ratings on the order of 20 to 40 megawatts (MW). Glenbrook Nickel, for example, has four 24-MW furnaces. Power is provided by the Bonneville Power Administration, a hydroelectric-based utility.

Glenbrook smelts the laterite by the Ugine Process. The process is not only power intensive, but also requires the addition of ferrosilicon—a source of chemical energy. This chemical energy is transferred to the molten ferronickel when the ferrosilicon is converted to slag.

The ferrosilicon can be produced onsite in a similar submerged arc furnace by reacting lumps of quartzite with shredded steel scrap and a carbon-rich reductant, such as coke. Electrical power consumption is the principal cost in producing ferrosilicon. Ferrosilicon and silicon metal are the most power intensive of the bulk ferroalloys, requiring 8,500 to 14,000 kilowatt hours of electrical energy per ton of contained silicon.

ANNUAL REVIEW

Legislation and Government Programs

On March 24, 1993, the Defense Logistics Agency (DLA) began selling nickel metal from the National Defense Stockpile (NDS). At least 29,212 tons of the 33,760 tons of nickel in inventory is in the process of being sold at auction twice per month. The auctions are to run for the next 5 years.

The Federal Government no longer has a stockpile goal for nickel. Until the end of 1992, the goal had been 181,437 tons. This goal was deemed unnecessary when the entire NDS program was reevaluated during the drafting of the fiscal year 1993 Annual Materials Plan. Nickel was only one of several strategic metals, including copper, lead, and zinc, whose goals disappeared. Goals were kept, but drastically reduced, for aluminum metal, titanium sponge, and cobalt.

Legislation supporting the disposal was passed by Congress on October 5, 1992, and signed into law by the President on October 23. (Title XXXIII of Public Law

102-484: The Defense Authorization Act of 1992). The revised fiscal year 1993 plan, which took effect on March 18, 1993, allows the Defense National Stockpile Center (DNSC) to sell a maximum of 9.072 tons (10.000 short tons) of nickel in the fiscal year ending September 30, 1993. Several nickel producers were concerned that the longterm selloff would unduly disrupt an weakened North American already market. A twice monthly auction schedule was adopted to ease their concerns, with only about 270 tons (300 short tons) being offered at each auction.

The new law established an advisory committee to oversee stockpile operations and a market impact committee to minimize market disruptions. The advisory committee is currently composed of officials from seven different Federal agencies as well as representatives from a mix of industries. The legislation requires the impact committee to consult with industry on a regular basis.

The bulk of the nickel in the NDS was purchased during the Korean War or the 5-year period immediately following the war. The first material offered for sale consisted of 21,013 tons of cathode of Canadian and Norwegian origin and 520 tons of oxide of Cuban origin. The cathode sheets ranged in size from 12 by 25 inches to 25 by 36 inches.

DLA found immediate buyers for the cathode, but was disappointed by the bids received for the fine-grained oxide powder. The Agency rejected all of the bids on the oxide and, in April 1993, temporarily withdrew the Cuban material from future bidding until an indepth market assessment could be conducted. The Cuban oxide was acquired between 1950 and 1959 and is currently stored at Scotia, NY, in drums holding about 180 kilograms each. The oxide averages about 76% Ni with less than 0.74% cobalt and 0.21% iron. The cathode dates from the same period and is stored at four different locations in the Mid-Atlantic and Ohio Valley region. All of the nickel is being sold on an as-is basis.

Strategic Considerations

Nickel is an essential ingredient in austenitic stainless steel and superalloys. As such, its availability is important to the national security. Domestic mine capacity was less than 14% of primary apparent consumption in 1992. Canada, however, a close ally and a geographically secure source, is capable of supplying U.S. needs under normal circumstances.

Issues

The U.S. Department of the Treasury continued to ban the importation of nickel and nickel-containing materials from Cuba. The ban has been in effect since 1962. In the past, more than two-thirds of the mixed nickel-cobalt oxide sinter from the Nicaro and Punta Gorda plants was exported to Europe. The mixed nickel-cobalt sulfide precipitate from the Pedro Sotto Alta smelter at Moa was shipped directly to refineries in the Ural Mountains of the former U.S.S.R. Since 1991, however, a significant amount of Cuban material has been going to Canada.

In June 1993, the Government of Cuba indicated that it might consider compensating the former owners of the nickel mines and plants that were nationalized in October 1960. The Cuban proposal, if followed up, would remove a major stumbling block to improving United States-Cuban relations.

The EPA was in the early stages of developing regulatory standards for shipping and processing recyclable materials that contain nickel and other transition elements. The Agency was still soliciting comments on the approach it will take to determine whether a solid waste is hazardous. The toxic constituents under review are listed in Appendix VIII of Subpart D of Title 40, Code of Federal Regulations, Part 261-Identification and Listing of Hazardous Waste. Nickel metal and its compounds both appear on the list, with nickel carbonyl and nickel cyanide being singled out for special scrutiny. EPA's approach is to classify appendix VIII constituentbearing waste as hazardous only after analysis leads the Agency to conclude that the waste is capable of posing a substantial environmental or human health hazard when mismanaged. Some environmentalists disagree and have pressed EPA to presume that a waste containing a measurable amount of any appendix VIII constituent is hazardous, unless the Agency determines otherwise. This second approach could discourage recycling and elevate disposal costs for some relatively benign wastes that contain small quantities of nickel.

Production

Glenbrook Nickel Co., the only domestic nickel producer, continued to mine and smelt local laterite ore at its Riddle, OR, complex. The company is a 50-50 venture of Cominco American Inc. and Cominco Resources International Ltd. The laterite deposit on Nickel Mountain has been mined intermittently since 1954, when Glenbrook's predecessor, the Hanna Nickel Smelting Co., first developed the property.

Ore from the reopened section on Nickel Mountain was averaging 1.18% Ni and was expected to last at least 2 years. The Riddle smelter was also using spent hydrogenation catalysts containing 5% to 10% Ni as supplemental feedstock. In June 1992, the smelter produced a record high 762 tons of nickel contained in ferronickel from these materials. However, management had already realized that higher grade ores from overseas would have to be used if unit operating costs were to be reduced and smelter output raised further.

In mid-1991, management gave final approval to plans that would raise the capacity of the smelter from 11,000 mt/yr of contained Ni in FeNi to 16,300 mt/yr. The additional feed requirements were to be met by importing garnierite ore averaging 2.2% to 2.4% Ni from New Caledonia. Feasibility studies had shown that it was cheaper to buy and ship ore from New Caledonia than to expand the mine. Société Minière du Sud Pacifique agreed to supply ore twice as rich as the material being mined on Nickel Mountain. The Sud Pacifique ore would be unloaded at Coos Bay, dried, and then

trucked to Riddle.

During the first half of 1992, Glenbrook spent \$33 million rehabilitating the dock facilities at Coos Bay and constructing an ore crushing, screening, and drying plant at dockside. On July 31, 1992, the first commercial shipment of Sud Pacifique ore arrived at Coos Bay. In September, Glenbrook signed a contract with Sud Pacifique to deliver additional ore. One month later, though, the LME price began to fall, and Glenbrook had to ask its New Caledonian supplier to slow mine production and delay loadings.

Rehabilitation of the docks and construction of the dryer and crushing plant was completed in the fourth quarter of 1992. A shot casting facility was also built at the smelter as part of the project. The casting facility allows Glenbrook to market 6-millimeter (1/4-inch) ferronickel shot in addition to the 28-pound ingots already being produced.

In 1992, Glenbrook mined 606,000 tons (dry basis) of ore containing 6,671 tons of Ni. The ore received from New Caledonia contained an additional 3,584 tons of Ni. From the two feedstocks, the company was able to produce 8,962 tons of Ni contained in ferronickel.¹⁰

The Knox Nickel Corp., a subsidiary of Black Hawk Mining Inc., has been seeking to develop a nickel-copper-cobalt deposit in southern Maine, about 20 kilometers (km) inland from the Atlantic coast. The 0.777-square-kilometer (192acre) site is on the southern side of Crawford Pond, between the towns of Warren and Union. The deposit, which was discovered in 1965, lies entirely within the town limits of Warren. Company officials estimate that the deposit contains 4 Mmt of sulfide ore grading 1.40% Ni, 0.64% Cu, and 0.12% Co at a Ni cutoff grade of 0.8%. The ore reserves are based on 165 diamond drill holes totaling about 18,000 meters (m).

On June 9, 1992, the residents of Warren approved a controversial set of local mining regulations by a vote of 651 to 534. The Warren ordinance closely follows a new metal mining law enacted by the State of Maine on August 26,

1991. The 1991 Maine mining law was already considered to be one of the most restrictive in the United States. The Warren ordinance incorporates 95% of the State regulations, but goes one step further. The local regulations require more restrictive setbacks for mine tailings than the State law and set stricter financial responsibility requirements for mining companies.

Knox officials said that they will continue with their plans to develop the deposit, despite the obstacles raised by the new ordinance. The company has already begun addressing issues that were raised by the Warren Planning Board, State officials, and the U.S. Army Corps of Engineers during public hearings that preceded the June vote.

Consumption and Usès

Western World nickel demand dropped slightly in 1992. Demand was estimated to be about 635,000 tons, down 35,000 tons from the record high set in 1990. Total U.S. apparent consumption, though, was about 8% higher than the figure for 1991 because of increased scrap purchases. Both U.S. and world demand continued to be driven by the stainless steel industry, which accounted for almost 50% of nickel demand in the United States and more than 60% of world demand.

Production of raw stainless and heatresisting steel in the United States inched up to 1.81 Mmt and was 6% higher than the corresponding figure for 1991.11 Nickel-bearing grades accounted for 70% of the production tonnage. Net shipments of all types of stainless totaled 1.373 Mmt. Shipments of sheets and strip jumped to 954,483 tons, breaking the record of 875,548 tons just set in 1991. The next largest category was plate [flat product 4.8 millimeter (3/16 inch) or more in thickness]. Shipments of plate were 158,033 tons, a slightly lower number than that of 1991. Together. plate and sheet accounted for 81% of total net shipments, compared with 79% in 1991.

Stainless steel sheet is used in the manufacture of a wide range of consumer

products, including household appliances, kitchen facilities, machinery, and medical equipment. In the past, automotive trim was an important end use for sheet, but aluminum and plastics have captured much of that market. Plate is primarily used in the fabrication of chemical reaction vessels and similar heavy-duty industrial equipment. The chemical, food and beverage, petrochemical, pharmaceutical, pulp and paper, and textile industries are all large consumers of stainless plate. The decrease in demand for plate was a direct result of cutbacks in spending on new and refurbished plants.

In 1992, U.S. consumption of primary nickel in superalloys decreased 27%. The decrease was due primarily to recessionary forces and weakening demand. Jet engine manufacturers, in particular, were hard pressed by (1) reduced defense spending and (2) lower sales of commercial aircraft by The Boeing Co. and McDonnell Douglas Corp. The two companies continued to work off a backlog of orders received between 1988 and 1990 for civil jet transport. However, new orders from U.S. and foreign customers dropped from 670 aircraft in 1990 to 231 in 1992.12 Orders for spare aircraft parts were also down significantly, further hurting upstream companies that produce castings for aircraft engines and airframes. (See tables 2 through 4 and figure 1.)

Stocks

The combined stocks of primary nickel maintained in the United States by foreign producers and metal-trading companies with U.S. sales offices decreased 14% during the year. At yearend, these stocks represented 31 days of apparent primary consumption. (See table 1.)

Markets and Prices

Nickel prices weakened significantly during the second half of 1992. The average LME cash price for the year was \$7,001.227 per metric ton, which equates to \$3.176 per pound. In terms of current dollars, this represented a drop of 14% from the 1991 average of \$8,155.612 per

metric ton. The four principal reasons for the weakening were as follows: (1) slumping demand for stainless steel in several developed countries, (2) a large buildup of stocks of Russian nickel in LME warehouses, (3) the increased availability of stainless steel scrap, and (4) improved productivity at primary production facilities.

LME stocks climbed precipitously in 1992, rising from 6,987 tons in December 1991 to 67,914 tons on December 21, 1992. This increase continued into 1993, passing the 85,000-ton mark at midyear. The inventory increase is largely the result of the influx of Russian cathode.

Despite growing stocks, the LME cash price was relatively stable during the first half of 1992, when compared to that of 1988 and 1989. Increased purchases by the Chinese and a moderate rise in U.S. stainless steel production helped support the price. A U.S. investment fund reportedly made a major purchase of LME nickel in early 1992, but did not take delivery. This meant that a large portion of the LME stocks was unavailable for immediate sale.

The weekly LME cash price began the year at \$7,168 per metric ton (\$3.25 per pound), gradually strengthened, and peaked at \$8,044 (\$3.65 per pound) in late February. In mid-March, the price, however, began to weaken. Some observers attributed the decline to the large increase in stocks at the LME warehouse in Rotterdam.

By August 14, the LME cash price had dropped back down to \$7,259 (\$3.29 per pound). At that point, the price continued to decline but at a considerably slower rate, eventually reaching a low for the year of \$5,336 (\$2.42 per pound) during the week of November 20. Uncertainty about the availability of stainless scrap caused the price to recover slightly at the end of the year. The last weekly price (for the week ending December 25) was \$5,815 (\$2.64 per pound). The settlement price on December 30 was \$5,810 (\$2.63 per pound).

Most North American producers cut back output in response to weakening nickel prices. The Norilsk Nickel Combine, the largest producer in the Commonwealth of Independent States (C.I.S.), also reportedly decreased its output. Few other overseas producers, however, followed suit.

On October 5, 1992, Inco Ltd. announced that it was reducing nickel production and curtailing capital expenditures in response to softening prices.

One month later, Falconbridge Ltd. announced that it would shut down its Sudbury Div. in Ontario, beginning June 27, 1993, for 10 weeks. Normally, the Ontario operation is closed 2 weeks each summer for vacation and maintenance. In 1992, Falconbridge's Sudbury Div. was down for 5 weeks instead of 2 because of reduced demand. The company's Nikkelverk refinery in Norway was also scheduled to shut down for 7 weeks during the summer of 1993. As a result of the two actions, Falconbridge was expecting to produce only about 54,000 tons of refined nickel in 1993, 7,000 tons less than had been The company has delayed planned. commissioning its new Craig shaft at Sudbury, lowering the 1994 production schedule by an additional 6,000 tons of contained nickel.

Glenbrook, faced with rising power costs and lower ferronickel prices, decided to shut down for the entire first quarter of 1993. The company tried to resume production during the second quarter but was further hurt by a U.S. International Trade Commission antidumping ruling in March 1993 that made the importation of ferrosilicon more expensive.

Foreign Trade

The U.S. net import reliance as a percentage of apparent consumption was 61% in 1992. The figure remained high, despite increased ferronickel production in Oregon, because of continued strong demand for stainless steel within the United States. Imports accounted for about 95% of primary supply in 1992. Canada, as usual, supplied most of the imported material. A significant part of

the nickel imported from Norway, the second largest source, was also of Canadian origin. Falconbridge's smelters have been shipping matte to Kristiansand, Norway, for refining since 1928. The refined products—principally metal granules, cathode, and crowns—are then exported to the United States for sale.

The relatively high level of demand for primary nickel in the United States also has meant high demand for nickelbearing scrap. Scrap processing accounted for about 85% of total domestic nickel production. U.S. exports of stainless steel scrap remained strong in spite of weakening prices. stainless scrap contained an estimated 16.740 tons of Ni. down less than 4% from the 17,407 tons of 1991. These figures are based on the assumption that stainless scrap has been averaging 7.5% Ni since 1989, when the changeover to the Harmonized Tariff System took effect.13 (See tables 5 through 9 and figure 2.)

The USBM data base for nickel exports was expanded in 1991 to include both catalysts (Schedule B 3815.11.0000) and waste and scrap (No. 7503.00.0000). The expansion was made so that nickel export categories would correspond more closely to import categories. These changes and earlier classification modifications were made in conjunction with the Nation's ongoing conversion to the Harmonized System. The nomenclature of the Harmonized System was adopted by the United States on January 1, 1989, following the enactment of the Omnibus Trade and Competitiveness Act (Public Law 100-418) in August 1988.

In several instances, nickel trade data published since 1989 may not be directly comparable to data of earlier years as a result of the conversion. The nine Harmonized export categories unalloyed wrought nickel illustrate this Because of significant problem. differences between the nine categories and their counterparts in the old tariff schedule, no comparable wrought data are available for 1988. All of the other data in tables 6 through 9 were revised to ensure future continuity.

Starting with this publication, the annual report will also contain foreign trade data on nickel alloys (HTSUS Nos. 7505.12, 7505.22, 7506.20, 7507.12, etc.). The trade data base is being expanded as part of a major effort by the USBM to develop a broader materials perspective and provide more information on the entire life cycle of each commodity.

On June 17, the United States granted most-favored-nation (MFN) status to the Russian Federation. The award, part of a comprehensive trade agreement signed by the Presidents of the two countries, was expected to encourage the importation of wrought nickel products from Russian fabricators who were formerly defense-oriented. Bars, plates, and tubes of nickel and nickel alloys are now exempt from stiff non-MFN duties, which vary from 25% to 45% ad valorem. The MFN duties on wrought nickel only range from 3% to 5.5%.

The change in trading status will be much less dramatic in the case of unwrought products, most of which come from operations of the Norilsk Combine in Siberia and the Kola Peninsula. Unwrought nickel, metal powder, and flake from Russia had carried a non-MFN duty of \$0.066 per kilogram of gross weight. This \$0.066 figure equates to \$0.030 per pound and was slightly less than 1% of the average 1992 LME cash price. All unwrought Russian nickel can now enter the United States free of duty. Americhem, a subsidiary of International Metals and Chemicals Co. (IMC), has already begun marketing nickel powder in the United States for Norilsk. material is apparently similar to the 123 grade sold by Inco Ltd. and is 99.9% pure Ni.

As part of a 1990 agreement with the former U.S.S.R., C.I.S. producers were still required to certify that their exports of nickel and nickel-bearing products were exclusively of Central EurAsian origin (and, ipso facto, free of Cuban material). Certificates of origin were required for products from both the Norilsk Mining and Metallurgical Plant at Norilsk in the Krasnoyarsk region and the Nickel Industrial Amalgamation Plant at

Monchegorsk in the Murmansk region. According to the Bureau of the Census, the United States imported 3,385 tons of cathode and 947 tons of powder and/or flake directly from Russia in 1992. No material was reported from the Ukraine. Combined imports of cathode from Russia and Estonia in 1992 were almost triple the 1991 figure. All of the Estonian material was believed to be of Russian origin. (See Russia section of this report.)

World Review

On April 1, 1992, the International Nickel Study Group (INSG) held its second general session at The Hague, the Netherlands. The INSG has two primary functions. The first function is to provide transparency by gathering, collating, and publishing statistical data on the international nickel market. The second is to provide an intergovernmental forum for discussion of issues of concern to nickel-producing and nickel-consuming countries. To date, Australia, Canada, Cuba, Japan, the Russian Federation, and nine other nations have joined the INSG. The EC also participates as a single entity. Together, the member countries account for about four-fifths of world nickel mine production, two-thirds of world primary nickel trade, and threefifths of nickel consumption. The United States and another five countries have been sending observers to the meetings on an irregular basis.

Because of the global recession and continuing low prices for a number of metals, several natural resource conglomerates began rethinking long-term investment strategies. This rethinking, spurred by the entry of Russian and Kazakh producers into Western markets, has triggered a new round of company restructurings.

In September 1991, Outokumpu Metals & Resources Oy (OMR) and Mooney Chemicals Inc. (MCI) merged their chemical businesses. A newly incorporated holding company, OM Group Inc. (OMG), now controls Mooney Chemicals Inc. as well as two OMR production units—Kokkola

Chemicals Oy of Finland and Vasset S.A. of France. At the end of 1992, OMR increased its ownership in OMG from 47% to 96% by redeeming shares held by Finnish insurance and investment companies. The remaining 4% is held by the former president of MCI.¹⁴

The merger made OMG the largest producer of cobalt and nickel inorganic salts in the Western World. It is also a leading producer of cobalt carboxylates and extra-fine cobalt powder. OMG has three production facilities—Franklin, PA; Kokkola. Finland: and Ezanville. France—that manufacture a total of more than 250 specialty chemical products. In 1992, the company had net sales of \$201 million. The Kokkola facility is one of only a few chemical plants in the world equipped to recycle industrial residues from nickel-plating operations and nickelcadmium battery manufacturers.

Toward the end of 1992, Gencor Ltd., a South African group with important mining investments, moved to expand its foreign holdings. The South African conglomerate approached the Royal Dutch/Shell Group, seeking to buy selected metal and mineral operations owned or controlled by subsidiary, Billiton B.V. At least nine other commodities were involved besides nickel-alumina, aluminum, bauxite, copper, gold, lead, silver, tin, and zinc. Shell was receptive to Gencor's offer, triggering lengthy negotiations that continued well into 1993. Because many of Billiton's operations are joint ventures, the sale of individual mines and smelters would depend upon whether the other shareholders choose to exercise their preemptive purchase rights. (See Colombia and Republic of South Africa sections of this report.)

Capacity.—The rated capacity for mines, smelters, and refineries as of December 31, 1991, was published in the 1991 Annual Report. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operation rate, based on the physical equipment of the plant, and given acceptable operating procedures involving

labor, energy, materials, and maintenance. (See table 10 of 1991 Annual Report.)

Australia.—Australia could conceivably double its output by the end of the decade. Western Mining Corp. Holdings Ltd. (WMC), one of the four largest nickel producers in the Western World, continued to increase production capacity in the face of weakening nickel prices.

Expansion and upgrading of WMC's Kalgoorlie smelter was proceeding on schedule. Management gave final approval to the project after WMC and the Western Australian Government reached an agreement on sulfur dioxide emissions. When the expansion is completed, the smelter will be able to treat at least 65,000 mt/yr of Ni in concentrate, up from 54,000 mt/yr. In December 1992, contractors began constructing a new oxygen plant for Kalgoorlie. Kalgoorlie has a flash furnace that has operated almost continuously since its commissioning in The smelter can treat limited amounts of high-grade nickel sulfide ores in addition to conventional concentrate. The bulk of the smelter feed has been coming from (1) the Kambalda Mine Group about 25 kilometers southeast of the smelter, (2) the revitalized Leinster Mine Group northeast of Agnew, and (3) the almost depleted Windarra Nickel Project near Laverton.

WMC also operates a refinery at Kwinana, near Perth, that produces metal powder and briquets. The capacity of the Kwinana refinery was being upgraded from 34,900 metric tons of metal per year to 42,000 mt/yr. Because smelter capacity will still exceed refinery capacity by about 20,000 mt/yr of contained Ni, part of the matte from Kalgoorlie will continue to be sold on the open market. The company was also planning to increase capacity at the Leinster Mine from 15,000 mt/vr of Ni in concentrate to about 35,000 mt/yr. A new concentrate drier was commissioned at the Leinster mill in mid-September. Plans to expand the Kambalda Mine were on hold, pending resolution of issues aimed at improving work practices. The Western Australian Government was considering legislation that would amend the Western Australian Mines Regulation Act and modernize key labor laws.

In the spring of 1992, Sumitomo Metal Mining Co. Ltd. of Japan renewed its long-term purchase contract with WMC. The new 10-year contract, signed on April 8, runs retroactively from April 1, 1992, to March 31, 2002. Sumitomo has agreed to take 20,000 tons of nickel matte annually from Kalgoorlie, an increase of 33% from the previous contract level of 15,000 tons. The 20,000-ton figure accounts for approximately 30% of Kalgoorlie's output. (See Japan section of this report.)

In July 1992, WMC completed initial bulk sampling of the Bulong laterite deposit in Western Australia. The company sold the deposit to Resolute Resources Ltd. in 1987, but later decided to reexamine the property as part of a special agreement with Resolute Resources. Under the terms of the agreement, WMC is expected to spend A\$16 million on a feasibility study of Bulong that began in early 1991. In exchange, WMC will earn a 70% interest in the project.

The Bulong deposit is about 35 km east of Kalgoorlie. According to Resolute officials, the deposit has measured resources totaling 11.34 Mmt averaging 1.32% Ni and 0.1% Co. The deposit reportedly has an additional 16 to 18 Mmt of inferred resources at approximately the same grade.

About 25,000 tons of ore has been mined from a trial pit and stockpiled sequentially at the surface in 20- by 20-m piles for orderly bulk sampling and metallurgical testing. The joint venture is hoping to use a continuous-pressure leaching process similar to those employed in Canada and Cuba to extract the nickel and cobalt. Water for the process would be obtained by desalinizing hypersaline water from area aquifers. The proposed open pit operation would produce about 12,800 mt/yr of nickel in concentrate and 800 mt/yr of cobalt.

WMC also began moving on the stalled Mount Keith project. The Mount Keith deposit contains an estimated 270

Mmt of sulfide ore averaging 0.06% Ni. Although the ore is considered low grade in terms of its Ni content, it is also low in pyrrhotite. Less sulfide in the concentrate translates directly into lower emissions of SO₂ and, thus, lower smelting costs.¹⁵

Mount Keith is about 70 km northwest of Leinster and Agnew and, up until mid-1991, had been controlled by Australian Consolidated Minerals Ltd. (ACM). The original plan called for the Mount Keith concentrate to be shipped to Finland for processing into ferronickel. OMR was to have built a new facility to handle the Australian concentrate while the mine was being developed. However, ACM and OMR decided to defer development of Mount Keith after some of the ore was found to contain as much as 10% magnesia (MgO). Because of the high magnesia, the ferronickel facility would have to be redesigned.

At that point, WMC moved in and tried to acquire Mount Keith through a complex takeover of ACM. The huge Mount Keith deposit was important to both WMC and OMR because it had very large reserves of nickel at a time when refinery feed had been tight. In June 1992, the day before the expected takeover, OMR disrupted WMC's plans by purchasing one-half of ACM's stake in Mount Keith for \$60 million. WMC went ahead with the takeover despite the change in equity. After the takeover was finalized, WMC and OMR signed an agreement to develop the project on a 50-50 basis. OMR was to receive 14,000 mt/yr of Ni in concentrate from Mount Keith instead of the 18,000 mt/yr promised by ACM. OMR would make up the deficit from its European operations and from future production from the Forrestania project.

All of these plans had to be modified at the end of 1992 when the Finnish producer found itself caught up in a major restructuring of its parent company, Outokumpu. At this point, WMC decided to develop Mount Keith by itself and began negotiating to buy back the 50% interest held by OMR.

Because of all of the delays at Mount Keith, OMR had to accelerate the development of its Forrestania nickel deposit north of Lake King. Forrestania was Outokumpu's first major nickel investment in Australia. In 1989, OMR acquired the 55% interest in the project held by Metals Exploration Ltd. The other 45% was split between Arimco N.L. and Cyprus Gold Australia Corp. One year later, the Finnish nickel producer bought out the two remaining partners and took control of the entire project.

The Forrestania Mine was officially commissioned on January 14, 1993, but the A\$100 million mine has been in production since November 1992. The Forrestania complex is about 170 km south-southeast of Southern Cross. consists of an open pit at Digger Rocks and two underground operations still under development-Cosmic Boy and Flying Fox. The concentrator can handle 400,000 to 500,000 mt/vr of ore. At full capacity, the mine should be able to produce 7,000 to 8,000 mt/yr of Ni in concentrates. The concentrates are currently averaging 10% to 16% Ni, all of which go to the Harjavalta smelter. A loading facility has been constructed on the southern coast at Port Esperance. According to company Forrestania has 4.4 Mmt of ore reserves, enough to permit the mine to operate for at least 10 years. There are about 1.2 Mmt of reserves, averaging 1.76% Ni, at Digger Rocks and another 2.3 Mmt. averaging 2.82% Ni, at Cosmic Boy.

Dominion Mining Ltd. considering a joint venture with overseas companies to develop its Six Mile deposit near Yakabindie, again in Western Australia. The Six Mile deposit is about 25 km south of Mount Keith. Results to date have been extremely promising, but the project has been threatened by aboriginal claims that the mine should be blocked on environmental and cultural grounds. The Parliament of Western Australia was considering legislation that would override existing aboriginal heritage laws and allow the Yakabindie project to go forward. If the claims can be successfully thwarted, the deposit could be in production as early as 1994. According to a feasibility study released

in 1991, at a cutoff grade of 0.35% Ni, there is a measured and indicated recoverable resource of 96.4 Mmt of sulfide ore grading 0.504% Ni to a depth of 350 m. Additional resources have been found 2 km to the south at the Golden North prospect. The Yakabindie mine plan called for a 350-m-deep open pit mine producing about 6 Mmt per vear of ore for at least 12 years. The 6 Mmt of crude would result in the production of about 110,000 mt/yr of concentrate containing about 21,000 tons of Ni. The low-impurity, 18%-Ni concentrate could be sold to smelters and some refineries. or a roasted calcine could be produced, which could then be sold to stainless steel mills. The entire project was put on hold in late 1992 when nickel prices began to crumble.

The Oueensland Nickel Joint Venture imported 19,235 tons of Ni in lateritic ore from New Caledonia during 1992. An additional 8,413 tons of Ni in ore came from Gebe Island in Indonesia.16 The material was being converted to nickel oxide (90% + Ni) at the company's Yabulu hydrometallurgical refinery at Townsville. The ore was being unloaded at outmoded berths in the Port of Townsville and railed to Yabulu. About \$70 million was needed to upgrade the berths and handling equipment. Queensland Nickel had wanted to construct a new port facility at Halifax Bay, but the Great Barrier Reef Marine Park Authority blocked construction because of possible future damage to the reef.

In early 1992, Inco offered to purchase the 72% interest in Queensland Nickel previously held by Dallhold Nickel Management Pty. Ltd. and controlled at that time by a consortium of financial institutions. The consortium, led by the Hong Kong and Shanghai Banking Corp., had been running the joint venture since July 1991, when Dallhold was placed in receivership. The remaining 28% of the equity was held by the Nickel Resources North Queensland, a parastatal entity of the State of Oueensland. The two principal assets of the venture are the 25,000-mt/yr refinery at Yabulu and the Greenvale Mine on the eastern slope of the Great Dividing Range, 220 km west of Yabulu. However, the mine's reserves were almost depleted and had to be supplemented by imported ore. About 3.2 Mmt/yr of lateritic ore was being sent to Yabulu from Indonesia and New Caledonia for processing. Queensland Nickel was also considering importing ore from the Philippines.

Inco reportedly was interested in the Yabulu refinery because it would give the Canadian company a supply source closer to the expanding stainless steel industries of Japan, the Republic of Korea, and would Taiwan. The acquisition effectively double Inco's cobalt production at a time when cobalt prices were at near-record levels. It also would be more cost effective for Inco to upgrade the Queensland operation than to construct a new refinery elsewhere. Inco and Oueensland Nickel were unable to reach an agreement. Inco agreed in principle to acquire Dallhold's interest for between \$200 to \$235 million, depending on which assets were sold, but later tabled its offer. In mid-July 1992, Inco finally withdrew from the negotiations.

After Inco withdrew, the consortium of financial institutions controlling the joint venture decided to take the company public. In August 1992, the consortium members transferred their assets to a new public company, QNI Ltd., registered its prospectus with the Australian Securities Commission. The initial stock offering, valued at A\$275 million, was quickly oversubscribed by the Australian investment community. According to the prospectus, QNI will have an 80% interest in the Queensland Nickel Joint Venture. The remaining 20% will be held by a vehicle of the Queensland Government. The State government also will have a 12.2% stake in QNI, for a total equity in the venture of almost 30%. The prospectus also disclosed that the Australian refinery has long-term nickel sales contracts with Metallgesellschaft AG (FRG), Allegheny Ludlum Corp. (USA), and Sammi Steel Co. Ltd. (ROK). The cobalt sulfides are sent to Outokumpu in Finland for further refining.

Botswana.—Falling nickel prices put Bamangwato Concessions Ltd. (BCL) in a difficult financial position. The Botswanan nickel and copper producer needed \$10 to \$40 million to deepen its Selebi and Phikwe Mines, but was already burdened by more than \$300 million of debt. To Ore reserves on the existing levels were almost depleted. The deepening program would allow BCL to mine seams of higher grade ore and maintain existing production levels.

Restructuring negotiations were under way between the Government of Botswana, the individual partners, and at least one key creditor. The mining operation is a joint venture of Botswana RST Ltd. (BRST) (85%) and the Government (15%). At the end of 1992, Amax Inc. and the Anglo-American Corp. of South Africa Ltd. each held about a 30% share in BRST, but Amax was unwilling to invest more money in the venture. The desert town of Selebi-Phikwe, which grew around the mine, is currently the fourth largest settlement in Approximately 6,000 Botswana. industrial jobs are at risk.

BCL produced 18,918 tons of nickel contained in matte in 1992. As in past years, the matte was shipped to Falconbridge's operations in Norway for refining. A new contract was negotiated with Falconbridge during the year. BCL has agreed to provide the Nikkelverk refinery with an average of 15,000 tons of Ni in matte each year until 2006.

Canada.—On October 5, 1992, Inco began reducing nickel production and curtailing capital expenditures in response to softening nickel prices. The company was planning to reduce mine production by 18,000 tons of contained nickel over the coming 12 months. Because of the cutbacks, the company's combined Canadian and foreign operations were expected to produce only about 170,000 tons of nickel in 1993, down from the 182,000 tons recovered in 1992.

Inco's mining and processing operations in Ontario bore the brunt of the cutbacks. The Shebandowan Mine, which was to have reopened on October 12, will remain closed until market

conditions improve. The mine, west of Thunder Bay near the U.S. border, has been on standby along with its mill since May 15. The temporary shutdown of the Shebandowan Mine reduced the company's 1992 production by 4,500 tons of Ni. At the time of the shutdown, Shebandowan employed 360 contract workers and had been the highest-cost producer of the 13 operating mines in Inco's Ontario division. The entire Ontario division has about 7,200 employees. The company also extended the 1992 summer vacation shutdown at the division's other 12 mines from 4 weeks to 5 weeks. In mid-December, the mines and nickel refinery at Sudbury were shut down again, this time for 3 weeks. The smelter complex and copper refinery at Sudbury, however, continued to operate during the 3-week period, although at a reduced rate, to work down a backlog of copper concentrates.

The end-of-year production cutbacks also affected a number of other company operations, including the nickel-cobalt refinery at Port Colborne, Ontario; the mining, smelting, and refining complex at Thompson, Manitoba; and the nickel refinery at Clydach, Wales, in the United Kingdom. Inco's downstream alloys and engineered products operations in the United States and the United Kingdom underwent similar temporary shutdowns.

The shutdowns and other measures were designed to conserve cash during a period of rising operating costs and lower realized prices for nickel. Inco's unit production costs at its Canadian operations have nearly doubled since 1987 as a result of declining ore grades, higher labor costs, and the strengthening of the Canadian dollar against the U.S. dollar.

Despite market problems, Inco's management remained optimistic about the future. The company was to spend \$40.1 million over the next 2 years to reopen its Garson Mine at Sudbury. The Garson Mine was closed in 1986 after a serious rockfall. Advanced mining methods and new technology were to be used to overcome bad ground conditions that existed in parts of the mine. Better pressure bolts and a new, much stronger

type of sandfill was to be used to help stabilize weak roof slabs and wallrock. The plan called for 179 workers to be transferred from the Little Stobie, Frood, and other area mines where reserves were almost depleted. The reopening still has to be approved by the Ontario Ministry of Labor.

The Garson Mine was scheduled to produce 1,800 tons of ore per day after it reaches full production in late 1995. According to company officials, the mine had 4.4 Mmt of ore grading 1.58% Ni and 1.09% Cu that would permit mining to continue at the 1,800-ton-per-day rate until 2004. Garson had additional proven reserves of 13.3 Mmt of even higher grade ore that could provide another 20 years of production.

In 1991, Inco announced the discovery of two nickel deposits in the Sudbury district of Ontario. The larger of the two, called Victor, is 25 km from Sudbury on the northeast rim of the Sudbury basin. Subsequent drilling indicated that the Victor deposit may contain as much as 36 Mmt of ore. Copper-nickel sulfide mineralization is present in both the Sudbury Breccia and an adjacent granite breccia, but ore grades are highly variable because of the deposit's complex geology. One of the richer zones intersected in the Sudbury Breccia averaged 2.16% Ni and 4.73% Cu. The main ore zone in the granite breccia appeared to be leaner, averaging 1.64% Ni and 0.28% Cu. The Victor deposit was considered unlikely to be exploited at prevailing prices because the bulk of the ore lies at depths of 2,000 to 2,500 m.

The second deposit is only 925 m from Inco's existing McCreedy East Mine and is much more likely to be developed. The new McCreedy East find is extremely rich in copper and precious metals and occurs between depths of 1,075 and 1,540 m. New drilling raised reserves. The McCreedy East deposit was estimated to have 6.2 Mmt of proven and probable reserves averaging 9.9% Cu and 0.9% Ni. 18

Inco has discovered additional mineralization in the Thompson nickel belt of Manitoba. The new discovery

was close to the Pipe No. 1 Mine. The Pipe No. 1 was on standby, together with the Pipe No. 2, the Soab North, and Soab South Mines. More definitive drilling was scheduled for 1993. The company had already begun spending \$248 million to develop the 1-D ore body and expand operations at the Birchtree Mine on the outskirts of the City of Thompson. The 1-D project was expected to be completed sometime in 1997.

Falconbridge had six mines in operation at Sudbury during 1992—the Craig, Fraser, Lindsley, Lockerby, Onaping, and Strathcona. The six underground mines hoisted a total of 2.4 Mmt of ore that yielded 35,400 tons of nickel, 37,600 tons of copper, and 800 tons of cobalt in matte. 19 The company continued to explore for nickel and copper in the Sudbury Basin and in the neighboring Wanapitie anomaly east of Levack. Efforts were being concentrated at the Nickel Rim prospect, 12 km north of Falconbridge. Company geologists believe that the Victor deposit recently discovered by Inco may extend onto Falconbridge's property at that point. A 2,950-m-deep drill hole intersected a very narrow zone of high-grade sulfide mineralization, but considerably more drilling is required.

Falconbridge embarked on a fullfledged feasibility study of its Raglan deposit. The world-class nickel deposit is in northeastern Quebec on the northern tip of the Ungava peninsula. Extensive drilling was carried out during the first 5 months of 1992. Work done through 1992 identified at least 18.1 Mmt of ore averaging 3.13% Ni and 0.88% Cu. The company cleaned up the original exploration site and completed an environmental baseline study preparation for permitting. Falconbridge was also conducting exploratory drilling in Botswana, Labrador, and Manitoba. Significant mineralization was identified at William Lake, Manitoba, under 100 m of limestone at the southwest extension of the Thompson nickel belt.

Sherritt Gordon Ltd. experienced startup problems at its new refining complex in Fort Saskatchewan, Alberta, but these problems were largely

overcome. The new facility replaced a less efficient operation that had been in operation at Fort Saskatchewan since the late 1950's. The first phase of the project was completed on schedule in May 1992. The new complex consisted of a nickel refinery and cobalt separation and reduction plants. The complex was designed to process nickel feedstock with a high cobalt content. Feed material was being supplied by Cubaniquel and Union de Empresas del Niquel under agreements concluded with the two Cuban organizations in 1991. Because of the switchover, Sherritt Gordon produced only 16,600 tons of nickel, down 17% from 20,000 tons in 1991. Cobalt production was also down 17%, dropping from 820 tons to 680 tons.20

The Cuban contracts came at an opportune time and solved some key problems for both parties. The Fort Saskatchewan refinery lost 60% of its feed material when Inco decided not to renew its 10-year feedstock contract with Sherritt in 1989. At one point, in 1990, the shortage of feed was so severe that Sherritt had to close the refinery for 2 months. Since then, the company had built up a feed stockpile to guard against future supply disruptions. In the case of the Cubans, the Sherritt sales helped offset reduced exports of nickel-cobalt feedstock to Russia and gained hard currency for the country. In 1992, Sherritt's oil and gas group began helping Cuba bring offshore oilfields in and around the Bay of Cardenas into production. Sherritt also had a contract to explore for oil onshore in central Cuba, south of the existing Pina oilfield. The new oil production should help ease fuel shortages at Cuba's nickel refineries.

Black Hawk Mining Inc. agreed to buy the Redstone nickel mine near Timmins, Ontario, from Timmins Nickel Inc. for \$117,000 (C\$150,000). The relatively small, high-grade underground mine had been producing 92,000 to 96,000 mt/yr of sulfide ore grading 2.32% Ni when it was idled in June 1992. Timmins was forced to halt operations after the company lost its lease on the nearby Carshaw mill where the ore was being treated. The 450 ton-per-day mill, in Shaw Township,

was owned by Marshall Minerals Corp. of Niagara Falls, Ontario. Redstone was originally a joint venture of BHP-Utah Mines Ltd. (49%) and Timmins Nickel (51%). As part of the agreement, Black Hawk was to pay Sherritt Gordon, which had been refining concentrates for Timmins, \$78,000 plus a 2% net smelter return royalty on any future production. The royalty was not to exceed \$244,000. In exchange, Sherritt was to cancel all of the debts owed the Albertan refiner by Timmins. Sherritt also would have the right to buy future concentrates from the mine at competitive prices.

Black Hawk was committed to spend \$312,000 over the next 18 months exploring the property, but did not expect to reopen the mine until nickel prices return to the \$3.50 per pound level. At the end of the 18-month period, Sherritt can elect to convert its royalty into a 40% working interest in the mine. According to Black Hawk officials, at the time of closure, about 36,000 tons of reserves had been developed to the 244-m (800foot) level, with an average grade of 2.6% Ni. Timmins engineers estimate that the mine had proven and probable reserves of more than 300,000 tons averaging 2.2% Ni.

Hudson Bay Mining and Smelting (HBMS) has decided to close its Namew Lake Mine in northern Manitoba. Reserves at the mine, a joint venture of HBMS (60%) and Outokumpu Mines Ltd. (40%), are nearly exhausted, and exploration efforts had failed to locate any new ore zones in the area. The mine had been capable of producing concentrate containing 9,200 tons of Ni and 3,500 tons of Cu.

Colombia.—Cerro Matoso S.A. was caught up in the spinoff of Billiton from Shell. Billiton had a 47% equity in the Colombian ferronickel producer. Another 48% was controlled by Instituto de Fomento Industrial, an agency of the Colombian Government. The remaining 5% was owned by Cia. de Niquel Colombiano S.A. Cerro Matoso recovers laterite from an open pit mine near Montelibano in the Department of Cordoba. The lateritic ore, which

averages 2.9% Ni, is smelted on-site in a 51-megavolt-ampere electric furnace built by Elkem A/S. In 1992, Cerro Matoso produced 20,195 tons of nickel contained in ferronickel ingots and granules. The ferronickel had traditionally assayed 40% to 42% Ni. Billiton had been planning to expand the capacity of the Colombian operation to more than 30,000 mt/yr of Ni, but these plans were put on hold in early 1993. Production had been running slightly below the 22,500-mt/yr design limit of the smelter when nickel prices began to weaken. The addition of a smaller, 12,000-mt/yr furnace would have given Cerro Matoso more flexibility during periods of peak demand and would have permitted the facility to produce as much as 35,000 mt/yr. The existing furnace was expected to operate at full capacity for the remainder of 1993.

Cuba.—The Cuban nickel industry had three plants in operation: the Rene Ramos Latour at Nicaro, the Pedro Sotto Alba at Moa, and the Ernesto Che Guvera at Punta Gorda, 3 km from Moa.²¹ The Nicaro and Punta Gorda plants both employed an ammonium carbonate leach process to recovery nickel serpentine laterites. The Nicaro plant could make four products: oxide sinter (90% Ni), nodular oxide (77% Ni), granular oxide (77% Ni), and oxide powder (76% Ni). The Moa plant used a sulfuric acid pressure leach to produce a mixed sulfide precipitate containing 50% Ni+Co from limonitic laterites. The leaching was carried out at 250° C and 4,000 kiloPascals to prevent large amounts of iron from dissolving along with the nickel and cobalt. Construction of a fourth plant, an ammonium carbonate leach operation at Las Camariocas, was behind schedule as the result of the political restructuring of Eastern Europe. The defunct German Democratic Republic had been providing substantial support for the 30,000-mt/yr Ni refinery project.

The Government of Cuba reportedly had given the three companies increased autonomy, making operations more efficient. However, fuel shortages continued to restrict production. The

Punta Gorda plant was closed in September 1990 as part of a number of energy-saving measures announced by the Government, but reopened in April 1991 after modifications were made to the operation. New extractive technology and equipment would enable the Cubans to become more energy efficient and to produce higher purity nickel. Help in this area was being provided by the United Nations Development Program and undisclosed Canadian companies. Part of the nickel-cobalt sulfide precipitate that had been going to the Russian refinery of Orsk was being shipped to Sherritt Gordon's refinery at Fort Saskatchewan, Alberta,

A stainless steel plant was commissioned in neighboring Las Tunas Province sometime during 1992, but detailed information about its design was meager because of the embargo. By yearend, the plant had consumed about 500 tons of Ni contained in some type of oxide sinter. Nickel consumption was expected to increase to 1,500 mt/yr after startup problems were overcome.

Finland.—Outokumpu Oy was restructuring some of its operations in anticipation of total privatization. Although the Finnish Parliament had given the Government authority to decide on ownership structures, no decision had been made on whether the Finnish State will actually relinquish its majority holding in Outokumpu. The Ministry of Trade and Industry had initiated studies on different aspects of privatization. On December 31, 1992, the Finnish State still held 57.5% of the stock in Outokumpu. Another 16.0% was controlled by the Social Insurance Institution. The remaining 26.5% was owned by private Finnish investors and institutions.

In November 1992, the Forrestania Mine in Australia came on-stream. (See Australia section of this report.) The mine was owned by OMR, the company's base metals subsidiary that had interests in copper and zinc as well as nickel. The mine, together with the long-term contract with WMC for Mount Keith concentrate, secured feed material for the

Harjavalta smelter for years to come. The smelter in Turku-Pori Province was expanded and upgraded in 1991 at a cost of \$17 million. In 1992, Outokumpu Harjavalta Metals Oy produced 14,800 tons of Ni, 110,500 tons of blister copper (a new record), and 70,900 tons of cathode copper (also a new record).²² Plans were made to expand the nickel production of the operation from 18,000 mt/yr to 32,000 mt/yr, pending approval from senior management.

Greece.—On November 10, Hellenic Mining and Metallurgical Co. Larymna S.A. (Larco) had to slash its output by 50% because of serious cashflow problems, aggravated by declining nickel prices. The Greek ferronickel operation was to produce only about 800 to 1,000 tons of contained Ni per month. About 46% of Larco's 1,700 work force was to be suspended at half pay for 8 months. The Larymna smelter was capable of producing 25,000 mt/yr of Ni contained in ferronickel, but had been hampered by relatively low ore grades and high-priced electric power. Significant increases in productivity had been made since the mid-1980's, but production costs reportedly have been running about \$3.65 per pound of contained Ni, with electric power accounting for 32% of the total cost. A new ore dressing plant commissioned in late 1992 was expected to help limit future power costs. Larco was controlled State-owned Industrial Reconstruction Organization, which had a 43% share in the operation since 1988. The next largest shareholder was the Public Power Corp. (DEH), with 27% equity. The parastatal operation reportedly was in arrears on its August and September power bills from DEH. The Greek Government had wanted to privatize the operation since 1990 and was being advised by the First Bank of Boston.

Indonesia.—P.T. International Nickel Indonesia produced a record high 36,300 tons of Ni in matte in 1992, up from 34,428 tons in 1991. The company

continued to increase capacity, after having just completed a 3-year, \$83 million expansion program in early 1991. Furnace No. 3, one of three electric furnaces at P.T. Inco's operation on the island of Sulawesi, was rebuilt during the first half of 1992 and was back in full operation by June. An improved modular electrode control system was added while the furnace was shut down. A new furnace roof was installed at the same time. The suspended roof was of advanced design and did not require water for cooling.

At the end of 1992, Furnace No. 2 was shut down for similar rebuilding and upgrading and was scheduled to return on-line by mid-1993. Construction of a 24-MW, three-unit diesel electric generating station began in March 1992. The additional power was to supplement the output of the company's existing hydroelectric facility. The furnace upgrading and other ongoing improvements were intended to raise the production capacity of the mining and smelting complex to 45,000 tons of Ni in matte by 1995. The bulk of the matte. which contained 77% to 80% Ni, had traditionally gone to Japan for refining under long-term contracts. The Sulawesi operation was a joint venture of Inco, Sumitomo Metal Mining. and Indonesian public.

P.T. Aneka Tambang was also expanding capacity. The operation at Pomalaa produced 5,507 tons of Ni in FeNi, up 4% from 5,318 tons in 1991. Production of ore for export rose from 32,086 tons of contained Ni to 35,745 tons in 1992, but was scheduled to drop slightly in 1993.

Japan.—Two Japanese nickel producers joined the ranks of smelters and refiners planning to cut back output in 1993. Pacific Metals Co. Ltd. announced that it would reduce ferronickel production from its current level of 29,000 mt/vr of contained Ni to possibly 25,000 tons. The company's plant at Hachinohe in Aomori Prefecture is capable of making a total of 42,000 mt/yr of Ni in FeNi with its three electric

37,682 tons of contained Ni—a record high for Hachinohe. Garnierite feed for the operation came from New Caledonia and the Indonesian island of Celebes.

Sumitomo Metal Mining was also considering reducing its output. The company operated a refinery at Niihama in Ehime prefecture on the island of Shikoku. The Niihama complex was expanded to be capable of producing 26,000 to 29,000 mt/yr of electrolytic nickel.

Sumitomo was switching from its existing solvent extraction-electrowinning process to a newer, more productive process called Matte Chlorine Leach Electrowinning (MCLE). The technology was developed in-house by Sumitomo. The company was in the final stages of completing a state-of-the-art refinery at Niihama based on the new technology. Construction of the new 24,000-mt/vr facility began in late 1991 and was scheduled for completion in March 1993 at a cost of \$60 million. The new refinery, together with the converted cobalt facility, would increase Sumitomo's refining capacity from about 22,200 mt/yr to at least 27,960 mt/yr. Sumitomo was Japan's only producer of refined nickel and produced 23,658 tons of the metal in 1991.

As mentioned earlier, Sumitomo renewed its long-term purchase contract with WMC on April 8, 1992. The Japanese refiner was to receive 20,000 tons of nickel matte annually from WMC until the year 2002. Sumitomo began buying concentrates from WMC in 1967, but changed to matte in 1972. Sumitomo also used matte from P.T. Inco and had a 20% interest in the Indonesian operation since 1988.

Sumitomo had a ferronickel plant at Hyuga, Miyazaki Prefecture, capable of producing 18,000 mt/yr of Ni in FeNi. In 1991, the Hyuga plant made four grades of ferronickel containing a total of 17,457 tons of Ni. The nickel content varied from 18% to 28% depending on the carbon level and other grade characteristics.

mt/yr of Ni in FeNi with its three electric furnaces. In 1991, the plant produced le Nickel (SLN) shipped 32,081 tons of

nickel in ferronickel, down from 38,469 tons in 1991. The company's three furnaces at Doniambo had a combined capacity of about 48,000 mt/yr of Ni in ferronickel. The operation could also produce about 10,000 mt/yr of Ni in matte. The ferronickel was averaging about 29% Ni; the matte, 75% Ni.

In 1991, Inco signed an agreement with Le Bureau de Récherches Geologiques et Minières (BRGM) to evaluate lateritic reserves on New Caledonia. Inco officials were so impressed with the preliminary evaluation reports that they subsequently purchased Compagnie des Mines de Xere (formerly Société de Promotion des Mines) from BRGM, thus gaining title to large resources at the southeastern tip of the island.

A new company, Goro Nickel S.A., was set up to study the feasibility of mining the newly acquired property, with Inco owning 85% of the equity. The Goro deposit reportedly had 150 Mmt of ore averaging 1.57% Ni. Inco also controls an additional 10 Mmt averaging 2.13% at Tiebaghi on the opposite end of If developed, the New the island. Caledonian ore conceivably could be sent to Inco's Indonesian subsidiary for The Soroako smelter on smelting. Sulawesi should be capable of producing 45,000 mt/yr of Ni (in matte) by 1995 and would need 25% more ore than it was receiving locally to operate at full capacity. An alternative would be to build a Doniambo-type smelter on-site. (See Indonesia section of this report.)

Philippines.—Ore and concentrates containing 12,701 tons of Ni were shipped to Japan, down from 14,238 tons in 1991. The production came from the Rio Tuba Nickel Mining Corp. on Palawan Island and two smaller mines near Surigao in northern Mindanao. The larger of the Mindanao mines was operated by the Taganito Mining Co., a subsidiary of Japan's Pacific Metals.

Attempts to rehabilitate the shuttered Surigao Mine and refinery on Nonoc Island were stymied by declining nickel prices, large exports of nickel from Russia, and a global slowdown in stainless steel consumption. The laterite operation had been shut down since mid-1986, following the liquidation of its former owner, the Marinduque Mining and Industrial Corp., by the Philippine Government.

In early January 1993, Inco sent a team of engineers and geologists to evaluate the island complex off the northern tip of Mindanao, but nothing immediately materialized. In 1991, the Jesus Cabarrus investment group bought the Nonoc operation from the Assets Privatization Trust, the Government agency responsible for selling off Stateowned enterprises. Since then, the group had arranged for some refinancing, settled with at least one major creditor, and tried to restart the operation under the name Philippine Nickel Co. (Philnico). Rehabilitation costs could easily exceed \$200 million.

Russia.—The sales manager for the Norilsk Nickel Combine told wire services that the company produced 240,000 tons of nickel in 1992. Production was down 15% from that of 1991 because of heavy snowfalls and unusually high winds during the 1992-93 winter. This was the first time that the giant combine had ever disclosed its production data. As of mid-1993, no official figures had been released by the new Government of Russia. Before the dissolution of the former U.S.S.R., information of this type was considered a Some Western analysts state secret. believe that the combine's preliminary figure is too high and will eventually be revised downward to about 225,000 tons. The figure apparently represented the combined output of the Norilsk operation north-central Siberia and company's two other operations. Monchegorsk and Pechenga, in the Kola Peninsula. The combine accounted for about 80% of Russian nickel production, the rest being in the Urals.

The Norilsk-Talnakh district had one open pit and five underground mines, but only two concentrators and two smelters, creating an imbalance in the system. The two smelters had a combined output of 180,000 tons of Ni in matte, but the local

refinery could handle only 100,000 tons. As a result, the excess ore, concentrate, and matte was being shipped to the combine's other refinery and two smelters on the Kola Peninsula. This material was being railed to Dudinka, near the mouth of the Yenisey River, and then loaded onto ocean vessels bound for the Port of Murmansk.

Official Russian customs data on 1992 nickel exports were still being compiled at the time of publication. According to data received by the INSG from importing countries, the former U.S.S.R. shipped a total of 93,192 tons of unwrought nickel (in unalloyed form) to 15 countries in 1991. A total of only 37,250 tons had been reported, as of this writing, from Russia for 1992, with the bulk going to Germany (11,093 tons), France (5,273 tons), the United States (3,385 tons), and Japan (3,300 tons). Norilsk also had been sending significant amounts of nickel matte to Norway for refining. In 1991, the former U.S.S.R. shipped 13,055 tons (gross weight) of matte to the Kristiansand refinery of Nikkelverk Falconbridge Preliminary data indicated that shipments of Russian matte to Kristiansand dropped off dramatically in 1992 and were partly replaced by matte from Canada.

In early 1992, the Russian Government became increasingly concerned about reports of massive smuggling of strategic raw materials through Estonia, the other two Baltic States, and the Kaliningrad enclave (formerly Königsberg). prevent a massive flow of metals to the Russian Western markets. Government imposed a new series of export tariffs and tightened the export licensing process. Exporters were also being required to exchange 50% of their foreign currency earnings at a rate set by the Russian central bank. Officials in the Ministry of Foreign Economic Relations insisted that the new export tariffs, which took effect July 1, 1992, were less stringent than the previous system of regulations and controls. The new Government still requires Norilsk to allocate most of its production to domestic consumers and reportedly reduced the combine's 1993 export license by 10,000 tons from the 1992 authorization level.

Norilsk officials, too, expressed concern about the flow of so-called "gray" (deliberately misclassified) or "black" (smuggled) nickel into Western markets but insisted that their company was powerless to prevent it. In early 1993, the price of nickel within Russia was about 2 million roubles (US\$1,700) per metric ton compared with \$5,800 to \$6,100 on the LME. The flow to the West was expected to slow somewhat in 1993 because Russian consumers apparently had sold off the bulk of their excess stocks and the internal price for nickel continued to rise. Estonia, Latvia, and Lithuania promised to do more to discourage smuggling of Russian metals through their ports. Norilsk officials believed that it would take at least 2 to 3 more years to stabilize the new Customs Frontier.

Solomon Islands.—Kaiser Engineers Inc. was evaluating two deposits of nickeliferous laterite in the north-central island province of Isabel. The larger deposit had an estimated 21 million cubic meters of ore; the smaller, 13 million cubic meters. Both average about 1.4% Ni. The main island of Santa Isabel is about 80 km northwest of Guadalcanal. Laterites were first discovered on Santa Isabel in the 1960's. NSR Environmental Consultants Pty. of Australia has been hired to study the environmental impact of future nickel mining on the island group.²³

South Africa, Republic of.—As previously mentioned, Gencor was seeking to buy selected metal and mineral operations owned or controlled by Shell's subsidiary, Billiton B.V. Gencor, which had holdings in coal, gold, manganese, and the platinum-group metals (PGM), reportedly wanted to concentrate on mining and divest its nonmining interests. Management was hoping to complete the unbundling by August 31, 1993. Under the plan, Gencor would relinquish control of its industrial arms—the paper and pulp company Sappi, the consumer products group Malbak, and the energy company

Engen.²⁴ Part of the money from the unbundling would be used to buy equity in mines outside South Africa.

Gencor is the second largest mining company in the Republic of South Africa after the Anglo-American Group. Impala Platinum Holdings Ltd. (Implats), one of Gencor's subsidiaries, produced nickel powder and briquets as a byproduct of its PGM operations in Bophuthatswana. The subsidiary had four underground mines extracting PGM/base metal sulfide ore from the Merensky and Upper Group 2 (UG2) Reefs of the Bushveld Complex. The sulfides were being concentrated at a central processing plant and then shipped to the company's refinery at Springs.

Samancor, the ferroalloys subsidiary of Gencor, has been involved in the production of chromium and manganese alloys for many years. In September 1991, Samancor acquired Middelburg Steel and Alloys Holdings (Pty.) Ltd., an important South African stainless steel and ferrochromium producer. That transaction enhanced Samancor's reserves chromite and increased ferrochromium production Samancor is a partner in the Columbus Project, a joint stainless steel venture with Anglo American Corp. With the commissioning of the Columbus stainless plant in 1995, South African consumption of nickel is expected to increase significantly. By the year 2000, South Africa could become a net importer of nickel.

Tanzania.—On June 1, 1992, Kagera Mining Co. Ltd. concluded comprehensive exploration and development agreement with Government of Tanzania. Kagera Mining was given the exclusive right to explore for nickel and several associated metals (cobalt, copper, lead, platinum, and zinc) in the northwest corner of the African country for 1 year, with options to develop and mine any target areas of the company's choosing. Sutton Resources Ltd. and Romanex International Ltd. of British Columbia own 90% of the newly formed Tanzanian enterprise. remaining 10% is held by the Tanzanian Government, which would also receive a

3% royalty on any minerals produced in addition to normal tax revenues.

Sutton Resources was evaluating a major nickel-cobalt-copper deposit at Kabanga on the Burundi border under a 1990 agreement with Tanzania. Additional drilling on a tighter pattern delineated 25.5 Mmt of ore grading 1.19% Ni, 0.10% Co, and 0.20% Cu at a cutoff grade of 0.5% Ni.25 The sulfide ore is associated with a series of ultramafic intrusives, primarily peridotites and pyroxenites. The Kabanga deposit lies in the southwest corner of the Kagera region and is only 1 of 101 anomalies identified by United Nations Development Program teams in the 1970's. At least 12 of the remaining 100 anomalies are also associated with ultramafic rocks.

Kagera Mining is named for the 26,400-square-kilometer region that is covered by the reconnaissance license. between the Rwanda border and Lake Victoria. The region includes the Biharamulo, Muleba, Ngara, Bukoba Rural, and Karagwe Districts. The new company must spend a minimum of \$1 million on its exploration program during the first year. This figure represented an expenditure of \$35 per square kilometer plus the license fees for the first year. Since the signing of the Government agreement, Sutton Resources has formed a joint venture with BHP Minerals International Inc. to evaluate certain unspecified properties in the Kagera region. The exploration work would earn BHP a 66.6% interest in the first mine developed in the Kagera belt and a 58% interest in the first mine at Kabanga. BHP was conducting airborne an geophysical survey of the entire concession.

Zimbabwe.—Bindura Nickel Corp. Ltd. (BNC) celebrated 25 years of operation. Although small-scale mining began in August 1964, the first nickel concentrates were not produced until July 1968.

A total of 2.817 Mmt of ore was milled in 1992, yielding 12,378 tons of Ni in concentrate. The concentrates came from four underground mines: the Trojan (5,519 tons Ni), the Shangani

(3,677 tons), the Madziwa (1,731 tons), and the Epoch (1,451 tons). Mill head grades ranged from 0.47% to 0.73% Ni. Additional reserves were found at Madziwa and the Epoch Mines, extending their lives by 1 to 2 years. The smelting and refining complex at Bindura (BSR) produced 11,370 tons of nickel cathode, 1,134 tons of copper, and 100 tons of cobalt (in cake). Of the 11,370 tons of nickel produced, 10,328 tons came from BNC operations and 1,042 tons was toll work.

The prolonged drought continued to make problems for Bindura by driving up the cost of electrical power and putting restrictions on power consumption. Bindura's management claimed that power rates were already excessive because of inefficiencies at the regional generating stations. To help cut power costs, BNC agreed in October 1992 to purchase part of the power entitlement given to Zimbabwe Alloys Ltd.

BNC made several improvements to its smelting and refining complex. December 1992, a new electrostatic precipitator was commissioned at the BNC smelter. The furnace, which had been in operation for 11 years, was shut down 4 months later for complete rebuilding. A new sodium sulfate crystallization plant was also commissioned in 1992. The byproduct sulfate was to go to the Zimbabwean detergent industry, where it would meet about one-half of that industry's needs. Until this development, all of the sulfate had to be imported. (See tables 10 and 11 for individual country data.)

Current Research

Queneau International Symposium.—A special international symposium was organized by The Minerals, Metals & Materials Society (TMS) to honor Dr. Paul E. Queneau, Sr., for his outstanding contributions to pyrometallurgy. Professor Queneau was coinventor of the Inco Flash Smelting Process and chief research officer at Inco Ltd. for many years. He coauthored The Winning of Nickel, a classic text on the metal, and is currently an emeritus faculty member at

Dartmouth College.

The symposium was held in Denver, CO, from February 21 to 25, 1993, in conjunction with the annual TMS About 115 papers were meeting. presented on the extractive metallurgy of cobalt, copper, and nickel, highlighting much of the research, development, and upgrading that occurred around the world between 1988 and 1992.27 The first half of the symposium dealt with fundamental aspects; the second, individual copper and nickel smelter operations. Many of the presentations dealt specifically with the production or recycling of nickel. Flash smelting, bath smelting, reverberatory furnace smelting were all discussed. Updates were given on nickel operations in Australia, Canada, China, Dominican Colombia, Cuba, the Republic, Russia, and Turkey.

Sulfur Dioxide Abatement.—A large part of the Denver program focused on dioxide (SO₂) abatement sulfur technology—one of the keys to minimizing acid rain. The Provincial government of Ontario has ordered Inco to reduce the SO₂ emissions from its Copper Cliff smelter complex at Sudbury to less than 265,000 mt/yr by January 1, Inco was in the midst of streamlining its mill-smelter operation and expected to be in compliance by the deadline. The Copper Cliff abatement program was one of the largest environmental projects ever undertaken by a mining company. Inco had already spent \$505 million on the project. More than 90% of the construction was completed by the beginning of 1993. A containment level of more than 75% was achieved in 1992, resulting in the recovery of 300,000 tons of sulfuric acid from smelter gases during the year.

The 1994 containment level will represent a 93% reduction in SO₂ from 1978 levels and will account for 90% of the sulfur mined.²⁸ Milling was being consolidated at one mill, instead of three. A single Cu-Ni bulk concentrate was to be flash smelted in two new flash furnaces, producing a matte of about 45% Cu+Ni. This matte was to be further processed to Bessemer matte in

conventional Pierce-Smith converters and sent to an upgraded matte separation plant. After separation, the copper sulfides (primarily chalcocite with 3% to 6% Ni at this point) were to be oxygen converted to a semiblister in a reactor of new design. The nickel sulfides were to be roasted separately to nickel oxide. The streamlined operation sharply reduced the number of emission sources. was more energy efficient, and eliminated several copper processing problems. At least six copper producers have followed suite and were upgrading their flash smelting operations.

Advanced Smelting Technologies.—In May 1991, Mitsubishi Materials Corp. put a new, more efficient copper smelter into operation at its Naoshima smelting and refining complex in Kagawa, Japan.²⁹ The new continuous smelter cost \$160 million and replaced two existing smelters—a Mitsubishi continuous furnace that had been in operation since 1974 and a conventional reverberatory furnace. The new smelter relied heavily on molten bath technology and differed significantly from both traditional matte smelting (where roasting, smelting, and converting are carried out in separate steps) and flash smelting (where the roasting and smelting stages are combined into a single At Naoshima, copper sulfide step). concentrates and flux materials were being injected together with 40% to 50% oxygen-enriched air into the molten bath through top-blowing lances. injection had to be done at very high speed to prevent premature ignition. The molten bath was mostly matte with a thin layer of slag on top. Copper scrap and sludges also could be added to the bath via a drop chute. This process conceivably could be adapted to the smelting of nickel sulfides because nickel and copper have similar affinities for oxygen.

A great deal of effort has gone into studying the combustion of metal sulfide particles in the reaction shaft of the flash furnace. WMC and the Australian Government currently have a joint research program aimed at better understanding the burner environment in

WMC's nickel flash furnace Kalgoorlie.30 The Outokumpu-type furnace had been treating about 550,000 mt/yr of concentrate containing about 10% Ni. Special ports were constructed in the upper walls and roof of the shaft so that samples of solids and gas could be collected in the vicinity of the burners. The ports also allowed researchers to measure particle temperatures determine shaft wall temperature profiles. The Commonwealth Scientific and Industrial Research Organization, the Australian Government agency collaborating with WMC, was also working with Mount Isa Mines Ltd. on adapting the Isasmelt lead smelting process to copper concentrate. In June 1992, Cyprus Miami Mining Corp. commissioned а full-scale Copper Isasmelt furnace at Miami, AZ, capable of handling 585,0000 mt/yr of concentrate.

Metallurgists in Russia and Kazakhstan spent more than 25 years developing and improving the Vanyukov furnace.³¹ The Vanyukov process, based on bath smelting technology, is an alternative to flash smelting, but is not well known outside central Eurasia. Pilot plant work at Ryazan, 200 km south of Moscow, demonstrated that the process can be used to continuously smelt a variety of coppernickel ores and concentrates. One of the principal advantages of the process is that the copper-nickel content of the matte can be adjusted over a wide range to compensate for differences in ore type. Mattes have been produced with a total nonferrous metal content ranging from 35% to 70%.

Commercial-size Vanyukov furnaces were treating copper and/or copper-nickel charge material at two locations in the C.I.S.—the Balkhash copper smelter in Kazakhstan and the Norilsk copper smelter in Siberia. The box-shaped furnace at Norilsk is divided into two parts by a partition. The first compartment is used to smelt the charge and is operated in a continuous mode under oxidizing conditions. Enriched air containing 70% oxygen (by volume) is blown through tuyeres in compartment walls. The second

compartment was originally designed for slag cleaning under reducing conditions. However, in actual practice, slag cleaning is minimal. The furnace walls are cooled by a series of copper water jackets.

A more revolutionary smelting process was being investigated at bench level. A thermal plasma arc can be used to produce high-grade matte directly from Ni-Cu concentrates. Work in this area was being conducted at the Kunming Institute of Technology in China and the University of Idaho. Thermal plasma arc smelting may prove especially useful for recovering nickel, chromium, and other transition metals from a variety of furnace dusts. The Kunming version of the process reportedly has worked well with nickel-bearing pyrrhotite from Jin Chuang. The Chinese were using a quartz-lined microwave reactor of special design to partially desulfurize the concentrates before smelting.

Intermetallics.—North American metallurgists were conducting research on fatigue and creep in nickel aluminides, titanium aluminides, titanium niobides, and similar intermetallic alloys as part of the domestic aerospace program. Both intermetallics and conventional superalloys, such as Waspaloy and Incoloy 907, can be reinforced with tungsten or molybdenum metal fibers. Nickel aluminides, a new class of lightweight and ductile high-temperature alloys, are six times as strong as stainless steel at 600° C. Nickel aluminide was first studied in the 1950's, but was found to be extremely brittle. In the late 1970's and early 1980's, researchers in Japan and at the Oak Ridge National Laboratory discovered that the addition of small amounts of boron and hafnium to Ni2Al turned the brittle compound into a strong, ductile alloy. Armco Inc. has been licensed by Oak Ridge to produce the new alloy, which shows extreme resistance to cavitation, making it useful for pump and turbine parts. Nickel and titanium aluminides are potential weightsavings alternatives to superalloys in advanced gas-turbine engines if the brittleness problem can be completely overcome.

U.S. Bureau of Mines Projects.— Liquid emulsion membrane (LEM) extraction technology being perfected at USBM's Albany Research Center could help both the domestic electroplating industry and producers of nickel chemicals. Work to date has shown that more than 95% of the copper in dilute mine waste solutions can be recovered using LEM technology. Nickel behaves similarly to copper in certain chemical environments and may be able to be recovered from residual processing effluents with similar success.

Other researchers at the Albany Center succeeded in producing a nickelchromium-iron master alloy directly from low-grade lateritic ores found in the coastal ranges of southern Oregon and northern California. These ores are associated with ultramafic ophiolite sequences of Jurassic age and typically contain only 1.1% Ni and 1.1% Cr. The smelting was carried out in a submerged furnace, using coke breeze. metallurgical coke, and wood chips as reductants. Pebble lime was added as a flux. The master alloy could be used to make inexpensive stainless steel if the process proves economically feasible.

The Rolla Research Center developed an electrochemical process for recovering individual metals directly contaminated superalloy scrap. The process is based on controlled-potential electrolysis. Superalloy chips and/or turnings are placed inside a cage-shaped anode and immersed in an acidic chloride-sulfate solution. The migrating nickel and cobalt cations are codeposited as a 99% + pure alloy at the cathode. while the chromium, molybdenum, and tungsten are precipitated from the anolyte in a side purification circuit as a mix of impure hydroxide residues. The process should work for a variety of de-oiled scrap materials, including turbine blades. turbine disks, grinding sludges, and machine turnings.

Rolla researchers were studying ways of recovering cobalt and nickel from lead tailings in Missouri. Their microscopy work showed that cobalt and nickel occur in the tailings primarily as minor siegenite [(Co,Ni)₃S₄] and bravoite

 $[(Fe,Ni)S_2].$

OUTLOOK

Between 1981 and 1991, demand for nickel in the Western World grew at an average rate of almost 4% per year. However, demand began to slow in early 1991 as recessionary forces spread from North America to Western Europe and eventually to Japan. Since then, the economic restructuring of Russia and other members of the former U.S.S.R. has allowed stocks of cathode and metal powder originally allocated to the Soviet defense industry to be exported to the West.

The arrival of the material came at a time when Western nickel demand was already weakening, causing LME stocks to build to excessive levels. September 1993, the LME warehouses in Rotterdam held more than 106,000 tons of nickel—almost a 2-month supply for the entire West. Export controls imposed by the new Russian Government have partially slowed the flow of cathode, but some smuggling will inevitably continue until the ruble completely stabilizes. Exports of cathode and nickel alloys masquerading as scrap have been especially difficult to control. Russian exporters of strategic metals now must have a license and provide detailed information on their foreign bank accounts to the Ministry of Foreign Trade.

The Russian push to export is being driven by two forces. First, demand for stainless within the former U.S.S.R. has been declining since 1989. Second, a large disparity still exists between internal nickel prices and the LME cash price. In January 1991, nickel was being sold in the former U.S.S.R. for about \$100 per metric ton, at a time when the LME price was about \$8,000 per ton. This gap narrowed considerably in late 1991 and early 1992. By July 1992, the internal price had skyrocketed to \$4,100 per ton and stood at about 55% of the LME Since then, the situation has price. deteriorated considerably. In March 1993, the internal price was only 43% of the LME cash price. The difference between 43% and 55% does not seem that large. However, during the 8-month period, the LME price gradually dropped from \$7,498 per ton to \$5,971 per ton and has been slowly sinking.

The global slowdown in economic activity and growing LME stocks have been putting more and more pressure on nickel prices. On September 16, 1993, the LME price fell below \$4,410 (\$2.00 per pound) for the first time in 6 years. This was a disaster for some marginal producers whose break-even point had been \$6,610 (\$3.00 per pound). All of the producers were being squeezed to some degree between declining prices for their products and rising operational costs. A fortunate few were partially protected by long-term sales contracts and were able to fill orders with material acquired through the LME.

The lower limit of the LME cash price will be determined by the willingness of producers in North America and the western Pacific Rim to retain market share by selling below cost. If the LME price continues to slide, several producers will have to begin slashing output at some point or face bankruptcy. The upper limit will be a measure of the eagerness of the Norilsk Nickel Combine to earn hard currency and secure a permanent sales position in the West. Norilsk signed a cooperative agreement with Outokumpu in September 1993 and has already strengthened ties to three or four Western trading companies. Outokumpu was considering helping Norilsk upgrade its facilities in exchange for nickel and copper. One or two Russian-Finnish joint ventures are also possible if the Russian Government acquiesces. Long-term financing could be provided by a consortium of Scandinavian and EC investment banks.

Austenitic stainless steel will continue to drive world nickel demand for both the short term (1994-96) and midterm (1997-99). Japan is expected to be the dominant austenitic producer for the rest of the century and will continue to rely heavily on Australia, Indonesia, New Caledonia, and the Philippines for nickel matte and mine products. Japan is also the largest consumer of stainless of all

types on a per capita basis. In recent years, Japanese stainless production has been 1.4 to 1.9 times greater than that of the United States. U.S. stainless production peaked in 1988 at 1.996 Mmt and has since been running between 1.70 and 1.85 Mmt. Prices could conceivably return to 1992 levels in early 1995 if Japan were to emerge from its current recession and dramatically increase stainless production.

Western demand for austenitic stainless in 1994 should be slightly less than the record high of 1990 because of the Japanese recession. The rest of East Asia will continue expanding stainless production capacity, although perhaps at a somewhat reduced pace. In recent years, there has been a significant shift in U.S. exports of stainless scrap from Japan and Western Europe to the Republic of Korea, Taiwan, and other rapidly developing "Tiger" countries. The Republic of Korea is already making more stainless than either Sweden or the United Kingdom, while Taiwan is hard on the heels of Finland, which currently ranks eighth in Western Europe. Little or no growth is planned for Western Europe, which accounted for 36% of the 12.4 Mmt of stainless (both austenitic and ferritic grades) produced worldwide in 1991. Production of stainless steel in Western Europe is expected to be flat in 1994 and could even decline slightly because of growing recessionary forces on the Continent.

The long-term (2000-2003) forecast is much more rosy. If the past is any guide to the future, world stainless steel production should grow on the average 3% to 5% per year over the next 10 years. Total nickel consumption should grow at an even faster rate because stainless currently accounts for only 60% of total nickel demand and many novel, nonsteel uses are being developed for the element. The successful revitalization of Russia and the rest of Eastern Europe, coupled with a restructuring of the Chinese economy, could generate unprecedented demand for nickel at the turn of the century.

A significant amount of nickel also goes into superalloys. In the United

States, much of this material ends up either in jet turbine engines or in sophisticated chemical processing equipment such as chemical reactors and pumps. Record numbers of orders for civil aircraft are expected to materialize sometime after 1995 because air traffic is steadily increasing and aging fleets need to be replaced. Demand for nickel by U.S. superalloy producers will probably be flat until then. Many domestic airlines are currently experiencing financial difficulties brought on by the recession, Government deregulation, environmental controls, and escalating costs for jet fuel, but should be able to overcome these problems in time. The sluggish U.S. economy and the slowdown in Europe and Japan have discouraged chemical manufacturers from building new plants. Chemical companies around the world are currently restructuring, downsizing, and making strategic alliances to penetrate previously closed markets. Orders for new chemical plants and equipment will continue to be weak through 1994, but the situation should change dramatically after Germany finalizes reunification and Japan escapes from recession. The long-term outlook for superalloys is optimistic.

Advanced batteries and electric vehicle technology probably will not significantly affect the nickel market before the year 2002. The nickel-metal hydride battery and the nickel-cadmium battery are both serious contenders for the power system of the futuristic automobile, but could lose out to their sodium-sulfur, advanced lead-acid, or zinc-air competitors. If a nickel battery were adopted universally, U.S. demand for the metal could easily double.

¹Formerly "oxide sinter." Chemical-grade oxide is included with salts.

Sources: Bureau of the Census and Journal of Commerce.

²For the different salts, the nickel contents are assumed to be as follows: chlorides (25%), sulfates (22%), other salts (22%), and oxide, sesquioxide and hydroxide (65%). The typical catalyst is assumed to have a nickel content of 22%.

³Data may not add to totals shown because of independent rounding.

The nickel content of waste and scrap is assumed to be 50%, while that of stainless steel has been shown to be about 7.5%.

Estimated. Revised.

'Insofar as possible, this table represents recoverable mine production of nickel. Where actual mine output is not available, data related to a more highly processed form have been used to provide an indication of the magnitude of mine output and this is noted parenthetically or by a footnote following the country name. Finland and the United States both reported receiving ferronickel originating from Macedonia in 1992, but definitive information on the output of the Kavadarci operation was not available. Table includes data available through Aug. 18, 1993.

²Reported figure.

This series (assay content of concentrates produced) differs from that published previously. The earlier series—refined nickel and nickel content of oxides and salts produced, plus recoverable nickel in exported matte and speiss—was as follows: 1988—198,744;1989—195,554 (revised); 1990—195,004 (revised); 1991—188,098 (revised); and 1992—180,947. Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁵Formerly part of Yugoslavia.

⁶All production in Yugoslavia from 1988-91 came from Serbia and Montenegro.

⁷Dissolved in Dec. 1991.

¹Dissolved in Apr. 1992.

Estimated. Revised.

In addition to the countries listed, North Korea is believed to have produced metallic nickel and/or ferronickel, but information is inadequate to make reliable estimates of output levels. Finland and the United States both reported receiving ferronickel originating from Macedonia in 1992, but definitive information on the output of the Kavadarci operation was not available. Several countries produce nickel-containing matte, but output of nickel in such materials has been excluded from this table in order to avoid double counting. Countries producing matte include the following, with output indicated in metric tons of contained nickel: Australia (estimated): 1988—45,000; 1989—45,000; 1990—45,000; 1991—45,000; and 1992—45,000; Botswana: 1988—22,539; 1989—19,759 (revised); 1990—19,022 (revised); 1991—19,294 (revised); and 1992—18,873; Canada: 1988—57,703; 1989—44,320; 1990—43,300 (estimated); 1991—40,000 (estimated); and 1992—40,000 (estimated); Indonesia: 1988—28,864; 1989—29,030; 1990—24,949; 1991—27,433 (revised); and 1992—39,307; and New Caledonia: 1988—10,470; 1989—10,650; 1990—9,683; 1991—9,041; and 1992—7,475.

³Brazil is believed to also produce nickel oxide, but information is not available on which to base estimates.

⁴Cuba also produces nickel sulfide but, because it is used as feed material elsewhere, it is not included to avoid double counting. Output of processed sulfide was as follows, in metric tons: 1988—19,811 (revised); 1989—20,017 (revised); 1990—19,652 (revised); 1991—14,593 (revised); and 1992—15,270.

⁵Reported figure.

¹Table includes data available through July 6, 1993.

⁶Formerly part of the U.S.S.R.; data were not reported separately until 1992.

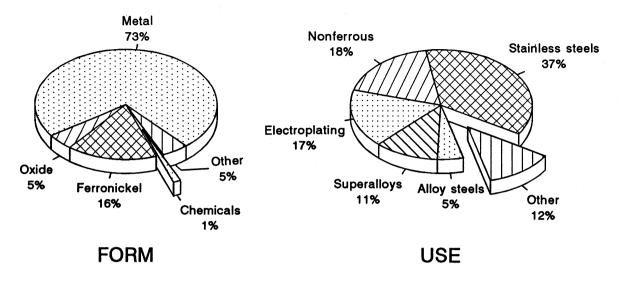

⁷Formerly part of Yugoslavia.

⁸All production in Yugoslavia from 1988-91 came from Serbia and Montenegro.

⁹Dissolved in Dec. 1991.

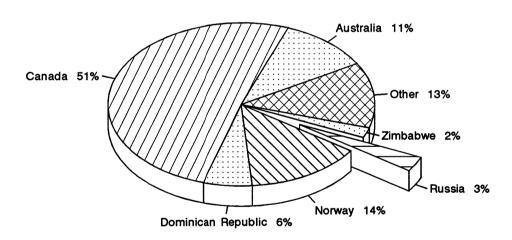

¹⁰Dissolved in Apr. 1992.

NITROGEN

By Raymond L. Cantrell

Mr. Cantrell joined the U.S. Bureau of Mines as a physical scientist in 1988. He formerly conducted fertilizer market research for the W. R. Grace & Co. Agricultural Chemicals Group (1972-87); plastics and rubber product development for Hasbro Industries (1968-72); and fertilizer and organics research and development for Columbia Nitrogen Corp. (1964-68). Domestic survey data were prepared by Gail D. Mason, statistical assistant; the world ammonia production table was prepared by Doug Rhoten, international data coordinator.

All life forms in the air, on land, and in the seas assimilate the Earth's renewable atmospheric nitrogen to sustain life and procreate. Elemental nitrogen gas and liquid, together with synthetic anhydrous ammonia—a derivative of atmospheric nitrogen and fossil fuels—form the base for a significant global agricultural fertilizer and industrial product industry.

Elemental nitrogen is used extensively by the electronics, metals, food, and aerospace industries because of its unique inert and cryogenic properties. Nitrogen contained in anhydrous ammonia and its downstream fertilizer derivatives is produced in about 75 countries around the globe and provides more than 50% of the world's essential plant nutrient demand for food and fiber. In the industrial sector, anhydrous ammonia derivatives are important for the production of synthetic fibers, resins and polymers, explosives, animal feeds, and a wide variety of inorganic and organic compounds.

U.S. ammonia output in 1992 rose to the highest level in 10 years, and total domestic demand reached levels not achieved since 1980; new production records were established for urea and ammonium phosphates. Industrial nitrogen gas demand continued to surge, and production reached a record 810 billion cubic feet, valued at \$0.9 billion. Record yields were established for U.S. corn and soybeans and near record yields for wheat under ideal weather conditions.

Heavy demand for domestic nitrogen products in 1992 was precipitated by a

significant increase in U.S. planted crop acreage, inordinately low carryout grain inventories at the domestic and global levels during the previous year, and a continuing trend of high production rates by the U.S. ammonium phosphate industry. Another factor of major significance was the entry of India as a major importer of global urea and the continued large-volume purchases by China and Vietnam. Producers outside the United States were hard pressed to meet urea demand in the face of product shortfalls in Eastern Europe and the Persian Gulf.

Ironically, global ammonia production plunged for the third consecutive year largely because of democratization initiatives in the former Eastern bloc, together with the dissolution of the U.S.S.R. in late-1991. Fertilizer production and consumption in these two regions fell collectively by 10% and 25% in 1992, although the former U.S.S.R. did manage to hold up nitrogen fertilizer trade in a quest to generate hard currency.

The ill-fated Uruguay Round of General Agreement on Tariffs and Trade (GATT), under negotiation since 1986, ended in a stalemate at the end of the year without any substantive progress toward removing agricultural trade barriers between the United States and the European Community. A last-ditch effort was made to finalize the negotiations by signing an Oilseed Accord between the two factions, but the French Government and farmers with the most to lose were apparently successful in quelling the

agreement.

Ammonia futures commenced trading on the Chicago Board of Trade (CBOT) on September 11, 1992. This action linked ammonia futures to the existing CBOT diammonium phosphate futures market and to the New York Mercantile Exchange (NYMEX) natural gas futures market, resulting in a valuable risk management tool for fertilizer producers and consumers alike.

The Environmental Protection Agency (EPA) issued Standards for the Use or Disposal of Sewage Sludge, final rule, under 40 CFR Parts 257, 403, and 503, in the Federal Register, Vol. 58. No. 32, February 19, 1993.

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on nitrogen compounds that are in compliance with Public Law 100-418, will begin to report nitrogen data in metric units. (See table 1.)

DOMESTIC DATA COVERAGE

Industry statistics for anhydrous ammonia and derivative products were developed by the Bureau of the Census, U.S. Department of Commerce. Preliminary monthly data were published under product codes 28731, 28732, and 28742 in Current Industrial Reports (CIR), Fertilizer Materials, M28B. In 1991, the Bureau of the Census adopted a quarterly format and replaced monthly series M28B with the quarterly series MQ28B, under the same title. Final data

are subsequently published in a companion annual report MA28B. During 1992, the Bureau of the Census surveyed approximately 250 known producers of inorganic fertilizer materials. Statistics covering industrial gases were reported in the Bureau of the Census CIR publications M28C, M28QC, and MA28C, Industrial Gases.

BACKGROUND

Nitrogen is an absolute requirement for all life forms on Earth. The gas cycles between its inert diatomic form (N₂) in the atmosphere and chemically fixed forms on Earth, weaving an intricate balance with the carbon cycle that is driven by the photosynthesis processes of living plants. Plants absorb carbon dioxide from the atmosphere, synthesize carbohydrates and essential amino acids and proteins (nitrogen forms), and emit oxygen, all prerequisite to life. The microorganisms of the rhizosphere topsoil supply available mineral nitrogen to nonleguminous plants and biological nitrogen to leguminous (nitrogen fixing) plants for human and animal nutrition.

Earth is enveloped by an atmosphere dominated by nitrogen (N_2) , oxygen (O_2) , and water vapor (H₂O), above which lies a delicately thin layer of protective ozone (O₃) that screens harmful ultraviolet radiation. Trace gases in the atmosphere such as carbon dioxide (CO₂) absorb much more radiant energy than they release, providing the additional warmth necessary for our habitation of the planet. The air we breathe consists of about 78% N₂ and about 21% O₂ by volume; argon makes up most of the remainder. Trace amounts of helium, hydrogen, krypton, neon, and xenon are natural atmospheric sources, together with the greenhouse gases-global warming gases-carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N_2O) .

Nitrogen chemical matter developed as part of our solar system about 5 billion years ago, according to astrophysics. About 4 billion years ago, volcanic activity was believed to have belched gases from the bowels of primordial

Earth, forming the nucleus for the nitrogen-rich atmosphere as we know it today. Nitrogen was discovered independently in 1772 by the Swedish druggist, Carl Scheele, and the Scottish botanist, Daniel Rutherford.¹

At the turn of the 20th century, natural sources of nitrogen chemical materials supplied virtually all of the nutrient requirements for agricultural crop production. Mineralized organic soil nitrogen, domestic animal manures and byproducts, guano, seed meals, and coke oven ammonia predominated. The mineralized occurrences of sodium nitrate found in the Atacama Desert of northern Chile also provided strategic supplies of agricultural nitrogen to the global community.

In the late-1800's, agronomists warned that a global food crisis would materialize unless supplemental nitrogen forms could be found to increase crop production for the exploding world population. Four major industrial nitrogen fixation technologies evolved between 1900 and 1920: (1) the electric arc process, developed by Birkeland and Eyde in Norway, produced nitric oxide (NO) from atmospheric nitrogen and oxygen that was used to produce nitric acid (HNO₃); (2) the cyanamide process, discovered by Frank and Caro in Germany, synthesized calcium cyanamide (CaCN₂) from calcium carbide (CaC₂) and N_2 ; (3) the cyanide process, developed by Bucher of Brown University in Rhode Island, produced sodium cyanide (NaCN) from N₂ and sodium carbonate (Na₂CO₃) as an intermediate to ammonia production; and, (4) the ammonia process, developed by Haber and Bosch in Germany, reacted N2 and hydrogen (H₂) under high temperatures and pressures in the presence of a catalyst to form ammonia (NH₃).

The Haber-Bosch process overshadowed all other industrial methods for producing nitrogen chemical materials and fostered today's mammoth ammoniabased nitrogen fertilizer and industrial sectors. This process was ideally suited for the large-scale commercial production of ammonia (82.2% N) because of the enormous natural resources of essential

chemical feedstock elements: nitrogen from the atmosphere, and hydrogen from fossil fuels (natural gas, petroleum, coal), and water.

Definitions, Grades, and Specifications²

At ordinary ambient temperature and pressure, anhydrous ammonia is a colorless gas with a very sharp, characteristic odor. Ammonia condenses to a liquid at minus 28° F. Anhydrous ammonia is not a poison and has no cumulative toxic effects on the human body. It, however, is corrosive and may cause lung, throat, mouth, nose, and eye irritation. When liquid anhydrous ammonia comes into direct contact with the skin, a severe burn may result. Anhydrous ammonia is not combustible except when its concentration in the air 16% 25% falls between to temperatures in excess of 1,560° F.

Ammonia vapor becomes "life threatening" only when exposure levels reach 2,500 to 6,500 part per million (ppm) for up to 30 minutes or "rapidly fatal" if exposure levels reach 5,000- to 10,000-ppm concentrations for up to 30 minutes. Steel is the only acceptable metal allowed in the process of transfer, storage, and transport of anhydrous ammonia.

Technology

Elemental nitrogen is mined from the air by cryogenic separation and membrane technologies. In a typical air separation plant, liquefied air is separated into its individual components by fractional distillation. The resources of nitrogen in the air are virtually unlimited and renewable because of the continuous nitrogen cycle between fixed forms on Earth and atmospheric nitrogen.

Mining.—Mineralized occurrences of sodium nitrate (NaNO₃) and potassium nitrate (KNO₃) are mined in significant quantities in the Atacama Desert of northern Chile. The extremely arid nature of this region, with its paucity of soil microorganisms, creates an ideal environment for preserving the nitrate

896 NITROGEN—1992

deposits that formed in Miocene times. The nitrate content of the deposits range from about 6.5% to 50%, with an estimated reserve base of about 2.5 billion tons.

Product grades of sodium nitrate and sodium nitrate-potassium nitrate mixtures are obtained through selective precipitation and filtering, followed by granulation. In 1992, Sociedad Quimica y Minera de Chile S.A. (SQM) produced more than 1 million tons of granular sodium nitrate and mixed potassium products for fertilizer and industrial use.³

SQM's principal product line, in order of importance, included sodium nitrate (16% N) and homogeneous chemical mixtures of sodium nitrate and potassium nitrate containing 15% N and 14% potash (K_2O). Sodium nitrate was also blended with potash to produce a mixed fertilizer containing 13% N and 44% K_2O .

Processing.—Anhydrous ammonia is typically produced through a sequence of catalytically driven reactions involving the steam reforming of natural gas in the presence of air to produce hydrogen and nitrogen in the proper ratio to effect ammonia synthesis. The latest state-of-the-art plants operate at less than 25 million British thermal units (Btu) per ton, resulting in an energy efficiency of more than 70%.

Modern ammonia plants employ efficient centrifugal compressors for air synthesis gas compression. Temperatures and pressures fluctuate throughout an ammonia plant depending on the process, but typically vary between 600° F to 1,800° F and 500 to 3,000 pounds per square inch gauge, respectively. A nickel catalyst is used in the reformer and associated front-end sections of the plant where nitrogen and hydrogen are manufactured from natural gas, compressed air and steam, while an iron-promoted catalyst is used to combine nitrogen and hydrogen to synthesize ammonia.

Urea is formed when ammonia is reacted with byproduct carbon dioxide (CO₂) generated during ammonia synthesis. The materials are reacted under high pressure in a two-step process

at about 400° F to first form ammonium carbamate, which then decomposes to urea (NH₂CONH₂).

Nitric acid is formed when ammonia is passed over a platinum-rhodium catalyst at about 1,700° F and 120-pound-persquare-inch gauge. As ammonia passes over the catalyst gauze, it reacts with oxygen to form nitric oxide (NO), which is converted to nitric acid by mixing with water in a countercurrent absorption tower

Ammonium nitrate, in turn, is formed by the simple acid-base reaction between ammonia and nitric acid, and urea and ammonium nitrate may be blended to produce the popular U.S. urea-ammonium nitrate (UAN) fertilizer solutions containing 28% to 32% N.

Economic Factors

Between 1970 and the early 1980's, natural gas prices rose dramatically, causing ammonia production costs to become much more sensitive to feedstock costs. Natural gas feedstock costs as a percentage of total production costs rose from 45% in 1970 to 75% by 1982. Natural gas prices have declined since 1985, and feedstock costs in 1992 represented about 65% of total ammonia production costs.

The U.S. ammonia industry experienced record profitability during 1974-75 because of a tight global supply-demand situation, in spite of the rising dependency on feedstock costs; a similar situation developed during 1979-81. Conversely, the U.S. ammonia industry suffered substantial losses in 1986-87 owing to a sustained period of oversupply in the world fertilizer and grain markets.

A dramatic recovery in the U.S. agricultural sector since 1987, accompanied by favorable energy prices, has led to a return to profitability in the domestic converted nitrogen industry. The profit margin for straight nitrogen compounds (urea, ammonium nitrate, and UAN solutions) has been more consistent, on average, than the more volatile, cyclical price swings experienced by the export-dependent ammonium phosphate industry.

On April 3, 1990, NYMEX established natural gas futures trading in the United States. Natural gas futures trading was designed to allow suppliers, producers, and end users to shift or hedge price risks. NYMEX believed that natural gas futures contracts would provide the same liquidity, unambiguous price reference, and hedge against risk characterized by its successful petroleum contract system. NYMEX futures trading suggested that a renewed upward spiral in natural gas prices would continue into 1993.

ANNUAL REVIEW

Legislation and Government Programs

The Food, Agriculture, Conservation, and Trade Act of 1990, Public Law 101-624, signed on November 28, 1990,4 introduced several creative mechanisms designed to promote environmentally sound and cost effective agricultural management practices, with the added objective of cutting discretionary Federal spending for farm programs. The 1990 farm bill provided the U.S. farmer with planting flexibility options ("triple base flexibility"), long-term Conservation Reserve and Wetlands Reserve Programs (CRP and WRP) designed to protect the environment and control grain inventories, and an Export Enhancement Initiative that would allow U.S. grain to compete in a global marketplace laden with unfair trade practices.

Under triple base, farmers lost Government deficiency payments on 15% of their base acreage but gained the flexibility to plant virtually any crop except fruits and vegetables on this land and still receive Government price support loans. The triple base initiative provided the impetus for a \$13 billion reduction in Government "entitlement" farm program spending over a 5-year period as prescribed by the Omnibus Budget Reconciliation Act of 1990 (Public Law 101-508), signed on November 5, 1990.5

Total Conservation Reserve Program (CRP) acreage was required to increase from a level of 34 million acres in 1990 to between 40 to 45 million acres by

1995. Following the 11th CRP signup in mid-1991, the U.S. Department of Agriculture (USDA) reported that total CRP acreage had increased to 35.4 million acres. Another 1.1 million acres was expected to be accepted following the 12th CRP signup in June 1992, raising the CRP to about 36.5 million acres. Congress, however, did not include money for the fiscal year 1993 signup, and allocations would reportedly be directed toward the WRP in the future. Lands available for WRP include restorable farmed wetlands that were converted to cropland prior to December 23, 1985, and functionally related wetlands, uplands, and riparian areas. In fiscal 1993, USDA was expected to accept about 50,000 acres in WRP.

The Alternative Agricultural Research and Commercialization Center (AARC) in Washington, DC, was empowered under title XVI (subtitle G) of the 1990 farm bill to create the world's most effective organization in generating new industrial (nonfood, nonfeed) market demand for U.S. farm and forestry products. AARC includes a distinguished board of directors from private industry whose mission is to apply sound business and technical practices that will facilitate the prudent development and commercialization of cost effective, environmentally friendly renewable industrial and consumer products. The new private ventures will create jobs, enhance rural economic development, and diversify agricultural markets.

AARC will serve to expand the commercial use of agricultural raw materials—traditional and new crops, forestry materials, and animal byproducts—through the introduction of industrial products such biodegradable automotive and industrial lubricants, biodegradable polymers for food packaging and eating utensils; and motor fuels and composites. The AARC legislation authorized two to six regional centers, and funds were appropriated to establish two centers in fiscal 1993. A major part of regional center work will be in developing private-public partnerships to submit applications for support from the AARC Center; at least 50% of the funding for a project must come from the applicant(s). By mid-1993, the AARC Board was to announce a \$10 million investment in projects.

The Clean Air Act of 1990 (Public Law 101-549)6 contained 11 titles that targeted 3 principal forms of pollution: acid rain, smog, and toxic air pollutants. One of the major impacts of the new clean air bill will be the emphasis placed on clean burning alternative fuels and the use of oxygenated fuels as air pollution control strategies. This strategy will have broad implications for both the United States and the international motor fuels market. The principal fuel oxygenates are methyl tertiary butyl ether (MTBE); ethanol, a derivative of corn; ethyl tertiary butyl ether (ETBE); and tertiary amyl methyl ether (TAME).7

EPA's Oxygenated Fuel Program became effective November 1, 1992, requiring gasoline marketers to supply oxygenated fuels for at least 4 months out of the year having a minimum average oxygen content of 2.7% by weight in the 39 cities that do not meet Federal air quality standards for carbon monoxide (CO). Information Resources Inc., a Washington, DC, consulting firm, estimates that in 1992, approximately 1.1 billion gallons of ethanol (419 million bushel corn equivalent) may be required to help meet the projected U.S. oxygenated fuel demand created by the Clean Air Act, and up to 2.4 billion gallons (894 million bushel corn equivalent) by the year 2000.8

EPA's Reformulated Fuel Program will commence on January 1, 1995, wherein the nine worst U.S. ozone nonattainment areas (Los Angeles, New York, Greater Connecticut, Baltimore, Philadelphia, Chicago, Milwaukee, Houston, and San Diego) will be required to sell gasoline with a minimum 2.0% by weight oxygen, 1% maximum by volume benzene, 25% aromatics maximum by volume, and no heavy metals (e.g., lead, manganese).

Acid rain is caused primarily by sulfur dioxide (SO₂) and nitrogen oxide (NO_x) emissions from coal-fired electrical powerplants. Under title IV, SO₂ emissions were slated to decline 10

million tons from 1980 levels by the year 2000 and NO_x emissions were to be cut by 2 million tons.

Under title III, a list of 190 hazardous chemicals and materials was established for regulation with the requirement that maximum achievable control technology (MACT) be applied to industries emitting major sources of air pollutants. Several important industrial nitrogen-containing compounds were on the list, including acrylonitrile, aniline, caprolactam, ethyl carbamate (urethane), hydrazine, coke oven byproducts, and cyanides.

Section 313 of EPA's Emergency Planning and Community Right-to-Know Act of the Superfund Amendments and Reauthorization Act (SARA) of 1986 (Public Law 99-499) required EPA to establish a national inventory of toxic chemical emissions from certain facilities, called the Toxic Release Inventory (TRI). The 1990 TRI indicated that for 275 chemicals surveyed, a total of 2.2 million tons was released to the environment or transported to publicly owned treatment works (POTW's).

In 1990, a total of approximately 240,000 tons of ammonia was released into the environment: 40% to the air; water, 8%; injection into underground wells, 49%; and disposal in landfills, 3%. Another 40,000 tons was disposed of in POTW's. The 1990 TRI data could not be compared statistically with prior surveys because of a change in survey methodology.

Between 1987 and 1989, ammonia losses to the atmosphere declined by 18%, and discharges into rivers, lakes, streams, and other bodies of water declined 25%. Ammonia processed through municipal waste-treatment plants rose 14%, and underground injection disposal methods increased 17%. Ammonium nitrate and ammonium sulfate solutions of unknown concentration were released to the environment in an aggregate total of about 65,000 tons in 1990.

The Energy Policy Act of 1992 (H.R. 776) was signed into law by the President on October 24, 1992. The comprehensive energy bill contained 30 titles covering nonrenewable and renewable energy

resources and was underscored by environmental and energy efficient mandates for the implementation of new technology and for long-range research and planning. Some of the provisions that apply to agriculture and the Department of the Interior may be found Title III—Alternative Fuels. General—the economic development of an 85% mixture of ethanol with gasoline or other nonrenewables; Title XII-Renewable Energy-biomass chemical conversion or direct combustion technology development; and Title XIII-Coal-clean coal technology that would reduce sulfur dioxide and nitrogen oxides in commercial powerplants and in nonfuel uses. The Secretary of the Interior was to provide consulting services to the Secretary of Energy for research and development of effective utilization of coal wastes and for the administration of mineral rights for coalbed methane projects on Federal lands. Title XVI-Global Climate Change—includes provisions for a 75% increase in energy derived from renewable resources over 1988 levels by the year 2005 and a reduction in the Nation's oil use from a level of approximately 40% of total energy consumption in 1990 to 35% by the year 2005.

Issues

Proposed Btu energy tax legislation on fossil fuels, together with environmental and transportation taxes, could result in a significant runup in prices for fertilizers and other agricultural commodities. An all-out assault against new taxes by The Fertilizer Institute (TFI) member companies and related agricultural organizations has drawn the attention of Congress and major media, including the Wall Street Journal and the Associated Press. A second wave of legislation involving fertilizer use taxes may also be proposed to help pay for the health care reform plan.

If the energy tax bill is passed at \$0.257 per million Btu as proposed, domestic production costs for fertilizer and industrial-grade ammonia will

increase about \$10 per metric ton (10%), or an additional \$160 million annually, and for urea about \$0.70 per ton, or \$6 million annually. The total Btu tax for all fertilizer products could easily reach the \$200 million mark annually.

The passage of an inland waterway user fee tax for fertilizer transport would amount to \$64 million in 1993 and gradually escalate to \$150 million by 1997. Therefore, the U.S. fertilizer industry and agricultural sector could be looking at total tax increases in excess of \$0.5 billion annually.

The large Saskferco ammonia and urea project came on-stream in the fall of 1992 at Belle Plaine, Saskatchewan, and continued to be monitored by the U.S. Ad Hoc Committee of Domestic Nitrogen Producers and the Canadian Council of Nitrogen Producers. The International Trade Commission (ITC), Department of Commerce, **Import** Administration (IA), and the U.S. Trade Representative had been lobbied by the groups in 1991 regarding potential injury to other North American nitrogen producers and unfair subsidization of the project, a joint venture between Cargill Fertilizer of Minneapolis, MN, the Crown Corp. of Saskatchewan, and Citibank Canada.

EPA's phase 2 Drinking Water Well Survey released in late 1991 gave new merit to industry calls for site-specificity in solving water quality problems. The multiyear study concluded that nitrate occurrence in U.S. waters is a limited, site-specific problem and cannot be generally predicted by a simple set of factors. EPA concluded that a variety of environmental conditions and human activities combine to affect the occurrence of pesticides and nitrate in drinking water wells and that no one single factor can explain their presence.

The TFI, Washington, DC, met with EPA to discuss the nitrate in drinking water issue. TFI pointed out that EPA's study had refuted the commonly held theory that a national drinking water quality problem exists and that a simple reduction in nitrogen fertilizer use would solve the problem. TFI also reported that the few documented cases of

methemoglobinemia ("Blue Baby Syndrome") on record involved nitrate levels at several multiples of EPA's 10ppm limit.

Production

The U.S. ammonia industry operated at 101% of design capacity in 1992, indicative of the tight supply-demand conditions for ammonia and downstream conversion products. Thirty-four firms in 24 States across the country, including Alaska, produced 16.3 million metric tons of anhydrous ammonia (82.2% N), 5% more than in 1991. (Louisiana, Oklahoma, and Texas, in order of importance, provided about 60% of total U.S. production; the Midwest, 15%; South and Southeast, 16%; and the Western States and Alaska, 9%.)

Natural gas feedstock was available in \$1.80-per-million-Btu range, providing the industry with favorable profit margins at the wholesale level in the case of straight nitrogen fertilizers and for industrial products. The TFI Production Cost Survey for 1992 indicated that overall ammonia production costs were up about 3%, from roughly \$99 per metric ton in 1991 to \$102 per ton in 1992. Production costs rose principally because of moderate increases in natural gas and electrical power.

About 90% of the ammonia produced in U.S. plants was allocated to domestic fertilizer use and trade, and about 10% went into industrial products. Major downstream ammonia fertilizer derivatives included urea, 46% N; diammonium phosphate (DAP), 18% N; monoammonium phosphate (MAP), 11% N; ammonium nitrate, 35% N; and ammonium sulfate, 21% N. Important industrial chemical derivatives were urea, ammonium nitrate, nitric acid (22% N), acrylonitrile (26% N), and caprolactam (12% N). (See tables 2 and 3.)

CF Industries of Long Grove, IL, one of North America's largest interregional cooperatives, supplies nitrogen, phosphate, and potash fertilizer products to more than 1 million farmers and ranchers in 46 States and 2 Canadian Provinces. CF's ammonia, urea, and

UAN Nitrogen Complex at Donaldsonville, LA, is the largest facility of its kind in the United States. The company also holds a joint-venture interest in Canadian Fertilizers Ltd., a large ammonia and urea complex at Medicine Hat, Alberta. CF also operates a wholly owned ammonium phosphate facility at Plant City, FL, having an annual capacity of 2 million product tons.

CF's \$87 million expansion project at Donaldsonville, LA, approved in mid-1991, was well advanced and scheduled for completion by mid-1993. This project will increase production capacity for granular urea and UAN solutions and provide CF with cost effective nitrogen fertilizers to meet the projected demand of its members during the 1990's.9

The Donaldsonville ammonia plants were capable of operating at 1.8 million tons per year—120% of design capacity—because of recent revamp and retrofit initiatives that led to further improvements in the cooperative's competitive economics. CF management reported that ammonia emissions were reduced by 60% and NO_x emissions by 33% from 1987 levels.

On July 22, 1992, CF acquired an ammonia terminal at Tampa, FL, for \$22 million, owned most recently by Mulberry Phosphates and earlier by the Royster Co. The primary acquisitions included an ammonia terminal on the Port of Tampa having a 40,000-ton storage tank and related distribution equipment, together with an ammonia pipeline joint venture with Seminole Fertilizer. The location of the storage facility is strategic in that only 37 rail miles will be required to deliver ammonia to CF's Plant City ammonium phosphate plant as an alternative to sourcing ammonia from Donaldsonville, about 850 rail miles. The Tampa Bay Pipeline system supplies ammonia to major producers ammonium phosphates in Polk County, FL.

Mississippi Chemical Corp. (MCC) completed a \$32 million state-of-the-art nitric acid plant and ammonium nitrate neutralizer section at Yazoo City, MS, late in the year. The new 550-ton-per-

day nitric acid plant was scheduled to replace two obsolete plants having a combined capacity of 330 tons per day. The new plant will provide for both a production increase and simultaneous output of Amtrate solid ammonium nitrate and N-Sol UAN solution. MCC joined Arcadian Corp. and Agricultural Minerals Corp. as a member of the UAN Solutions Export Association during the year.

In early 1992, MCC's ammonium phosphate facility at Pascagoula, MS—Mississippi Phosphates—was brought to full capacity, based on the reaction between ammonia and wet-process phosphoric acid produced from imported Moroccan phosphate rock. Atlantic Fertilizer and Chemical Corp. contracted to market the DAP output rated at 700,000 tons per year.

Early in the year, Koch Industries, Inc., assumed control of the large ammonia complex at Sterlington, LA, formerly owned by the IMC Fertilizer Group, Inc. (IMCF). The Sterlington complex consists of two ammonia trains having a total capacity of 1 million tons per year. The acquisition provided a good fit for Koch Industries, owner of the Gulf Central Ammonia Pipeline that serves the Sterlington plant. An ammonia supply contract for a portion of IMCF's New Wales, FL, DAP-MAP complex was also to be negotiated. During October, IMCF reached an agreement in principal to purchase the Conserv, Inc. 550,000-ton-per-year DAP plant at Nichols, FL, owned by EniChem Agricoltura S.p.A. of Milan, Italy.

In August, Cargill Fertilizer of Minneapolis, MN, commissioned C\$435 million nitrogen fertilizer complex—the Saskferco project—in Belle Plaine, Saskatchewan, through corporation formed between its Canadian subsidiary. Cargill Ltd., the Crown Investments Corp. of the Province of Saskatchewan, and Citibank Canada. The plant was designed to produce 510,000 tons per year of ammonia and 680.000 tons per year of granular urea. 10

More than one-half of the Saskferco output was scheduled to move through Cargill retail and wholesale distribution outlets. Agreements were reportedly reached with other large retail distributors for the sale of the remaining product, including Land O'Lakes, Inc., and Farmland Industries, Inc. in the United States. Product was to be marketed in western and eastern Canada, the north-central region of the United States, and offshore.

Farmland Industries, Inc. and J.R. Simplot assumed joint-venture ownership of the former Chevron phosphate rock mine at Vernal, UT, and DAP plant at Rock Springs, WY, in early 1992. Annual DAP production capability at Rock Springs is 410,000 tons. Farmland was moving the former Chevron Finley, WA, nitrogen solutions plant to its primary nitrogen production complex at Enid, OK.

In late July, Arcadian Corp's. urea synthesis reactor at Lake Charles, LA, sustained irreversible damage that resulted in the closure of the complete facility. The closure represented a loss of 190,000 annual tons of urea capacity and about 400,000 annual tons of ammonia, tightening U.S. nitrogen supplies for the fall season. Arcadian ultimately decided to mothball the ammonia facility for an indefinite period.

BP International completed a \$17 million, 90,000-ton-per-year nitric acid replacement-expansion at Lima, OH, that came on-stream in September 1992. Weatherly Inc. was contracted to build the plant, which increased capacity by 27%, improved the ammonia efficiency and energy recovery, and lowered NO_x emissions by 95%. At Lima, BP produces about 500,000 tons of ammonia, 310,000 tons of urea, and 200,000 tons of nitrogen solutions per year.

Unocal permanently closed the former Chevron 130,000-ton-per-year ammonia plant at Finley, WA, purchased in 1991, but continued to use the complex for storage and distribution. Unocal was to toll ammonia from Chevron's 20,000-ton-per-year El Segundo, CA, plant. Chevron planned to continue operating a wholly owned 80,000-ton-per-year ammonia plant at St. Helens, OR, until a buyer could be found and planned to sell its 1,000-ton-per-day nitric acid plant at Riverton, KS, shuttered since 1982. (See

900 NITROGEN-1992

table 4.)

In late October, Nitrogen Products Inc's. 190,000-ton-per-year ammonia plant at Helena, AR, was closed in bankruptcy proceedings by the Dutchowned bank NMB and was reportedly to be dismantled. The fledgling former Big River ammonia project at Helena had been purchased by an investment consortium in bankruptcy proceedings during 1989 and renamed Five Rivers. The plant was subsequently closed in mid-1990 owing to a lack of reliable power sources and equipment failures, and ownership was transferred to the original lending institution, NMB.

Diamond Shamrock acquired the Center Plains ammonia facility at Dumas, TX, in bankruptcy proceedings through a repurchase agreement in 1990 and reactivated one of the two 70,000-ton-per-year plants on-site in early 1991. The second train was reactivated during 1992.

Agricultural Minerals Corp. (AMC) of Tulsa, OK, went public on the New York Stock Exchange as Agricultural Minerals Co. LP. AMC was founded by former Agrico executives to facilitate a leveraged buyout of the firm's nitrogen fertilizer production facilities at Verdigris, OK, and Blytheville, AR, on March 1, 1990. Ammonia, urea, and UAN solutions are the primary products produced by AMC, along with the highly efficient slow-release Super N fertilizers containing dicyandiamide. AMC was among the top five U.S. nitrogen fertilizer producers.

Coastal Chem, Inc. planned a 175,000-ton-per-year ammonia expansion at Cheyenne, WY, based on the reconstruction of a plant to be purchased and moved from another nitrogen complex. Coastal completed a 130,000-ton-per-year nitric acid plant at Elko, NV, to be used for the production of ammonium nitrate-based explosives.

Hydro Agri Ammonia, Inc. (HAAI), a U.S. affiliate of the Norwegian firm Norsk Hydro, continued to market ammonia from the former W.R. Grace & Co. joint-venture Tringen plants now run by Norsk and the Government of Trinidad and Tobago at Point Lisas. HAAI is headquartered in Tampa, FL,

for this purpose and is staffed by key personnel from the former Grace marketing team in Memphis, TN.

In late 1991, Norsk became a joint-venture partner in Farmland Industries' Green Bay, FL, phosphate operation. The Farmland Hydro Ltd. Partnership group began operating from headquarters in Bartow, FL, on November 16. The Green Bay facility had a DAP/MAP production capability of about 1 million tons per year.

Terra International, Inc. completed a 70,000-ton-per-year ammonia expansion at Port Neal, IA, in late 1992 that was to bring total annual capacity to about 270,000 tons. Emissions were also to be reduced 30%. Terra also announced a \$15.5 million retrofit project that would provide for the optional production of up to 400 tons per day of methanol in the existing 1,200-ton-per-day ammonia plant at Woodward, OK, by early 1994. Ammonia capacity would reportedly be reduced by up to 20% because of the swing with methanol, but there was an upside advantage in hedging against fertilizer market seasonality. Methanol was to be sold to producers of methyl tertiary butyl ether (MTBE), the leading automotive fuel oxygenate.

American Cyanamid's 680-ton-per-day ammonia plant at Fortier, LA, idle since 1983, was also to be converted to methanol production for MTBE synthesis. Lurgi and the U.S.-based Pritchard Corp. were contracted to execute a detailed engineering design for a 1,700-ton-per-day methanol plant to be operated as a joint ventrue between Cy Tech., the new American Cyanamid chemicals business, and the firm Methanex.

Consumption and Uses

U.S. apparent domestic consumption of ammonia reached 13.4 million tons N in 1992—5% above the prior year—representing a level that had not been achieved since 1980. Fertilizer materials accounted for about 80% of domestic ammonia demand and industrial applications accounted for about 20%.

Urea and ammonium nitrate found

extensive use in the fertilizer and industrial sectors in both solid and liquid form. UAN solution fertilizers that contain 28% to 32% N were growing in popularity because of their safe handling and storage characteristics and ease of application.

In the industrial sector, urea was used in the production of synthetic fibers, resins, and polymers and as a protein supplement in ruminate animal feeds. Ammonium nitrate-fuel oil explosives (ANFO) dominated the industrial explosives sector. Nitric acid was used in chemical synthesis and in metal treatment. Acrylonitrile and caprolactam found respective use in the production of acrylic and nylon fibers, resins, and plastics. (See table 5.)

Other uses for ammonia and ammonia-base compounds included consumption as ammonia refrigerant, in specialty horticultural and lawn and garden fertilizers, home and industrial cleaners, fuel ethanol derived from corn and other biomass species, and as sodium azide propellant in vehicular air bags. Ammonia and urea were also becoming popular low-cost agents that significantly reduced NO_x atmospheric emissions when injected into combustion gas streams. 11

In 1992, ammonia and ammonia derivatives accounted for 55% of the 18.7-million-ton primary fertilizer nutrient market in the United States. The ratio of nitrogen nutrient consumption to phosphate and potash fertilizer nutrient consumption was 2.7:1 and 2.3:1, respectively.

U.S. nitrogen fertilizer consumption reached 10.3 million tons N in 1992 compared with 10.2 million tons N in 1991. Single-nutrient compounds led by direct application ammonia, UAN solutions, urea, and ammonium nitrate, in order of importance, provided 80% of the total. Nitrogen solutions were up 5% in 1992, but direct application ammonia fell 2%. (See table 6.)

The six States that comprise the Midwest Corn Belt—Illinois, Indiana, Iowa, Missouri, Nebraska, Ohio—together with Minnesota, consumed 4.3 million tons N, 41% of the U.S. total. Texas, Kansas, California,

North Dakota, and Oklahoma, in order of importance, accounted for 2.5 million tons N, 24% of the total.

Planted crop acreage rose 6 million acres to a total of 343 million acres in 1992, from 337 million acres in 1991, and another 54 million acres was idled by crop programs and the CRP. Record yields were recorded for corn and soybeans, and near record yields recorded for wheat and cotton. Carryout inventories of major feed and food grains did not increase significantly, except for corn. U.S. net cash farm income in 1992 was expected to approximate \$60 billion, only \$1 billion below the record \$61 billion established in 1990. The Secretary of Agriculture raised the acreage setaside (ARP) on corn to 10% for next year, but dropped the wheat and barley setaside to 0%. In the fall of 1992, Doane Agricultural Services Co., St. Louis, MO, reported that net cash farm income could reach a record \$63 billion in 1993.

Stocks

U.S. stocks of major nitrogen compounds increased about 11% at the producer level and ended the year at 1.8 million tons N. There was a 9% drawdown in ammonium nitrate inventories. (See table 7.)

Transportation

Ammonia was transported refrigerated barge, rail, pipeline, and truck. In late 1990, the Research and Special Programs Administration (RSPA) of the U.S. Department of Transportation (DOT) classified anhydrous ammonia as a nonflammable gas linked to a required "inhalation hazard" label. **RSPA** officially classified anhydrous ammonia a Division 2.2 nonflammable. nonpoisonous compressed gas for domestic shipments. 12 The inhalation hazard label requirement, including nurse tanks, became effective October 1, 1992.

International shipments, however, were classified as a Division 2.3 "poison gas" consistent with United Nations regulations. International shippers were

originally required to comply under the new regulations on January 1, 1991. Because of the documented inhalation hazards of anhydrous ammonia when released in large quantities, RSPA was also requiring the words "INHALATION HAZARD" on packages and shipping papers, in addition to other current hazard communications information.

The Interstate Commerce Commission (ICC) replaced the Federal Energy Regulatory Commission (FERC) as the Federal agency responsible for ammonia pipeline regulation in late 1990. FERC had been responsible for ammonia pipeline regulation since 1977, when ICC transferred power of control under the Department of Energy act.

Koch Industries operated the Gulf Central Pipeline built in 1969 that extended about 1,900 miles from the Gulf of Mexico into the Midwest, as far north as Iowa. The annual capacity of this pipeline is about 2 million tons, and storage tanks along its path have an additional capacity of more than 1 million Koch Nitrogen, a subsidiary, tons. purchased four Midwest ammonia terminals from ConAgra Fertilizer in 1991 having a combined capacity of 150,000 tons. The pipeline was to be extended 15 miles to the firm's Wood River, IL, terminal by the end of the year.

Mapco Ammonia Pipeline Inc. operated Mapco Ammonia Pipeline and its sister company, Mid-America Pipeline, along a 1,098-mile corridor that extended in a northeasterly direction from Borger, TX, in northern Texas, to Mankato, MN, in southern Minnesota. Mapco built the first leg of the pipeline in 1968-69 and, by 1978, had added six extensions. The Mapco pipeline has an annual capacity of about 1 million tons, and about 500,000 tons of ammonia storage capacity was located along the pipeline.

Mapco Ammonia Pipeline neither produced nor marketed ammonia independently, but transported ammonia on behalf of five shippers. Competition from the rail and truck transportation sectors was minimized because areas served by Mapco Ammonia Pipeline did not have river access. Mid-America Pipeline had more than 400 shippers and competed with the other transportation sectors. 13

Seminole Fertilizer and CF Industries were operating the Tampa Bay Pipeline system, a joint-venture ammonia pipeline that serves ammonium phosphate producers in Polk County, FL.

Markets and Prices

Anhydrous ammonia prices continued to decline through the first quarter, following a trend established during December 1991, and reached a low of \$91 per metric ton, f.o.b. barge, New Orleans, in early March. Prices reached about \$111 per ton near the end of the strong domestic spring fertilizer season, but declined to first quarter levels during July and August. Ammonia prices rose steadily thereafter as supplies tightened owing to steady demand, the closure of Arcadian's Lake Charles, LA, plant in late July, and gas shortages on the gulf coast precipitated by Hurricane Andrew in the fall. Ammonia prices peaked at \$130 per ton by yearend. At yearend, September 1993 ammonia futures contracts were trading on the Chicago Board of Trade (CBOT) for \$136 per ton, f.o.b. barge, Louisiana.

In contrast, urea and ammonium nitrate prices were stable to firm for most of the year. Granular urea prices peaked at a heady \$165 per ton, f.o.b. New Orleans, from mid-May to mid-June and averaged \$150 per ton for the year.

DAP prices, f.o.b. Central Florida, continued to trend downward following a pattern established in the fourth quarter of 1991. In January, prices stood at \$151 per ton, but gradually deteriorated to a meager \$125 per ton at yearend. The U.S. DAP industry was plagued by an inordinate supply overhang during 1992 that was accompanied by a combination of record production, stagnant domestic demand, and a significant decline in export sales to China and India. At yearend, September 1993 DAP futures were trading on the CBOT for \$136 per ton, f.o.b. central Florida. (See table 8.)

Foreign Trade

In 1992, the U.S. ammonia trade deficit was estimated at 2.8 million product tons, slightly larger than the 2.6-million-ton deficit of 1991. A trade deficit occurs whenever more product is imported than is exported.

Ammonia imports originated from Trinidad, Canada, the former U.S.S.R., and Mexico, in order of importance. Ammonia imports from the former U.S.S.R. were down about 30% from 1991 levels because of a substantial drop in fall shipments. Most of the loss was made up by an increase in Mexican shipments, however. U.S. ammonia imports in 1992 were valued at \$366 million, representing an average landed price of \$112 per ton, c.i.f., in comparison to \$392 million, or \$118 per ton, in 1991. (See tables 9 and 10.)

Anhydrous ammonia import tonnage data from the former U.S.S.R. continued to be withheld from the public domain during 1992 because of a previous ruling by the Bureau of the Census that determined Occidental Petroleum to be the proprietary U.S. agent. Occidental's long-term trade pact with the former U.S.S.R. involving ammonia superphosphoric acid may no longer apply, however, owing to the dissolution of the U.S.S.R. in late 1991. Although Occidental was successful in dealing for ammonia, the new independent Republics were forced to discontinue purchases of Occidental superphosphoric acid because of a lack of hard currency; only one shipment was known to occur in 1992.

Ammonia shipments originated predominately from the Black Sea port at Yuzhnyy in the Ukraine with minor shipments from Estonia and Latvia on the Baltic Sea. MAP shipments from Russia and the Ukraine to the United States were 122,000 tons, somewhat of a surprise in light of the depressed U.S. ammonium phosphate market, but in line with the global press for hard currency. Russia and the Ukraine landed MAP at a value of \$16.4 million, or \$134 per ton, c.i.f.

The United States continued to experience a significant urea trade deficit amounting to 0.6 million product tons in

1992, about the same as in 1991. Approximately 1.6 million tons of urea was imported from 19 countries in 1992 that carried a landed value of \$204.5 million, or \$131 per ton, c.i.f. Urea import volume and landed prices did not change significantly in 1992. Canada shipped 75% of the total; Mexico, Trinidad, Brazil, and Venezuela, 13% in aggregate; Italy, the Netherlands, and France, 8%; and Poland and Bulgaria. 3%. The landed price of Bulgarian urea was reported to be \$82 per ton, c.i.f., well below average. Germany shipped only 403 tons at a value well above the average. ITC urea antidumping duties levied against the former U.S.S.R., the former German Democratic Republic, and Romania have been effective preventing the subject countries from landing urea at prices below fair market value.

Ammonium nitrate was also imported in significant quantities amounting to 0.4 million tons, valued at \$55.5 million, or \$125 per ton, c.i.f. More than 93% of the total was Canadian product. The United States exported a modest 40,000 product tons in 1992.

U.S. ammonium phosphate exports in 1992 fell to 9.2 million product tons (1.6 million tons N equivalent), representing a net decline of 1.3 million tons, 13% below the 10.5 million tons shipped in 1991. The major decline can be traced to DAP trade with China, where volume plunged 1.4 million tons (29%), and to India, where volume fell 0.4 million tons (23%). Industry analysts reported that the actual decline was lower than indicated because Chinese DAP tonnage in 1991 had been double counted in certain instances. MAP trade was up about 5% to 0.9 million tons in 1992.

The United States experienced a total converted nitrogen trade deficit of 1.0 million tons N in 1992, about 67% above the 0.6-million-ton N deficit established in 1991. In total, the United States imported about 3.8 million tons of N in compounds that carried a landed value of \$866.3 million. (See tables 11 and 12.)

World Review

Global ammonia production fell precipitously for the third consecutive year to a level of 92.5 million tons N, representing a decline of 1.6% from 94.0 million tons N in 1991 and 6.8% from the near-record 99.3 million tons N produced in 1989. Since 1989, production in the former Eastern bloc countries has declined 4.2 million tons N (-43%); the former U.S.S.R., 3.8 million tons (-19%); Western Europe, 1.0 million tons (-11%); and the Middle East, 0.6 million tons (-15%). This 9.6-million-ton N drop has been tempered somewhat by rising net production in other regions, especially Asia and North America.

Anhydrous ammonia N was produced in some 75 countries during 1992, of which about 10 million tons N (10%) was directly traded. Ammonia was converted into about 35 million tons of urea N in 59 countries, of which about 9 million tons (26%) was traded. Total world nitrogen fertilizer consumption fell about 4% to a level of 74 million tons N, according to data available in November, and trade accounted for about 19 million tons N, or 26% of the total. China, the world's largest urea importer, together with the recent entry of India and Vietnam as large-volume urea importers, served to maintain a relatively tight global nitrogen materials trade balance in 1992.

Eastern Europe and the former U.S.S.R. have suffered significant losses in domestic production and consumption because of sweeping political reforms, accompanied by high inflation and foreign exchange problems. Western Europe has been negatively impacted by inflated natural gas prices, an attendant decline in competitive economics, and a downturn in domestic agriculture. Recession, the reunification of Germany, transition to the new European Community reform (EC-92), and declining demand in Eastern Europe and the former U.S.S.R. have also been contributing factors. Mideast downturn was primarily a result of events surrounding the Persian Gulf Crisis and ensuing Operation Desert Storm initiatives of 1990 and 1991.

It is estimated that between 1989 and

1992, domestic nitrogen fertilizer consumption has declined 3.7 million tons N (-37%) in the former U.S.S.R.; 2.8 million tons (-62%) in Eastern Europe; and 1.5 million tons (-14%) in Western Europe.

dissolution of the centrally The planned economy of the U.S.S.R. commanded global attention in 1992 and resulted in the evolution of 15 independent republics. The new republics were plagued by a combination of high inflation and drastic cuts in domestic nitrogen fertilizer production and consumption. Ironically, the region continues to dominate global nitrogen trade, accounting for 3.5 million tons N, or 37% of global ammonia exports, and 2.8 million tons N, or 29% of global urea exports in 1991.

In 1992, the former U.S.S.R. was further pressed to generate hard currency through ammonia and urea export volume, at the expense of domestic production and consumption. Urea export volume rose another 8% to 3.0 million tons N, but ammonia trade may have fallen by as much as 10% to the 3-million-ton N level. Exports of ammonium phosphates may also have reached significant proportions in 1992.

Ammonia was produced in 9 of the 15 new independent republics in 1992, of which Russia accounted for 56% of the total; the Ukraine, 25%; Uzbekistan, 8%; Belarus, 6%; Estonia and Lithuania, 3%; together with Kazakhstan, Georgia, and Turkmenistan, 2%. The ammonia plants were designed for output but not efficiency, and gas costs were reported to have risen dramatically in 1992. Natural gas in the Russian Republic at midyear was about \$16 per thousand cubic meters, or \$0.45 per million Btu, equating to an ammonia production cost of about \$40 per metric ton.

If gas is fully deregulated by the end of 1993 in Russia, as planned, feedstock prices may increase to roughly \$60 per thousand cubic meters, or \$1.70 per million Btu. This could potentially escalate ammonia production costs to about \$90 per metric ton and urea to \$100 per ton, values that may be prohibitive to export competitiveness on

the U.S. gulf coast. A full-scale revamp of Russian ammonia and urea plants was needed. Russian gas was deregulated and priced at \$2.55 per million Btu to Europe.

All Eastern European countries are now forced to rely heavily on costly, deregulated Russian gas for ammonia and urea production and other Romania, Hungary, Poland, and the former Yugoslavia, in order importance, have sizable gas production, but still require significant imports. Bulgaria and Czechoslovakia rely almost exclusively on Russian gas imports. Romania, Poland, Bulgaria, the former Yugoslavia, Czechoslovakia, Hungary, in respective order importance, are all major participants in the Eastern European ammonia industry. In 1992, about 47% of the natural gas consumed in Eastern Europe was supplied from domestic production and 53% was imported from the former U.S.S.R. Escalating natural gas prices have driven ammonia and urea production costs up to near-prohibitive levels. precipitating critical shortages of nitrogen fertilizers for domestic use and export.

Operation Desert Storm resulted in severe damage to nitrogen plants in both Kuwait and Iraq during January and February 1991. Information available on the damage and destruction of nitrogen production facilities in the two countries last year indicated that it would take a minimum of 5 years to bring nitrogen output back to normal, but recent information indicates that production facilities will come back into operation on a more timely basis.

In Kuwait, a 271,000-ton-per-year N ammonia plant and 216,000 annual tons of urea N came back into operation during 1992 at Shuaiba, and preinvasion capacity levels were scheduled to be operational by 1994. In Iraq, the new 272,000-ton-per-year N ammonia plant at Baiji was operational in 1992, together with a 265,000-ton-per-year N urea facility. Preinvasion capacity was also scheduled to be restored to full operation by 1994.

Iraq and Kuwait, in combination, had represented about 1.5% of total world

ammonia capacity and 2.5% of world urea capacity. In 1989, Iraq and Kuwait accounted for about 5% of total world urea and ammonia N trade. This, together with the supply potential of the other Persian Gulf countries, accounts for about 15% of world nitrogen trade in the form of ammonia and urea.

Industry Structure.—Global ammonia was produced in 75 developed and developing countries that had access to fossil fuel feedstocks, principally, natural gas, naphtha, petroleum refinery offgases and condensates, and coal and coke gases. The supply pattern, in general, followed the world population trend, with Asia and Eastern Europe, including the former U.S.S.R., accounting for more than 60% of the global ammonia supply capability and 58% of production in 1992. The developed regions-North America (United States and Canada), Western Europe, and Oceania-produced ammonia primarily for domestic use and accounted for about 26% of world supply capability and 30% of global production in 1992. The energy-rich countries of the Middle East accounted for about 5% of the world supply capability and 4% of global production in 1992 and exported significant quantities of ammonia and urea to the global community. Latin America and Africa, in order of importance, accounted for the remaining 7% of global ammonia supply capability.

Capacity.—Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

In 1992, there was a net gain in global ammonia capacity of about 1.6 million annual tons N (1.4%) and about 2.1 million annual tons N (5%) of urea. At

yearend, world ammonia capacity stood at about 119 million annual tons N and urea at 46 million annual tons N.

New ammonia and urea capacity was brought on-stream during 1992 in Asia: Bangladesh, China, India, Indonesia, and Pakistan; the Middle East: Kuwait and Iraq (repairs), and Turkey; Western Europe: Belgium; North America: Canada; and, Africa: Egypt, in relative order of importance. Approximately 1.3 million annual tons of ammonia N and 0.3 million annual tons of urea N was closed in Eastern Europe: Hungary, Romania, and the former Yugoslavia.

Major world ammonia and urea capacity contracted or under construction and scheduled on-stream during 1992-95 approximates 7 to 8 million annual tons of ammonia N and 4 to 5 million annual tons of urea N. Potentially, up to 1 million annual tons of ammonia N could close in Western Europe during this timeframe, assuming that the following capacity materializes as planned.

Asia.—China.—1.5 million annual tons ammonia N and 1.3 million tons urea N. Bangladesh—0.4 million annual tons ammonia N and 0.3 million tons urea N. India—2.0 million tons ammonia N and 1.1 million tons urea N. Indonesia—0.8 million tons ammonia N and 0.7 million tons urea N. Pakistan—0.5 million tons ammonia N and 0.5 million tons urea N.

Middle East.—Iran.—0.3 million tons ammonia N and 0.2 million tons urea N. Iraq (reconstruction)—0.3 million tons ammonia N and 0.3 million tons urea N. Kuwait (reconstruction)—0.6 million tons ammonia N and 0.2 million tons urea N. Saudi Arabia—0.4 million tons ammonia N and 0.3 million tons urea N. Turkey—0.2 million tons ammonia N.

Eastern Europe.—Romania—0.3 million tons ammonia N (restart idle plant). Former Yugoslavia—0.2 million tons ammonia N (restart idle plants).

Africa.—Egypt.—0.1 million tons ammonia N. Republic of South Africa—0.2 million tons ammonia N.

Former U.S.S.R.—Ukraine.—0.4 million annual tons urea N.

Latin America.—Trinidad and Tobago.—0.1 million tons ammonia N and 50,000 tons urea N. (See table 13.)

Current Research

USDA and DOE's "memorandum of understanding" on biomass research will accelerate the development of ethanol and other alternative fuels and fuel additives from agricultural and forestry products. ¹⁴ This agreement promised significant new markets for U.S. farmers and supported the President's National Energy Strategy that focused on a reduction in foreign energy dependency.

In September 1991, the President designated the Solar Energy Research Institute at Golden, CO, as the National Renewable Energy Laboratory (NREL). Elevating the status of this facility to a National Laboratory reflects the strong commitment to renewable technology research and development (R&D). During 1991, NREL signed a cooperative R&D agreement with a cornethanol producer to test a process to convert the cellulose in corn into ethanol. Later in the year, DOE signed a similar cooperative agreement with a major oil company to explore ethanol production from waste paper.

In April 1992, work began on the National Alcohol Fuels User Facility in Golden, CO. This work will include construction of a process development unit for testing new biofuel conversion technology. DOE will develop a cellulose-to-ethanol process development unit at NREL. The unit will evaluate methods for converting wood cellulose into ethanol fuels and serve as the centerpiece for the National Alcohol Fuels User Facility. 15

M. W. Kellogg of Houston, TX, announced two major advances in its ammonia process technology: the Kellogg Reforming Exchanger System (KRES) and the Kellogg Advanced Ammonia Process (KAAP), a joint technology development with British Petroleum.

Kellogg's KRES design was

revolutionary in that it completely eliminated the conventional fired primary reformer from the ammonia production process. KRES is environmentally attractive because without a primary reformer, nitrogen oxide emissions are substantially reduced. The system could be easily installed in new or existing plants and would save up to 10% on capital costs.

The KAAP process employs a novel ammonia synthesis catalyst that was claimed to be the first significant breakthrough in catalyst technology since 1927. The proprietary KAAP catalyst is up to 20% more active than conventional iron catalysts. The KAAP system was to be employed in a retrofit project designed to increase production capability by 40% at Ocelot's ammonia plant in Kitimat, British Columbia.

Tetra Technologies, Inc. of The Woodlands, TX, developed a continuous countercurrent ion exchange (CCIX) method for the removal of nitrate contaminants from mine waste streams, including residual unreacted ammonium nitrate-fuel oil explosives, and in gold mining where waste nitrates result from the nitric acid washing of activated carbon and the oxidation of cyanide during heap detoxification. The system was also reported to be effective in controlling nitrate effluent levels in dairy and other agricultural operations.

Exxon Research and Engineering Co. of Florham Park, NJ, developed a process that significantly reduced NO_x emissions by injecting ammonia into flue gas streams emanating from stationary combustion sources. It is a noncatalytic process for NO_x reduction based on the gas phase homogeneous reaction between NO_x in flue gas and ammonia that produces nitrogen and water. The patented process was offered for license by Exxon Research and Engineering Co.¹⁶

The SNOX catalytic process was developed for the cleanup of flue gas from fossil fuel burning equipment. Nitrogen oxides and sulfur oxides emanating from industrial and utility boilers burning fossil fuels are converted to elemental nitrogen, water vapor, and sulfuric acid. The SNOX Process was

developed in Denmark by Haldor Topsoe A/S and is offered under license in North America by ABB Environmental Systems.

Deshen International of Newton, MA, continued to develop markets for mobile power-intensive nitrogen plants based on the electric arc nitrogen fixation process. Several electrical power utility facilities worldwide were interested in the process, which could be used to improve powerplant efficiencies during off-peak periods.

OUTLOOK

Global ammonia demand and operating rates continued to fall for the fourth consecutive year, dropping to an exceptionally weak 78% in 1992, 3% below the 81% operating rate estimated in 1991. The downturn can be traced largely to the dramatic fall in domestic demand in the former U.S.S.R., Eastern Europe, and Western Europe, in respective order of importance. Global per capita nitrogen consumption dropped to 17 kilograms in 1992 compared with the pre-1991 norm of about 19 kilograms.

The world ammonia supply-demand outlook anticipated by the U.S. Bureau of Mines suggests that soft market conditions will continue into 1993 and persist for an indefinite period because of significant new additions to world capacity and a protracted period of recovery anticipated in the former U.S.S.R. and Europe.

The upside to the global ammonia supply-demand situation is that demand may gradually rise 8 million tons N during the next 5 years to a new record level of about 100 million tons N, principally in regions outside of Europe and the former U.S.S.R. Furthermore, there is much uncertainty surrounding the future geopolitical and agronomic events that may surface in the former U.S.S.R., Eastern Europe and Western Europe. Fertilizer consumption has conceivably dipped to levels that could result in future plant closures, and/or the diversion of more nitrogen export materials to domestic use. This could potenitally result in a tighter global supply-demand situation than indicated.

The U.S. Bureau of Mines ammonia nitrogen demand forecast was developed from World Bank-United Nations Fertilizer Working Group projections¹⁷ taking into consideration world per capita consumption trends and geopolitical factors in the former U.S.S.R., Europe, and the Mideast. Steady-state conditions World were assumed for weather. ammonia capacity projections were provided by the International Fertilizer Industry Association Ltd. (IFA), Paris, France. It should be pointed out that IFA's most recent analysis of the global fertilizer N supply-demand situation was less optimistic. (See table 14.)

In the United States, the outlook for continued strength in the nitrogen fertilizer and grain sectors is anticipated. The U.S. ammonia industry is running at near capacity, grain stocks are still relatively low at the global level, and U.S. and North American ammonia capacity expansion plans are minimal.

The mechanisms of the new CRP and WRP programs, together with regular farm program acreage reductions, should hold U.S. crop acreage at about the current 340-million-acre level. This, together with the Export Enhancement Initiative, should control crop inventories and provide favorable crop prices for the U.S. farmer.

The U.S. nitrogen supply-demand outlook will be critically dependent upon the following: (1) a continuation of reasonably priced natural gas for U.S. ammonia production; (2) new industrial outlets for U.S. agricultural crops, including corn-based ethanol in reformulated motor fuels under the provisions of the Clean Air Act of 1990, and USDA's new AARC initiative; (3) new markets for the Saskferco ammonia and urea nitrogen complex, which came on-stream in the fall of 1992 in Saskatchewan, that would minimize the closure of U.S. nitrogen fertilizer capacity; (4) a favorable resolution of the ongoing Uruguay Round of GATT negotiations that would liberalize global agricultural trade and provide opportunities for the United States to compete more effectively in world grain trade; (5) favorable U.S. implications for

the proposed Free Trade Agreement with Mexico and for the granting of most-favored-nation (MFN) status to the former U.S.S.R. and other Eastern European countries; (6) a more expedient transition in democratic reforms in Eastern Europe and the former U.S.S.R., and (7) resolution of the MFN status debate with China.

²Statistical Abstract of the United States 1991; Bureau of the Census.

NONRENEWABLE ORGANIC MATERIALS

By Raymond L. Cantrell and Deborah A. Kramer

Mr. Cantrell and Ms. Kramer are physical scientists in the Branch of Industrial Minerals. In combination, they represent more than 40 years of diverse technical experience in the public and private sectors, including the industrial organic chemicals, plastics, rubber, agricultural chemicals, and nonferrous metals industries. Ms. Michele R. Simmons, industry program manager, Branch of Materials, prepared the salient organic materials statistics table. Ms. Deborah A. Nolan, statistical specialist, Division of Statistics and Information Services, researched and updated the information contained in other data tables.

This report is the third annual series prepared by the U.S. Bureau of Mines (USBM) to address the situation and outlook for nonrenewable organic materials in the U.S. and global marketplace. Nonrenewable organic materials refer to nonfuel derivatives of finite fossil fuel feedstocks of petroleum, natural gas, and coal, as opposed to those derived from renewable natural organic biomass sources. All organic materials contain carbon, most commonly associated with hydrogen, oxygen, nitrogen, and sulfur, and comprise a vast number of chemical compounds.1 Organics range from the simplest hydrocarbon compound, methane (CH₄), to high-molecular-weight thermoplastic and thermoset polymers and complex biological matter associated with all life forms on Earth. The terms "plastics," "resin," and "polymers" are often used interchangeably by the synthetic organic chemicals industry.²

Polymeric materials, including thermoplastic and thermoset polymers, synthetic fibers, and synthetic rubber, are important products derived predominately from nonrenewable organic feedstocks. In addition, lubricants, asphalt, road oil, waxes, solvents, and numerous other petrochemicals fill many important nonfuel uses. Products manufactured from nonrenewable organic materials include a variety of items such as household goods, beverage containers, food packaging, cosmetics, sporting goods, paints and coatings, ink,

pigments, pipe and hose, electrical devices and computer goods, textiles, automotive components, tires, battery casings, engine oil, grease, construction materials, fertilizers, pesticides, pharmaceuticals, medical devices, eyewear, and a multitude of other items vital to modern society.

In 1992, restricted economic growth in the United States, Europe, Japan, and the former U.S.S.R. continued to suppress overall profitability and limit consumer spending for nonrenewable organic goods, even though fossil fuel feedstocks were in a general state of oversupply. Although production increased about 6% in the high-volume U.S. resin industry. for example, profitability was down 6%, and gross revenues did not change significantly from the prior year, according to The Society of the Plastics Industry, Inc. U.S. synthetic rubber production and apparent consumption were up 12%, according to the Rubber Manufacturers Association, but value information was not available. Crude oil prices dipped to the lowest level since 1986, averaging \$16.18 per barrel, and natural gas and coal prices were also depressed.

Fossil fuel feedstock and byproduct consumption for the manufacture of U.S. nonrenewable organic materials did not change significantly from 1991 levels, and in 1992, was estimated at 121 million metric tons valued at about \$13.4 billion. (See table 1.) Petrochemical feedstocks, intermediate and finished organic

chemicals, resin, synthetic fibers, and rubber continued to account for about 61% of total consumption. The remaining 39% was converted into asphalt and road oil (23%); lubricants and waxes (9%); and petroleum coke and coal products (7%).

The U.S. International Trade Commission (ITC) annual survey of U.S. synthetic organic chemicals estimated producer sales for noncaptive use at about \$90 billion, representing a turnover, or value added aspect, of roughly sevenfold relative to feedstock values.3 reported by the International Trade Administration (ITA), U.S. Department of Commerce, estimated the value of all U.S. nonfuel petrochemical shipments at about \$130 billion.4 The United States experienced a positive trade balance in petrochemicals of about \$15 billion in 1992 and continued to be a major net exporter of polymers and resin, synthetic fibers, paints and coatings, synthetic rubber, and agricultural pesticides.

Domestic merchant sales values for many of the high-volume thermoplastic resins declined significantly in 1992. The large high-density polyethylene (HDPE) and polystyrene businesses were particularly hard hit by a combination of overcapacity and depressed prices. Occidental Chemical Corp., the Nation's second largest producer of HDPE, responded by closing its HDPE plant at Orange, TX, at yearend.⁵

E.I. du Pont de Nemours & Co. Inc. announced a major long-term

reorganization of its 200-year-old organic A five-point chemicals business. program was announced that included divesting the acrylics business and focusing on core businesses such as nylon, pharmaceuticals, and energy. Du Pont officials unveiled a comprehensive antipollution initiative that would reduce the firm's toxic air emissions by 60% in 1993 and airborne carcinogens by 90% toward the end of the decade. Du Pont also announced a major work force reduction designed to reduce overhead and improve efficiency, together with a renewed commitment to research and product development (R&D).6

The U.S. Department of Energy (DOE) reported that about 6.2% of total U.S. energy consumption in 1992 was for feedstock direct nonfuel organics purposes, excluding external energy used in chemical processing.⁷ Feedstock costs were estimated at the closest point of delivery based on reported DOE data. Energy conversion efficiency in the has improved chemical industry dramatically in recent years; thus, it is possible that chemical production may have increased in 1992 although energy consumption was about the same as that in 1991.

DOMESTIC DATA COVERAGE

Data were obtained from a variety of government sources, including the ITC publication, Synthetic Organic Chemicals, derived from an annual canvass of the U.S. organic chemicals industry under the authority of Section 332g of the Tariff Act of 1930; the Annual Energy Review 1992, Petroleum Supply Annual 1992, and coal reports published by the Energy Information Administration, DOE; U.S. Department of Commerce reports; U.S. Bureau of Labor statistics; and the U.S. Environmental Protection Agency (EPA).

Several private groups assisted the USBM, including The Society of the Plastics Industry, Inc.; American Plastics Council; Chemical Manufacturers Association; Federation of Societies for Coatings Technology; Fiber Economics Bureau, Inc.; American Fiber Manufacturers Association, Inc.; Rubber

Manufacturers Association; International Institute of Synthetic Rubber Producers; The Asphalt Institute; Asphalt Roofing Manufacturers Association; The Fertilizer Institute; and National Agricultural Chemicals Association. Information was also sourced from industry trade journals.

BACKGROUND

The Industrial Revolution that commenced in Europe during the early 1700's gave birth to innovative technologies for the manufacture of iron and steel, the spinning machine, agricultural harvesting equipment, and inorganic chemicals production. It was not until the late 1700's, however, that America began to gradually emerge from its traditional agrarian posture, based primarily on manual labor.

Eli Whitney's invention of the cotton gin in 1793 revolutionized the industry, and Robert Fulton's invention of the steamboat in 1807 opened river traffic to industrial commerce. The roving-frame spinning machine and reaping machine were invented by Charles Danforth and Cyrus McCormick between 1829 and 1831. Charles Goodyear invented the vulcanization process for natural rubber in 1841. Commerce in the United States continued to gather impetus with the advent of rail traffic, and by the 1860's the United States was evolving into a substantial heavy-duty industrial economy on renewable agricultural based resources, together with steel and other nonrenewable mineral commodities.

In the mid-1800's, John Wesley Hyatt and his brother Isaiah experimented with the natural polymer cellulose nitrate, a reaction product of nitric acid and cellulose, with the idea of coming up with a viable substitute for billiard balls made traditionally from expensive ivory. This is just one example of how many American scientists/entrepreneurs like the Hyatt brothers made a meaningful materials substitution. In 1872, the term "celluloid" was coined by Isaiah Hyatt for materials made from cellulose nitrate and camphor, and the Hyatt's firm, Celluloid Manufacturing Co., is known today as Hoechst Celanese Corp. In 1907, Leo Bakeland introduced Bakelite, an industrially significant phenolformaldehyde thermosetting heat-resistant polymeric resin.

The Petroleum Age

A major wildcat oil strike by Edwin L. Drake near Titusville, PA, on August 27, 1859, gave birth to a new technological era in the United States-the petroleum age. An abundant source of fluid organic chemical feedstock containing a multitude of carbon compounds had been found that was relatively easy to pump and process, unlike solid coal minerals. Although the first U.S. petroleum refinery was built in 1860 near the Titusville oilfield, the major contributing factor that transformed petroleum into an industrial giant was the commercial development of the internal combustion engine in the early 1900's, merging minerals technology with the nonrenewable organics sector. The horse and buggy days gradually became a thing of the past as oil production began to increase, and California and Oklahoma alternated as production leaders until 1928, when Texas took the lead.

The 1920's served as the benchmark for major oil discoveries in the United States, and during the 1930's there were enormous finds in east Texas, and at Prudhoe Bay, AK, by 1967. U.S. oil output exceeded 3 billion barrels in 1966 and reached a peak of more than 3.5 billion barrels in 1970. During this period, the United States was the world's leading oil producer, but by 1974 the U.S.S.R. assumed first place, and Saudi Arabia captured second place in 1976. Today, the United States continues as the world's leading consumer of petroleum, with about 20% of world consumption, by carrying a significant net import dependency in the mid-40% range.

The petroleum industry initially supplied crude oils for lighting, etc., and later developed sophisticated distillation and associated technologies for the production of gasoline and lubricants for the growing automotive industry. Heating oils, diesel fuel, asphalt for road building, and a number of consumer products were also produced. Many light

fractions of petroleum manufacture such as ethane (C_2H_6) , propane (C_3H_8) , and butane (C_4H_{10}) were vented and flared because technology had not been developed for their use. Natural gas, or methane, also was found to be associated with petroleum and was contained in deposits by itself. Natural gas was found to be an excellent clean burning fuel source, but much was flared as a nuisance item of oil production.

Petrochemicals

During World War II, important organic synthesis technology, developed earlier by noted research scientists, was put to practical use. Petroleum engineers learned how to recover the lighter, more reactive organic molecules and crack both small and large ones into forms that could be turned into nonrenewable organic chemical feedstocks and downstream polymers and other items of commerce. Nylon was developed by Wallace Carothers and Du Pont between 1927 and 1940, and used in parachutes during the war. Following the war, nylon hosiery and other nylon fabrics precipitated a maior synthetic fiber revolution. Synthetic rubber (styrene-butadiene, neoprene, and butyl) was developed to augment supplies of natural rubber cut off from Indonesia, Malaysia, Singapore, and Thailand during the war. Military explosives also were involved in the organics revolution, including trinitrotoluene (TNT) and nitroglycerine (dynamite).

Rapid growth in the U.S. economy was experienced during the postwar years through the 1970's. The early 1980's marked the beginning of a major downturn in the global economy and in most major U.S. commodity businesses, but petrochemicals trends anomalous to the general trend. HDPE and other nonrenewable organic materials continued to displace minerals and renewable organic resources traditionally used in the manufacture of bottles, "wax paper," "butcher paper," oil cans, fiber, and rubber, for example. There also was solid demand for polyvinyl chloride (PVC) materials compounded with

andustrial minerals such as calcium carbonate, clays, talc, and titanium dioxide, and extruded into pipe, vinyl siding, and garden hose, or fabricated into vinyl sheet as a superior substitute for "linoleum" flooring. Athletic goods were improved by the substitution effect of high strength, low density polymeric materials. Polyvinyl acetate water-based emulsions and many other polymers continued to replace natural resins and oils in glue and paints. Microcircuitry revolutionized the computer, communications. and timepiece industries. Integrated circuits and computer chips merged high-tech polymeric resins and minerals-derived materials. Synthetic organic urea nitrogen fertilizers replaced low analysis fertilizers and, along with effective organic pesticides, improved crop yields.

Acrylic resin is integral to the manufacture of various water-based paints. sheet film. and coatings: polystyrene is integral to fabricated housewares and industrial applications; and polypropylene is integral to the production of fishing line, bottles, and safety helmets. A multitude of polymeric substitutions in the automotive industry has resulted in reduced weight, improved gas mileage, and improvements in structural stability, safety, performance. Other significant nonrenewable organic materials include adhesives and epoxy plasticizers, polyamide hotmelt adhesives, solventless powder coatings, medical equipment, and pharmaceuticals.

Polyethylene terephthalate (PET) soda bottles and the popular polyurethane roller blades are recent successful entries in the marketplace, along with a growing repertoire of other new polymeric materials such as aromatic copolyester and liquid crystal polymers for electrical applications introduced in 1984 and 1985, together with polymethylpentene, a high-temperature, transparent polymeric material introduced in 1988.

The petrochemicals materials expansion and sweeping development of new materials technologies during the past 40 years has revolutionized life in the United States and around the globe,

driving demand for high-tech skills in the workplace.

Definitions, Grades, and Specifications

Petrochemical feedstocks for nonfuel organics use are obtained principally from crude oil, natural gas, and to some extent from coal. There are about eight primary organic chemical feedstocks needed to produce intermediate finished and petrochemical materials, as shown by figure 1. It is interesting to note that of the eight, only methane is directly available from petroleum and natural gas. The other seven must be synthesized from crude petroleum and liquid hydrocarbon fractions of natural gas by processes such as catalytic cracking (cat cracking), reforming, and other chemical engineering processes to obtain chemically reactive ("unsaturated") bonds between the carbon atoms. (See table 2.)

Crude Oil.—Petroleum is a complex mixture containing thousands of different organic compounds ranging from the most simple hydrocarbon form, methane, some high molecular weight compounds containing as many as 85 carbon atoms. Most of the compounds are straight chain saturated hydrocarbons called alkanes or paraffins, which are in the family of compounds grouped with methane. This simply means that the four available reaction sites for each carbon atom are filled. But, for C3 saturated forms and higher, the molecules also can be arranged in a ring structure as

Benzene is an important ring compound found in petroleum in limited amounts (0.5% to 1.0%), but synthesized in large quantities from petroleum feedstock. Benzene is an organic ring compound belonging to a unique family of organic compounds known as aromatics. The benzene ring (C_6H_6) contains only one-half as many hydrogen atoms as its saturated cyclic paraffin cousin cyclohexane (C₆H₁₂). This means that benzene is "unsaturated," and has three "double bonds" between the carbon atoms that can be reacted with other elements. All aromatic organic molecules are arranged in rings and contain reactive "unsaturated" carbon bonds of a special type.

Crude oil is characterized as being "sweet" or "sour" depending upon its sulfur content and "heavy" or "light" depending upon its particular distribution of large and small organic chemical compounds, as measured by specific gravity or weight per unit volume. Oil is measured by the barrel, containing 42 gallons. A significant amount of elemental sulfur is recovered from refinery oil, typically through the Claus process, wherein hydrogen sulfide and sulfur dioxide are reacted to produce elemental sulfur.

Most of the components of oil can be separated by fractional distillation, taking advantage of a wide range of boiling points. The distillate fractions that are made into reactive, petrochemical feedstocks include the gaseous C_1 to C_4 components removed overhead, the C_5 to C_{20} naphthas and gas oil liquid fractions, the heavy residues beyond C_{20} , and the asphalt and petroleum coke residues.

Lubricating Oils.—Lubricating oils used in vehicles and in industrial machinery and processes are made from a relatively small number of crude oilbase stocks blended with several additives designed to achieve specific properties. Special additives allow for relatively constant or variable viscosity change with temperature, promote oxidation resistance, and regulate acidity and pour points.

Asphalt.—Asphalt, a product of petroleum refining, is generally the bottom product left after all other products have been taken out. It is always blended with cutter stock, similar to kerosene but with a lower flash point, into three grades: fast cure (less of the kerosene material added so that it sets up faster), medium cure, and slow cure, for use as road base at different ambient temperatures.

Not all refinery operations produce asphalt because it is a natural product only from heavy crude oils; the amount of asphalt produced will be in rough proportion to the specific gravity of the crude oil. Further processing is necessary to make the asphaltic material suitable for roofing applications.

Asphalt serves as an highly effective binder in roadway construction. Asphalt roadways typically consist of only 5% to 10% asphalt, filled with an enormous quantity of crushed stone and modified with hydrated lime to facilitate impact resistance.⁸

Petroleum Coke.—Petroleum coke is obtained by severe thermal cracking of the bottom residues remaining after petroleum refining. The feed is heated to about 560° C and charged to the bottom of a coking drum. The cracked lighter product is drawn off overhead; the heavier product remains and, because of the retained heat, cracks to coke, a solid coal-like substance. Coke yields may approximate up to 30% of the feed.

Coke comes in two principal forms—"sponge coke" and "needle coke." Sponge coke varies from a hard, porous, irregular-shaped lump to a fine powder. The main uses for sponge coke are in the manufacture of electrodes and anodes, as a carbon source for carbides, and for the manufacture of artificial graphite used in motor brushes. The strength of sponge coke is not sufficient for its use in blast furnaces for pig iron or in foundry work.

"Needle coke" derives its name from its microscopic elongated crystalline structure. Needle coke requires special coker feeds and more severe operating conditions. Its qualities make it the preferred material for graphite electrodes because of its lower electrical resistivity and lower coefficient of thermal expansion. Graphite electrodes are integral to the production of steel based on the electric arc process.

Carbon Black.—This significant carbonaceous black pigment is an extremely fine soot, primarily carbon (90% to 99% C), that contains some hydrogen and oxygen and is produced by the partial combustion or thermal decomposition of hydrocarbons in the vapor phase. Although carbon blacks are available as furnace black, thermal black,

lampblack, acetylene black, and bone black, furnace black is the dominant commercial material of choice. Carbon black is one of the most important pigments in industrial use today; significant quantities are used as a reinforcing agent in tires and other rubber products and as the primary black pigment in printing inks, paints, and plastics.

Petroleum Waxes.—Waxes are also a natural product of the refining processes and are derived from the gas oil fraction in the distillation process. Waxes come out of all crude oils. If the crude oil contains a large proportion of wax, then the final "pull" becomes unsuitable for asphalt production, even if it is a heavy crude oil.

Natural Gas.—Methane must be separated from various components before sale as "dry gas" for fuel use and as chemical feedstock. According to recent DOE statistics, about 83% of the total process feed is recovered as dry natural gas, 2% was removed as nonhydrocarbon gases (carbon dioxide, helium, hydrogen sulfide, and nitrogen), with some of the remainder being injected for repressurizing. Substantial amounts of other natural gas liquids (ethane, propane, and butane) also may be recovered during methane processing. Natural gas is sold on a dollars per million British thermal unit (Btu) basis. Substantial amounts of elemental sulfur also may be recovered as a marketable byproduct depending on the hydrogen sulfide content of the gas.

Natural gas is used extensively in catalytic steam reforming processes to produce inorganic ammonia (NH₃) and byproduct carbon dioxide, both of which are subsequently used to synthesize organic urea (NH₂CONH₂) for fertilizer and industrial use. Ammonia is also integral to the production of nylons and other important polymers and synthetic organic chemicals. Methanol, or methyl alcohol (CH₃OH), also may be produced from methane by a similar reforming process.

Coal.—Coal is a black or brownishblack combustible sedimentary organic rock that contains more than 50% carbonaceous organic material by weight. In popular usage, coal commonly is called a mineral because it was formed in the earth. However, the scientific use of the term "mineral" is reserved for a naturally occurring inorganic material that has a definite chemical composition and a regular internal structure. Coal has neither of these. Coal is called a fossil fuel because it is derived from plants that grew in vast swamps millions of years ago and was subsequently reworked and metamorphosed. Recoverable coal reserves in the United States are considered to be the largest in the world. and the United States ranks as the leading producer at about 1 billion tons per year.

Outside of fuel uses for electrical power generation, the most important use of coal is for the production of metallurgical coke from bituminous coals sourced principally from the Appalachian region of the United States. Typically, a 1-ton charge of low-sulfur bituminous coal when heated in a high-temperature coking oven in the absence of air will yield about 700 kilograms of coke containing 97% carbon and a variety of organic byproducts, including about 32 liters of crude tar containing creosote, naphthalene, phenol, pitch, pyridine, and other aromatic hydrocarbons, and 10 liters of crude light oil containing benzene with smaller quantities of the aromatics toluene (C₆H₅CH₃), xylene (C₆H₄(CH₃)₂), naphtha, and related hydrocarbons.9

Products for Trade and Industry

Approximately 50% of all U.S. polymeric materials derived from nonrenewable organics is currently fabricated into packaging, and building and construction materials, while consumer and institutional products account for another 10%; transportation equipment, 5%; electrical and electronic goods, 5%; furniture and furnishings, 4%; adhesives, inks, and coatings, 3%; and other merchandise, 11%. Exports account for 12% of the total.

Packaging materials include bottles, jars, vials and food containers, refuse bags and film, and items such as tubes, tape, pallets, shipping crates, blister and bubble containers, buckets, and drums. Building and construction materials vary from pipe, conduit and fittings—including drainage, irrigation, plumbing fixtures, and septic tanks—to siding, flooring, and insulation materials. Other construction materials consist of panels, doors, windows. skylights, bathroom units, gratings, and railings.

Consumer and institutional products encompass disposable food serviceware, dinner and kitchenware, toys and sporting goods, health care and medical products, hobby and graphic arts supplies, together with footwear, luggage, credit cards, and other items. Transportation equipment includes parts and composites for motor vehicles and bicycles, railroad equipment, travel trailers, campers, golf carts, snowmobiles, aircraft, ships, and boats.

Electrical equipment is composed of wire and cable coverings, and industrial equipment, while electronic components include resistors, magnetic tape, records, and batteries. Furniture and furnishings include household and office furniture, bedding, carpets, rugs, backing, curtains, blinds, awnings, lamps, picture frames, and wall coverings. Adhesives, inks, and coatings consist of adhesives and sealants, printing ink, magnet wire enamels, core binders, foundry facings, paper coating and glazing, paints, varnishes, and enamels.

A variety of products ranging from pipe to window trim may be produced from PVC and polypropylene resins. These rigid, high-strength polymeric products contain significant quantities of reinforcing fillers, extenders, pigments that include varying combinations of organic pigments, titanium dioxide, calcium carbonate, talc, treated kaolin, wollastonite, mica, feldspar, alumina trihydrate, barytes, silica, stearic acid, and derivatives.

Plastic coated handles on pliers, tin snips, scissors, and other items like the coated wire trays in dishwashers are derived from finely divided PVC dispersion resins processed into fluid plastisols or organisols that cure out or plasticize with heat. Plastisols are most commonly made by dispersing PVC resin in a suitable phthalate plasticizer. Organisols are made the same way except that an organic solvent is added to produce more solvation and fluidity. 10

Phenolic thermosetting resins are used in the production of foundry sand molds that withstand high temperatures associated with the molding of products such as engine blocks. Thermoset polymers also are used as a binder with organic and inorganic fillers in automotive brake linings, drum brake blocks, disk brake pads, clutch facings, and abrasives grinding wheels.¹¹

Synthetic rubber containing carbon black reinforcement pigment is used extensively in automotive components, including tires, motor mounts, nylon reinforced V-type drive belts, and hightemperature radiator, heater, and powerassist hoses. The modern-day radial tire comes equipped with steel-reinforced belts that span the tire circumference. Tire walls generally consist of tough, molded natural rubber vulcanized with sulfur and sulfur curing accelerators. while tire treads consist predominately of the more flexible molded and vulcanized styrene-butadiene synthetic rubber forms, which provide for better handling and wear characteristics.

Synthetic organic materials are integral to the construction of shingles and other Bitumen materials roofing materials. ranging from asphalt to coal tars comprise the major components of shingles. while protective roofing granules in shingles are derived from the minerals industry. "Built-up roofing" (BUR) systems are commonly employed in the industrial roofing sector. At the heart of the roofing system are two components: bitumens and felts. There are two types of roofing felts: organic and fiberglass-based. The roofing membrane is protected from solar radiation by a cap sheet of gravel embedded in bitumen.¹²

Technology

The production of petrochemical

feedstocks, downstream intermediates, and end-use products encompasses an enormous array of organic chemical reactions and technologies as demonstrated by the descriptive flow diagrams contained in this report. (See figures 1-9.)

Oil Refining and Petrochemical Feedstocks.—The feedstocks for petrochemical plants are sourced from oil refineries and from light fraction hydrocarbon extracts of natural gas and from natural gas itself. Several industrial minerals and other minerals-related catalysts are used to effect the complex chemical reactions required to produce the essential petrochemical feedstocks shown in figure 1.

Cracking catalysts are used in oil refineries to facilitate the conversion of heavier molecules into lighter, more desirable products. High temperatures are needed, but pressures can be more moderate. Bentonitic clays in the form of granular pellets are typical natural cracking catalysts, while synthetic catalysts generally are silica-alumina, silica-magnesia, or silica-zirconiaalumina. One process uses a platinum catalyst to reform naphthas petrochemical compounds. The catalytic cracking process uses operating pressures ranging from about 15 pounds per square inch (psi) to 700 psi [1 to 49 kilograms per square centimeter (kg/cm²)] and temperatures ranging from 425 to 590° C.

Polymerization.—A number of highly complex chemical reaction mechanisms and technical processes are involved in the synthesis of polymers from petrochemical feedstocks. In 1929, W. H. Carothers subdivided polymers into two general groups, "condensation" and "addition" polymers. Polyester resins, for example, are formed by typical condensation reactions between bifunctional organic acid and alcohol monomers, with the elimination of water. Addition polymers, unlike condensation polymers, are formed by direct molecular linkup mechanisms in which no byproduct is generated. Polyethylene is an example of addition polymerization whereby ethylene molecules combine in large numbers to form continuous chains of high molecular weight polymer. The terms "step reaction" and "chain reaction" are used in deference to the more classical condensation and addition polymerization terminology whenever a more precise definition between reaction mechanisms is needed.

There are two basic types of polymers, "thermoplastic" and "thermoset." Thermoplastic polymers soften repeatedly at elevated temperatures and may be processed under pressure into a variety of products and recycled. Polyethylene, PVC, nylon, and polypropylene are examples of thermoplastic resins. Thermoset resins, once processed, will not soften again as the temperature is raised, but eventually degrade or decompose at highly elevated temperatures. Phenol-formaldehyde, phenol-furfural, urea-formaldehyde, melamine, and epoxies are typical thermosetting resins.

Ethylene Synthesis.—Ethylene (C₂H₂) is the simplest unsaturated hydrocarbon, or "olefin," and is by far the largest of all the petrochemical feedstocks shown in figure 1 in terms of volume, sales value, and number of downstream derivatives. Figure 3 details the enormous family of downstream derivatives obtained from ethylene, the most important of which are the polyethylenes, PVC, styrene, vinyl acetate polymers, and ethylene-propylene elastomers. Other important derivatives include ethylene oxide and linear alcohols such as ethyl alcohol (C₂H₅OH).

Thermal cracking of hydrocarbons in the presence of steam is the most widely used process for producing ethylene. Cracking is accomplished at about 1,600° C and 30 psi, followed by rapid quenching to below 1,000° C. Ethylene is recovered by low-temperature fractionation at 500 to 550 psi and purified by low-temperature (-65° C) gasseparation processes to remove hydrogen, methane, and ethane.

In the United States, hydrocarbon gases—ethane through the butanes—from

natural gas condensates and petroleum refinery offgases dominate the feedstocks used to produce ethylene. With these clean feedstocks, yields may approach 80%. Liquid refinery products such as naphthas and gas oils also may constitute up to 25% of process feedstocks, but yields are less than 40%, and process costs are relatively higher. Ethylene also may be recovered by petroleum cat cracking, but the only practical source is from the hugh refineries in the United States owing to economies of scale.

Ethylene Polymerization.—Ethylene is a colorless gas that condenses to a liquid at -169° C. In high concentrations, it is a simple asphyxiant without other significant physiologic effects. Ethylene is commonly transported by pipeline to downstream processing facilities. About 50% of ethylene production in the United States is used to manufacture polyethylene polymers-HDPE: low-density polyethylene (LDPE), and linear lowdensity polyethylene (LLDPE). LLDPE has made significant inroads relative to the other polyethylene resins because of its unique properties derived from a number of copolymer derivatives. versatility of usage, and breakthroughs in synthesis technology. Polyethylene resin density varies between about 0.90 to 0.96 g/cm³.

HDPE resins are produced by a variety of low-pressure processes. Since the introduction of novel LLDPE technology in the 1970's, also based on low-pressure processes, the classic process-based distinction between LDPE and HDPE has become obsolete. Many of the newer polyethylene plants are designed with LLDPE/HDPE swing capabilities to meet changing market demands.

HDPE resins are characterized by greater toughness and by superior mechanical strength and high modulus, low gas-permeability, coupled with higher service temperature limits. HDPE resins compete with polypropylene resins in a variety of molding applications. Resin price and other factors affecting total conversion economics may favor one or the other material for a given end-use

article. As a result, some back-and-forth substitution is always taking place. Most HDPE resins are converted to end products by various polymer processing technologies: blow molding, injection molding, and variations of the extrusion process.

HDPE manufacturing processes fall under three basic categories: gas-phase, fluid-bed, or stirred-bed reactor polymerization; slurry-phase polymerization using isobutane diluent or C₆ or higher diluents; and solution-phase polymerization processes using cyclohexane or a paraffinic hydrocarbon.

Major advances in polymerization technology have resulted from the introduction of innovative catalyst systems incorporating either complex chromium compounds impregnated in silica or silica-alumina support or complex titanium compounds chemically bound to a solid magnesium-containing support. Recently, single-site metallocene catalysts have been developed or are under development. These new catalysts allow precise control of molecular properties, enabling products to be specifically tailored to match the performance needs of a given application.

LDPE resins, conversely, are derived under high-pressure environments ranging from 15,000 to 50,000 psi, using organic peroxide initiators. Two types of reactors are used: a continuous-flow stirred autoclave: and tubular reactors. Autoclave reactors produce homopolymers with a high degree of longchain branching, resulting in polymers useful for extrusion-coating markets and high-strength industrial heavy-duty film. In contrast, tubular reactors produce resins that have much lower degrees of long-chain branching. These resins are well suited for clear packaging film production.

Other commercial synthesis reactions include the palladium-catalyzed oxidation of ethylene to produce acetaldehyde (CH₃COH), or if synthetic acetic acid (CH₃COOH)—"vinegar" in nature—is used as the solvent, vinyl acetate. Chlorination and oxychlorination processes are used to make vinyl chloride monomer (CH₂CHCl), which in turn is

polymerized to the industrially significant PVC and PVC copolymers like polyvinyl alcohol and polyvinyl acetate. Ethylene oxide, a ring compound containing oxygen (C₂H₄O), is produced by the silver-catalyzed oxidation of ethylene. About 50% of the ethylene oxide produced is converted to ethylene glycol (HOCH₂CH₂OH), most commonly sold as automotive "antifreeze" and used in the manufacture of polyester resins. Acid catalyzed hydration of ethylene produces ethanol, ethyl alcohol, competitively priced with alcohol from traditional fermentation processes.

Methane and Propylene.—These petrochemical feedstocks are eclipsed only by ethylene in terms of volume. The flow diagrams of figures 4 and 8 track the downstream synthesis products of propylene and methane, respectively. Some of the more familiar reaction products of propylene are isopropyl alcohol, used as a solvent and rubbing alcohol, acrylonitrile that goes into acrylic-based resin and fibers, and the significant polymer polypropylene.

Methane (natural gas), as already described, is the feedstock for ammonia and methanol. Ammonia is used to produce nitrogenous-based organic compounds including urea, TNT, amines (-CNH₂), and downstream polymers, such as nylon-6; urea-formaldehyde, phenolic, and melamine thermosetting resins; and many other important resin intermediates. Methanol is important to the synthesis of methyl methacrylate from which acrylics ("plexiglass") are made, together with polyester fibers and resins. Methanol is commonly used in automotive windshield washer and deicing fluids.

Benzene.—This important petrochemical feedstock ranks fourth in terms of volume behind ethylene, methane, and propylene. Benzene is probably most notable for its use in the production of polystyrene, one of the more important resins in commercial use. It is also essential to the production of cyclohexane, cyclohexanol, and cyclohexanone, precursors of the

important nylon polymers nylon-6 and nylon-6,6.

Properties of Organic Chemicals.— Organic chemicals are highly useful participants in chemical synthesis, in purification processes, and as end-use products themselves. Many organic synthesis processes require an aqueousfree environment and may be conducted in an organic solvent system. Organic solvents are important extractants in the purification of products owing to different affinities for contaminants and end-use synthesis materials. Some organic synthesis materials such as caprolactam. the monomer for nylon-6, may be cycled back and forth between organic and aqueous phases to effect purification.

Many separation processes use the azeotropic properties of organic whereby organic compounds two compounds boil at a constant temperature and composition, and may be removed by simple distillation. Undesirable organic carboxylic acid (-COOH) byproducts may be removed by countercurrent extraction using aqueous sodium hydroxide. Other undesirable ionic impurities may be removed by ion exchange resins polymerized organic beads having cationic (positive charge) or anionic (negative charge) exchange properties. Another interesting feature of organic chemicals is that separation may be more easily effected by distillation under reduced pressure, or vacuum conditions. creating a wider variation in the vapor pressures of the various organic components. Organic products may be further purified and decolorized by filtration through a medium of activated charcoal.

Materials Processing.—The processing of solid polymeric resin and rubber materials into marketable products is accomplished through a series of operations ranging from the initial compounding of ingredients to the final process steps of molding, calendaring, or extrusion. Liquid products or intermediates, such as paints and coatings, are commonly produced by shear milling processes and special-high-

intensity liquid mixing from aqueous or organic dispersion resins incorporating solid fillers and pigments.

Both resins and rubber may be compounded or blended with varying combinations of ingredients-fillers, extenders and pigments, processing aids, blowing agents, curing agents and accelerators, antioxidants, etc. Compounding usually is effected in highintensity steel alloy pressure mixers containing a pair of rotating sigma, or Zshaped, mixer arms and jacketed for temperature control. **Following** compounding, the formulated mixtures may be processed on an alloyed steel roller mill consisting of two horizontal rotating drums revolving at different speeds to provide shear to complete the mixing process, sheet out the mix, and remove moisture and other volatiles.

In rubber compounding, extra care must be taken to shear, or "break down," the elastomeric molecules into rheological forms suitable for compounding and to precisely control the mix temperature to prevent "kick-off" of sulfur and associated curing accelerators. Many rubber compounders prepare "master batches" containing premixed rubber, curing agents, and pigments that are added during the processing step to facilitate more exacting quality control.

Compounded plastics and rubber materials may be prepared for downstream processing by "dicing" or "extrusion chopping" to produce granules or pellets that provide uniform flow or by "calendaring" sheets through vertically mounted compression drums that more precisely control thickness or gauge. Calendaring also may represent the final step in processing.

Extrusion, injection molding, and blow molding are the most popular methods of production of thermoplastic materials, while compression molding dominates the thermoset resin and rubber arena. Several important rubber items of commerce—hoses, gaskets, and pencil erasers, etc.—are extruded and cured under pressure in autoclaves.

Thermoplastic extruders are made of heavy-duty special alloy materials capable of withstanding high temperatures and

pressures. The integral parts of a typical extruder consist of a feed hopper; highalloy steel internal chamber or barrel: specialty feed/shear screw; a die of suitable geometry, together with a face plate. Plastic pellets or granules flow from the extruder hopper to the screw chamber where plasticization is effected through a combination of temperature and screw shearing rheology. The plastic medium is then forced through a die, producing the desired Typical marketable products range from writing elements, soda straws, plastic pipe and hose to vinvl siding and window trim.

Coextrusion is a process in which two extruders facilitate the cojoining of materials in a mutual chamber, creating a two-component or multilayer system. The inner polymeric resin component is extruded through a die of desired shape and is then sheathed or coated by the second extruder system whose shape is determined by a mutual die exiting the One unusual and mixing chamber. commercially significant form coextrusion involving metals and plastics is wire and cable coating. process, a thermoplastic resin of suitable dielectric properties is extruded around a continuous feed of wire or cable that passes through an individual and common die. The coated wire is wound on drums after cooling.

In the production of wide film or sheeting, resin is extruded in the form of a tube that may be split as it comes from the die and then stretched and thinned to the desired dimensions of the finished film. An alternate method involves inflating the tubing as it comes from the die, with the degree of inflation regulating the thickness of the final film.

Injection molding is a process in which the hopper feed is pushed into a long heating chamber by a plunger, where the polymer is softened to a fluid state. The fluid resin is then forced at high pressure through a nozzle into a cold mold. As soon as the material cools to a solid state, the mold opens and the finished product is ejected from the press.

Blow molding is the most popular process for producing thermoplastic

bottles. Blow molding consists of stretching and then hardening a polymeric resin against a mold. There are two general methods, direct and indirect, each encompassing several variations. These processes basically involve the air blowing of a glob of resin or heated thermoplastic sheet into a mold or die of the desired shape.

Compression molding is simply the squeezing of a material into a desired shape by application of heat and pressure to the material in a mold. The three compression molding factors—pressure, temperature, and time—vary with the design of the finished article and the material being molded.

Thermoforming of resin sheet has developed rapidly in recent years. This process consists of heating thermoplastic sheet to a formable state and then applying air and/or mechanical assists to shape it to the contours of a mold. Pressures of up to 14 psi may be obtained by evacuating the space between the sheet and the mold in a process called "vacuum forming," which is used in the majority of thermoforming applications. (See tables 3 and 4.)

Operating Factors

Both ethylene and vinyl chloride prices rose by about 20% during the year, reflecting significant improvement in demand for LDPE, LLDPE, and PVC resins and an apparent tightening of inventories. Butadiene prices were up 43% by yearend, indicative of strong growth in the demand for synthetic rubber and synthetic rubber elastomers. The steady decline in benzene and styrene prices as the year progressed was anticipated in light of declining domestic merchant sales and profitability. (See table 5.)

Total industrial employment in the synthetic resin, fiber, and rubber sectors fell by about 2% to 133,000 workers in 1992, compared with roughly 136,000 workers in 1991. The average hourly workweek and wages of those employed increased, however. Average hourly wages of employees engaged in the synthetic organic chemicals business

increased about 4% to \$15.37 in 1992, 34% ahead of all manufacturing jobs, and indicative of the high-tech skills required by employees in this industry. (See table 6.)

ANNUAL REVIEW

Legislation and Government Programs

The Energy Policy Act of 1992 (H.R. 776) was signed into law by the President 1992. on October 24, This comprehensive energy bill contained 30 titles covering nonrenewable and renewable energy resources and was underscored by environmental and energy efficient mandates for the implementation of new technology and for long-range research and planning. Under Title XIII—Coal—clean coal technology, the Secretary of the Interior was to provide consulting services to the Secretary of Energy for research and development of effective utilization of coal wastes and for the administration of mineral rights for coalbed methane projects on Federal lands.

Title XVI—Global Climate Change-included provisions for a 75% increase in energy derived from renewable resources over 1988 levels by 2005 and a reduction in the Nation's oil use from a level of approximately 40% of total energy consumption in 1990 to 35% by 2005.

Section 313 of EPA's Emergency Planning and Community Right-to-Know Act of the Superfund Amendments and Reauthorization Act (SARA) of 1986 (Public Law 99-499) required EPA to establish a national inventory of toxic chemical emissions from certain facilities, called the Toxic Release Inventory (TRI).

The 1991 TRI indicated that for 285 chemicals surveyed, a total of 3.3 million tons was released to the environment or transported to publicly owned treatment works (POTW's), of which about 1.5 million tons (45%) was released directly to the air, water, land, or injected underground. Based on available information, about 60% of this total was organic chemicals.

The remaining 1.8 million tons (55%) was transported to POTW's, where

approximately 61% was recycled and another 11% was recovered in the form of energy. About 35% of the organics was recycled. (See table 7.)

Under TRI is a voluntary industry toxic chemicals control program known as 33/50, implying an interim goal of reducing emissions of 17 high-priority toxic chemicals by 33% between 1988 and 1992, with an ultimate goal of 50% reduction by 1995. One of the more noteworthy findings revealed in the 1991 TRI was that emissions had declined by 34% between 1988 and 1991, surpassing Twelve of the program objectives. seventeen high-priority toxic chemicals listed under the 33/50 program were organics: benzene, carbon tetrachloride, chloroform, cyanides, dichloromethane, methyl ethyl ketone, methyl isobutyl tetrachloroethylene, ketone, toluene. trichloroethane, trichloroethylene, and xvlenes.

The Clean Air Act of 1990 (Public Law 101-549) contains 11 titles that target 3 major forms of pollution: acid rain, smog, and toxic air pollutants. The most important facets of the act relative to nonrenewable, nonfuel organics deal with volatile organic carbon (VOC) emissions from industrial processing, industrial solvents, paints and coatings, together with emissions from coke ovens.

Issues

The issue of sustainable development was near the top of the list on the public and private global agendas during 1992. Environmental concerns continued to be at the forefront of such issues during 1992, highlighted by an Earth Summit sponsored by the United Nations in Rio de Janeiro, where global population, deforestation, global warming. damage to the ozone layer were major topics of discussion. There was allied concern by those Federal and private sources responsible for managing our Nation's nonrenewable resources—the magnitude of recoverable reserves coupled with the most prudent use of post-consumer material resources in the supply-demand equation.

Many communities throughout the

United States were struggling with the issue of how to safely and effectively manage municipal solid waste. discovered that there are no quick-fix solutions to the waste management problem and that the only real solution is an integrated waste management approach utilizing four basic methods: (1) source reduction, (2) recycling, (3) waste-toenergy incineration, and (4) landfilling. According to the latest EPA figures, plastics account for 21.1% of the municipal waste stream by volume; paper and paperboard, 31.9%; metals, 11.1%; yard waste, 9.8%; food waste, 3.2%; and all others, 20.7%.

A study conducted for the American Plastics Council by R. W. Beck and Associates revealed that post-consumer plastics recycling increased significantly between 1991 and 1992. The recycling of plastics packaging was up 47% in 1992 to about 430,000 tons. Plastic bottles recycled in all forms increased from 14% PET soda bottle recycling to 19%. amounted to 170,000 tons, or 41% of total production between 1991 and 1992. Recycled HDPE milk, juice, water and household chemical bottles, and film bags was about 200,000 tons in 1992, up 67%, while colored HDPE bottle recycling rose dramatically to about 60,000 tons. Recycled polypropylene was 100,000 tons, while LDPE, polystyrene, and PVC, in combination, was about 60,000

In response to an ongoing nationwide survey conducted by the Council, over 6,850 cities and towns confirmed that plastics were being collected for recycling through either curbside, dropoff, or buyback programs during 1992.

The North American Free Trade Agreement (NAFTA) was a topic of debate during the 1992 presidential campaign. Both the public and private sectors were divided over the issue of whether NAFTA would aid and abet, or serve as a deterrent to the U.S. economy. Candidates also debated the issue of imposing new taxes on fossil fuels that would be designed to raise revenues for deficit reduction and for proposed new government programs.

The Uruguay Round of General

Agreement on Tariffs and Trade (GATT), under negotiation since 1986, had still not been resolved at yearend. The United States and European Community (EC) ended the year in a stand off over agricultural subsidy issues, while the Cairn group of nations observed from the sidelines.

Ethylene and Derivatives

Although the HDPE market was in an overcapacity situation in 1992, LDPE and LLDPE were in short supply. Only small expansions in capacity are planned for the near-term for LDPE and LLDPE, and no new capacity came on-stream in 1992. Producers of these materials were looking to increase prices and expand production.

Most of the U.S. producers were working on process and catalyst technology to improve yields and production efficiencies, but at the same time, the polyethylene market continued to change. Traditionally, the United States exported only 10% to 15% of its polyethylene production. The remaining material was destined for the domestic market. The exported material was sold at reduced prices so that U.S. producers could maintain high operating rates. Asia, Europe, and South America were expanding their resin capacities: consequently, the export market for U.S. polyethylene was expected to decrease over the next few years.

Occidental Chemical Corp. (OxyChem) planned to discontinue HDPE production at its 118,000-ton-per-year Orange, TX, plant by yearend. Oversupply and industry projections for a continued supply-demand imbalance led to the decision. The company has 658,000 tons per year of HDPE capacity elsewhere in Texas.

Propylene and Derivatives

U.S. production of polypropylene in 1992 increased slightly from that of the previous year, but there was a significant drop in the export market for polypropylene. As with polyethylene, significant increases in capacity within the

past few years in Asian countries have mitigated the export market for material produced in the United States and Europe.

According to industry analysts. polypropylene is expected to have strong growth throughout the rest of the decade. despite the current period of overcapacity. Operating rates are expected to fall to about 80% because of planned increases in world capacity before starting to rise in 1994. Growth in U.S. demand is expected to average 5.8% per year, and exports are expected to continue to drop significantly. Growth in western Europe is expected to average 7.6% per year. Overbuilding in recent years has overtaken healthy growth rates. and the market suffered from overcapacity. Capacity additions of 320,000 tons per year in Europe in 1992 were set to raise the European total to 5.3 million tons per year, with demand estimated at 4.2 million tons.

Amoco Chemical began production at a new 136,000-ton-per-year polypropylene plant in Chocolate Bayou, TX. This plant brings Amoco's total North American polypropylene capacity to 953,000 tons per year, making the firm the second largest North American producer after HIMONT, Inc. and the third largest producer in the world after Shell Chemical. This was the only new U.S. capacity installed in 1992.

Vinyl Chloride and Derivatives

PVC production in the United States increased by almost 9% from that in 1991. Growth in this market is generated by both a recovering economy and substitution of PVC for traditional materials in windows and injection-molding compounds. Exports for PVC declined as plants in the Asia-Pacific region supplied some of the U.S.'s traditional export markets.

World vinyl chloride monomer demand is expected to increase at an average rate of 3.6% per year through 2000, to reach 27.5 million tons, according to industry analysts. Growth is almost entirely attributable to the growth in PVC markets. U.S. growth in demand

will average only about 2% because of the threat of future regulations affecting the use of disposable packaging that would end up in landfills.

Styrene and Derivatives

Demand for styrenics is projected to grow at an average annual rate of 3.7% per year through 2000, but a surge of capacity additions will result in low operating rates. Interpolymer competition between polystyrene and polypropylene and high-heat polystyrene and acrylonitrile butadiene styrene, and styrenics and engineering resins will cause problems. Environmental issues also were causing the displacement of polystyrene on disposable packaging.

Chevron Chemical announced plans for a new \$250 million benzene plant at its Pascagoula, MS, refinery. The plant, to be completed in 1994, was constructed to supply feedstock to the downstream styrene market. Westlake Styrene completed its ethylbenzene/styrene plant at Lake Charles, LA, with a capacity of 160,000 tons per year of styrene.

Novacor Chemicals announced that it would close its 54,400-ton-per-year Leomister, MA, polystyrene plant by August 31 to improve the competitiveness of its styrene/polystyrene business. With recent closures at Cambridge, Ontario, and Copley, OH, Novacor reduced its North American polystyrene capacity by 35% to 356,000 tons per year.

Industry analysts estimated that acrylonitrile butadiene styrene (ABS) demand in North America will increase at an average rate of 4% per year through 1996, to reach a total demand of 1.45 million tons per year. The growth is a result of automotive and construction rebounds from 1991 lows. By yearend 1992, total North American ABS capacity was 950,000 tons per year. Monsanto had 34%, GE Plastics had 47%, and Dow Chemical had 19% of the total.

Monsanto completed an 36,000-tonper-year expansion of its ABS capacity in Addyston, OH. The expansion will raise Monsanto's worldwide capacity to 600,000 tons per year.

Polyethylene Terephthalate (PET)

PET bottle resin supply was tight during 1992. As a result of the tight supply, several companies announced capacity increases. Goodyear planned to expand its PET capacity by 35% or 90,700 tons per year by the first quarter of 1994. Eastman Chemical planned improvements to increase process capacity by 10% from 408,000 tons per year to 454,000 tons per year. In the United States, total PET capacity was 962,000 tons per year and is broken out by company as follows: Eastman Chemical. 51%; Goodyear, Hoechst Celanese, 14%; and ICI Americas, 9%.

Bottle-grade PET demand was expected to remain strong in the North American market, but prices will remain stable until early 1993. Demand is expected to grow at an average annual rate of 7% to 8% through 2000, with a dramatic increase in capacity between 1992 and 1995. The additional capacity will reduce operating rates, but will allow PET to be used in applications such as bottles, jars, and custom containers because of increased supply.

Toray Plastics America, a subsidiary of Japan's Toray Industries, planned to more than double its production of PET film to 20,000 tons per year at a cost of \$100 million. The expanded facilities in North Kingstown, RI, were expected to begin production in March 1994 and will give the Toray group as a whole, 108,000 tons of annual capacity, making it the world's largest producer of PET film for audio and videotapes.

Tejin and Du Pont reached an agreement to jointly develop polyethylene napthalate (PEN) films, an analog of PET. Tejin is currently the only commercial producer of PEN films, with a plant in Japan. PEN films are stronger than PET films and are expected to see significant growth in the next few years. They already are used in Japan for audio and videotapes, and Du Pont hopes to market PEN for thin-film capacitors and for insulating film used in motors, traditional PET markets.

John Brown was awarded a contract

by Goodyear for the design, engineering, and procurement of a 90,000-ton-per-year PET plant in Point Pleasant, WV. The project, to begin construction in September, will increase PET capacity at the site to 295,000 tons per year.

Hoechst Celanese planned to increase its PET capacity by 56,700 tons per year in Mexico in response to the country's increasing growth in the PET market. This is a part of Hoechst's plan to increase total North American capacity by nearly 227,000 tons per year by 1995.

Other Organics

Industry analysts projected growth for ethylene glycol to increase by an average of 4.3% per year through 1997. In the United States and Europe, demand will be driven by PET bottle and engineering resin demand. In Asia and the Pacific, demand growth will be directly related to polyester fibers growth.

Maleic anhydride demand in the United States is expected to increase by 5% per year, to reach 211,000 tons per year by 1996. Recovering demand for unsaturated polyester resins, accounting for more than 50% of maleic anhydride demand, plus increasing demand for copolymers such as styrene-maleic-anhydride will account for the projected growth.

Demand for tert-butylamine in the United States is projected to grow at an average rate of 7% per year. The material is used primarily in the production of sulfonamide-type vulcanization accelerators for rubber. The increased growth rate is expected to occur because of growing concern about the use of morpholine-based products for environmental reasons.

New Clean Air Act regulations for reformulated gasoline prompted increased interest in methyl tert-butyl ether (MTBE) production. In November, Chevron started up a 2,100-barrel-per-day MTBE plant at its Pascagoula, MS, refinery, and in December, Enron Petrochemicals started up a 15,000-barrel-per-day MTBE plant in LaPorte, TX. The company will sell 75% of the output under long-term contract. Jacobs Engineering was

awarded a contract to build a 2,050-barrel-per-day MTBE unit for Chevron in Richmond, CA. Completion was scheduled for February 1993.

Shell Oil planned to construct an MTBE plant at its Wood River, IL, refinery. This is in addition to units already announced at Deer Park, TX, and Norco, CA. The Illinois facility is scheduled for completion in 1994. Combined capacity of the three units is 15,000 barrels per day.

The MTBE market was soft during the latter part of 1992 because of stockpiling in advance of new regulations for reformulated gasoline effective November 1.

Hüls America planned to construct a multipurpose nylon polymer facility at Theodore, AL, to produce nylon-12 and copolyamide specialties. World demand for nylon-12 is estimated to be 40,000 tons per year. It is expected to be increasingly in demand for use in pneumatic tubes for industrial robots and tubes and hoses for automobiles.

Mixed xylenes demand was expected to grow by 4.3% per year through 1997, according to industry sources. Capacity additions to para-xylene will reduce operating rates from 85% in 1989 to 79%. Ortho-xylenes capacity utilization was expected to increase from a 1991 level of 70% to 76% by 1997.

Texaco planned to cease production of cyclohexane, and its departure from the market was expected to leave the United States without sufficient domestic supplies. As a result of the closure, Du Pont was investigating the restart of a mothballed facility at Corpus Christi, TX, was investigating the BASF construction of a new U.S. facility. Texaco's closure will reduce U.S. capacity to about 360 million gallons per year, with demand estimated at 400 million gallons per year, including product shipped to Canada. Demand was expected to increase gradually as the nylon fiber and resin markets improve.

Because of strong demand increase projections, acrylic acid producers were planning capacity increases. New capacity was expected to be required as soon as 1995 in the United States and by 1997 in Europe. Europe and the Far East have been in an overcapacity situation. BASF officials estimated worldwide growth at 5% to 6% per year and as great as 10% per year in some Asian markets. (See tables 8-17 and figure 10.)

World Review

Europe.—In polyethylene, recent capacity additions in Europe have led to a significant oversupply situation for all three major product lines. In 1991, about 570,000 tons per year of HDPE capacity came on-stream, and 320,000 tons per year came on-stream in 1992. Introduction of the new capacity represents a 7% to 8% increase in total European capacity, and the market has had only a 4% growth rate.

In May, Compagnie Industrielle des Polyethylenes de Normandie began production at its 220,000-ton-per-year LLDPE plant in France. The startup came at a time when polyethylene markets were depressed because of overcapacity and economic recession. In October, because of the slump in Europe's polyethylene market, the company temporarily closed its new LLDPE plant to correct "inventory imbalances." In addition, Dow Europe plans to close 55,000 tons per year of LLDPE capacity in Spain for at least 1 year and then reevaluate the market.

Shell Chemical commissioned a new ethylene pipeline to feed downstream units in England. The company planned to have a 100,000-ton-per-year LDPE plant on-stream by yearend and to close 40,000 tons per year of existing capacity, leaving the company with a total of 170,000 tons per year of LDPE capacity.

In November, closures of four LLDPE plants in Europe allowed producers to increase prices, but the restart of one plant moderated the price increases.

For polypropylene, overcapacity was depressing prices, despite a growth rate of about 10%. Some capacity has closed in Europe during the year, but closed capacity has not compensated for scheduled plant startups. Since 1987, European polypropylene capacity additions have increased capacity by

40%

Overcapacity in Europe's polypropolypropylene industry was cited as one of the reasons for the closure of Neste Chemicals' 70,000-ton-per-year facility in Portugal. European polypropylene growth is projected at 7% through 1998. The current overcapacity is expected to be absorbed by 1996.

Neste Corp. has been authorized to construct a \$150 million polypropylene plant in Porvoo, Finland, to be completed by 1994. The plant also will produce LLDPE and HDPE. The company may close one of the existing LDPE lines at the plant when the new capacity comes on-stream, because it is already balanced in ethylene.

Hoechst AG announced that it would close its 135,000-ton-per-year polypropylene plant at Kelsterbach, Germany, by gradually phasing out production by the end of the year. The company recently opened a 140,000-ton-per-year polypropylene plant in Knapsack, Germany, and the Kelsterbach plant was opened in the early 1970's and used some of Hoechst's oldest technology.

OMV plans to mothball 70,000 tons of annual polypropylene capacity in Austria in June, citing low prices. The closure is for an indefinite period of time.

BASF is investing \$32 million in an expanded polypropylene plant in Germany to be complete by 1994. Expanded polypropylene is used primarily for packaging and impact absorbing applications in the automotive industry.

Elf Atochem plans to close its 110,000-ton-per-year polystyrene plant in France in 1992, because the polystyrene market is at overcapacity and restructuring is necessary. According to industry analysts, polystyrene demand in western Europe was 7% less than the 1990 peak, and significant capacity additions were due on-stream by early 1994. The increased capacity plus competition from imports from the Mideast and Asia would continue the overcapacity situation unless some capacity was closed.

In June, a fire at Dow Chemical's new 450,000-ton-per-year styrene plant in the Netherlands closed the plant for an

indefinite period. This problem, along with unscheduled closures in North America and western Europe, drove styrene prices up significantly.

Eastman Chemical plans to double PET capacity at its United Kingdom facility to 100,000 tons per year by early 1993. After the expansion, the company will be tied for the largest European producer with EniChem (Milan, Italy). European PET consumption is projected to increase from 465,000 tons in 1992 to 630,000 tons by 1995 and to 950,000 tons by 2001. Production is expected to increase as well: from 335,000 tons in 1992 to 560,000 tons in 1995 and 890,000 by 2001.

Melamine demand in Europe, which has dropped significantly in the past 2 years, has resulted in severe overcapacity in that sector. One new 50,000-ton-peryear plant in the Netherlands completed in 1991 was never started up. In the past, eastern Europe was an important destination for melamine imports from western countries, but this region has practically stopped buying because of a shortage in foreign exchange, although the melamine demand still exists. The weak U.S. dollar led to an influx of U.S. imports from an already oversupplied U.S. market, and product is arriving from Saudi Arabia. Melamine producers are projecting a flat demand in Europe for 1992 and average annual growth rates of 1% through 1995.

Central America and South America.—ABB Lummus Crest was awarded a contract to build a 150,000ton-per-year LLDPE plant in Venezuela. The plant was scheduled for completion in the first quarter of 1994.

Brazil was set for a restructuring of its chemical industry after privatization. Polyethylene capacity was more than 1 million tons per year, with domestic demand estimated at less than 600,000 tons per year. Two new polyethylene plants were added during the year, with a total capacity of 240,000 tons per year. Two units were closed for one quarter because of operating difficulties. For polypropylene, capacity was at 650,000 tons per year, and demand was estimated

at 300,000 tons per year. In Argentina, restructuring is also occurring after privatization, but the country was expensive for capital investment.

Increases in polypropylene in South America from 1990 to the end of 1992 would allow the area to become a net exporter of polypropylene. Additional capacity in Argentina, Brazil, and Mexico, coupled with existing capacity in these countries and Venezuela and Colombia, would bring total capacity to 908,000 tons per year. Latin American consumption was estimated to be about 600,000 tons annually.

Braspol Polimeros inaugurated its 150,000-ton-per-year polypropylene plant in Brazil. This brings total Brazilian polypropylene capacity to 700,000 tons per year, with domestic demand estimated at 384,000 tons per year. Consequently, a large portion of the new unit's output must be destined for the export market.

Former U.S.S.R.—Belarus.—Eastman Chemicals and Pepsico International formed a joint venture with two Belarus companies to produce polyethylene terephthalate and PET bottles at Mogliev. PET resins were expected to be produced beginning in September. One-half of the output will be used to produce bottles for use in the former U.S.S.R., and the remaining PET resin was destined for the western European market.

Kazakhstan.—The French company Litwin reportedly signed a contract with Shevchenkovski Zavod Plastmass to build a 370,000-ton-per-year styrene plant in Kazakhstan. The existing plant also will be modernized.

Russia.—Major Russian chemical producers have joined to form a new company, A/O Neftek-Techno. This brought together some of the country's largest chemical producers, with a goal to coordinate plans to improve earnings and profitability. For example, rather than selling excess propylene in western markets, the material will be converted to polypropylene before being sold to add value.

Tecnimont signed a contract to supply a 100,000-ton-per-year polypropylene complex for the Kapotnia Refinery in Moscow.

Ukraine.—The Chlorvinyl enterprise at Kalush, Ukraine, announced that it signed a \$200 million contract with Linde (Germany) and Union Carbide (United States) for the construction of a 100,000-ton-per-year LLDPE and an 80,000-ton-per-year polypropylene plant. The plants could be completed as early as 1995. Uhde will expand capacity of vinyl chloride monomer and polyvinyl chloride in Ukraine. The monomer plant will be expanded from 250,000 tons per year to 370,000 tons per year.

Asia and the Pacific Basin.—This region accounted for about one-third of world chemicals demand, with the potential to increase to 40% of the total by 2000. The area's first major impact on the world chemical market was as a textile supplier, so chemical fibers were the first to undergo expansion. As a result, Taiwan and the Republic of Korea have larger polyester fiber production capacities than western Europe—each produces about 1.2 million tons per year of polyester filament yarn and staple fiber. This area has been primarily a market for Japan, which accounts for about two-thirds of the region's GNP. Large multinational companies have been increasing their investment in the region: however, impending overcapacity has led to a slowdown in investments. China, Indonesia, and Taiwan have some room for growth. Other countries in the region are faced with overcapacity. Between 1990 and 1992, ethylene production capacity in Asia (China, Indonesia, Japan, the Republic of Korea, Malaysia, Singapore, Taiwan, and Thailand) grew from 10.6 million tons to 13.3 million tons, and in 1995 capacity is projected to reach 16.0 million tons. Polymeric resin production capacity growth in China from 1991 to 1995 is projected to grow by the following quantities: LDPE, 1.26 million tons; LLDPE, 330,000 tons; HDPE, 300,000 tons; polystyrene, 301,000 tons; polypropylene, 980,000 tons; and PVC, 480,000 tons.

Regional growth in the Far East led several companies to announce expansion plans for PVC. Tosoh Corp. (Japan) plans to expand production in Indonesia and Malaysia, while Thai Plastic & Chemicals also plans to increase its capacity in Thailand. Postwar reconstruction programs in Cambodia and Vietnam were cited as reasons for increased PVC demand.

Amoco Chemical Corp. and a local conglomerate formed a joint venture to build a 350,000-ton-per-year purified terephthalic acid plant in West Java. Completion is slated for 1995. Amoco also formed a joint venture with several Japanese firms and completed a feasibility study for a 250,000-ton-per-year purified terephthalic acid plant in the Republic of Korea. The new capacity, to be completed by mid-1995, will bring the country's total capacity to nearly 900,000 tons per year, all to be used in the domestic market.

ICI commissioned its 350,000-ton-peryear purified terephthalic acid plant in Taiwan to serve the Asia/Pacific market, which accounts for about 60% of total world demand. The Far East market has been oversupplied following several startups in the past few years, and analysts do not believe this market will be able to absorb the additional capacity until 1993. Between 1993 and 1995 at least six new purified terephthalic acid plants were planned in the region, increasing capacity by about 1.5 million tons per year.

China.—The Chinese Government approved construction of a 140,000-ton-per-year ethylene plant at Dongying, Shandong, and discussions began with foreign suppliers for an associated \$600 million complex that also will produce 100,000 tons per year of polyethylene, 60,000 tons per year of acrylonitrile, and 30,000 tons per year of acrylic fibers.

The Italian firm Snamprogetti won an order to build a 120,000-ton-per-year LLDPE plant in China. The plant will form part of the Zhongyuan complex at Puyang, Henan. Mitsui Engineering won a \$35 million contract to build a 40,000-

ton-per-year polypropylene plant at the Daqing petrochemical complex in Heilongjiang Province.

Chi Mei Industrial plans to build a 300,000-ton-per-year acrylonitrile butadiene styrene (ABS) plant and a 300,000ton-per-year polystyrene plant in China by mid-1995.

In China, two new styrenics complexes One in Heilongjiang are planned. Province will have annual capacities of 60,000 tons of styrene monomer, 25,000 tons of polystyrene, and 50,000 tons of ABS. At Guangzhou, annual capacities will be 60,000 tons of styrene monomer and 50,000 tons of polystyrene. China also started a new ethylene plant in Liaoning Province, with a capacity of 120,000 tons per year. The country plans to increase ethylene capacity from 1.8 million tons per year in 1990 to 3.7 million tons per year by 1995 and has plans for 12 additional ethylene-based complexes.

Snamprogetti won an order to build a 100,000-ton-per-year styrene monomer unit, and Mitsui Engineering won an order to build a 100,000-ton-per-year ethylene oxide/glycol unit at the Maoming petrochemical complex in China. SNC-Partec was awarded a \$55 million contract for a 60,000-ton-per-year styrene plant in Panjin, Liaoning Province, China.

India.—India has had shortfalls in domestic capacity and production to meet petrochemical demand. With Government's liberalization of economy, enough new petrochemical capacity was expected to be installed to meet the demand and perhaps provide some material for export. By the end of the decade, ethylene capacity was projected to increase from 230,000 tons per year to more than 2 million tons per year. In 1992, production of LDPE. LLDPE, HDPE, polypropylene, PVC, and polystyrene was estimated to be 471,000 tons, with demand at 755,000 tons. By 1995 production is expected to be 1.1 million tons, with a demand of 1.06 million tons.

Simon-Carves (Manchester, England) was awarded a contract for the basic

design and engineering of a 55,000-tonper-year LDPE plant to be built in India. The plant is due on-stream in 1994.

Reliance Petrochemicals (Bombay, India) formed a joint venture with Mitsubishi Corp. to build a new 250,000-ton-per-year polypropylene plant at the petrochemical complex in Hazira, Gujarat. Startup is scheduled for 1994, to coincide with the complex's 320,000-ton-per-year cracker coming on-stream. Italy-based Tecnimont was awarded a contract to build a 75,000-ton-per-year polypropylene plant for Indian Petrochemical Corp. Ltd. at Baroda, Gujarat. Completion was scheduled for 1995.

ABB Lummus Crest (Bloomfield, NJ) was selected to build a 60,000-ton-peryear styrene monomer/polystyrene complex in India. The company also will provide basic engineering and other services for a 100,000-ton-per-year ethylbenzene/styrene monomer plant. Both plants will be near Nagothane and were scheduled for completion in 1994.

Reliance Industries plans to build a 350,000-ton-per-year purified terephthalic acid plant at Hazira at a cost of \$528 million. Also to be constructed are downstream facilities for the production of polyester filament, polyester staple, and PET, totaling 200,000 tons per year. Initial production was scheduled to begin at the end of 1993, and the complex completion date was in 1995.

Indian Petrochemicals Ltd. closed its 48,000-ton-per-year para-xylene plant because of poor demand from purified terephthalic acid and dimethyl terephthalate producers.

Indonesia.—In Indonesia, textile company P.T. Polyfin announced that it would build a complex with a capacity of 63,000 tons per year of polyester fiber to be completed by mid-1994. Total polyester filament capacity in Indonesia was 170,000 tons per year and was scheduled to double by 1993 when capacity expansions announced earlier are brought on-stream. Also, P.T. Pusaka Warna Polypropylene plans to construct the country's first integrated polyethylene/polypropylene plant,

scheduled for completion by the fourth quarter of 1994. Annual capacities for the two products will be 200,000 tons for polyethylene and 140,000 tons for polypropylene.

Indonesia has approved construction of the Chandra Asri petrochemical complex at Cilegron, West Java, as long as it is 100% foreign-owned; the project was postponed in 1991. The first stage is a 450,000- to 500,000-ton-per-year ethylene plant, with downstream units to produce polyethylene and polypropylene.

Golden Key Group completed engineering for its \$300 million styrenics complex in Serang, West Java. The project is expected to come on-stream in 1994. The complex will include plants for styrene monomer, polystyrene, high-impact polystyrene, ABS, styrene acrylonitrile, styrene butadiene rubber, and styrene butadiene latex.

P.T. Tripolita Indonesia will shortly begin production of polypropylene at its 160,000-ton-per-year plant in Anyer, West Java.

PT Styrene Monomers Indonesia completed its 100,000-ton-per-year styrene plant in West Java. Dow Chemical and the Salim Group were setting up a plant in Indonesia to produce 30,000 tons per year of styrene butadiene latex. The plant was due on-stream early in 1993.

Japan.—Because of the continued slump in the Japanese petrochemical market, several projects have been postponed or downsized. Maruzen Polymer delayed plans to build a 100,000-ton-per-year HDPE plant at Chiba. Asahi postponed the April startup of its 40,000-ton-per-year LLDPE plant in Mizushima by 3 months. Sumitomo and Tosoh postponed the opening of a new 80,000-ton-per-year LLDPE plant from February to May. Nippon Petrochemical postponed the startup of its 50,000-ton-per-year LLDPE plant from March until September. In polypropylene, 150,000 tons per year of capacity will be delayed by at least 6 months. In styrene, a 240,000-ton-peryear unit scheduled to be on-stream in the summer will be delayed until July 1993,

and production at a 100,000-ton-per-year unit will be suspended for 3 months. Nippon Petrochemical postponed commissioning of its 50,000-ton-per-year LLDPE reactor until yearend. Ube Polypropylene postponed startup of its new 80,000-ton-per-year polypropylene plant from October until 1993, citing poor demand and overcapacity. Showa Denko planned to cut back production of ethylene and derivatives through December. Projections from MITI are that ethylene equivalent demand was expected to decrease by 3.5% from that of 1991 because of declines in the automotive, construction, packaging, and electronics sectors.

An 80,000-ton-per-year PVC plant was completed at Sumitomo Chemical's Chiba complex, but startup was delayed by 6 months because of the depressed state of Japan's PVC market.

Idemetsu Petrochemical began limited production at its 80,000-ton-per-year polypropylene plant. The product was destined for Malaysia, and the company does not expect to start full-scale operations until the spring of 1993.

Sumitomo Chemical and Denki Kagaku reached an agreement to build a 250,000-ton-per-year styrene plant at Chiba by 1993. If this project proceeds, the proposed expansion of Nihon Oxirane's Chiba unit from 330,000 tons per year to 450,000 tons per year may be canceled. Also coming on-stream is 300,000 tons per year of styrene capacity in the Republic of Korea that is aimed at the Japanese market.

Nippon Polystyrene will cut production of polystyrene as a result of lower demand for electronic appliances and office equipment. The company will close its 30,000-ton-per-year plant for 1 month.

Asahi Chemical announced that it would close its 80,000-ton-per-year Kawasaki styrene plant for 6 months because of decreasing demand, starting in early April. Mitsui Toatsu delayed completion of its 240,000-ton-per-year styrene plant in Ube City to July 1993, and Mitsubishi Yuka is extending the closure of its Yokkaichi plant until August. The styrene supply situation was

worsened by the recent startup of Idemitsu Petrochemical's 200,000-ton-per-year plant at Tokuyama.

Mitsui Toatsu will begin construction of its 240,000-ton-per-year styrene plant, despite the poor market situation. The plant had been postponed earlier because of the poor market conditions. ABB Lummus Crest was providing technology and basic engineering to Chiba Styrene Monomer Ltd. for a new 250,000-ton-per-year styrene monomer complex at Chiba. The \$160 million venture was scheduled for completion in mid-1994.

Japanese manufacturers of polystyrene have been working to reduce 1991 high inventory levels, and plant operating rates have decreased below 80%. Total Japanese polystyrene capacity is about 1.4 million tons, and 1991 demand was about 1.05 million tons. Exports for Japanese polystyrene were not growing as expected because of competition from other producers in countries such as the Republic of Korea.

Idemitsu Kosan planned to construct a 100,000-ton-per-year MTBE plant at its Chiba refinery. Completion was scheduled for June 1993. In Japan, MTBE was approved for use in gasoline blending in 1991, which prompted several companies to build production capacity.

In September, Kashima Oil completed the first MTBE plant in Japan, with an annual capacity of 60,000 tons; the plant relies on imported methanol.

Korea, Republic of.—In the Republic of Korea, the trade and industry ministry banned construction of new ethylene plants and some derivatives until 1995, including styrene and caprolactam. Ethylene capacity in the Republic of Korea was at about 20% above domestic demand. Two years before, the deficit was about 20% between capacity and domestic demand. But, to meet upcoming clean air regulations, the Republic of Korea plans to increase its MTBE capacity.

Malaysia.—Titan Himont Polymers recently commissioned a 120,000-ton-peryear polypropylene plant in Pasir Gudang. A 140,000-ton-per-year plant is being constructed at the same site for a third quarter 1993 startup.

Japan's Mitsui Engineering & Shipbuilding reportedly won an order to build Idemitsu's \$50 million 60,000-ton-per-year polystyrene plant in Malaysia. This plant is a part of Idemitsu Chemicals' ethyl benzene/styrene monomer, polystyrene, and ABS production facilities.

Taiwan.—After a 6-year delay, Formosa Plastics (Taipei, Taiwan) received tentative approval from Taiwan's Environmental Protection Administration to begin construction of a \$3.3 billion petrochemical complex. The complex will include the country's sixth ethylene plant and 24 downstream units, including styrene, MTBE, acrylonitrile, PVC, polyethylene, polycarbonate, and ABS.

Taiwan's Environmental Protection Administration will require polystyrene foam recycling beginning in late September.

ICI formally commissioned a 350,000ton-per-year purified terephthalic acid plant in Taiwan. This plant will bring the company's global capacity to 872,000 tons per year. Taiwan is the second largest user of purified terephthalic acid, and if predicted growth rates materialize, Taiwan will be the largest user within a few years. ICI estimates demand will grow by an average of 8% per year during the 1990's, with 60% of that growth in Asia and the Far East. At the same time, the other large producer in Taiwan is operating at below 50% of rated capacity, and prices are depressed.

Taiwan faces a significant oversupply of polyester filament. Demand has fallen to about 25,000 tons per month, while production is about 70,000 tons per month. Although exports have fallen, producers have shown no effort to reduce production.

Thailand.—Dow Chemical and Siam Cement received a license to build a 75,000-ton-per-year polystyrene plant at Map Ta Phut, at a cost of about \$50 million. Completion is scheduled for mid-1995. Several other projects are already under way at Map Ta Phut—a

25,000-ton-per-year polyols plant, a 20,000-ton-per-year styrene butadiene latex plant, and a 200,000-ton-per-year styrene plant.

Mideast Region.—Iran.—Iran reportedly gave permission for 10 new privatesector chemical projects. These include one project to produce 30,000 tons per year of aniline and a project for 25,000 tons per year of isocyanates, 24,000 tons per year of acetic acid, and 10,000 tons per year of monochloroacetic acid. Also included are a project for 10,000 tons per year of melamine; a 70,000-ton-per-year PVC plant; a 15,000-ton-per-year ABS and styrene acrylonitrile resins complex; a plant for 40,000 tons per year of dioctyl phthalate and 10,000 tons per year of petroleum resins; and two 10,000-tonper-year plants for petroleum resins.

A new 1 million-ton-per-year MTBE plant is planned to be constructed in Iran by the third quarter of 1994. State-owned National Petrochemical Co. and an Irani businessman Abdul Wahab Galandri signed a letter of intent for the \$300 million venture to be constructed in Bandar Imam. About 15% to 20% of the output from the plant is expected to be sold in the domestic market, with the rest to be exported to North America, western Europe, and Japan.

Kuwait.—Petrochemical Industries Co. reportedly revived plans to construct a petrochemical complex at Shuaiba that had been shelved since the war with Iraq. Along with an overseas investor, the company plans to build a 600,000-ton-per-year ethylene plant and include facilities to produce polyethylene, polypropylene, ethylene oxide, and glycol.

Saudi Arabia.—Dow Europe formed a joint venture with a Saudi Arabian firm to manufacture and market styrene butadiene latex in Saudi Arabia. The first 30,000-ton-per-year unit is due onstream at the end of 1994, and a doubling of capacity is planned.

United Arab Emirates.—The Abu

Dhabi National Oil Co. announced plans to begin petrochemical manufacture. The first stage of the project will include an ethylene and polyethylene complex with an annual capacity of 300,000 to 500,000 tons. No timetable was given for construction. (See tables 18, 19, and 20.)

OUTLOOK

The United States continued as the leading producer of polymeric resin materials, with nearly 36% of global production, followed by Japan and Germany. Steady growth has been experienced in U.S. synthetic organic chemicals and downstream products over the past 25 years. Since 1967, the production of polymeric resins has increased at a compound annual rate of 6.3% and sales and captive use by 7.1%. Since 1977, however, growth has been somewhat lower, averaging about 5%. The recessionary period and sluggish economic situation since 1987 have resulted in even lower growth rates, approximating 3.5% for production and 3.9% for sales and captive use. Production and sales volume in 1992 rebounded to between 6% and 7%, even though overall profitability did not change markedly. Still, the total increase in production and sales and captive use during the past 12 years has been remarkable, approximating 78% and 83%, respectively.

The value of industry shipments for resin materials and products miscellaneous polymeric products was \$92.5 billion (1987 dollars) in 1992, according to the ITA. ITA estimates for 1993 indicate a growth rate in industry shipments of about 3%, valued at \$95.2 billion (1987 dollars), ranking the monetary value of the U.S. plastics and resins industry as the fourth largest in the country, eclipsed only by motor vehicles and car bodies, petroleum refining, and automotive parts and accessories. Highperformance characteristics production economics have resulted in price pressures that have driven significant substitution patterns polymers for traditional materials such as wood, glass, and metal.

U.S. exports of the large commodity polymers, including polypropylene, PVC, PET, and polystyrene, more than doubled during the 1980's and reached 3.3 million tons by 1990. Even so, the U.S. trade surplus has remained at about 2 million tons because imports increased about eightfold to 1.1 million tons by 1990. This trend is likely to continue as Saudi Arabia, other Mideastern countries, and the Far East continue to develop petrochemicals businesses, and Canada, Japan, Germany, the United Kingdom. and other EC countries continue to seek markets in the United States. The United States is also a major net exporter of petrochemicals—methanol, ethylene. propylene, butadiene, benzene, toluene, and xylene—approximating \$15 billion in 1992.

Although the United States should continue to be a strong competitor in the global petrochemicals and resin business, long-term market share seems destined to decline in face of increasing pressures from foreign competition. Countries in the Far East, now heavily dependent on U.S. products, are building their own domestic supplies of primary petrochemicals. Of 28 new ethylene producers set to start up in the 1990's, for example, 18 are in the Far East. Also, about 46% of the 4.6 million tons of new styrene capacity to be added to global production by 1995 is in the Far East. Significant new global capacity will increase competition, reduce U.S. market access, and most probably depress margins and profitability.

Other factors that will affect the longterm outlook for U.S. petrochemicals and downstream businesses include environmental movement and drive to recycle more plastics materials, and full implementation of the Clean Air Act in 1995. Industry analysts believe that up to 12% of U.S. HDPE may be recycled by 2000. Although the precise percentage is uncertain, the trend toward more recycling will potentially reduce U.S. competitiveness in the global high-quality virgin resins market. The Clean Air Act will require reductions in the benzene and butane content of gasoline. This, in turn,

could bring more of these feedstocks into the organic chemicals sector, potentially creating an imbalance in supply-demand for other important chemical feedstocks such as propylene, isobutane, and aromatics.

Future developments in the energy-rich former U.S.S.R. and currently depressed central European nations also will pose problems and opportunities for the U.S. petrochemicals industry, together with the outcome of NAFTA and GATT trade negotiations.

Paints and coatings are classified under three main categories: architectural, for interior/exterior mainly used applications in commercial and residential original equipment installations; manufacture, used as final coatings for a variety of durable goods; and specialpurpose or specialty coatings for numerous and highly specific uses in the maintenance, marine, transportation, and electronics markets. There have been many changes in the marketplace during recent years, including industry restructuring, a gradual expansion of specialized end user markets, and much stricter environmental regulations. continue to Environmental concerns pressure producers to develop more environmentally friendly products that minimize the use of organic solvents.

A gradual turnover to aqueous-based systems is under way, especially for architectural coatings, which comprise about one-third of industry production. Long term, the industry is expected to place more emphasis on performance High-density characteristics. formulations, already a high-growth market, are expected to expand. The use of high-diffusion wetting agents shows promise. High U.S. growth rates also are expected for solventless powder coatings. The prospects for radiationcuring, however, remain mixed, owing partially to unfavorable consumer acceptance.

Turning to the outlook for synthetic rubber, industry shipments were about \$4 billion (1987 dollars) in 1992, with an expected increase of about 4% in 1993, mostly related to automotive industry products. Most synthetic rubber (SR) or

elastomers fall into two distinct groups: commodity or general purpose, and specialty elastomers. Typical general purpose elastomers include styrene butadiene latex, polychloropropylene, nitrile, ethylene-propylenediene monomer (EPDM), carboxylated styrene, butadiene, and polybutadiene.

Commodity SR accounts for the bulk of SR production and is used in the production of tires and fabricated rubber products. Fast growing, but still minor compared with SR, are the specialty elastomers, including the thermoplastic elastomers and olefins (TPE's and TPO's), which tend to be used where resistance to extreme temperature and chemical and mechanical stress is required. Material substitution is growing, especially in automotive usage, at the expense of traditional materials. Environmental concerns also may gain in prominence as firms are pressured to switch to less toxic chemical processes.

Industry consolidation has significantly changed the face of the tire industry. The bulk of the industry is now held by a few European and Japanese multinationals. U.S. tire shipments were valued at about \$12 billion in 1992 (1987 dollars), according to ITA statistics, of which about 20% to 30% is estimated to be synthetic rubber. Consolidation has left few American firms unaffiliated with a major multinational concern. U.S. tire exports have grown rapidly during the past 3 years, while imports have Export growth can be declined. attributed to the combined effects of global restructuring and the depreciation of the dollar. Canada remains our largest trading partner in both imports and exports. Long-term growth prospects in the U.S. tire market are likely to come from niche markets such as recreational tires and high-performance varieties.

Fabricated rubber products outside of tires that may include both synthetic and natural rubber include: rubberized fabrics; vulcanized rubber clothing; health supplies for medical, druggist, and pharmaceutical use; and rubber goods made from reclaimed and recycled materials. Other articles of commerce include rubber and synthetic elastomeric

footwear, hose and belting, gaskets, packing and sealing devices, and molded, extruded, and lathe-cut mechanical rubber goods. Fabricated rubber products were valued at more than \$6 billion (1987 dollars) in 1992.

DISTRIBUTION OF RESINS IN MAJOR MARKETS IN 1992

PEAT

By Raymond L. Cantrell

Mr. Cantrell, a physical scientist with 29 years of U.S. Bureau of Mines and industry experience, has served as the Bureau peat commodity specialist since entering public service in 1988. Virginia Harper, statistical assistant, monitored the survey and also prepared domestic data tables. The international data table was prepared by Audrey Wilkes, international data coordinator.

More than 90% of Earth's 1.1 billion acres of natural organic peat and peatland resources remain untouched, forming the basis for a continuous biological procreation mechanism for biomass. It is estimated that carbon stock in peat is approximately 330 billion short tons, representing about 13% of the total carbon resources on Earth.

Significant quantities of peat are consumed by the global horticultural and agricultural sectors for use as a plant growth medium and soil amendment. In addition to its large volume use by the home gardener and professional nursery and landscape businesses, peat also enjoys substantial use in a myriad of industrial applications and consumer products, including potting soils, turf cultivation, golf course greens construction and course maintenance, mushroom cultivation and earthworm culture, poultry litter. fertilizers. composting, seed inoculants, humic acid extracts, toxic waste filtration, oil absorption, hygienic products, and fuel for electrical power generation.

In 1992, the U.S. peat industry continued to be disrupted by a weakened domestic economy, regulatory constraints, the large-scale recycling of yard wastes and other natural organic materials, and record imports of Canadian sphagnum peat, peat mixtures, and other articles of peat. For the first time, Canadian peat imports surpassed U.S. domestic production and equalled domestic sales tonnage, f.o.b. U.S. plant.

Several entrepreneurial domestic peat firms capitalized on the abundance of recycled yard and animal wastes by

selling blends of composted natural organic materials and peat. The utility of U.S. sphagnum peat in specialty value added applications also continued to generate new demand in the areas of oil sorption products and wastewater effluent treatment. Peat-based oil sorbents were accepted as environmentally friendly substitutes for clay sorbents in industrial and emergency cleanup applications in selected northeastern States and cities where clay has been banned from landfill disposal because of bulk, undesirable disposal economics, and potential health risks associated with clay dust containing crystalline silica. Minnesota's new sphagnum peat operations optimized capacity utilization and experienced competitiveness improved profitability.

The Bureau's annual survey of domestic peat producers in the 48 contiguous United States reflected a 5% decline in production accompanied by the closure of 6 U.S. peat operations in the States of Florida, Michigan, Minnesota, Montana, New Jersey, and Wisconsin. An idle bog in North Dakota was reactivated during the year. Sales volume fell 7% to 0.7 million short tons, dropping the total value of producer sales to \$16.7 million, f.o.b. plant, a decline of \$1 million or 6% below the prior year. operations and discontinued continued to liquidate stocks.

Alaskan peat production in the Fairbanks vicinity was estimated at 70,000 yards by personnel of the State Division of Geological and Geophysical Surveys, Fairbanks, AK. The Alaskan peat carried a value of about \$400,000,

or \$5.71 per yard, representing a decrease of 5% in unit value compared to 1991. Peat production from the Anchorage area was not available for publication.

Canadian peat shipped predominately from the Provinces of Quebec and New Brunswick in eastern Canada and Alberta, Manitoba, and Saskatchewan in western Canada accounted for a record 50% of the total U.S. peat supply. Canadian import volume was a record 702,229 short tons and was valued at \$110.6 million, equating to a new record price of \$157 per ton at U.S. Customs. Another \$19 million of Canadian finished peat products was declared at U.S. Customs.

The total U.S. peat supply was valued at \$127 million based on f.o.b. domestic plant and U.S. import Customs values. The monetary significance of peat as a value added product at the retail level in the United States is many times greater and is estimated to be well in excess of \$1 billion.

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on peat that are in compliance with Public Law 100-418, will begin to report bottom line totals in both metric units (metric tons, kilograms) and U.S. customary units (short tons, pounds). Volume measurements (cubic yards, cubic feet) will continue to be reported in U.S. units only. Comments on the Bureau's plan to gradually convert U.S. peat data to the metric system are welcomed and may be addressed to the author. (See table 1 and figure 1).

DOMESTIC DATA COVERAGE

The Division of Statistics and Information Services, U.S. Bureau of Mines, conducts an annual survey of domestic peat producers in the 48 contiguous United States. Information obtained from the Bureau's voluntary canvass was used to develop data tables for publication. Of the 97 peat operations surveyed in 1992, 71 were reported to be active, 21 were idle, and 5 were reported to have closed permanently. Estimates were made for active operations that did not report data, based on past trends.

Alaskan peat producers were surveyed independently by the Department of Natural Resources, Division of Geological and Geophysical Surveys, Fairbanks, AK. In 1992, operations in the Fairbanks area reported active production.

BACKGROUND

Peat is a unique natural organic material of botanical origin and commercial significance that is found deposited in abundant quantities at the Earth's surface, where it plays an active role in the dynamics of our planet's ecosystem. Peat deposits function as natural hydrological control sources for vast areas of wetlands, provide an effective natural filtration medium for waterborne contaminants, and also serve as a biomass-related carbon link between the land and air. Today, peat deposits cover about 1 billion acres, or 4.4% of the Earth's total land mass, of which the United States ranks third in importance. eclipsed only by the large deposits found in the former U.S.S.R. and Canada.

The U.S. peat industry developed from small "mom and pop" operations that today comprise about 70% of all active peat operations and account for about 20% of total production. They provide essential peat supplies to surrounding communities that contribute significantly to cash-flow and liquidity within local economies. About 80% of U.S. peat is produced in high-volume operations by

30% of the producers. Large operations move peat in interstate commerce owing to economies of scale.

Peat deposits developed typically through the gradual decomposition of plant matter under anaerobic conditions in shallow aquatic basins. Most of the peat deposits in existence today lie at the Earth's surface and have formed since the last ice age approximately 10,000 years ago, although much older Pleistocene peats, typical of the deposits buried beneath the sands of Trail Ridge in Bradford and Clay Counties, FL, are known. Peat is a precursor of lignite and coal.

Peatlands, or mires as they are sometimes called, are more extensive in the temperate, boreal, and subarctic zones of the Northern Hemisphere and more limited in the cool and humid zones of the Southern Hemisphere. Peat deposits may be called bogs, fens, or "poor fens"—combinations of bog, fen, or swamp formations—depending on the aquatic mechanisms of the particular setting.

Most of the world's peatlands are classified as bogs. Bog is from the Celtic word "bocc," meaning "soft," which is an apt description for these waterlogged terrains. A bog is typically an acidic peatland that depends principally on rainfall to perpetuate the waterlogged conditions necessary for its survival. Because there is less decomposition in these nutrient-poor, acidic environments, the more fibrous peats—sphagnum moss, hypnum moss, and reed-sedge—may be found as the predominant species in the upper zone of the deposit.

The term "fen," as derived from the Anglo-Saxon language, translates to "mud" in modern day English. Fens are peatlands that depend mainly on ground water sources for their formation and survival and, thus, are less dependent on rainfall. Fens, unlike bogs, are found in less acidic nutrient-rich environments. Plant matter tends to decompose more rapidly under these relatively chemically neutral conditions, leading to a less fibrous, more mineralized material that in advanced stages of decomposition is known as muck or peaty muck. The

majority of fens are over sites of sand and gravel deposits that are buried within more clayey glacial materials (intertill), providing a ground water seep over which the peat forms. It, therefore, is not uncommon to find fens on hillsides.¹

Definitions, Grades, and Specifications

Methods adopted by the American Society for Testing and Materials (ASTM) find widespread use for the characterization of peat matter.² ASTM Classification of Peats, Mosses, Humus, and Related Products requires the use of three parameters: ash content, fiber content, and botanical composition. Earthy organic materials must have an ash content of no more than 25% by dry weight to be classified as "peat." Botanical characteristics and fiber content govern peat types. Fibrous peat is defined as material retained on an ASTM No. 100 screen: that is, material 0.15 millimeters or larger.

Sphagnum moss peats must have a fiber content greater than 66%, all of which must be derived from the genus Sphagnum, as determined by screening and botanical analysis. Hypnum moss peats must have a 33% minimum fiber content, of which at least 50% must be derived from the genus Hypnum. Reedsedge peats must have a 33% minimum fiber content containing more than 50% reed-sedge and other nonmoss fibers.

The U.S. Department of Agriculture Soil Conservation Service subdivides peat into three general categories: (1) fibric (peat moss), which is composed of sphagnum, hypnum, and other mosses; (2) hemic (reed-sedge), which is formed from reeds, sedges, swamp plants, and trees; and (3) sapric (humus), which is composed of materials that are decomposed beyond recognition of botanical origin.³

Fibric peats such as sphagnum and hypnum are relatively young moss species that are light in color in comparison to other peat varieties. Fibric peats, because of the lower order of decomposition, have a relatively high water-retention capacity and, in general, are quite acidic. Fibric peats have a low

bulk density that averages about 250 pounds per cubic yard on an air-dried basis and very little ash. These peats are not suitable for fuel owing to the low degree of decomposition.

Hemic, or reed-sedge peats, are somewhat older and more decomposed than fibric peats and originate from reeds, sedges, and other nonmoss type plants. Hemic peats are considered to be intermediate between fibric and sapric in degree of decomposition, bulk density, and ash content. The average density of air-dried reed-sedge peat is about 950 pounds per cubic yard. Reed-sedge peats are usually slightly acidic and have a high energy value owing to fixed carbon content and low ash.

Sapric, or humic peats, are the oldest and most decomposed peats, with color ranging from dark brown to black. Normally, sapric peats are the first peats formed in the filling of basins and are the most dense and colloidal. Sapric peats, because of their colloidal nature, take on less water, but retain it more strongly than other peats. Many sapric peats are excellent energy sources and are quite acidic. Sapric, or humus peat, has an average bulk density of about 1,300 pounds per cubic yard.

The von Post scale was developed in Sweden as a field method, or squeeze test, for determining the degree of peat humification or breakdown and is utilized by peat enthusiasts worldwide. According to the von Post method, peats are ranked on a scale from H 1 to H 10 relative to their degree of humification. A von Post of H 1, for example, would represent undecomposed peat that ejects colorless, clear water when squeezed, with the remainder containing easily discernible plant matter. At the opposite end of the scale, at H 10, the peat would be completely decomposed, with no plant remains recognized, and, upon squeezing, the whole amount would come out between one's fingers as a homogeneous material. In general, fibric peat mosses are in the von Post range between H 1 and H 3; hemic reed-sedges, H 4 to H 6; and saphric humus peat, H 7 to H 10.4

A typical proximate analysis for peat would yield a moisture content of about

50%; carbon, 26%; oxygen, 16%; hydrogen, 3%; nitrogen, 1%; sulfur, 0.1%; and ash, 4%. Fuel-grade peats may vary between 4,000 British thermal units (Btu's) per pound to as high as 10,000 Btu's per pound depending on moisture content and peat type.

Geology-Resources

In the United States, peat is deposited to some extent in all 50 States. About 25 million acres of peatlands has been identified in the lower 48 States, representing an estimated reserve base of 7 billion tons. Alaska contains an enormous peat resource estimated at 125 million acres. Minnesota, Florida, Michigan, Wisconsin, and Maine, in order of importance, account for the major reserves that are available for commercial harvesting in contiguous United States. Peat reserves are also found in about 10 Western States, of which active harvesting is known to occur in Colorado, Montana, North Dakota, and Washington. current mining rates, the U.S. permitted reserve base estimate of 16 million tons could theoretically be depleted within the coming 20 years.

Large peat resources are protected by Federal and State agencies in a vast area known as the Great Dismal Swamp near the southeastern coast of Virginia, extending south into northeastern North Carolina. Vast peat resources are also found in the sensitive wetlands areas of North Carolina's Pamlimarle Peninsula, Pamlico River Basin, and along the South Carolina coast. Peat resources are also found along the east coast and southern regions of Georgia and along the U.S. Gulf Coast from Alabama to Texas.

Although Florida, Maine, Minnesota, and many other States have done a credible job in estimating individual State peat reserves, there has not been a comprehensive effort to consolidate individual State reports to establish the extent of U.S. peat resources since the 1922 U.S. Geological Survey (USGS) publication "The Occurrence and Uses of Peat in the United States." ⁵

As a result of the energy crisis in the

mid-1970's, the Department of Energy (DOE) initiated a Peat Resource Estimation project in several States to provide information on the extent of our Nation's availability of peat resources for energy utilization, but the results were incomplete and never fully tabulated.

In the mid-1980's, the University of North Dakota and the USGS submitted a joint proposal to the U.S. Department of the Interior designed to survey the peat resources of the United States. principal objective of the proposal was to systematically bring together and analyze the information obtained from DOE's Peat Resource Estimation program that had been conducted by the individual States. Other non-DOE-sponsored research in other States was also to be included. To date, a Federal program has not been established to research and publish a comprehensive report of U.S. peat reserves and resources. This posture could change given that the Secretary of the Interior is currently formulating a proposed plan to conduct an extensive biological survey across the United States.

Technology

Mining.—Peat is mined or harvested by numerous methods in the United States dependent upon the prevailing conditions and the type of peat involved.

Sphagnum peat is mined through a combination of milling, aeration, and vacuum harvesting. A wide variety of equipment is required, including light and heavy power equipment; ditching machines to provide drainage; stumper, wood rake, and turner-aerator equipment to clear and aerate the surface; milling machines; vacuum harvesters; and wagons or trucks for transporting the harvested peat to the processing plant.

Reed-sedge peat may be harvested with conventional agricultural disking equipment, wide track bulldozers, and front-end loaders. Alternate methods involve milling or bulldozing, followed by windrowing and product pickup with a force feed loader equipped with a side-loading attachment. Smaller operations sometimes mine humus peat with power

shovels, small draglines, and front-end loaders.

Fuel-grade peat, following conventional field preparation methods, is compressed into 4-inch-diameter cylinders with sod harvesting equipment. The cylinders break off at lengths ranging from 8 to 12 inches and drop to the surface for air drying. After windrowing to effect complete drying, the cylinders are picked up by a force feed conveyor loader and discharged into trailers for transport to the powerplant.

Processing.—All peat usually requires screening to remove debris and to produce a desirable marketable product. In state-of-the-art sphagnum operations, harvested peat is fed to a radar screen for sifting and the removal of large debris. The raw product is next discharged to a double-deck vibrating screen to effect sizing and to remove the smaller debris. Product oversize passing over the primary screens is hammermilled and recycled to the screening process. Processing is effected in a closed system equipped with an overhead vacuum takeoff for fine or dusty material. The fines may be recycled or conveved to a closed waste bin outside the plant.

Product-grade material is discharged to a surge bin from which peat is processed in a four-step automated turntable process, wherein product is gravity metered into plastic containers, compressed into bales on a 2:1 volume ratio, sealed, and conveyed to storage. Four-cubic-foot bales are the most popular size produced, but 2-cubic-foot and 6-cubic-foot bales are also produced in significant quantities.

Reed-sedge and humus peats are screened, packaged in bags, or sold in bulk. The materials may also be blended with perlite, vermiculite, sand, and sphagnum moss and packaged as potting soils, or for a variety of other uses. Peat-sand mixtures are popular bulk materials that are sold to golf courses for greens construction and for top dressing greens, tees, and fairway turf.

Economic Factors

U.S. peat prices, without adjustment for inflation, have increased at an average annual rate of 5% per year over the past 22 years (1970-92). Prices expressed in terms of constant 1992 dollars, however, have declined at an average annual rate of about 2% per year over the same period. The U.S. peat industry has overcome inflationary pressures principally through the rationalization of capacity, together with a move to higher volume modern and efficient plants, the proliferation of value added consumer products, and through the importation of more peat and finished peat products from Canada.

ANNUAL REVIEW

Legislation and Government Programs

The Environmental Protection Agency (EPA) issued final rules for Hazardous Waste Management; Liquids in Landfill, 40 CFR Parts 260, 264, 265, and 271. The rule was published in the Federal Register on November 18, 1992, and was to become effective on May 18, 1993. EPA's ruling addressed the final of three congressional requirements developed under the 1984 Hazardous and Solid Waste Amendments to the Resource Conservation and Recovery (RCRA)—"landfill disposal containerized liauids mixed with sorbents."

This rule satisfies the statutory requirement that EPA issue a rule prohibiting the disposal of liquids in "hazardous waste landfills" that have been sorbed in materials that biodegrade or that release liquids when compressed, as might occur during routine landfill operations, and is intended to ensure the stability of materials in "hazardous waste landfills."

The Assistant Surgeon General, U.S. Public Health Service, clarified several points relative to EPA's seemingly complicated ruling. It was emphasized that the rule prohibits only the "direct" landfilling in "hazardous waste" landfills of liquids that have been sorbed into "biodegradable" sorbents. Thus, the rule

does not in any way prohibit or restrict the use of sorbents (organic or otherwise) to address wastes or products going to a nonhazardous waste landfill (e.g., municipal nonhazardous or waste industrial landfill). Furthermore, it does not affect the use of sorbents with hazardous waste that is not landfilled; for example, that is burned for energy recovery, incinerated, recycled, or treated through bioremediation or land treatment.

EPA, in its rulemaking, did not conduct tests on the degradation of organic sorbents in an anaerobic landfill environment. Also, EPA did not test and made no judgment on the efficacy of different sorbents, including organic sorbents, in spill situations. Factors like absorption and retention—important considerations in the performance of sorbents in responding to spills—lay outside the scope of the rulemaking.

The U.S. Fish and Wildlife Service continued to act as custodian for the preservation of a 93,000-acre peatlands on the environmentally sensitive Pamlimarle Peninsula in northeastern North Carolina. About 35 million dry tons of high-energy fuel-grade peat was deposited to an average depth of 6 feet over 70,000 acres of the property, formerly owned by First Colony Farms.

The Fish and Wildlife Service combined these lands with its adjacent 10,000-acre Pungo National Wildlife Refuge to form Pocosin Lakes National Wildlife Refuge. The development includes fire control, maintenance of drainage canals, provision of grain for feeding, and enforcement of wild game hunting. Deer, black bear, and wood duck were native to the area.

The Pamlimarle Peninsula is the site of North Carolina's largest peat reserves. The peninsula is estimated to include 360 square miles of peatlands containing about 210 million tons of peat on a moisture-free basis. Only two small peat operations are currently active on the peninsula.

Large-scale commercial composting programs, fueled by environmental regulation, continued to proliferate in both the public and private sectors during 1992 and competed with peat in selected applications. Compost could lead to further growth in mulching and soil amendment activity dependent upon economic factors and consumer acceptance. In any event, several peat-compost product blends were marketed by major U.S. peat producers in 1992, representing a new trend that will most probably continue to increase in proportion to the availability of quality compost materials.

Issues

Peat deposits along the U.S. eastern seaboard, extending from Maine to Florida, are regulated by Federal, State, and local environmental agencies owing to population density and sensitive wetlands areas; this is also true in California along the U.S. west coast, and to an extent in several Midwestern and Northeastern States. Conversely, the northern tier Great Lakes States are situated, for the most part, in more environmentally friendly surroundings. This is particularly true in Minnesota, where the prudent development of the State's tremendous peat reserve base—representing about 30% of total reserves in the 48 contiguous United States—is encouraged to generate employment and contribute to economic growth.

Since 1987, U.S. domestic peat sales have declined 25%, apparent domestic consumption has fallen by 13%, and 21 U.S. peat operations have been closed. During the same period, imports of Canadian peat have increased 37%, and the U.S. import reliance has skyrocketed from 33% of total domestic consumption in 1987 to a record 52% in 1992.

About 55% of the decline in domestic peat production and sales was in the leading States of Florida and Michigan, but equally disturbing was the fact that about one-third of the loss was attributable to five States in mid-America (Iowa, Illinois, Indiana, Ohio, and Pennsylvania). Production in New Jersey has fallen 45% during the same period, while operations in California, Georgia, and Maryland have ceased altogether. Small operations in Maryland, New

Jersey, and New York, for example, have been shut down for an indefinite period by various regulatory agencies.

In total, about 35 U.S. peat operations have been idled or have gone out of business since 1987. Many producers and consumers felt that a more equitable balance between environmental regulation and peat mining was needed, given the importance of peat to the U.S. economy and its value to the U.S. consumer. Industry sources were becoming increasingly cognizant of the role that Minnesota's tremendous sphagnum peat reserves will play in advancing future competitiveness and growth in the U.S. peat business.

Production

Peat was harvested and processed by 71 operations in 20 States, excluding Alaska. Florida and Michigan produced about 64% of the U.S. total, followed by Minnesota with 6%. The majority of U.S. peat production, about 80%, was conducted in high-volume operations that accounted for about 30% of the total number of active facilities. Geographically, about 40% of the total U.S. peat output by weight was from four southeastern States; 35% from the Great Lakes region; the Midwest and Northeast, 10% each; and 5% from the Western States. The States of California, Georgia, and Maryland did not report production in 1992.

On a weight basis, reed-sedge peat was 60% of total U.S. production; humus, 23%; hypnum moss, 8%; sphagnum moss, 5%; and other forms, 4%. On a volume basis, the product distribution may be altered dependent upon variations in peat bulk density, from sphagnum moss at the low end of the scale, having a density of about 500 pounds per ton, to humus, having a bulk density of more than 1,000 pounds per ton. Thus, reed-sedge was 59% of production by volume; humus, 20%; sphagnum moss, 10%; hypnum moss, 9%; and other forms, 2%.

In Alaska, A&A Services, The Dirt Co., and Landscape Supply Corp. produced peat in the Anchorage area,

while Great Northwest, Inc., was active near Fairbanks. Alaskan peat demand increased dramatically during the early 1980's coincident with the economic boom precipitated by the development of the Alaskan Oil Pipeline. Production peaked at 125,000 cubic yards in 1984 and carried a value of \$859,375 or \$6.88 The potential for future per yard. development of Alaska's tremendous peat resources will be dependent upon Alaska's economic growth, peat's emergence as an effective filtration medium for the control of toxic waste effluents in mining, and logistical factors. (See tables 2 & 3).

production and sales volume were each up 21% by weight in 1992, given better weather conditions and improved demand for quality sphagnum and reed-sedge peat products. During the year, eight producers were active, of which there were three major sphagnum producers in Carlton County and St. Louis County, and one major bulk producer of reed-sedge in Aitkin County, all near Duluth, MN. Minnesota's premium peat was valued at \$69 per ton, f.o.b. plant, threefold above the U.S. average.

Davidson Peat was harvesting reedsedge peat from a 35-acre bog in Rice County, MN. Raw peat was extracted with a 4-cubic-yard swinghoe power shovel and stockpiled on-site. Following windrowing to effect drying and weathering, tractor-trailer rigs transported the peat to Davidson's processing plant at Kenyon, MN, near the town of Webster. Davidson sells fine milled bulk peat and peat-sand bulk blends. The firm, operating under county mining permits because peat harvesting permits were not available, was working with local officials to study the feasibility of introducing peat harvesting permits.

Aitkin Agri-Peat began harvesting and selling reed-sedge at its bog in Aitkin County in 1984. The operation was improved and expanded through the lease and later purchase of specialized equipment from the Natural Resources Research Institute (NRRI), University of Minnesota at Duluth. Aitkin also

designed and constructed unique harvest machinery that provides an efficient and economical method of harvesting bulk peat. Production capacity is about 20,000 cubic yards annually, from 100 acres of the 300-acre deposit. Aitkin Agri-Peat markets bulk reed-sedge to general contractors and golf courses within a 250-mile radius of the harvest site near McGregor, MN.

Minnesota Sphagnum, Inc. (MSI) commenced sphagnum harvesting in 1987. The past 5 years has been devoted to improvements in processing facilities and field expansion. Expansion of this operation will continue for the next 3 to 5 years. MSI currently harvests peat from 250 acres and markets sphagnum peat in bale and bulk in the Midwestern and Southwestern States. The MSI organizational structure is through Hyde Park Products and Conrad Fafard, Inc.

Peatrex Ltd. began sphagnum production in 1985 near the town of Cromwell, MN, in Carlton County. The operation is of Finnish design with good drainage. The fields are profiled for fast turnaround after heavy rains. In 1989, Peatrex was purchased by Premier Enterprises of Canada, and since, has constructed a state-of-the-art sphagnum processing facility on the property. Harvested sphagnum from the 250-acre operation is processed into 2-, 4-, and 3/4-cubic-foot bales or sold in bulk.

Michigan Peat Co. is a major supplier of retail soil amendments and professional grower horticultural products in the north-central States, providing a wide range of peat-based products to an area containing more than 40% of the Nation's population. Peat was harvested and processed in five locations, including sphagnum moss production at Cromwell, MN; two facilities in the "Thumb" area of Michigan, near Sanilac; together with one operation each in north-central Colorado and central Florida.

Michigan Peat is headquartered in Houston, TX, from which a \$15 million annual business is coordinated. The firm has the capacity to harvest 150,000 tons of reed-sedge peat and sphagnum peat moss annually, or about 20% of current U.S. production. Michigan Peat products

are marketed under the BACCTO and Garden • magic labels.

Hyponex Corp. harvested and processed reed-sedge peat from facilities in six States extending from New Jersey to Colorado. Hyponex markets peat and peat blends throughout much of the United States. The firm operates from parent headquarters, the O. M. Scott & Sons Co., in Marysville, OH. Scotts is a recognized leader in the lawn and garden fertilizer market.

Hyponex was also operating 12 organic composting process facilities and a like number of additional sites across the country that were open to receive yard trimmings in line with the national thrust by the EPA and municipalities to recycle waste materials that otherwise contribute significantly to landfills overloading. Waste collection firms contracted by various municipalities transfer natural organic yard waste materials such as leaves, grass, and hedge trimmings, which in turn are recycled into marketable compost materials. The composting/recycling approach has proven to be a win-win-win situation for municipalities, taxpayers, and the environment. Consumer demand for Hyponex organic products, such as Compost plus Organic Peat, Rich Dark Top Soil, and all purpose Potting Soil, ensure a steady market for composted yard trimmings. The firm believes that enough demand could be generated for its organic products to allow for recycling virtually all yard trimmings generated by the major metropolitan areas of the United States.

Domestic Projects.—New horticultural peat projects were reported to be under consideration in the States of Georgia, Maine, New Mexico, North Dakota, and possibly in North Carolina. Fisons Horticulture, Inc. verified the transfer of its peat bogs in Minnesota and Iowa to State regulatory agencies.

NorthWoods Organics, a new Duluth, MN, subsidiary of Faulks Brothers Construction Co., Inc. of Waupaca, WI, was developing a new sphagnum peat bog in St. Louis County, MN. NorthWoods Organics will provide technical support and new product development for Faulks Brothers in the area of organic products for commercial landscape and construction applications. The new 150-acre bog and processing facility were targeted for completion by late 1993.

Fuel Peat Projects.—Plans by EcoPeat Co.—a U.S. affiliate of the Finnish firm Outokumpu—to develop 360 megawatts of peat-fueled electrical powerplants in cooperation with south-central Florida utility companies were postponed indefinitely. Central Florida utilities have reportedly opted to build powerplants based on natural gas fossil fuel.

The Down East Peat LP peat-fueled powerplant at Cherryfield, ME, was purchased in early January 1993 under the provisions of a reorganization that involved the formation of Worcester Energy Co., Inc. and Worcester Peat Co., Inc. The energy company acquired the 22.8-megawatt biomass powerplant, ancillary buildings, equipment, and 20 acres of adjoining land. The peat company, in turn, purchased about 900 acres of the adjoining Denbow Heath peat bog. At full capacity, the powerplant will require about 165,000 tons of bonedry peat annually.

Worcester Energy Co. closed the powerplant in mid-January 1993 pending negotiations of a proposed power contract with Bangor Hydro-Electric Co. in which Bangor was asked to pay \$0.02 above the normal \$0.03 per kilowatt-hour "avoided" rate. Bangor Hydro was required by law to purchase the plant's power at the avoided rate, the cheapest price that the utility would pay for additional electricity. The new firms projected a good harvest season on the bog and planned to bring the powerplant back online in June 1993.7

Down East Peat LP of St. Petersburg, FL, originally brought the \$51 million peat-fueled powerplant on-stream in June 1989 under the provisions of a 20-year supply agreement with Boston Edison, but the owners were ultimately faced with the prospect of continuing losses and opted to allow the utility to buy its way out of the contract in mid-1992. The plant operated on a combination of woodchips and peat

depending upon the availability of peat. Former Down East Peat officials reported that the project could potentially become one of the more viable sources of power in the country were enough peat acreage available, given that peat can be harvested at a fraction of the cost of wood, oil, or coal. Down East Peat also cited technology problems, high transmission costs, and an oversupply of electricity in the northeast as other factors that had been detrimental to the project's success.

Humate Production.—Humates were mined from the San Juan Basin deposits in northwest New Mexico and sold primarily for use as soil conditioners and drilling mud additives. In 1985, the last year of available data, humate production was about 23,000 cubic yards, with an f.o.b. mine value of \$404,000. Mining and processing were conducted by three companies in McKinley, Sandoval, and San Juan Counties.

Humate and weathered coal occur in the Upper Cretaceous Fruitland, Menefee. and Crevasse Canvon formations in the San Juan Basin. All of these humate deposits-high in humic acid content-represent a facies in poorly drained swamps in nearshore deltaic and fluvial sequences accumulated during marine regression in the Cretaceous. Most humate occurrences consist of carbonaceous claystones rich in organic matter, or weathered coal ("leonardite"), having a high humic acid content.8

Humate is commonly associated with both coal and lignite. When associated with lignite, humate is called leonardite, after A. G. Leonard of the North Dakota State Geological Survey. Through use, the term leonardite has been informally expanded to include coal-derived humate. Humic acid-rich deposits also exist in Arkansas, Florida, Louisiana, New York, North Dakota, Michigan, Minnesota, Texas, and Wyoming.

Consumption and Uses

Demand for U.S. peat products in 1992 continued to mirror the relatively flat profile of the past few years, underscored by a general downturn in the U.S. economy and the importation of more Canadian peat and peat products. In 1992, domestic sales tonnage declined 7% from 1991 levels, while imported material rose by more than 11% and captured a record 50% of the total U.S. peat market.

Packaged peat commanded 56% of the domestic sales volume by weight in 1992 and was valued at a 59% premium relative to bulk forms, according to the U.S. Bureau of Mines annual survey. Approximately 90% of U.S. producer sales was for general soil improvement, horticultural use, and agricultural use. In horticulture, peat was used predominately for general soil improvement, as an ingredient in potting soils, and in the nursery business. In agriculture, peat was used for general soil improvement, in mixed fertilizers, as a carrier and coating agent in seed inoculants, for vegetable cultivation, and as poultry litter.

Specialty applications included peat's use in golf course greens construction and course maintenance, as an earthworm culture medium, for mushroom cultivation, oil absorption and wastewater filtration, and for use in hygienic products. Minor quantities of peat were used as fuel for electric power generation.

One major challenge facing U.S. mushroom growers, according to the U.S. Department of Agriculture (USDA), arises when other natural organic products are substituted for peat as a growing medium. The storage and disposal of the natural organic peat substitutes can reportedly lead to environmental problems, not just for growers but for their nonfarm neighbors as well. (See tables 4 and 5).

Stocks

In 1992, primary producer peat stocks did not vary significantly from prior year levels and stood at about 0.3 million tons at yearend, according to the Bureau's annual survey of domestic peat producers. Producer peat stocks in all forms were about 50% of production, typical of the industry. Reed-sedge peat accounted for

about 60% of total stocks by weight. (See table 6).

Transportation

Peat was moved predominately by truck in both bulk and packaged form. Small producers were restricted to local market areas because of the sensitivity of peat prices to transportation charges. High-volume producer costs were less sensitive to transportation charges, allowing for interstate movement of peat and peat products.

Lindqvist Business Development Corp. of Minnetonka, MN, was evaluating the feasibility of the CARGO 2000, an innovative side dumping trailer developed by BURE VERKSTADS A.B. of Sweden for tractor-trailer or rail transport of peat, woodchips, beet pulp, and other bulk materials. During unloading, the roof, floor, and one side of the trailer are raised hydraulically. The lifting action of the floor and side wall will break up the cargo as it is dumped from the trailer, allowing even frozen cargo to be safely unloaded at rates in excess of 90 cubic yards per minute.

Markets and Prices

Domestic peat prices averaged \$23 per ton f.o.b. plant in 1992, relatively unchanged from the prior year. Packaged peat was quoted at a premium \$28 per ton compared with \$18 for bulk peat; however, packaged forms captured about 56% of the total sales tonnage. Sphagnum moss sold at a premium \$81 per ton, about 3 1/2-fold above the national average. (See table 7).

Foreign Trade

The United States has shipped minor quantities of peat offshore averaging about 20,000 tons per year over the past 4 years. In 1992, the U.S. peat industry exported 24,000 tons to 22 countries that was valued at \$2.1 million f.a.s., or about \$85 per ton. Mexico, Saudi Arabia, Canada, the United Arab Emirates, and Argentina, in order of importance, accounted for 86% of the

total.

In 1992, Canada continued to provide more than 99% of total U.S. peat imports-principally sphagnum moss-and new records were again established for both volume and value. Canadian imports reached a record 702,000 short tons, roughly 50% of the total U.S. peat supply, and carried a U.S. Customs value of \$110.6 million. equating to \$158 per ton. The value of Canadian shipments at the U.S. border exceeded total U.S. domestic peat sales, f.o.b. plant, by more than 560%. Another \$19 million in Canadian peat merchandise was recorded by U.S. Customs under the "Articles of Peat" category. Peat pots and other specialty peat-based products, including some peat mixtures, were reportedly included under this category.

Although Canadian peat shipments in all forms entered the United States duty free, a tariff of 10.2% was imposed by Canada on U.S. peat in 1992. United States exported a minuscule 2,000 tons of peat to Canada in 1992, valued at \$164,000 or \$82 per ton, according to U.S. Department of Commerce trade statistics. Under terms of the United States-Canadian Free Trade Agreement, the Canadian tariff on U.S. peat was to be removed effective January 1, 1993. A Canadian duty of 3.4% is currently imposed on U.S. "Articles of Peat," down from a maximum of 6.8%. This duty is scheduled to be gradually phased out at a rate of 10% per year over the next 10 years. The U.S. Bureau of Mines could not find a record for U.S. articles of peat export shipments in the U.S. Department of Commerce trade data base.

The United States accounted for roughly 90% of total Canadian export shipments in 1992. About 70% of the total was shipped from central and Atlantic Canada and the remaining 30% from western Canada. Officials of Energy, Mines and Resources Canada in Ottawa, Ontario, reported that Canada's improved performance in the United States was largely attributable to a greater visibility brought about by an intensive national promotional campaign, together

with more aggressive marketing by Canadian producers. Canada typically exports between 75% to 80% of its total peat shipments. (See table 8).

Energy, Mines and Resources Canada reported that about 75% of all Canadian shipments in 1992—domestic and export—originated from Quebec and New Brunswick in eastern Canada. Alberta, in western Canada, supplied about 10% of the total. The remaining 15% was reported to originate principally from Manitoba and Saskatchewan in western Canada, with minor contributions from the eastern Provinces of Nova Scotia and Newfoundland.

World Review

After peaking at 221 million tons in 1989, global production is estimated to have declined by 58 million tons to current levels, representing a drop of more than 26%. The major decline can be traced to the former U.S.S.R., where U.S. Bureau of Mines production estimates indicate that production has fallen about 57 million tons or 29% during the period cited.

In 1992, global peat production declined to 160 million short tons (10%). principally because of continuing geopolitical events in the U.S.S.R. The centrally planned economy of the former U.S.S.R. was replaced by 15 independent republics during the year, and the political and socioeconomic reforms of the recent past intensified. Finland rebounded from a poor harvest year in 1991 to near record levels of 6 million tons in 1992. Production in all other countries was believed to be comparable to 1991 levels with the exception of Ireland, which should recover somewhat from a poor harvest The total value of world peat production, assuming an average f.o.b. plant value of \$30 per ton, was about \$5 billion.

Ireland and Finland, in order of importance, accounted for about 63% of the estimated 21 million tons of peat produced outside the former U.S.S.R. in 1992. In Ireland, greater emphasis was being placed on fuel peat technology

transfer, environmental technology, and the marketing of horticultural peat, while in Finland, plans for additional peatfueled powerplants were under consideration. Germany provided 16% of global production outside the former U.S.S.R.; Sweden, 9%; Canada and the United States, 8%; and other countries, 4%.

Although peat was known to be deposited in the United Kingdom, tropics of Africa, Argentina, Brazil, China, Indonesia, Malaysia, New Zealand, Paraguay, and Uruguay, production data were not available. (See table 9).

Industry Structure.—The former U.S.S.R. was estimated to account for about 87% of global peat production in 1992, followed by Ireland and Finland, 4% each; Germany, 2%; Sweden, 1%; the United States and Canada, 1%; and all other countries. 1%.

Canada.—Energy, Mines and Resources, Ottawa, Ontario, reported that the total area of peatlands in Canada is estimated at 111 million hectares (275 million acres) covering approximately 12% of the country's surface. Canada produces sphagnum peat for the most part typically from May to September, primarily in the eastern and southeastern parts of the Province of Quebec, in the eastern and northeastern parts of the Province of New Brunswick, and in the western Provinces near Edmonton. Alberta: Carrot River, Saskatchewan; and Giroux and Elma, Manitoba. Some peat production is also found in the Provinces of Nova Scotia, Prince Edward Island, and Newfoundland. Canada's massive peat resources can probably be harvested for centuries.

Production from about 77 operations declined about 13% in 1992 owing principally to bad weather in Quebec. Shipments—predominately for export—rose, indicative of inventory liquidation from the prior year. Production increased 58% in Nova Scotia, 20% in Manitoba, and 3% in New Brunswick. Production was down 49% in Newfoundland, 16% in Saskatchewan,

7% in Alberta, and 40% in Quebec. Production figures are confidential for the Provinces of Manitoba, Nova Scotia, and Saskatchewan.

Two new operations were opened or under development in New Brunswick in 1992 near Shediac and Acadieville, respectively. Tourbières Premier Enterprises Ltd., a subsidiary of the important Canadian peat producer Premier CDN, was opening the bog at Acadieville. A new bog was also opened and harvested in New Brunswick by Berger Mix Inc. at Bay-au-Vent, and plans were developed by Le Groupe Qualite' Lamèque Ltèe to put a plant in place in 1993 that will produce peat-based mixes. Fafard et Frères Ltd. increased its activity at Sainte-Marguerite, Ouebec. to respond to a growing demand for Johnson and Johnson Inc's. new sanitary napkins. Peat was harvested in blocks and, as such, was unaffected by the bad weather conditions that prevailed in Ouebec during the summer and fall of 1992.

The United States and Japan were Canada's principal export targets, in respective order of importance. A 1990 study supported by the Canadian Embassy in France indicates that substantial quantities of peat could be sold to France and eventually to other European countries if producers took full advantage of backhauling to reduce freight costs. ¹⁰

The Newfoundland and Labrador Peat Association, in cooperation with many other Canadian agencies, was to hold an international peat conference— Newfoundland Peat Opportunities—in the fall of 1993. The conference was to the current situation in examine Newfoundland and around the world, identify barriers to development, and formulate a plan of action aimed at appropriate development of the province's peat resources. The island Newfoundland is blessed with more than 1 million hectares (2.5 million acres) of peatlands. These deposits represent a largely untapped natural resource offering significant business development opportunities. The resources Labrador, while yet to be quantified, are likely to offer far greater potential.

Finland.—In 1992, Finland's peat production totaled 21.5 million cubic meters (28.2 million cubic yards) representing an increase of 115% compared to 1991, when production declined significantly owing to inclement weather. This production was very near the alltime production record established in 1986. Milled fuel peat production was 18.5 million cubic meters, 86% of the total, and sod fuel peat 1.4 million cubic meters, or 6.5%, bringing total fuel peat to 92.5% of total production. Horticultural peat was 1.6 million cubic meters, or 7.5% of total production.11

Peat production in Finland was very small in 1970, but grew to about 3 million cubic meters by 1975 and to a record of about 22 million cubic meters by 1986.¹² The potential for utilization of fuel peat in Finland is currently about 30% above actual use and is projected to potentially more than double during the next 10 to 15 years.¹³

Former U.S.S.R.—The peat resources in the former U.S.S.R. are commonly referred to as the largest in the world, and more than 90% are found in Russia. The total area of peatland in the former U.S.S.R. is about 80 million hectares, and the quantity is 200 to 250 billion metric tons at 40% moisture. western Siberian plain is a vast peatland covering about 30 million hectares with a resource base in excess of 100 billion metric tons. The world's largest deposits lie here with Vasyugaskoe alone having an area of 5 million hectares containing about 10 billion metric tons of peat. The resource has been extensively exploited for fuel use for more than 50 years.¹⁴

Production was confined to the Baltic Republics, the Moscow-Gor'kiy area, Belarus, and the Ukraine, although peat was known to be deposited throughout much of the country. Peat was burned in thermal powerplants in the European Republics and was also used to fire industrial boilers and large heating plants.

The use of peat in the former U.S.S.R. was reportedly declining because of insufficient reserves in the

primary consuming areas around Moscow and St. Petersburg and restricted demand in the energy and agricultural sectors owing to a radical shift in sociopolitical and socioeconomic philosophy. The chemical industry produced methanol and synthetic natural gas from peat.¹⁵

Changes have caused extensive restructuring in the various new republics that, in turn, have created a number of alterations in the membership structure of the International Peat Society (IPS). In June 1992, the IPS Council meeting in Uppsala, Sweden, resulted in the approval of membership applications from the Russian National Committee and the Belorussian Peat Society. The Ukrainian company "Ukrtorf" (Ukrainian Peat) was accepted as a collective member of the IPS. Earlier, in a meeting at The Hague, The Netherlands, the IPS Council approved Estonia's application. Latvian Peat and the Lithuanian Peat Society from Lithuania were also approved as collective members.

The entry of major producing regions from the former U.S.S.R. was warmly greeted by the IPS Council. Estonia has already reported detailed peat information, and expectations were that comprehensive information would soon be available from IPS members in other areas of the former U.S.S.R.

Estonian officials reported that in 1992 a total of 6.1 million cubic meters of peat was produced, of which 4.0 million cubic meters (66%) was horticultural peat and 2.1 million cubic meters (34%) was peat fuel. Estonia exported 111,000 metric tons of peat, representing a volume of about 555,000 cubic meters. Peat was harvested from an area of 14,000 hectares. Estonian peat resources were reported to cover about 1 million hectares. ¹⁶

In the Ukraine, annual agricultural peat use dropped sharply between 1991 and 1992, from 18 million annual metric tons to just less than 5 million annual tons. Fuel use has remained level at about 2 million tons of dried peat, about 50% of which was used to produce briquettes in about 20 factories.

In Belarus, fuel peat production was reported to be about 2 million tons,

almost all in the form of briquettes. Lithuania has only three small briquette plants with a total annual capacity of 20,000 tons.¹⁷

Ireland.—In the fiscal year ending March 25, 1992, Ireland's Bord na Móna peat production fell owing to inclement weather conditions, but, most importantly, the sales volume was up and profitability reached an alltime high. These positive results were a reflection of the success of a major reorganization effected in 1988.¹⁸

Bord na Móna, established by the Turf Development Act of 1946 to develop Ireland's peat resources, sells milled peat to the Electricity Supply Board for use in domestic peat-burning power stations, briquettes and machine turf on the domestic fuel market, moss peat and other growing media in the garden and horticultural industries on a worldwide basis, and manufactures pollution abatement products.

A reorganization in 1988 established four core business divisions. The largest of the new divisions is the Peat Energy Division, which is responsible for milled peat operations, with sales accounting for about one-half the group's turnover. Milled peat productivity has been doubled and unit costs dramatically reduced. The Division's principal objective was to continue to improve the comparative economics of milled peat relative to oil, gas, and coal. Gains in productivity have reached a point where milled peat costs are becoming more competitive in terms of world energy prices. The Division decided to conduct a prefeasibility study for a new 125-megawatt peat-fired power station that could take advantage of recent advances in technology.

The Solid Fuels Division is responsible for the production and sales of "briquettes and machine turf." The outlook for solid fuels has been clouded by a swing in demand to natural gas by industrial users of solid fuels as an inevitable consequence of the extension of the national gas grid and a significant rise in privately produced turf in the Midlands region, a traditionally strong market area for briquettes. Production of private

turf—promoted by the Turf Development Act of 1981—rose to 1.5 million tons in 1990, representing a fourfold increase over that of the past decade. In the recent fiscal year, the Division registered a significant improvement through the development of a capacity rationalization program that will ultimately result in the closure of the Lullymore Briquette Factory in County Kildare in 1992-93.

The Horticultural Products Division is a major exporter, with more than 90% of production being sold abroad, mainly to markets in the European Community (EC). A minority holding in a Dutch cooperative was established in 1990 to enhance the Division's presence in what is regarded as Europe's leading market in horticultural products. Effective January 1990, the Division established its own distribution subsidiary, Du Móna France S.A., with offices in Lyon. strategy, together with the previous acquisition of the French horticultural peat subsidiary, Pouget Solami, should further enhance the Division's competitive advantage in the French peat market.

The United Kingdom is the largest market for the Division's exports, and much effort was spent in restructuring marketing strategy to deal with declining disposable income in the United Kingdom and an increasing awareness environmental considerations on the part of consumers. Shamrock Horticulture, a wholly owned subsidiary, was processing peat at a new plant in Liverpool. A new composting plant was successfully commissioned at Liverpool during the year in response to a growing trend in consumer preference for blended products (fertilizer and other).

Bord na Móna reiterated its opposition to the unacceptable practice of exploiting boglands of special scientific interest and continued to transfer environmentally sensitive boglands to the Wildlife Service. Ultimately, 3,400 hectares of boglands will be protected in accordance with Government policy.

Netherlands.—In the 11th and 12th centuries fuel peat cutting in the bogs was practiced throughout the country, and by

the 15th and 16th centuries, peat production was also active in the lowmoor deposits. Not only was the landscape radically changed and land reclamation commenced, but also extensive lakes were formed, which today contribute to the beauty of the surrounding countryside. After World War II, demand for fuel peat had been reduced to the small-scale production of activated carbon.

Sphagnum peat moss began to be harvested by 1880, and many mills were founded in the east of the country and in the neighboring German peat areas, where Dutch producers bought bogs. The peat moss industry flourished until the end of World War I, when there were large-scale exports of sphagnum peat moss litter to Belgium, England, France, and many other countries.

Peat production in the Netherlands today is essentially nonexistent. There are still a few state-owned bogs reserved for conservation, and a few thousand hectares of boglands is managed by environmentalists. Demand continues to grow, however, and in addition to traditional black peat imported from Germany, supplies continue to increase from Scandinavian countries, the Baltic States, Ireland, and Russia. Canada may also become a future supply source. ¹⁹

Sweden.—The 9th International Peat "Peat Congress, in Nature Industry—a Matter of Balance," was held in Uppsala, Sweden, June 22-27, 1992. under the auspices of the Swedish National Committee of the International Peat Society. Approximately 308 representatives from 26 countries attended the Congress, and 141 papers were presented by a global spectrum of noted peat scientists during the Congress proceedings. The Congress proceedings were published in three volumes and may be obtained from International Peat Society headquarters in Jyskä, Finland.²⁰

In 1992, Sweden was producing about 1 million cubic meters of horticultural peat and about 3 million cubic meters of fuel-grade peat, annually. Swedish peatlands were reported to cover an area of about 6.3 million hectares (15.6)

million acres), or about 15% of the total land area. About 865,000 acres of peatland was available for fuel peat production. The overall area suitable for horticultural peat production has not yet been surveyed.

Sweden currently has about 50 producers of horticultural peat, mainly in the south and middle regions. Roughly 400,000 cubic meters is produced as milled peat and 600,000 cubic meters as sod peat, of which 30% to 35% is exported. More than one-half of the consumption is used by domestic and amateurs for home garden applications.²¹

After reaching a maximum production and sales of about 2.5 million cubic meters in 1950, fuel peat declined dramatically because of its economic disadvantages to cheaply priced fuel oil. By 1970, fuel peat production in Sweden was nonexistent. There was a subsequent revival in fuel peat demand beginning in the early 1980's, however, as an aftershock of the global energy crises of the 1970's.

Unfortunately, the Government's philosophy regarding Swedish fuel peat and peatland research has changed during the past 3 years. Environmental and ecological concerns have apparently dampened further progress in fuel peat output. So far, fuel peat has been taxed based on sulfur dioxide and nitrogen oxide emissions. The Swedish Peat Producers Association recent promotional activities have again generated moderate optimism by Government agencies.

Kingdom.—A private United consortium of peatland conservationists, called the Commission of Inquiry into Peat and Peatlands, held three public hearings between September 29, 1991, and November 27, 1991, two at the Natural History Museum, London, and another in the Council Chamber, Strathclyde Regional Council in Glasgow, Scotland. The commission was concerned primarily with the conservation of lowland raised bogs, because this was identified as the most immediately and seriously threatened of peatland types in the United Kingdom. The commission also expressed concern for the conservation of blanket bogs, fens, and other British peatlands, but considered this issue to merit separate consideration.

The commission reached several important conclusions and recommendations. Current data suggested that there was 1,421,194 million hectares of "blanket boglands" in England, Wales, and Scotland; 10,060 hectares of "intermediate bog," and 67,058 hectares of "lowland raised bog." The best available scientific evidence suggested that the maximum area of natural, undamaged raised bog remaining in the United Kingdom was less than 6,200 hectares. 10,000 hectares in Great Britain. The predominate reduction resulted from forestation and conversion of peatlands to agricultural use.

It was recommended that Country Conservation Councils: English Nature, the Countryside Council for Wales, Scottish Natural Heritage, and the Department of the Environment (Northern Ireland) should adopt a rigorous policy to protect raised bogs and rehabilitate damaged bogs where necessary. The commission also stressed the use of alternative natural organic composts.²²

Current Research

Peat research continued at a rapid pace during 1992, and many projects were reaching commercial fruition. Commercial ventures were established to produce and market peat-based oil sorbent products in significant quantities in the United States. Consumers of the peatbased products liked the superior absorbency and environmentally friendly aspects of disposal relative to clay-based products. Peat was also shown to be an effective filtration source for the removal of toxic wastes from secondary sewage effluents, management control of urban stormwater, elimination of offensive odors, and as a superior bulking agent in the composting of natural organic waste products.

The NRRI, at Duluth continued to provide technical assistance to Mat Inc., a Floodwood, MN, peat firm that produced peat sorbents for D M S & D

Associates, Inc. of Ocean, NJ, and Fisher Steven Inc. NRRI researchers reported that additional sorbent products were in the development stage, including peatbased socks, booms, and wood fiber pads. Mat Inc. was already receiving orders for the new products although NRRI had just begun to identify tooling requirements for production.

According to a recent NRRI study, sorbents manufactured from the higher density, more decomposed Minnesota peats carry an optimal unit value that gives Minnesota product more than a twofold competitive transportation cost advantage over Canadian sorbents. NRRI researchers also reported that properly dried and processed Minnesota sphagnum peat performs as well or better than Canadian peat and surpasses clay, paper, sawdust, and corn. All peats tested were reported to exceed clay-type sorbents. ²³

During 1992, a 2-year commercialscale turkey litter waste management project was initiated between NRRI, the Agriculture Utilization Research Institute (AURI). and Langmo Farms of Litchfield, MN, in association with Minnesota Technology, Inc. and Howe Best waste management Chemical. practices must be developed given that Minnesota is the second largest turkey producer in the United States with about 46 million birds generating about 1 million tons of manure annually, in with new environmental concert regulations formulated by the Minnesota Pollution Control Agency (PCA) placing limitations on manure application rates.

Traditionally, farmers have tilled turkey droppings into wood shavings litter that remain in the barn with the birds throughout the year. Heavy applications of turkey manure to agricultural lands can lead to an excessive buildup of fertilizer nutrients that may lead to serious water quality problems. A novel feature of the landmark research was to incorporate turkey-friendly and environmentally sound sphagnum peat, oat, and sunflower hulls with the traditional wood shavings Peat is used in the litter to maintain low ammonia and odor levels and to control micro-organisms that can cause disease in the birds. Additionally, sphagnum peat is low in dust—beneficial to the birds' health—and provides a low pH and high nitrogen content; ideal conditions for producing high-quality compost for horticultural applications.

In addition to high waste litter production levels and avoidance of PCA violations, the project should provide a new commercial horticultural substrate product outlet for turkey farmers. Howe Chemical planned to collect 1,000 tons of composted turkey litter produced during the project to manufacture and test market an organic-based, premium-grade lawn and garden fertilizer and a low-grade organic agricultural fertilizer. Howe planned to be at the test market stage by late 1993.²⁴

Michigan Peat Co. of Houston, TX, developed a unique compacted peat that served as a natural potting soil additive, providing improved aeration and drainage. Michigan peat representatives said that its particle size could be tailored to individual needs, while maintaining integrity and resistance to breakdown during watering cycles.

D M S & D Associates, Inc. developed and test marketed a unique hydrophobic sphagnum peat moss product having superior hydrocarbon sorption properties. The firm reported that 1 pound of the product would effectively sorb 1 gallon of oil typically weighing about 8.2 pounds. D M S & D personnel said that the new product represented an advanced concept in spill cleanup.

The new peat product was reported to be cost efficient and safe to use compared with traditional products. Savings per gallon for the cleanup and disposal of a 1-gallon spill were favorable to traditional clay products, corn-based materials, and paper absorbents, in respective order of importance.

In addition to its unique hydrocarbon sorbent properties, the product has disposal advantages. It is biodegradable, fuel blendable, EPA qualified as an alternative fuel with a low ash content, and is vapor suppressive. Thus, the product is environmentally friendly, helping to minimize waste going into diminishing landfills. Its native population of micro-organisms assist in

bioremediation, and it can be recycled as an alternative fuel. When used on water, it locks in the hydrocarbons, protecting wildlife and reducing environmental impact.

State transportation agencies in the northeastern United States, where clay sorbents have been banned, found that peat sorbents represent an environmentally friendly and economically viable clay substitute. In one northeastern State where clay has been banned since 1990, it was found that the use of peat sorbents was advantageous to employee health, represented indirect cost savings via disposal and less bulk, avoided landfills, and could be consumed in industrial fuel applications.

Several domestic and foreign parties continued to be interested in sphagnum moss bioaccumulation processes developed by the U.S. Bureau of Mines Salt Lake City, UT, Research Center that were effective in extracting toxic metal ions from a variety of wastewaters. 25 Bureau researchers developed porous polymeric beads, designated BIO-FIX beads, that were prepared by blending sphagnum peat moss or algae into a polymer solution and spraying the mixture into water.

Batch and continuous tests demonstrated that BIO-FIX beads removed arsenic, cadmium, lead, and other toxic metals from acid mine drainage waters collected from several sites. Selectivity for heavy and toxic metal ions over calcium and magnesium was demonstrated. The sorption process was reversible, and metal ions were eluted from the beads using dilute mineral acids. Cyclic tests indicated that the beads continued to extract metal ions after repeated loading-elution cycles.²⁶

STS Consultants, Ltd., Minneapolis, MN, continued to develop a unique peat wetlands treatment approach to acidic mine drainage abatement. The firm reported that peat wetlands demonstration plots constructed and operated during the past 2 years had effectively removed 80% to 95% of copper and nickel emanating from acid mine drainage streams. STS was constructing the first commercial peat wetlands system in Minnesota. The

system will be designed to treat a flow of approximately 10,000 gallons per day, constructed for subsurface flow utilizing 1 foot of limestone as a substrate, covered by about 3 feet of fibrous screenings and peat mixture.²⁷

The Department of Environmental Programs, Metropolitan Washington Council of Governments, was developing peat-sand filter systems for stormwater management in the Anacostia River Basin. The River Terrace Peat-Sand Filter Project, situated on a 155-acre drainage area in the District of Columbia. was under contract for completion by late 1993. Engineering was underway for the Hollywood Branch Peat-Sand Filter Project in Montgomery County, MD, scheduled for construction beginning in the fall of 1994.28

Prodex Inc. of Ravenna, OH, continued research into humic acid extracts. The firm developed Biogene products that were sold as agricultural and horticultural plant stimulants, animal feed additives for improved nutrition and health, and as an accelerator in anaerobic biological sludge digestion in municipal and industrial wastewater treatment. Prodex was developing processes for improved peat fuel and horticultural applications, together with the separation of organic and metal contaminants from industrial wastewater streams.²⁹

Johnson & Johnson (J&J) successfully marketed a new line of ultrathin feminine hygiene napkins in Canada having an absorbent core of processed peat moss. J&J officials said the processed moss could absorb 20 times its weight in liquid. The firm claimed that its peat moss pad provided the same absorbency at one-fifth the thickness of ordinary hygienic pads and was slightly thinner and superior to "ultra thin" pads that relied on superabsorbent polymers. The product was developed by the company's Montreal-based Canadian unit.³⁰

MULTITEK of Prentice, WI, introduced a modular system designed to separate and pulverize peat and other natural materials to desirable marketable consistency at rates up to 150 tons per hour. The unique tumbler screen rotates the material while 32 hammers pulverize

to produce unequalled productivity. The system is totally portable and is hydraulically powered, permitting variable adjustment to peak performance speeds. This machine was reported to outperform a typical vibrator screen system. A portable unit was available that could be towed at highway speeds with a 1-ton truck. In addition to peat, the system can handle top soil, sand and gravel, compost, grade rock, composted manure, clay, woodchips, bark, coal, and composted sewage sludge.

Enviro Industrial Technology Corp. (E.I.T.C.) of Alberta, Canada, developed a novel line of peat harvesting and wetlands transport equipment. The products currently developed include a Field Profiler, Root Picker, Spoon and Rotary Harrow, Chain Miller, Ditcher, Vacuum Harvester, and Transport Wagons. E.I.T.C.'s equipment was designed to meet the rigorous durability demands associated with high production rates and low maintenance costs expected by the North American peat industry.

In Canada, fuel peat projects were under consideration in Alberta, Newfoundland, Nova Scotia, Ontario, and Saskatchewan. Energy, Mines and Resources Canada cited peat as being increasingly perceived as a low-sulfur fuel alternative to coal for power generation.³¹

SaskPower and a Meadow Lake company in Saskatchewan planned to build a \$22 million peat-burning powerplant at Jans Bay, north of Meadow Lake. It would reportedly generate 15 megawatts, enough to heat a community of 3,000 homes.

Peat Resources was planning a \$4.5 million pilot plant to produce fuel-grade peat at a prime peatland 35 miles northwest of Thunder Bay, Ontario, Canada. Data collected from the pilot plant operation would be used for the potential design of a \$95 million commercial plant capable of producing 1 million tons per year of peat fuel. The fuel would reportedly be used as an environmentally attractive alternative energy replacement for coal in electrical power generation plants.

The pilot plant would test a process

for producing high-grade industrial peat fuel with a heating value comparable to bituminous coal. In a recent test burn completed by Ontario Hydro, the experimental peat fuel produced less than 5% ash, and a mixture of coal and peat fuel reduced sulfur emissions in direct proportion to the quantity of peat blended. Peat Resources, which had been developing the peat fuel process since 1984, applied for a Canadian patent.³²

Peat also showed promise as a biodegradable medium in disposable diapers and in food packaging.

OUTLOOK

During the past 21 years, U.S. domestic peat production has grown at an average annual rate of about 2.0% per year and apparent domestic consumption by about 3.5%. The most recent upturn in the U.S. peat supply-demand cycle was experienced between 1981 and 1987. Domestic peat production hit the bottom of the latest cycle in 1981 at 0.7 million tons and gradually increased to a record 1.0 million tons by 1987, representing an average annual growth of about 7%. Total apparent domestic consumption during the same period followed the domestic production trend and grew at an average annual rate of 7%, from 1.1 million tons in 1981 to a record 1.5 millon tons in 1987.

Between 1987 and 1992, domestic peat production and total apparent domestic consumption have declined 7% and 2%, respectively, owing to a downturn in the U.S. economy. Canadian imports as a percent of the total U.S. supply, however, increased from 35% in 1987 to a record 50% in 1992.

A review of the projections by various members of the U.S. horticultural and community substantiates the existence of a widely held opinion that horticulture will continue as a strong growth industry. The Horticulture Research Institute, National Landscape Association, Society of American Florists, and the National Gardening Association all forecast significant future growth.³³

In December 1992, USDA officials were cautiously optimistic about near-

term growth in the floriculture and environmental horticultural industry. USDA officials said that the greenhouse and nursery industry business remained on the verge of another wave of expansion, dependent upon the fate of the U.S. economy. Mr. Doyle C. Johnson, an agricultural economist with USDA, in speaking before the Annual Agricultural Outlook Conference in Washington, DC, "As the economy slowly improves, consumer demand for flowers and plants will accelerate. The 1993 Greenhouse/Nursery industry outlook for consumer expenditures and producer receipts is for a gradual, renewed expansion at a more moderate rate than the rapid expansion of the 1980's. For 1993, the Gross Domestic Product is forecast to grow 3.1% which projects to an 8% growth in retail Greenhouse/ Nursery product sales to nearly \$44 billion (\$170 per capita)."

The U.S. Bureau of Mines forecast for horticultural peat during the next 5 years is based on a gradual recovery in the economy and a resultant rebound in domestic production and total apparent domestic consumption. Domestic production of horticultural peat is forecast to grow at an average annual rate of about 2% to levels approaching 0.8 million tons by 1997.

Total apparent domestic consumption for horticultural purposes is forecast to grow at an average annual rate of about 4% per year to about 1.6 million tons by 1997. Canadian imports are forecast to rise from a current 50% of the U.S. supply to about 55% by 1997. Per capita consumption is forecast to approximate 12.5 pounds by 1997 and approach the 12.7-pound average experienced during the peak years of 1986 and 1987.

The Bureau's forecast for domestic peat production and demand could be optimistic in the event that Canadian competition becomes more intense, environmental regulations inhibit growth, composting captures an increasing market share, or a continued downturn in the economy persists. However, new uses for peat as a filtration medium for the cleanup of waste streams, oil absorption, composting natural organics, and for

hygienic and other purposes could potentially drive U.S. peat demand to levels higher than forecast, regardless of the supply source, domestic or Canadian.

The outlook for future growth in domestic fuel peat demand for electric power generation has been deferred beyond the forecast period because of the loss of four 80-megawatt power contracts in Florida to the competitive economics of natural gas. Natural gas is currently in oversupply, and gas prices have declined significantly in recent years. Additionally, the capital costs associated with the construction of natural gas powerplants are favorable to peat-based plants.

Florida Power and Light, and Florida Power Corp. had previously signed letters of intent with EcoPeat—a U.S. subsidiary of the Finnish firm, Outokumpu—to purchase peat-fueled electrical power from proposed plants adjacent to vast peat reserves to the northwest and southeast of Lake Okeechobee in south Florida.³⁴ The plants were to be brought into production sequentially beginning in mid-1995 and, at full capacity, would have required about 2.5 million tons of peat annually, representing a threefold increase in current U.S. peat production.³⁵

The global outlook for peat supplydemand is shown in table 10. Last year's outlook for balanced supply-demand conditions, long-range, has been clouded by the continuing downturn in former U.S.S.R. production. If the projected downturn only impacts the internal supply-demand situation, then the rest of the world should still anticipate reasonably balanced conditions during the next 5 years. If the former U.S.S.R. becomes pressured to move surplus product to the international marketplace, however, a global imbalance in peat supply-demand may be precipitated for an indefinite period. (See table 10).

The U.S. Bureau of Mines basic forecast methodology has been modified to include the assumption that peat production in the former U.S.S.R. will not return to 1990 levels in the foreseeable future. Otherwise, the former methodology that based global demand on the historic trend in per capita

consumption has not changed. The long-term trend based on the current forecast shows that, between 1992 and 1997, global peat demand is projected to grow at an average 1% per year, about one-half of the projected 2% growth in population. This forecast is consistent with historic trends.

FIGURE 1
PRODUCTION AND IMPORTS OF PEAT IN THE UNITED STATES

PHOSPHATE ROCK

By David E. Morse

Mr. Morse, a Supervisory Physical Scientist with 16 years of U.S. Bureau of Mines experience, has been the acting phosphate rock specialist since May 1992. Domestic survey data were prepared by Christopher Lindsay, mineral data assistant; and the international data table was prepared by Jeremy Tidwell, international data coordinator.

Domestic and world production of phosphate rock decreased 2% and 4%, respectively, compared with output in 1991. World phosphate rock trade decreased to less than 30 million metric tons from the nearly 34 million tons traded in 1991; U.S. phosphate rock exports decreased from 5.1 million tons to 3.7 million tons primarily because of decreased consumption in Western Europe and the loss of exports to Mexico.

The historic events of recent years that include the restructuring of the former U.S.S.R. and the significant changes in the political and economic structures of countries in Eastern Europe will affect the demand for phosphate fertilizers in this region for several years. immediate effect of these events caused a decline in fertilizer consumption, in production, and in trade. In Eastern Europe and the former U.S.S.R., the political changes will probably encourage markets rather than state planning organizations and will determine production and trade patterns in the region. (See table 1.)

DOMESTIC DATA COVERAGE

Domestic production data for phosphate rock were developed by the U.S. Bureau of Mines from two separate voluntary surveys of U.S. operations. Of the 16 operations to which a survey request was sent, all responded, representing 100% of the U.S. production data shown in table 1.

BACKGROUND

Phosphate rock deposits occur as marine phosphorites, apatite-rich igneous

rock, and modern and ancient guano. All U.S. production was from marine phosphorites. It is the practice of the U.S. industry to express production and reserves in terms of beneficiated product. The grade of the product may be reported as a percentage of phosphorus pentoxide (P₂O₅) or as tricalcium phosphate or expressed as percentage bone phosphate of lime (BPL). Conversion factors are: $P_2O_5 = \%BPL \times 0.4576$; $\%BPL = P_2O_5 \times 0.4576$ 2.1853; and $P=P_2O_5 \times 0.436$. The phosphate ore bed or the zone of phosphorus-bearing material is commonly called the matrix in Florida and North Carolina.

Marketable phosphate rock was produced by 16 companies in the United States. Eight companies in Florida and one in North Carolina produced 87% of the phosphate rock. The balance of 13% was produced in Idaho, Montana, and Utah. Approximately 85% of the phosphate rock sold or used by U.S. producers was consumed domestically to produce fertilizers and feed supplements; about 8% was exported and the balance was used to produce a variety of industrial chemicals.

Sedimentary apatite has a range of chemical compositions. The general formula for marine carbonate-apatite is Ca₁₀(PO₄CO₃)₆Fe₂₋₃. Apatite is host to many cation, anion, and anionic radical substitutions for PO₄. Accessory elements may be associated minerals or those that are chemical substitutions in the phosphate mineral.

The part of phosphate resources that can be profitably recovered is called reserves. Reserves may increase as new deposits are discovered and as technology is improved. Estimates of phosphate rock reserves are made for a specific date and are subject to changing economic or environmental conditions. Operating and holding companies companies phosphate lands estimate the recoverable tonnages based on current and future economics. Mining plans evolve from this planning. Estimates indicate that about 1 billion tons will be recoverable from the North Carolina deposit and another 1 billion tons will be recoverable from Florida deposits.

The phosphate rock bed of the Pungo River Formation in North Carolina is a primary marine phosphate 6 to 12 meters (20 to 40 feet) thick, overlain with 27 to 40 meters (90 to 130 feet) of sand, clay, and marl overburden. The underlying aquifer was depressurized by pumping water to the surface to ensure a dry pit. Currently, bucket wheel excavators have replaced dredges to strip the top 12 meters (40 feet) of overburden. Largecapacity draglines with buckets as large as 55 cubic meters (72 cubic yards) were used to strip the remaining overburden and mine the matrix. The matrix was slurried with high-pressure waterjets, pumped to the beneficiation plant, washed, and classified to produce a minus 16-mesh, plus 200-mesh flotation feed. Flotation concentrate was either calcined or dried.

Most of the phosphate mines in central Florida recover phosphate rock from the Bone Valley Formation. In north Florida, the formation is of equivalent age. Overburden averages about 6 meters (20 feet). The overburden consists of a lay sand and a leach-zone material that overlays the matrix. The materials were selectively strip-mined with large electric draglines. The matrix was slurried in a sump and pumped to the washing plant. Cleaned, screened

material from the washer that was plus 14 or 16 mesh was separated and may be a salable pebble product. The minus 16-mesh fraction was deslimed, and the 16-by 150-mesh fraction was floated to produce a concentrate.

Improvement in recovery percentages from phosphate rock deposits in the United States with the introduction of the flotation process occurred in 1927 and 1928. Values in the 14 mesh by 150 mesh became recoverable, adding to the coarser plus 14-mesh pebble fraction. Conversion of phosphate rock with controlled quantities of sulfuric acid to single superphosphate, which contains about 20% P₂O₅, was the major phosphate fertilizer through the 1950's and into the 1960's. High analysis triple superphosphate, which contains more than 40% P₂O₅, is manufactured by acidulating phosphate rock phosphoric acid. Ammonium phosphates, which contain 46% to 54% P₂O₅, are produced by reacting phosphoric acid anhydrous ammonia. The ammonium phosphates triple and superphosphate have become the preferred fertilizers for domestic consumption and international trade. The intermediate chemical for these preferred fertilizers, phosphoric acid, is produced by acidulating phosphate rock with sulfuric acid. Phosphoric acid itself may be used as a fertilizer and is traded internationally; importers of phosphoric acid may manufacture fertilizers from the acid or use it to produce other phosphate chemicals.

At the farm level, advances in the use of mineral-base fertilizers have been made by following recommended application rates, timing and methods of application, using efficient spreaders, and having sufficient material and technical resources. The effect of correct use of mineral fertilizers can double crop yields and minimize the waste of fertilizer.

ANNUAL REVIEW

Legislation and Government Programs

State and local jurisdictions in Florida studied regulations to control the disposal

of phosphogypsum and process wastewater. Final rules from the Florida Environmental Regulation Commission were expected early in 1993. A consensus appears to have developed from phosphoric acid producers on how to prevent ground water contamination and emissions from stacks. Polyethylene liners and caps probably will be required by Florida regulations.

The U.S. Environmental Protection Agency (EPA) announced establishment of the Dialogue Committee on Phosphoric Acid Production Wastes in the November 24th issue of the Federal Register. The committee included the EPA, various State agencies, industry representatives, the Fertilizer Institute, and public interest groups. committee was to address any existing or potential risks to human health or the environment from the producing of phosphoric acid wastes by identifying technically and economically feasible changes to the current production process.1

The EPA promulgated a final rule that announced the Administrator's final decision on reconsideration of 40 CFR part 61, subpart R, National Emission Standards for Radon Emissions From Phosphogypsum Stacks.²

In October, the President signed a bill (HR 5679) into law (Public Law 102-389) that had a provision that prevented the EPA from expending funds to promulgate, implement, or enforce subtitle C or subtitle D regulations under the Resources Conservation and Recovery Act for phosphoric acid production waste in fiscal year 1993.

Issues

Phosphate rock mining involves the movement of huge volumes of soil and other materials in overburden and large quantities of material in the matrix. Operating mines cover large areas of land surface and are unsightly while active operations are being conducted. Washing and floating the gangue constituents from the mineral consumes large volumes of water. Processing phosphate rock into phosphoric acid creates phosphogypsum

and process wastewater to store and recycle. Runoff from excessive or inefficient application of fertilizer can contaminate ground water and receiving waters. The concern over negative environmental impacts frequently overshadows the understanding of the mineral fertilizers. importance of Without providing and replenishing soil nutrients, production of food to satisfy a world population that will exceed 6 billion by the year 2000 will not be possible. The inevitable increase in world population puts extreme pressure on world agriculture to raise food production. The increase in the food needs is met by increasing total farmed acreages and increasing productivity with fertilizers.

Production

Production of marketable phosphate rock in the United States decreased 2.4% in 1992 to about 47 million tons. Production during the first three quarters of 1992 was about the same as it had been in 1991; production in the fourth quarter, however, was more than 1 million tons less than in the fourth quarter of 1991.

Florida and North Carolina.— Phosphate rock was produced in central Florida by Agrico Chemical Co., a division of Freeport-McMoRan Resource Partners L.P.: Cargill Fertilizer, Inc.: IMC Fertilizer Inc. (IMCF); Mobil Mining and Minerals Corp.; Nu-Gulf Industries Inc., owned by Wingate Creek Acquisition Corp.; Seminole Fertilizer Corp., owned by Tosco Corp.; and U.S. Agri-Chemicals Corp., owned Sinochem (USA) Inc. Mobil closed its Fort Meade mine and announced plans to develop its South Fort Meade property with production expected in 1995. Nu-Gulf suspended operations and began a temporary layoff in early September; mining operations were not restarted during 1992. In northern Florida, Occidental Chemical Agricultural Products Inc. produced phosphate rock for production of phosphoric acid, superphosphoric acid, and diammonium phosphate. In north-central Florida, low-fluorine soft phosphate rock was recovered from hard phosphate rock tailing ponds.

Texasgulf Chemical Co. (TG), a division of Texasgulf Inc., a subsidiary of Elf Aquitaine Inc., produced phosphate rock from the Aurora Mine in eastern North Carolina. TG employed bucket wheel excavating systems to remove the top 12 meters of overburden. Draglines were used to remove the remaining overburden and mine the 10 to 12 meters of matrix.

Western States.—Phosphate rock was mined in Idaho by J. R. Simplot Co., Monsanto, and Rhône-Poulenc Basic Chemicals Co. Simplot produced phosphate rock from the Gay Mine on the Fort Hall Indian Reservation. Mainbed ore was used by Simplot to manufacture phosphoric acid, and the lower grade shale was used in FMC Corp. electric furnaces in Pocatello, ID. Simplot also produced phosphate rock from the Smoky Canyon Mine in the Caribou National The concentrate was pumped Forest. from the mine to Simplot's fertilizer plant west of Pocatello, ID. FMC began mining at its Dry Valley facility, but did not ship material to its Pocatello plant; dry valley material will replace shale from the Gay Mine, which was expected to be depleted during 1993. Monsanto supplied its electric furnaces in Soda Springs, ID, with phosphate rock from its Enoch Valley Mine in the Caribou National Forest. Rhône-Poulenc produced phosphate rock from the Wooley Valley Mine, Caribou National Forest, ID, and shipped to its electric furnace plant in Silver Bow, MT. Nu-West Industries Inc., a member of the Conda Partnership with Western Coop Fertilizer Co., produced phosphate rock from the Mountain Fuel Mine, Caribou National Forest, ID. The phosphate rock was shipped by rail to Conda, ID, beneficiated, calcined, and used to produce phosphoric acid. Cominco American operated the only underground phosphate rock mine in the United States near Garrison, MT. In April, FS Industries, a limited liability company,

formed by Simplot and Farmland Industries, purchased Chevron Resources Co.'s phosphate operations, which included a phosphate rock mine near Vernal, UT, slurry pipeline, and a Rock Springs, WY, fertilizer facility. (See tables 2 and 3.)

Consumption and Uses

The demand pattern for phosphate rock was similar to that of 1991. In 1992, approximately 93% of the U.S. primary demand was used to manufacture wetprocess phosphoric acid; about 93% of the wet-process acid or approximately 87% of total phosphate rock demand was used to manufacture fertilizers. The 13% other remaining was applications. Both domestic and foreign markets were supplied by the industry. Of the total demand, 33% was consumed domestically as fertilizer and 55% was converted to fertilizer and exported. About 11% of the total demand was consumed as phosphorus chemicals domestically, and 1% was exported in chemical products.

Nearly 93% of the phosphate rock sold or used by U.S. producers was for the manufacture of wet-process phosphoric acid, single superphosphate, and triple superphosphate; the balance was used to produce elemental phosphorus. Most of the phosphate rock imported was used to produce wet-process phosphoric acid. (See tables 4 and 5.)

Stocks

Phosphate rock stocks were maintained in wet rock piles in Florida and North Carolina and, after drying or calcining, were stored in silos. In the Western States, phosphate rock was stockpiled during the nonfreezing months of the year near electric furnaces or wet-process phosphoric acid plants to avoid railroad car or truck unloading problems in the winter. Phosphate rock inventory levels are of interest to analysts who follow inventory levels to indicate the strength of the demand for phosphate rock. In the United States, ending stocks in 1991 were 10.2 million tons. In 1992, phosphate

rock ending stocks were 12.6 million tons, which indicates an increase of more than 2 million tons; nearly 50% of the increase was because of inventory adjustments by producers reported to the U.S. Bureau of Mines, indicating that inventories at the end of 1991 were actually more than 11.3 million tons. (See table 6.)

Transportation

From production centers in central and north Florida, phosphate rock was moved by rail to terminals on Hillsborough Bay, FL, and Jacksonville, FL. In central Florida, CSX Transportation railroad moved phosphate rock to terminals on Hillsborough Bay. The Rockport terminal was owned and operated by the CSX railroad; Port Sutton was owned and operated by IMCF. Eastern Associated Terminal (E.A.T.) was owned and operated by E.A.T., and Big Bend terminals were owned and operated by Agrico Mining Co.

In North Carolina, barges were used to transport phosphate rock from the Aurora Mine to the port at Morehead City for Railroad facilities were also export. available at the Aurora Mine to move phosphate rock to the port or domestic markets. Both railroads and trucks were used in the Western States to move phosphate rock from mines to plants. Two pipelines were used to move slurried phosphate rock from mines to plants. One pipeline was used to pump slurried concentrate from Vernal, UT, to Rock Springs, WY, and another was used to pump phosphate rock from the Smoky Canyon Mine in the Caribou National Forest to Pocatello, ID.

Markets and Prices

The price or value of phosphate rock, f.o.b. mine, was obtained from a semiannual survey of producing companies. The data from the survey were used to develop the weighted average price or value for each grade of phosphate rock sold or used in the domestic market or exported. In the 1950's, the actual selling price of

PHOSPHATE ROCK—1992 979

phosphate rock varied from \$5.67 per ton in 1950 to \$6.12 in 1959. In the 1960's, the price varied from \$6.57 in 1960 to \$6.14 in 1969. In 1970, the price was \$5.80 per ton and, in 1974, the average price increased to \$12.04 per ton. The price increased to \$25.00 per ton in 1975 and decreased to \$21.15 in 1976. The abrupt increase in price was initiated by an arbitrary price increase by Morocco's Office Cherifien des Phosphate for exported phosphate rock. Although the actual price declined to \$17.39 per ton in 1977, cost increases caused the price to plateau at more than \$20.00 per ton in 1979; the price peaked again in 1980 to \$22.78 per ton, responding to a strong demand. The price gradually declined to \$19.37 per ton in 1987 and increased to \$23.20 per ton in 1990; the price decreased slightly in 1991 and by an additional 53 cents in 1992. (See tables 7, 8, and 9.)

Foreign Trade

Exports of phosphate rock from Florida and North Carolina declined from 14 million tons in 1979 to 3.6 million tons in 1992. Imports of phosphate rock into the United States increased by about 180% in 1992 compared with 1991. Nearly all of the imported phosphate rock was supplied by Morocco and came into ports on the Gulf of Mexico.

Although phosphate rock exports continued to decline, exports of monoammonium phosphate. triple superphosphate, and phosphoric acid increased. Exports of diammonium phosphate, however, decreased sharply to nearly 8.3 million tons from the recordhigh level of 9.7 million tons reached in 1991. Of the high analysis fertilizers, diammonium phosphate, monoammonium phosphate, and triple superphosphate. produced by the U.S. industry in 1992, 56%, 41%, and 57%, respectively, were exported. (See tables 10, 11, 12, 13, 14, 15, 16, and 17.)

World Review

World phosphate rock production was less in 1992 compared with the peak year

of 1989. Production from major producing countries has either remained constant or has declined. estimated that world fertilizer consumption declined by 4% in 1992. This was principally caused by reduced consumption in Eastern Europe and the former U.S.S.R. The declining consumption of phosphate fertilizers in Central, Eastern, and Western Europe was the principal reason for a decline in phosphate rock production and trade in 1992. In Western Europe, during 1991 and 1992, phosphate rock imports decreased an estimated 2.5 million tons, which reflected the closure or idling of 11 phosphoric acid plants with an annual capacity of about 1.3 million tons P₂O₅. The acid plants were closed or idled for environmental and/or economic reasons.

Kazakhstan.—Phosphate rock production was centered at Kara Tau, northwest of Dzhambul. Output was significantly below the production in 1990 when about 12 million tons was produced.

Russia.—Production was centered in igneous apatite deposits at Khibny and Kovodor on the Kola peninsula; phosphate rock was also produced from sedimentary phosphate deposits at Kimovsk, Lopatinsk, Voskresenik, and Yegoryevsk south of Moscow. Production from the Kola peninsula was well below the 1990 output of approximately 20 million tons; production from other areas and total consumption was considerably lower than during the previous year.

The U.S. Bureau of Mines estimates of world phosphate rock reserves and the reserve base are shown in table 19. Included are reserves and reserve base estimates with costs of less than \$40 and \$100 per ton, respectively. (See tables 18, 19, and 20.)

OUTLOOK

World production and consumption has declined steadily since 1989, primarily as a result of the political and social

restructuring of the economies of Eastern Europe and the former U.S.S.R. addition, imports into Western Europe have mirrored the closure of numerous phosphoric acid plants. China has increased production substantially during the same period, while consumption by developing nations has been stagnant or only increased slightly. North American consumption of phosphate fertilizers has shown a downward trend in recent years as farmers adopted more efficient application practices. The fertilizer industries of Brazil and Mexico have been restructured because of Government actions, and India reduced fertilizer subsidies to its farmers. Overall. significant dislocations, worldwide, have contributed to the decline in phosphate consumption and trade.

A further decline in world consumption and trade during 1993 is probable. After 1993, a modest increase in 1994 is forecast. World consumption will probably not return to the levels attained in 1988-89 until late in the 1990's. The continuing growth in world population will require increased use of fertilizer for food production. The long-term growth in phosphate rock production should average about 1.3% annually beginning in 1997.

Estimated. Revised.

¹Table includes data available through May 10, 1993. Data for major phosphate rock-producing countries derived in part from the International Fertilizer Industry Association; other figures are from official country sources where available.

²In addition to the countries listed, Belgium may have produced small quantities of phosphate rock and Namibia may have produced small quantities of guano, but output is not officially reported, and available information is inadequate for formulation of reliable estimates of output levels.

³Reported figure.

⁴Less than 1/2 unit.

⁵Beneficiated.

⁶Formerly part of the U.S.S.R.; data were not reported separately until 1992.

⁷Includes only output used to manufacture fertilizers.

⁸Production from Western Sahara area is included.

Does not include aluminum phosphate production, gross weight as follows in thousand metric tons: 1988—119; 1989—140 (estimated); 1990—127 (estimated); 1991—92 (estimated, revised); and 1992—70 (estimated).

¹⁰Dissolved in Dec. 1991.

PLATINUM-GROUP METALS

By J. Roger Loebenstein

Mr. Loebenstein, a physical scientist with 18 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for platinum-group metals for 12 years. Domestic survey data were prepared by Evangeline Hemphill, statistical assistant; and international data tables were prepared by H. Willis, international data coordinator.

The platinum-group metals (PGM) are composed of six closely related metals: platinum, palladium, rhodium, ruthenium, iridium, and osmium. They commonly occur together in nature and are among the scarcest of the metallic elements. In terms of commercial importance, platinum and palladium are the two most important metals of the group. All of the metals are valued for their corrosion resistance and catalytic activity.

Johnson-Matthey PLC, United Kingdom, reported that Russian sales of platinum declined to 23 metric tons in 1992, down from the alltime high of 34 tons sold in 1991. Almaz, the Russian PGM marketing agency, had sole responsibility for export sales of PGM after sharing it for 2 years with the Soviet Bank for Foreign Economic Affairs, Vneshekonombank.

Demand for platinum, palladium, and rhodium by the U.S. automobile industry increased in 1992, but total demand for all end uses was not much different than the 1991 level.

DOMESTIC DATA COVERAGE

Domestic production data for PGM are developed by the U.S. Bureau of Mines (USBM) from a voluntary survey of U.S. refiners. Of the 18 refiners to which a survey request was sent, 12 responded. These respondents represent 67% of the total refined metal production shown in tables 1 and 2. Production for nonrespondents was estimated using prior-year levels adjusted for general industry trends.

BACKGROUND

Products for Trade and Industry

The basic forms of PGM are sponge or powder, which may be converted to other forms such as bars, pastes, or chemicals. The industry employs an extensive number of homogenous and heterogeneous catalysts containing PGM. A typical PGM catalyst may consist of a platinum-rhodium gauze woven from wire. The electronics industry purchases PGM pastes, and the dental industry uses wire and a variety of alloys.

Geology-Resources

PGM deposits are associated with magmatic intrusions of mafic and ultramafic rocks. They also occur to a lesser extent as placer deposits. Layered deposits associated with stratiform complexes are the only ones mined principally for the PGM, with nickel, copper, and cobalt sometimes produced as byproducts. These are found in the Bushveld Complex, Republic of South Africa, and the Stillwater Complex, United States. In other PGM deposits, such as those found in the Sudbury Complex, Canada, and Noril'sk, Russia, the PGM are produced as byproducts of nickel and copper mining.1 Republic of South Africa, base metals such as nickel and copper are important in generating revenues from the Merensky and Platreef ores. This is not the case at the Stillwater Mine in the United States, where platinum and palladium contribute almost 100% of revenues.

Technology

Processing.—The processing of PGM ore entails four general steps: mining, concentrating, smelting, and refining. In the concentrating step, platinum ore is crushed and treated by froth flotation. The concentrates are dried, sometimes roasted, and then fused in a smelter furnace, producing a sulfide matte containing the PGM. The matte is treated in a refinery using solvent-extraction techniques to separate and purify the six PGM.

Recycling.—In North America, PGM are recovered by a small number of scrap refiners. Other companies collect scrap materials such as catalysts and PGMbearing solutions and process them to increase the grade. These upgraded secondary materials are then sold to refiners. For example, Multi-Metco Inc., Anniston, AL, produces about a 90% concentrate of PGM from scrapped autocatalysts, which in turn is refined by another company. World Resources Co., McLean, VA, collects electroplating solutions, upgrades them, and sells the concentrate to another refiner. Most companies specialize in refining or upgrading a particular type of scrap, such as petroleum catalysts, autocatalysts, or electronic scrap.

Refiners often charge a fee or toll to "toll refine" scrap, ownership of the PGM content of the scrap remaining with the customer. For example, a refiner and/or fabricator would replace worn out catalyst with fresh catalyst and charge the customer for the refining and fabrication costs. In other cases, refiners purchase scrap, process it, and sell the refined

metal. When scrap changes ownership in this way, it is referred to as nontoll scrap. For statistical purposes, nontoll refined scrap is considered old scrap and is added to supply, along with newly mined metal.

Because of their high value, PGM are routinely recovered from petroleum catalysts, chemical catalysts, automobile catalysts, glass fiber bushings, electronic scrap, laboratory equipment, dental materials, and jewelry.

In the United States, only Multi-Metco processed any substantial quantities of autocatalyst PGM. The other major processors of scrapped automobile catalysts are in Belgium, Canada, and Japan. Japanese companies that recycled precious metals from spent catalysts were: Asaka Riken Kogyo, Ishifuku Kinzoku Kyokai, N.E. Kemkat, Nippon Kogyo, Hakko Kagaku Kogyo, Matsuda Precious Metals, Sankin Recycling, Yokohama Metals, and Chugai Kogyo.²

Because used precious-metal scrap varies widely in value and grade, proper sampling and assaying is important to the industry. Fire assay techniques have long been used to determine the presence of precious metals. In addition to fire assays, PGM can be determined by chemical methods and instrumental methods such as X-ray fluorescence and spectroscopy.3 The flow of PGM through their metallurgical, catalytic, chemical applications is discussed in USBM IC 9303. This study highlights areas in which significant losses occur because of downgrading, export, or disposal.4

Economic Factors

Futures contracts are traded on the New York Mercantile Exchange (NYMEX), the Commodity Exchange (COMEX), the Tokyo Commodity Exchange for Industry (TOCOM), and to a lesser extent on the MidAmerica Exchange, through the Chicago Board of Trade (CBOT). Platinum and palladium futures contracts, specifying 99.95% metal content, were traded on the NYMEX in units of 50 and 100 troy ounces, respectively. The TOCOM

contract unit is 500 grams, the quality specifications are 99.9% purity, and prices are quoted in Japanese yen per gram. Futures contracts help producers and consumers of platinum and palladium lock in prices and allow speculators an opportunity to make profits. By comparing the current price with the price for future delivery, one can surmise whether market participants expect prices to rise or fall.

In London, prices of physical platinum and palladium bullion are set each day in the morning and afternoon for the wholesale market. The eight companies participating in establishing prices are members of the London-Zurich Good Delivery Agreement, which sets standards for platinum and palladium trading in Europe. London and Zurich are the two most important European trading centers for platinum and palladium.

A time series of historical prices for each of the six PGM and a brief discussion of factors influencing prices are given in a USBM publication entitled, "Metal Prices in the United States Through 1991."⁵

ANNUAL REVIEW

Strategic Considerations

Although some platinum and palladium was produced at the only PGM mine in the United States, the Stillwater Mine, the great majority of PGM consumed in the United States was imported.

There were no changes in inventories of platinum, palladium, and iridium in the National Defense Stockpile in 1992, as shown in table 1. No purchases of rhodium or ruthenium were made, even though there are stockpile goals for these two metals.

Issues

The USBM received many inquiries in 1992 about osmium 187 isotope. Most of the callers asked about markets for this material, which reportedly was sourced from Russia with asking prices varying from \$50,000 per gram to more than \$100,000 per gram. There are no known

commercial markets for osmium 187. Scientific applications may consume perhaps only a few grams per year.

Osmium (atomic number 76) has seven naturally occurring isotopes, all of which are stable. They are osmium 184, 186, 187, 188, 189, 190, and 192. Osmium 187 is produced in nature when radioactive rhenium 187 decays to form stable osmium 187 by emission of a beta particle. Rhenium is most strongly concentrated in molybdenite (MoS₂). Geologists have used the rhenium-osmium isotope ratio method to determine the age of iron meteorites that cannot be dated directly by other methods.

An article entitled "Osmium-187: An Intriguing Isotope" appeared on page 3 of the December 1992 issue of Elements. published by Concord Trading Corporation, Denver, CO. The first line of the article reads: "In what seems to be the latest scam emerging from the former Soviet Union, osmium-187 is being peddled in the international metals market as a rare, mysterious and very expensive material." The article continues "Legal authorities clearly are disturbed by the upswing in Os-187 activity, mostly because they fear that innocent people are being used to ferry material that is not actually Os-187, but instead is a radioactive substitute. This coincides with other fears about the black market trade of radioactive and other valuable substances that has grown out of Eastern Europe since the fall of the U.S.S.R."

Production

The Stillwater Mine, Nye, MT, southwest of Billings, was operated by the Stillwater Mining Co. (SMC), owned 50% by Chevron Corp. and 50% by Manville Corp. Estimates from published sources showed that production of PGM at the mine, mainly palladium and platinum, increased somewhat in 1992, as shown in table 1. Small amounts of PGM were recovered by other companies as byproducts of domestic copper refining.

On April 1, the Federal Register published a notice that SMC wished to increase ore production at Nye from the

current 1,000 tons per day to 2,000 tons per day. A final environmental impact statement was expected to be released at a later date.

Catalytic Converter Refining (CCR) of Northlake, IL, a major collector of scrapped catalytic converters, announced the closing of its plant in July. CCR was operated by Sloan Metal Co. and financially backed by Nissan Motor Co. Sloan Metal purchased some of CCR's equipment and reentered the catalytic converter recycling business in November as Sloan Precious Metals Co. Sloan collects converters, removes the outer shells, and ships the catalyst contents to other companies for refining.

Consumption and Uses

Reported sales of PGM by refiners is shown in table 3. For comparison purposes, the calculated apparent consumption for the individual PGM is also shown. Use of platinum, palladium, and rhodium in the automotive industry recovered from one of its worst years in 1991.

Platinum, palladium, and rhodium were used in emission catalysts for light trucks (trucks weighing 14,000 pounds or less, gross weight) and automobiles. An informal survey of automobile catalyst manufacturers indicated that a typical emission catalyst in 1992 contained a total of about 2.7 grams PGM (approximately 2.18 grams platinum, 0.31 gram palladium, and 0.31 gram rhodium). There were variations in the quantities of PGM in each catalyst, depending on the vehicle's engine size, the normal operating temperature of the engine, and the manufacturer of the catalyst. addition to emission catalysts, platinum was used in automobile oxygen sensors and in spark plugs. Platinum plugs provide cleaner combustion and last much longer than conventional plugs. Although Ford has been using platinum plugs for some time, Nissan and General Motors plan to use start using platinum spark plugs in some 1993 models. Conventional platinum-tipped plugs are believed to contain 0.01 to 0.02 gram of platinum each.6

In electronic applications, ruthenium was the principal PGM used in thick film resistors and palladium was the principal PGM used in thick film conductors, multilayer ceramic capacitors, and connectors. Platinum "targets" were used for sputtering thin films on circuit boards. Platinum-rhodium alloys were used for manufacturing thermocouples for precise temperature measurement.

For glass applications, most of the PGM, specifically platinum, rhodium, and palladium, were used in bushings for the extrusion of textile (continuous filament) glass fiber.

The nonautomotive catalyst applications of PGM were numerous. The petroleum refining industry used PGM, principally platinum, in reforming, cracking, and isomerization reactions. Chemical catalysts containing platinum and rhodium were used in inorganic syntheses of nitric acid and hydrogen cyanide. Palladium was used in the production of hydrogen peroxide. A wide variety of organic chemicals and pharmaceuticals were produced using PGM catalysts.

In its first quarter 1992 report to stockholders, Engelhard Corp. reported "Russia's electrochemical consortium, UEIP, is licensing Engelhard technology to manufacture automotive exhaust catalysts. In addition, Engelhard will assist UEIP in the design of Russia's first auto catalyst plant at an existing facility in Ekaterinburg. The plant will have a capacity of up to two million catalyst units per year and is scheduled to be in operation by mid-1994. Engelhard also will be supporting UEIP with an ongoing testing program of the plant's catalysts to ensure that they qualify for use on Russian cars."

In addition, Engelhard is proceeding with plans to build a new auto catalyst manufacturing plant in Nienburg, Germany, after buying out its German venture partner, Kali-Chemie AG. Slated to be fully operational in 1993, the new plant at full capacity is expected to produce more than 6 million auto catalysts annually, up from its current level of 2 million units.

In April, Engelhard Corp. said that its

catalysts sharply increase the yield of a refinery byproduct, isobutylene, that is combined with methanol to make methyl tertiary butyl ether, or MTBE. MTBE is an additive used in gasoline to increase its oxygen content, which in turn helps the fuel burn cleaner. There has been some concern in the industry that there is not enough isobutylene to make MTBE sufficient to supply demand to comply with the 1990 Clean Air Act. Under the Act, 41 U.S. cities must use oxygenated gasoline during the winter starting in 1992.

Stocks

In addition to the reported stocks held by refiners, importers, and dealers shown in table 4, end users held sizable quantities of PGM that were not reported to the USBM.

Markets and Prices

Generally, prices for PGM were lower in 1992, with the largest declines in prices for rhodium, iridium, and ruthenium. The average dealer prices for all six PGM are shown in table 1.

In August, the Commodity Futures Trading Commission (CFTC) approved trading of platinum and palladium futures contracts on the COMEX, placing that exchange in direct competition with the The COMEX requires a NYMEX. minimum purity of 99.9%, while the NYMEX requires a purity of 99.95%. In December, the CFTC approved the NYMEX's after-hours electronic trading system known as "Access." The system is designed to allow traders to buy and sell platinum futures contracts after normal trading hours. (See tables 1, 2, 3, and 4.)

Foreign Trade

Exports of PGM were up in 1992 because of an increase in exports of scrap to the United Kingdom, as shown in table 5. Imports of osmium shown in table 6 totaled 57 kilograms, all of which came from the Republic of South Africa. It is interesting to note that despite reports of

exports of osmium isotope 187 from Russia, U.S. import statistics do not show any imports of osmium originating from Russia (see Issues section). (See tables 5 and 6.)

World Review

Canada.—The main Canadian PGM producers were Canada's primary nickel producers-Inco Ltd. and Falconbridge Ltd. Both companies shipped contained PGM to refining facilities in Europe for final recovery. In addition, Inco recovered PGM from scrapped autocatalysts from both Canadian and United States sources. In a typical year, Inco recovers about 2,800 kilograms of PGM from autocatalysts at its Sudbury plant. Noranada Inc. recovers about 4,700 kilograms of palladium and platinum annually from electronic scrap and telecommunications equipment at its Horne smelter in Quebec.

Russia.—In July, Russia imposed new taxes on companies, including foreign firms and joint ventures, extracting mineral resources within its territory. The taxes were retroactive to June 1 and were set at 10% of extraction costs for PGM. Table 7 shows Russia's production of PGM beginning in 1992 and the former U.S.S.R.'s production ending in 1991.

South Africa, Republic of.—Impala Platinum suspended the Messina project and closed the Crocodile River Mine acquired after the takeover of Barplats in 1991. Impala workers returned to work in March after a work stoppage that reduced Impala's annual platinum production in 1992.

Northam Platinum, owned by Goldfields of South Africa Ltd., began producing PGM in January 1993 from the Merensky reef. Output of the mine is being toll refined by Heraeus in Germany. (See table 7.)

Current Research

Researchers at the University of Minnesota discovered that they could produce syngas by running a mixture of methane and oxygen or air over either a platinum or a rhodium catalyst. The reaction takes place 1,000 to 10,000 times faster than in the old steam reforming reaction. This means that much smaller reactors would be needed for a commercial syngas plant. Once syngas is produced, it can be easily converted to methanol or diesel fuel.⁷

Mintek, a research agency of the South African Government, and Western Platinum Ltd., a South African platinum producer, have developed a new series of jewelry alloys that ranges in color from yellow to shades of orange and pink. Platinum is difficult to color because it tends to bleach any coloring addition. The Mintek Annual 1992 report stated that "Test items are being manufactured in collaboration with local and overseas jewelers."

OUTLOOK

Future demand for PGM should continue to grow worldwide given the strong demand for a cleaner environment. Catalytic converters for controlling automobile emissions are currently used in Australia, Canada, Japan, Mexico, Republic of Korea, Taiwan, the United States, and many Western European nations. Brazil, Hong Kong, Indonesia, Malaysia, Singapore, and Thailand are expected to start using catalytic converters in the very near future. The potential market for the catalytic converter is huge—there are 500 million motor vehicles worldwide. The use of palladium is growing because the wider use of cleaner, lead-free fuels permits its use as a substitute for more expensive However, platinum will platinum. probably continue to remain the dominant metal in catalytic converters for some time in the future.

In the United States, California has for years had the most stringent automobile emission regulations, setting the tone for Federal standards. The California Air Resources Board is seeking to introduce zero emissions for 2% of vehicles by the year 2000. Some other States, such as New York and Massachusetts, are opting for California standards instead of the

more lenient Federal standards.

Revised.

¹Comprises primary and nontoll-refined secondary metals.

²Data may not add to totals shown because of independent rounding.

³Defined as mine production plus nontoll production of secondary metal plus refined imports minus refined exports plus beginning stocks minus ending stocks. In 1988 unspecified PGM imports and exports were divided evenly between platinum and palladium. Export data for iridium, osmium, and ruthenium are not available separately; in this calculation, the collective export figure was assigned to ruthenium.

¹⁹⁸⁸⁻⁹² platinum, palladium, and rhodium sales to the automotive industry are estimated based on U.S. light truck sales and U.S. automobile production.

Estimated. Revised.

¹Table includes data available through May 18, 1993. Platinum-group metal production by Germany (western states), Norway, and the United Kingdom is not included in this table because the production is derived wholly from imported metallurgical products and to include it would result in double counting.

²In addition to the countries listed, China, Indonesia, Papua New Guinea, and the Philippines are believed to produce platinum-group metals, and several other countries also may do so, but output is not reported quantitatively, and there is no reliable basis for the formulation of estimates of output levels. However, a part of this output not specifically reported by country is presumably included in this table credited to Japan. (See footnote 8).

³Partial figure; excludes platinum-group metals recovered in other countries from nickel ore of Australian origin; however, a part of this output may be credited to Japan. (See footnote 8).

⁴Unless otherwise indicated, data show estimated proportions of platinum, palladium, and other platinum-group metals within the reported total.

⁵Reported preliminary estimate.

⁶Data are for years ending June 30 of that stated.

⁷Reported figure.

^{*}Japanese figures do not refer to Japanese mine production, but rather represent Japanese smelter-refinery recovery from ores originating in a number of countries; this output cannot be credited to the country of origin because of a lack of data. Countries producing and exporting such ores to Japan include (but are not necessarily limited to) Australia, Canada, Indonesia, Papua New Guinea, and the Philippines. Output from ores of Australian, Indonesian, Papua New Guinean, and Philippine origin are not duplicative, but output from Canadian material might duplicate a part of reported Canadian production.

Formerly part of the U.S.S.R.; data were not reported separately until 1992.

¹⁰All production in the U.S.S.R. from 1988-91 came from Russia.

¹¹Formerly part of Yugoslavia.

¹²All production in Yugoslavia from 1988-91 came from Serbia and Montenegro.

¹³Includes osmiridium produced in gold mines.

¹⁴Dissolved in Dec. 1991.

¹⁵ Estimates for the Stillwater Mine, from published sources. A very small quantity of byproduct platinum and palladium produced from gold-copper ores was excluded.

¹⁶Dissolved in Apr. 1992.

¹⁷Data may not add to totals shown because of independent rounding.

POTASH

By James P. Searls

Mr. Searls, a physical scientist and economist, has been a commodity specialist for 13 years. Domestic survey data were prepared by Kelly Dorney, mineral data assistant; and international data were prepared by Theodore Spittal, international data coordinator.

U.S. potash production in terms of potassium oxide (K_2O) equivalent decreased less than 3% relative to that of 1991, and apparent consumption increased less than 2% from a downward revised 1991 value. The average price, f.o.b. mine, increased more than 5%. Yearend stocks decreased more than 17%.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines developed potash domestic data from voluntary semiannual surveys of U.S. operations. Of the 12 survey requests sent to operations, 11 responded, representing more than 97% of total production shown in table 3.

BACKGROUND

Geology¹

Potassium is the seventh most abundant element in the Earth's crust and the sixth most abundant element in seawater. It is found in silicate minerals of igneous, metamorphic, and sedimentary rocks and is also a major constituent of many surface and subsurface brines. The large majority-perhaps 90%-of potassium minerals in the Earth's crust is in insoluble silicate forms, such as potassium feldspar, micas, and clays. They are not considered potash resources. The majority of the world's potash resources-soluble forms-are found in subsurface bedded salt deposits, which occasionally are high-grade, large tonnage ore bodies that are amenable to low-cost mining and beneficiation. Because of the

relatively high solubility of these potassium minerals, usually potassium chloride or potassium magnesium sulfate, potash from salt deposits is nearly ideal for use as fertilizers. Some potash production is from evaporation of naturally occurring brines, but the vast majority of current domestic and international production is from bedded salt deposits.

Sylvite, langbeinite, carnallite, and kainite are some of the more important potassium minerals. (See table 1.) Sylvinite, a mixture of KCl and NaCl, is the highest grade potash ore. Langbeinite, though rarely found, is a natural form of chloride-free potassium sulfate that also contains magnesium sulfate. Carnallite can be considered a potash ore when removal of magnesium chloride is included in the beneficiation process, but it can also be considered a contaminant when mining for sylvinite. Kainite is a relatively minor potash form, containing potassium chloride magnesium sulfate. Potassium sulfate and potassium nitrate are typically manufactured products. Potassium sulfate is produced from mined minerals through conversion processes in Germany, Italy, and Carlsbad, NM, and from brines in southern California and at the Great Salt Lake in Utah. Natural deposits of potassium nitrate occur only in dilute amounts and only in the arid mountains of Chile.

The majority of potash-bearing bedded salt deposits are believed to have originated from the evaporation of seawater or mixtures of seawater and other brines in (restricted marine) large basins² that had a narrow, shallow connection to the sea. The reflux depositional model for

evaporite deposition was first described in literature in 1877 by Ochsenius.³ shallow bar, or sill, across the mouth of a basin lets in a restricted flow of seawater that evaporates into a saltprecipitating brine. (See figure 1.) The density of the brine increases as the brine flows from the entrance to the basin. The most insoluble salts form first and the most soluble salts form at the end of the basin farthest from the sill. The least soluble salts are precipitated nearer the sill, and the most soluble components come out of solution at the far side of the basin. Salt crystals fall out as critical brine densities occur due to evaporation. A recent nongeology publication describes the evaporation of seawater in detail⁴ along with the brine densities. The salt calcium carbonate crystallizes first, then hydrated calcium sulfate, followed by calcium sulfate. These precipitates indicate a brine volume reduction of 5 to 1 for hydrated calcium sulfate to start to precipitate, which corresponds to a density of 1.131 grams per liter. At a brine volume reduction of 10 to 1, which is a density of about 1.22, halite starts to precipitate and continues to about 80% of the contained halite when the next type of salts start to crystallize. At brine densities of 1.261 and higher and a volume reduction to 1.57% of the original volume, 5 a mixture of halite, sylvite, and carnallite starts to crystallize. kainite, schoenite, (possibly glaserite), and langbeinite crystallize. The remaining brine, now called bittern, is extremely difficult to evaporate owing to its low vapor pressure. (If this bittern were evaporated to dryness, bischofite would be crystallized.)

Provided that the flow volume entering the basin is balanced properly with the width and length of basin, and evaporation occurs as necessary, the brine then sinks to the bottom or is overridden by the lighter brines, and sets up a reflux current of higher density brine back toward the sill (ocean). It is clear that if basins were too short or the flow volume into the basin were too high, only earlier parts of this evaporation cycle would occur before the brine reaches the end of the basin and sinks underneath the brine incoming where no more evaporation could occur. The sill that restricts the inflow of seawater also stops the flow of evaporation-concentrated brines back to the ocean. The result is a sequence of precipitated salts in a flatlying deposit that is longer than it is wide, and that occurs because of the increasing concentration of the surface brine caused by continuous evaporation from the sill to the far end of the basin. The noncontinuous (See figure 2b.) marine sediment zone content (asymmetrical facies distribution) of the Paradox Formation in Utah⁶ and the Salado Formation in New Mexico⁷ might be explained by such a model. The distributions of the various salts in the Paradox Formation in Utah (Middle Pennsylvanian of the Paleozoic Era or about 380 million years ago) and the Salado Formation (the late Mississippian period through the Pennsylvanian period and into the Permian period, all of the Late Paleozoic period, extending from about 390 million years ago to 280 million years ago) in New Mexico could probably be explained by such a model. Other deposits, such as the Salina Formation of the Silurian Period, about 430 million years ago in Michigan, 8 show a compositional distribution that is closer to a bull's-eye pattern, in which the potash is in a central part of the basin surrounded by successively less soluble (See figure 2a.) Sedimentary features in the surrounding ring of carbonates in some evaporite basins suggest exposure to the air. This could have resulted in a basin that underwent evaporative drawdown as was suggested by Hsu¹⁰ for the Mediterranean evaporite of Miocene age (24 million years ago), the Permian Upper Zechstein (Permian Period or 280 million years ago) in Europe, the Silurian Salina evaporite deposit (430 million years ago) in Michigan, and the Devonian evaporites (400 million years ago) in Canada. The brine depth in any ancient evaporite basin could have undergone fluctuations related to sea level, ground water inflow, precipitation, and rainwater runoff so that the depositional environment of saline mineral precipitation could have occurred in deep or shallow water. Depositional and petrographic features found in evaporite deposits show evidence of the entire range of these environments, and, therefore, it is possible that many evaporite deposits that show evidence of being disconnected from free inflow of seawater were derived from mixtures of seawater and atmospheric or other waters brines that traveled (such as underground).

The evaporation of seawater results in the precipitation of alkaline earth carbonate minerals, followed by calcium and magnesium sulfates, and then magnesium and potassium chlorides. The ratio of sodium to potassium in seawater is 27:1, and, in general, minable potash beds are accompanied by thicker halite deposits. Often, the potash ore zone is near the top of halite beds in relatively thin layers because the potash is precipitated from brines of higher salinities occurring near the end of the evaporation sequence. The potash salt precipitated from evaporation of seawater after precipitation of magnesium sulfates is carnallite (KCl MgCl 6H₂O) rather than sylvite (KCl) owing to the high concentration of magnesium in seawater.

The origin of evaporites believed to be marine deposits that are lacking magnesium sulfate and magnesium chloride minerals is often explained by postdepositional dissolution processes in which the carnallite in the salt was altered to sylvite by reaction with a magnesium-poor brine¹¹ or atmospheric water.¹² In the sylvinite deposits of Thailand, Congo, and the Elk Point Basin of Canada, there is evidence that the introduction of atmospheric water, or seawater of nearly

normal salinity, brought about partial destruction of a precursor deposit of carnallite, leaving behind sylvinite or only barren halite. This process of changing the character of a crystallized deposit in some instances began shortly after the deposition of the carnallite layer ore, and as in the case of the Thailand deposits, may even be taking place today. 13 However, recognition that nonmarine evaporite deposits are not necessarily restricted to small, terrestrial saline lake basins has lead some workers to reassess the importance of mixing brines of seawater origin with brines of other origin and with atmospheric water.14 Some modern evaporites, such as the Basque Lakes in British Columbia, Canada, 15 and those that occur in the Oaidam Basin of Western China, 16 which are clearly nonmarine in origin, precipitate upon evaporation a suite of minerals very similar to that calculated to precipitate from seawater.

Theoretical and experimental sequences of salts precipitated from brines that were calculated by D'Ans in 1933 bore close resemblance to naturally occurring sequences, and the presence or absence of some of the accessory minerals found in naturally occurring evaporite deposits was explained by temperature changes in the precipitating brines, mixing of brines of different compositions, and reaction of brines with previously precipitated salt. theoretical sequence of primary precipitates from seawater at 25° C was estimated by Braitsch.¹⁷ (See table 2.) The sequence and amounts of minerals calculated with more recent computer simulations of the evaporation of seawater¹⁸ shows a slightly different mineral sequence from that calculated by The computer-generated Braitsch. sequence predicts the occurrence of polyhalite, which was not predicted in the earlier theoretical models, which does occur in many evaporite salts believed to be of marine origin, such as to the south of the Delaware Basin in New Mexico-Texas. (See table 1.) For deposits such as the Stassfurt horizon of the Permian Zechstein potash in Germany, computer-predicted sequence predicts the

1008 POTASH—1992

mineral assemblage as a primary assemblage not extensively chemically altered by postdepositional processes. The initial brine composition is critical to the sequence of minerals that precipitate upon evaporation, but the mixing of waters during evaporation can also have a profound effect on the resulting precipitates. Computer simulations of evaporation show that it is possible to produce widely varying mineral suites by altering the relative amounts of only one or two of the initial aqueous species.

Microscopic analysis (petrographic and textural relationships) and chemical analysis of fluid inclusions of associated halites in potash evaporites suggest that sylvite has occurred in many instances as a primary mineral.¹⁹ Enrichment of seawater with respect to calcium will result in early depletion of sulfate with gypsum/anhydrite precipitation and nondeposition of magnesium sulfates. If some mechanism by which magnesium can also be removed is present in the system, then carnallite also cannot precipitate, and the primary potash mineral laid down will be sylvite. Mechanisms bv which calcium enrichment and magnesium depletion can occur include dolomitization of associated limestones or of a limestone precursor,²⁰ interactions with hydrothermal waters,21 and clay mineral cation exchange.²² Sulfate depletion, which also will lead to nondeposition of magnesium sulfates, can be accomplished through brine mixing.²³

Potash-bearing evaporites can be divided into two different types: magnesium sulfate-rich deposits (containing the minerals polyhalite, hexahydrite, kieserite, and epsomite), and magnesium sulfate-poor deposits.²⁴ In the former type, the primary potash mineral is carnallite, while the latter is characterized by sylvite and carnallite. magnesium sulfate-rich evaporites, such as the Stassfurt horizon of the Permian Zechstein 2, exhibit the same mineralogy that is expected to result from evaporation of modern seawater. The magnesium sulfate-poor potash deposits probably precipitated from brines that were high in calcium and constitute 60% or more of known potash basins.25 The

fact that these two types of potash deposits also display a distinctive temporal relationship, with magnesium sulfate-rich types occurring only in the Permian (280 million years ago), Miocene (24 million years ago), and Quaternary (2 million years ago) (see figure 3), may suggest changes in the composition of seawater throughout Phanerozoic (the whole period from 570 million years ago to now) time, or that many potash evaporite deposits did not precipitate from seawater, but are the result of evaporation of nonmarine or waters. 26 marine-nonmarine mixed Figure 4 shows the geographical distribution of potash deposits that contain little or no associated magnesium sulfate salts. Many of these basins are smaller than the magnesium sulfate-rich evaporite basins, and some show an elongated shape that could suggest formation in a graben valley (a valley formed by the subsidence of rock between at least two vertical fault plans) setting.

Exploration

Evaporite deposits that are found in cratonic basins are usually associated with biogenic deposits such as shelf carbonates and fringing reefs, and with clastic redbed deposits. Some evaporite deposits are found at continental margins that were sites of tectonic extension during the Mesozoic and Cenozoic periods. high solubility of evaporite minerals precludes the formation of salt outcrops in most parts of the world, and their occurrence is generally limited to the subsurface. The proximity of evaporite deposits may be inferred from saline waters in springs and wells, solution breccias, or thick outcrops of gypsum or anhydrite. Domal or collapse structures at the surface may indicate salt domes, or piercement structures, such as those found under and around the Gulf of Mexico.²⁷ and under the North Sea and in the Zechstein hasin.²⁸ Domes or anticlines that show on outcrop several periods of upward growth during a broad range of geologic time can generally be expected to have a central core of evaporites. The distribution and shape of subsurface salt structures can also be determined by geophysical techniques such as gravity and seismic methods.²⁹

The origin of salt domes is believed to be due to the effect of gravity on layered rock where a lower density material (salt) is overlain by higher density material (sandstones, compacted shales, carbonates). The shear strength of halite and potash salts is very low compared to other geologic materials, and their low compressibility maintains their low density even under deep burial conditions. Low shear strength is further abetted by high temperatures associated with deep burial. Over geologic time, salt can be squeezed upward due to the effect of gravity on a denser overburden with or without the addition of lateral tectonic compression, and its flow can be modeled as a viscous fluid.30 Points of instability, brought about by intersections of fault systems or differential loading, are sites for nucleation of salt "pillows," or salt hills in the subsurface. As the salt masses continue to rise, anticlines formed in the overlying layers can be pierced by upward salt movement and result in the development of mushroom-shaped salt diapir structures which, in extreme cases, can become completely detached from the rest of the salt deposit.31 In the arid climate of northern Iran, the salt diapirs have pierced the surface and flow downhill as "salt glaciers." The structure of the original depositional layering in the salt inside of a diapir is highly deformed and chaotic, 32 and may not be suitable for conventional potash mining techniques.

The vast majority of evaporite deposits were discovered as a result of drilling for petroleum. Evaluation of oil and gas exploration geophysical logs, such as gamma-ray, neutron, sonic, caliper, density, and resistance logs is useful in interpretation of evaporite lithology, stratigraphy, and mineralogy.³³ gamma-ray log detects the gamma radiation from the natural potassium isotope K⁴⁰ and is particularly useful for providing a continuous measure of the potassium content of the salt section.34 Bromine content of salt layers has been used to evaluate potash potential and is useful as an indication of the stage of

POTASH—1992 1009

evaporation, especially in waters that were predominantly marine in origin. During evaporation of a halite precipitating brine, the substitution of bromine for chlorine in the crystal lattice Because precipitation of increases. potash occurs in highly concentrated brines, the halite in and near potash beds should contain more bromine. bromine concentration profile from seawater would show a regularly increasing bromine content toward the top of the halite bed (see figure 5), while a salt precipitated from mixtures of seawater and other waters or brines or a salt that has undergone extensive postdepositional recrystallization ground waters may show an irregular profile or one that shows no increase in bromine concentration. In northeastern Thailand, one of few potash deposits that was not found by accident by petroleum exploration was discovered by the use of bromine geochemistry.35

Some general guidelines for evaluating the features peculiar to an evaporite deposit that may determine the success of a mining operation were given by Adams and Hite.³⁶ The initial appraisal of a deposit is based on drill cores spaced on 0.5 to 1.5 km centers, depending on the depth and complexity of the deposit. The salt cores are logged with attention all to mappable stratigraphic, lithologic, and mineralogic features, and the potash horizons are sampled by individual geological units for It is generally chemical analysis. sufficient to analyze for K, Na, Ca, Mg, Cl_2 , SO_4 , and H_2O . The chemical analysis and the megascopic mineralogy estimated from hand specimen and thin section are used together with the stratigraphic data to develop a geologic interpretation to be evaluated in terms of the factors listed in Adams and Hite³⁷ to determine the potential for a minable deposit or the need for additional drilling or metallurgical tests.

ANNUAL REVIEW

Issues

NM, closed for 2 months at the end of the year when its export market to Latin America became unprofitable due to low prices. The aggressive (price cutting) marketing by some offshore potash sources into the Brazilian market has caused prices on the coast of Brazil to drop below \$158 per ton.38 Carlsbad, NM, producers cannot sell all that they produce in the domestic market and depend on the Latin American market to maintain sales levels, and therefore, production levels.

Production

Domestic potash production, in K₂O equivalents, declined about 3%, to 1.7 million metric tons in 1992, from that of 1991. Of the total production for the vear, 73% was standard, coarse, and granular muriate of potash, also known as potassium chloride, and 14% was sulfate of potash, also known as potassium sulfate.

Great Salt Lake Minerals Corp. increased its potassium sulfate production by purchasing potassium chloride from two States and Canada. Those purchases were subtracted from the production of the two States and the imports from Canada to prevent double counting in the "apparent consumption" calculation.

The remaining 12% of production included manure salts, soluble and chemical grades of muriate of potash, and sulfate of potash-magnesia, also known as potassium magnesium sulfate. In muriate of potash, "standard," "coarse," and "granular" refer to their particle sizes and are known as the three muriates, a term that ignores the soluble and chemical grades. "Standard" and "soluble" grades of muriate of potash and sulfate of potash also have industrial end uses. "Manure salts" formerly referred to high-grade "run-of-mine" ore and was applied to a few crops; 25% K₂O sylvinite ore is approximately 40% KCl, which can be used on sugar beets. Currently, it refers to a mixture of white KCl and NaCl for industrial uses.

The New Mexico potash producers accounted for 82% of the total marketable Horizon Potash Corp. of Carlsbad, potash salts production, down from last

year's 84% due to the temporary closure of Horizon Potash Corp.'s operation at the end of the year. The production of crude salts (ore) in New Mexico was 16 million tons with an average K₂O content of 12.7%, a 9% decrease in ore grade compared with that of 1991. comparisons with the mined ore grades of other countries, langbeinite ore is mined in New Mexico and 8% K₂O langbeinite ore is 35 % K₂SO₄ • 2MgSO₄, a profitable ore grade. There were five producers operating six mines in 1992. Horizon Gold Corp. purchased AMAX Potash Corp. in February and renamed the operation Horizon Potash Corp. Horizon Gold Corp. renamed itself Horizon Resources Corp. Other producers were Eddy Potash Inc. owned by Trans-Resources Inc., IMC Fertilizers Inc. (IMCF), Mississippi Chemical Corp., New Mexico Potash Corp. owned by Trans-Resources Inc., and Western Ag-Minerals Co. owned by Rayrock Resources of Canada. All the New Mexico potash producers mined underground bedded ore zones and all except Western Ag-Minerals mined sylvinite ore (the mixture of sylvite and halite from which most muriate of potash originates) and beneficiated the ore to 95% pure (60% K₂O) muriate of potash. Several forms of beneficiation were used: the flotation of sylvite (potassium chloride) from halite was used at Eddy Potash, Horizon Potash, and Mississippi Chemical. The IMCF plant used both heavy-media separation and flotation, and New Mexico Potash used dissolutionrecrystallization. Western Ag-Minerals and IMCF mined langbeinite ore and beneficiated the ore by washing, heavymedia separation, and flotation to sulfate of potash-magnesia. The IMCF personnel mined both sylvinite and langbeinite ores and reacted fractions of each potash product to produce sulfate of potash. Some muriate of potash from New Mexico was sold to a domestic potassium nitrate manufacturer who produced about 50,000 tons.

In Utah, Moab Salt Inc. produced muriate of potash for Texasgulf Inc., which is owned by Elf Aquitaine Inc., from an underground bedded sylvinite deposit by two-well solution mining and solar evaporation. The sylvinite salts from the solar ponds were beneficiated by flotation to separate sylvite from halite. Great Salt Lake Minerals Corp. (GSLMC) produced sulfate of potash from the brines of the North Arm of the Great Salt Lake by solar evaporation and a proprietary process of fractional crystallization. The company announced plans to increase the potash production by about 80% by about 1995. The plan is for an 80.94 square km acre solar evaporation pond on the west side of the North Arm of the Great Salt Lake, which will preevaporate brine. This brine will be transferred to the present ponds for continued evaporation. **GSLMC** purchases muriate of potash from other sources for conversion to sulfate of potash owing to an excess of sulfate ions in the lake brine concentrate. The Reilly-Wendover operation of Reilly Industries Inc. produced muriate of potash and manure salts from near-surface brines at the west end of the Bonneville Salt Flats The Reilly-Wendover Raceway. operation has agreed to a Bonneville Salt Flat Raceway rebuilding process that is contingent upon a Bureau of Land Management 3-year study.

One oil and gas firm in Utah sought partners for testing inclined solution mining along potash anticlines and beneficiation by solar evaporation about 10 km north of the Moab Salt site.

The sulfate of potash manufacturing plant in Utah reopened during the year and produced about 5,000 tons. The company continued to operate under chapter 11.

In California, the muriate and sulfate of potash (and other products) operation at Searles Lake owned by North American Chemical Corp. continued to produce by solar evaporation and selective crystallization from the underground brines of the lake bed. Although there are plans to increase soda ash production at the Argus plant, it is not clear how this will affect the potash production capacity at the Trona plant.

In Michigan, Kalium Chemical Ltd. continued pilot plant development of a deep ore body and the technology to

extract muriate of potash from that ore body.

Greensand, also known as glauconite, a natural silicate of potassium, aluminum, iron, and magnesium, was produced by Inversand Co., a subsidiary of Hungerford and Terry Inc., near Clayton, NJ. Production and sales information are withheld to avoid disclosing company proprietary data. Processed greensand was sold as a filter media for the removal of manganese, iron, and hydrogen sulfide from drinking water supply systems. Classified raw greensand was resold by Zook and Ranck Inc. as a soil conditioner and as a slowly released potash, with a K₂O equivalent between 5% and 10%, to the organic farmers of North America.

Consumption and Uses

Due to several corrections in 1991, import data that were not included in the 1991 Annual Report apparent domestic consumption of all forms of potash in 1991 declined about 4% compared with that of 1990. Using the recalculated 1991 apparent domestic consumption of all forms of potash, apparent domestic consumption of all forms of potash in 1992 increased 2%. About 55.5% of domestic sales of potash was in the first half of the year, indicating good spring sales that made up for the poor sales, due to wet weather, in the fall of 1991.

According to the Potash & Phosphate Institute, the shipments of agricultural potash from Canadian and United States producers increased 9% from 1991 to 1992. The shipments of nonagricultural potash were essentially unchanged for a total (agricultural plus nonagricultural) increase of 8% from 1991 to 1992. The major States receiving agricultural potash from Canadian and United States producers, in decreasing order, were Illinois, Iowa, Ohio, Indiana, Minnesota, Missouri, and Wisconsin. These seven States received 53% of the total. Domestic producers accounted for 6% of the agricultural shipments to Illinois, 6% of the agricultural shipments to Iowa, 7% of the agricultural shipments to Ohio, 6% of the agricultural shipments to Indiana, 2% of the agricultural shipments to

Minnesota, 59% of the agricultural shipments to Missouri, and 2% of the agricultural shipments to Wisconsin. The major receiving States of domestically agricultural potash, produced decreasing order, were Missouri, Texas, California. Kansas. Florida, and Arkansas, and these States received 57% of the total. The major States receiving agricultural sulfates of potash were Florida, California, Georgia, Kentucky, and Texas. These five States accounted for 55% of the total. These figures do not account for the imports from the rest of the world. The rest of the world potash import tonnages are counted only at the entering port and are not tracked to the States in which the potash is used.

The major States for shipments of nonagricultural potash from Canadian and United States producers, in decreasing order, were Alabama, Ohio, Delaware, and Mississippi. These four States accounted for 69% of the total.

Stocks

Yearend producers' stocks declined more than 17% compared with those of 1991. Yearend stocks represented about 16% of annual production or about 8 weeks of average production.

Prices

The average annual price, \$189.30 per ton f.o.b. mine, of U.S. potash sales of all types and grades was about 6% greater than that of 1991. The average price was \$189.12 for the first half of the year and \$189.56 for the second half of the year. The average annual price of the three grades of muriate was \$135.43, up slightly from that of last year. For the full calendar year standard grade averaged \$134.79 per ton; coarse grade, \$131.94; and granular grade, \$136.41. The average annual price for all grades of sulfate of potash averaged \$329.31 per ton, an increase of 3%.

Foreign Trade

Total potash exports of the United States as reported by the Bureau of the

Census increased 6%, with most of the increase in sulfate of potash. The major destinations for U.S. potash exports were Latin America and the Pacific Basin countries. Latin America received about 62% of all U.S. potash exports. About 87% of U.S. exports to Latin America was muriate of potash while sulfate of potash was about 9% and sulfate of potash-magnesia was about 4%. In this region, receiving about 62% of the shipments, in decreasing order, were Brazil and Mexico. The Pacific Basin countries were the second largest destination with more than 25% of the total. About 64% of the U.S. exports to the Pacific Basin was sulfate of potash while muriate of potash was 21% and sulfate of potash-magnesia was about 15%. In the Pacific Basin countries. China and Japan, in decreasing order, received about 76% of the shipments. China received only sulfate of potash, and Japan received muriate of potash, sulfate of potash, and sulfate of potashmagnesia, nearly one-half of which was sulfate of potash-magnesia. Europe received about 47,500 tons of potash, 86% of which was muriate of potash. "Other," which includes Canada and Middle Eastern and African countries, received about 5% of the exports, of which 62% was sulfate of potashmagnesia.

Considering exports by product, 81% of the muriate of potash went to Latin America while 10% went to Europe and 8% went to the Pacific Basin and 1% went to "other." For sulfate of potash, 68% went to the Pacific Basin, 24% went to Latin America, 4% went to "other," and 4% went to Europe. For sulfate of potash-magnesia, 42% went to the Pacific Basin, 31% went to "other," 25% went to Latin America, and 2% went to Europe.

Potash Co. of Saskatchewan (PCS) agreed in February to be the sales agent for Horizon Potash Corp. in the southwestern United States and in Latin America. In early summer, three other U.S. potash producers hired PCS as their sales agent into Latin America. These were Eddy Potash Inc., Mississippi Chemical Corp. and New Mexico Potash Corp.

Potash imports for consumption into the United States as reported by the Bureau of the Census increased less than 2% compared with those of 1991. Muriate of potash imports increased more than 1% while sulfate of potash increased about 22%. Imports of muriate of potash from Canada increased about 1% to 3.82 million tons. Imports of muriate of potash from the former U.S.S.R. increased about 70%, to about 196,000 tons, while imports from Germany and Israel combined dropped about 39% from that of 1991.

World Review

World potash production was estimated to have declined about 7% from that of 1991. World prices,³⁹ as exemplified by the per ton price of standard muriate of potash, f.o.b. Vancouver, Canada, were level at \$183 per ton (\$110 per ton of product) through July then rose about \$7 per ton. In late August, the Government of India announced a cessation of fertilizer price subsidies for the Indian farmer. From that date forward prices tended to decline to the end of the year for some producers as they attempted to maintain cash-flow and not for other producers as they reduced production given the lower expected demand. In December, it became apparent that the Government of China was also reducing the fertilizer subsidies to the Chinese farmers through the announcement of independent traders in a free-market import sector. The lower subsidy is likely to decrease the consumption of fertilizer, including potash, in China for several years. By the end of December, the Vancouver price had returned to \$183 per ton (\$109 to \$111 per ton product) but the delivered price in Brazil was reported at \$183 per ton. Sources of potash that were competing into the Brazilian market seemed to be Germany, Spain, the United States, and some unofficial sources in the former U.S.S.R. Three countries in Latin America, Columbia, Peru, and Venezuela, and three countries in Asia, Bangladesh, Indonesia, and Sri Lanka, are rumored to be reducing their subsidies for fertilizer.

Concerning the future demand for potash and the GATT talks, should price protection, for example, for Japanese rice farmers be dropped, the demand for potash in Japan will drop. Any increase in rice production in some other country for export to Japan, such as a developing country in Latin America or the Pacific Basin (or perhaps the United States), may not increase potash consumption in the same amount as the Japanese farmers decrease potash consumption. Russia, which was a net exporter of grains before the 1917 Revolution, launched an initiative called Russia's Bread to reach self-sufficiency in grain production again. The attitudinal, technological. infrastructure changes that will be needed for self-sufficiency will be difficult. The 2-year initiative is probably optimistic but will eventually succeed, decreasing demand for Australian. Canadian. European, and United States grains (and the demand for potash in those countries). Perhaps Russia may eventually export grains to Western Europe, further decreasing the demand for potash in that region in the intermediate term.

Population growth in many developing countries will not necessarily increase the demand for potash through the demand for food. There has to be wealth increases along with the population increases to pay for the food and the potash. Some developing countries may choose to invest their money, in the short and intermediate term, in other areas leading to wealth creation, such as infrastructure or education, rather than into fertilizer, which is almost a "present consumption" commodity.

Brazil.—Companhia Vale do Rio Doce announced plans to increase production capacity at the Taquari-Vassouras site from 120,000 tons to 300,000 tons.

Canada.—In 1991, Potash Co. of America, owned by Rio Algom Ltd. of Canada, reported production at the Sussex Mine at 443,000 tons, above the 420,000-ton rated capacity for the plant. Because the company reported a total of 643,000 tons, this means that the solution mine at

Patience Lake produced about 200,000 | Denison Mining Ltd., having suffered a large financial loss in 1990. sold its 60% share of the Denison-Potacan Mine in New Brunswick in April. The price was estimated to be \$15 million plus the assumption by the buyers of \$104 million in debt. The company was renamed the Potacan Mining Co. and the mine was renamed the Potacan Mine. The buyers were Potacan (Potash Co. of Canada, Ltd.), a 50%-50% joint venture of France's Groupe Entreprise Miniere et Chemique and Germany's Kali und Salz AG, who had owned 40% of the mine. The joint venture started as a sales organization for French and German potash producers before the Second World War and developed the Alwinsal Mine in Saskatchewan between 1964 and 1968. The Alwinsal Mine was the third mine expropriated by PCS in 1977 and was renamed the PCS Lanigan Mine Div. In 1991, PCS sold the experimental potassium sulfate plant at Big Quill Lake to the employees. The plant uses ion exchange resins to capture sulfate ions from the sodium sulfate-laden lake water. Using under-grade muriate from PCS, the process washes away the sulfate ions with potassium ions. The resulting solution enters crystallizers where a high-purity potassium sulfate forms.

In 1992, Canadian potash mines had 114 mine-weeks of shut downs in addition to Cory Mine operating only its crystallizers, Lanigan Mine not operating its older mill, and Allan Mine operating on a 5-day week. PCS formed a limited partnership with Florida **Favorite** Fertilizer Inc., which was delinquent on payments for potash, among other items. Florida Favorite operates in Florida and Georgia of the United International Minerals & Chemicals (Canada) Ltd. received approval for plans to replace the present mines, known as K1 and K2, with a new mine shaft and mine that would be about 6.5 km from the present K2 mill and 11 km from the present K1 mill. A second shaft is planned. The new shaft will provide access to its present reserves but will not be connected underground to the present mine workings, which has a direct

connection to an aquifer. The Saskatchewan Environment and Public Safety Department approved the plans. Ore would be transported from the new shaft to the mills by capsules in a 1.0668 m subsurface pipeline using air pressure. RTZ Corp. PLC of England sold its interest in Rio Algom Ltd. in Canada but kept control of Potash Co. of America. Environmental concern has become evident concerning the potash mine salt tailings piles in Saskatchewan but the final disposition of the salt piles has not become evident. Both mines in New Brunswick designed their mines for returning tailings to the mines, but it may not be financially possible to retrofit such processes to the earlier Saskatchewan mines. Both New Brunswick mines have found that returning mill tailings to the mine adds significant costs. PCS Sales became the sales agent for Horizon Potash Co. of Carlsbad, NM, early in the year. PCS Sales will be the agent for Horizons' sales into the southwestern United States and exports to Latin America. Later in the year, Mississippi Chemical Co. and Trans-Resources' mines, New Mexico Potash and Eddy Potash, signed agency agreements that PCS will handle their potash sales into Latin America. Late in the year the Province of Saskatchewan exchanged the PCS bonds for PCS stock and reduced its ownership of PCS from about 38% to about 11%.

Chile.—Sodiedad Quimica y Minera de Chile (Soquimich) bought Amax Corp.'s 63.75% ownership in the long-studied Sociedad Minera Salar de Atacama (Minsal) Project in the Salar de Atacama. Soquimich is an iodine, sodium nitrate, and mixed sodium nitrate-potassium nitrate producer in northern Chile. The ore being mined at the present time by Soquimich cannot be beneficiated to better than a 30% mixture of potassium nitrate in sodium nitrate. By purchasing potassium chloride Soquimich can convert sodium nitrate to potassium nitrate. Potassium chloride from the Minsal site would decrease imports of potassium chloride from Canada. Soquimich has also been buying some potassium chloride from the Cyprus Foote Mineral lithium production site on the Salar de / cama. Soquimich will reduce Amax's original potassium chloride production plans to about 300,000 tons per year of product. Soquimich also announced plans to increase its potassium nitrate capacity from 240,000 tons of product to 340,000 tons of product, which would require more potassium chloride.

China.—The production capacity at Lake Oarhan (Chaerhan) in the Tsaidam Basin in Qinghai Province should move forward with technical help from Dead Sea Works (DSW) of Israel and financial investment from DSW and the Eisenberg Group's UDI finance and trading company of Israel. The two Israel groups will purchase 12.5% each of equity in the China National Chemical Co. for \$20 million each. DSW will also supply technical expertise and capital equipment worth \$70 million toward the \$300 million plant of 800,000 tons per year of KCl. DSW hopes to apply its cold crystallization process to a site remote from indigenous energy supplies. The site was first developed by the Chinese after the Second World War, producing up to about 20,000 tons of KCl per year. In 1982, Jacobs International of Dublin, Ireland, contracted with Chinese authorities to develop a 200,000ton-per-year KCl plant as a pilot plant for the 800,000-ton-per-year KCl plant. The resource was a near-surface brine, and solar ponding was the desired method of crystallization. (The Tsaidam Basin is about 37° N. while the solar evaporation ponds of the Great Salt Lake are about 42° N. and the two sets of solar ponds at the southern tip of the Dead Sea are about 31° N.) The brine crystallizes carnallite, as do the Dead Sea potash In 1992, the site was operations. reported to have never surpassed 100,000 tons per year of KCl production.

Egypt.—BHP Minerals International reports potash ore intersections of 32 m during exploration by drilling to 2,164 m near the Red Sea about 27° N.

European Community.—The European Potash Producers Association (APEP) filed charges of dumping before the European Economic Commission against the "peristroika" potash (always potassium chloride) from the former U.S.S.R. in 1990. In April 1992, the imposed Commission provisional minimum prices on those imports of potassium chloride. The minimum price for standard muriate was \$189.35⁴⁰ per ton (ECU92 per ton product or \$113.60 per ton product) and for granular muriate was \$212 per ton (ECU103 per ton product or \$127.20 per ton product). In October, the definitive ruling was published using lower minimum prices of \$185 per ton (ECU86.92 per ton product or \$111 per ton product) for standardgrade muriate and \$210 per ton (ECU 98.65 per ton of product or \$126 per ton of product) for granular muriate. This was a 2% discount for the perceived lower quality of potash from the former U.S.S.R.

Germany.—Rossleben of Mitteldeutsche Kali AG (MdK) was shut down permanently on the last day of 1991. Salzdetfurth of Kali und Salz AG (K+S) shut down permanently in March 1992. Mitteldeutsche Kali AG was owned through 1992 by Treuhandanstalt and consists of three plants at Zeilitz, Bischofferode, and Unterbreizbach, and four mines at Zeilitz, Bischofferode, Merkers, and Unterbreizbach.

At the end of the year K+S and Treuhandanstalt announced their intention of forming a joint-venture company. K+S will own 51% of the joint-venture company and will manage the company.

K+S will, sometime in the next 5 shut down the mine years, Bergmannsseggen-Hugo and the mine and plant at Niedersachsen-Riedel. Mitteldeutsche Kali will close down the plant at Merkers Mine while connecting the mine underground to the other mine the area. Unterbreizbach. Mitteldeutsche Kali will eventually shut down the Bischofferode plant in the Sud-Harz district. This will leave open the Zielitz Mine and plant and the Unterbreizbach Mine and plant. The Merkers Mine and K+S Hattorf Mine will feed the Unterbreizbach plant. The remaining operations will be Wintershall Neuhof Ellers, Sigmundshall (of K+S), and Unterbreizbach and Zeilitz of MdK. Employment changes in the potash industry in Germany have been truly wrenching. The former East German potash industry employed 32,000 workers in 1988 and is heading toward 7,000 workers. K+S lost 1,400 workers when it closed Salzdetfurth at the end of 1991 and will lose another 1,000 to reach 6,500 workers. K+S has not announced the job loss due to the closure of Bergmannsseggen-Hugo and Neidersachsen-Reidel.

India.—India announced cessation of subsidies for fertilizers to farmers in August. Demand is forecast to drop by as much as 50% in the next fertilizer year (April 1993 to March 1994). For the current Indian fertilizer year (April 1992 to March 1993), potash usage is forecast to drop to 1.7 million tons KCl, from a previously expected 2.4 million tons.

Israel.—Haifa Chemicals, owned by Trans-Resources of the United States, announced plans to increase capacity from 300,000 to 400,000 tons of KNO₃ with a \$105 million investment near Mishor The Israeli Government will Rotem. grant about \$63 million for this project. World consumption of KNO₃ is put at 600,000 tons per year with a growth rate of 7% to 8% per year. One magazine⁴¹ reported KNO₃ plant closures in France, Poland, and the former German Democratic Republic. The Government of Israel sold 18% of its holdings in Israel Chemicals Ltd., parent of DSW, for \$225 million in February on the Tel Aviv Stock Exchange. It is not clear how this affects DSW. DSW announced studies to build evaporation ponds south of the Dead Sea Graben, near Yotvata, to which Dead Sea brine would be pumped for the production of salt, making this a preconcentration pond. The salt would be exported from Eliat, and the bitterns would be piped back to the present DSW

ponds for carnallite production. The added potash production was expected to be sold to China and India. DSW apparently withdrew from the U.S. east coast market (1990, 221,600 tons; 1991, 113,000 tons; and 1992, 72,000 tons).

Jordan.—Arab Potash Co. will finish a 240,000-ton-per-year capacity increase in 1994 and is considering another 240,000 tons per year by 1997. Final tonnage is estimated at 1.3 million tons as KCl.

Spain.—The decline of Grupo Torres SA into receivership did not affect the Spanish potash industry because all of the potash mines are currently state owned.

Former U.S.S.R.—It has been estimated⁴² that former U.S.S.R. potash consumption has fallen by 2.5 million tons of product between 1988 and 1991 or 35% while the Eastern European countries' potash consumption has fallen by 1.5 million tons of product or 50% between 1988 and 1991. There was a 2month strike at the Belarus potash mines for higher wages. The European Community placed a floor price for imported former U.S.S.R. potash in April by a provisional finding of dumping and set definitive minimum prices, in October, on former U.S.S.R. potash (see European Community section). The new former U.S.S.R. fertilizer export firm, AgroChimExport, did not handle all of the potash leaving the country in the latter half of the year. "Peristroika potash" flowed into the world potash trading arena, which drove down prices on the east coast of Latin America and, to a lesser extent, in the Pacific Basin and Asia. AgroChimExport and three potash firms, Sylvinit, Uralkali, Byeloruskali, formed two joint-venture trading firms during the year. One was based in Austria and named Belurs GmbH. The other was based in Singapore and named Agrosin.

United Kingdom.—Cleveland Potash Ltd. increased its granular potash capacity by 33% to 320,000 tons per year of KCl

with the addition of a fourth compactor.

OUTLOOK

The world potash industry currently is in a situation of overcapacity, even with the recent shutdowns of capacity in Germany, and seems likely to remain so for a decade. The United States will lose some capacity before the year 2000, Thailand is likely to replace that capacity, while China and Egypt may add more capacity.

The problem is the decline in demand among the developed market countries since 1979 (the second world oil shock) and in many of the former centrally planned economies since 1988. Demand in several developed economies may drop as subsidies for agriculture are revised downward in those countries. This demand may shift demand to several developing countries, giving developing economy countries in Latin America and the Pacific Basin added growth. The Latin America and Pacific Basin countries are the regions of potash demand growth in the world. They were approximately one-third the level of the developed countries in 1988 and no reasonable growth rate would bring these regions' aggregate demand level to the developed market economy countries' 1988 level in the near future. Another region of declining demand, the former centrally planned economies once consumed as much as the developed countries, and some of these countries have decreased their level of potash consumption to one-half their former level. It is currently unclear what a reasonable demand path into the future for the Eastern Europe and former U.S.S.R. countries is, or even what direction that path will take for the next 5 years.

TABLE 1 SOME MINERALS, ORES, AND PRODUCTS OF POTASH DEPOSITS

Name	Formula	K₂O, equivalent weight percent	Remarks
	MARINE EVAPORIT	E DEPOSITS	
	MINERAL	LS	
Chlorides:			
Sylvite	KCI	63.17	Principal ore mineral.
Carnallite	KCl•MgCl ₂ 6H ₂ O	16.95	Ore mineral and contaminant.
Kainite	4KCl•4MgSO ₄ •11H ₂ O	19.26	Important ore mineral.
Bischofite	2MgCl ₂ •12H ₂ O		Accessory contaminant.
Halite	NaCl		Principal ore contaminant.
Sulfates:			
Polyhalite	K ₂ SO ₄ •MgSO ₄ •2CaSO ₄ •H ₂ O	15.62	Ore contaminant.
Langbeinite	K ₂ SO ₄ •2MgSO ₄	22.69	Important ore mineral.
Leonite	K ₂ SO ₄ •MgSO ₄ •4H ₂ O	25.68	Ore contaminant.
Schoenite (picromerite)	K ₂ SO ₄ •MgSO ₄ •6H ₂ O	23.39	Accessory.
Glaserite (aphthitalite)	3K ₂ SO ₄ •Na ₂ SO ₄	42.51	Do.
Syngenite	K ₂ SO ₄ •CaSO ₄ •H ₂ O	28.68	Do.
Bloedite	Na ₂ SO ₄ •MgSO ₄ •4H ₂ O	_	Do.
Loeweite	6Na ₂ SO ₄ •7MgSO ₄ •15H ₂ O	-	Do.
Vanthoffite	3Na ₂ SO₄•MgSO₄	_	Do.
Kieserite	MgSO ₄ •H ₂ O	-	Common ore contaminant.
Hexahydrite	MgSO ₄ •6H ₂ O		Accessory.
Epsomite	MgSO ₄ •7H ₂ O	_	Do.
Anhydrite	CaSO ₄	-	Common ore contaminant.
	ORES		·
Sylvinite ¹	KCI + NaCI	10-35	Canada, United States, former U.S.S.R., Brazil, Congo, Thailand.
Hartsalz	$KCl + NaCl + CaSO_4 + (MgSO_4 \circ H_2O)$	10-20	Germany.
Carnallitite ²	KCl•MgCl ₂ •6H ₂ O + NaCl	10-16	Germany, Spain, Thailand.
Langbeinite ³	K ₂ SO ₄ •2MgSO ₄ + NaCl	7-12	United States, former U.S.S.R.
Mischsalz	Hartsalz + Carnallite	8-20	Germany.
Kainite	4KCi•4MgSO ₄ •11H ₂ O + NaCl	13-18	Italy, Ethiopia.
	PRODUC	TS	
Potassium chloride	KCI	63.17	Principal potassium product.
Potassium sulfate	K ₂ SO ₄	54.05	Artificial product.
Potassium-magnesium- sulfate (langbeinite)	K ₂ SO ₄ •2MgSO ₄	22.69	Natural product (New Mexico).
Manure salts	KCI + NaCl	40-60	Former U.S.S.R., East Germany.
	OTHER SOU	RCES	
Alunite	K ₂ Al ₆ (SO ₄) ₄ (OH) ₁₂	11.4	
Niter (caliche)	KNO ₃ + NaNO ₃ + Na ₂ SO ₄ + NaCl	.6-1.9	Chile.
Potassium nitrate	KNO ₃ + NaNO ₃	10-14	

¹May contain one or more sulfate minerals or camallite.

Source: Modified after Adams, 1968.

1017 POTASH-1992

²May contain sylvite.

³May contain sylvite and leonite, kainite, or other sulfate minerals.

RARE EARTHS

THE LANTHANIDES, YTTRIUM, AND SCANDIUM

By James B. Hedrick

Mr. Hedrick is a physical scientist in the Branch of Industrial Minerals. He has been the commodity specialist for rare earths since 1981. Domestic survey data were prepared by Ms. Kelly A. Dorney, management analyst; Mr. John C. Macke, management analyst; and Mr. Renaldo Summerset, management analyst. The international data tables were prepared by Mr. Harold Willis, international coordinator.

The rare earths are a relatively abundant group of elements that range in crustal abundance from cerium, the 25th most abundant element of the common elements at 60 parts per million, to lutetium, the 61st most abundant element at 0.5 part per million. The rare earths were discovered in 1787 by Lieutenant Karl Axel Arrhenius when he collected the black mineral vtterbite (later renamed gadolinite) from a fluorspar mine near the village of Ytterby, Sweden. With similar chemical structures, the rare-earth elements proved difficult to separate. It was not until 1794 that the first element, an impure yttrium oxide, was isolated by Finnish chemist Johann Gadolin.

The rare earths are iron gray to silvery lustrous metals; typically soft, malleable, and ductile; and usually reactive, especially at elevated temperatures or when finely divided. Densities range from 2.99 grams per cubic centimeter for scandium, a lightweight metal slightly denser than aluminum, to 9.84 grams per cubic centimeter for lutetium, a moderately dense metal similar to bismuth and actinium. The rare earths' unique properties are used in a wide variety of applications.

Domestic mine production of rare earths increased in 1992. The domestic economy recovered slowly during the year and inflation rose a modest 3%. Estimated domestic apparent consumption declined about 9%; however, reported sales by the major domestic processor increased 3%. (See table 1.) Demand increased for rare earths used in automobile catalytic converters,

permanent magnets, and lighting phosphors.

The domestic use of scandium in 1992 remained small. Commercial demand was extremely small, with most metal and compounds sold for research and analytical standards. Minor amounts were used in specialty lighting and semiconductors.

DOMESTIC DATA COVERAGE

Domestic mine production data for rare earths are developed by the U.S. Bureau of Mines (USBM) from the voluntary survey, "Rare Earths, Thorium, and Scandium." The two mines to which a survey form was sent responded, representing 100% of known mine production. Production data from one company processing tailings was also collected. Mine and tailings production data are withheld to avoid disclosing company proprietary data.

BACKGROUND

Definitions, Grades, and Specifications

The rare earths are defined by the USBM as a group of 17 elements composed of scandium, yttrium, and the lanthanides. Rare earths are classified chemically as members of the IIIB subgroup of the periodic table.¹

Scandium, atomic number 21, is the lightest rare earth. It is the 31st most abundant element in the Earth's crust with an average crustal abundance of 22 parts per million. Although its

occurrence in crustal rocks is greater than lead, mercury, and the precious metals, scandium rarely occurs in concentrated quantities as a result of its affinity to combine with the common ore-forming anions. It is a member of the first transition series of elements.

Yttrium, atomic number 39, is chemically similar to the lanthanides and commonly occurs in the same minerals. The average concentration of yttrium in the Earth's crust is 33 parts per million, the second most abundant rare earth in the Earth's crust. Yttrium is a member of the Second Transition Series.

The lanthanides comprise a group of 15 elements with atomic numbers 57 through 71, and include: lanthanum, praseodymium. neodymium cerium. samarium, europium, promethium, gadolinium, terbium, dysprosium, holmium, erbium, thulium, ytterbium, and lutetium. The lanthanides are part of the third transition series. Cerium, the most abundant of the group at 60 parts per million, is more abundant than copper. Thulium, the least abundant of the lanthanides at 0.48 part per million, occurs in the Earth's crust in higher concentrations than antimony, bismuth, cadmium, and thallium.

Due largely to differing ionic radii, the rare-earth elements are broadly classified into two groups: the light rare-earth elements (LREE) or cerium subgroup, composed of the first seven lanthanides (atomic numbers 57 through 63) and the heavy rare-earth elements (HREE) or yttrium subgroup, composed of the remaining lanthanides and yttrium (atomic

numbers 64 through 71 and 39). Yttrium is classed with the heavy subgroup because of its occurrence, ionic radius, and other similar properties.

Bastnasite can theoretically contain 74.81% rare-earth oxide (REO).² Flotation concentrates of bastnasite average 60% REO, which can be upgraded to 70% REO by acid leaching and to 85% REO by a combination of acid leaching and calcining.

Monazite can theoretically contain 69.73% REO. Monazite concentrate is usually sold at 55% minimum REO contained plus thorium, with product grading from 55% to 65% REO. Thorium contents are variable, but typically occur in the range of 4% to 10% equivalent thorium oxide.

Xenotime can theoretically contain 61.40% yttrium oxide. However, xenotime concentrates from Southeast Asia and Australia typically contain 25% to 30% yttrium oxide. Xenotime is commonly upgraded by acid leaching to produce an yttrium concentrate grading 60% yttrium oxide and the balance primarily other rare earths.

Various metallic rare-earth products are produced. The term "mischmetal" is used to denote a mixture of rare-earth elements in metallic form. It generally has the same ratio of rare-earth elements as that found in the ore and is typically 98% to 99% pure. Recently, a higher purity "battery-grade" mischmetal was produced to supply the market for rechargeable rare-earth-nickel hydride batteries.

Ferrocerium is a pyrophoric alloy of mischmetal and iron. A typical ferrocerium alloy contains 74% mischmetal, 23% iron, 2% copper, and 1% magnesium.

Rare-earth silicide is an alloy typically containing about one-third mischmetal, one-third iron, and one-third silicon. The rare-earth content of a silicide may be as high as 50%.

The rare-earth content of master alloys range from tenths of a percent in nodularizing alloys for ductile iron to tens of a percent in inoculants for gray cast iron. Alloys containing nearly 100% rare-earth metals, such as mischmetal,

are additives to certain steels.

The purity of separated rare-earth elements, produced primarily by solvent extraction or ion exchange, usually grade 96% or higher in purity. High-purity rare-earth compounds and metals are produced up to 99.99999% purity. Rare-earth products grading higher than 99.9% purity are often produced to specification. As a result of the wide range of products in which rare earths are consumed, many grades of rare-earth concentrates, compounds, alloys, and metals are produced.

Products for Trade and Industry

A wide variety of products is available for trade and industry, including concentrates, individual and mixed compounds, and pure and alloyed metals.

Bastnasite concentrate produced in the United States is available in three grades, an unleached concentrate grading 60% REO, an acid-leached concentrate containing 70% REO, and a calcined concentrate upgraded to 85% REO. A mixed bastnasite-monazite concentrate (predominantly bastnasite) from China is produced in three grades, a 30% minimum REO, a 60% minimum REO, and a 71% minimum REO.

Mixed compounds derived from bastnasite include rare-earth chloride, rare-earth nitrate, lanthanum-rare-earth carbonate, lanthanum carbonate, cerium carbonate, cerium nitrate, cerium fluoride, neodymium carbonate, neodymium fluoride, praseodymium fluoride, cerium-rare-earth hydrate, and rare-earth hydrate.

Monazite is marketed as a concentrate containing 55% to 60% minimum REO plus contained thorium. Mixed compounds produced from monazite include cerium chloride, ceric ammonium nitrate, ceric sulfate, cerium carbonate, cerium hydroxide, cerium nitrate, cerium octoate, rare-earth carbonate, lanthanum carbonate. lanthanum-neodymium carbonate, lanthanum-neodymium nitrate. neodymium carbonate, neodymium nitrate, praseodymium oxalate, rare-earth octoate, and yttrium nitrate.

Xenotime concentrate with a minimum

25% yttrium oxide content is a source of yttrium. It is typically upgraded chemically to a 60% yttrium oxide product known as yttrium concentrate, the balance of the concentrate being mostly other rare earths. The primary product derived from yttrium concentrate is high-purity yttrium oxide.

Rare-earth ion adsorption ore, produced in southern China, is the principal source of yttrium. The ores vary by locality, but two principal concentrates, an yttrium concentrate and a europium concentrate, are produced. The yttrium concentrate is enriched in the heavy-rare earths and has greater than 60% yttrium oxide. Although the europium concentrate grades from 0.5% to nearly 1% europium oxide and 12% yttrium oxide, it is predominantly enriched in lanthanum oxide, 33% to 43%.

Individual rare-earth oxides and other compounds, except promethium, are produced from bastnasite, monazite, xenotime, and ion adsorption ore. Purities from 96% up to 99.9999% are available for most oxides. Compounds for almost all of the rare earths are available as oxides, acetates, carbonates, chlorides, fluorides, nitrates, oxalates, and sulfates.

High-purity rare-earth metals are marketed in the form of sponge, lump, ingot, crystal, rod, wire, chips, powder, sheet, foil, plate, sputtering plates, and custom cast and machined shapes. Alloys such as mischmetal, rare-earth silicide, ferrocerium, and other rare-earth alloys are available in a variety of ingot shapes and sizes.

Rare-earth magnet alloys are produced to individual requirements. Magnet alloys are marketed in ingot form, crushed ribbon, or may be purchased as mixed oxides for powder metallurgical processes. Magnets are available in finished and semifinished shapes, bonded and unbonded, and magnetized and unmagnetized.

Scandium is marketed primarily as a high-purity oxide. Oxide purities from 98% to 99.9999% have been produced in the United States. In addition to the oxide, scandium compounds are available

as the acetate, bromide, carbonate, chloride, fluoride, hydride, iodide, nitrate, oxalate, acetylacetonate, and sulfate. Scandium metal is produced in ingot, powder, lump, and foil form.

Industry Structure

Few rare-earth companies are fully integrated. Rare earths are typically mined and processed by different companies. In the United States, Molycorp, Inc. is the only fully integrated producer from its mine, mill, and refinery at Mountain Pass, CA. The other principal producer, RGC (USA) Minerals Inc., operated a mine and wet and dry concentrating plants at Green Cove Springs, FL. Except for Molycorp, all other domestic refiners have operated independently.

Rare-earth ore is beneficiated by mine producers into concentrates that are sold directly to processors or, to a lesser extent, are sold to brokers for resale.

Rare-earth concentrates undergo extensive processing to produce mixed or separated compounds. The major processes used in separating rare earths are precipitation, solvent extraction (SX), and ion exchange (IX). Processors sell refined rare-earth products directly to consumers or brokers.

The scandium industry, for the most part, is separate and distinct from the lanthanide and yttrium industry. high-price and very limited demand have made scandium one of the smallest commodity markets in the world. As with lanthanides, the scandium industry is rarely fully integrated. Due to limited demand scandium is not currently mined in the United States. **Byproduct** production is reported only from China and the Commonwealth of Independent States (C.I.S.). Although minor amounts of scandium have been separated from lanthanide and yttrium ores, most scandium is produced as a byproduct from other ores. In the United States, scandium has been recovered as a byproduct during processing of uranium at a copper mine, from tailings from a mined-out fluorite mine, and from tungsten byproduct from a molybdenum

operation. Tailings and concentrates from these sites were shipped to processors for production of high-purity scandium oxide and other compounds. Most scandium is sold in oxide form. A small group of companies produce scandium metal, primarily for lighting and research purposes.

Geology-Resources

Rare-earth minerals occur in a variety of geologic environments. Concentrations exist in igneous, sedimentary, and metamorphic rocks. Rare earths are mined primarily from igneous and sedimentary deposits. The geologic age of the deposits range from Recent to Precambrian.

The rare earths are constituents in more than 100 minerals, but only a few are recovered for commercial production. Bastnasite, monazite, xenotime, and rare-earth-bearing clay are the major sources of the world's rare-earth supply. Other sources are loparite, uraniferous phosphorites, synchisite, and byproduct solutions from processing uranium.

Bastnasite.—Bastnasite. a rare-earth fluocarbonate mineral, is found in vein deposits, contact metamorphic zones, pegmatites, and carbonatites. typically enriched in the LREE (Bastnasite-Ce); however, a rare HREE variety (Bastnasite-Y) is known from Kazakhstan. Bastnasite forms in the trigonal crystal system and ranges in color from yellow to reddish-brown. It has the following mineralogical properties: transparent to translucent; vitreous to greasy luster; density of 4.78 to 5.2 grams per cubic centimeter; and a hardness of 4 to 4½ on the Mohs scale.3 It forms as an igneous or hydrothermal mineral and occurs as an accessory mineral in several large deposits. Deposits containing bastnasite as a high-grade accessory mineral are at Mountain Pass, CA, United States; Bayan Obo, Nei Monggol Autonomous Region, China; Wigu Hill, Tanzania; and Karonge, Burundi.4 Bastnasite and other independent rare-earth minerals commonly form by hvdrothermal

processes, although its occurrence at Mountain Pass, CA, is considered primary igneous. Concentration of the rare earths can occur as a result of coprecipitation with calcium carbonate or by precipitation in the presence of fluorine. While the Mountain Pass bastnasite is believed to have formed by the coprecipitation process, the Bayan Obo's bastnasite is hydrothermal in origin and formed by alteration of dolomite in the presence of large amounts of fluorine. Most of the world's rare-earth resources are recovered from bastnasite.

Monazite.—Monazite, a rare-earth phosphate, is one of the most abundant rare-earth minerals. It occurs as an accessory mineral in granitic and metamorphic rocks, pegmatites, vein deposits, as a detrital mineral in placer deposits, and as a hydrothermal and supergene mineral in carbonatites. It is classified as a LREE and is usually enriched in cerium (Monazite-Ce). Rarer monazite varieties are a lanthanum-rich monazite (Monazite-La) and a neodymium-rich monazite (Monazite-Nd) described from Italy and from Marmara, Greece, respectively.6 Monazite, which forms as a monoclinic mineral, is found in a wide range of colors, including honey yellow, greenish brown, reddish brown, yellowish brown, brown, pink, yellow, grayish white, dark grey, and black. It has the following mineralogical properties: transparent to subtranslucent; resinous. waxy, vitreous. subadamantine luster; density of 4.6 to 5.4 grams per cubic centimeter; and a hardness of 5 to 5½ on the Mohs scale.7 Monazite forms primarily as an accessory mineral in igneous and metamorphic rocks, including granites, gneisses, aplites, and pegmatites, and occasionally as a vein mineral (VanRhynsdorp, Republic of South Africa).

Economic placers develop where monazite has been weathered from its original host rock and concentrated by wind and water. Placer monazite is mined as a byproduct of titanium and zirconium minerals or tin minerals. Significant placer deposits are in Australia, Brazil, Malaysia, Thailand,

and the United States.8

Monazite of hydrothermal and supergene origin in carbonatites also represents a large rare-earth resource. Deposits of this type occur at Araxá, Minas Gerais, Brazil; Catalao I, Goiás, Brazil; Bayan Obo, Nei Monggol Autonomous Region, China; and Mount Weld, Western Australia, Australia.

Although China's Bayan Obo deposit is known primarily as the world's largest bastnasite deposit, it contains substantial tonnages of monazite. Formed by hydrothermal alteration of dolomite, the Bayan Obo monazite occurs in veins and stockworks in the footwall rocks. 10 One of the richest grade deposits in the world, the Mount Weld carbonatite grades 15 million metric tons at 11.2% REO. including a 1.3-million-metric-ton zone at 23.6% REO.¹¹ Enriched by supergene solutions, the deposit's primary ore minerals are secondary monazite and cheralite, along with lesser amounts of rhabdophane, monazite. cerianite. florencite, and churchite.

Technology

Exploration. — Commercial exploration for rare-earth minerals (primarily thorium) began in the 1880's, for the purpose of locating thorium and cerium for incandescent gas mantles. After electric lighting came into general use about 1912, demand for gas mantles fell. Subsequently, most rare-earth deposits have been located during the search for other minerals and metals, especially gold, ilmenite, rutile, uranium, and zircon.

Exploration methods to locate rare include surface and earths reconnaissance with magnetometric. electromagnetic, and radiometric equipment. Other techniques include satellite imagery, aerial photography, and remote sensing. The application of geologic principles to develop depositional models is also used. After identifying a match for a depositional model or an indicator from one of the other methods, a ground survey of the region is conducted. A typical ground survey would include geologic mapping; rock,

soil, and gas sampling; geophysical testing; surface radiometric surveying; and geochemical testing of the water, rocks, and plants.

Following visual identification of a rare-earth mineral, a systematic subsurface drilling and sampling program is conducted to determine ore grades and individual rare-earth contents.

Because rare-earth minerals are often associated with the radioactive elements uranium and thorium, many rare-earth deposits were discovered during exploration for these elements. Prospectors searching for radioactive minerals discovered the Mountain Pass, CA, bastnasite deposit.

Most monazite heavy-mineral deposits were discovered by exploring for recent and ancient alluvial deposits using radiometric and magnetometric equipment. Discovery of buried alluvial deposits are typically located by depositional modeling.

Mining and Beneficiation.—
Bastnasite is mined domestically as a primary product from a hard-rock carbonatite. The carbonatite is mined via bench-cut, open pit methods. Ore is drilled and blasted, loaded into trucks by rubber-tired loaders, and hauled to the mill. At the mill the blasted ore is crushed, screened, and processed by flotation to produce a bastnasite concentrate.

In China, bastnasite and lesser amounts of associated monazite are also mined from a hard-rock deposit. The ore is recovered as a byproduct of iron ore mining by open pit methods. However, after primary crushing at the mine site, the ore is transported by train 135 kilometers southeast to the mill because of the scarcity of water at the mine site. A bastnasite concentrate and a mixed bastnasite-monazite concentrate are produced as flotation byproducts during processing for the iron ore.

Heavy-mineral sands are the source of most monazite and xenotime mined in the world. Most of these minerals are recovered by surface placer methods from unconsolidated sands. Almost all mining of these sands is done by floating

cutterhead or bucket wheel dredges that concentrate the heavy minerals ("heavies") onboard and discharge the unwanted tailings back into previously mined areas. An onboard wet mill separates the "heavies" (specific gravity greater than 2.9) from the lighter weight fraction through a series of wet-gravity equipment that includes screens, hydrocyclones, spirals, and cones.

Consolidated and partially consolidated sand deposits that are too difficult to mine by dredging are mined by dry methods. Ore is stripped by typical earth-moving equipment with dozers, scrapers, and loaders. Sand recovered by these techniques is crushed and screened and then processed by the wet mill equipment describe above.

Wet mill heavy-mineral mixed concentrate is sent to a dry mill to separate the individual heavy minerals and produce a concentrate. Dry mill processing includes a combination of scrubbing, drying, screening, electrostatic, electromagnetic, magnetic, and gravity processes. Monazite, in contrast to ilmenite, rutile, and many other heavy minerals, is nonconductive and can be separated, with zircon, by electrostatic methods. Monazite, which is susceptible to induced moderately magnetism and may be slightly higher in specific gravity, can be separated from zircon by electromagnets or by additional gravity methods. Xenotime, which has a specific gravity and magnetic properties similar to monazite, is usually separated from monazite by precise gravity methods. Certain deposits also require acid-leach treatment and calcining to eliminate iron oxide or other grain coatings.

Economic Factors

Prices.—Time-price relationships for bastnasite and monazite concentrates, based on 1992 constant dollars, were lower. The 1992 price for bastnasite concentrate remained unchanged from that of the previous year. Adjusting for inflation using U.S. Government implicit price deflators for gross domestic product, bastnasite prices were actually

3.1% lower or in terms of dollars, cost the consumer \$0.08 less per kilogram of REO. Monazite concentrate's price in 1992 decreased substantial from last year's level, down almost 54%. Adjusted for inflation, monazite's price was an additional 3.1% lower or in terms of dollars, cost the consumer \$0.53 less per kilogram of REO.

Concentrates of bastnasite and monazite have traditionally been low priced. Significant value is added when the concentrates are separated into the individual REO's or other compounds. Mischmetal prices also have been historically low, with kilogram prices remaining in the \$7 to \$13 range over the past 20 years. Individual high-purity metals have commanded the highest prices of the rare-earth products. Metal prices typically run from two to six times the separated REO price.

Initially available in 1954, bastnasite concentrate was priced at \$3.31 per kilogram. By the early 1960's, the development of the first significant commercial applications for the rare earths caused its price to drop to less than \$0.50. Bastnasite prices have increased progressively since that time, doubling in price between 1974 and 1980 as a result of the domestic energy crisis.

Monazite's price is more complex than bastnasite's. As a byproduct, the supply and price of monazite is partially dependent on production and demand of the primary minerals. As a result of Australia's dominant position as a monazite producer, fluctuations in monazite's domestic price are also based on United States-Australian foreign exchange rates. Monazite's historical price trend, shown in table 6, shows an overall increase in price through 1985. In the 1950's, its price was \$0.33 to \$0.40 per kilogram of REO, decreasing to \$0.22 to \$0.33 per kilogram in the early 1960's. By the mid-1960's. monazite's price began to increase steadily, with a major increase appearing in 1985, the result of a weak Australian economy and increased competition for monazite supplies. Balanced supply and demand was seen in monazite's price through 1990. In 1991, however, a decline in monazite prices signaled an oversupply, the result of the availability of low-cost separated rare earths from China, a downturn in the U.S. economy, and the decision by a major domestic consumer to switch from monazite to a thorium-free rare-earth feed material. Monazite's price continued to decline in 1992 as a result of decreased demand. (See figures 1 and 2.)

Costs.—U.S. mine and mill operating costs to produce concentrates of bastnasite and monazite differ substantially. The cost to mine bastnasite is greater than that for monazite. Bastnasite, as a primary product, incurs all costs of production, whereas monazite, as a byproduct, accounts for only a fraction of the production costs. The cost to recover monazite is based almost entirely on the expenses made to recover the primary minerals. Mine production costs for bastnasite are also higher than monazite's because of the type of deposit. Costs to mine a hard-rock deposit (bastnasite) are significantly higher than mining a placer deposit (monazite).

Because both domestic mines have been in production for several years, mining costs are related mostly to direct costs, which include labor, mining equipment (trucks, drills, loaders, dredges, pumps, etc.), supplies (explosives, drill bits, etc.), and utilities (fuel, natural gas, water, and electricity). Capital expenditures for plant expansions and other major capital improvements represent the balance of significant costs. These costs are commonly added to long-term debt, but occur intermittently and are typically based on an increase in market demand.

Costs to comply with environmental regulations continue to increase. These costs are mostly indirect operating costs, which include waste treatment and disposal, water purification, systems monitoring, reclamation, administration, and legal and technical personnel.

Tariffs.—U.S. tariff rates, specific to the rare earths, including scandium and yttrium, are unchanged for 1992 and 1993. The duties reflect results from the 1979 Tokyo Round of Multilateral Trade Negotiations under which the tariffs on many items were reduced in several stages over the period January 1, 1980, to January 1, 1987. Tariffs are expected to remain at present rates until new negotiations are completed. U.S. tariff rates for rare earths are listed in the Harmonized Tariff Schedule for 1993, publication 2567, as compiled by the United States International Trade Commission.

Depletion Provisions.—Depletion is defined as the exhaustion of mineral or oil and gas reserves by mining or drilling of wells and the resulting production from these mines or wells. 12 Depletion allowance is a tax deduction that may be taken against income provided by the U.S. Internal Revenue Code to compensate mining companies in the United States for decreasing capital brought about by production. The allowance is based on gross income.

There are two ways of figuring depletion allowance: cost depletion and percentage depletion.¹³ Cost depletion is calculated by dividing the adjusted basis of the mineral property by the total number of recoverable units. Percentage depletion is figured by taking a percentage, specified for certain minerals (elements), of the gross income from the mineral property during the tax year. The depletion deduction may not be more than 50% of the taxable income from the property figured without the deduction.

The depletion allowance for monazite is 22% on the thorium content and 14% on the rare-earth content when mined from domestic deposits and 14% on the thorium content and 14% on the rare-earth content from foreign deposits. Bastnasite's depletion allowance is 14% on the rare-earth content on both domestic and foreign production.

Operating Factors

Toxicity.—Toxicity of rare earths may be broadly classified into two groups—nonradioactive and radioactive. The relative risk is greater from

nonradioactive rare earths because there are few naturally occurring radioactive isotopes.

Nonradioactive.—Toxicity of rare earths is dependent on the chemical form. its route of administration, and the individual rare earth. 14 Only limited data are available for humans, with most research acquired from experiments on Overall, the rare small vertebrates. earths are considered only slightly toxic. 15 Orally administered lanthanides are poorly absorbed by the gastrointestinal tract and have very low toxicity. Administered at levels as high as 1 to 10 grams of lanthanide oxides and lanthanide sulfates per kilogram (kg) of body weight, the compounds were not lethal to small vertebrates. 16

Lanthanides administered by routes other than orally are absorbed at greater rates and are thus more toxic. Intravenous injection is the most toxic method. Pharmacologic responses to intravenous-administered lanthanides were calcification, hypotension, hypoglycemia, and an increase in the time for blood coagulation. The production of skin and lung granulomas (in rats and mice) after exposure to oxides, fluorides, chlorides, and metals by prolonged breathing, intradermal or intraperitoneal injection, or subcutaneous implantation requires extensive protection to prevent exposure through cuts and abrasions of the skin or through inhalation. Symptoms of toxicity observed (in mice and rats) included anorexia, writhing, ataxia (loss of voluntary muscle control), diarrhea, dyspnea (labored respiration), walking on the toes with arched back, and sedation.

Humans exposed to airborne lanthanides reported itching, insensitivity to heat, and a sharpening of the senses of taste and smell.¹⁷ Chronic exposure to lanthanide dust can lead to rare-earth pneumoconiosis.¹⁸ This condition has been noted in those exposed to lanthanide oxide-bearing fumes from carbon arc lamps. Intravenous injections of lanthanum chloride solutions in humans produced abdominal cramps, chills, fever, hemoglobinemia, hemoglobinuria,

and muscle pain. 19

Intratracheal injections of 50 milligrams (mg) of a mixed lanthanide oxide into rats were 100% lethal within 24 hours, the result of pulmonary edema.²⁰ However, a similar injection of 200 mg/kg of the rare-earth ore monazite into mice produced no ill effects.21 Extreme care also must be taken when exposed to finely divided rare-earth metals and metallic powders to avoid burns from rapid and possibly instantaneous oxidation, especially if inhaled. Certain finely divided rare-earth metals, alloys, and metal powders also may present the additional hazard of oxidizing rapidly enough to explode.

Radioactive.—Toxicity from rare earths also may occur from radioactive Only neodymium, lanthanides. samarium, gadolinium, and lutetium have naturally occurring radioactive isotopes. Neodymium's one radioactive isotope, Nd¹⁴⁴, represents 23.85% of the naturally occurring material and is an alpha emitter. Samarium has three alpha emitting natural isotopes: Sm147, Sm148, and Sm149, which represent 14.97%, 11.24%, and 13.83% of the natural occurring material, respectively. Gadolinium's sole alpha emitting isotope is Gd¹⁵², with a natural abundance of only 0.2%. Lutetium also has one naturally occurring radioactive isotope, Lu¹⁷⁶, with an abundance of 2.59%. It is the only natural lanthanide isotope that decays by negative beta emission.

Manufactured isotopes were produced primarily for use in nuclear medicine. The relative health risks for these materials varied depending on the application and dosage.

It should be noted that the rare earths often exist in ore and concentrates in association with other elements that have vastly different properties, including varying toxicities and possibly radioactive emissions. Care should be taken to assess the health factors associated with each substance present.

Employment.—Rare-earth mine and mill employment statistics, based on the domestic quarterly average number of

employees on-site, are shown in figure 3. Following a 5-year trend of increasing employment, industry employment dropped almost 10% in 1992. The decrease was primarily the result of several plant closures by Molycorp, Inc. Data were furnished by the U.S. Department of Labor and compiled by the USBM. (See figure 3.)

Productivity Trends.—The 11-year trend for U.S. rare-earth mine productivity, based on capacity utilization for bastnasite concentrate and monazite concentrate, are shown in figures 4 and 5.

Bastnasite production increased in 1992, changing its previous 11-year productivity trend from a slight decrease to a slight increase. (See figure 4.)

The 11-year trend for domestic monazite capacity utilization continued to show a decline. However, monazite's decrease, because it is a byproduct of titanium and zirconium minerals, is primarily a function of demand for the primary products and to a lesser extent a function of decreased demand for monazite in 1991 and 1992. (See figure 5.)

ANNUAL REVIEW

Legislation and Government Programs

The calendar year 1992 included the U.S. Government fiscal years for 1992 and 1993. Public Law 102-109, the National Defense Authorization Act for Fiscal Years 1992 and 1993, covered the year 1992 through October 22 and continued specific previous authorizations for disposal of all stocks in the National Defense Stockpile (NDS) classified as excess to goal. Public Law 102-484, the National Defense Authorization Act for Fiscal Year 1993, covered the remainder of the year 1992. Stocks of rare earths in sodium sulfate were all classified as excess to goal at yearend 1992 and were inventoried at 457 tons. However, rare earths in the NDS were not authorized for disposal in the calendar year.

Issues

Molycorp, Inc. closed its plants at Louviers, CO, and Washington, PA, and consolidated operations at Mountain Pass, CA.²² The closures were reportedly in response to continued competitive world markets, especially from suppliers in China, Japan, and Eastern Europe. A 3-year modernization and expansion was completed at Mountain Pass, with startup scheduled for the first half of 1993. Sales of lanthanides reportedly increased 3% in 1992, primarily from increased demand for cerium for use in automobile catalytic converters and ultravioletabsorbing glass.

Production

Three domestic operations, two mines and a tailings processor, produced rare earths in 1992. The United States was the world's second largest producer of rare earths in 1992. Producers were Molycorp, Inc., a wholly owned subsidiary of Unocal Corp., RGC (USA) Minerals Inc., and Nord Ilmenite Corp., a subsidiary of Nord Resources.

Bastnasite was mined by open pit methods by Molycorp at Mountain Pass, CA. Molycorp's mine was the leading producer of rare earths in both the United States and the rest of the world. Mine production increased from the previous year's level of 16,465 tons REO to 20,699 tons REO.

Monazite was produced as a byproduct of titanium and zirconium minerals production by RGC (USA) Minerals Inc. RGC (USA) operated a placer dredging operation at Green Cove Springs, FL. Production decreased 57% from last year's level, primarily the result of decreased demand for the primary products.

Monazite was also recovered by Nord Ilmenite Corp., a subsidiary of Nord Resources, from tailings at Jackson, NJ. The tailings were reprocessed primarily for their zircon and ilmenite content. Reprocessing of the tailings was completed at yearend, and all remaining stocks of low-grade monazite were reportedly sold for further upgrading.

Refined lanthanides were produced by three companies. Molycorp produced refined compounds from bastnasite at its separation plant at Mountain Pass, CA. Rhône-Poulenc Basic Chemicals Co. produced lanthanide compounds from rare-earth intermediate compounds at its facility at Freeport, TX, and Davison Specialty Chemical Co. refined rare earths from rare-earth chloride at its operations in Chattanooga, TN.

Three scandium processors operated in 1992. High-purity products were available in various grades with scandium oxide produced up to 99.999% purity.

Sausville Chemical refined scandium concentrates at its facilities in Garfield, NJ, to produce scandium oxide, fluoride, nitrate, chloride, and acetate.

Boulder Scientific Co. processed scandium at its Mead, CO, operations. Scandium concentrates were derived from a variety of ores. Boulder's main ore source was thortveitite-bearing tailings from the mined-out Crystal Mountain fluorite mine near Darby, MT.

Interpro, a subsidiary of Concord Trading Corp., refined scandium at its plant in Golden, CO. Interpro processed stocks of scandium concentrates previously generated by the Energy Fuels Nuclear uranium plant at Bingham Canyon, UT.

Reactive Metals and Alloys Corp. (REMACOR) was the only domestic producer of mischmetal.

Principal domestic producers of neodymium-iron-boron magnet alloys were the Delco Remy Div. of General Motors, Anderson, IN; Molycorp, Inc., York, PA; Neomet Corp., West Pittsburg, PA; and Rhône-Poulenc Basic Chemicals Co., Phoenix, AZ. Leading U.S. producers of rare-earth magnets were the Delco Remy Div. of General Motors. Anderson, IN: Hitachi Edmore, Crucible Magnetics, MI; Materials, Elizabethtown, KY; and IG Technologies, Valparaiso, IN.

Consumption and Uses

Domestic reported consumption of rare earths increased 9% in 1992 compared with that of 1991. Bastnasite

consumption was 1% higher than in 1991, while monazite consumption remained the same. Shipments of rare-earth products from domestic processors of ore, concentrates, and intermediate concentrates were equivalent to 11,736 tons of REO, down 15% from the 13,753 tons shipped in 1991.

Consumption of mixed rare-earth compounds remained unchanged from the 1991 level, while consumption of purified compounds decreased 18%. Higher consumption of purified compounds was primarily the result of continued strong demand for neodymium-iron-boron magnets and increased domestic demand for lamp phosphors. Growth in the permanent magnet sector was estimated at 7% to 12% in 1992.

The producers of mischmetal, rare-earth silicide, and other rare-earth alloys consumed 19% more rare earths in 1992 than in 1991, while shipments of these goods gained 20% during the same period. Shipments of high-purity rare-earth metals decreased during the year.

The approximate distribution of rare earths by use, based on information supplied by primary processors and some consumers, was as follows: catalysts in petroleum, chemical, and pollution control, 34%; metallurgical uses as iron and steel additives and as alloys, 27%; ceramics, glass polishing compounds, and glass additives, 26%; and miscellaneous uses in phosphors, electronics, permanent magnets, lighting, and research, 13%.

Rare earths are used in hundreds of applications, ranging from 19th century traditional applications to modern high-technology uses. The applications encompass a wide range of products from mixed rare-earth compounds and alloys to ultrahigh-purity individual metals and compounds. Ouantities varv application and range from tonnage quantities to milligrams. Following are some of the uses, in order of increasing atomic number, of rare earths, including the metals, oxides, and both inorganic and organic compounds.

compared Scandium.—Metal halide lamps to improve color appearance and produce

high output, laser crystal (GSGG), aluminum alloys, dual-anode tube in X-ray spectrometers, semiconductors, tracer material, collimators in neutron lenses.

Yttrium. - High-temperature superconductor (YBaCuO), incandescent lamp mantle, phosphor for cathode-ray tubes (reddish orange), trichromatic fluorescent lighting phosphor (reddish orange), metal halide lamp phosphor (reddish orange), high-temperature sensing phosphor, oxygen sensor ceramic, laser crystals (YAG, YLF), gemstone simulants (CZ and YAG), microwave ferrite (YIG), cast iron alloys, magnesium castings. superallovs. dispersion strengthened nickel and titanium alloys, aromatization of n-hexane, prostheses, stabilizer for silicon nitride and zirconia ceramics, microwave filter, and semiconductors, acetylene lights, deoxidizer for vanadium and other nonferrous metals, solid oxide fuel cell electrolyte and anode, refractory crucibles and coatings, high-temperature furnace electrodes.

Lanthanum.—Petroleum fluid cracking catalyst, glass additive to increase refractive index and decrease dispersion (eyeglasses, cameras. binoculars, rifle scopes, and telescope lenses), nickel hydride rechargeable batteries, hydrogen storage alloys, optical glass, solid oxide fuel cell cathode and interconnect, trichromatic fluorescent lighting phosphor (green), X-ray intensifying screen phosphor (violet, blue, yellow-green, and blue green), low-temperature sensing phosphor, phosphor lamp coating, laser glass, calcium lighting, lighting electrode, tungsten welding electrode, cast iron allovs. steel alloys, superalloys, aromatization of n-hexane, fluoride determination, conductive ceramic heating elements (chromites), dielectric ceramic capacitors (titanates), electrooptical ceramics, oxidative dimerization of methane to ethylene, antiseptic, electronic thermoemissive cathode (boride), insulation, reducing agent to convert nitrogen oxides to nitrogen, low-temperature superconductor, cryogenic refrigerant using hydrogen (LaNi₅), semiconductors (LaAs, LaSb, LaP).

Cerium.—Glass, metal, and gemstone polishing, radiation shielding glass, glass colorization and decolorization. discolorization stabilizer, photochromic glass opacifier, ceramic pigment, ceramic glaze, enamel opacifier, carbon arc lighting, incandescent lamp mantle, trichromatic fluorescent lighting phosphor (yellow green), pyrophoric alloys including lighter flints, cast iron alloys, steel alloys, aluminum alloys, magnesium alloys, superalloys, automotive catalytic converter monolith, heat stabilizer in alumina catalyst, fluid cracking catalyst, hydrolysis of phosphoric acid esters, oxidation of naphthalene, polymerization catalyst for olefins, corrosion inhibitor, getter in azide manufacture, getter in vacuum tubes, developing agent for aniline black, heavy metal soaps for lubricating greases and flatting agents, waterproofing and mildewproofing, dying and printing textiles, ceramic capacitors, semiconductors, cathodes, desulfurizing catalysts, high-strength glass, catalyst for ammonia production, illuminant in photography, radiation dosimeter, diluent in plutonium nuclear fuels, fluorinating agent, oxidant for organic compounds, antiknock fuel additive, oxidizer in self-cleaning ovens, and pharmaceutical for sea sickness and morning sickness.

Praseodymium.—Ceramic pigment (yellow), glass colorization (light green), refractory ceramic heating element, laser crystal, aluminum alloys, magnesium alloys, permanent magnets, oxidative dimerization of methane to ethylene, cryogenic refrigeration (PrNi₅).

Neodymium.—Permanent magnets (NdFeB), glass colorization (violet), glass decolorization, dopant in laser crystals and glass, ceramic capacitors, ceramic glaze (pinkish violet), magnesium alloys, welder's protective glass, carbon arc lighting electrodes, catalyst for

polymerization of olefins, fiber-optic temperature sensor.

Promethium.—Fluorescent lighting starter, coatings for self-luminous watch dials, beta particle source for thickness gauges, miniature atomic batteries, semiconductor battery, X-ray source (Pm-147), tungsten cermet for space power system.

Samarium.—Permanent magnets (SmCo), dopant in laser crystals, neutron absorber, nuclear reactor control rod, catalyst in dehydrogenation of ethyl alcohol, catalyst in oxidative dimerization of methane to ethylene, infrared absorbing glass.

Europium.—Cathode-ray tube phosphor (reddish orange), trichromatic fluorescent phosphor (reddish orange and blue), X-ray intensifying screen phosphor (violet), metal halide lamp phosphor (reddish orange), high and low temperature sensing phosphors, nuclear reactor neutron absorber, nuclear reactor control rods, ceramic sensor, organic shift reagent in nuclear magnetic spectroscopy, dopant in laser crystals, tagging agent in postage stamp glue.

Gadolinium.—Trichromatic fluorescent lighting phosphor (yellow green), X-ray intensifying screen phosphor (yellow green), nuclear reactor control rods, nuclear reprocessing, neutron absorbing paint, high refractive index glass, synthetic garnet for computer memory (GGG), scavenger for oxygen in titanium production, dielectric ceramics, laser crystal, cryogenic refrigeration, pharmaceutical isotope in scanning devices to detect osteoporosis (Gd-153), magneto-optical recording,

Terbium.—Trichromatic fluorescent lighting phosphor (yellow green), X-ray intensifying screen phosphors (yellow green, violet, and blue), magnetostrictive alloys for transducers (TbFeNi), dopant in laser crystals.

Dysprosium.—Permanent magnet addition (NdFeB), nuclear reactor control

rods, semiconductors (DyAs, DySb, DyP), measurement of neutron flux, atomic weight determination, high-temperature sensing phosphor.

Holmium.—Dopant in laser crystal, getter in vacuum tubes, refractories.

Erbium.—Fiber-optic amplifier, glass colorizing of crystal and glassware (light pink), additive for colorization and nonreflective coating for sunglasses, infrared-absorbing glass, colorization of simulant gemstones, lasers, burnable poison in nuclear reactor, chemical catalyst for n-hexane, permanent magnet additive.

Thulium.—X-ray source (Tm-170), dopant in laser crystal, ferrites.

Ytterbium.—Portable X-ray source for blood irradiation, dielectric ceramics, carbon rods for industrial lighting, dopant in synthetic garnet, dopant in laser crystal, additive in special glass.

Lutetium.—High-temperature sensing phosphor, nuclear technology.

Stocks

U.S. Government stocks of rare earths in the NDS remained at 457 tons throughout 1992. Rare-earth stocks held in the stockpile were contained in sodium sulfate and were inventoried on a contained-REO basis. NDS stocks of rare earths were not available for sale in 1992.

Industry stocks of rare-earth ores and concentrates held by 17 producing, processing, and consuming companies decreased 6%. Bastnasite concentrate stocks held by the principal producer and three other processors increased 71% from the 1991 level. Yearend stocks of monazite increased 24%.

Stocks of other rare-earth concentrates gained 199%. Stocks of mixed rare-earth compounds were essentially unchanged, as stocks of purified compounds decreased 6%. Yearend stocks of mischmetal, rare-earth silicide, and other

alloys containing rare-earths gained 19%, while inventories of high-purity metals remained steady.

Prices

Prices for rare earths were mixed in 1992. Published prices were generally nominal and subject to change without notice. Competitive pricing policies remained in effect with prices for most rare-earth products quoted on a daily basis.

The price range of Australian monazite (minimum 55% rare-earth oxide including thoria, f.o.b./f.i.d.),²³ as quoted in Australian dollars (A\$),24 decreased substantially from A\$650 to A\$700 per metric ton at yearend 1991 to A\$300 to A\$350 per metric ton at vearend 1992. Changes in the United States-Australia foreign exchange rate in 1992, resulting from a weaker Australian dollar, caused the corresponding U.S. dollar to be up \$0.07 against the Australian dollar at yearend. The U.S. price range, converted from Australian dollars, decreased from US\$494 to US\$532²⁵ per metric ton in 1991 to US\$207 to US\$24126 per metric ton in 1992.

Prices quoted by Molycorp for unleached, leached, and calcined bastnasite in standard quantities, containing 60%, 70%, and 85% REO, were \$2.87, \$2.98, and \$3.42 per kilogram (\$1.30, \$1.35, and \$1.55 per pound) of contained REO, respectively, at yearend 1992. Concentrate prices have been unchanged since 1990.

The price of cerium concentrate was quoted by Molycorp at \$5.73 per kilogram (\$2.60 per pound) of contained cerium oxide at yearend 1992, an increase of \$0.66 from the 1991 price of \$5.07 per kilogram (\$2.30 per pound). The yearend price of lanthanum concentrate was unchanged from the 1991 level of \$3.08 per kilogram (\$1.40 per pound) of REO contained. Prices for cerium concentrate and lanthanum concentrate are quoted for 907-kilogram minimum (2,000-pound minimum), f.o.b. shipping point.

The nominal price for basic

neodymium-iron-boron alloy, compiled by the USBM, was \$28.66 per kilogram (\$13.00 per pound) at yearend, f.o.b. shipping point, 1,000-pound minimum. Most alloy was sold with additions of cobalt (up to 15%) or dysprosium (up to 5%). The cost of the additions was based on market pricing; with cobalt at \$33.07 per kilogram (\$15.00 per pound) the cost would be about \$0.33 for each percent addition per kilogram (\$0.15 for each percent addition per pound).

The price for standard-grade mischmetal was \$12.68 per kilogram.

Molycorp quoted prices for lanthanide (rare earth) and yttrium oxides, net 30 days, f.o.b. Louviers, CO, Mountain Pass, CA, or York, PA, effective June 1, 1992, and through the end of the year, as shown in table 2. (See table 2.)

Molycorp also quoted prices for lanthanide (rare earth) compounds, net 30 days, f.o.b. York, PA, Louviers, CO, or Mountain Pass, CA, effective June 1, 1992 as shown in table 3. (See table 3.)

Rhône-Poulenc quoted rare-earth prices, per kilogram, net 30 days, f.o.b. New Brunswick, NJ, or duty paid at point of entry, effective at yearend 1992 as shown in table 4. (See table 4.)

No published prices for scandium oxide in kilogram quantities were available. Yearend 1992 nominal prices for scandium oxide per kilogram were compiled by the USBM from information from several suppliers and processors. Prices trended lower and were as follows: 99% purity, \$1,500; 99.9% purity, \$3,000; 99.99% purity, \$5,000; and 99.999% purity, \$10,000.

Scandium metal prices, as listed by the Johnson Matthey Aesar Group, were as follows: 99.99% purity, lump, sublimed dendritic, ampouled under argon, \$312.00 per gram; 99.9% purity, 250-micron powder, ampouled under argon, \$559.00 per 2 grams; and 99.9% purity, lump, vacuum remelted, ampouled under argon, \$405.00 per 2 grams; 99.9% purity, foil, 0.025 millimeters (mm) thick, ampouled under argon, 25 mm by 25 mm, \$117.00 per item.

pound Prices for kilogram quantities of scandium metal in ingot form have basic historically averaged about twice the cost

of the oxide while higher purity distilled scandium metal was approximately five times the cost.²⁷

Foreign Trade

Rare-earth imports showed mixed results in 1992. Imports increased in four major categories and declined in two categories. U.S. imports of ore and compounds are shown in tables 5 and 6. As in the previous 3 years, France dominated the import market. (See tables 5 and 6.)

U.S. imports of monazite concentrate (thorium ores and concentrates) remained at zero for the second consecutive year as a major domestic processor switched to a thorium-free rare-earth feed material. Imports of cerium compounds increased 48% from those of last year as cerium demand increased for use in automotive exhaust catalysts, UV-absorbing glass additives, and polishing compounds. Principal sources, by quantity, were China, France, and Japan. Imports of individual rare-earth compounds, other than cerium compounds, also increased in 1992. The 12% gain was mainly for feed material for permanent magnet alloys. Principal sources were China and France.

Imports of mixed rare-earth compounds decreased almost 67% as demand fell for plant feed materials. India, China, and Malaysia were the major suppliers, in order of decreasing U.S. imports of rare-earth volume. metals increased 24% during the year. Principal sources for the metals were Austria and China. Increased demand for permanent magnet alloys were believed to be the primary reason for the increased imports. Imports of mixed rare-earth chlorides fell 53%, with India as the principal source. Ferrocerium imports increased about 13% with most material originating from Belgium, Brazil, and France. The principal sources of U.S. imports, in terms of volume of equivalent REO contained, are displayed in figure 6. (See figure 6.)

U.S. exports of rare earths were mixed. Exports of cerium compounds increased 41% from 1991's level. Principal destinations were Brazil and

Canada. Exports of ferrocerium and other pyrophoric alloys also increased, up almost 30%. Rare-earth compound exports declined 27%, mostly the result of decreased demand from Japan. U.S. exports of rare-earth metals fell 38%. with principal destinations reported as Canada and the Republic of Korea. Domestic exports of rare earths are shown in table 7. Based on the limited available export data, Brazil, Japan, and Taiwan were the leading destinations of rare earths from the United States in 1992. This was a shift from 1991 data when, in order of decreasing volume, Canada, Japan, and Brazil were the leaders. Principal destinations of U.S. exports are displayed in figure 7. (See table 7 and figure 7.)

World Review

Industry Structure.—Bastnasite, the world's principal source of rare earths, was mined as a primary product in the United States and as a byproduct of iron ore mining in China. Minor production was also reported from Madagascar. Significant quantities of rare earths were also recovered from monazite, a byproduct of heavy-mineral sands mined for titanium and zirconium minerals or tin minerals in Australia, Brazil, China, the C.I.S., India, Indonesia, Malaysia, the Republic of South Africa, Sri Lanka, Taiwan, Thailand, and the United States.

Smaller amounts of rare earths. especially yttrium, were obtained from the mineral xenotime. Xenotime was recovered primarily as a byproduct of processing for tin minerals in Indonesia, Malaysia, and Thailand, but was also produced as a byproduct of processing titanium and zirconium minerals in Australia and China. Rare earths. including yttrium, were also produced from rare-earth-bearing clay in China. The C.I.S. also produced rare earths from the minerals and rocks loparite, synchisite-(Y), and uraniferous phosphorites. (See table 8 and table 9.)

Scandium was recovered as a byproduct of processing ore for beryllium, iron, tin, and tungsten in China, and was previously produced as a byproduct of uranium processing in the United States. In the C.I.S., scandium was recovered as a byproduct of uranium.

Reserves.—World reserves of rare earths were estimated by the USBM at 100 million metric tons of contained REO. World reserves were revised upward for 1992 as a result of additional data on the C.I.S. Rare-earth reserves for the C.I.S., which were previously estimated, were reported at 21.4 million tons.²⁸ China has the largest share of world reserves with 43%. (See figure 8.)

Australia.—Ashton Rare Earths Ltd... a subsidiary of Ashton Mining Ltd.. postponed its decision to develop the Mount Weld rare-earth deposit until 1993.²⁹ Ashton secured mining and environmental approvals and continued rare-earth market studies. Located 35 kilometers south of Laverton. Western Australia, the carbonatite's principal ore minerals are a low-thorium secondary monazite and cheralite. Mount Weld is one of the richest grade rare-earth deposits in the world with reserves of 15.4 million tons grading 11.2% REO, which includes 1.3 million tons grading 23.6% REO.30

Woodburn Mineral Sands closed its mineral sands mine at Newrybar, New South Wales, in response to depressed market demand and low prices. Capacity of the plant was 24,000 tons per year. Production from Woodburn was mostly low-grade ilmenite and high-grade (ceramic-grade) zircon.³¹ The closure was not expected to affect monazite markets.

Westralian Sands Ltd. (WSL) reported production of 1,590 tons of monazite in 1992. Production increased 300 tons from the previous year's level. Price weakness and overcapacity in the mineral sands industry caused the company to operate only one mine in 1992, the Yoganup North, near Boyanup, Western Australia. Rehabilitation continued at WSL's two other mines, the North Capel and Yoganup Extended.³²

Production of monazite in Queensland (small quantities) ceased at the end of

1991.³³ The decline in demand is the result of the growing availability of alternative concentrates and compounds that are free or nearly free of radiation.

Consolidated Rutile Ltd. (CRL) cut back production at its mines on North Stradbroke Island, Queensland, during the year due to poor market conditions. Production from the Gordon and Bayside Mines was scaled back to 5 days per week starting August 1991 followed by closure of the Bayside operation in February 1992. Production at CRL's smaller Amity operation was closed permanently in May 1992. The Bayside Mine resumed production by yearend.

The Queensland Department of Resource Industries introduced new guidelines for environmental management of mined lands. CRL developed a comprehensive plan for the long-term management of its resources on North Stradbroke Island to address the new guidelines. The plan includes detailed studies of the flora and fauna, research to improve rehabilitation of mined land, and periodic audits of rehabilitation procedures and objectives.³⁴

Exploration activity for mineral sands continued in the Eucla Basin area of Western Australia. Centenary International Mining Ltd. had previously reported Eocene age deposits in the Balladonia area grading up to 3.6% heavy minerals in a 12-meter section. Exploration by Ramsgate Resources Ltd. on the Kakarook mineral sands project in the basin discovered two sections, one 8 meters thick at 2.35 % heavy minerals and another 6 meters thick at 2.18% heavy minerals. Ramsgate reportedly dropped its interest in the project due to poor market conditions and a lack of additional capital investment.35

RGC Mineral Sands Ltd., a subsidiary of Renison Goldfields Consolidated Ltd., applied for exploration licenses to search for heavy minerals on the Northern Territory islands of Bathurst and Melville. The exploration will reportedly be a joint venture among the Tiwi Land Council, Tiwi Resources Pty. Ltd., and RGC Mineral Sands Ltd. As Renison's mineral sands operations have continued to move northward, the company

announced that it would close its Perth office and open a smaller divisional office at Geraldton, Western Australia.

Brazil.—In 1991, the latest available data, production of rare-earth chlorides, other rare-earth compounds, and mischmetal was 1,308 tons, 152 tons, and 277 tons, respectively. Reserves are distributed in the States of Rio de Janeiro, 54%; Espírito Santo, 6.7%; Bahia, 10.6%; and other localities, 28.7.36

Nuclemon Mínero-Química Ltda. started work on a project to construct a rare-earth refinery in Brazil. Facilities to produce high-purity compounds of europium, gadolinium, and samarium was scheduled to be installed in the second quarter of 1992.

Brazil and China signed an international agreement in 1990 to collaborate on future research to produce Brazilian minerals, oxides, and metals of rare earths. Representatives in the agreement are the Centro de Technologia Mineral (CETEM) and the Institute for the Research and Applications of Rare-Earth Minerals and Metals at the Technical University of Peking, China.

CETEM and two European countries, Italy and Germany, agreed to study the separation of rare earths, using Brazilian minerals. Research on the processing and separation of REO's will be done at an Italian university in Trento, where the Italians have obtained elements using new methods of separation. researchers will focus on identifying and analyzing rare-earth ore minerals and will forward the data to CETEM. As part of the project a group of about 30 Government and private companies are trying to enter the rare-earth market. which is valued at millions of dollars per vear. Brazil's exports totaled about \$1.87 million in 1991.

Canada.—Exploration by geologists from Formosa Resources Corp. located a suite of alkalic igneous rocks containing rare earths in the Kechika River region of northern British Columbia. Yttrium oxide values up to 1.13% were found locally. The company also reported

locating a phosphorite deposit in southeastern British Columbia grading 20% to 22% phosphorus and 600 to 700 parts per million yttrium.³⁷

China.—Rare-earth production in 1992 totaled 21,340 tons of REO, edging out the United States as the world's leading producer.³⁸ The 32% increase was due to increased production of concentrates from Baotou, Nei Monggol Autonomous Region, and in the Provinces of Shandong and Sichuan. China reportedly consumed 9,270 tons of REO domestically in 1992, up 12% from that in 1991. Exports of rare earths increased 23% to 9,875 tons of REO. principal increase was in the export of rare-earth chlorides (thorium-free) used separation plant feed and in mischmetal production.

Gansu Rare Earth Corp. has reportedly developed a new separation technology. Capacity of its refinery in Baiyin City, Gansu Province, is 10,000 tons per year of rare-earth chloride.

India.—Indian Rare Earths Ltd. (IRE) completed plans to increase capacity to produce cerium hydrate and didymium carbonate from rare-earth chloride. Recovery rates at IRE's mineral sands processing plants in southern India were also upgraded.³⁹ Mineral production at IRE's Chavara and Manavalakurichi plants reportedly improved substantially during the 1990-91 fiscal year.

IRE began a prefeasibility study for installation of a rare-earth separation plant at Alwaye. The plant is slated to produce high-purity separated compounds, including neodymium and praseodymium.

Various mineral sands projects were under development by IRE. A mineral sands deposit at Kudiraimozhi, Tamil Nadu, has proceeded to the environmental permitting phase. The Bhimli project in the State of Andhra Pradesh entered the prefeasibility stage, and a flowsheet for the project was completed. Development of the Ayiramthengu project in Kerala was in the land acquisition phase. Ayiramthengu was estimated to contain mineral sands reserves sufficient for a 20-

to 30-year mine life.

Japan.—Demand for rare earths increased to 5,316 tons of REO in 1989. The market depended entirely on imported materials, primarily from China, France, and the United States. Japanese rare-earth processors produced 4,052 tons REO in 1989. In 1992, market prices for rare earths in Japan, in yen per kilogram, were as follows: yttrium oxide, 99.99%, 8,000; lanthanum oxide, 99.99%, 1,800 to 2,000; cerium oxide, 99.95%, 2,600 to 2,900; europium oxide, 99.99%, 30,000; samarium-cobalt alloy, 8,500 to 10,000; neodymium-iron-boron alloy, 4,000.40

Russia.—Mining with nuclear bombs reportedly occurred in Kola Peninsula apatite deposits between 1972 and 1984. A primary source of phosphate and rare earths, the Khibini nepheline syenite deposit was fractured with 2-kiloton plutonium explosive charges to improve recovery rates. Environmental concerns that the residual radioactive contamination may be above safe levels warrants investigating any apatite and loparite mined from the region, including phosphate and rare-earth products processed from the ores.41

Thailand.—Production values of the rare-earth minerals monazite and xenotime, and other mineral sands byproducts decreased in 1990. Based on data from the Thailand Department of Mineral Resources, the value of production, in millions of dollars, for 1986 through 1990 was 4.1, 4.8, 7.1, 5.2, and 1.4, respectively.

Turkey.—The state-owned mining and banking company, Etibank, was seeking foreign partners in the development of a thorium-barite-fluorite-rare-earth deposit. Near the city of Karkin, the deposit contains rare earths in the mineral bastnasite. Drilling to 50 meters has delineated 30.3 million tons of ore grading 3.14% REO.⁴²

Vietnam.—A pilot plant for processing monazite was supplied to Vietnam by the

Government of India. At Phung in Ha Tay Province (25 kilometers from Hanoi), the plant has a capacity to process 50 tons of monazite per year to produce rare-earth chloride and trisodium phosphate. Radioactive thorium also will probably be produced as a byproduct. The plant was supplied to Vietnam under a co-operative agreement on the utilization of atomic energy for peaceful purposes.⁴³

Current Research

Researchers at Schott Glass Technologies, Inc. developed a glass that will allow up to 30 weight-percent rare-earths as dopants. The glass, lanthanum-sodium silicate, was designed to accommodate various rare earths for application in absorbing narrow band light emission. The filter glass may be used for eye protection from lasers, fiber optics, and research.⁴⁴

Nippon Mining Co. of Japan has produced an ultrahigh-purity yttrium. At 99.99999% purity, the yttrium was produced by a combination of chemical and electron beam refining. The ultrapure material may have use in a variety of high-tech applications, including superconductors, electronics, optics, and lasers. 45

Using rare-earth phosphors, scientists at Hitachi Maxwell created invisible bar codes for use in packaging. Benefits of the invisible bar code is that it will not detract from the packaging design and will be difficult to counterfeit or alter. 46

Matsushita Battery Industrial Co. announced the development of a rare-earth-nickel hydride battery for automobiles. The new batteries will power an electric car for 70 kilometers on a 15-minute charge and can be recharged up to 1,500 times, 3 times more than a lead acid battery.⁴⁷

A theoretical model on grain size, density, and gradient as it relates to heavy minerals in the Fall Zone, a region of abrupt change in stream gradient in the Eastern United States, was prepared by the U.S. Geological Survey. Development of the model and additional research will allow development of more effective

predictive models of placer mineral occurrences. Dependent on the upstream source terranes, areas at or near the Fall Zone may be targeted for coarse-grained sediments and placer gold exploration whereas the Inner Coastal Plain has potential for finer grained monazite, zircon, rutile, and ilmenite deposits.⁴⁸

Research at the U.S. Geological Survey examined the use of geochemical and sediment survey data in exploring for titanium-hafnium-rare-earth element-and uranium placers in the Mid-Atlantic States. Using data from the National Uranium Resource Evaluation Program (NURE), hydrogeochemical and stream sediment element analyses were determined to be diagnostic and may predict the presence of commercially important heavy-mineral concentrations. Concentrations of these elements can indicate the presence of commercially important heavy-minerals, including ilmenite (Ti), rutile (Ti), zircon (Zr), monazite (REE), and xenotime (REE). This method is potentially important for identifying similar studies in other largely unexplored regions in the United States. especially the Central Plains. 49

OUTLOOK

Known world rare-earth reserves are sufficient to meet world demand well into the 21st century. Considering the likelihood that additional deposits of rare earths will continue to be located and assuming reasonable increases in energy, transportation, processing, and environmental costs, world resources are more than adequate to fulfill demand for the foreseeable future.

Recent shifts in the rare-earth industry to nonradioactive or low-radioactive feed materials is expected to continue because the costs to monitor and dispose of radioactive waste products continues to increase. In the long-term, however, thorium-bearing monazite is forecast to return as a principal feed material due to its low cost and availability.

Domestic demand in 1993 is expected to grow modestly in line with the economy. Particular segments of the industry, including neodymium-iron-boron

permanent magnets and cerium-containing automobile catalytic converters, are expected to show strong growth.

Competitive world markets are expected to continue in the future. In addition to the strong presence of Australia, China, and the United States as rare-earth suppliers, the future economic restructuring of Eastern Europe and the C.I.S. may greatly expand potential market opportunities. Significant reserves and production capacity exist in Kazakhstan, Russia, and the rest of the C.I.S. Australia's future potential is also considerable, possessing both large reserves and several high-grade deposits.

The long-term outlook is for an increasingly competitive and diverse group of rare-earth suppliers. The economic base of the rare-earth industry has continued to grow. Future market fluctuations are expected to diminish as the industry rapidly matures and diversifies. Demand is forecast to continue to grow as improved knowledge of the rare earths continues to generate new commercial applications, a trend that is expected to continue.

^{*}Estimated. Revised. NA Not available. W Withheld to avoid disclosing company proprietary data.

¹Comprises only the rare earths derived from bastnasite, as reported in Unocal Corp. annual reports.

²Comprises only the rare earths derived from bastnasite, as obtained from Molycorp, Inc., company representative.

Because of the implementation of the Harmonized Tariff System in Jan. 1989, import and export categories for 1989-92 are not necessarily comparable with those of previous years.

⁴Data from The Journal of Commerce Trade Information Service.

⁵Employment at a rare-earth mine in California and at a mineral sands operation in Florida, and a mineral sands tailings operation in New Jersey. The latter mines produced monazite as a byproduct, and employees were not assigned to specific commodities.

 $^{^6}$ Imports minus exports plus adjustments for Government and industry stock changes.

TABLE 2 MOLYCORP RARE-EARTH OXIDE PRICES

Product	Percent ¹	Quantity (pounds)	Price
(oxide)	(oxide) purity		per pound
Cerium	99.00	200.00	\$10.50
Dysprosium	96.00	50.00	60.00
Erbium	98.00	50.00	65.00
Europium	99.99	25.00	450.00
Gadolinium	99.99	55.00	65.00
Lanthanum	99.99	300.00	8.75
Neodymium	96.00	300.00	6.75
Do.	99.90	50.00	40.00
Praseodymium	96.00	300.00	16.80
Samarium	96.00	55.00	30.00
Terbium	99.90	44.10	375.00
Yttrium	99.99	50.00	52.50

¹Purity expressed as percent of total REO.

TABLE 3 MOLYCORP RARE-EARTH COMPOUND PRICES

Product	Percent ¹ purity	Quantity (pounds)	Price ² per pound
(compound)			
Cerium carbonate	99.0	150	\$5.75
Cerium fluoride	Tech. grade	250	3.50
Cerium nitrate	96.0	250	2.90
Lanthanide chloride	46.0	525	1.25
Lanthanum carbonate	99.9	175	5.90
Lanthanum-lanthanide carbonate	60.0	200	2.45
Lanthanum-lanthanide chloride	46.0	525	1.05
Lanthanum-lanthanide nitrate	39.0	250	1.75
Neodymium carbonate	96.0	300	4.50

¹Purity expressed in terms of REO equivalent, ²Priced on a contained REO basis.

TABLE 4

RECYCLING—NONFERROUS METALS

By James F. Carlin, Jr., Daniel Edelstein, James H. Jolly, Janice L. W. Jolly, John F. Papp, and Patricia A. Plunkert

Mr. Carlin, a physical scientist in the Branch of Metals, has been the tin specialist for 13 years and is currently the acting lead specialist. Mr. Edelstein, a physical scientist in the Branch of Metals, has 10 years of experience as a commodity specialist dealing with copper and its byproduct metals. Mr. Jolly is a geologist with more than 35 years of mining experience, including positions with Hecla Mining Co., Roan Selection Trust, and the U.S. Geological Survey. He was a mineral commodity specialist for the U.S. Bureau of Mines (USBM) for 20 years and the zinc specialist for the past 11 years before retiring in mid-1992. Mrs. Jolly is a geologist with more than 30 years in the mining industry, including 17 years with the USBM. Mrs. Jolly served as the copper specialist for the USBM for 10 years and is currently the Statistician for the International Copper Study Group, in Lisbon, Portugal. Dr. Papp, a physical scientist with 21 years of USBM experience, has been the commodity specialist for chromium since 1983 and was the coordinator for this report. Ms. Plunkert, a chemist with 24 years of USBM experience, has been the commodity specialist for aluminum since 1987.

INTRODUCTION1

Recycling, a significant factor in the supply of many of the key metals used in our society, provides environmental benefits in terms of energy savings, reduced volumes of wastes, and reduced emissions associated with the energy savings.

The estimated value of recycled nonferrous metals in 1992 exceeded \$7.6 billion and is an increasingly important component of economic activity in the United States. Table 1 shows salient U.S. recycling statistics for selected metals. Table 2 shows salient U.S. apparent supply and recycling statistics for those same metals. Figure 1 shows a general flow scheme for recycling.

As part of its Commodities and Materials Program, the USBM provides information and analysis on more than 100 raw and/or processed minerals. Collected data are assessed by commodity specialists, and information is disseminated to government, industry, and academia through consultative services and more than 100 recurring publications. This publication examines and reports on minerals and materials trends as well as environmental aspects of the entire life cycle of minerals use.

The USBM's Research Directorate conducted research in 1992 on recycling of advanced materials and of metallurgical residues and effluents

currently discarded, on impurity control during recycling, and on design for reuse or waste minimization. To increase the efficiency of recycling, the USBM investigated the control of impurities such as magnesium and zinc in aluminum scrap and the removal of copper from The USBM also ferrous scrap. investigated methods to remove heavyfrom mineral contaminants processing and manufacturing wastes and to stabilize those heavy metals not removed.

Because of the increasing importance of recycling to domestic metal supply and the intense public interest, the USBM initiated this separate chapter on nonferrous metal recycling as part of its Annual Report series in 1991. A separate chapter on iron and steel scrap already has been part of this series for many years. The focus of this chapter is on aluminum, copper, lead, tin, and zinc recycling.

ALUMINUM²

Domestic Data Coverage

Domestic recycling data for aluminum are developed by the USBM from a voluntary survey, "Aluminum Scrap," of U.S. operations. Of the 94 companies and/or plants to which monthly or annual survey requests were sent, 83 responded, representing 92% of the total scrap

consumed shown in table 5.

In 1992, the number of companies responding to the USBM's aluminum scrap survey increased. This was partially responsible for the large increase in recovered secondary aluminum compared with that of the previous year. Also, the secondary data for 1991 were revised downward, owing to a double-counting error that did not become evident until this year.

Background

Definitions, Grades, and Specifications.—New aluminum-base scrap, generated in the production of intermediate and end products of aluminum metal, may be pure (unalloyed), segregated (one alloy type), or mixed (two or more alloys). It includes solids, such as new casting scrap; clippings or cuttings of new sheet, rod, wire, and cable; borings and turnings from the machining of aluminum parts; and residues, drosses, skimmings, spillings, and sweepings.

New scrap is further defined as either "runaround" (home) scrap or purchased scrap. Runaround or home scrap is new scrap that is recycled by the same company that generates it; such scrap by definition never leaves the company generating it and, therefore, is never marketed as scrap. Purchased scrap is new scrap that is purchased, imported, or

treated on toll by secondary smelters, the original aluminum product suppliers, or others. New aluminum scrap that is purchased from manufacturers of end products may be referred to as consumer scrap. Purchased scrap is sometimes referred to as prompt industrial scrap.

Old scrap, all of which is considered as purchased, comes from discarded. used, and wornout products. It includes aluminum pistons or other aluminum engine or body parts from junked cars. aluminum used beverage cans (UBC) and utensils, and old wire and cable. Sweated pig is scrap that has been sweated or melted into a pig or ingot form for convenience and economy in shipping and storage. Obsolete scrap is new, unused, but technologically obsolete aluminum nd products, outdated inventory materials, production overruns. and spare parts for machines and equipment no longer being used. In the United States, both sweated pig and obsolete scrap are considered old scrap.

Industry Structure.—The secondary aluminum industry was born shortly before World War I at a time when the United States had only one primary aluminum producer. There was little need for a secondary industry before that time because the supply of aluminum scrap was limited. Although the secondary industry did grow during World War I and after, that growth was modest until World War II. World War II created many changes in the domestic aluminum industry. The primary industry had changed from a monopoly to a triopoly, while the secondary industry had progressed from a remelter to a smelter. Secondary smelters thus emerged from the war years with the technology needed to process huge quantities of aircraft scrap and other partially manufactured aluminum products. It was at this point in history that the secondary aluminum industry started its phenomenal growth.

Aluminum recovery from scrap has become an important component of the supply-demand relationship in the United States. Between 1950 and 1974, aluminum recovered from old scrap

(post-consumer scrap) accounted for approximately 5% of the total domestic demand for aluminum. Increased costs for energy and growing concerns over waste management have provided the impetus for increased recycling rates.

Aluminum recovered from scrap has shown a tenfold increase since 1950. The recovery of aluminum from old scrap has shown an even more rapid expansion over the same period of time. In addition to improvements in recycling technologies, some of the increase in aluminum scrap recovery can be attributed to a changing growing end-use consumption pattern. Aluminum products, developed for the construction, transportation, and electrical industries, tend to have a fairly long life cycle and are slow to enter the scrap supply stream. The emergence of the aluminum beverage can in the mid-1970's with a life cycle of less than 1 year added dramatically to the potential aluminum scrap supply.

Aluminum scrap, in one form or other, is recovered by almost every segment of the domestic aluminum industry. Integrated aluminum companies, secondary aluminum smelters, independent mill fabricators, foundries, and chemical producers can recover aluminum from scrap. Integrated aluminum companies and secondary smelters are the major consumers of aluminum scrap.

The independent secondary aluminum smelter is the core of the commercial secondary aluminum industry. Unlike scrap dealers, who buy and sell many different metals, and die casters, who cast other metals, the secondary aluminum smelter is totally dependent upon one metal—aluminum. The sole purpose of the secondary smelter is to transform aluminum scrap into a marketable product. Scrap is purchased by smelters wherever it can be purchased economically. Purchasing habits also can depend on how badly a smelter needs scrap. During periods of excess scrap supply, smelters tend to be very selective in their scrap purchases. When the supply of aluminum scrap becomes short, however, it is frequently necessary to buy scrap that would not ordinarily get melted down.

Independent secondary aluminum smelters, by definition, consume scrap and produce alloys for the diecasting industry. A cursory look at the distribution of these secondary smelters in the United States consequently reveals a heavy concentration of smelters in the automotive and appliance manufacturing areas of the country.

The other major consumers of aluminum scrap are the integrated aluminum companies. The types of scrap processed by these companies tend to be more segregated than those processed by the secondary smelters. Integrated aluminum companies participate in either the collection or utilization of new aluminum scrap. They frequently purchase scrap from their industrial customers or on a contract conversion basis. Integrated aluminum companies also operate can recycling programs. These companies have set up thousands of collection centers around the country for used beverage containers. The largescale aluminum beverage can reclamation programs of these aluminum producers have added substantially to the rate of aluminum recovery from old scrap. The UBC component of old scrap consumption has doubled since 1975.

Aluminum scrap also is traded in the international marketplace. Price and shipping costs are usually the determining factor in choosing whether to sell scrap in the domestic or international markets. U.S. trade in aluminum scrap has grown dramatically over the past 30 years. Most of the scrap shipped into the United States comes from Canada. However, since the mid-1970's, the major recipient of U.S. scrap exports has been Japan.

The secondary aluminum industry has developed into a major market force in the domestic aluminum industry. The recycling of scrap provides a source of aluminum that not only helps the aluminum industry to maintain its growth but also helps to conserve energy and to slow the depletion of bauxite resources.

Technology.—In recycling, aluminumbase scrap is usually melted in gas- or oil-fired reverberatory furnaces of 30,000 to 100,000 pounds capacity. furnaces have one or two charging wells separated from the main bath by a refractory wall that permits only molten metal into the main bath. The principal refining of aluminum-base scrap is the removal of magnesium by treating the molten metal with chlorine or with various fluxes such as aluminum chloride. aluminum fluoride, or mixtures of sodium and potassium chlorides and fluorides. To facilitate handling, a significant proportion of the old aluminum scrap, and in some cases new scrap, is simply melted to form a solid ingot called "sweated pig," which must be treated further to produce specification-grade

Aluminum drosses containing about 30% metallics are usually crushed and screened to bring the metallic content up to about 60% to 70%. They are then melted in a reverberatory furnace, with the molten aluminum metal collecting on the bottom of the furnace. Salt slags containing less than 30% metallics may be leached with water to separate the metallics.

Annual Review

In 1992, the USBM estimated that more than 2.7 million metric tons (Mmt) of metal was recovered from purchased aluminum scrap. Of this total, approximately 60% was recovered from old scrap. The recovery of metal from old scrap supplied almost 30% of the total domestic aluminum metal demand for the year. The predominant type of purchased scrap processed was UBC scrap, accounting for more than one-half of the old scrap consumed. aluminum industry reported that the recycling rate for all-aluminum beverage cans reached a record high of 67.9%. (See figure 2.)

With the introduction of its secondary aluminum ingot contract, the London Metal Exchange (LME) began storing aluminum alloy ingot in its warehouses around the world. At yearend 1992, the LME reported that its U.S. warehouses held a total of 10,120 metric tons of aluminum alloy ingot. Worldwide the

total was 15,540 tons by yearend. (See tables 3, 4, 5, and 6.)

Production.—According to a survey conducted by the Aluminum Association Inc., the Institute of Scrap Recycling Industries (ISRI), and the Can Manufacturers Institute, the recycling rate for all-aluminum beverage cans reached a record high, as 62.74 billion aluminum UBC's were recycled in 1992. It was the 21st consecutive year that the number of cans returned for recycling has increased. In 1972, when statistics were first tabulated, 1.2 billion cans were returned. The recycling rate in 1992 was 67.9%, up from the 1991 rate of 62.4%.

The three largest domestic automakers, Chrysler Corp., Ford Motor Co., and General Motors Corp., announced the formation of the Vehicle Recycling Partnership (VRP) to research and promote the recovery and reuse of materials from junked cars. According to the companies, the partnership was expected to propose methods increasing the amount of recycled materials used in autos and trucks as well as recovering more from the vehicles. The automakers also stated that the partnership was expected to look into developing industry guidelines in such areas as materials selection and compatibility, bonding methods materials, painting, and design for disassembly. Research in these areas reportedly would be carried out in the laboratories of the three automakers and by other industries, universities, and research institutes.

Reynolds Metals Co. announced that it was expanding its aluminum foil and foil container recycling program from the 5 cities that served as the test markets for the program in 1991 to more than 60 metropolitan areas covering half the nation. In its expanded program, Reynolds would extend its "Great Balls of Foil" contest to schools in 30 of the new locations. A total of more than 2,000 schools in these markets would compete to build the largest ball of aluminum foil and then recycle it for cash and other prizes.

Alcan Rolled Products Co. and

Anheuser-Busch Recycling Corp. reportedly teamed up in Florida for a "Foil to Foliage" program. The program enabled residents of Brevard County to drop off their aluminum foil at an Anheuser-Busch collection center, and cash equal to the value of the returned aluminum would be donated to the nonprofit "Keep Brevard Beautiful" organization.

Barmet Aluminum Corp. and IMCO Recycling Inc. announced plans to construct a \$16 billion, 120,200-metricton-per-year (mt/yr) (265-million-poundper-year) aluminum recycling facility to be situated near Barmet's Urichsville, OH, rolling mill. Under the reported agreement, IMCO would have the exclusive rights to recycle Barmetpurchased scrap at this plant for a period of 10 years. As the new plant comes onstream, Barmet's recycling plant at Urichsville will be phased out. plant, which reportedly would recycle UBC's and dross and would increase IMCO's aluminum recycling capacity by 50%, was expected to be fully operational by mid-1993.

Metal Resources Inc., a scrap metals recycler and processor of aluminum drosses and aluminum UBC's, announced plans to double the capacity of its Loundon, TN, facility. Upon completion of the project, scheduled for early 1993, the company reportedly would be able to process about 10,900 tons (24 million pounds) of aluminum per month. Before the planned expansion, the company stated that it processed nearly 2 billion UBC's per year.

U.S. Reduction Co. reported that construction had begun on a new 27,200-mt/yr (60-million-pound-per-year) aluminum recycling plant in Tipton, IN. The company expected the plant to reach full production capacity by the second quarter of 1993. The plant reportedly would provide specification liquid metal and ingot to aluminum automotive diecasters and foundries.

Aluminum Smelting and Refining Inc. reported that the company had closed its secondary aluminum plant. The decision to close the privately owned plant reportedly came after months of attempts

to sell the company had failed.

Markets and Prices.—Purchase prices for aluminum scrap, as quoted by the American Metal Market (AMM), fluctuated during the year, and closed the year at higher levels than those at the beginning of the year. The yearend price ranges for selected types of aluminum scrap were as follows: mixed low-copper-content aluminum clips, 45 to 46 cents per pound; old sheet and cast aluminum, 38 to 39 cents per pound; and clean dry aluminum turnings, 39 to 40 cents per pound.

Prices for UBC's also fluctuated during the year, but closed about 8 cents per pound higher than prices at the beginning of the year. Aluminum producers' buying prices for processed and delivered UBC's, which began the year at a range of 32 to 37 cents per pound, reached a high for the year of 44 to 47 cents per pound in late April. The price range at the end of the year was 40 to 42 cents per pound.

Secondary aluminum ingot prices, as quoted by AMM, fluctuated during the year, but closed higher than prices at the end of 1991. The yearend 1992 price ranges for selected secondary aluminum ingots were as follows: alloy 380 (1% zinc content), 68 to 69.5 cents per pound; alloy 360 (0.6% copper content) and alloy 413 (0.6% copper content) 71.5 to 72.5 cents per pound; and alloy 319, 69.5 to 71 cents per pound.

Metals Week instituted an A-380 aluminum alloy price with the following specifications; 8% to 9.5% silicon, 1% iron, 3% to 4% copper, 0.5% manganese, 0.1% magnesium, 0.5% nickel, 0.35% tin, and 2.9% zinc. The price was for standard ingot in 45,000-pound truckload amounts delivered customer works. The price represented a range of spot transaction prices conducted by a survey of major suppliers and buyers. Weekly and monthly quotations began in July. The 1992 annual average price, based on 6 months of prices, was 57.081 cents per pound.

In May, the LME announced the introduction of a secondary aluminum alloy contract. Three-month trading

began on October 6, and cash trading began on January 4, 1993. Trading was conducted in U.S. currency. The LME based its contract on three secondary aluminum alloy specifications: U.S.380-1, Japanese ADC12, and German DIN226.

Foreign Trade.—Exports of aluminum scrap decreased dramatically in 1992, reaching their lowest level in 8 years. Japan continued to be the principal destination of aluminum scrap exported, accounting for almost one-half of the total in 1992.

Imports for consumption increased about 25% compared with those of the previous year. Canada remained the major shipping country to the United States, supplying almost two-thirds of the total aluminum scrap imports in 1992. (See tables 7 and 8.)

World Review.—According to preliminary data published by the World Bureau of Metal Statistics in August 1993, world production of secondary aluminum was about 5.9 Mmt in 1992. According to its statistics, the United States was the world's largest producer of secondary aluminum, followed by Japan at about 1.5 Mmt and Germany at about the 0.5-Mmt level.

Italy.—Reynolds Europe Recycling, a subsidiary of Slim Cisterna, announced the start up of a 65,000-mt/yr secondary aluminum facility in Venafro. The new plant consisted of two production lines. One line recycled aluminum scrap and produced extrusion billet, and the other recycled aluminum UBC's and produced rolling ingot. The new plant reportedly would concentrate on the production of extrusion billets until the aluminum UBC collection network was extended to support the feed material required by the rolling ingot portion of the plant.

Japan.—Mizushima Ferroalloy Co. announced the completion of a 15,000-mt/yr secondary aluminum alloy ingot plant. The company stated that about three-fourths of the UBC feed for the plant would be imported.

Malaysia.—Several companies from Finland, Japan, Malaysia, and Singapore announced the formation of a joint venture, Johore Aluminium Processing Sdn Bdh, to construct a 7,500-mt/yr secondary aluminum smelter in the southern Malaysian state of Johore. Construction reportedly was set to begin in January 1993 with full commissioning set for July. The plant was expected to produce diecasting and casting-grade material for sale to markets in Southeast Asia.

Switzerland.—Alusuisse-Lonza Holding Ltd. announced plans to close its subsidiary, Metallwerke Refonda, at the end of May. The company cited low prices, high operating costs, and a shortage of scrap as reasons for the closure of its 35,000-mt/yr secondary aluminum plant in Niederglatt.

Current Research.—Bench-scale tests by the USBM have shown that magnesium (Mg) and zinc (Zn) can be readily distilled from common aluminum alloys. For example, treating a 50-gram charge of alloy 7075 at 840° C under a vacuum of 0.1 torr decreased Mg and Zn from 2.2 and 5.6 weight-percent (wt %), respectively, to less than 0.1 wt % in 10 minutes. The results show that temperature and pressure strongly influence distillation rates. Changes in the alloy composition did not have a noticeable effect on distillation rates. Even though the distillation rates were high, they were less than predicted by distillation equations. Possible explanations for this were explored. A conceptual apparatus for integrating distillation into a secondary smelter is discussed.3

Outlook

As the public and industry become more sensitive to the issue of waste management, the benefits of recycling will become more evident. The aluminum industry, with its long history of recycling experience and its vast network of collection centers, will be well-positioned to take advantage of this

increased interest. The domestic and | world secondary aluminum industries should continue to expand. In the short the growing acceptance of aluminum beverage cans (with their very short life cycle) in overseas markets could lead to a more rapid growth rate in the recovery of aluminum in countries outside the United States, where the aluminum beverage can already dominates the market. In the long term, as more aluminum is used in products with longer life cycles, such as automobiles, more scrap will enter the market for recovery and increase the secondary production levels in both the domestic and world markets of the future.

COPPER AND COPPER ALLOY SCRAP⁴

Background

Definitions, Grades, and Specifications.—The Institute of Scrap Recycling Industries, Inc. (ISRI) recognizes about 53 classes of copper and copper alloy scrap. Although there are several grades within each, the major unalloyed scrap categories are No. 1 copper (common names-Barley, Berry, Candy, and Clove), which contains greater than 99% copper, and No. 2 copper (common names-Birch, Cliff, and Cobra). Although No. 1 copper may be consumed directly (remelt) or processed through a refinery, No. 2 copper requires refining before it is In addition, there are consumed. numerous scrap types designated by alloy composition, and special designations for low copper content scrap such as skimmings, ashes, and residues, which contain 12% to 30% copper. Even lower copper content scrap includes electronic scrap, refining slags, printed circuit board and other clad materials, and metal-laden waste liquors.

Copper scrap for trade may be classified as new, generated during the manufacturing of finished products, or old, recovered from used, wornout, or obsolete products. Scrap that is recycled internally by the producer or consumer

(home or run-around scrap) is generally discounted when measuring scrap demand.

A manufacturer may generate up to 60% scrap as clippings, trimmings, stampings, borings, and turnings when processing copper and copper-base products into finished articles. This new, or mill-return, scrap is readily used by brass and copper tube mills to generate new semifabricates. Secondary materials, both old and new scrap, that require minimal processing are commonly called direct melt scrap. In 1992, direct melt scrap provided about 830,000 tons or about 70% of copper from all secondary materials.

Resources.—Since World War II, the ever-increasing reservoir of copper products in use, much of which is eventually recycled as old copper, has provided annually between 19% and 33% of U.S. apparent industrial consumption, and on average, has provided about 18% of world copper consumption. The U.S. industry's contribution to the secondary materials reservoir of items in use. discarded, or abandoned in place, over the same period, has increased from about 16 Mmt in 1940 to more than 71 Mmt in 1992. This secondary materials reservoir does not include a sizable and growing pool of new scrap that is New scrap recycled every year. currently makes up about 24% of U.S. apparent consumption of copper; copper in old and new scrap comprises about 44% of apparent consumption. In 1940, the world copper reservoir of copper materials in use, or abandoned in place, By 1992, this was about 33 Mmt. reservoir of potentially recoverable secondary materials was estimated at about 194 Mmt of copper.

The annual U.S. contribution to the unrecovered copper reservoir of items in use or abandoned has been increasing since 1983 at the rate of about 1.2 Mmt/yr. Of this amount, more than one-half of the unrecovered copper remains in the consumer and general use sectors. Copper that is not recovered may be placed in one of three categories: (1) still in use and unaccountable, (2)

solid waste disposal, and (3) dissipated and lost. Copper is one of the most recycled of metals, but still much would appear to be entering solid waste disposal sites; the amount has been estimated as high as 50% of the unrecovered products. Copper has few applications that are dissipative by nature; only about 0.5% of total copper consumed may be lost and unretrievable from uses such as chemical production.

The availability of secondary copper is linked with the quantity of products consumed and their life cycles, or duration. Many estimates have been made about individual products; product life cycles may even vary from country to country, according to construction methods and concepts. However, copper in electrical plants and machinery averages 30 years; in nonelectrical machinery, 15 years; in housing, 35 years; and in transportation, 10 years. The average useful life for copper products is about 25 years, before being scrapped and entering the market as old scrap. New (manufacturing) scrap, on the other hand, has a short life of about 30 days, and its recovery is limited by domestic manufacturing rates This wide difference in efficiencies. turnaround and availability has resulted in a gradual increase of new scrap versus old scrap as a component in all scrap collected in the United States. The rate of old scrap recovery is limited not only by copper's long life and its essential uses, but also by the sensitivity of scrap collection to market prices.

Technology.—Because scrap is a bulky material, the customary practice is to bale light scrap and cut heavy scrap to size so that it can be handled. An important source of secondary copper is cable scrap. Whereas previously burning of the cable to remove the plastic parts was acceptable, this is no longer always possible or desirable. Thus, mechanical dismantling of the cables is common practice through cutting, granulating, and use of various sorting techniques to separate the insulating materials (fluff) from the metal.

Processing complex copper-containing

materials, such as drosses, flue dust, catalysts, collector dust, slimes from electroplating wastewater, and metal-rich slags from converter processes, requires versatile production processes. Most old scrap must be reprocessed by either smelting and refining, or by leaching and electrowinning to form a pure copper product. Fire refining in a reverberatory or other furnace may be sufficient for the better grades of scrap. The fire-refining process uses oxidation, fluxing, and reduction to produce refined ingot, wire bar, slab, or billet. For higher grades of refined cathode, however, the poorer grades of scrap must be first smelted with various fluxes, poled to remove oxygen. and then cast into anode form for further processing in an electrolytic refinery. Byproducts, such as tin and precious metals, may be recovered during the preliminary procedures of smelting, or during refining from the tankhouse sludges. Other impurities, such as antimony, arsenic, iron, and lead, may be removed in the slag by fluxing. Reverberatory or electric rotary melting furnaces are used for casting various copper forms, such as slabs, cakes, or ASARCO Incorporated shaft billets. furnaces may be used in series with holding furnaces in conjunction with continuous casting systems.

Most processing plants have built-in water recirculation systems in which some of the metal content is recaptured and reused. In general, a combination of various hydrometallurgical techniques such as precipitation, cementation, ion exchange, solvent extraction, reverse osmosis, gaseous reduction, electrolysis are used to treat process waters. Cementation has successfully employed to recover copper from waste effluents. Solvent extraction and ion exchange are highly selective methods for separation of copper from other common metals in solution. Mechanical and thermal dismantling, and more recently, leaching and solvent extraction and electrowinning procedures. have proved effective in treatment of certain types of electronic scrap. Electrowinning recovery also is used for processing waste liquors that contain

copper and other metals.

Black copper (75% to 80% copper) is the principal product of the blast furnace and still contains some iron and zinc along with most of the lead, nickel, and tin of the charge. Traditionally this material is refined in a scrap converter, which is of a more modest size than its primary cousin; also, coke is added liberally to the charge, adding extra heat and providing a mildly reducing condition, thus facilitating removal of lead, tin, and zinc in the gas stream. A copper anode is poured for final refining in an electrolytic tankhouse.

Economic Factors.—Prices paid for scrap are related generally to the current refined copper price, but the spread between the two prices must be sufficient to allow for processing costs and the inherent costs of scrap preparation (collection, sorting, shipping, chopping, briquetting, etc.). Processing by scrap smelters becomes uneconomic as the gap between scrap and refined price narrows. The spread between refiners' buying price for No. 2 scrap and the producers' refined copper price has varied from 9 cents in 1970, 27 cents in 1980, to 19 cents in 1992. The low spreads in the early 1970's were caused by price controls placed on U.S. copper during this period. The very high spreads of the late 1980's, which averaged more than 30 cents per pound, as shown in figure 3, were the result of high refined copper prices and a good supply of scrap. Price spreads also tend to widen when speculative interest is active on the exchanges, such as is the case when the copper price is high. The spreads have been decreasing since the high point of 1987, as a result of lower refined prices.

Annual Review

Consumption.—Copper ranks third in world metal consumption after steel and aluminum. The major copper consuming nations or areas of the world are Western Europe (29%), United States (20%), Japan (15%), the former U.S.S.R. (7%), and China (6%); about 11 Mmt of primary and secondary refined copper

was consumed in 1992. About 72% of the metal consumed in the United States was for electrical and electronic uses, finding widespread application in all sectors of the economy. Nonelectrical construction (14%), machinery (5%), transportation (5%), ordnance (2%), and miscellaneous (2%) end uses make up the remainder of demand.

In 1992. about 1.7 Mmt of copper-base scrap (old and new), containing an estimated 1.22 Mmt of recoverable copper, was consumed in the United States. An additional 57,000 tons of copper was recovered from aluminum-. nickel-, and zinc-base scrap. The total copper recovered from scrap was valued at \$3 billion. Recycled copper was derived 57% from new scrap and 43% from old scrap. Purchased new scrap derived from fabricating operations yielded 722,351 tons of contained copper, 74% of which was recovered at brass mills. Copper recovered from old scrap made up 24% of U.S. apparent copper consumption (primary refined production plus copper recovered from old scrap plus net imports and net stock changes). (See figure 4.) About 20% of U.S. refined copper production was from scrap. Five secondary smelters and a small 450-mt/yr secondary electrowinning plant had a combined copper capacity of 440,000 tons in 1992. In addition, about 28 ingotmakers, 40 brass mills, and 750 foundries, chemical plants, and other manufacturers also consumed copper scrap in the United States. Brass mills, smelters, and ingotmakers accounted for most of scrap consumption.

In 1992, the major copper scrap types consumed were: No. 1 copper, 27%; No. 2 copper, 23%; leaded yellow brass, 17%; yellow and low brass, 7%; automobile radiators, 5%; red brass, 4%; and low-grade ashes and residues, 10%. A wide variety of alloys made up the remaining 8%. Brass and copper tube mills processed 65% of the No. 1 copper and most of the cartridge cases and yellow brass, while the secondary smelters and ingotmakers processed 88% of the No. 2 scrap and most of the autoradiators and red brass scrap. (See tables 9-17.)

Foreign Trade.—The United States is one of the largest international sources for copper scrap, followed by France, Germany, and the United Kingdom. U.S. exports of copper scrap have been increasing since the 1960's, when the Far East nations began to industrialize. More recently, China has become a significant importer of U.S. copper scrap. Canada and Mexico were the leading sources for U.S. imports of copper and copper alloy scrap in 1992. U.S. copper scrap exports increased from 17,000 tons in 1950 to 247,000 tons in 1992. In 1992, U.S. scrap exports were valued at \$282 million, while scrap imports were valued (c.i.f.) at \$284 million. (See tables 18 and 19.)

World Review.—The Western European countries make up the largest single market for scrap in the world. Germany, Italy, France, the United Kingdom, and Belgium are the leading consumers. The United States is second after the European Community (EC) in total scrap consumption. Asia, mostly Japan, is the third largest scrap consuming area of the world. Copper scrap accounted for 36% of annual copper consumption in the countries of the EC, compared with about 42% of total annual copper consumption in the United States. In recent years, about 21% of refined copper in the United States and 40% of the refined copper produced in Western Europe was derived from copper scrap. On average, copper from scrap accounts for about 18% of the world's refined copper production.

The EC, as a group, makes up the largest single scrap trading area in the world. Nearly all imports and exports from the EC are to or from other European nations. The Asian countries export very little scrap, and most of this goes to other Asian countries. Asian imports of scrap from Western countries have grown significantly in recent years. China, in particular, has increased its imports of U.S. generated scrap over the past 3 years.

Outlook

Over the next decade, copper scrap will continue to be a premium material for the U.S. semifabricating industry. Because scrap is usually a lower cost alternative to primary metal, it will continue to be of great interest to Far Eastern countries as they expand their industries. Recovery of copper from the large and growing reservoir of copper products in use may be limited by the following factors: (1) copper prices, (2) life of products, (3) available recovery technologies, and (4) rate of copper consumption. Affecting the availability of new scrap is the recent industry observation that the amount of new scrap being generated by manufacturing plants has been cut by as much as 50%, owing to increased production efficiencies. Another factor that will affect copper scrap collection, use, and processing over the next decade is the limitation on lead in copper plumbing alloys, as a result of legislation limiting the content to 2% lead or less.

Without successful implementation of new recovery technologies, the recovery of copper in all parts of the economy will be impeded by increased legislative requirements. New technologies, some of which have been introduced, are expected to increase recovery of copper from wastewaters, electronic scrap, and other scrap with low copper content. With increased environmental and labor safety requirements, some types of ingot will be difficult to produce economically. New technologies will be required to decrease the lead content of machinable and other leaded-copper alloys.

World consumption of copper in scrap was estimated to be 5 Mmt in 1992 and is forecast to be about 7.2 Mmt by the year 2000. Of this amount, 1.8 Mmt in 1992 and 2.8 Mmt in 2000 will be as secondary refined copper.

LEAD⁵

Refined lead is a soft, heavy metal, that was one of the first metals used by humankind. It has a low melting point, which makes it among the easiest metals

to cast, it is the most corrosion-resistant common metal, and has unusual electrical properties. In terms of tonnage of metal consumed, demand for lead is surpassed only by aluminum, copper, iron, and zinc. The United States is the world's largest producer and consumer of refined lead. The domestic demand for lead has changed significantly over the past 20 years. In 1972, dissipative uses of lead, particularly gasoline additives, pigments, ammunition, and chemicals, amounted to more than 400,000 tons, or about 30% of reported consumption of 1.35 Mmt. In 1992, following the phase out of leadbased gasoline additives and pigments for interior paint, dissipative use accounted for less than 10% of a total demand of 1.24 Mmt.

74% of the domestic About consumption of lead metal is metal recovered from both new and old lead scrap. In 1992, 917,000 tons of metal valued at \$494 million was recovered from both new and old scrap. Lead scrap is traded on world markets. In 1992, the United States exported about 63,000 tons of lead scrap with a value of \$15 million. Imports of lead scrap for the year totaled about 200 tons worth \$65,000. (See tables 20, 21, 22, and 23.)

Old scrap is the predominant form of recovery of lead scrap. In 1992, old scrap accounted for 94% of the total of 917,000 tons of lead scrap recovered. Used batteries supply about 91% of that old scrap. The battery industry dominates the lead scrap field just as it dominates the primary lead usage In recent years, integrated category. battery manufacturers and secondary smelters have expanded smelting capacity to fill a vacuum left by the closure of small- and medium-sized, nonintegrated, battery breaking, and/or secondary smelters that have closed due to environmental-related pressure. Similarly, the independent scrap dealer is playing a diminished role as battery manufacturers are entering into buy-back arrangements with retail outlets, both as a marketing tool for new batteries and as a means of ensuring feedstock to their smelters and downstream manufacturing operations.

Domestic Data Coverage

Domestic data for lead scrap are developed by the USBM from voluntary canvass survey forms sent to the firms monthly and annually. The larger firms tend to be canvassed monthly, while the smaller ones tend to be canvassed annually. Of the 39 companies producing secondary lead, exclusive of copper base, to which a survey request was sent, 29 responded, representing 82% of the total refinery production of secondary lead. Production and consumption for the nonrespondents were estimated using prior-year levels adjusted for general industry trends.

Background

At yearend 1992, the secondary lead industry was composed of 16 companies that operated 23 battery breakers-smelters with capacities of between 10,000 and 120,000 mt/yr; 5 smaller operations with capacities between 6,000 and 10,000 mt/yr; and 18 small plants (less than 1,000 mt/yr) that produced mainly specialty alloys for solders, brass and bronze ingots, etc.

Annual Review

Domestic secondary production in 1992 was estimated to have nearly achieved 1990's alltime record as capacity utilization for the year was an optimum 88%. This was mainly because a major battery recycler in Alabama was permanently closed by the U.S. Environmental Protection Agency (EPA) early in the year.

Operations were indefinitely suspended at a smaller battery recycler in midyear in Tennessee, but this was offset by Refined Metals Corp.'s, Memphis, TN, plant, which had been shut down at the beginning of the year, coming back onstream. During the year, several smaller nonbattery recyclers who mainly produced specialty alloys for such uses as solders, brass or bronze ingots, bearing metals, etc., closed permanently, a result of being overcome by very low to nonexistent margins and increasingly

enforced environmental emissions and workplace standards.

A new, small, "just-in-time" battery recycler came partially on-stream in Ohio, but was not producing at yearend owing to financial and technical problems. However, at yearend, the secondary lead industry had an estimated production capacity of 1.04 Mmt, 1.0 Mmt of which resided with 15 battery These 15 recycling companies. companies operated 20 breakers and 22 smelter-refineries with capacities of 10.000 to more than 100,000 mt/yr, although two in Ohio and Tennessee were still shut down at yearend and several had curtailed operations. Also operating were five midlevel, nonbattery smeltersrefineries, including Asarco's Omaha, NE, refinery, with furnace and kettle capacities of 6,000 to 10,000 mt/yr. In addition, 13 small specialty alloy producers were operating, 3 with capacities of 1,000 to 2,000 mt/yr; the other 10 had considerably smaller capacities.

Total production from the nonbattery plants in 1992 was 38,000 tons, much of which was from copper-base scrap and/or new scrap. In the first full year of operation, Doe Run Company's new secondary plant at Boss, MO (on the site of its former Buick primary smelterrefinery), produced at full capacity. However, overall, for 1992, the RSR Corp. (Dallas, TX) was the Nation's largest secondary lead producer. outproduced both Doe Run's and Asarco's individual (primary secondary) pig lead outputs.

Outlook

Primary and secondary lead production as well as consumption have been negatively impacted by numerous Federal and State laws targeted at specific areas to reduce the hazards of lead for more than a decade. The trend of increasing secondary share of production and consumption is expected to continue until optimum recycling is achieved. The year 2000 growth in scrap lead production is expected to average about 1.5% yearly.

TIN6

Tin was one of the earliest metals known to humankind. Tin occurs in nature mostly as the oxide mineral cassiterite. Tin metal is commonly used as a protective coating or as an alloying metal with other metals. Metal is generally used as the starting point for most uses of tin. The major uses for tin are as follows: cans and containers. 32%; electrical, 22%; construction, 10%; and transportation, 11%; other uses account for the remaining 25%. Tinplating currently uses no scrap tin, but most other fabricated end-use items, especially solder and brass/bronze, use substantial quantities of tin scrap.

About 30% of the domestic supply of tin metal is metal recovered from both new and old tin scrap. In 1992, 13,700 tons of metal valued at an estimated \$85 million was recovered from new and old tin scrap.

Old tin scrap is collected at hundreds of domestic scrap yards, at nine tinplate and can detinning plants, and at most municipal collection centers. New tin scrap is generated mainly in the tin mills at six steel plants, numerous brass and bronze plants, and numerous soldermaking plants.

Detinning facilities are unique to the tin scrap industry, in that no other major metal industry has such large-scale facilities to remove plated metal. Nine plants are spread across the country. Until about 1989 they processed almost solely new tinplate scrap that originated in the tin mills of steel plants and canmaking plants. Since 1989, with new technology that shreds used tin cans, some of the Nation's detinning facilities have the capability of also detinning old tin cans. Only in the detinning process does free tin metal see its way to the marketplace; all the alloy forms of tin are merely recycled within their own productline industries and thus reappear as regenerated alloys. (See tables 24, 25, 26, and 27.)

Most tin scrap processing facilities are close to the tin-using industries and to densely populated areas. Most are in the Midwest and Northeast.

Domestic Data Coverage

Domestic scrap data for tin are developed by the USBM from a voluntary survey of the U.S. tin scrap industry. The smaller side of this industry is covered by a canvass sent to five detinning companies monthly; all five respond or are estimated for. The larger side of the tin scrap industry, involving the alloys of tin, is covered largely by a canvass of the copper and lead scrap industries (tin's major coalloys) from which estimates are made for the tin content.

Background

Secondary tin was derived 30% from new scrap and 70% from old scrap. New tin scrap consists mostly of forms of tinplate (side scrap, flitters, cobbles, skeletal punch-outs from can-making etc), drosses from soldering skims, and plating residues and sludges from tinplating lines. Old tin scrap consists mostly of used brass/bronze items (often faucets, fixtures, etc.) and used soldered items (both electronic solders from computers, television and radio sets, etc. and plumbing solders from houses and office buildings); since about 1989 some used tin cans have been detinned, and the scrap tin recovered qualifies as old tin scrap.

The solder industry has traditionally consumed large amounts of tin scrap to make solder products. Tin scrap accounts for 38% of the total tin used for solder. The brass/bronze industry, although smaller than the solder industry, has also traditionally been a major consumer of tin scrap. Scrap accounts for 56% of the total tin used for brass/bronze.

The average life of tin in its end uses is estimated at 20 years. It is estimated that about 10% of the tin placed in use in any year is dissipated in that same year. Tin in such chemical products as wood preservatives, marine boat hull antifoulant paints, fungicides, tin oxides, and tin tetrachlorides sprayed on glass bottles is

quickly dissipated. Some longer lasting tin products also release tin to the environment while in use. For example, tinned electrical copper cables lose tin through weathering or corrosion, whether overhead or underground. The tin in some other end uses is dissipated, even though the products are disposed of in a controlled way; an example would be the used tin cans collected by municipal trash departments and placed in landfills. Currently, about 13% of the domestic requirement for tin is satisfied by old scrap.

Technology.—Tin recycling processes vary according to the nature of the tin scrap. Tin-plated products such as tinned kitchen trays or tinned electrical copper cables or tinplate or tin cans typically are treated in a batch process at elevated temperatures with a sodium hydroxide solution for a considerable period of time. Typically, an electric current is applied in a reversal of the original plating process. The tinned product is made anodic, and electrodes in the batch are made cathodic. Positively charged tin ions leave the tinned product and travel through the electrolytic bath to the negatively charged electrode, where the tin is plated and then can be used as scrap tin for a variety of uses.

For tin alloys, generally there is no attempt to recover the tin as a separate element. Instead, during the alloy refining process the matt is analyzed periodically, and as needed, tin is added to bring the molten batch to the desired specifications.

Secondary tin generally is utilized in the various alloys of tin, especially brass/bronze and solder. These alloys often take the shape of a bar or ingot, but also sometimes appear as rod, wire, plate, pellets, or powder. Traditionally, the brass/bronze industry utilizes the largest percentage of scrap tin to total tin.

Economic Factors.—Scrap prices are generally available only within the industry. But, occasionally, publications such as AMM publish some alloy scrap prices and prices for baled old tin can scrap.

There is an active international market in some forms of tin scrap. Generally, the United States has been the world's leading generator of tin scrap, and in some years substantial amounts are exported.

Annual Review

Production.—MIDCO Inc., St. Louis, MO, announced the startup of its new tin smelter, designed to produce Grade A tin from secondary sources. The MIDCO brand, which was sanctioned by the LME, will be sold in ingot form. Expected production was 3,000 mt/yr. Before this year, MIDCO had been producing a tin/lead solder.

AMG Resources Corp., Pittsburgh, PA, the world's largest processor of tinplated steel scrap and used tin cans, announced it would supply all used steel can scrap purchased by Weirton Steel Corp., Weirton, WV. Weirton ranks as one of the major domestic tinplate The agreement producers. considered the first step in AMG's filling the majority of Weirton's overall scrap needs with AMG's processed cans. Although much of the steel can scrap that would be shipped to Weirton would be detinned material, some would still have the tin coating.

USX Corp. announced steps to increase its consumption of beverage can scrap to ensure recyclers that a viable market would continue to exist for and bimetal cans. recycled steel Previously, most of USX's can scrap purchases were melted at its Chicago, IL, and Gary, IN, plants. Henceforth, USX would accept can scrap at all its melt shops, adding its Braddock, PA, and Fairfield, AL, plants. Tube City Inc., which operated the scrap yards at all USX integrated plants, would handle the processing of all the can scrap, which totaled 70,000 tons in 1991. completion this year of a continuous caster at USX's Mon Valley Works in Braddock, PA, the company would have converted completely to continuous Because continuous casting casting. generates considerably less internal scrap than ingot-cast steelmaking, used can scrap from the Nation's solid waste stream will probably become increasingly important to USX and other steel producers.

Weirton announced it had joined a collaborative effort with Nippon Steel Corp., Japan, and the Sollac Div. of Usinor, France, to maximize the recycling of steel cans. All three firms are major tinplate producers. The companies intend to examine the various methods of separating steel cans from the refuse stream and recycling them back into the steelmaking process. They also planned to work together to develop a lighter weight steel can to increase the competitiveness of the 2-piece steel beer and soft drink can.

The Steel Can Recycling Institute, Pittsburgh, PA, funded by the major domestic tinplatemakers, announced that the recycling rate for steel beverage cans in 1991 was 46%, while the overall rate for steel cans was 34%. This compares to the following rates for competitive materials: aluminum beverage cans, 62%; glass containers, 31%; and plastic polyethylene terephthalate (PET) soft drink bottles, 36%.

World Review.—The United States, along with France, Germany, Japan, and the United Kingdom, generally lead the world in tin recycling activity and innovation. Environmental pressures in these countries for the past 20 years have acted as a powerful incentive. In contrast to the United States and Europe, Japanese industry does little or no detinning because they feel that tin coating on tinplate has become so thin in the past 20 years that detinning is not economical.

In Germany, 1992 marked the start of the Government's new controversial and more stringent packaging recycling law. The new quotas required under the law require business and industry to collect 30% of all aluminum sold as packaging material (based on weight) and to recycle 60% of that collected waste. They require collection of 40% of all tinplate sold, 65% of which must be recycled. The reason for the differential between tinplate and aluminum is that aluminum is combined more often with other

materials, such as plastic and paper in beverage cartons or boxes and thus can be much more difficult to recycle. In July 1995, higher quotas are to be established-about 80% would have to be collected and about 90% of collected aluminum and tinplate will have to be recycled. Germany used 109,000 tons of tinplated cans and 7,000 tons of aluminum cans in 1991, a total of 4.3 billion cans. Germany was the first nation to require business and industry to collect and recycle materials used to package their products. environmental group Bund für Umwelt und Naturschutz Deutschland began an intense campaign of its own calling for a ban on the use of tinplate and aluminum beverage cans, and a return to refillable glass bottles. The group argued that there was duplicity in the packaging industry's promotion of beverage can recycling and questioned the high recycling rate the industry has claimed. It targeted Viag AG, the large German container producer, for much of its attention.

In the Republic of South Africa, Iscor Ltd. organized a joint effort to clean up the nation's environment by recycling more used tin cans. The program was expected to increase the level of steel can recycling during the first year from 15,000 tons to 30,000 tons. This would represent 30% of the annual tin can production in South Africa. Organizers of the program set a 5-year goal of 50% tin can recycling. Driving the venture was National Metal Co., Iscor's scrap reclamation and trading subsidiary. Other partners in the venture were two major canmakers, Bevcan Co. and Crown, Cork & Seal Corp., plus a recycling firm, Collect-A-Can Co. National Metal was proceeding to establish a countrywide network of steel can delivery points. Collect-A-Can recovered cans through about 2,000 collection points. Cans were crushed, baled, and delivered to Iscor's steel works in Pretoria and Vanderbijlpark for use in their scrap charge.

AMG Resources, the large recycler of tinplate and used cans, began offering British smelters aluminum extracted from

bimetallic beverage cans (these are tinplated cans with an aluminum easyend). **AMG** had experimenting with ways of extracting the aluminum for the past year, and the process became commercially viable this year. The breakthrough meant that AMG could offer shredded steel scrap, tin, and shredded aluminum from its recycling operations in Hartlepool and Llanelli. AMG capacity in used can recycling was about 35,000 tons annually, with only a 50% utilization rate due to problems in finding feedstock. Bimetallic cans represent about 30% of the total cans recycled by AMG. Previously. nonferrous materials extracted from the bimetallic cans were unsalable because of contamination from plastic and other packaging materials. Now, with the introduction of air and magnetic separation systems at both Hartlepool and Llanelli, a salable 80% pure aluminum scrap was obtained.

In the United Kingdom, the British Steel Can Recycling Information Bureau (SCRIB) announced that the country's steel can recycling rate had reached 21% in 1991, with 1.2 billion steel cans recycled compared with 1.1 billion in 1990. SCRIB attributed much of the growth to the Save-A-Can bank program, which increased its number of collection points from 322 in early 1991 to more than 600 this year; a goal of 1,000 can banks was set for 1994. No data had yet been collected for 1992.

Current Research.—In Japan, a steel recycling research program for development of new technology to produce high-grade steel from 100% scrap was launched by the Research Institute of Innovative Technology for the Earth, a Government-industry foundation supported by the industrial Technology Agency of the Ministry of International Trade and Industry (MITI). Japanese steel producers were slated to participate in the program, on which it was planned to spend about \$77 million over the next 8 years. The Institute noted that increasingly, steel products have come to contain tin, copper, zinc, etc., making them more difficult to recycle, and that this calls for a next-generation steelmaking technology. The project would focus on new technologies for separating copper, tin, zinc, etc., from scrap. Three steel plants would host the project: the Kimitsu Works of Nippon Steel Corp., the Keihin Works of NKK Corp., and the Chiba Works of Kawasaki Steel Corp.

Outlook

The near- and long-term outlook for tin recycling is positive, with modest growth of less than 1% annually. Tin consumption is expected to grow at about the same modest rate. Scrap is expected to grow from a current 17% of total metal consumed to about 18% by the year 2000. A major incentive is expected to be environmental legislation, mostly at the local and State level. If tin prices remain relatively high compared with prices of other major metals, the industry will have sufficient incentive to recycle this costly metal.

ZINC⁷

Zinc is the fourth most widely used metal after iron, aluminum, and copper. About three-fourths is used in metal form and one-fourth in compound form. More than 90% of the metal is used for galvanizing steel and for alloys; the remainder is used to produce dust, oxide, and various chemicals. Most metal products find widespread use in the automotive, construction, electrical, and machinery sectors of the economy. Compounds are similarly dispersed in distribution and use, but are mainly used in the agricultural, chemical, paint, pharmaceutical, and rubber sectors of the economy. Nearly one-third of the 1.2 Mmt of zinc consumed annually by domestic industries is secondary zinc. In 1992, about 366,000 tons of secondary zinc, valued at about \$471 million, was recovered in basic forms—refined metal, alloys, dusts, and chemicals. containing about 82,000 tons of zinc and valued at \$48 million was exported in 1992, whereas 43,000 tons of zinc in scrap, valued at \$23 million, was

imported.

Old zinc and brass scrap is collected at hundreds of domestic scrap vards, at more than 200 U.S. automobile and appliance shredding operations, and at numerous municipal collection centers. New zinc scrap is generated mainly in galvanizing plants, diecasting plants, brass mills, and manufacturing facilities when basic zinc materials are consumed. There are 4 primary and 11 secondary smelters that process scrap, drosses, skims, and/or steelworking electric arc furnace (EAF) dust into slab zinc, zinc alloys, and zinc dust. Seven other plants process skims, drosses, scrap, and residues into zinc sulfate and/or chloride chemicals. Secondary brass and bronze are recycled at more than 500 secondary smelters, foundries, and ingotmakers. A plant in Illinois produces Americanprocess zinc oxide from oxidic secondary materials. Most secondary zinc plants are in the Eastern and Midwestern United States; one plant in Pennsylvania is, by far, the single largest processor of secondary zinc. Crude zinc concentrates extracted from EAF dust are produced at six plants. (See tables 28 and 29.)

Background

Sources of Secondary Zinc.— Recycled zinc was derived 70% from new scrap and 30% from old scrap. New zinc scrap consists mostly of drosses, skims, furnace dusts, and residues (from galvanizing and diecasting operations, brass mills, and chemical plants) and clippings from the processing (stamping, trimming, etc.) of galvanized steel sheet and strip, rolled zinc, and brass sheet. Old scrap, historically, has consisted almost entirely of diecastings, mainly from scrapped automobiles: brass products; and rolled zinc items, such as gutters, roofing, and engraving plates. Only in the past decade has any zinc been recovered from discarded rubber tires or from old galvanized steel scrap. Zinc recovery from the burning of tires for energy is small but growing, whereas recovery from both old and new galvanized steel scrap has increased dramatically.

New zinc-base scrap, as shown in tables 27-29, has remained essentially unchanged in quantity over the past 40 years despite a sharp drop in zinc used for diecastings; zinc recovery from new galvanized steel sheet scrap, generated mainly in automobile manufacture, has offset declines in scrap generation from diecasting and improved manufacturing processes. Old zinc scrap, on the other hand, has increased substantially in the past few years, owing to the additive effects of zinc recovery from old galvanized steel scrap generated mainly from the shredding of discarded automobiles and appliances.

Common types of zinc scrap have been categorized by the industry such that they are identifiable as to their derivation or source and minimum grade and quality requirements. Specifications for the various zinc scrap types were updated by the ISRI in 1991 and published by ISRI (1325 G St., NW, Washington, DC 20005) in "Scrap Specification Circular 1991."

The life cycles of zinc-containing products vary widely from days, for some chemical products, to more than 100 years for some rolled-zinc and brass products. The average life of zinc in end uses is estimated to be 14 years. Despite recent improvements in the recovery of old zinc, most zinc products are disposed of in landfills or are dissipated into the environment. About 10% of the zinc placed in use in any year is dissipated in that same year. The zinc in such products as fertilizers and animal feeds. oils, inks, pharmaceuticals, vitamins, welding fluxes, and fungicides is dispersed in a relatively short time to the environment and is not recoverable. Many longer lasting products also release and dispense zinc to the environment while in use. For example, galvanized surfaces lose zinc through weathering or corrosion, vehicle tires abrade, paint weathers, and sacrificial anodes are slowly consumed. The zinc in many other end products is dissipated or lost to recycling even though the products are disposed of in a controlled way (placed in landfills) because recovery is economical, or in some cases, not technologically feasible. Because zinc uses are largely dissipative, the net cumulative rise in total zinc in the overall pool in use in the United States is only 10% to 20% of annual zinc consumption.8

Currently about 10% of the domestic requirement for zinc is satisfied by old scrap. In earlier times, the recovery from old scrap was much smaller. This was illustrated in a recent USBM study in which it was estimated that of the 73 Mmt of zinc placed in use in end products in the United States in the period 1850 to 1990, an estimated 23 Mmt (32%) was still in use at the end of 1990, 46 Mmt (63%) had been dissipated, and only 4 Mmt (5%) had been recovered by recycling.

Technology.—Because of wide differences in the character and content of zinc-bearing scrap, zinc recycling processes vary widely. Zinc-containing metals are generally separated from other materials initially by physical means such as magnetics, sink-float, and hand sorting. In the case of mixed nonferrous metal shredder scrap, zinc can be separated from higher melting metals such as copper and aluminum, by selective melting in a sweat furnace. Zinc in galvanized scrap is largely recovered in furnace dust when the scrap is charged into a steelmaking furnace; however, one commercial process has been developed to strip zinc from galvanized scrap with a caustic leach before recycling the substrate steel to the steelmaking process.

Clean new scrap, mainly brass and rolled zinc clippings and reject diecastings, generally only required remelting before reuse. Drosses, fragmentized diecastings, and mixed highgrade scrap typically are remelted, followed by zinc distillation with recovery as metal, dust, or oxide. Sometimes, high-purity drosses are simply melted and reacted with various fluxes to release the metallic content; often the recovered metal can be used directly as a galvanizing brightener or master alloy. Medium and low-grade skims, oxidic dust, ash, and residues

generally undergo an intermediate | reduction-distillation pyrometallurgical step to upgrade the zinc product before further treatment: or, they are leached with acid, alkaline, or ammoniacal solutions to extract zinc, which is subsequently recovered as a compound by precipitation-crystallization or as a salable chemical retained in solution. Almost all of the zinc in EAF dusts is first recovered in an upgraded, impure zinc oxide product: however, several commercial, EAF-dust-treatment plants are able to bypass the intermediate step and directly recover zinc metal. The upgraded zinc oxide pyrometallurgical product is almost always shipped to a primary pyrometallurgical zinc smelter refinement to metal. For the most part, the zinc metals, alloys, dust, and chemicals recovered from secondary materials are comparable in quality to those derived from primary materials.

Recovery efficiency is very high from simple remelting but declines as the number of processing steps increases and, generally, as the zinc content of the scrap declines. Zinc recovery from most secondary processes range between 40% to 85%; however, oxide materials, slags, and residues resulting from initial processes may in turn be recycled, resulting in further zinc recovery.

Secondary Refined Products.—Zinc materials made from zinc-base scrap are slab zinc, alloys, dusts, and compounds. Brass scrap, on the other hand, typically is remelted and, with alloy adjustment, recast as brass. Zinc chloride and sulfate compounds are produced largely by acid leaching of zinc skims, drosses, and chemical residues. Impure zinc oxide products and zinc-bearing slags are sometimes used as trace element additives in fertilizers and animal feeds. Zinc in brass is the principal form of secondary recovery, although in the past few years secondary slab zinc has risen substantially because it has been the principal zinc product of EAF dust recycling.

Economic Factors.—Prices paid for scrap and secondary materials are generally negotiated, often on the basis of

a daily or average LME price for zinc Bids are required for U.S. metal. Department of Defense scrap sales. Prices depend on factors such as geographic location, quantity available, quality, grade, the presence of other components or elements, and environmental difficulties in handling, transporting, or treating. In the case of EAF dust, the dust generator usually pays the dust processor a fee to recycle the Typically, there is a basic charge for dust with 20% zinc content; generators of dust with lower zinc content pay more, whereas generators of dust with higher zinc content pay less. Zinc and brass scrap prices are generally not available, although average daily, weekly, or monthly prices for a few specific common types are published in AMM, Metal Bulletin, and Metal Bulletin Monthly. Basic guidelines for scrap metal transactions (contracts, packing, shipping and receiving, weighing, rejections, downgrades, and claims) are available in the aforementioned ISRI publication.

Outlook

Driven by public concern for the environment and legislation intended to protect the environment, domestic and world secondary zinc recovery is expected to increase as a percentage of zinc consumption in the next decade. However, the prospect for recovery equivalent to more than 35% to 40% of consumption is relatively poor because of the dissipative nature and diversity of zinc uses. Galvanizing has been the major growth area for zinc, and greater secondary zinc recovery can be expected from this source in the future. Increased processing of low-zinc EAF dust, dust from other steelmaking processes, and energy-generating tire burning appear to be other sources for near-term gains in secondary zinc output. Increased zinc recovery from the recycling of carbonzinc and alkaline batteries, and municipal incinerator dusts and residues are longer term possibilities. Secondary zinc recycling could dramatically increase after the year 2000 if substantial numbers of electric cars, powered by zinc-air batteries, become a reality.

¹Recycled metal is metal recovered from purchased new plus old scrap.

²New scrap is scrap that results from the manufacturing process, including metal and alloy production.

³Old scrap is scrap that results from consumer products.

Quantity is the calculated metallic recovery from aluminum-base scrap, estimated for full industry coverage. Value is estimated based on average annual U.S. market price for primary aluminum metal.

⁵Recoverable copper values in scrap based on annual averages for refined copper.

⁶Transaction value estimated to be London Metal Exchange (LME) average cash value plus 6.5 cents/lb.

⁷Nickel scrap is nickel contained in ferrous and nonferrous scrap receipts. Value is estimated as average annual LME cash price of nickel cathode.

⁸Value estimated based upon Metals Week (MW) Tin Composite price. Reevaluation of the tin canvass in 1991 resulted in a substantial lowering of estimated old scrap.

Value based on average annual U.S. zinc metal price published in MW; for 1988-90, the MW average prices were based on U.S. or North American Producers' High Grade zinc delivered prices and for 1991-92, the LME spot prices for Special High Grade zinc plus premiums based on market conditions.

*Revised

¹Apparent supply is production plus net imports plus stock changes. Production is primary production plus recycled metal (see table 1, footnote 1). Net imports are imports minus exports. Apparent supply is calculated on a contained weight basis.

²Recycle is metal recovered from purchased scrap.

³Same as apparent supply defined above but calculated on a monetary value basis.

Monetary values estimated based on the U.S. market price for primary aluminum ingot. Recycle calculated as metal recovered from reported purchased new and old scrap estimated for full industry coverage.

⁵Copper recovered for consumption valued on average annual refined prices.

Lead processors are segregated by primary and secondary producers. This segregation permits inclusion of stock changes in recycle lead supply. Transaction value for U.S. primary production and net imports estimated to be London Metal Exchange (LME) average cash plus 6.5 cents/lb. Stock adjustments value based on actual proportion of stock change to secondary production.

Value of apparent supply and recycle estimated as average annual LME cash price of nickel cathode.

³Value estimated based upon Metals Week (MW) Composite price.

⁹Value based on average annual U.S. zinc metal price published in MW; for 1988-90, the MW average prices were based on U.S. or North American Producers' High Grade zinc delivered prices and for 1991-92, the LME spot prices for Special High Grade zinc plus premiums based on market conditions.

Revised

¹Positive figure indicates a decrease in stocks; negative figure indicates an increase in stocks.

²Metallic recovery from purchased, tolled, or imported new and old aluminum scrap expanded for full industry coverage.

³Apparent aluminum supply available for domestic manufacturing less recovery from purchased new scrap (a measure of consumption in manufactured end products).

¹Excludes recovery from other than aluminum-base scrap.

²Rounded.

Total of all scrap consumed ⁶	[*] 98,216	2,944,955	2,960,674	82,497

Revised.

¹Includes imported scrap. According to reporting companies, 3.87% of total receipts of aluminum-base scrap, or 112,286 metric tons, was received on toll arrangements.

²Includes inventory adjustment.

³Includes data on foil, can stock clippings, and other miscellaneous.

⁴Used beverage cans toll treated for primary producers are included in secondary smelter tabulation.

⁵Includes municipal wastes (includes litter) and fragmentized scrap (auto shredder).

⁶Data may not add to totals shown because of independent rounding.

⁷Revised to zero.

SALT

By Dennis S. Kostick

Mr. Kostick, a physical scientist with 14 years of U.S. Bureau of Mines experience, has been the commodity specialist for salt since 1980. Domestic survey data were prepared by Christopher Lindsey, statistical assistant; and international data tables were prepared by Doug Rhoten, international data coordinator.

Sodium chloride, commonly known as salt, is a universal commodity that is known and used by virtually every person in the world. It is an important compound that has a multitude of applications with approximately 14,000 different reported uses. Most individuals usually only associate salt with highway deicing and food processing; however, the largest end-use of salt is as feedstock chlorine and caustic soda manufacture. These two important inorganic chemicals have a multitude of consumer-related end use products, such as polyvinyl chloride (PVC) plastic made from chlorine and pulping chemicals manufactured from caustic soda.

Beginning with this report, all data will be reported in metric units to comply with Public Law 100-418 of August 23, 1988. This Federal law required all Federal agencies to use the metric system of measurement by the end of fiscal year 1992. Although the use of the metric measurement standards was authorized by law since 1866 (Act of July 28, 1866; 14 Statute 339) and the United States was an original signatory party to the 1875 Treaty of the Meter (20 Statute 709), the United States has been the only industrially developed nation that has not universally converted to the metric system from the English system of measurements. Therefore, all data in this report are in metric tons unless overwise noted. For comparison, 1 metric ton is equal to 2,204.62 pounds whereas 1 short ton is equal to 2,000 pounds. To convert metric tons to short tons, multiply the metric ton figure by 1.10231. To convert short tons to metric tons, divide by 1.10231.

As foreign trade of salt with the United States increases and foreign

participation in U.S. salt companies continues, such as with the U.S. subsidiaries of Akzo Salt and Basic Chemicals International of the Netherlands and Sifto Canada of Canada, communicating information with an international standard of measurement becomes more important.

DOMESTIC DATA COVERAGE

Domestic production data for salt are developed by the U.S. Bureau of Mines (USBM) from an annual voluntary survey of U.S. salt-producing sites and of company operations. Of the 70 operations to which a survey request was sent, 68 responded, representing 97% of the total production shown in this report. Production for the nonrespondents was estimated on the basis of their prior response to the 1992 production estimate survey or brine production capabilities for chloralkali manufacture based on chlorine production capacities.

BACKGROUND

Salt has been an important commodity throughout history. Its presence has determined the location of cities, migration of populations, and routes of trade caravans. One of the earliest accounts of using salt in politicaleconomic societies was traced to 2200 B.C. in China where Emperor Hsia Yu decreed that Shandong Province would supply the court with salt. The Phoenicians (1200 B.C.-300 B.C.) were one of the first maritime civilizations to trade salt. Salt became an important universal medium of exchange. English word "salary" is derived from the Latin term "Salarium argentum," which

were the salt rations that Roman soldiers were partially paid for their services. Aside from its use as a medium of monetary exchange, salt also has been used to signify hospitality. The custom of presenting newlyweds wine, bread, and salt shows salt as a lifegiving and sustaining substance. In many areas of the world, it is still the custom for the host to offer bread and salt upon entering the home. The custom is also practiced "out of this world"—it has been a tradition that all former U.S.S.R. staffed spaceflights carry aloft bread and salt and leave them behind on the orbiting space station as presents for the next visiting crew.

The first production of salt in the United States was in 1614 by the Virginia colonists who evaporated seawater. The practice of extracting salt from subsurface brine was first employed in the United States at Onondaga, NY, in 1788. The first salt "mine" in the United States was dug in 1799 at Saltville, VA. A 1.8meter-wide by 61-meter-deep (6-footwide by 200-foot-deep) shaft was dug to the top of the salt formation before ground water flooded the workings. The saline water in the shaft provided the feedstock to iron kettles, in which the water was evaporated and the salt recovered. In 1862, the first commercial rock salt mine in North America began operating at Avery Island, LA. Solution mining of salt began in about 1882 and consisted of drilling a small diameter well down to a salt bed, pumping freshwater down to dissolve the salt, and pumping the resultant brine to the surface for subsequent evaporation. In 1887, the vacuum pan was adopted for salt production, which incorporated a vacuum during evaporation to allow the water to

boil from the brine at a lower temperature. This technological achievement reduced fuel consumption below that of direct-heated units.

Definitions, Grades, and Specifications

Technically, salt is a generic term that describes compounds formed by the partial or complete replacement of the hydronium ion of an acid by a metal or metallic radical. Water and salts are the end products from the chemical reaction between acids and bases. Through time, however, "salt" has become synonymous with sodium chloride (common salt) and will be considered synonymous throughout this chapter.

Naturally occurring sodium chloride is mineralogically known as halite. Pure salt contains 39.3% sodium and 60.7% chlorine by weight. Halite deposits usually contain between 1% and 4% impurities, mainly gypsum, shale, dolomite, and quartz. Rock salt is halite that is mined underground by conventional room-and-pillar techniques.

Evaporated salt is the term applied to fine crystals of salt obtained by evaporating brines, either natural or manufactured from solution mining, in large, vacuum-enclosed or open steamheated kettles. Solar evaporated salt is the product harvested from shallow ponds after the brine has been exposed to solar and wind evaporation.

The physical characteristics of salt vary with the type of production process. Salt specifications from vacuum pan operations are the same because the process is similar throughout the country. Rock salt, however, can vary in color and composition with locality, and these characteristics influence the specifications of the final product. Some impurities must be removed by chemical treatment or filtration to meet specifications for certain end uses.

There are various standards issued by different organizations that apply to salt. These standards may vary, depending on the intended end use. For example, salt for human consumption requires different specifications than those of salt for deicing highways.

Uses and Products for Trade and Industry

Salt for human consumption is packaged in different sized containers for several specialized purposes. Table salt may contain 0.01% potassium iodide as an additive that provides a source of iodine that is essential to the oxidation processes in the body. Kosher salt, seasalt, condiment salt, and salt tablets are special varieties of salt.

Water conditioning and animal feedstock salt are made into 22.7-kilogram (50-pound) pressed blocks. Sulfur, iodine, trace elements, and vitamins are occasionally added to salt blocks to provide missing nutrients not found naturally in the diet of certain livestock. Salt is also compressed into pellets and used for water conditioning.

There are reportedly about 14,000 different direct and indirect uses of salt. The USBM annually surveys 8 major categories comprising 29 separate end uses.

Chemical.—The greatest quantity of salt used in the chemical industry is by the chloralkali sector. Traditionally, the chloralkali sector included salt consumed for chlorine, coproduct sodium hydroxide (also known as caustic soda and lye), and synthetic soda ash. Since 1986, when the last synthetic soda ash plant closed because of high production costs and competition with less expensive natural soda ash, no synthetic soda ash has been manufactured in the United States. Aside from a few economic deposits of natural soda ash, several countries in the world continue to use salt for synthetic soda ash production.

Salt is used as the primary raw material in chlorine manufacture because it is an inexpensive and widely available source of chlorine ions. For sodium hydroxide production, salt is the main source of sodium ions. About 97% of the domestic chlorine and sodium hydroxide produced is obtained from the electrolysis of salt brine feedstock using three different cell technologies. The types of cells and percent chlorine manufactured by them are diaphragm,

75%; mercury, 16%; and membrane, 6%. It takes about 1.59 metric tons, (1.75 short tons) of salt to make 1.0 ton of chlorine and 1.1 tons of coproduct caustic soda. The electrolytic process ionizes the sodium chloride compound and selectively allows the ions to migrate through special membranes. Chlorine gas forms at the anode while sodium ions bond with water molecules at the cathode to form sodium hydroxide with hydrogen gas evolving.

Chlorine and caustic soda are considered to be the first generation of products made from salt. These two chemicals are further used to manufacture other materials, which are considered second generation products from salt.

Salt is also used as a feedstock by chemical establishments that make sodium chlorate (by the electrolysis of an acidified salt brine using hydrochloric acid adjusted to a pH of 6.5), metallic sodium (by the electrolysis of a molten salt mixture containing 33.2% sodium chloride and 66.8% calcium chloride. which is added to reduce the melting temperature of salt). and downstream chemical operations. powdered soaps and detergents, salt is used as a bulking agent and as a coagulant for colloidal dispersion after saponification. In pharmaceuticals, salt is a chemical reagent and is used as the electrolyte in saline solutions. It is also used as a cofeedstock with sulfuric acid sodium sulfate to produce hydrochloric acid. This subsector is relatively small, representing only 10% of domestic salt sales for the entire chemical sector and only 5% of total domestic salt consumption.

Food Processing.—Every person uses some quantity of salt in his or her food. The salt is either added to the food by the food processor or by the consumer through free choice. Salt is added to food as a flavor enhancer, preservative, binder, fermentation control additive, texture aid, and color developer. This major category is subdivided into six applications, in descending order of salt consumption: meatpackers, canning, other food processing, baking, dairy, and

grain mill products.

In meatpacking, salt is added to processed meats to promote the color development in bacon, ham, and other processed meat products. preservative, salt inhibits the growth of bacteria, which would lead to spoilage of the product. Early pioneers used to store their perishables in salt barrels for protection and preservation. Salt acts as a binder in sausages to form a binding gel composed of meat, fat, and moisture. Salt also acts as a flavor enhancer and a tenderizer. In canning, salt is primarily added as a flavor enhancer and preservative. It also is used as a dehydrating agent, tenderizer, enzyme inhibitor, and as a carrier for other ingredients.

In the "other food processing" category, salt is used mainly as a seasoning agent. Other food processing includes miscellaneous establishments that make food for human consumption (i.e., potato chips, pretzels) and domestic pet consumption (i.e., dog and cat food). In baking, salt is added to control the rate of fermentation in bread dough. It also is used to strengthen the gluten (the elastic protein-water complex in certain doughs) and as a flavor enhancer, such as a topping on baked goods. In the dairy industry, salt is added to cheese as a fermentation control agent and as a color and texture control agent. The dairy subsector includes that companies manufacture creamery butter, natural and processed cheeses, condensed evaporated milk, ice cream, frozen desserts, and specialty dairy products. The final food processing category is grain mill products, which consists of milling flour and rice and manufacturing cereal breakfast food and blended or prepared flour.

General Industrial.—The industrial uses of salt are diverse. They include, in descending order of salt usage, oil and gas exploration, metal processing, other industrial, pulp and paper, textiles and dyeing, tanning and leather treatment, and rubber manufacture.

In oil and gas exploration, salt is an important component of drilling fluids in

well drilling. It is used to flocculate and to increase the density of the drilling fluid to overcome high down-well gas pressures. Whenever drilling activities encounter salt formations, salt is added to the drilling fluid to saturate the solution and minimize the dissolution within the salt strata. Salt is also used to increase the set rate of concrete in cemented casings. In metal processing, salt is used in concentrating uranium ore into uranium oxide (yellow cake). It is also used in processing aluminum, beryllium, copper, steel, and vanadium.

In the pulp and paper industry, salt is used to bleach wood pulp. It also is used to make sodium chlorate, which is added along with sulfuric acid and water to manufacture chlorine dioxide—an excellent oxygen-base bleaching chemical. Although the chlorine dioxide process originated in Germany after World War I. it is becoming more popular because of environmental pressures to reduce or chlorinated bleaching eliminate compounds. In textiles and dyeing, salt is used as a brine rinse to separate organic contaminants, to promote "salting out" of dyestuff precipitates, and to blend with concentrated dyes to standardize them. One of its main roles is to provide the positive ion charge to promote the absorption of negatively charged ions of dyes. In tanning and leather treatment, salt is added to animal hides to inhibit microbial activity on the underside of the hides and to replace some of the moisture in the hides. In rubber manufacture, salt is used to make neoprene rubber, white rubber, and buna rubber. Salt brine and sulfuric acid are used to coagulate an emulsified latex made from chlorinated butadiene.

Agricultural Industry.—Since prehistoric times, humankind has noticed that animals satisfied their salt hunger by locating salt springs, salt licks, or playa lake salt crusts. Barnyard and grazing livestock need supplementary salt rations to maintain proper nutrition. Veterinarians advocate adding loose salt in commercially mixed feeds or in block forms sold to farmers and ranchers. Salt also acts as an excellent carrier for trace

elements not found in the vegetation consumed by grazing livestock. Sulfur, selenium, and other essential elements are commonly added to salt licks, or salt blocks, for free-choice feeding.

Water Treatment.—Approximately 1.2 trillion liters (325 billion gallons) of water is used daily in the United States for residential and commercial uses. Many areas of the United States have "hard" water, which contains excessive calcium and magnesium ions that contribute to the buildup of a scale or film of alkaline mineral deposits in household and industrial equipment. Commercial and residential watersoftening units use salt to remove the ions causing water hardness. The sodium ions captured on a resin bed are exchanged for the calcium and magnesium ions. Periodically, the water-softening units must be recharged because the sodium ions become depleted. Salt is added and dissolved, and the brine replenishes the lost sodium ions.

Ice Control and Road Stabilization.— The second largest end use of salt is for highway deicing. Gabriel Daniel Fahrenheit, the developer of the Fahrenheit temperature scale (° F), discovered that salt mixed with ice (at a temperature below the freezing point) creates a solution with a lower freezing point than water by itself. The brine forms below the surface of the ice and snow and prevents the water from freezing into ice and bonding with the road surface. Therefore, salt causes snow and ice to melt. Salt is an inexpensive, widely available, effective ice control agent. It does, however, become less effective as the temperature decreases below about -9.4° C to -6.7° C (15° F to 20° F). At lower temperatures, more salt would have to be applied to maintain higher brine concentrations to provide the same degree of melting. Most winter snow storms and ice storms occur between -3.9° C to 0° C (25° F and 32° F), a range in which salt is most effective.

In highway deicing, salt has been associated with corrosion to motor

vehicles, bridge decks, unprotected steel structures, and reinforcement bar and wire used in road construction. Surface runoff, vehicle spraying, and windblown actions also affect roadside vegetation, soil, and local surface and ground water supplies. Although there is evidence of environmental loading of salt during peak usage, the spring rains and thaws usually dilute the concentrations of sodium in the area.

Salt is also added to stabilize the soil and to provide firmness to the foundation on which highways are built. The salt acts to minimize the effects of shifting caused by changes in humidity and traffic load in the subsurface.

Distributors.—A tremendous amount of salt is marketed through various distributors, some of which specialize in certain markets such as agricultural and water-treatment services. In addition to these two categories, distributor sales include grocery wholesalers and/or retailers, institutional wholesalers, U.S. Government resale, and other wholesalers and retailers.

Other.—The other uses of salt include categories not discussed above.

Geology-Resources

The definitions of reserves and reserve base are published in the U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals."

The oceans are the world's largest resource of salt. Seawater contains 3.5% dissolved solids by weight with sodium chloride representing the major component, approximately 2.5% by weight. The world's oceans contain about 42 x 10¹⁵ tons (46 x 10¹⁵ short tons) of sodium chloride, which is equivalent to 530 million cubic kilometers (4.5 million cubic miles) in volume or a cube measuring 795 kilometers (165 miles) on edge.

Domestic salt resources are found mainly in four large depositional basins, covering an area totaling about 0.2 million square hectacres (0.5 million square miles) in 18 States. These basins are (1) the gulf coast, which covers part of Florida, Alabama, Mississippi, Arkansas, eastern Texas, and all of Louisiana; (2) the Permian, which is in part of New Mexico, Colorado, Kansas, Oklahoma, and Western Texas; (3) the Salina, covering part of New York, Pennsylvania, West Virginia, Ohio, and Michigan; and (4) the Williston, encompassing part of North and South Dakota, Montana, and Wyoming. The gulf coast and Permian basins extend into Mexico: the Salina and Williston both extend into Canada. The identified salt resources of the United States are estimated at 55 x 10^{12} tons (61 x 10^{12} short tons) and are being depleted at the rate of about 35 million tons (39 million short tons) annually. At the present level of production, the United States has enough salt to mine for more than 1.6 million years. Solar evaporation of coastal seawater would extend this rate virtually forever.

Salt can be geologically classified by its occurrence as evaporite deposits and in solutions.

Evaporite Deposits.—Bedded, diapiric flow, and playa salts are the major types of dry salt deposits. Bedded salt deposits were formed by the accumulation of precipitated salts on the sea floor of ancient landlocked marine bodies of water. Extensive and widespread evaporation was essential to form these massive rock salt deposits, some of which measure up to 914 meters (3,000 feet) in thickness.

Salt domes form when vertical or lateral pressures are applied to stratified salt deposits in which low-density salt will flow plastically through the surrounding rocks of higher density. The salt domes of Romania, Germany, and the gulf coast of the United States are examples of diapiric salt flows. The appearance is usually cylindrical with circular or elliptical diameters. A cap rock of anhydrite is common with overlying layers of gypsum and calcite. Oil, gas, and sulfur are associated with many domes and represent large mineral

resources. There are 329 proven salt domes in the gulf coastal province and offshore regions of the United States. Louisiana has 183 domes onshore and offshore; Texas, 83; Mississippi, 61; and Alabama, 2.

Playas are flat, vegetation-free floors of an undrained desert basin that may occasionally be covered by water. Postevaporation minerals such as sodium carbonate, sodium sulfate, sodium chloride, borates, nitrates, phosphates, and potash result from the leaching of the rocks surrounding the basin by water flowing into the playa. Searles Lake in California is a classic example of a saltbearing playa lake.

Salt in Solution.—Ocean, lake, and ground water are the primary aqueous mediums in which salt is dissolved. Seawater contains many dissolved minerals, the major one being sodium chloride. Other dissolved minerals include various sulfate, magnesium, calcium, and potassium compounds.

Water tends to accumulate on land in topographic depressions created by tectonic uplifts or subsidences of the Earth's upper crust. As mineralized solutions from upland sources drain into these basins, solar evaporation concentrates the salts to form saline lakes. The Aral Sea in the former U.S.S.R., Great Salt Lake in Utah, and the Dead Sea between Jordan and Israel are examples of this process.

Ground water is composed of mineralized connate and meteoric water found in permeable sedimentary formations. In some areas, sodium chloride-rich brines migrate to the surface through intersecting fractures and joints in the rock strata to form local salt These springs have attracted springs. animals because they are a source of salt. The springs also indicate where buried salt deposits are located. The salt springs at Saltville, VA, are an example of a locality that was developed based on an occurrence of salt springs.

Technology

Exploration.—Exploring for new salt deposits is based on examination of various geochemical and geophysical information. Analysis of the underlying strata by core drilling, oil and water well logs, or other techniques is the basis for establishing the size of the deposit. Usually the most favorable areas for mine development will be near the market regions and convenient transportation routes.

The development of mines incorporates strict safety precautions while permitting for the maximum economic recovery of salt. During shaft sinking, water-bearing strata may be encountered, and waterproofing techniques must be employed to prevent mine flooding. At least two access shafts are constructed in room-and-pillar mines to provide adequate safety and ventilation.

Mining.—Rock Salt.—Rock salt is mined by the room-and-pillar method, which is similar to that used in coal and trona mining. The salt is drilled, cut, blasted, mucked, crushed, and transported to the surface for processing, which usually involves removing the impurities and screening the material to finer size fractions.

Underground mining practices of bedded rock salt and domal salt formations are similar except for the height differences within the mines of the two types of operations. For example, bedded formations usually are laterally extensive but are vertically restricted. Salt domes are laterally restrictive but are vertically extensive. Many salt domes have depths in excess of 6,100 meters (20,000 feet), yet many outcrop at the surface. Most gulf coast salt mining operations are generally less than 300 meters (1,000 feet) below the surface. Working at deeper depths is difficult because of higher temperatures and denser rock.

Solar Evaporation.—Solar evaporation is an effective method of producing solar

salt in areas of high evaporation and low precipitation. Along coastal margins in many parts of the world, seawater is collected and allowed to evaporate in specially constructed evaporating ponds. Saline lakewater is also processed using this method. The ponds are separated by levees that isolate the brine during different stages of fractional crystallization.

The initial step concentrates the brine to increase the salinity and allow many calcium, magnesium, and iron compounds to precipitate from solution. The brine is network circulated among а interconnecting ponds, with salinity increasing with each transfer. The brine is then treated with lime to remove excess calcium sulfate and then pumped to evaporation ponds and then transferred to harvesting ponds to permit the salt to crystallize. After about 85% of the salt is precipitated, the remaining supernatant liquid, called "bitterns," can be drained to adjacent ponds for subsequent extraction of magnesium, potassium, bromine, and sodium compounds. The harvesting pond is flooded again with new brine from the lime pond to repeat the cycle. It takes about 5 years once seawater is first introduced into the system for the completion of the crystallization process. The salt is harvested by special tractors equipped with scrapers and ready for processing.

Solution Mining.—The first reported use of solution mining was about 250 B.C. in China when holes were drilled into deep salt deposits. The brine was brought to the surface by pipes made of bamboo. The brine was evaporated over fires fueled with wood, coal, or natural gas. The basis of current technology began in France about A.D. 858. An injection well is sunk, and pressurized freshwater is introduced to hydraulically fracture the bedded salt. Once communication with the production well is established, the brine is pumped to the surface for treatment.

Roof collapse of the overlying strata and surface subsidence are potential problems associated with solution mining; however, producers have taken precautions to minimize these hazards. One method that was once used was injecting air with the water into the salt caverns. The air formed a protective cover between the water and the top of the cavity that reduced the amount of dissolution of the roof.

Processing.—Rock Salt.—About 52% of total rock salt produced and imported is for highway deicing. Crushing and screening to the proper physical size is usually the only processing that road salt undergoes. In many operations, these steps are done underground in the mine to minimize haulage and storage costs. In addition, the extremely fine fraction, which often is unusable, remains underground rather than on the surface, which would represent a waste product to be disposed.

Solar Salt.—After harvesting, the salt crystals are washed with dilute brine to remove residual bitterns and impurities. The salt is transferred to processing facilities where it is washed with saline water, dried for about 8 minutes at approximately 300° F, and screened into fine to coarse sizes, depending on the end use of the salt to be sold. Most operations ship solar salt in bags and in bulk, using barges, truck, and rail transportation.

Mechanical Evaporation.—Salt obtained by dehydrating brine using heat alone or in combination with a vacuum is vacuum pan salt. The vacuum pan process conserves energy by utilizing multiple-effect evaporators connected to vacuum pumps. A saturated salt solution will boil at a higher temperature than pure water. When a vacuum is applied, the brine boils at a lower temperature, enabling the superheated vapor that is generated to act as the heating medium for the next evaporator.

The grainer or open pan process uses open, rectangular pans with steam-heated immersion coils to evaporate the water in the brine. Rotating rakes scrape the salt precipitate into a sump or up a ramp, depending on the method, and onto conveyors for debrining and drying

treatment. The final product is usually flake shaped rather than the typical cubic form. Flake salt is preferred for production of cheese, butter, and baked goods.

The Alberger process is a modified grainer operation that produces cubic salt with some flake salt. The pans are shallow, circular units with external heating units, rather than heating coils. The open pan process cannot be operated successfully in regions with high humidities because the evaporation rate is too slow and more energy is required to evaporate the brine.

Desalination.—The conversion of saline water into freshwater has important municipal, industrial, and agricultural applications. Aside from obtaining pure water, desalination also produces byproduct salt. There are four processes presently employed in water desalinization, and each has different cost and energy factors. The processes are distillation, membrane, freezing, and ion exchange. Some salt from these processes is used by the chemical industry. In some regions, salt is returned to the saline water source. Seawater typically contains 3.5% to 4.5% salt, or 35,000 to 45,000 parts per million. The standard for drinking water in the United States is 500 parts per million.

Byproducts and Coproducts

Salt is a coproduct from various seawater and saline lake operations. Depending on the cost of recovery and processing. certain magnesium, potassium, and bromine compounds can produced from the bitterns. Subterranean brines also contain borax. calcium chloride, sodium carbonate, and sodium sulfate in addition to the above. Certain potash operations in the world also produce salt as a coproduct. When discharged to tailing ponds as a byproduct of potash mining, salt is often harvested and sold by second parties.

Economic Factors

Energy and labor costs are important factors that affect production costs, and ultimately the selling price, for all types After the salt is produced, of salt. shipping costs become very important when attempting to sell to a customer that is in proximity to other salt producers. Industry sources indicate that within the United States, a 485-kilometer (300-mile) radius is an effective limit of competition for a producing location before the influence of other competitors is noticed. Some of the major U.S. producers also have foreign subsidiaries that produce salt, which is imported at prices favorable to many consumers because transportation costs are less.

Capital investment and energy costs are important factors that influence the selling price of the type of salt produced. Vacuum pan and open pan processing requires more equipment and energy than solution mining, and consequently, the average value of evaporated salt is considerably higher than that of salt in brine.

Prices.—The four types of salt that are produced each have unique production. processing, and packaging factors that determine the selling prices. Generally, salt sold in bulk is less expensive than salt that has been packaged, pelletized, or pressed. Salt in brine is the least expensive salt sold because costs are less. Vacuum pan salt is the most expensive because of the energy costs involved in processing. Table 2 lists the historical values of the different types of salt since 1973. The data are compared with 1992 constant dollars to show the effect of inflation and general economic conditions on the values. (See table 2.)

Tariffs.—The United States historically imports more salt than it exports. In 1992, U.S. salt imports were more than five times the level of salt exports. Imports from countries having most-favored-nation (MFN) status enter duty free. However, salt imported from non-MFN countries have a 26% ad valorem

tax imposed. The non-MFN countries are Afghanistan, Albania, Azerbaijan, Byelarus, Cuba, Georgia, Kampuchea, Kazakhstan, Laos, North Korea, Romania, Tajikistan, Turkmenistan, Uzbekistan, and Vietnam.

Operating Factors

Environmental Requirements.—The environmental problems associated with salt mining are few and tend to be localized without major impacts on the environment. A major concern in solution mining is the potential of land subsidence. As the salt is dissolved, some roof collapse may occur, causing sections of the surface to partially or totally fill the cavity. Subsidence is unpredictable, and once the process begins, it must be allowed to finish and reach equilibrium. Another issue pertaining to solution mining is the potential problem of well casing leakage. Any excursion of salt brine could affect ground water supplies, which are protected by various State and Federal water quality regulations. evaporation facilities may substantially disturb coastal marsh areas because of the large extent of the lagoons needed for efficient operation.

Environmental Issues.—The USBM has been actively assessing environmental issues pertaining to the type and quantity of waste generated in the different steps from mining through postconsumption for many commodities. Some waste that traditionally may have been discarded after mining and processing may be recovered for reuse: other waste in the form of discarded consumer products may be recycled to reclaim various valuable raw materials. Several material flow studies have been completed by the USBM that trace the flow of a commodity from "cradle to grave." A material flow study on salt was conducted by this author.

Salt was selected as a commodity to study because it had a couple of associated environmental issues, such as the environmental effects from deicing salt and salt used in water treatment. In addition, there were issues pertaining to some of the downstream uses, such as in PVC manufacture, that uses salt as feedstock. Cumulative historical data on salt consumption for highway deicing indicates that 243 million tons (268 million short tons) has been applied to the Nation's roads since 1940, when salt usage for this purpose first became significant. Although there are several site-specific studies that have been done to measure the concentration of salt in the soil and ground water from deicing runoff, there is no indication of any serious and permanent ill-effects from the use of about one-quarter billion tons of salt in the 50 years that salt has been used.

After analyzing all the categories that salt is used in, it is estimated that about three-fourths of the domestic salt consumed is released to the environment and unrecovered while about one-fourth is discharged to landfills, incinerated, or recycled as consumer products derived from salt, such as PVC plastic containers. For further information about the study, please refer to USBM Information Circular IC-9343, "The Material Flow of Salt."

Employment.—According Bureau of Labor Statistics, 1,285 people were employed in the mining and processing of rock salt in 1992. Of the 11 rock salt facilities surveyed, 784 personnel worked 1.42 million hours underground, 264 people worked 521,425 hours on surface duties, and 237 people worked 538,445 hours in the mills. There were 187 people who worked 396,078 hours in the office. Total employment in the domestic rock salt industry amounted to 1,472 individuals who worked a total of 2,880,794 hours. Employment data for solar salt, vacuum pan salt, and salt in brine were incomplete or not surveyed by the Bureau of Labor Statistics.

Transportation.—The locations of the salt supplies often are not in proximity of the consumers' location, and

transportation can become an important cost. Pumping salt brine through pipelines is an economic means of transportation, but cannot be used for dry salt. Large bulk shipments of dry salt in ocean freighters or river barges are low in cost, but are restricted in points of origin and consumption. River and lake movement of salt in winter is often severely curtained because of frozen waterways. As salt is packaged, handled, and shipped in smaller units, the costs are increased and are reflected in higher selling prices.

Oceanborne imports of salt have been increasing in some areas of the United States because they are less expensive with respect to transportation costs than what could be purchased from many domestic suppliers using rail transportation. Salt continued to be one of the most heavily traded chemical industry ores in the world, representing about 66% of world seaborne mineral trade according to a study done in 1989.

ANNUAL REVIEW

Strategic Considerations

Hunter Industrial Facilities Inc. continued its efforts to apply for permits to store hazardous waste in a salt dome near Dayton in Liberty County, TX. Construction of the \$70 million underground repository had been delayed for more than 1 year already because of delays in obtaining the necessary permits. The Texas Water Commission that is involved in the permit process developed new regulations governing waste storage in salt domes. It held public hearings to hear concerns of local residents. Hunter and Secured Environmental Management Inc., a second company with a waste storage project slated for Boling, TX, had not learned of the decision by the commission by yearend regarding Hunter's effort to obtain its permits.1

The U.S. Department of Energy issued a Draft Environmental Impact Statement on the proposed plan for the final 250 million barrel segment of the 1 billion barrel Strategic Petroleum Reserve (SPR). Two new underground crude oil

storage facilities are to be constructed from five salt dome candidates in Louisiana, Mississippi, and Texas: Cote Blanche in St. Mary Parish, LA: Weeks Island in Iberia Parish, LA; Richton in Perry County, MS: Big Hill in Jefferson County, TX: and Stratton Ridge in Brazoria County, TX. North American Salt Co. and Morton International presently operate rock salt mines in the first two domes, respectively.² The SPR has 750 million barrels of storage capacity distributed among five salt domes in Louisiana and Texas: Weeks Island, Bayou Choctaw, and West Hackberry, LA, and Bryan Mound and Big Hill, TX. Although comments would be accepted until December 29, 1992, no decision on which two sites would be made until May 1993.

Issues

A survey of chemicals used by the domestic pulp and paper industry was conducted by the American Forest and Paper Association. Its results showed a declining trend in chlorine consumption and a rising use of alternative bleaching agents. The association estimated that the industry's use of chlorine will decline 50% to 70% by 1995 from the level of the late 1980's. Production of sodium chlorate. an alternative bleaching chemical derived from salt, was estimated to grow from 650,000 tons in 1990 to 1.05 million tons by 1996, or about 62%.

The U.S. Environmental Protection Agency (EPA) continued its reassessment of the dioxin risk. EPA presently lists dioxins as "probable" carcinogens and not "known" carcinogens. Although its draft report showed that the danger to human beings from dioxin exposure is small, except for groups that live near or work in chemical plants that produce or dispose of dioxin, EPA also reported that the danger of dioxins to fish and other animals was greater than previously believed. The final report had not been published by yearend.³

In a separate investigation, a study was completed by the Institute of Paper Science and Technology and Batelle Laboratory for the Chlorine Institute.

The report studied the mechanisms of dioxin formation in pulp mills and found that dioxin could be reduced by pretreating the dioxin precursors in the wood. In addition, adsorbable organic halide levels in effluents could be reduced by 50% using an anaerobic-aerobic process.4

Production

The Retsof Mine in Livingston County, NY, owned by Akzo Salt Inc., reportedly is the largest room-and-pillar underground mine in the Western Hemisphere. Since production began in the 1880's, more than 100 million tons of rock salt has been extracted from the mine 335 meters (1,100 feet) below the surface, leaving behind more than 40,000 separate "rooms" comprising about 61 million cubic meters (80 million cubic yards) of space. These abandoned cavities are being considered as potential storage sites for waste incinerator ash. Akzo is evaluating a process that would allow industrial byproducts, such as incinerator ash, fly ash, and cement kiln dust, to be combined with a 10% mixture of portland cement and slurried using salt brine. The slurry would be discharged underground in the empty cavities where it would harden into a chemically and physically stabilized cementlike material suitable for mine backfilling. backfilling would improve mine stability by reducing subsidence, and the salt brine in the slurry would reduce discharge of saline water into the Genesee River. Between 4,000 to 8,000 tons of ash is expected to be processed and slurried daily. Aside from providing Akzo with additional revenue and a more uniform income flow to offset any occasional poor-seasonal salt sales, the proposed project also would reduce the future quantity of industrial byproducts landfilled, thereby lessening the impact on the environment. There also is the possibility that certain ferrous metals, which comprise about 20% of the municipal waste incinerator ash by weight, could be magnetically separated from the ash and recycled.⁵

1992, 28 companies operated 67 saltproducing plants in 14 States, as shown in figure 1. Nine of the companies and 11 of the plants produced more than 1 million tons each and accounted for 92% and 56%, respectively, of the U.S. total. Several companies and plants produced more than one type of salt. In 1992, 12 companies (15 operations) produced solar-evaporated salt; 5 companies (17 operations), vacuum pan salt; 10 companies (14 operations), rock salt; and 15 companies (31 operations), salt brine. (See tables 1, 3, 4, and 5 and figure 1.)

The five leading States in terms of total salt sold or used were Louisiana, 35%; Texas, 23%; New York, 14%; and Kansas, 5%. Although Louisiana, New York, and Ohio were major rock saltproducing States, a substantial amount of salt was produced in Alabama, Kansas, Louisiana, New York, Ohio, Texas, Utah, and West Virginia as brine for the chemical industry. (See table 6.)

U.S. salt production accounted for about 20% of total world production. Production and trade of salt increased slightly compared with the previous year. World production of all types of salt decreased slightly. The depressed market for chlorine and environmental problems associated with emissions of chlorinated compounds may affect the short-term status of the world chloralkali industry, which is the largest single consumer of

Consumption and Uses

The Transportation Research Board, which is a committee under the National Research Council of the National Academy of Science, issued a report that compared salt and calcium magnesium acetate (CMA) as highway deicing agents. The report was completed for the Federal Highway Administration at a cost of \$212,230. The committee concluded that rock salt remained the more effective and practical deicer at a lower cost per ton. The full range of relative costs was measured of the alternative deicer's affect on road structures, motor vehicles, bridges, drinking water, and vegetation. According to the USBM survey for | The large-scale use of CMA as a general

replacement for salt was determined to be unlikely and unwarranted.6

More than 37.8 million tons of domestic and imported salt was consumed in the United States in 1992, based on the annual survey of the U.S. salt producers. Some of the data submitted by one of the major domestic producers appeared to understate sales to the ice control sector and overstate sales to the "miscellaneous" The reported percent category. distribution of salt by major end use was chemicals, 44%; ice control, 21%; distributors, 11%; food and agricultural, 7%; industrial, 7%; primary water treatment, 1%; and other combined with exports, 9%. Distributors represent a substantial share of salt sales by the salt industry; however, all the salt ultimately is resold to many end users. Some customers have specific uses. For a more complete analysis of end-use markets, specific sectors of distribution in table 7 can be combined, such as agricultural and water conditioning with agricultural and water conditioning distribution, respectively.

The chemical industry is the largest consumer of salt, primarily salt brine. Although most salt brine is captively produced by chemical producers, many chloralkali manufacturers now purchase brine from independent brine supply companies. In certain cases, brine is captively produced by one chemical company, and any excess brine is sold to neighboring competitors. According to a survey of domestic salt-based chlorine facilities, about 48% of the salt used to manufacture chlorine was captive and 31% was purchased brine. Purchased solar or rock salt comprised 12% and imported rock, solar, and vacuum pan salt was 9%. (See tables 7 and 8.)

Using Bureau of the Census data, the chlorine and caustic soda industry consumed about 17.8 million tons (19.6 million short tons) of salt for feedstock, based on the industry average ratio of 1.75 tons of salt required to produce 1.0 ton of chlorine and 1.1 tons of coproduct sodium hydroxide. Reported consumption of total domestic and imported salt for chlorine manufacture was 15.1 million tons, as noted in table 7. The difference

between the calculated and reported quantities was the amount of salt unreported to the USBM from imports or captive brine production of chloralkali producers. Production of chlorine gas and liquid sodium hydroxide, as reported by the Bureau of the Census and The Chlorine Institute, is shown in table 9. (See table 9.)

There are approximately 18 domestic companies that operate 38 chlorineproducing plants that used only salt as feedstock. Estimates were made on the capacity chlorine production individual plants. Based on these estimates and using Bureau of the Census chlorine production data, the U.S. saltbased chlorine industry operated at 88% of capacity. According to The Chlorine Institute, the industry operated at an average of 89% of nominal capacity and 94% of effective capacity in 1992. Because these capacities include chlorine produced from nonsalt sources; i.e., from the electrolysis of magnesium chloride and the oxidation of hydrochloric acid, these data may differ from other reported chlorine capacity utilization information.

Stocks

Total yearend stocks reported by producers were 2.5 million tons. Most of these inventories were rock salt and solar salt. Many States, municipalities, distributors, and road-deicing contractors stockpiled additional quantities of salt in anticipation of adverse weather conditions.

Markets and Prices

Price quotations are not synonymous with average values reported to the USBM. The quotations do not necessarily represent prices at which transactions actually occurred, nor do they represent bid and asked prices. They are quoted here to serve only as a reference to yearend price levels. Yearend prices were quoted in Chemical Marketing Reporter, as shown in table 10. (See tables 10 and 11.)

Foreign Trade

Under the Harmonized Tariff Schedule nomenclature, imports only have one category known as "Salt (including table and denatured salt) and pure sodium chloride, whether or not in aqueous seawater." The solution. same classification also applies to exports. The trade tables in this report list the previous and current identification codes for salt. Figure 2 shows the quantity and customs value for salt imports and exports in 1992 and the location of the customs districts within the Nation. The United States is divided into three regions so that each region has at least three salt producers for each type of salt. Three are required to avoid disclosure of company proprietary Figures 3 and 4 show the distribution by region for domestic salt sales and consumption. (See figures 2, 3,

Based on Bureau of Census statistics, the United States imported 5.39 million tons (5.95 million short tons) in 1992, or about 5.4 times more than the quantity of salt that it exported. Although this would indicate that the United States is import reliant on salt to meet its salt requirements, the majority of imported salt was brought into the country by foreign subsidiaries of major U.S. salt producers. Generally, imported salt can be purchased and delivered to many customers at costs lower than the comparable domestic product because production costs are lower abroad and currency exchange rates are more favorable.

The Journal of Commerce's Port Import/Export Reporting Service (PIERS) reported that 4.48 million tons (4.93 million short tons) was imported; however, PIERS data include only ocean freight and do not include salt shipped by rail or truck over the U.S. land borders with Canada and Mexico. Therefore. Census data and PIERS data often are dissimilar. Using PIERS data, Akzo Salt Co., Cargill Inc., Morton International, North American Salt Co. and Western Salt Co. imported 52% of the total imports. Six companies that manufacture chlorine, which was the single largest

domestic salt market, consumed 25% of total imports, which were primarily solar These companies were Atochem North America, Brunswick Pulp and Paper Co., Georgia Pacific Corp., LCP Chemical & Plastics Inc., Occidental Chemical Corp., and Weyerhaeuser Co. The salt and chloralkali producers imported 77% of total imports; the remainder were to many small direct buyers. Five domestic salt-producing companies exported 79% of the 315,946 tons (348,270 short tons) exported in 1992, according to PIERS. Tables 12 through 15 list the import and export statistics reported by the Bureau of Census for 1991 and 1992. (See tables 12, 13, 14, and 15.)

World Review

Table 16 lists world salt production statistics for 101 countries based on reported and estimated information. The unification of the two Germany's and the dissolution of the former U.S.S.R. and Yugoslavia in 1992 have modified the list of nations surveyed. World production decreased 4% in 1992 compared with that of the previous year. The decline was because of stagnant economic conditions in many world industries that consume salt, reduction in salt brine usage for worldwide chlorine manufacture, and the changes brought about in the political, social, and economic situations in the former U.S.S.R. and Yugoslavia that affected salt consumption. (See table 16.)

Industry Structure.—The United States remains the world's leading salt-producing nation, representing about one-fifth of total world production. The structure of the U.S. industry has changed throughout the years. In 1970, there were 50 companies operating 95 plants in the United States. Market competition, energy and labor costs, less expensive imports, and an excess of production capacity reduced the size of the industry to 28 companies and 67 plants by 1992.

Most countries possess some form of salt production capability with production

levels set to meet their own domestic demand requirements with additional quantities available for export. Many developing nations tend to develop their agricultural resources first to feed their population. Development of easily extractable mineral resources follows, with salt being one of the first commodities to be mined. Some countries, such as the United States, import a substantial amount of salt to meet total demand requirements because of economic factors.

Capacity.—Each type of salt produced in the world has unique mining, processing, and marketing characteristics that determine the criteria for deriving rated capacities. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable longterm operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgement of the author, can be brought into production within a short period of time with minimum capital expenditure. Capacity data were derived from industry sources, published reports, and estimates based on production trends.

Rock.—Because the majority of rock salt was used for deicing, the operating rate of rock salt facilities fluctuated with the demand for deicing salt, again dependent on the severity of winter weather conditions. During periods of strong demand, production levels often achieve, or exceed in certain situations, the rated capacities. Full mine capacity generally is a function of the hoisting capabilities of the mines. Assuming that the workweek is 5 days (250 workdays per year), two working shifts and one maintenance shift per day, and at least one short-term planned turnaround for the mine and mill per year, the production capacities for domestic rock salt operations in 1992 was 15.78 million tons (17.39 million short tons).

Solar.—Solar salt, also known as marine and sea salt, is obtained from the solar evaporation of seawater, of landlocked bodies of saline water, and of discharged brines. Because evaporation rates must exceed the precipitation rates, the climatic conditions and geographic locations of solar evaporation facilities are critical to the successful production and harvesting of solar salt. Therefore, rated capacities generally are based on the historical evaporation patterns within a region and vary depending on the location and the surface areas of the evaporation Only unpredictable seasonal ponds. precipitation and market conditions usually affect the production, and market conditions usually affect the production rates of the facilities. In 1992, total domestic solar salt production capacity was 3.95 million tons (4.35 million short tons).

Vacuum Pan.—The mechanical evaporation of salt by the vacuum pan process is dependent on the number and size of the vacuum crystallizers operating in series. Rated capacities are usually easier to establish because of the proven design performance of the equipment. The total production capacity of the domestic vacuum pan salt producers in 1992 was 4.30 million tons (4.74 million short tons).

Brine.—Brine capacities are difficult to derive because they are based on the variabilities of the injection rate of the solvent and the solubility rates of the underground salt bodies. Both determine the quantity of brine produced. addition, production levels are dependent on the demand for the products that the brine is being used to manufacture. Therefore, brine production capacity is assumed to be equal to the quantity of brine produced annually. Although data cannot be published for individual companies, the aggregate domestic brine production capacity in 1992 was 17.57 million tons (19.37 million short tons), which was the total quantity of salt brine produced.

Australia.—A 2.5-million-ton-peryear solar salt facility is planned for construction south of Onslow on the east coat of the Exmouth Gulf in Western Australia. The A\$85 million project by Gulf Holdings Pty. Ltd. will create about 60 permanent jobs when the plant is in operation. The company has obtained environmental clearance and State Government endorsement for the solar salt works. The majority of the output will be sold to Asian industrial and chemical markets.⁷

China.—Construction is nearing completion on a solar salt facility along the northern area of the Fulandian Bay in Dalian, China. The project is slated to be completed in 1994 and is expected to produce 200,000 tons of salt annually.8

United Kingdom.—The U.S.-based D. George Harris and Associates Inc., which owns North American Salt Co., Great Salt Lake Minerals and Chemicals Corp., Carey Salt Co., and Sifto Salt of Canada, acquired the rock salt mine of Imperial Chemical Industries (ICI) at Winsford in Cheshire, England, in February 1992. The mine has been in operation since 1844 and supplies about two-thirds of the deicing salt used in the United Kingdom. The purchase also includes ICI's white salt business at Weston Point, Runcorn, Cheshire. The majority of this salt is used by the domestic chemical and animal feed markets. The salt company will operate as Salt Union Ltd., the historic name that was first used in 1888.

OUTLOOK

Because salt is the primary feedstock used to make a multitude of consumer products, the outlook for salt in the 1990's is optimistic. The privatizing of former state-owned salt operations in Eastern Europe and the commercializing of certain salt mines in the newly formed republics of the former U.S.S.R. will probably affect competition within those regions.

As many developing nations strive for self determination, salt will be one of the

1112 SALT—1992

first natural resources developed for trade because of its virtual universal existence. The United States is usually viewed as one of the first markets to be considered as a trading partner because of its large import-to-export ratio (5:1). Although the statistics show that the United States is import reliant, the majority of imported salt is under the control of the U.S. salt industry that imports through its foreign subsidiaries in Canada and in the Caribbean. Consolidations restructuring within the U.S. salt industry during the past several years have strengthened it into a competitive North American enterprise operating in the Western Hemisphere.

Total ¹	3,811	3,221	11,411	17,574	36,016

XX Not applicable.

Estimated. Revised.

¹Data may not add to totals shown because of independent rounding.

²Represents that amount sold or used captively within the industry, from the quantity produced and any sold from inventory. Accurate data on beginning and yearend inventories of salt are unavailable and often are underreported because of additional storage underground at mines, warehouses, terminals, etc. However, about 2.5 million tons is estimated to be stored annually nationwide.

The total quantities of salt in inventory are underreported and are excluded in determining the supply-demand balance relationship for salt. However, the difference between production and sold or used is assumed to be because of changes in inventory.

⁴Includes imports for consumption.

⁵Includes salt used in rubber, tanning, other industrial, institutional wholesalers and/or retailers, U.S. Government resale, other wholesalers. Some exports for consumption in overseas territories administered by the United States, and other various minor uses are included.

⁶Represents the difference between the quantity reported to the U.S. Bureau of Mines and total U.S. primary demand. The amount of discrepancy is attributed to variances in inventory and import statistics.

^{&#}x27;Values are based on the average of all salt producers' valuations reported for bulk, f.o.b. plant, and includes all processing costs, depreciation of equipment, taxes, and profit.

¹Data may not add to totals shown because of independent rounding.

NA Not available. XX Not applicable.

^{&#}x27;As reported at salt production locations. The term "sold or used" indicates that some salt, usually salt brine, is not sold but is used for captive purposes by the plant or company. Because data do not include salt imported, purchased, and/or sold from inventory from regional distribution centers, salt sold or used by type may differ from totals shown in tables 9 and 10, which are derived from company reports.

²Data may not add to totals shown because of independent rounding.

¹The quantity of imports included in the total for each type of salt is the amount reported by the U.S. salt industry, not the quantity reported by the Bureau of the Census that

appears in tables 13, 14, and 15.

2 Data may not add to totals shown because of independent rounding. Because data include salt imported, produced, and/or sold from inventory from regional distribution centers, salt sold or used by type may differ from totals shown in tables 1, 2, 5, and 8, which are derived from plant reports at salt production locations. Data may differ from totals shown in table 8 because of changes in inventory and/or incomplete data reporting.

⁵Less than 1/2 unit.

⁴Includes exports.

Revised.

Sources: Bureau of the Census and The Chlorine Institute.

¹Each salt type includes domestic and imported quantities. Brine is excluded because brine usually is not shipped out of State.

²Data may not add to totals shown because of independent rounding.

³Less than 1/2 unit.

^{*}Includes shipments to overseas areas administered by the United States, Puerto Rico, exports, some shipments to unspecified destinations, and shipments to States indicated by symbol W.

⁵Because data include salt imported, purchased and/or sold from inventory from regional distribution centers, evaporated and rock salt distributed by State may differ from totals shown in tables 1, 2, and 5, which are derived from plant reports at salt production locations. Data may differ from totals shown in table 7 because of changes in inventory and/or incomplete data reporting.

TABLE 10
SALT YEAREND PRICES

	1991	1992
Salt, evaporated, common:		
80-pound bags, carlots or truckloads:		
North, works, 80 pounds	\$4.02	\$4.02
Bulk, same basis, per ton	\$60.00-61.20	\$60.00-61.20
Salt, chemical-grade, same basis:		
North, works, 80 pounds	4.30	4.30
Salt, rock, medium, coarse:		
Same basis, 80 pounds	2.70	2.70
Bulk, same basis, per ton	18.00-25.00	18.00-25.00
Sodium chloride, U.S.P.:		
Granular bags, per pound	.29	.29

Packaged	129.93	54.35	63.23	XX	
Average ³	112.53	32.56	19.63	4.35	
Pressed blocks	105.40	82.13	93.88	XX	

XX Not applicable.

'Salt value data previously reported were an aggregate value per ton of bulk, compressed pellets, and packaged salt. For time series continuity, an average of these three types of product forms is presented, which is based on the aggregated values and quantities of the product form for each type of salt shown in table 5.

¹Net selling value, f.o.b. plant, excluding container costs.

²Average values calculated using unrounded totals.

Estimated, Revised.

¹Table includes data available through July 19, 1993.

²Salt is produced in many other countries, but quantities are relatively insignificant and reliable production data are not available. Some salt brine production data for manufacture of chlorine, caustic soda, and soda ash are not reported because of incomplete data reporting by many countries.

³Reported figure.

⁴Year ending June 30 of that stated.

⁵Less than 1/2 unit.

⁶Formerly part of Yugoslavia.

Brine salt production as reported by the Burmese Government in metric tons, was as follows: 1988—59,768; 1989—60,229; 1990—49,670; 1991—46,835 (revised); and 1992—43,488.

³Year begining Mar. 21 of that stated.

⁹Does not include production from Sardinia and Sicily, estimated at 200,000 metric tons annually.

 $^{^{10}\}mathrm{Year}$ ending July 15 of that stated.

¹¹Formerly part of the U.S.S.R.

¹²Dissolved in Dec. 1991. In addition to the former republics of the U.S.S.R. listed in this table, it is believed that Armenia, Azerbaijan, and Turkmenistan also produce salt; however, information is inadequate to formulate reliable estimates of individual country production.

¹³Great Britain only.

¹⁴Data captioned "Brine salt" for the United Kingdom are the quantities of salt obtained from the evaporation of brines; that captioned "Other salt" are the salt content of brines used for purposes other than production of salt.

¹⁵Dissolved in Apr. 1992.

CONSTRUCTION SAND AND GRAVEL

By Valentin V. Tepordei

Mr. Tepordei, a geological engineer with more than 20 years of industry experience, has been the construction sand and gravel commodity specialist with the U.S. Bureau of Mines since 1979. Domestic survey data were prepared by the construction sand and gravel survey staff of the Branch of Data Collection and Coordination.

Construction sand and gravel is one of the most accessible natural resources and a major basic raw material used mostly by the construction industry. Despite the relative low-value of its basic products, the construction sand and gravel industry is a major contributor to and an indicator of the economic well-being of the Nation.

Complying with the provisions of the Metric Conversion Act of 1975 and the Omnibus Trade and Competitiveness Act of 1988 (Public Law 100-418), beginning with this issue of the Annual Report for Construction Sand and Gravel the U.S. Bureau of Mines (USBM) will publish its statistical information on construction sand and gravel in U.S. customary units as well as metric units. Initially, the reporting in dual units will be applied to the totals only, with increased emphasis on metric units in successive years.

A total of 919 million short tons [834 million metric tons (Mmt)] of construction sand and gravel was produced in the United States in 1992, a 17.8% increase compared with the estimated total of 1991, but only a 0.6% increase over the actual total of 1990. This tonnage represents the third year since 1988 of production of more than 900 million short tons of construction sand and gravel, an indication of continuing strong demand for construction aggregates in the United States. (See table 1.)

Foreign trade of construction sand and gravel remained relatively minor in 1992. Exports increased 37.4% to 1.6 million tons (1.4 Mmt), while value decreased 5.7% to \$18 million.

Imports decreased slightly to 1.4 million tons (1.3 Mmt), while the value decreased 7.1% to \$15.5 million. Domestic apparent consumption of

construction sand and gravel was 919 million tons (834 Mmt).

The major issues of concern to the construction sand and gravel industry are: the implementation of the Clean Air Act Amendments of 1990 and its complex legal and technical provisions: the amended Federal Water Pollution Control Act of 1977, the Clean Water Act, Section 404, dealing with "wetlands" and the associated "no net loss of wetlands" policy; the Storm Water Pollution Prevention Program; the Occupational Safety and Health Administration's (OSHA) Hazard Communication Standards regulating the use of products containing more than 0.1% crystalline silica; and the provisions of the Federal Endangered Species Act.

The removal of nonasbestiform Anthophyllite, Tremolite, and Actinolite (AT&A) from the scope of the present Occupational Safety Health Advisors standards for regulating occupational exposure to asbestos in 1992 eliminated one of the major areas of concern for the construction aggregates industries.

DOMESTIC DATA COVERAGE

Domestic production data for construction sand and gravel are developed by the USBM from voluntary surveys of U.S. producers. Full surveys of construction sand and gravel producers are conducted for even-numbered years only. For odd-numbered years, only annual estimates for each State are generated based on information provided by the new quarterly sample survey of construction sand and gravel and crushed stone producers. This survey provides production estimates by quarters for each State and the nine geographic regions.

The sample surveys canvass most of the large companies in each State, accounting for up to 80% of each State's total tonnage. The results of this survey are published each quarter in a separate publication, the Quarterly Mineral Industry Survey.

Of the 8.237 construction sand and operations surveyed. operations with 8,424 pits were active. Of these, 4,994 operations with 7,342 pits representing 83.3% of the total number of operations reported to the USBM survey. Their total production of 809 million short tons (734 Mmt) represents 88% of the total U.S. construction sand and gravel output. Of the 4,994 reporting operations, 586 operations with 1,123 pits did not report a breakdown by end uses. Their production, about 124.7 million tons (113 Mmt), is included in table 6 under "Unspecified uses, actual." The nonrespondents' production was estimated using employment data and/or adjusted prior-years production reports. The estimated production of 1,005 operations representing 12% of the total U.S. output of construction sand and gravel is included in table 6 under "Unspecified uses, estimated." A total of 946 operations were idle in 1992.

BACKGROUND

Sand and gravel is a granular, unconsolidated, and usually rounded agglomeration of particles of rocks and minerals, resulting primarily from the natural disintegration and abrasion of rocks through weathering or erosion. Sand and gravel, as one of the most accessible natural resources, has been used since the earliest days of civilization, mostly as a construction

material. At the beginning of the 20th production of the U.S. construction sand and gravel, the sand and gravel used mostly for construction purposes, was relatively small and its uses limited. Today, annual sand and gravel production tonnage ranks second in the nonfuel minerals industry after crushed stone and is the only mineral commodity produced in all 50 States. The United States is, in general, selfsufficient in sand and gravel, producing enough to meet all domestic needs and to be a small net exporter, mainly to consumption points along the United States-Canadian and United States-Mexican borders.

Most sand and gravel is used for construction purposes, mainly aggregate in concrete; as road base material in the construction and repair of highways, railways, and runways; and as aggregate in asphaltic concrete for paving highways, streets, etc. Construction sand and gravel has one of the lowest average per ton values of all mineral commodities. The constant dollar price has changed relatively little over the past 20 years. Increased operating costs have been partially offset by automation and other means of increasing operating efficiency.

Although construction sand and gravel resources are widespread and in adequate supply nationally, local shortages exist. Land use conflicts and environmental problems associated with rapid urban expansion are major factors contributing to these shortages. In addition, in some geographic areas with sufficient resources, some shortages occur because the proportions of various size fractions of sand or gravel may not meet size specifications of the construction industry. Demand pressures, land use regulations, and the cost of meeting environmental and reclamation requirements are factors that will cause a rising price trend. Larger operations with more efficient equipment, more automation, and better planning and design will be the trend of the industry in the future. This will permit increased use of less accessible and lower quality deposits and will keep prices at

competitive levels.

Definitions, Grades, and Specifications

Sand is defined throughout the industry and by the American Society for Testing and Materials (ASTM) as naturally occurring unconsolidated or poorly consolidated rock particles that pass through a No. 4-mesh (4.75-millimeter) U.S. standard sieve and are retained on a No. 200-mesh (75-micrometers) U.S. standard sieve. Gravel consists of naturally occurring unconsolidated or poorly consolidated rock particles that pass through a sieve with 3-inch (76.2millimeters) square openings and are retained on a No. 4-mesh U.S. standard sieve.

Sand and gravel is made up of varying amounts of different rock types and is, varying chemical therefore. of Silica is the major composition. constituent of most commercial sands, and lesser amounts of feldspar, mica, iron oxides, and heavy minerals are common. Most applications of sand and gravel have specifications for size, physical characteristics, and chemical composition. A compilation of 42 ASTM Specifications and Test Methods. including the latest revisions and updates pertaining to aggregates, concrete, and admixtures, was reprinted by the National Aggregates Association (NAA).1

Specifications for sand and gravel used in roadbuilding and concrete construction are often rigid regarding particle size gradation and shape and include physical as well as some chemical properties. However, these specifications can differ in detail from State to State or even from city to city within the State. Soil conditions, climate, and peculiarities in different deposits may necessitate adjustments of requirements of sand and gravel mixtures and chemical composition.

Specifications are written by commercial users; Government agencies, including Federal; State, county, and city construction and highway departments; and the ASTM. Problems arise for the producers of construction aggregates when their product is sold or used in

several different cities, counties, or States, many of which may have different specifications. Some progress is being made toward the standardization of aggregate sizes for similar requirements. A need exists for a more active interchange of data and experience among aggregate consumers and producers.

Uses and Products for Trade and Industry

Concrete is made by mixing properly sized aggregate, portland cement, and water into a slurry. Chemical action between the cement and the water results in the crystallization of hydrous calcium aluminum silicates, which causes the mass to bind and harden. Round particles in the aggregate are desirable because they improve the workability of the concrete as it is poured. If broken material is used and angular or flattish fragments exceed about 15% of the total volume, workability can be maintained only by increasing the amount of sand and water, thus reducing strength, or by adding more cement, thus increasing the cost of the concrete.

Sized and broken sand and gravel is used to make asphaltic concrete aggregate and road bases. Broken surfaces adhere to the hot asphaltic mixture better than do rounded surfaces and provide interlocking surfaces that tend to strengthen the asphaltic concrete. Broken particles pack better and tend to move less under load than do rounded particles and, therefore, make better road bases for highway and road construction. This is essential because bases and asphaltic concrete tend to flow when placed under great or long duration stresses.

Industry Structure

Because of the low unit value, construction sand and gravel is produced near the point of use; therefore, the industry is concentrated in or nearby large, rapidly expanding urban areas and, on a transitory basis, in areas where highways, dams, and other large-scale public and private works are under construction. In the United States, sand

and gravel is produced in every State. The largest operations tend to be concentrated in the States with the largest population and largest production of sand and gravel.

Construction sand and gravel is produced in virtually all countries, but relatively few of them survey this industry and even fewer regularly publish official statistics on sand and gravel.

On the basis of tonnage, the construction sand and gravel industry is the second largest nonfuel mineral industry in the United States. In 1992, there were 4,213 companies producing construction sand and gravel from 5,999 operations with 8,424 pits. individual operations range in size from those producing millions of tons annually to those reporting less than 25,000 tons per year. Most operations are small, turning out one product or a limited number of products, but most of the tonnage comes from large operations. For example, the 18 operations reporting more than 2.0 million tons each in 1992 represented only 0.2% of the total number of operations, but produced 6.7% of the total tonnage, while 81 operations reporting between 1 and 2 million tons each, representing only 1.4% of the total number of operations, produced 12.2% of the total tonnage. In 1992, most of the construction sand and gravel was produced by operations reporting between 200,000 and 1,000,0000 tons each—1,191 operations or 20% of the total produced 52.1% of the total tonnage.

The leading companies producing construction sand and gravel, in descending order of tonnage, based on the 1992 survey, were CalMat Co. of Los Angeles, CA; Beazer U.S.A. Inc./Hanson PLC of Walnut Creek, CA; CSR America, Inc. of Atlanta, GA; APAC Inc., of Atlanta, GA, a subsidiary of Ashland Oil of Russell, KY; and Western Mobile, Inc., of Fort Collins, CO, a subsidiary of Redland PLC of Groby, Leicester, United Kingdom. The top 5 companies operated 203 pits and produced 10.1% of the U.S. total. Three of these five companies are subsidiaries of foreign companies.

Many producers are in the sand and

gravel business exclusively, but others are diversified in various degrees in the production of other mineral raw materials, intermediate construction products such as ready-mixed concrete and concrete blocks, final manufactured products, or construction of buildings, roads, and other structures. At the same time, construction companies are entering more and more into the sand and gravel business to integrate their operations.

Geology-Resources

The processes of formation and deposition impart to sands and gravels the physical characteristics that largely determine the commercial value for a particular use and influence the manner of development. The principal types, based on origin, are stream, glacial, residual, marine, and lake. Windblown deposits are of minor importance. Much of the commercial production is from stream deposits, many of which are deficient in the fines required by present-day grading specifications for concrete aggregates. Stream deposits usually exhibit stratification and often large-size gradation. The beds vary in thickness and sometimes have interspersed lenses of clay or fine sand. The degree of roundness and the particle size varies with the hardness and distance transported. Glacial deposits have the least sorting of all transported deposits, while marine and lake deposits exhibit the best sorting with coarse and fine particles, often well segregated. Residual deposits are found overlying the parent rock and are unstratified mixtures of pebbles, boulders, sand, and clay. They often contain much soft material that prohibits commercial production. Marine or offshore deposits could become more important as inland deposits become depleted or environmentally less desirable to extract. A comprehensive report showing geologic occurrences of potential sources of sand and gravel and crushed stone of the conterminous United States for use as natural aggregates was published by the U.S. Geological Survey.²

On the basis of geologic evidence,

world reserves are sufficient to meet demands, although not necessarily at precisely the locations where needed. Reserves, which are measurable amounts of sand and gravel that can be produced profitably with current technology under existing economic and political conditions, are controlled mostly by land use and/or environmental constraints. The total sand and gravel resources of the United States are very large. However, the geographic distribution and/or quality of the reserve base often does not match market patterns or requirements.

Technology

Major technological developments that have been instrumental in maintaining adequate production at relatively stable real costs include use of larger operating units, more efficient portable and semiportable plants, unitized plants for versatility of plant capacity, new prospecting methods utilizing aerial and geophysical surveying methods, and greatly increased rehabilitation and resale of mined areas. Use of mined-out pits as lakebeds and as sanitary landfill areas has been successful at numerous localities. Automatic controls. along monitoring by closed-circuit television coordinated with automated counting and recording and radio communications systems, have been installed in many of the larger and newer operations; these, along with the use of improved equipment, have permitted recovery of salable fractions from deposits previously considered too low in quality for profitable exploitation. These practices will increase as pressures build to increase productivity and minimize environmental conflicts.

Exploration.—Sand and gravel deposits, like any mineral deposit, must be explored and evaluated before development. Preliminary examination can establish the extent and nature of the deposits. This is followed by a detailed exploration program aimed at obtaining reasonably accurate information on the quantity of material available, the degree of uniformity throughout the deposit, and

especially, variations in particle size, both vertically and horizontally. Also, the nature and amount of waste materials and the economic feasibility of their removal must be studied.

Geophysical methods are of value in preliminary surveys. Detailed exploration may be achieved by a systematic arrangement of test pits, trenches, boreholes, or other procedures designed to obtain a cross section of the deposit in conjunction with sampling and testing. Advances in interpretation of aerial photographs and increased application of geophysical techniques have made evaluation of sand and gravel deposits more quantitative. For underwater exploration, mining devices such as dredges and draglines are used. Pilot runs are necessary to determine if required specifications can be met consistently and economically.

Much of the sand and gravel that is being mined in stream, flood plain, alluvial fan, riverbeds and terrain, and glacial deposits is good quality material with nearly equal amounts of gravel and sand and small amounts of unusable material. As these deposits become depleted in future years, less desirable and more expensive sources will have to be developed where mining, reserves, ratio of sand to gravel, quality of material, waste factors, and environmental factors such as waste disposal will present more problems.

Exploration and planning will become more important in assessing deposits, particularly hillslope deposits of older sand and gravel. Grading to meet required slope and setback requirements at hillslope sites may necessitate leaving large tonnages of material unmined. Many millions of tons of material is available, but it may not be of proper quality or ratio of sand to gravel. More deposits of marginal quality will have to be developed to provide for future demand.

Mining.—Sand and gravel generally occur in the same deposit, but the relative proportions of each vary greatly within most deposits. Consequently, the control problem of producing aggregate to rigid

specifications involves combinations of many types of equipment like screens, washers, classifiers, crushers, grinding mills. The two basic sand and gravel mining methods are open pit excavation and dredging. Open pit excavation and processing has four major steps: (1) site clearing—removing trees and vegetation, stripping overburden and topsoil, and transporting, redepositing, or stockpiling it at or off the site; (2) mining-removing the sand and gravel from the deposit; (3) processing screening, washing, crushing, blending, and stockpiling the mined material to conform to standards and specifications; and (4) reclamation of the extraction area. Processing may or may not take place at the mining site. Mining equipment ranges from small, simple units such as tractor-mounted high-loaders and dump trucks to more sophisticated systems involving large power shovels, draglines, bucket wheel excavators, and belt conveyors. Increasingly, mining systems are being designed to provide for more efficient and economical land reclamation.

Mining with a dredge usually involves mounting the equipment on boats or barges. Suction or bucket-type dredges are used most commonly to harvest sand and gravel from the bottom of a body of water. The sand and gravel is processed either on board or transported to land for processing.

Processing.—Although small amounts of unprocessed bank-run sand and gravel are used for fill, most of the U.S. production is processed in some way. Present methods include washing with water during the screening process, in some cases followed by crushing of the larger particles in cone or gyratory crushers. Secondary crushing may be done by roll crushers. Sizing is done in most plants, by horizontal or sloped single- or multideck vibratory screens. If necessary, heavy-media separation or jigging is used to remove heavy, unusable materials. Sand for use in construction is freed from clay by log washers or rotary scrubbers. The scrubbing is followed by classification, use of separatory cones or hydroseparators to remove water, and fine screening for grading. Rodmilling is often required for production of small-sized fractions of sand. Transfer of processed sand and gravel from the processing plant to stockpiles or bins is accomplished by flexible combinations of conveyor belts, bucket elevators, and screw conveyors.

Permanent installations are built when large deposits are to be operated for many years. Portable and semiportable units are used in many pits that have an intermediate working life. Several such units can be tied together to obtain large initial production capacity or to add capacity as needed. Mobile screening plants can be quickly moved from one deposit to another without undue interruption or loss of production.

Recycling.—As the Nation moves into an age of increased environmental consciousness, recycling of old concrete and asphalt, used mostly in pavements, is increasing. Local scarcity or high cost of construction aggregates in some areas as well as waste disposal problems are making recycling more attractive economically. In some States, limited recycling, especially in road construction. is either encouraged or required by law. The best utilization for recycled cement concrete is as road base material, because the matrix of concrete cannot be converted back to cement, and also because of the lower strength of concrete compared with that of natural aggregates. Sound crushed concrete can make good coarse aggregate, but the fines produced in crushing the concrete have a higher absorption, are more friable, and will require a higher amount of asphalt in asphaltic concrete and a higher amount of mixing water in portland cement.³ The amount of asphalt roads recycled is significantly larger than that of concrete roads, mainly because asphalt can be rejuvenated with oil additives and used in pavements, significantly reducing the cost of the finished road. Experience has shown that about 35% of crushed asphalt pavement can be recycled into new asphalt mixtures. Proper testing under engineering supervision in all construction projects using recycled materials as aggregates should be performed to ensure that the technical specifications are met.

Byproducts and Coproducts

Small amounts of gold and silver are recovered as a byproduct or coproduct of sand and gravel extraction, particularly in highly sorted deposits.

Economic Factors

Construction sand and gravel is a highvolume, low-value commodity. industry is highly competitive and is characterized by thousands of operations serving local or regional markets. Production costs vary widely depending on geographic location, the nature of the deposit, and the number and type of products produced. Constant dollar unit values have been quite steady during the past 20 years. As a result of rising costs of labor, energy, and mining and processing equipment, the average unit price of construction sand and gravel increased from \$1.1 per ton, f.o.b. plant, in 1970 to \$3.63 in 1992. However, the unit price in constant 1982 dollars fluctuated between \$2.64 and \$2.71 per ton for the same period. productivity achieved through increased use of automation and more efficient equipment was mainly responsible for maintaining the prices at this level. Constant dollar prices are expected to rise in the future because of decreased deposit quality and more stringent environmental and land use regulations.

Accessibility is a problem for the construction sand and gravel industry. The high-volume, low-unit value of sand and gravel requires that operations be close to the market location. Markets for sand and gravel are construction sites that are mostly in areas of high population density. New operations, close to population centers, are difficult to develop because the land is often attractive for other uses such as housing, shopping centers, agriculture, parks or recreational areas, and because of public dislike for mining operations close to populated areas. Existing operations in

expanding communities face increasing costs because of increasing land values and increasing restrictions on operations as suburban development comes closer. Deposits are often small and, once exhausted, the operation must be moved to a new site that invariably is farther from the market because closer sites are being used for other purposes.

The industry also faces increasing competition from crushed stone that can substitute for sand and gravel in most of its applications. Stone operations are generally longer lived, can afford greater capital investment for higher efficiency, and are often located where competing land use pressures are less severe. The topographically rugged stone-bearing areas are usually less desirable for construction purposes than sand-and-gravel-bearing areas, which are generally flatter.

A 5%-depletion allowance based on gross income is allowed for construction sand and gravel. There are no import tariffs

Operating Factors

Many States, counties, and cities in the United States have zoning laws, and land within each governmental unit is usually zoned to indicate acceptable land uses. If mining is permitted in a zone and a sand and gravel company owns or leases land within that zone, the company may apply for a use permit or its equivalent to begin an operation. If the parcels to be quarried are on lands under both city and county jurisdiction, permits usually must be obtained from each. An acceptable reclamation plan that meets the guidelines regulations of the appropriate governmental agency must also be approved. Environmental concerns such as noise, dust, beautification, and storage of wastes must be accounted for in a manner satisfactory to the governmental entity involved. Wastewater discharge requirements must be planned for and met. If the deposit to be worked is on a river or land controlled by a river or water or flood control agency, whether municipal, State, or Federal, agency's requirement must also be

satisfied.

In most States, permits for sand and gravel operations require an Environmental Impact Report (EIR) or Statement (EIS). A reclamation plan and a use permit application also may be required, with considerable overlap of subject matter with the EIS. A complete EIS may cover all the problem areas at once and facilitate acceptance.

Environmental Requirements.—Two main points are involved in environmental land use and reclamation factors. First, the industry must be concerned about any practices that can affect the community environment. An effective effort must be made to reduce noise, air, and water pollution; to reclaim pits after the operation is complete; and to improve the overall appearance of the operating mine, processing plant, and transportation facilities. Second, the industry and community must recognize the time and costs required to protect the environment and the importance of agreeing on fair and realistic environmental standards.

Because sand and gravel is a local the effect of supply commodity. deficiencies and cost of material will affect the local community first. Undue delay and unreasonably high cost can strongly affect the movement of sand and gravel into the marketplace. stringent controls by the local government that prevent permits being issued to operators can have adverse economic effects on the communities around them. These conditions can make it difficult to assess the timing and even the possibility of plants going on-stream and can therefore affect the supply of sand and gravel into the marketplace.

Although much progress is being made through premining planning, the sand and gravel industry continues to have problems with environmental controls, land use conflicts, and reclamation practices. Many of these problems are acute because extraction areas and plants must be reasonably near to consumers who are largely in metropolitan areas. Major environmental considerations that must be dealt with in mining and processing sand and gravel are emission

of particulate matter into the air, processing water discharge, noise abatement, and employee and public health and safety.

Transportation.—Transportation is a major factor in the delivered price of construction sand and gravel. The cost of moving construction sand and gravel from the plant to the market often exceeds the sales price of the product at the plant. Because of the high cost of transportation, construction sand and gravel continues to be marketed locally. Economies of scale, which might be realized if fewer, larger operations served larger marketing areas, would probably not offset the increased transportation costs.

Truck haulage is the main form of transportation used in the construction sand and gravel industry. Many producers have their own truck fleet and deliver their own raw materials and products. A significant and increasing amount of sand and gravel, however, is being hauled by independent truckers because of the cost of maintaining a truck fleet, particularly when the market is highly variable or down. Rail and water transportation combined account for about 10% to 20% of total construction sand and gravel shipments.

ANNUAL REVIEW

A total of 919 million short tons (834 Mmt) of construction sand and gravel was produced in the United States in 1992, a 17.8% increase compared with the estimated total of 1991, but only a 0.6% increase over the actual total of 1990. This tonnage represents the third year since 1988 of production of more than 900 million short tons of construction sand and gravel, an indication of continuous strong demand for construction aggregates in the United States. (See table 1.)

Legislation

On June 8, 1992, OSHA announced that it was amending its standards governing the "Occupational Exposure to

Asbestos, Tremolite, Anthophyllite, and Actinolite (AT&A)"4 by removing nonasbestiform AT&A from the scope of the present standards affecting the general industries, including the construction industries. OSHA has determined that substantial evidence is lacking to conclude that AT&A presents the same type or magnitude of health effect as asbestos or that employees would be at significant risk because nonasbestiform AT&A were not regulated in the asbestos standards. The nonasbestiform varieties will be regulated according to limits set for "particulates not otherwise regulated." The latest administrative stay of enforcement of the revised standards was also removed by OSHA effective May 29, 1992.

The U.S. Environmental Protection Agency (EPA) issued final general stormwater permits to regulate discharges resulting from industrial and construction activities that disturb five or more acres. Facilities that must be covered by a stormwater permit include many mining operations where water comes into contact with raw materials or wastes. All facilities covered by a general permit must prepare and implement a sitespecific stormwater pollution-prevention plan. To assist industry in complying with the stormwater requirements, the EPA has developed guidance manuals on sampling and on pollution prevention management practices.

The removal of nonasbestiform AT&A from the scope of the present OSHA standards for regulating occupational exposure to asbestos in general industries, including the construction industries, eliminates a major area of concern for the construction aggregates industries.

Issues

The new complex legal and technical provisions of the comprehensive amendments of 1990 to the Clean Air Act and the implementing regulations for these provisions constitute a major area of concern to the crushed stone industry. One major emphasis of the amendments is expanded authority given to EPA and the States to enforce the new law and

assess increased penalties. EPA is now authorized to issue administrative orders with penalties of up to \$200,000 for noncompliance, and its field inspectors can issue citations for minor violations with penalties of up to \$5,000 per day for each violation. The law also includes provisions for new Federal permits to be issued by the State agencies that include source specific emission limitations and related monitoring, recordkeeping, and reporting requirements. Complying with the new provisions of the Clean Air Act Amendments will constitute a major challenge to all crushed stone producers.

The implementation of the provisions of the amended Federal Water Pollution Control Act of 1977, the Clean Water Act, Section 404, dealing with "wetlands" and the establishment of a "no net loss of wetlands" policy constitutes one of the major areas of concern to the crushed stone industry. There is a significant amount of uncertainty regarding the process of designating some lands as wetlands and whether the current exemptions to the Clean Water Act, Section 404, permit program will be maintained in the future. Several bills were reintroduced in the 103d U.S. Congress to replace the current section 404 of the Federal Water Pollution Control Act. The new proposed bills plan to provide a concise and structured program for the delineation of wetlands based on their functions and values and will balance the need for effective protection of the Nation's important wetlands with the need for essential community growth and the constitutional rights of landowners.

Another issue of concern to the construction aggregates industries is the classification of crystalline silica as a probable human carcinogen by the International Agency for Research on Cancer, an agency of the World Health Organization. OSHA-regulated sites that receive and/or use products containing more than 0.1% crystalline silica must comply with OSHA's Hazard Communication Standard. Both the classification of crystalline silica as a probable human carcinogen and the requirement to quantitatively analyze for

crystalline silica at the 0.1% level are controversial.

Production

U.S. production of construction sand and gravel increased 17.8% in 1992 to 919 million tons (834 Mmt) compared with the estimated total of 1991, and only 0.6% compared with that of 1990, the year when the previous full annual survey was conducted. (See table 1.)

Of the four major geographic regions, the West again led the Nation in the production of construction sand and gravel with 331 million tons (300 Mmt), or 36% of the U.S. total, followed by the Midwest with 295 million tons (267 Mmt), or 32% of the total; the South with 189 million tons (171 Mmt), or 20.6%; and the Northeast with 104 million tons (95 Mmt), or 11.4%. Compared with that of 1991, production by major geographic regions increased 29.3% in the Northeast, 20.8% in the Midwest, 16.2% in the West, and 10.8% in the South. (See table 2.)

Of the nine geographic regions, the East North Central led the Nation in the production of construction sand and gravel with 189 million tons (171 Mmt), or 20.6% of the U.S. total, followed by the Pacific with 185 million tons (168 Mmt), or 20.2%; and the Mountain with 146 million tons (132 Mmt), or 15.8% of the total. (See table 2.) Compared with that of 1991, production increased in all regions, with the largest increases recorded in New England, 30.7%, the Mountain, 29.2%, and Middle Atlantic, 28.5%, and the smallest increases in the East North Central, 17.3%, and East South Central, 7.1%.

A review of the production by size of operation indicates that 45.6% of the construction sand and gravel produced in 1992 came from 1,872 operations reporting between 100,000 and 499,999 tons per year; 21.7% came from 289 operations reporting between 500,000 and 999,999 tons per year; and 18.9% came from 99 operations reporting more than 1,000,000 tons per year. A total of 5,999 operations were active in 1992. (See table

8.)

The estimated production by quarters for 1992 indicates that most of the construction sand and gravel in the United States was produced in the third quarter, followed by the second quarter and the fourth quarter. (See table 3.) Estimated production by each quarter of 1992 was also available for most of the States. (See table 5.)

Construction sand and gravel was produced in 1992 in every State. The 10 leading States, in descending order of tonnage, were California, Michigan, Ohio, Texas, Washington, Minnesota, Illinois, Arizona, New York, and Colorado. Their combined production represented 50.3% of the national total. Compared with that of 1991, production increased in 37 States, including 9 of the top 10 States. (See table 4.)

Limited information about the production of construction sand and gravel in foreign countries may be found in the USBM "Minerals Yearbook, Volume III, Area Reports: International." For nonreporting countries, estimates of sand and gravel and crushed stone outputs can be based on indirect sources such as the level of cement consumption.

Significantly fewer changes in ownership, acquisitions, and mergers occurred in the construction sand and gravel industry in 1992 compared with prior years. Granite Construction Co. of Watsonville, CA, acquired from Tarmac America of Herndon, VA, 13 sand and gravel and crushed stone operations located in southern California. The transaction also included 10 ready-mixed concrete plants and 5 asphalt operations.

CalMat Co. of Los Angeles, CA, acquired in the second half of 1992 the Jamieson Co. of Pleasanton, CA, a major producer of construction aggregates in the San Francisco Bay area. This is the first time that CalMat will own and operate a sand and gravel plant in the northern part of the State.

Consumption and Uses

Construction sand and gravel reported by producers to the USBM is actually material that was "sold or used" by the companies and is defined as such. Stockpiled production is not reported until it is sold to a user or consumed by the producer. Because no consumption surveys are conducted by the USBM, the "sold or used" tonnage is assumed to represent the amount produced for domestic consumption and export. Because some of the construction sand and gravel producers did not report a breakdown by end use, their total production is reported under "Unspecified uses, actual." The estimated production of nonrespondents is reported under "Unspecified uses, estimated."

Of the 919 million tons of construction sand and gravel produced in 1992, 235 million tons (213 Mmt) or 25.6% of the total was unspecified uses. Of the remaining 684 million tons (621 Mmt), 38.8% was used as concrete aggregates; 28.4% for road base and coverings and road stabilization; 14.1% as asphaltic concrete aggregates and other bituminous mixtures: 13% as construction fill: 1.7% for concrete products such as blocks. bricks, pipes, etc.; 1.4% for plaster and gunite sands: and the remainder for snow and ice control, railroad balast, roofing filtration. granules, and other miscellaneous uses. (See table 6.)

To provide a more acurate estimation of the consumption patterns for construction sand and gravel, the "Unspecified uses" are not included in the above percentages. It is recommended that in any marketing or use pattern analysis the quantities included in "Unspecified uses" be distributed among the reported uses by applying the above percentages.

A review of consumption by major geographic regions indicates that most of the sand and gravel for concrete aggregates, including concrete sand, was used in the West, with 31.9%; the South, with 31.5%; and the Midwest, with 21.7%, with high levels of construction activity. Most of the sand and gravel for road base and coverings was used in the West, 44.4%, and the Midwest, 39.2%, while most of the sand and gravel used for asphaltic concrete aggregates and other bituminous mixtures was used in the West, 43.6%, and the Midwest, 31.5%.

(See table 7.)

Additional information regarding production and/or consumption of construction sand and gravel by major uses in each State and the State districts is published in the USBM Annual Reports State chapters, Volume II of the Minerals Yearbook.

Transportation

Information regarding the method of transportation of construction sand and gravel from the pit or processing plant to the first point of sale or use is now available for each geographic region. Total U.S. reports regarding the method of transportation were provided by the producers for 643 million tons (583 Mmt) or 69.9% of the total U.S. production of construction sand and gravel. Of this total, 72.8% was transported by truck, 4% by waterway, and 1.1% by rail. A significant amount of construction sand and gravel produced, about 21.6%, was not transported and used at the production site. (See table 11.) Because most producers either did not keep records or did not report shipping distances or cost per ton per mile, no transportation cost data were available.

Prices

Prices in this chapter are f.o.b. plant, usually at the first point of sale or captive use. This value does not include transportation from the plant or yard to the consumer. It does, however, include all costs of mining, processing, in-plant transportation, overhead costs, and profit.

Compared with that of 1990, when the last full annual survey was conducted, the 1992 average unit prices increased only 1.7% to \$3.63 per ton. By uses, the unit prices varied from a high of \$5.32 for filtration sand to a low of \$2.16 for fill. The largest increases in unit prices by uses were recorded for plaster and gunite sands, 22%; road stabilization cement, 21.7%; and railroad ballast, 19.4%. Average unit prices declined for filtration sands, 12.2%; fill, 9.2%; and snow and ice control sand, 2.3%. (See table 6.)

Foreign Trade

The widespread distribution of domestic sand and gravel deposits and the high cost of transportation limits foreign trade, mostly to local transactions across international boundaries. U.S. imports and exports are small, representing only about 1% of the domestic consumption.

Exports.—Exports of construction sand increased 118.5% to 959,000 tons (870,000 Mmt), compared with that of 1991, while the value decreased 3.1% to \$12.6 million. Mexico was the major destination, receiving about 54.3% of the total, followed by Canada with 34.2%. Exports of construction gravel declined 13.4% to 606,000 tons (550,000 Mmt), while the value decreased 11.2% to \$5.4 million. Canada was the major destination receiving about 83.7% of the total. (See table 12.)

Imports.—Imports decreased slightly to 1.4 million tons (1.3 Mmt), while the value decreased 7.1% to \$15.5 million. Canada was the major source of imported construction sand and gravel with 71.7% of the total, followed by the Bahamas with 15%. (See table 13.)

Current Research

Recognizing the need for research into properties and adequate use of aggregates, crushed stone and sand and gravel, as well as the need for reliable technical information in this area, the NAA and the National Stone Association established in 1990 the Aggregates Foundation for Technology, Research, and Education (AFTRE). The main purpose of the foundation was to establish and provide the funding for a new Aggregates Research Center (CAR). On August 25, 1992, the formal ceremonies establishing CAR took place at the University of Texas at Austin. The center will be operated jointly by the University of Texas at Austin and Texas A&M University and financed by the AFTRE. The center's mission is to conduct scientific and technical research related to aggregates; coordinate technology transfer activities; establish a central information clearinghouse on aggregates technology; and develop undergraduate and graduate engineering courses and continuing education programs related to aggregates research.

A technical advisory committee overviewing the center's activity identified six priority areas of research that include the following: fine aggregates properties and their influence on end products; uses for fines resulting from the processing of aggregates; performance-related tests for aggregates; proper use of aggregates in asphaltic concrete to minimize rutting; prevention of alkalisilica and alkali-carbonate reactivity of aggregates in portland cement concrete; and nature and effects of coatings on aggregates.

Nineteen ninety-two was the last year of the 5-year Strategic Highway Research Program (SHRP) created by the U.S. Congress through the Surface Transportation and Uniform Relocation Assistance Act of 1987. SHRP's mission was to produce usable research results targeted toward technical areas where there is potential for improvement of our highways and the materials used to build them, research that could also yield significant cost savings. SHRP's research activities account today for more than one-quarter of all highway research conducted in the United States by Federal agencies, States, and the private industry.

SHRP's four areas of research are asphalt, concrete and structures, highway operations, and long-term pavement performance. To improve the performance of asphalt-concrete mixtures, a new set of specifications called Superpave is being finalized by SHRP. Superpave specifications use performancebased criteria and take into account environmental factors and traffic volumes and loads, a dramatic departure from earlier mixture specifications.5 SHRP also continues to refine and improve its asphalt binder specifications that will produce a superior-quality asphalt and address the rutting, low-temperature cracking, fatigue cracking, aging, and loss of adhesion problems.

SHRP's concrete program is in the final stage of developing new engineering guidelines, materials tests, and specifications that will produce consistently a more durable concrete for use in highway construction work. SHRP's program identified materials and the processes needed to produce a very early high strength concrete that requires only 4 hours of curing time, and therefore speeds the construction process and reduces the interruptions of the traffic flow.

Alkali-Silica Reactivity (ASR) of concrete is a major cause of deterioration in highway structures and pavements. SHRP's research found that lithium hydroxide introduced into concrete can prevent or inhibit ASR. Laboratory evaluations also showed that lithium hydroxide alone, or in combination with class-F fly ash, is very effective in inhibiting expansion even in concrete made with highly reactive aggregates.

SHRP's structure program developing guidelines for evaluation, protection. and rehabilitation structures. The presence of chloride in concrete is the number-one cause of distress in highway structures. Unprotected reinforcing steel used in concrete structures is highly susceptible to chloride-induced corrosion. Several of SHRP's research projects are exploring new ways of evaluating structures and preventing corrosion.

As the U.S. highway system ages and traffic volumes and weights continue to increase, roadway maintenance expenditures have become the fastest growing portion of highway budgets. The performance of materials, methods, equipment used in highway maintenance and repair continued to be investigated by SHRP's highway operation program. Field tests to evaluate materials and procedures for pavement repair are being conducted by cooperative States under different climatic and installation conditions. Twenty-two such test sites have been built. The performance of the test sites will be monitored by the Federal Highway Administration (FHWA).

SHRP's Long-Term Pavement

Performance (LTPP) program addresses the issue of how best to use and protect the very large investment made every year in building and maintaining highway pavements. SHRP's LTPP program, the largest and most comprehensive pavement performance test in history, is collecting data on pavement conditions, climate, traffic, and load conditions over a 20-year period. Eight hundred of the LTPP test sections contain common types of pavement in use throughout the United States, general pavement studies, and 340 other sites have been specially constructed to study certain engineering factors in pavement design. The collected data will provide vitallv needed information regarding improved design techniques to highway agencies and pavement design organizations. its inception, the LTPP program has been international in scope. Fifteen countries participating in the program, conducting research and forwarding data to SHRP.

In July 1992, responsibility for the ongoing LTPP research and data collection effort was assumed by the FHWA, while the Transportation Research Board has assumed responsibility for maintaining the LTPP data base.

A low-cost dewatering technique for fine-grained slurries usually produced in the processing of crushed stone has been developed by the USBM. The technique consists of injecting a polymer into the line carrying the slurry and dewatering the resulting flocs on a static, hydrosieve screen. The key to successful dewatering is the formation of strong flocs that will not break apart as the floc moves down the screen. To produce strong flocs, the mixing time and the turbulent conditions in the flow line to the screens must be This is accomplished by optimized. varying the feed rate and the length of pipe carrying the slurry and the polymer mixture to the screens.6 The initial field tests were conducted at a Birmingham. AL, limestone quarry. The waste slurry consisted of fine-grained calciummagnesium carbonate. The testing program included an evaluation of the parameters for polymer concentration,

mixing time, and effect of turbulence during the mixing. Field test results showed that 50% solids were produced using 1.4 pounds of polymer per ton of solids treated, at a cost of \$0.50 per pound of polymer.

Just a few years ago, plant automation was considered to be something that can be implemented only in large crushed stone and sand and gravel operations. Today, plant automation has become a necessity essentially for operations of any size. The principal advantages of plant automation are improved product quality; lower unit cost for the final product; reduced plant wear; and improvements in health and safety of the operators. The current requirements to limit dust and noise exposure, for example, in many cases, can be best handled by automating high-exposure tasks and removing workers from potentially high-exposure areas. These factors also apply to retrofitted plants.7

Looking at plant automation and the future, two emerging technologies will have a significant impact on this industry: "smart sensors" and "expert systems." Smart sensors will play an important role flexible in more efficient, more automation processes, while expert systems will be used for diagnosis of plant problems and early prediction of impending failures. Some basic research in the areas of adaptive learning networks (ALN's), fuzzy logic, and neural networks, the underlying technologies for smart sensors, as well as research in the development of expert system to diagnose equipment failures are being conducted by the USBM.

Technology

The Metric Conversion Act of 1975 declared a national policy of coordinating the increasing use of the metric system in the United States and provided for the establishment of a U.S. Metric Board to coordinate the voluntary conversion to the metric system. It was followed by the Omnibus Trade and Competitiveness Act of 1988 (Public Law 100-418) that declared the metric system of measurement "the preferred system of

weights and measures for United States trade and commerce." The act stipulates that each agency of the Federal Government, by a date prior to the end of fiscal year 1992, will use the metric system of measurements in its procurements, grants, and other business-related activities. The only allowed exceptions are for circumstance that will demonstrate that the use of the metric system is impractical or is likely to cause significant inefficiencies or loss of markets to U.S. firms.⁸

MSHA and the FHWA, two Federal Government agencies working closely with the crushed stone and sand and gravel industries, developed plans and schedules for their conversion to the metric system that were published for public comments during 1991. Although the MSHA metrication plan is scheduled to be completed in 18 months in place by July 1993, the FHWA metrication schedule expands over a longer period of time and is scheduled to be completed by September 30, 1996.

The USBM is also in the process of completing the conversion to the metric system of all its publications. Beginning with this issue of the Annual Report for Construction Sand and Gravel, the statistical information on construction sand and gravel will be published in metric units as well as U.S. customary units. Initially, the reporting in dual units will be applied to the totals only, with increased emphasis on metric units in successive years.

The participants of the 1992 European Concrete Study Tour sponsored by the American Association of State Highway and Transportation Officials, the FHWA, and the American Concrete Pavement Associations observed highways and met with experts in Austria, Belgium, France, Germany, and the Netherlands. They also attended presentations made by experts from Italy, Portugal, Spain, and Switzerland concerning portland cement concrete pavements in their countries. The group of 21 American highway and pavement experts concluded that "the new and recently built portland cement concrete highways observed were built with a common philosophy—worry more about design, materials, and construction excellence, and less about cost. The European highways featured wellconceived, durable concrete slabs placed on thick, well-drained bases, resulting in superior pavement structures. pavements were built with the best technology available, much of which has been developed in the United States. The European nations are building their portland cement concrete highways for the future with 30- to 40-year designed service life, compared with our 20 years. The European highways carry a large volume of trucks, with allowable axle weight substantially above those in the U.S. "9

Jointed plain concrete pavements (JPCP) are constructed most often in Europe, and their design has been improved over time through effective research. Continuous reinforced concrete pavements (CRCP) have been built in several countries, most commonly Belgium and France. The new and rehabilitation designers in most countries are developed by teams of experts and placed in "pavement design catalogs" for use by design engineers. Emphasis is on the design of the total pavement system, not just the thickness of the concrete slab.

Warranties for pavement construction work are used in Europe. For concrete pavements, warranties range from 4 to 9 years. Two-layer slab construction is common in some countries for safety, noise, and economic reasons. A hard, high-quality aggregate is used in the upper 4 to 7 centimeters (1.6 to 2.8 inches) of the slab. Two-layer paving equipment is available to place this pavement in one pass.

Rehabilitation of pavements is performed at a higher level of condition than in the United States Designer CRCP and JPCP overlays are common on old concrete pavements, which are often cracked and seated or picked up and crushed and used as base. Jointed, steel-fiber-reinforced concrete and AC pavements have been used successfully in Belgium.

Recycling of pavements is on the rise in Europe, with total recycling of concrete and other construction materials required by law in Austria. Recycled concrete that includes up to 10% recycled asphalt concrete materials is used routinely in Austria. Concrete durability problems do not exist in Europe because high-strength concrete is used. Reduction of pavement-tire noise levels is an important environmental issue in Europe.

Recycling of construction materials, especially concrete and asphalt pavements, as well as construction debris is increasing throughout the United States as well as most industrialized countries. Construction and demolition debris (C&D) is bulky, difficult to handle, and expensive to move and dispose of. C&D represent 5% to 15% by weight of the wastestream, and for economic as well as environmental reasons, are becoming a subject of increased interest for expanded recycling programs. The reuse and recycling of C&D can make a significant contribution to aggregates conservation and also reduced landfill requirements. The European Demolition Association, which represents more than 1,000 European demolition and recycling companies in Western Europe, recently conducted a survey of its members. The purpose of the survey was to determine the present status and practices in recycling and the future requirements of its members related to the expected growth of this industry. The review of the information provided by the survey indicated that: recycled material produced from concrete or mixed debris can be used as aggregates in new concrete; there is a need to create a larger market for recycled material by establishing national or preferably European specifications; and despite significant differences between the European Community countries, the volume of recycled C&D is expected to grow faster than in the past. 10 A similar report reviewing the status of recycling of construction materials in Canada was published by the Ontario Ministry of Natural Resources.11

More and more specialized software programs that increase efficiency and productivity of crushed stone and sand and gravel operations are now available, covering operations from mine planning to drilling and blasting, conveying, dispatching, and equipment management. Many of these software systems can be combined for overall computer management of aggregates operations. The programs can assist quarry and plant operators in increasing output by providing accurate, up-to-the-minute information, some of it not available in the past. 12

OUTLOOK

The demand for construction sand and gravel in 1993 is expected to be about 940 million tons, a 2.5% increase compared with that of 1992. Gradual increases in demand for construction aggregates are anticipated after 1993 as well, based on increased volume of work on the infrastructure that is being financed by the Intermodal Surface Transportation Efficiency Act of 1991, some State highway projects, and the recovery of the U.S. economy. It is estimated that the demand construction sand and gravel will reach 975 million tons in 1995. The projected increases will be influenced construction activity, primarily in the public construction sector.

Construction sand and gravel f.o.b. prices are not expected to increase significantly, even if the demand for construction aggregates rise over the forecasts. However, the delivered prices of construction sand and gravel are expected to increase, especially in and near metropolitan areas, mainly because more aggregates are transported from distant sources.
