Another defect occaſioned in trees by the ſevere *froſts* of that year, and probably in a greater or leſſer degree by thoſe of many others, is, that the blea, and with it the bark, has in part periſhed, and the reſt has remained either wholly unhurt, or, at the worſt, in a much better condition than that. This is diſcovered when a number of years afterwards the trees are felled for timber. In ſawing theſe horizontally through the body, there is found a piece of dead blea covered with a dry and decayed bark, which is buried as it were in the wood of the tree, being covered by ſeveral circles of living wood. This decayed matter generally occupies about a fourth part of the circumference of the body of the tree, and is ſometimes much browner, and ſometimes much whiter than the reſt of the wood; and it is a general obſervation, that theſe decayed parts are uſually found on that ſide of the tree which has faced the ſouth. The great number of trees that were examined after felling in the different parts of France, were found to have this dead blea and bark all covered under an equal number of annual circles of ſound wood, which being counted were found to be the ſame number with the years that had paſſed ſince the year 1709; and conſequently all muſt have been the effect of the terrible *froſts* of that winter. A part of the bark and blea of the trees having periſhed by the *froſt*, and the reſt remaining alive, that part had finally been grown over and covered by the ſucceeding increaſe of the other parts of the tree. The reaſon of its being uſually found to the ſouth ſeems to be, that the frozen juices being then thawed every day by the ſun, ſuffered the violence of a new freezing every night. This defect was ſeldom found to run the whole length of the trunk, but uſually left part quite free, and ſeemingly ſound.

Finally, another accident attending trees from very ſevere *froſts* is, that they are ſometimes ſplit by them according to the direction of their fibres, and this often with a very loud crack.

It is not uncommon in large foreſts to meet with trees that have been thus ſplit, and which having outlived the winter that occaſioned it, are found to have a long rib marking the place where the crack was, and forming a ſort of cicatrix or ſcar over the wound. This cicatrix or rib is however only ſuperficial; and where-ever it is, the crack is ſtill found remaining under it in the tree; for though the bark and blea can in this manner conſolidate and form a covering for a wound, the fibres of the ſolid wood when once broken or ſeparated never cloſe again. It is the general opinion of the workmen that all theſe cracks in timber are the effects of *froſts*; and it is very eaſy to conceive, that it may be natural for *froſt* to effect it, as it is well known that all frozen liquors take up more room, then they did while in a fluid ſtate. It is not certain however, that all the cracks in timber are from this cauſe, many of them may have been occaſioned merely by a redundance of ſap.

On examining the trees felled in France in the year 1736, great numbers of them were found to be thus cracked, and that not in any particular part, as is the caſe in the other diſtemperatures occaſioned by *froſt*, which are uſually to the South, but in all expoſitions, and in trees growing in all ſoils. They were found to bemoſt frequent, however, in the trees that had grown on moiſt ſoils, and in the North and Weſt expoſitions. This ſeems to have happened from the *froſts* having acted more violently at north and weſt; and becauſe the texture of the fibres of wood is much more lax and rare in thoſe trees which ſtand on marſhy ground than in others, and their ſap being more plentiful and watery, the effects of the *froſt* will be the greater, as the quantity of juices for it to act upon is greater, and as the fibres are capable of leſs reſiſtance. That the watery nature of the juices of trees is what expoſes them to theſe injuries from *froſts* appears very probable from hence, that the pine and fir, and other trees whoſe juices are of a reſinous nature, are not found to be ſubject to theſe injuries. We well know that oils and reſinous juices are not ſo ſubject to congeal by *froſts* as water, and that when they do, they contract, not increaſe in their bulk by the congelation; and therefore the injuries from *froſt* which depend on the ſwelling of the ſap from freezing, can by no means affect theſe.

In the trees which have been ſplit by *froſt*, there is always found in the crack under the cicatrix a remainder of decayed wood or of ſap; and the appearance is no way different from thoſe defects which ariſe from a decay of the woody fibres by mere redundance or diſtemperature of the ſap, only that theſe laſt are never covered with any cicatrix.

It is poſſible that the *froſts* in ſevere winters may do many other damages to trees beſide theſe; but theſe are very certainly known to be wholly owing to it. Nor are the *froſts* of the ſpring ſeaſon, tho' leſs violent, to be ſuppoſed to do us any leſs injury; for they attack vegetables, at a time they can leſs bear them, and what they want in violence, they have in frequency.

The opinions of authors about the expoſitions of trees to the different quarters, have been very different, and moſt of them grounded on no rational foundation. Many are of opinion that the effects of *froſt* are moſt violently felt on thoſe trees which are expoſed to the north; and others think, the ſouth or the weſt the moſt ſtrongly affected by them. There is no doubt, but the north expoſure is ſubject to the greateſt cold. It is denied the benefit of the ſun, whoſe heat alone can attemperate the rigour of ſevere *froſts*; and beſide this, it is expoſed to the north, north-eaſt and north-weſt winds, which are ever the coldeſt of all others, as is proved abundantly, not only by our own ſenſations, but by the thermometer; and the earth on the north ſide of a hedge is often found perfectly frozen, while that on the ſouth is ſoft enough to bear working. The ſnow found on the north ſide of mountains, when there is none elſewhere, is another proof; and from the whole, it is certain, that the north expoſure is of all others the coldeſt, and the *froſt* there the ſtrongeſt. It does not however follow from this, that the injury muſt be always greateſt on the trees expoſed to the north in *froſts*; on the contrary, there are abundant proofs among the preceeding obſervations, that it is on the ſouth ſide that trees are generally more injured by *froſt*; and it is plain from repeated experiments, that there are particular accidents, under which a more moderate *froſt* may do more injury to vegetables, than the moſt ſevere one which happens to them under more favourable circumſtances.

It is plain from the preceeding accounts of the injuries trees received by the *froſts* in 1709, that the greateſt of all were owing to repeated falſe thaws, ſucceeded by repeated new *froſts*. But the *froſts* of the ſpring ſeaſon furniſh abundantly more numerous examples of this truth; and ſome experiments made by Mr. de Buffon, at large in his own words, prove inconteſtably, that it is not the ſevereſt cold or moſt fixed *froſt*, that is the greateſt injury to vegetables.

This gentleman cauſed ſeven or eight acres of coppice wood which ſtood in an open plain, and in a dry ſoil, ſurrounded every way with cultivated land, to be cut down in the courſe of the winter, in the year 1734. He ordered ſeveral ſquare cluſters of trees to be left in the place; theſe were left ſquare, and were ſo contrived, that their four faces directly pointed to the four expoſures, north, ſouth, eaſt and weſt; the reſt of the wood being all cut clean down, he obſerved in the ſpring what would be the manner of ſhooting of the old ſtocks, and of the trees of theſe cluſters. On the twentieth of April he found that there were ſtrong ſhoots on the ſouth ſide of every cluſter,

cluſter, where the whole body of the trees in the cluſter kept off the north winds, and where the ſouth ſun had moſt power. It was in theſe places that the young ſhoots made their firſt appearance, and were the moſt ſtrong and vigorous; the eaſt ſides of the cluſters next ſhot out; after theſe the weſt, and finally the north. A week afterwards there came on a very ſevere *froſt* with a clear air, and examining the ſhoots on the ſouth ſides of the cluſters, they were found all decayed and withered, and looked black, while thoſe which were expoſed to the north wind, which at that time blew very ſharply, were found very little hurt. The eaſt and weſt ſides were about equally damaged; aud the ſtate of the ſhoots on the ſame ſides of all the cluſters or thickets was the ſame. On the fourteenth, fifteenth and twenty-ſecond of May, there were ſevere *froſty* mornings; and inquiring into the ſtate of the ſhoots again, the caſe was juſt the ſame as before, all the ſhoots on thoſe ſides of the thickets which were defended from the north and north-weſt winds, which then blew, were greatly damaged, while every thing that was expoſed to the wind was ſcarce found to have ſuffered at all.

Theſe obſervations indiſputably prove, that tho' the *froſt* is moſt violent at the north, yet the injury done to vegetables by *froſt* is leaſt of all in that expoſure.

This is an obſervation directly oppoſite to the common opinion, yet it is not the leſs true, nor is it any way diſcordant to reaſon. We find by a number of experiments, that humidity is the thing that makes *froſt* fatal to vegetables, and therefore every thing that can occaſion humidity in them, expoſes them to theſe injuries, and every thing that can prevent or take off an over proportion of humidity in them, every thing that can dry them, tho' with ever ſo increaſed a cold, muſt prevent or preſerve them from thoſe injuries. Numerous experiments and obſervations tend to prove this. It is well known that vegetables always feel the *froſt* very deſperately in low places where there are fogs. The plants which ſtand by a river ſide, are frequently found deſtroyed by the ſpring and autumnal *froſts*, while thoſe of the ſame ſpecies, which ſtand in a drier place, ſuffer little, or perhaps not at all by them; and the low and wet parts of foreſts are well known to produce worſe wood than the high and drier; and the coppice wood in wet and low parts of common woods, tho' it puſh out more vigorouſly at firſt than that of other places, yet never comes to ſo good a growth; for the *froſts* of the ſpring killing theſe early top ſhoots, obliges the lower part of the trees, to throw out lateral branches: and the ſame thing happens in a greater or leſſer degree to the coppice wood that grows under cover of larger trees in great foreſts; for here the vapours not being carried off, either by the ſun or wind, ſtagnate and freeze, and in the ſame manner deſtroy the young ſhoots, as the fogs of marſhy places. It is a general obſervation alſo, that the *froſt* is never hurtful to the late ſhoots of the vine, or to the flower-buds of trees, except when it follows heavy dews, or a long rainy ſeaſon, and then it never fails to do great miſchief, tho' it be ever ſo ſlight.

The *froſt* is always obſerved to be more miſchievous in its conſequences on newly cultivated ground than in other places; and this is becauſe the vapours which continually ariſe from the earth, find an eaſier paſſage from thoſe places, than from others; trees alſo which have been newly cut, ſuffer more than others by the ſpring *froſts*, which is owing to their ſhooting out more vigorouſly.

Froſts alſo do more damage on light and ſandy grounds, than on the tougher and firmer ſoils, ſuppoſing both equally dry; and this ſeems partly owing to their being more early in their productions, and partly to their lax texture, ſuffering a greater quantity of vapours to tranſpire.

It alſo has been frequently obſerved, that the ſide ſhoots of trees are more ſubject to periſh by the ſpring *froſts*, than thoſe from the top; and Mr. Buffon, who examined into this with great accuracy, always found the effects of the ſpring *froſts* much greater near the ground than elſewhere. The ſhoots within a foot of the ground quickly periſhed by them: thoſe which ſtood at two or three foot high, bore them much better; and thoſe at four foot and upwards frequently remained wholly unhurt, while the lower ones were wholly deſtroyed.

Theſe are a ſeries of obſervations, which have proved beyond all doubt, that it is not the hard *froſts* which ſo much hurt plants, as thoſe *froſts*, tho' leſs ſevere, which happen when they are full of moiſture; and this clearly explains the account of all the great damages done by the ſevere *froſts* being on the ſouth ſide of the trees which are affected by them, tho' that ſide has been plainly all the while leſs cold than the north. Great damage is alſo done to the weſtern ſides of trees and plantations, when after a rain with a weſt wind, the wind turns about to the north at ſun ſet, as is frequently the caſe in ſpring, or when an eaſt-wind blows upon a thick fog before ſun riſing. Memoirs, Acad. Scien. Par. 1737.

FROST *ſplit*, a phraſe uſed by our farmers to expreſs ſuch trees as have large cracks in their trunks and branches, rendering them unfit for the uſes they would otherwiſe have ſold for, and by that means greatly debaſing their value. It has been pretended by ſome, that theſe rents and cracks in trees, were owing to other cauſes; but we have had innumerable inſtances and thoſe well recorded of the immediate effect of hard *froſts* on the ſtrongeſt trees ſpoiling them in this manner; and it appears very rational, to ſuppoſe all theſe injuries do really come by the ſame means, and are properly called by this term. Vid. ſupra, and the Phil. Tranſ. N°. 165.

FROTH, in the manege, is a moiſt white matter that oozes from a horſe's mouth, otherwiſe called foam. A horſe that by champing on his bridle, throws out a great deal of *froth*, is judged to be a horſe of mettle and health, and to have a cold freſh mouth.

FROTH *ſpit*, or *cuckow ſpit*, a name given to a ſort of white *froth* or ſpume very common in the ſpring, and firſt months of the ſummer, on the leaves of certain plants, particularly on thoſe of the common white field lychnis, or catch-fly, thence called by ſome *ſpatling poppy*. All writers on vegetables have taken notice of this *froth*, tho' few have underſtood the cauſe or origin of it, till of late. Many imagined it an exhalation from the earth, ſome have eſteemed it as its name expreſſes the ſaliva of the cuckow, others the extravaſated juices of the plant, and ſome a hardened dew. But all theſe are erroneous opinions, and the true account of it is that it owes its origin to a ſmall inſect.

There are very frequently to be ſeen in the ſummer months a ſort of ſmall leaping animals, called by ſome the flea-graſs-hoppers, becauſe they are very ſmall, and leap like a flea; theſe little creatures have each a pointed proboſcis, by means of which they ſuck the juices of the plants, they are found upon. Theſe animals lay their eggs in autumn, from which in the ſpring following the young ones are hatched, and theſe are at firſt tenderly ſhelter'd from injuries by a delicate and thin membrane, which makes a ſort of nymph, having the lineaments of all the parts of the animal, which is to iſſue from it. When it is firſt hatched from the egg, it is a ſmall white point on the leaf, not larger than the point of a needle; a few days after, it is greeniſh, its colour changing with the juices of the plant on which it feeds: in this ſtate it not unaptly reſembles that ſmall ſpecies of frog, called the tree-frog, which is common on the branches of trees in many places; it moves about very ſwiftly in this ſtate, tho' ſtill covered with its membrane, but till it gets rid of that, it can neither leap nor fly.

The manner in which this little creature forms this *froth* upon the plant is this; it applies its anus cloſe to the leaf, and diſcharges upon it a ſmall drop of a white viſcous fluid, which containing ſome air in it, is ſoon elevated into a ſmall bubble; before this is well formed, it depoſits ſuch another drop, and ſo on till it is every way overwhelmed with a quantity of theſe bubbles, which form the white *froth* which we ſee. It adds to this upon occaſion, but never moves from under it, till it has got rid of its enveloping membrane, or arrived from the nymph ſtate to that of the perfect animal. It throws out theſe globules of viſcous humor, by a ſort of dilatation, and contraction of its belly; and as they ſucced one another, it diſpoſes them every way round it with its feet. A proof, that while theſe animals are in this imperfect ſtate, and covered with *froth*, they yet feed on the juices of the plant, is, that if one of them be placed on a leaf of mint, or any other ſuch plant, the leaf on which they live will never grow beyond the ſize it was of, when the animal was placed upon it, while the oppoſite leaf will acquire its full dimenſions. When the animal has quitted its nymph ſtate, it makes no more *froth*, but leaves that under which it had lived, and takes its courſe freely about the plant.

FROWER, an edged tool uſed in cleaving wood into laths. *Ray*'s Engl. Words, p. 37.

FRUCTIFEROUS properly denotes any thing that produces fruit; but in a more large or figurative ſenſe, is uſed by lord Bacon, and others, for ſuch experiments in natural philoſophy, as prove advantageous to the experimenter in point of gain or profit.

FRUCTIFICATION *of plants*. See GENERATION, PLANT, *&c.*

FRUCTISTÆ, in botany, that ſet of authors who have attempted the eſtabliſhing the claſſes and diſtinctions of plants upon the fruit, ſeed, or receptacle of theſe in plants. Of this liſt are Cæſalpinus, Moriſon, Ray, Herman, and Boerhaave. *Linnæi* Fund. Bot. p. 2.

FRUIT, (*Cycl.*) the production of a tree or plant for the propagation or multiplication of its kind. In this ſenſe the word takes in all kinds of ſeeds with their furniture. But botaniſts uſually underſtand by it that part of a plant wherein the ſeeds are contained.

The *fruit* in all plants is the product or reſult of the flower, or that for the production and nutrition of which the flower was intended. The ſtructure and parts of different *fruits* are different in ſome things; but in all the ſpecies, the eſſential parts of the *fruit* appear to be only continuations or expanſions of thoſe which are ſeen in the other parts of the tree; and the ſame fibres are continued to them from the root. An apple

cut in two tranſverſely is ſeen to be principally compoſed of four parts. 1. A skin or rind, which is only a continuation and expanſion of the outer bark of the tree. 2. A parenchyma or pulp, which is an expanſion and intumeſcence of the blea, or the inner bark of the tree. 3. The fibres, which are ramifications of the woody part of the tree. 4. The core, which is the produce of the pith of the wood, indurated or ſtrengthened by twigs of the woody fibres intermixed with it. This ſerves to furniſh a proper lodging for the ſeeds, and filtrates the juices of the parenchyma or pulp, and conveys them to the ſeeds.

Of the fibres there are generally reckoned fifteen branches, of which ten penetrate the parenchyma, and incline to the baſis of the flower; and the other five aſcend more particularly from the pedicle or ſtalk, and meet with the former at the baſe of the flower; and to theſe branches the capſulæ, or coats of the kernels, are faſten'd. Theſe branches being firſt extended through the parenchyma to the flower, furniſh the neceſſary matter for the vegetation of it; but as the *fruit* increaſes, it intercepts the aliment, and by this means the flower is ſtarved, and falls off.

In a pear there are five parts to be diſtinguiſhed; the skin, parenchyma, ramification, ſtone, and acetarium. The firſt three parts are common to the apple; the ſtone, obſerved chiefly in choak pears, is a congeries of ſtrong corpuſcles, which are diſperſed throughout the whole parenchyma, but in the greateſt plenty, and amaſſed cloſeſt together, about the center of the acetarium. This ſeems formed of the ſtony or calculous part of the nutritious juice. The acetarium is a ſubſtance of a tart, acid taſte, and of a globular figure, incloſed in an aſſemblage of ſeveral of the ſtony parts before-mentioned.

In plums, cherries, *&c.* there are four parts, the coat, parenchyma, ramification, and ſtone. The outer part or ſhell of the ſtone ſeems formed of the calculous part of the nutritious juice of the plant, and the inner part or kernel of the pith of the tree, derived thither by ſeminal branches, which penetrate the baſe of the ſtone. The acorn conſiſts of a ſhell, cortex, and medulla. The ſhell conſiſts of a coat and parenchyma derived from the bark and wood of the tree. The cortex conſiſts of an inner and outer part; the firſt of which is a duplicature of the inner trunk of the ſhell; the ſecond is a ſofter ſubſtance derived from the ſame ſource as the parenchyma of the ſhell. But authors are not agreed whether the medulla or pulp of the kernel does ariſe from the pith of the tree, or from the cortical part thereof.

Berries, grapes, *&c.* contain, beſide three general parts, *viz.* coat, parenchyma and ramification, grains of a ſtony nature, which are the ſeeds. *Miller*'s Gard. Dict.

The uſe of *fruits* with us might, under proper regulations, be render'd much more extenſive than it is. Many *fruits* which do hurt when eaten raw, would make wines equal in flavour to many of thoſe now obtained at great prices from abroad; and lands which will not bear corn, yet would bear trees and ſhrubs producing ſuch *fruits*; and the conſequence of our falling heartily into it would be, that much ground, at preſent lying waſte, would be occupied, and great employment found for the numerous poor of ſome of our counties, where the quantities of waſte land are proportionably ſo great, that there is not employment for the people of one half of the county. Cherries properly managed make an excellent wine, and that in very large quantities; and plums alſo make a very agreeable kind, but that it has an auſtereneſs, which muſt be taken off by mixing a little ſugar with it when in the glaſs, not before it is drawn off.

A coarſe plum, ſomewhat larger than a damſon, is the beſt kind for this wine. This is a ſort of plum that grows wild in ſome of our hedges. It will ſucceed on any ground, the pooreſt that can be imagined, and it produces a great abundance of *fruit*. The wine that is made from it is of a very conſiderable ſtrength, and affords a pleaſant brandy by diſtillation in conſiderable quantities. Our common garden currants afford a very agreeable wine, and our gooſeberries are not ſecond to any thing. All theſe produce *fruit* in great abundance; and the planting and taking care of them is very cheap, and the operation very eaſy. The common way of making theſe wines yields very good ones; but when the art of the experienced Vigneron is employed in it, the liquors will prove greatly better. Phil. Tranſ. N° 124.

We have a very remarkable account of the production of flowers and *fruit*, given in a treatiſe of Franc. de Lanis, with ſuch an air of aſſurance and demonſtration, that many would be apt to ſuppoſe it indubitable. He ſays, that he took a quantity of orange flowers, and put them into half a pound of oil of ſweet almonds, with a little roach alum, this was expoſed together to the ſun, and he added freſh flowers every week as the others putrified. The oil after this being poured off into ſeveral vials, and ſet by till the next ſpring, he tells us that there were then ſeen flowers ſwiming in the oil, wholly reſembling the orange flowers firſt put in; and that as the ſeaſon advanced, theſe flowers ripened into *fruit* as thoſe growing on the tree; and the *fruit* in the vials he ſays, was no way deficient from the oranges growing on the tree, but in ſize. The author is not content with declaring this, on his own poſitive knowledge, but brings in as a witneſs of the truth of it, a nobleman of the ſame place, who he ſays, had one of the vials of oil, which annually produced flowers, and *fruits*, at the time that the orange trees did ſo.

This author is very free in his cenſures of the Engliſh philoſophers, particularly of our lord Bacon, and gives this as an inſtance of his own improvements in that ſtudy; but the thing is in itſelf ſo abſurd, that probably no body will pay reſpect enough to this author, to think it worth a trial.

The Petersbourg academy furniſhes us with two very ſingular inſtances of *fruits* growing in an unnatural manner; the one of theſe in the fig-tree, the other in the apple-tree. In both thoſe caſes, the *fruit* inſtead of its common ſituation, was placed upon the trunk of the tree with no branch or leaf near it, but only a ſhort pedicle for its ſupport. The inſtance of the fig-tree afforded three figs in a cluſter, the middle one of which withered, but the other two grew to their proper ſize, and were like the reſt of the figs on the ſame tree. The other inſtance of the apple tree afforded only one ſingle *fruit*, but there was in it ſomething very ſtrange, or that appeared ſo however at firſt ſight, for the apples produced on the branches of the tree were of one kind, and this of another. The tree had been grafted, and all the *fruit* of the branches grew from the graft; this ſingle one which ſtood upon the trunk of the tree below the graft, was of the ſpecies produced by the ſtock. This had doubtleſs been preceeded by a flower, tho' unobſerved, and it could only be as it appeared of the nature of the genuine *fruit* of the ſtock. All gardeners know that the ſtock ſuffers no change from the graft; in both theſe caſes there was probably the rudiment of a branch where the ſingle *fruit* appeared, and every other part of it except the bud of the *fruit* alone had periſhed, while that arrived at its deſtined ſize and maturity. We have alſo an account in the Philoſophical Tranſactions [a], of an apple-tree bearing a conſiderable quantity of *fruit* for many years together, without bloſſoming. [a N°. 385.]

FRUIT-*flies*, a name given by gardeners, and others, to a ſort of ſmall black *flies*, found in vaſt numbers among *fruit* trees, in the ſpring ſeaſon, and ſuppoſed to do great injury to them.

Theſe are a ſpecies of ſmall black fly. Mr. Lewenhoek preſerved ſome of them for his microſcopical obſervations.

He found that they did not live longer than a day or two, but that the females in this time uſually laid a great number of longiſh eggs. The gardeners who ſuppoſe that theſe flies wound the leaves of the trees, are miſtaken: it is true that they feed on their juices, but they have no weapons, with which to extract this themſelves; they feed on ſuch as is naturally extravaſated, and when there is not enough of this for their purpoſe, they haunt thoſe places where the pucerons reſort, and feed on the juices which theſe little creatures extravaſate by means of the holes they bore in the leaves with their trunks. Theſe pucerons are a ſmall ſort of inſect very common on our *fruit* trees, and other plants and trees; they are of a greeniſh colour, and are commonly called tree lice. Philoſ. Tranſ. N°. 262. See PUCERON.

FRUIT *ſtones*. The miſchiefs ariſing from the bad cuſtom of many people ſwallowing the ſtones of plumbs and other *fruit* are very great. The Philoſophical Tranſactions give us an account of a woman who ſuffered violent pains in her bowels for thirty years, returning once in a month or leſs. At length a ſtrong purge being given her, the occaſion of all theſe complaints was driven down from her bowels to the anus, where it gave a ſenſation of ſtoppage, and diſtenſion, and produced a continual deſire of going to ſtool, but without voiding any thing. On the aſſiſtance of a careful hand in this caſe, there was taken out with a forceps, an oblong ball of an oval figure, of about ten drams weight, and meaſuring five inches in circumference; this had cauſed all the violent fits of pain ſhe had been ſo many years afflicted with, and after the taking it out, ſhe became perfectly well. The ball extracted looked like a ſtone, and felt very hard, but it ſwam in water; on cutting it thro' with a knife, there was found in the center of it a plum-ſtone, round which, ſeveral coats of this tough and hard matter reſembling a ſtone, had gathered. Another inſtance given in the ſame papers is of a man who dying of an incurable colic, which had tormented him many years, and baffled the effects of medicines, was opened after death; and in his bowels was found the cauſe of his diſtemper, which was a ball of the like nature with that juſt mentioned, but ſomething larger, being ſix inches in circumference when meaſured, and weighing an ounce and half; in the center of this, as of the other, there was found the ſtone of a common plum, and the coats were of the ſame matter with thoſe of the former. Theſe and ſeveral others inſtances mentioned in the ſame place, ſufficiently ſhew the folly of that common opinion, that the ſtones of *fruits* are wholeſome.

For tho' by nature the guts are ſo defended with their proper mucus, that people very ſeldom ſuffer by things of this kind, yet if we conſider the various circumvolutions of the guts, their

their valves and cells, and at the ſame time conſider the hair of the skins of animals we feed on, the wool or down on herbs and fruit, and the fibres, veſſels and nerves of plants which are not altered by the ſtomach; it will appear a wonder that inſtances of this ſort of miſchief, are not much more frequent. Cherry-ſtones ſwallowed in great quantities have occaſioned the death of many people, and there have been inſtances even of the ſeeds of ſtrawberries, collecting into a lump in the guts, and cauſing violent diſorders, which could never be cured till they were carried off. Philoſ. Tranſ. N°. 282. p. 1282.

FRUIT-*trees*. There is in the Philoſophical Tranſactions, a method of making *fruits* and flowers grow in winter inſtead of ſummer without the common way of doing it by heat. This method is to take up the trees with their roots in the ſpring-ſeaſon, juſt as they begin to ſhoot out their buds; let them be placed upright in a cellar, and ſtand there till the end of September following, then fit veſſels to them, and place the roots in them, covering them in a proper manner with earth, and bring them up into a common ſtove, water them at times with a ſolution of the bigneſs of a wallnut of crude ſal armoniac in a quart of rain water, and they will make their natural progreſs as in ſummer; and in the months of February or March following, the *fruit* will be full ripe, and as well taſted as if it had grown on them in the common way, and ripened at its natural ſeaſon. Philoſ. Tranſ. N°. 282, p. 44.

The ſuperfluous ſhoots from theſe trees muſt be pruned off at ſuch times of the year, when the trees are full of juice, and furniſhed for a farther ſupply; and by this means, there will be no marks of the wounds, they will cloſe up ſo perfectly. The manner of producing pyramidal trees by ingrafting, is not only applicable to *fruit* trees, but has been tried on oaks, limes and roſes, with the ſame ſucceſs. Vid. infra.

Laurembergius tells us of a peculiar way of managing *fruit* trees for ready ſervice and beauty, by means of which they will bear *fruit* the firſt year. The method is this: draw a branch of a *fruit*-tree thro' a pot of earth, and prick it full of holes with a knife, ſo far as it is to ſtand in the pot; let it be well watered for the firſt ſeven or eight days, to make it ſhoot out a great quantity of roots; in the March following cut off the branch from the tree, and let it depend wholly on itſelf for nouriſhment; break the pot away, and place the clump of earth with the young tree in it in the place where it is intended to ſtand. The author aſſures us it will partake ſo much of the nature of the ſtock, as to bear *fruit* the firſt year. Phil. Tranſ. N°. 3.

An anonymous author has given us in a treatiſe publiſhed at Hamburgh, under the title *Amænitates Hortenſes Novæ*, a new method of grafting trees, ſo as to have very beautiful pyramids of *fruit* on them, which will exceed both in quantity, beauty and flavour, all that can be otherwiſe produced. This he ſays he had long experienced, and the method he gives of doing it, is this. The trees are to be tranſplanted in autumn and all their branches cut off; early in the following ſummer, the young ſhoots are to be pulled off, and the buds are then to be ingrafted into them, in an inverted direction; this he ſays, adds not only to the beauty of the pyramid but makes the branches alſo more fruitful. Theſe are to be cloſely connected to the trunk, and to be faſtened in with the common ligature; they are to be placed circularly round the tree, three buds in each circle, and theſe circles at ſix inches diſtance from one another. The old trees may be ingrafted in this manner, the ſucceſs having been found very good in thoſe of twenty years ſtanding; but the moſt eligible trees are thoſe which are young, vigorous and full of juice, and have not more thickneſs, than a finger or two. When theſe young trees are tranſplanted, they muſt be fenced round with pales to defend them from the violence of the winds, and there muſt be no dung put to them till they are thoroughly rooted, for fear of rotting them before the fibres ſtrike. The buds ingrafted muſt be ſmall, that the wounds made in the bark to receive them, not being over large, may heal the ſooner, and if any of the buds do not ſucceed, which will be found in a fortnight, there muſt be others put in their place. The wound made to receive theſe buds muſt be a ſtrait cut parallel to the horizon, and the piece of bark taken out muſt be downward, that the rain may not get in at the wound. In the autumn of the ſame year, this will be a green and flouriſhing pyramid, and the next ſummer it will flower, and ripen its *fruit* in autumn. Act. Erud. Ann. 1710.

FRUMENTUM *ſaracenicum*, in botany, a name by which ſome authors expreſs the fagopyrum, or buck-wheat. *Herm.* Hort. Lugd. Bat. p. 263.

FRUMENTUM *indicum*, *Indian corn*, a name given by our American planters to maiz. See MAIZ.

FRUMENTATION, *frumentatio*, among the Romans, a largeſs of corn beſtowed on the people. This practice of giving corn to the people, was a very antient cuſtom among the Romans, and frequently uſed to ſooth the turbulent humour of the populace.

At firſt the number of thoſe to whom this largeſs was given, was indeterminate, till Auguſtus fixed it at two hundred thouſand. *Pitiſc.* Lex. ant. in voc.

FRUMGYLD, in our old writers, is the firſt payment made to the kindred of a perſon ſlain, towards the recompence of his murder.—*Prima capitis æſtimationis penſio vel ſolutio.* L. L. Edmund.

FRUMSTOL, in our old writers, the chief ſeat or manſion houſe; which is called by ſome the *homeſtal*. Leg. Inæ, cap. 38.

FRUSO, in zoology, a name given by ſome to the *coccothrauſtes criſtata Indica*, commonly called the Virginia nightingale. See NIGHTINGALE.

FRUSSURA, in our old writers, a breaking down; alſo a ploughing or breaking up. *Fruſſura domorum*, is houſe-breaking; and *fruſſura terræ*, new broke land. Mon. Angl. Tom. 2. p. 394.

The word comes from the French *froiſſure*, a bruiſe; and that from the verb *froiſſer*, to bruiſe or break.

FRUSH or FRUG, in the manege, is a ſort of tender horn which ariſes in the middle of the ſole, and at ſome diſtance from the toe of a horſe; it divides into two branches running towards the heel, in the form of a fork.

FRUTEX *Æthiopicus*, in botany, A name given to the ſilver-pine-tree. See PINE-*tree*.

FRUTEX *Africanus*, in botany, a name given to a ſpecies of trees brought from the Cape of Good Hope; a deſcription of which ſee under the article *ſpurge-leaved* PINE.

FUCA, in ichthyology, a name given by Gaza, and ſome other writers to the fiſh called phycis, by Ariſtotle, Ælian and the other writers; and *tinca marina*, by Salvian and Rondeletius. It is a fiſh nearly allied to the genus of the blenni.

FUCHSIA, in botany, the name of a genus of plants ſo called by Plumier, in memory of the famous botaniſt Fuchſius; the characters of which according to Linnæus are theſe: the cup has an undivided edge, and ſtands upon the germen of the piſtil; the flower conſiſts of one petal, which is a clavated tube, divided at the edge into eight ſegments, which ſtand nearly even one with another, and are pointed, the alternate ones being placed a little lower than the others. The ſtamina are four filaments of the length of the tube, the antheræ are didymus, and of a roundiſh figure; the germen of the piſtil is roundiſh, and is placed under the flower-cup; the ſtyle is ſimple and of the length of the ſtamina, and the ſtigma is obtuſe. The fruit is a roundiſh berry, furrowed with four ſtrong lines, and containing four cells. The ſeeds are numerous and placed in double rows, and are of an oval figure. It is to be obſerved, that Plumier has figured only four ſtamina in his genera plantarum, but in his hiſtory, he has drawn eight, and this is a point, that can only be determined by ſome perſon who ſees the recent flower. *Linnæi* Gen. Plant. p. 522. *Plumier*, p. 9.

FUCUS, in botany, the name of a genus of plants; the characters of which are, that they are of a tough ſtructure, and grow under the water without affording any diſtinguiſhable flowers or ſeeds. See Tab. 1. of Botany, Claſs 17.

The ſpecies of *fucus* enumerated by Mr. Tournefort are theſe. 1. The common ſea *fucus* with bladders. 2. The greater, broad-leav'd dentated *fucus*. 3. The narrower-leav'd ſea *fucus* with few bladders. 4. The *fucus* with tumid extremities to the leaves, called by ſome the ſea oak with acorns. 5. The knotted ſea *fucus*. 6. The broad-leav'd ſea *fucus* with very few bladders. 7. The low, broad-leav'd ſea *fucus* without bladders. 8. The ſmall narrow-leav'd ſea *fucus*. 9. The ſmall broad-leav'd curled ſea *fucus*. 10. The ſmall Italian fimbriated and curled ſea *fucus*. 11. The bullated, ſhrubby ſea *fucus* with naked ſtalks and compreſſed bifid leaves. 12. The narrow-leav'd *fucus* with broad veſicles in the form of pods. 13. The podded *fucus* with very finely divided leaves. 14. The dwarf ſhrubby bladder *fucus*. 15. The hand-like ſea *fucus* with broad bifid leaves and long ſwoln pods joined one to another. 16. The narrow-leav'd palmated ſea *fucus* with verrucoſe bladders at the extremity of the leaves. 17. The low foliaceous *fucus* reſembling a hand. 18. The low membranaceous palmated *fucus* with fimbriated and curled edges. 19. The ſea *fucus* with roundiſh fimbriated leaves bifid at the extremities. 20. The great membranaceous many-leav'd *fucus*. 21. The red membranaceous narrow-leav'd *fucus* with fringed edges. 22. The red membranaceous ſea *fucus* with broad leaves dentated at the ends. 23. The white membranaceous *fucus* with very jagged ſegments. 24. The yellowiſh green ſea *fucus* making roundiſh angles. 25. The low bifid-leav'd *fucus* with broad membranaceous leaves, uſually verrucoſe. 26. The ſmall purple ſea *fucus*. 27. The ſea *fucus* with veſicles marginated with membranaceous edges. 28. The ſea *fucus* with tumid barbated leaves. 29. The long and broad belt-like ſea *fucus*, called the ſea girdle. 30. The ſea *fucus* with leaves like the bloody dock. 31. The arboreſcent many-leav'd eatable ſea girdles. 32. The broad-leav'd coriaceous *fucus*. 33. The ſhrub *fucus* with leaves narrow at the bottom, and growing broader toward the ends. 34. The erect unbranched ſea *fucus* with thick fleſhy leaves divided at the ends.

35. The

35. The long, narrow and thick-leav'd *fucus*. 36. The narrow-leav'd ligulated *fucus*. 37. The ſea *fucus* with a very long and broad and tender leaf. 38. The five-leav'd dentated *fucus*. 39. The ſmall *fucus* with long cylindric and pointed branches. 40. The *fucus* with a ſingle, long, and very broad leaf, rugoſe in the middle. 41. The ſea *fucus* with a long, broad, and very thick leaf. 42. The long, leafy, black *fucus*. 43. The ſmall purple ſea *fucus* with cylindric branches and leaves. 44. The green upright branched, cylindric, ſpongy *fucus*. 45. The tall, not branched, green, ſpungy, cylindric *fucus*. 46. The ſmall *fucus* with cylindric and fiſtulous leaves. 47. The ſtag's horn ſea *fucus* with globules at the ends of the branches. 48. The fine orbicularly ſpreading *fucus* with ſhort bifid or trifid cylindric ſegments. 49. The *fucus* reſembling ſilk or cloth in its texture. 50. The white narrow-leav'd, compreſſed, ſcrupoſe *fucus* with the extremities of the branches ſeemingly cut off. 51. The ramoſe ſea *fucus*. 52. The folliculated *fucus* with ſerrated leaves, called the cut-leav'd ſea lentils. 53. The folliculated *fucus* with toad flax leaves. 54. The American *fucus* with broad, ſhort, and ſerrated leaves. 55. The American *fucus* with very ſhort broad leaves. 56. The ſmall denticulated triangular *fucus*. 57. The ſmall white cylyndric, fungous, coralloide *fucus* with few ſegments. 58. The lettuce-leav'd *fucus*, or lactuca marina, called oyſter-green. 59. The endive-leav'd ſea *fucus*. 60. The tubular *fucus* of the ſhape of guts, commonly called the ſea chitterling. 61. The coronopus-leav'd *fucus*. 62. The ſea *fucus*, called *rocella*, and ſea dyer's-weed, or alga tinctoria. 63. The verrucoſe rocella. 64. The great ſpiral-leav'd ſea *fucus*. 65. The ſmaller ſpiral-leav'd ſea *fucus*. 66. The turkey-feather ſea *fucus*. 67. The round-leav'd ſea *fucus*. 68. The ſmall American opuntia-like *fucus*. 69. The hand-ſhap'd *fucus*. 70. The feather *fucus*. 71. The great horned ſea *fucus*. 72. The broad-leav'd dentated purple ſea *fucus*. 73. The elegant finely divided purple *fucus*. 74. The purple ſerrated ſea *fucus*. 75. The ſpongy ſelinoide ſea *fucus*. 76. The prickly, undulated, river *fucus*; and, 77. The low fimbriated and curled Italian *fucus*. *Tourn.* Inſt. p. 566.

Mr. Reaumur has diſcovered, that all the *fucus's* produce regular flowers and ſeeds, and that in the ſame regular manner. The flowers ſtand all over the leaves from the origin of them at the root to their utmoſt extremities, only the ribs in the middle are free from them. Every flower is compoſed of a cluſter of ſmall and extremely ſlender threads. Theſe are uſually all of the ſame length in the ſame flower, but they are ſo numerous as not to be eaſily counted; the longeſt of theſe threads are not above one twelfth of an inch in length, and the reſt are not half ſo long. They all iſſue out of a ſmall hole in the leaf, which ſerves as a ſort of cup to them. The threads are too feeble to ſupport their own weight in the air. When the ſea has left the plants, they are all found lying flat upon the leaves; though while the water covers them, they ſtand ſomewhat erect. They are not terminated at the top by apices containing a farina; but they may very eaſily contain that powder in their whole ſubſtance, and throw it off as ſoon as they expand themſelves. They are diſpoſed with no ſort of regularity on the leaves; for in ſome places they ſtand very cloſe together, in others they are placed at much greater diſtances. They grow equally on both ſides of the leaves; but the ſame flower never perforates the leaf, but all its parts appear on the ſame ſide. The flowers are much more eaſily diſcerned on the plant when it is dry, than while it is moiſt; for when dry, the filaments that compoſe them are white; whereas when moiſt, they are of a deep brown, like the leaves on which they ſtand. Of all the flowers which cover theſe plants, there are none that produce ſeeds but thoſe which are placed near the extremities of the leaves, and not all of theſe. In thoſe places where the ſeed is beginning to form itſelf, the extremity of the leaf ſwells, and forms a ſort of capſule, which contains the fruit, while the reſt of the leaf retains its former thinneſs. When the flowers are fallen, the holes in the leaf, which ſerv'd them for cups, become eaſily viſible in the places where the thickneſs happens, and where the ſeeds are to be lodg'd; and the margin of each hole is ſurrounded with a little circular protuberance, which ſtands out beyond the reſt of the ſurface. The ſwelled ends of the leaves often grow to half an inch in thickneſs, and uſually terminate in two horns, which form an acute angle; and the rib of the leaf is not viſible in theſe ſwoln parts. When theſe are cut open, whether it be tranſverſely or horizontally, they are found filled with a thick viſcous liquor, and in this are ſeen ſeveral roundiſh bodies of about a twenieth part of an inch in length; they are of a reddiſh colour, and are eaſily diſtinguiſhed, and are all found to be fixed to the ſides of the leaf. Theſe are what Dr. Robinſon, who ſeems to have been the firſt perſon who diſcover'd them, took for the ſeeds; and they have really much the appearance of naked ſeeds; but, when cloſely examined, they are found to be in reality capſules containing each a great number of minute round ſeeds, which are faſten'd to their ſides, as they were to the ſides of the tumor in the leaf: and theſe ſmaller capſules are in the ſame manner with thoſe full of a tranſparent viſcous liquor.

Though theſe capſules appear at firſt ſight plain roundiſh bodies; yet when more nearly examin'd, they are found to be rather ſhaped like glaſs bottles with ſhort necks, the neck being fixed into the ſubſtance of the leaf, and its extremity forming the protuberant circular rim that ſurrounds the little hole in the leaf, which had ſerved as a cup to the flowers. See Mem. Acad. Par. 1711, where we have figures of the *fucus*.

The antients uſed a purple ſea plant to dye woollen and linnen things to that colour, and called it *fucus*. The dye was very beautiful, but not laſting; for it ſoon began to change, and in time went wholly off. This is the account Theophraſtus gives of it.

The women of thoſe times uſed alſo a thing called *fucus* to ſtain their cheeks red; and many have ſuppoſed, from the ſame word expreſſing both, that the ſame ſubſtance was uſed on both occaſions. But this, on a ſtricter enquiry, proves not to be the caſe. The Greeks called every thing *fucus* that would ſtain or paint the fleſh. But this peculiar ſubſtance us'd by the women to paint their cheeks, was diſtinguiſhed from the others by the name *rizion* among the more correct writers, and was indeed a root brought from Syria into Greece on that occaſion. The Latins, in imitation of the Greek name, called this plant *radicula*; and, as Pliny has mention'd it, it is not improper to obſerve, that he has very erroneouſly confounded it with the *radix lanaria* or *ſtruthion* of the Greeks.

The word *fucus* was in theſe times become ſo univerſal a name for paint, that the Greeks and Romans had a *fucus metallicus*, which was the ceruſs or white lead uſed for painting the neck and arms white; after which they uſed the purpuriſſum, or red *fucus* of the rizium, to give the colour to the cheeks. They alſo in after-times uſed a peculiar *fucus* or paint for this purpoſe prepared of the creta argentaria, or ſilver chalk, and ſome of the rich purple dyes that were in uſe in that time; and this ſeems to have been very little different from our roſe pink, a colour commonly ſold at the colour ſhops, and uſed on like occaſions.

FUCUS *Palmatus*, *handed Fucus*. The name given to a ſpecies of ſea *fucus*, diſtinguiſhed from the reſt by its having no ſtalk, its leaves being divided in the manner of a hand, and its extremities divided into many curl'd ſegments. It is common on almoſt all the ſea coaſts of Europe, and is one of the ſeveral ſpecies of ſea plants in which Mr. Reaumur has diſcover'd regular flowers and ſeeds. They are in this ſpecies however ſo ſmall, as to require the aſſiſtance of a microſcope to diſcover them; though after they have been once ſeen in that manner, as is the caſe in many microſcopic objects, they may then be eaſily diſtinguiſhed by the naked eye. This plant is faſten'd to ſome ſtone by a round root, from which there ariſe four or five leaves, which at about an inch diſtance from the root divide into a number of branchings which conſtitute the whole plant. This ſpecies carries its ſeeds at the extremities of the leaves, where they are incloſed in the interior ſubſtance of the plant; and nothing is to be diſcover'd on the ſurface without the aſſiſtance of glaſſes, unleſs it be that the leaves are of a ſomewhat more dusky hue there than elſewhere. With the help of glaſſes this obſcurity is found to be cauſed by a number of ſmall opake bodies; and to diſtinguiſh theſe well, the part muſt be examined by holding it againſt the light, and even in this examination the ſurface of that part of the plant does not appear different from the reſt, nor can there be diſtinguiſhed any mark of the filamentous flowers of the common ſpecies, nor any ſign of the protuberances made by the necks of the capſules, as is the common caſe. When this obſcure part of the plant is opened, there appears a number of ſmall round and hard reddiſh ſeeds; there are uſually about twenty of theſe in every extremity of a leaf, and as the leaves are tender, they may be cruſhed under one's nail, and by this means the ſeeds may be diſtinguiſhed from the fragments of the bruiſed plant by their colour. Notwithſtanding the ſmallneſs of theſe bodies however, it is much to be doubted whether they are not capſules, or ſeed veſſels, rather than ſingle ſeeds; ſince in all the larger *fucus's* the ſeeds are found of an extreme ſmallneſs incloſ'd in capſules. An inſtance of this may be ſeen in the *fucus polyſchides*. Mem. Acad. Par. 1712. See POLYSCHIDES.

FUCUS *polyſchides*. See POLYSCHIDES.

FUCUS *thermalis*, in botany, the name of a remarkable ſpecies of plant, found only in the hot water ſprings. It was firſt diſcovered by Monſ. de Monteſquieu, in the great baſon, at the boiling ſpring in Gaſcony; he was not able to diſcover that it produced either flowers or ſeeds. Its ſubſtance is intirely compoſed of ſmall bladders full of air, the ſurfaces of which are reticular, as worked in the manner of a coarſe canvas. It is obſerved to grow only in the hotteſt waters.

FUDDER, among the miners, a load of lead, which is eight pigs, or ſixteen hundred weight. *Ray*'s Engliſh Words, p. 19.

FUEL, (*Cycl.*) in chemical operations. — A great deal of nicety is required in chooſing the proper *fuel* to raiſe and continue the ſeveral degrees of fire. The natural heat of the ſummer ſun is ſufficient for inſolations. A ſpirit lamp may be made to give the next degree of heat to this, which may be much augmented

mented or decreaſed according to the number of wicks kept burning at a time.

The next degree of fire to this, is made of the lighter *fuel*, ſuch as dry ſtraw, leaves, twigs and the like: the next in order, is that from oils, wax, reſin, pitch, &c. And laſtly ſolid wood, coals, and turf may be employed for the ſtrongeſt. Theſe by means of proper furnaces made to contain different quantities, may be made to give a greater or leſs degree of a ſtrong fire. To excite the greateſt degree of heat in a furnace, the rule is to uſe the denſeſt *fuel*, and in the largeſt quantity, and to have bellows placed all round the furnace: theſe are to be inceſſantly blown, and directed to the central part of the fire, in which the matter to be worked upon is lodged. Thus the greateſt degree of heat from culinary fires, is to be given, and this is ſufficient for the known operations on metals, glaſs, &c. *Shaw*'s Lectures, p. 38.

It is a known truth, that *fuel* cannot conſume by means of heat alone, without the admiſſion of freſh air, and this is no way more clearly proved, than by this eaſy experiment. Let a ſtrong cylinder of iron, hollow within, be fitted with a firm skrew at each end, in the cavity of this cylinder, incloſe a long piece of charcoal, and then skrew up both the ends faſt, and place the whole in a ſtrong fire, let it continue there for ſeveral hours, and when it is taken out and cooled, open it, and the piece of charcoal will be found ſtill black, in its own form, and no way apparently altered or diminiſhed.

It is plain from this, that the conſumption of *fuel* depends upon the rarefaction, diſlodgement, brisk agitation, and diſcharge of its oil, by means of freſh air; and hence we have the reaſon of the known rule of extinguiſhing fires by ſmothering them.

FUGA *demonum*, in botany, a name uſed by ſome authors for the hypericum, or St. John's-wort. *Ger.* Emac. Ind. 2.

FUGAM *fecit*, in law, a term uſed where it is found by inquiſition, that a perſon fled for felony, &c. And if flight and felony be found on an indictment for felony, or before the coroner, where a murder is committed, the offender ſhall forfeit all his goods, and the iſſues of his lands, till he is acquitted or pardoned: and it is held, that when one indicted of any capital crime, before juſtices of oyer, &c. is acquitted at his trial, but found to have fled, he ſhall, notwithſtanding his acquittal, forfeit his goods; but not the iſſues of his lands, becauſe by the acquittal, the land is diſcharged, and conſequently the iſſues. 3 Inſt. 218. H. P. C. 27. 2 Hawk. P. C. 450. The party may in all caſes, except that of the coroner's inqueſt, traverſe the finding of a *fugam fecit*; and the particulars of the goods found to be forfeited, may be always traverſed: alſo whenever the indictment againſt a man is inſufficient, the finding of a *fugam fecit*, will not hurt him. 2 Hawk. 451. making default in appearance on indictment, &c. whereby outlawry is awarded, is a flight in law.

FULGURATING *phoſphorus*, a term uſed by ſome Engliſh writers to expreſs a ſubſtance of the phoſphorus kind, the preparation of which, does not ſeem to have been well known to any, but the inventor of it. It was prepared both in a liquid and a dry form; and not only ſhone in the dark in both ſtates, but communicated its light to the things it was rubbed on. If incloſed in a glaſs veſſel well ſtopped, it ſometimes would *fugurate*, or throw out little flaſhes of light, and ſometimes fill the whole vial with waves of flame. It does not need recruiting its light at the fire, or in the ſunſhine, like the phoſphorus of the Bolonian ſtone, but of itſelf continues in a ſtate of ſhining for ſeveral years together, and is ſeen as ſoon as expoſed in the dark; the ſolid or dry matter always reſembling a burning coal of fire, though not conſuming itſelf. Phil. Tranſ. N°. 134.

FULICA, in the Linnæan ſyſtem of zoology, the name of a diſtinct genus of birds of the order of the anſeres, the diſtinguiſhing character of which is, that the beak is pointed, the thighs are half naked, and the forehead wholly naked. *Linnæi* Syſtem. Nat. p. 46.

The *Fulica* is a water fowl diſtinguiſhed from the moor-hen kind, by having its toes widened by a membrane, tho' not joined together by it, or webb'd like the ducks. Of this there are two ſpecies, the common *coot*, and a larger kind called *macroule*, or *diable de mer*, the ſea devil.

The common *coot* is a conſiderably large bird, weighing uſually a pound and half, its beak is of a bluiſh white, and is a finger's breadth and half long, ſomewhat flatted and ſharp at the point; its legs are bluiſh or greeniſh, it has ſemicircular membranes at the joints of its toes: but what is its moſt obvious diſtinction is, that it has from the beak to the crown of the head, a fleſhy excreſcence, which is roundiſh, ſoft and ſmooth, and is always naked or deſtitute of feathers, and hence the bird is commonly called with us, the bald *coot*. It is all over black above, but of a deeper black about the head, than in any other part, and its breaſt and belly are of a ſort of lead colour; its wing-feathers have a browneſs, mixed among the black, and ſome of them are tipped with white.

The other ſpecies or *macroule*, called by Bellonius, the *fulica major*, is larger and of a finer black than this, and has a larger white excreſcence on its head.

The common *coot* is ſo plentiful about Peterbourough in Northamptonſhire, that in the ſeaſon of its laying, whole hampers full of its eggs, are there brought to market and ſold at an inconſiderable price; the people boil them, and the ſhell is ſo thin, that they often eat them without taking it off. *Ray*'s Ornith. p. 239.

FULIGO *metallorum*, a term uſed by the chemiſts, ſometimes to expreſs arſenic, and ſometimes crude mercury.

FULIGULA, in zoology, a name given by Geſner to a ſpecies of duck, ſeeming to be the ſame with a kind common on the Yorkſhire ſhores. The ſame author alſo deſcribes another ſpecies under the name of *anas fuligula prima*, which ſeems the ſame with the *capo negro*, or tufted duck. See CAPO *Negro*.

FULLER'S *earth* (*Cycl.*) —The greateſt quantity and the fineſt earth of this kind in the world, is dug in the pits at Wavedon, near Woburn in Bedfordſhire. The ſtrata in theſe pits lie thus; from the ſurface to the depth of ſix foot, there are ſeveral layers or beds of ſand, all reddiſh, but ſome lighter coloured than others. Under theſe there is a thin ſtratum of a ſandſtone, which they break through, and then there is the *fuller*'s earth. The upper ſtratum of this, is about a foot thick, and they call it *cledge*; this is thrown aſide as uſeleſs, being commonly foul'd with the ſand, which originally covered it, and uſually inſinuates itſelf conſiderably into it. After this, they come at the fine *fuller*'s earth for ſale, which lies to the depth of eight foot more. The matter of this is divided into ſeveral layers; there being commonly about a foot and half between one horizontal fiſſure and another. Of theſe ſeveral layers, the upper half where the earth breaks itſelf, is tinged red; this ſeems to be owing to the running of the water on it, from among the ſands above, ſome of which are probably of a ferrugineous nature, or have ferrugineous matter among them. This reddiſh *fuller*'s earth, the workmen call *crop*; and between the cledge and this, there is a thin ſtratum of matter of leſs than an inch, which in taſte, colour and external appearance, reſembles the terra Japonica of the ſhops. This may probably alſo, have a ſhare in the tinging of the earth, as the water may be coloured in running thro it. Philoſ. Tranſ. N°. 379. p. 419.

The lower half of the ſtrata of *fuller*'s earth, they call wall-earth; this is untinged with the red colour of the other, and ſeems the moſt proper for fulling. Under the *fuller*'s earth, there is a ſtratum of a rough and coarſe white ſtone, about two foot thick; they ſeldom dig thro' this, but if they do, they find more ſtrata of ſand.

The ſtratum of *fuller*'s earth ſeems all the way to lie very level, not to riſe and fall with the upper ſtrata, for when the ſurface is higher, they always find they have farther to dig for it. There are a great number of perpendicular fiſſures in the ſtratum of *fuller*'s earth, and beſide this, it forms itſelf in every interval into a multitude of pieces of different ſhapes and ſizes by cracking. The place where it is dug, is that ridge of ſand hills, which runs to Shotover in Oxfordſhire; and as the ſtrata of the earth are uſually found to continue much the ſame, for long tracts of ground; it is probable, that the *fuller*'s earth ſtratum runs the whole length of theſe hills, and that ſomebody will at one time or other, be enriched by finding it in ſome other part of their courſe.

FULLONICA *terra alba*, white *fuller*'s earth, in natural hiſtory, a name given by ſome authors to the common white tobacco-pipe clay. *Kentman*'s Nomenclat. Foſſ. p. 11.

FULLO, in ichthyology, a name given by Theodore, Gaza, and others to the tench, or black cyprinus, called by the Greeks pſylon. See the article TENCH.

FULLONIANI, in church hiſtory, heretics who anathematized all who did not acknowledge, that Chriſt ſuffered in his divine nature; or who diſtinguiſhed his human and paſſible nature from his divine and impaſſible. See *Hoſm.* Lex. in voc.

FULMINATING *damp*. See the article DAMP, *Cycl.*

FULUSCULUM, in botany, a name given by the antient Romans to a peculiar ſpecies of mullein or *verbaſcum*, of which they uſed to make the wicks of the torches with which they kindled their funeral piles. The Greeks for the ſame reaſon called this ſpecies *necuia*. Dioſcorides indeed calls it *lychnies*, λυχνῖτις, and Nicander, *thryallis* θρύαλλις. The way they uſed it was this: they beat out the ſtalk of the plant, as we do hemp, and when it was ſeparated into looſe fibres, they plunged it into melted reſin; this gave it a conſiſtence again, and when cold, it was a kind of flambeau.

FUMADOES, in commerce, a name given to pilchards garbaged and ſalted, then hung in the ſmoak and preſſed; ſo called in Spain and Italy, whither they are exported in great abundance. Vid. Stat. 14 Car. 2. cap. 31.

FUMARIA, *fumitory*, in botany the name of a genus of plants, the characters of which are theſe. The flower is of the polypetalous anomalous kind, approaching ſomewhat to papilionaceous ones, but conſiſting only of two leaves, and as it were bilabiated, the upper lip running out into a tail behind, and with the under one joined to the ſtalk. Between theſe

lips as it were in the palate of a mouth, whoſe opening is occupied by a ſmall ligula, the piſtil ſtands, covered with a membrane; this finally becomes a membranaceous fruit, ſometimes ſhorter, ſometimes longer, which contains a roundiſh ſeed. *Tourn.* Inſt. p. 21.

The Species of *Fumitory* enumerated by Mr. Tournefort, are theſe. 1. The common purple flowered *Fumitory*. 2. The common *Fumitory* with white flowers. 3. The fine leaved Montpelier *Furmitory*, with white flowers. 4. The great *Fumitory*, with pale purple flowers. 5. The climbing *Fumitory*, with tendrils to lay hold on other things, with yellow flowers, black at the top. 6. The little fine leaved *Fumitory*, with bright purpliſh red flowers. 7. The little fine leaved *Fumitory*, with variegated flowers. 8. The ſmall procumbent fine leaved *Fumitory*. 9. The ſmall *Fumitory*, with leaves like crooked fennel, and white flowers, each variegated with a ſingle red ſpot. 10. The ſmall Roman *Fumitory*, with flixweed leaves. 11. The broad leaved climbing *Fumitory*. 12. The climbing *Fumitory*, with narrower leaves. 13. The Spaniſh rock *Fumitory*, with large heart faſhioned leaves, and compreſſed ſeeds. 14. The greater hollow rooted *Fumitory*, with pale purple flowers. 15. The great hollow rooted *Fumitory*, with bright red flowers. 16. The great hollow rooted *Fumitory*, with white flowers. 17. The great hollow rooted *Fumitory*, with yellow flowers. 18. The great hollow rooted *Fumitory*, with greeniſh flowers. 19. The great bulbous rooted *Fumitory*, with ſolid roots, and 20. The ſmaller bulbous *Fumitory*, with ſolid roots.

The common *Fumitory*, which is frequent in our gardens and cornfields, and flowers in June, is eſteemed a very great medicine in obſtructions of the liver and ſpleen; it attenuates ſerous, bilious and aduſt humours, and carries them gently off by ſtool and urine. It is famous for the ſcurvy, and is alſo given in infuſion in the jaundice, and in the itch and all other cutaneous diſorders.

FUMIGATION (*Cycl.*)—*Fumigations* with cinnabar have often been recommended as very efficacious in ſome of the worſt circumſtances of the venereal diſeaſe. From a caſe related in the Medic. Eſſ. Edinb. Vol. 4. Art. 8. it appears, that this practice may be attended with very violent effects. Half a dram of factitious cinnabar burnt under the noſe and mouth of the patient, is there mentioned as having raiſed a ſpitting in three hours.

FUMITORY, in botany, &c. See FUMARIA.

FUMING, in metallurgy, the firſt calcination of the ores of metals, intended to diveſt them of their ſulphurs. *Boerhaave*'s Chem. p. 76. See ROASTING.

FUNDAMENTO, in the Italian muſic, is in general every part that plays or ſings the baſs; but the thorough baſs is more particularly ſo called, becauſe it is the baſis or foundation of all harmony. *Broſſ.* Dict. Muſ. in voc.

FUNDUCLÆ, an Ægyptian coin, a ſort of ſequin of the value of a hundred and forty ſix medines. *Pocock*'s Egypt. p. 175.

FUNDULUS, in zoology, a name uſed by many for the ſmall fiſh, called by others cobitis, and by the generality of people in England, the loche. *Willughby*'s Hiſt. Piſc. p. 265. See COBITIS.

FUNDULUS is uſed alſo by Schoneveldt, and ſome others to expreſs the common gudgeon. The confuſion of calling two fiſh by the ſame name which is peculiarly appropriated to neither, is very evident in this and numerous other inſtances; but it is always to be avoided by uſing expreſſive and genuine names. Thus even the word gobio the common name of the gudgeon confounds that fiſh with another very different genus; and Artedi is greatly to be applauded, who has found that our common gudgeon is no peculiar genus of fiſh at all, but is a ſpecies of the cyprinus. As ſuch he has given it the proper ſpecific name of the five inch ſpotted cyprinus, with the lower jaw ſhorter than the upper, and with two cirri or beards at the mouth; under this name the ſpecies is always to be known at ſight, and can never be confounded with any other genus. *Artedi*, Gen Piſc.

FUNERAL. See BURYING and BURIAL.

FUNGIFER *lapis*, the *muſhroom bearing ſtone*, a name given by authors to a coarſe ſtone found in Italy and many other places lying near the ſurface of the earth, which they ſay will at any time produce *muſhrooms*, on being moiſtened with warm water.

FUNGITÆ, in natural hiſtory, a name given by authors to a ſpecies of ſea coral, often found adhering to ſea ſhells, or to the larger corals in its recent ſtate, and very often found alſo foſſil or buried at great depths in the earth; they are uſually immerged in ſtone, and ſometimes in clay. The more frequent of theſe are of a conic ſhape, ſometimes they are flatted and diſcoide, and uſually ſtriated longitudinally; they ſometims are found in their foſſil ſtate adhering to ſhells or corals, but more uſually ſeparate. To theſe and ſome other bodies of this kind, Mr. Lloyd has given the name *columella*; to one of them that of *branchiale*, from its reſembling the gills of a fiſh; and to another, that of *undulago*, from its undulated figure. *Hill*'s Hiſt. of Foſſ. p. 641.

FUNGOIDES, *baſtard muſhroom*, in botany, the name of a genus of plants, the characters of which are the ſame with thoſe of the fungus, from which it differs only in being of a hollowed form, reſembling a cup, or empty open box.

The ſpecies of *Fungoides*, enumerated by Mr. Tournefort are theſe. 1. The ſmall cup *Fungoides*, containing large ſeeds. 2. The ſaucer ſhaped angular *Fungoides*. 3. The grey funnel ſhaped Canada *Fungoides*. 4. The curled ſaucer ſhaped *Fungoides*. 5. The coriaceous orange coloured *Fungoides*. 6. The ſcarlet ſaucer ſhaped *Fungoides*, with hairy edges. 7. The ſcarlet, ſaucer ſhaped *Fungoides*. 8. The brown *Fungoides*, with hairy edges, of the ſhape of a drinking glaſs. 9. The orange coloured ſcutellate *Fungoides*. 10. The black ſpotted ſcutellate *Fungoides*, and 11. The tree *Fungoides*, of a ferrugineous colour within. *Tourn.* Inſt. p. 560.

FUNGOUS *tumours*. See the article TUMOUR.

FUNGUS, *muſhroom*, in botany. See MUSHROOM.

FUNGUS *of the brain*.—Mr. Queſney aſſures us, that ſpirits are not ſo proper for preventing the growth of *Funguſes* from the brain, as balſam fiorivanti, or oleum terebinth. Mem. de l'Acad. de Chirurg. tom. 1.

FUNGUS, in mineralogy, a name given by Dr. Liſter, to a blackiſh bituminous ſubſtance, found in ſome of the mines of Derbyſhire. It adheres to the ſides of the fiſſures of rocks and lies in ſeams of the ſtrata. It is of a blackiſh colour and fatty ſubſtance, which never dries in the air, but always remains as moiſt, as when taken out of the mine. Some maſſes of it are ſoft and like a jelly, others are hard and firm, and in theſe there are ſeveral lumps of pure bitumen in many parts. This is inflammable like reſin. It is light, but breaks finer, and ſhines like good aloes when freſh broken, but that it is a little darker coloured, and has ſome tinge of purple in it. In ſome pieces the purple is wanting, and there is a green in the place of it. On being diſtilled, it yields firſt a limpid and inſipid water, then a whitiſh water of a ſharp taſte, and finally a yellow and clear oil, much reſembling oil of amber, but the proceſs affords no volatile ſalt in the neck of the reciever, in which it differs from amber when treated in the ſame manner. Phil. Tranſ. N°. 6. See SUCCINUM.

FUNGUS *oculi*, a name given by ſome of the writers on the diſeaſes of horſes, to a diſtemper of the eye, to which that animal alone is ſubject. The firſt author who has communicated an obſervation of this diſorder to the world is Dr. Lower, in the Philoſophical Tranſactions. He obſerves, that horſes alone are ſubject to it, and calls it a ſpungy excreſcence of the uvea; it is commonly of a dark musk colour, and grows out of the edge of the uvea, and though of little conſequence in its firſt ſtages, yet if it grows very large, or if the number of theſe *funguſes* increaſe, it weakens and obſtructs the creature's ſight, and ſometimes wholly takes it away. The uvea is a muſcular part, and its chief uſe is to dilate or contract itſelf in a proper manner for the admiſſion of objects with as much light as the eye can bear, ſo that the brighter the light is, to which the eye is expoſed, the more this membrane is contracted into a narrow compaſs, and the more dark the place is, the more the opening is dilated. This ſudden change, and the office of this part, may be more conveniently ſeen in the eye of a cat, than in that of any other animal, but it is the ſame in all, in a greater or leſſer degree. If the edges of this coat be loaded with a very large excreſcence of this kind, or if ſeveral tho' ſmaller grow all round it, it muſt neceſſarily happen, that the pupil, or ſight, is very much if not totally obſtructed, and the creature ſees very little, or not at all. The horſes of this kind are very ill furniſhed for ſeeing in the ſunſhine, but do very well in dark days, or in the dusk of the morning or evening, when the diſeaſe is not too violent.

A horſe moderately afflicted with this, uſually ſtumbles in the middle of the day, but goes very well in the dusk, and if brought out of the ſtable into the clear ſunſhine will ſuffer any one to put their finger up to the ſight of his eye without flinching; whereas when taken back into the ſtable, he will not ſuffer it to come within ſeveral inches without winking, and toſſing his head about. The dealers in horſes ſometimes perceive this, and attribute it to over running or drawing, or to ſtraining by any other means; but this is not the caſe, for it is found to affect colts that have never been backed or rid, as well as thoſe which have been worked. It is obſervable, that when theſe *Funguſes* grow in the eyes of young horſes, they become much ſmaller, when the creature is taken to a dry meat in the ſtable, and increaſe again when they are turned out again to graſs. Whether this be owing to the difference of dry and moiſt food, is not eaſy to determine, but it is moſt probably owing to the difference of paſture; the horſe at graſs, being obliged to carry its head much lower, than thoſe which feed in the ſtable. The more in number, or the greater in bulk, theſe excreſcences are, the more danger there is of the horſes wholly loſing its ſight, and the degree of the diſtemper is beſt judged of, by turning the eye to the light, and obſerving how much of the pupil is obſtructed by it, and how much is free. Thoſe *Funguſes* that are fixed on the upper part of the uvea, are apt to grow the largeſt, and to hinder the ſight moſt; and thoſe which

grow

grow in the middle of the uvea, hinder the ſight more by diſtracting the object, than thoſe which grow in either corner or angle of it. The cure is not eaſy; all that can be attempted muſt be by dry diet, and attenuating medicines; and a palliative remedy may be the hanging ſomething over to ſhade the eye, and keeping it from being expoſed nakedly to the ſun, the conſequence of which will be, that the pupil will not be ſo cloſely contracted, and conſequently, the light not ſo much obſtructed. Phil. Tranſ. N°. 32.

FUNNEL *faſhioned flowers*. See INFUNDIBULIFORM.

FUNNEL *polype*. See POLYPE.

FURIA, in the Italian muſic, is uſed for a very quick and ſtrong manner of ſinging or playing.

FURIGELDUM, in our old writers, a mulct paid for theft.

FURLONG (*Cycl.*) — In Scotland the *furlong* is equal to forty falls. Tr. Pract. Geom. p. 3. See FALL.

FURNACE (*Cycl.*) —*Metallurgic* FURNACES. Swedenborg has laid down from his own experience, certain rules for the general conſtruction of theſe *metallurgic furnaces*, by which they will always be made more advantageous to the proprietor, cæteris paribus, than any other kind. Theſe rules are, that the chimney be always placed as nearly as may be, behind the center of the *furnace*; that the ſmaller the depth of the fire place, provided it be ſufficient to hold the coals, the better; that all *furnaces* muſt be the better, the wider they are forwards, and the higher they are, ſo as not to loſe the benefit of reverberation.

Iron FURNACES. See IRON.

FURNAGE. See the article FORNAGE.

FURO, in zoology, a name given by ſome authors to the ferret, called by others alſo *furunculus* and *ictis*. See VIVERRA.

FURRING *of a ſhip*, is laying on double planks on her ſides. This is done after the ſhip is built, and is by the ſailors called *plank upon plank*. But there is another way of *furring*, which is more properly ſo called; and that is, when a ſhip's planks are ripped, and new timbers are put on the former timbers, and on them other planks; which is done ſometimes to make a ſhip bear the ſails the better.

FURUNCLE, or BOIL, is a ſmall reſiſting tumor, with inflammation, redneſs, and great pain ariſing in the membrana adipoſa under the skin. As there is no part of the body free from being the ſubject of this tumor, ſo the whole body is ſometimes ſo miſerably infeſted with them, that the patient knows not how to ſtir, or on what part to lie. Young infants, and adults, are equally liable to this diſorder; and tho' in adults there is ſeldom any great danger in it, yet it ſometimes happens when they are very numerous in tender infants, that they not only excite violent pains, reſtleſſneſs and toſſings, with great weakneſs, convulſions and epilepſies, but death itſelf ſometimes follows them.

The principal cauſe of *boils*, is a too glutinous and inſpiſſated ſtate of the blood, and the cure of them principally depends upon the reſtoring the blood to its due conſiſtence and proper circulation. People who are very ſubject to theſe tumors ſhould bleed and take purging medicines at proper intervals, and drink plentifully of warm and weak liquors, abſtaining from wine, ſtrong ſpirituous liquors, aud from the uſe of tobacco.

When the diſorder is recent or not habitual, external remedies alone are ſufficient for the cure: honey mixed to a proper ſharpneſs with ſpirit of vitriol is a very good external application. The touching the *boils* with ſpirit of vitriol alone, is often alſo of great ſervice; and ſometimes the diſcutient plaiſters are to be applied, as the diachylon, ſperma ceti, and ſoap plaiſter. If theſe applications however, do not prove ſucceſsful in the diſperſing a *boil*, the only method to be taken, is that of bringing it to ſuppuration. This however is in ſome caſes no eaſy task, but the tumor remains ſometimes very hard and troubleſome; even after a proper treatment of many weeks and ſometimes the humour that occaſions it, becomes ſo acrimonious by its long detenſion, and great inſpiſſation, that it produces ulcers, which grow gradually worſe and worſe, till at length they end in incurable fiſtulæ. To promote and quicken the ſuppuration, it is generally found of great ſervice to apply plaiſters of diachylon with the gums, and of honey and flower mixed, and made to a proper conſiſtence; and where theſe prove inſufficient, maturating cataplaſms are to be applied, and very frequently repeated. When the *boil* is ſufficiently maturated by one or other means, which will be known from the ſoftneſs and yellowneſs of its head; it muſt be opened by inciſion, and when the matter it contained is diſcharged, the ulcer muſt be daily cleanſed, till perfectly freed from all malignity, and then healed with the vulnerary balſams.

When infants which ſuck are afflicted with *boils*, the proper method is to give cooling medicines and purges to the nurſe, and enjoin her a due regimen in diet; and the infant ſhould at the ſame time be got to take ſome gentle laxative, and the abſorbent powders, as thoſe of crabs-eyes and the like, to allay the acrimony of its juices. *Heiſter*'s Surgery, p. 195.

FURUNCULUS, in zoology, the name given by many authors to the ferret, called alſo the *furo* and *ictis*. See VIVERRA.

FURZE. We ſometimes uſe this prickly ſhrub for fences, but the French uſe it much more, and that in a peculiar manner. They make hedges of it ten or twelve foot thick, or ſometimes twice or three times that thickneſs. This makes an excellent ſhelter for game, and is done in this manner: they dig the ground where they intend to plant this hedge, in winter, to kill the groſs weeds; when the ſpring comes on they dig it over a ſecond time to make the earth fine; in the latter end of March, or beginning of April, they ſow this cultivated ground thick with the *furze* ſeeds, and when they come up, they cut the young plants when grown up a little; this makes them grow the more vigorouſly, and in a few years they make a hedge of the utmoſt uſe and value to the owners on ſeveral accounts.

It is ſaid that the common Engliſh *furze* will grow upon the dry ſands that are in the neighbourhood of the ſea, tho' ſubject to be waſhed ſometimes by the water; this is a thing extremely worth the trying, as it would then be of the greateſt advantage to thoſe who have walls or banks next the ſea, to plant it on them to preſerve them.

This being a very unprofitable plant in reſpect of many others, it is often neceſſary to deſtroy it. This may be done by plowing and burning the buſhes upon the land. Marling the land well in countries where marle is plentiful, is alſo a very good way; and there is yet another much better, which is to make wood land, not arable, of the place; to this purpoſe it is only neceſſary to ſow or plant acorns at proper diſtances. The *furze* will ſhelter the acorns till the time of their growing up to two or three foot high, and then they will ſoon ſtarve and deſtroy all the *furze* and every other weed. *Mortimer*'s Huſbandry, p. 308.

FUSA, in the Italian muſic, the name of one of the muſical notes, frequently alſo called *chroma*, and by us *quaver*. See CHROMA and QUAVER, *Cycl.* and *Suppl.*

FUSANUS, in botany, a name given by many authors to the ſhrub, more uſually called *euonymus*. This was ſometimes called *attractylis* by the Greeks, and had both this and its Roman name *fuſanus*, from its being of uſe for making the diſtaff, uſed by the women in ſpinning. Some have ſuppoſed that this was the ſame with the *euonymus*, ευωνυμος of Theophraſtus and the Greek writers, but very erroneouſly. Our *euonymus* has a ſhort fruit divided into four lobes, each containing a ſingle bud divided from the reſt by a partition; and theſe when the fruit is ripe, and ſplits open, ſhew themſelves between the fiſſures, and finally fall out one after another. The *euonymus* of the Greeks bore, according to the expreſs words of Theophraſtus, a long pod like that of the ſeſamum; this is in no ſort like our *euonymus* fruit, but is long, ſlender and terminated in a point, having four ribs running along it, which divide it into a ſort of ſquares. Theophraſtus adds, that within this pod there were contained very hard ſeeds diſpoſed in four orders or ſeries, each ſeries containing ſeveral ſeeds. The author who has given occaſion for this miſunderſtanding of the words of Theophraſtus is Pliny. He has tranſlated the paſſage in which that author deſcribes the *euonymus* very ill; he ſays indeed that the fruit is like that of the ſeſanum, but that it contains within a dry hard ſeed, of a quadrangular figure. This ſeems to be meant as expreſſing only one ſeed to be placed in each cell; but Theophraſtus neither ſays this, nor that the ſeeds are ſquare, but that they are diſpoſed in three orders; he has expreſſed this, by the word *tetraſtæchon*, which Pliny has ſuppoſed to be the ſame with *tetragonon*, but without reaſon. See TETRASTÆCON.

Theophraſtus ſays alſo, that the leaves and fruit of the *euonymus* were poiſonous to cattle; therefore it cannot be the *euonymns* or *fuſanus* of theſe times, which is innocent, and which cattle eat without injury, every time they can come at it. The manner of its operation alſo was as an aſtringent; the cattle that eat of it, were rendered coſtive, and unleſs a purging was brought on by art or nature to their aſſiſtance, they died of it. This alſo is greatly contradictory to the nature of our *fuſanus* or *euonymus*; for three or four of its ſeeds taken internally, ſerve as a purge, and often work briskly both upwards and downwards. The deſcription the antients give of the other parts of the tree, do not agree with our *euonymus*: they ſay its leaves were ſomewhat like thoſe of the chamædaphne, or of a middle ſize between that and the pomegranate-tree, and were very ſoft to the touch. Pliny tranſlates the word chamædaphne, by laurus, or the bay-tree, by this means doubling the confuſion in this paſſage. Our *fuſanus* has leaves tolerably anſwering indeed in ſhape and ſize to thoſe of the *euonymus* of the Greeks, but then they are not ſoft to the touch. They ſay alſo that the flowers of their *euonymus* ſmelt like corrupted fleſh, or ſtinking blood; this does not at all agree with our *fuſanus*, whoſe flowers have no ill ſmell. The *euonymus* of the Greeks was finally a very rare ſhrub, growing only in the iſland of Lesbos and two or three other peculiar places; the Romans had never ſeen it, nor had any name for it in their language, but borrowed the Greek name and account of it. Our *euonymus* or *fuſanus* is a ſhrub common all over Europe, and in many other parts of the world.

FUSILE *marble*, a very common but very improper term uſed for the green or greeniſh grey marble full of ſmall ſea ſhells, of which the ſlender pillars of our Gothic buildings are made. The two kinds of marble called by this general name are diſtinguiſhed by Dr. Hill, by the names of, 1. *marmor viresſcens conchyliis frequenter aſperſum*, green marble, thick ſet with ſea ſhells; and 2. *marmor cinereovirens conchyliis pauciоribus refertum*, greyiſh green marble, more thinly interſperſed with ſea-ſhells. The firſt is moſt frequent in Italy, and is the *fuſile marble* of that part of the world; and the ſecond is dug in Derbyſhire, Dorſetſhire, Suſſex, and many other parts of England, and is what the pillars in our cathedrals are made of, and is conſequently the ſpecies called *fuſile marble* in England. *Hill*'s Hiſt. of Foſſ. p. 470.

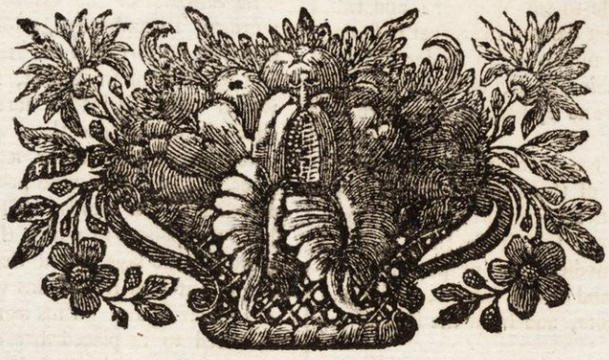
From the length and ſlenderneſs of thoſe columns it has been vulgarly ſuppoſed, that they were caſt in moulds, but reaſon and a knowledge of nature, ſufficiently explode the conjecture, ſince we well know that marble will burn to lime inſtead of melting in the fire, and that the ſhells it contains muſt have been calcined to powder alſo, not have been found as they now are, if it were poſſible that the marble could have been run.

We have in England in many places vaſt quarries of marble all full of ſea-ſhells, and theſe pillars have been all cut out of the marble of ſuch quarries. The ſhells it contains are of different kinds, ſome turbinated, and others bivalve, and of the tellina and pectunculus kind; and theſe being filled with a pure and white ſpar, give a fine variety to the whole marble when wrought.

FUSILUS, in botany, a name given by ſome to the *fuſanus*, a more common name for the *euonymus*. See FUSANUS.

FUSTIGATIO, in the Roman cuſtoms, a puniſhment inflicted by beating with a cudgel. This puniſhment was peculiar to freemen; for the ſlaves were ſcourged or laſhed with whips. *Pitiſc.* Lex Ant. in voc.

FUSTIGATION, *Fuſtigatio*, is alſo a penance enjoined by the Roman inquiſition. *Hofm.* Lex.



FUSTUARIUM, in antiquity, a Roman puniſhment, the ſame with *fuſtigatio*. See FUSTIGATIO.

FUSTUC, in botany, a name given by ſome of the old writers to the tree which produces the piſtachia nuts. The word ſounds ſo like the name of a wood uſed in dying, and called at this time *fuſtick*, that it might be ſuppoſed to expreſs ſome tree of the ſame kind; but it is of a very different origin. The Jews and Arabians, have called the piſtachia tree *fiſtic* and *fuſtack*, and from thence ſome have written the name *fuſtuck* or *fuſtuc*. The Greeks have written it φυστικ, and the barbarous Latin writers *fiſticio*, which ſounds very like the name *piſtachio*. See PISTACHIO.

FUTTOCKS, in a ſhip, the timbers raiſed over the keel, or the compaſſing timbers which make her breadth. Thoſe next the keel are called *ground futtocks*, and the reſt *upper futtocks*.

FUZEE, (*Cycl.*) in the manege, two dangerous ſplents, joining from above downwards: commonly a *fuzee* riſes to the knee and lames the horſe.

Fuzees differ from ſcrews or thorough ſplents, in this, that the latter are placed on the two oppoſite ſides of the leg.

G.

GABIREA, in the materia medica, a name given by ſome of the old writers to ſuch myrrh as was remarkably fatty.

GAD, in mining, an inſtrument uſed to dig out the ore. It is a ſmall punch of iron with a long handle of wood. One of the miners holds this in his hand, directing the point to a proper place, while the others ſtriking it with a large ſledge hammer drive it into the vein.

The working by this inſtrument is thence called *gading*. *Ray*'s Engl. words, p. 118.

GAD-*bee*, in natural hiſtory, the common name for a winged inſect, called alſo the dun fly or ox fly; a creature very troubleſome to cows, horſes, *&c.* This creature examined by the microſcope has ſeveral peculiarities worthy obſervation. It has, like the gnat, a long proboſcis, with a ſharp dart, or two darts, ſheathed within it; the uſe of theſe darts is to penetrate the fleſh of animals for the ſucking their blood, whereas the proboſcis can only ſerve to ſuck the dews from flowers, *&c.*

The eggs of this fly are laid in the waters, and there produce a very remarkable ſort of maggot. It is a brown one of a long flatted figure, with a pencil of fine downy hairs at its tail, which it ſpreads into a circular form on the ſurface of the water, while its head is ſunk down in ſearch of food. When the creature would deſcend toward the bottom, theſe hairs are made to approach one another in an oval form, and in this ſtate they incloſe a bubble of air, by means of which it is able to riſe again; and if this bubble by any accident eſcapes, the creature immediately ſqueezes out of its own body another to ſupply its place. The ſnout of this maggot has three diviſions, whence are thruſt out three little pointed bodies like ſerpents tongues. Theſe maggots are very common on the ſurface of ditch water, and the motion of their inteſtines is very ſingular and obſervable. *Baker*'s Microſcope, p. 206.

GADING, among miners. See GAD.

GADUS, in ichthyology, the name of a genus of the malacopterigious, or ſoft fined fiſhes, the characters of which are theſe. The bronchioſtege membrane on each ſide contains ſeven bones of a ſomewhat cylindric form; the back in ſome ſpecies has three fins, and in others only two; the head in moſt ſpecies is compreſſed, but in ſome it is depreſſed. Of thoſe which have three fins on the back, the following ſpecies are enumerated by Artedi.

1. Of thoſe which have no cirri there are theſe. 1. The *gadus* with three back fins, with a white body, with no cirri at the mouth, and with the upper jaw longeſt. This is our common whiting. 2. The beardleſs *gadus* with three back fins, with the lateral line ſtrait, and the lower jaw longeſt. This is the fiſh we call the raw pollock, or cole fiſh. 3. The beardleſs *gadus* with three fins on the back, with the lower jaw longeſt, and with the lateral lines crooked. This is the whiting pollock.

2. Of the *gadi* with three back fins, and with cirri or beards, there are the following ſpecies. 1. The variegated bearded *gadus* with an even tail, and the upper jaw longeſt. This is the cod fiſh. 2. The white bodied forked tail'd *gadus*, with a bearded mouth, and three back fins. This is our haddock. 3. The bearded *gadus* with three back fins, with thirty rays in the firſt pinna ani. This is our pouting, or whiting pout. The ſide lines in this fiſh are black, and very crooked. 4. The ſmall two inch *gadus*, with beards at the mouth, and with three back fins, and the anus in the middle of the body. This is the mollo of the Venetians; in Cornwall we call it the poor, or the power.

3. Of thoſe *gadi* which have only two fins on the back, the following are the ſpecies. 1. The *gadus* with two back fins, and with the lower jaw longeſt. This is the fiſh we call the hake. The head of this fiſh is broad, the body oblong, and ſomewhat cylindric. 2. The bearded *gadus* with two back fins, and the upper jaw the longer. This is the fiſh we call the ling. Its body is very long, and roundiſh; its head flat and depreſſed; its mouth very wide, and its tail rounded at the end. 3. The bearded *gadus* with two back fins, and both jaws even. This is the *muſtela fluviatilis* of authors, the eelpout of the Engliſh. The head is of a depreſs'd figure, the body long and rounded, variouſly coloured, and lubricous to the touch; the tail nearly oval, and the linea lateralis ſtrait.

4. The bearded *gadus* with two back fins, and with a furrow at the firſt back fin. This is the kind named by the people of Cornwall the whiſtle fiſh. *Artedi* Gen. Piſc. 15.

GADWALL, in zoology, the name of a ſpecies of duck which frequents freſh waters, and is called, in ſome parts of England, *the gray*. It is called *anas ſtrepera* by authors. It is of the ſize of the widgeon, or ſomething larger; its body is of a longiſh ſhape, and its rump black; its back is brown, but the edges of the feathers are edged with white; the front of the head, and upper part of the throat, are white, ſpotted with ſmall brown ſpecks; the head is of a blueiſh black, the throat of a greyiſh white, and toward the breaſt ſomewhat rediſh; the upper part of the breaſt, and the ſhoulders are beautifully variegated with brown, white, and black; the breaſt is white, and the belly browniſh, with ſmall tranſverſe ſtreaks of black; the beak is blackiſh and yellow, and the legs are whitiſh. The female is different from the male in many reſpects, particularly it wants the blackneſs of the rump; but both the male and female are diſtinguiſhed at ſight from the other ſpecies, by having marks of three different colours one above another on their wings; theſe are white, black, and a rediſh brown. *Ray*'s Ornitholog. p. 287.

GÆELÆUM, *earth oil*, in natural hiſtory, a name given by ſome of the old writers to the petroleum, or as we uſually call it, oil of Petre. See PETROLEUM.

GAFET, in the materia medica of the Arabians, a name given by Aviſenna and others to the ſarcocolla of the Greeks. So the word is tranſlated; but it is to be obſerved, that the ſarcocolla of the Greeks expreſſes two very different things; the one a gum, now known among us by that name; the other a plant, called alſo argemone, and agrimonia, for they have ſometimes called the one of theſe plants, and ſometimes the other by that name. The agrimony ſeems however to have been generally meant by this name, and this is the gafet of the Arabians, for they call the other or right ſarcocolla, both the gum, and the tree which produces it, arizarut.

GAFOLD-*land*, or GAFUL-*land*, *terra ſenſualis*, in our old writers, land liable to taxes, and rented, or letten for rent. Sax. Dict.

GAGATES, *jet*, in natural hiſtory, the name of a foſſile ſubſtance, the characters of which are theſe. It is a ſolid, dry, opake, inflammable body, found in large detached maſſes of a fine and regular ſtructure, having a grain like that of wood, ſpliting more eaſily horizontally than in any other direction, very light, and moderately hard, not fuſible, but readily inflammable, and burning a long time with a fine greeniſh white flame.

This is a ſubſtance about which there have been many errors, and which has been very little underſtood even in our own kingdom, where the fineſt in the world is produced, having been uſually confounded with a thing greatly inferior to it in value, the common cannel coal, ſo that many believe that there is no other *jet* than that ſubſtance; and of the few who ſuppoſe them different, none ſeem to have had any clear idea of their diſtinguiſhing characters, but they are eaſily known aſunder when theſe are properly conſidered.

Jet is always found in detach'd maſſes lodged in other ſtrata; cannel coal conſtitutes of itſelf whole ſtrata. *Jet* has the grain of wood, and ſplits horizontally much more eaſily than in any other direction; cannel coal has no peculiar grain, and ſplits with equal eaſe any way. *Jet* is but moderately hard, cannel coal not leſs ſo than many ſtones, and jet when ſet on fire flames a long time; cannel coal but a little while. *Jet* is found in Italy, Germany, and the Eaſt Indies, but no where ſo plentifully as in England; it is very common in Yorkſhire, and other of the northern counties, and is found in many of our clay pits about London. *Hill*'s Hiſt. of Foſſ. p. 413.

Jet, in medicine, is highly praiſed by the antients, but the modern practice has never enquired whether juſtly or not. Dioſcorides tells us, that it is an excellent emollient and diſcutient; he recommends a fumigation of it for diſeaſes of the womb, and ſays that water, in which burnt *jet* has been quenched, is a cordial. Aëtius orders it to be extinguiſhed in wine for the ſame purpoſe. *Hill*'s Hiſt. Mat. Med. p. 170.

GAGATRONICA, a word uſed by the writers of the middle ages, as the name of a diſtinct ſtone, but ſeeming only a falſe ſpelling of the word garatronium. See GARATRONIUM.

GAGNOLA, in ichthyology, a name given by the Spaniards to a ſpecies of the acus, or ſyngnathus of Artedi. The particular ſpecies meant by it, is that called by Artedi, the hexagonal bodied ſyngnathus with the pinnated tail; others call it the acus Ariſtotelis, or acus ſecunda, and the French the trompette; we call it ſometimes the needle fiſh, ſometimes the trumpet fiſh, and ſometimes the tobaccopipe fiſh.

GAHALA, in botany, a name given by ſome writers to the colocaſia.

GAIDEROPSARUS, in ichthyography, a name given by ſome to a fiſh of the truttaceous kind caught in the Mediterranean, and more uſually called *callarias*. *Bellonius* de Piſc. See CALLARIAS.

GALACHIDES, or GARATIDES, in natural hiſtory, the name of a ſtone to which the writers of the middle ages have attributed many ridiculous virtues. They have left us no farther deſcription of it, than that it was of a blackiſh colour; but they tell us, that to try whether it was the right ſtone, a man was to be daubed over with honey, and ſet in the open air in a ſummer's day, and that holding this ſtone in his hand, provided it was a right one, no fly nor other inſect would dare to approach him: after this trial they held it ſacred, and pretended that it would diſcover the thoughts of people if only held in the mouth.

GALACTITES, in the hiſtory of foſſils, a ſubſtance much reſembling the morochthus, or French chalk, in many reſpects, but different from it in colour. The antients found it in the Nile, and ſome rivers of Greece, and uſed it in medicine as an aſtringent, and for defluxions and ulcers of the eyes. At preſent it is common in Germany, Italy, and ſome parts of France, and is wholly overlooked, being eſteemed only a worſe kind of the morochthus. See MOROCHTHUS.

It is a very hard, and dry ſubſtance, an indurated clay, of a cloſe compact texture, very heavy, and in colour of a pale grey, without the leaſt admixture of any other tinge. It is of a leſs even ſurface than the morochthus, and is leſs hard. It melts but ſlowly in the mouth, and leaves ſomething of a luſcious ſweetneſs on the tongue. It does not adhere to the lips or tongue, and if rubbed down on a marble with water it diſſolves into a ſubſtance of a pure white, reſembling milk. It does not ferment with acids, and in burning becomes of a pure white. *Hill*'s Hiſt. of Foſſ. p. 23.

GALACTODES, *milky*, a word uſed by the antients in two or three different ſenſes. Some uſed it to expreſs tepid, or a little warm, with ſuch a heat as that of milk juſt drawn from the cow: others expreſſed by it a white, ſomewhat opake, or milky colour: others expreſſed by it only a want of tranſparence in fluids. Galen frequently uſes it in the ſecond of theſe ſenſes, when treating of urines.

GALACTOPSIA, a method of curing diſeaſes by drinking milk only. The gout, conſumption, and many other chronical diſeaſes, are by many affirm'd to be curable by this means. See *Cheyne*'s Nat. Meth. of curing Diſeaſes.

GALACTOSPONDA, γαλακτοσπονδα, in antiquity, a libation made with milk. *Pott.* Archæol. Græc. l. 2. c. 4. T. 1. p. 213. See LIBATION, *Cycl.*

GALADES, in natural hiſtory, an epithet given by Rondeletius to a ſpecies of chama, remarkable for its milky whiteneſs. It is derived from the Greek γαλη, *milk*. This chama is a very elegant ſhell. See CHAMA.

GALANGA, *galangals*, in the materia medica. There are two roots kept in the ſhops under this name, a greater and a ſmaller; of theſe however the ſmaller is by far the moſt in eſteem, and is almoſt the only kind ever heard of in preſcription.

The *galanga minor*, or leſſer *galangal*, is a ſmall ſhort root, of an irregular figure, of the thickneſs of a man's little finger, and is ſeldom met with in pieces of more than an inch or two long. It has ſeveral protuberances at its ends, and on its ſurface, and is ſurrounded with many circular rings, that ſtand out a little beyond the reſt of the ſurface. It is of an extremely firm and compact texture, yet not heavy; it cuts difficultly with a knife, and leaves a poliſhed ſurface. Its colour is a browniſh red on the outſide, and a ſomewhat brighter red within, though ſtill with a conſiderable admixture of brown.

The ſmall *galangals* are to be choſen full and plump, and of a bright colour, very firm and ſound, and of an acrid and inſupportably hot taſte.

The larger *galangal* anſwers pretty much to the above deſcription, only that it is larger in bulk, and leſs unequal and tuberous than the leſſer kind.

The *galangals* are both brought us from the Eaſt Indies, and are the roots of the ſame plant which is of the number of the *herbæ bulboſis affines* of Mr. Ray. Herman calls that which produces the larger, *bauchale Indorum*; and that which produces the leſſer, *lagoudi Indorum*.

The people of the Eaſt Indies uſe theſe roots by way of ſpice. With us the leſſer is eſteemed an excellent ſtomachic, and as ſuch is an ingredient in almoſt all bitter infuſions and tinctures. The great one poſſeſſes the ſame virtues, only in a more remiſs degree. Vid. *Hill*'s Hiſt. Mat. Med. p. 573, ſeq.

GALARCIDES, or GALARICTIS, in natural hiſtory, a name uſed by the writers of the middle ages for a ſtone, to which they attribute great virtues. It is evidently only a corrupt way of ſpelling the word *galactites*. See the article GALACTITES.

GALAXIUS, in natural hiſtory, a name by which many of the antients have called the morochthus, or French chalk. *Hill*'s Hiſt. of Foſſ. p. 22. See the article MOROCHTHUS.

GALBULA, in zoology, the name of a bird of the thruſh kind, common in Italy and Germany, very remarkable for the elegant ſtructure and hanging of its neſt; and thence called by ſome *picus nidum ſuſpendens*, and by others *oriolus*, *chloreus*, and *icterus*, being ſuppoſed to be the icterus of Pliny, and the old writers.

It is ſomewhat larger than the common thruſh; its beak is of a finger's breadth long and red; its wing feathers are black, but ſome of them are tipped, and others edged with white; others of the ſmaller feathers have alſo a variegation of yellow, and the reſt are wholly black; the bird is in all other parts of an extreamly bright and beautiful yellow, ſo elegant, as very much to approach to the luſtre of ſome of the American birds. The female is leſs beautiful, and has a blackiſhneſs and browniſhneſs mixed with the yellow. It feeds on inſects, and is a very delicate taſted bird; it is in moſt places very much eſteemed at the table, but is no where to be had at all ſeaſons, being a bird of paſſage. *Aldrovand* de Avibus.

GALEA, in natural hiſtory, the name of a genus of the echinodermata, or ſea hedgehogs, whoſe ſhape is that of a large elevated helmet, compoſed of ſeveral tranſverſely joined plates, or aſſulæ, and covered with very ſmall and rough tubercles, in the ſhape of little granulæ. This genus, when foſſile, is called in Engliſh the helmet ſtone, and is marked with ten rows of double lines, either crenated, or punctated, and running from the top to the baſe; the anterior ones being much longer than the reſt.

Of this genus there are three known ſpecies. 1. The ſcutated headed one, which has on its ſummit an oblong pentagonal plate like a ſhield. 2. The naked headed one, diſtinguiſhed by its wanting this ſhield. 3. That with the tæniæ lacerated and torn, and ſhewing plainly that they have been once of the variolated kind. *Klein*'s Echinod.

GALEA *Piſcis*, in ichthyology, a name given by Geſner, and ſome other writers, to the fiſh called by other writers muſtela alia, and by Artedi reduced to the genus of the blenni. It is the blennus with four bifid beards under the throat. See BLENNUS.

GALEA *Venetorum*, in zoology, a name given by ſome authors to the common muſtela. *Willoughby*, Hiſt. Piſc. p. 121. See the article MUSTELA.

GALEANTHROPIA, in the writings of the antient phyſicians, a term uſed to expreſs a ſpecies of madneſs, in which the patient fancied himſelf a cat, and endeavoured to perform all the motions of that animal.

GALEETTO, in zoology, the name of a fiſh of the alauda kind, called by Rondeletius, *alauda non criſtata*, and in Engliſh the mulgranoc and the bullcard. It is a ſmall fiſh of a greeniſh yellow, or olive colour, without any variegation in ſome, but in others a number of faint blue tranſverſe lines are diſpoſed on the back, the ſides, and the fins; the intermediate ſpaces between theſe lines on the back are of a rediſh brown, and in ſome two olive coloured and browniſh lines run longitudinally down the back. The colours, in ſhort, vary extremely in this fiſh.

The contour of the head is roundiſh, but it is compreſſed, and ſwells out over the gills, and its top riſes into a ſort of ridge, and is flatted at the back part, as if the creature had a kind of neck; the upper jaw ſtands out beyond the lower; it has no ſcales, and reſembles in many things the gutterugine, but that it wants the eye fins; it is very full of life, and lives, like the eel, many hours without water. It is caught among rocks and ſtones about the ſhores in the Mediterranean, and alſo in our own ſeas. *Willoughby*, Hiſt. Piſc. p. 133.

Artedi reduces this fiſh to the genus of the blenni, and diſtinguiſhes it by the name of the *blennus*, having the upper jaw longer than the under, and the top of the head acuminated.

GALEGA, *goats rue*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the papilionaceous kind, and the piſtil ariſes from the cup, and finally becomes an oblong cylindric pod, containing uſually oblong and ſomewhat kidney-ſhaped ſeeds: to this it is to be added, that the leaves ſtand in pairs on pinnated ribs, to the end of which there grows a ſingle or odd leaf.

The ſpecies of *galega* enumerated by Mr. Tournefort are theſe. 1. The common *galega* with blue flowers. 2. The common *galega* with blueiſh purple flowers. 3. The common *galega* with white flowers. 4. The African *galega* with larger flowers, and thicker pods: and 5. The American ſhrubby *galega*, with purple flowers, and ſilky pods.

GALEGA, in medicine, is eſteemed a great alexipharmic and ſudorific. It is much uſed in Italy, but amongſt us only as an ingredient in ſome compoſitions.

GALENA, a name given by mineraliſts to a ſpecies of poor lead ore. It was alſo the original name given by Andromachus to the theriaca, from its effect in bringing on a pleaſing calm over the blood and ſpirits on taking it.

GALENA *inanis*, in mineralogy, a name given by authors to a glittering ſubſtance, very much reſembling ſome of the plated ores of lead, but really containing none of that metal. It is more uſually called mock lead and blende.

GALENIA, in botany, a name given by Linnæus to a genus of plants, called by Pontedera, *Sherardia*. The characters are theſe: The perianthium is very ſmall, and is compoſed of one leaf divided into four oblong and hollowed ſegments. There are no petals. The ſtamina are eight in number,

they are very ſlender, and of the length of the cup; the antheræ are double; the germen of the piſtil is roundiſh; the ſtyles are two, they are ſimple and reflex, and the ſtigmata are ſimple; the fruit is a roundiſh capſula, containing two cells, in which are two oblong angular ſeeds. *Linnæi* Gen. Pl. p. 169. Ponteder. Epiſt. 14.

GALENION, the name of an anodyne cataplaſm, preſcribed by Ægineta.

GALEOBDOLON, in botany, the name of a genus of plants deſcribed by Dillenius in his Hortus Elthamenſis, and ranked by Linnæus, together with the cardiaca, under one genus, by the name leonurus. *Dillen.* Hort. Elth. p. 84.

GALEOLA, in natural hiſtory, the name of a genus of the echinodermata, or ſea hedgehogs of the galeated or helmet kind.

They have their name from the Latin *galeola*, a diminutive of the word galea, and which ſignified with the ancient Romans a drinking veſſel, made in the ſhape of a ſmall helmet. Of this genus, there are three known ſpecies. 1. A papilloſe kind, covered with ſmall eminences. 2. An undulated or waved kind, ſo called from its ſtriæ repreſenting waves. They are finely dotted at the top, but the granulæ become larger as they go toward the baſe. 3. The ſmooth kind. *Klein*'s Echinod.

GALEOPSIS, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of the labiated kind; the lower lip is divided into three ſegments, the middle one being larger than the reſt, and either ſharp pointed or obtuſe, and the upper lip is hollowed like a ſpoon. The piſtil ariſes from the cup, and is fixed in the manner of a nail into the hinder part of the flower, and ſurrounded with four embryos, which ripen into four oblong ſeeds contained in a tubular capſule divided into five ſegments at the end, which was the cup of the flower.

The ſpecies of *galeopſis* enumerated by Mr. Tournefort, are theſe.

1. The tall ſpiked ſtinking *galeopſis*. 2. The taller purple flowered *galeopſis*, with prickly flower cups. 3. The taller white flower'd *galeopſis*, with prickly flower cups. 4. The taller yellow flowered *galeopſis*, with prickly flower cups. 5. The narrow leaved *galeopſis* with variegated flowers. 6. The purple open flowered common *galeopſis*. 7. The white open flowered common *galeopſis*. 8. The betony leaved alpine *galeopſis*, with variegated flowers. 9. The betony leaved marſh *galeopſis* with variegated flowers. 10. The yellow flowered *galeopſis*, or dead nettle. 11. The yellow flowered *galeopſis*, with large ſpotted leaves. 12. The round leaved annual Spaniſh *galeopſis*: and 13. The teucrium leaved Spaniſh ſhrubby *galeopſis*. *Tournefort*, p. 185.

GALEUS *glaucus*, the *blue ſhark*, a very fierce and voracious fiſh of prey. It is of a fine deep blue colour on the back, and of a bright ſilver white on the belly. The ſkin is ſmoother than that of the white ſhark, and the noſe long pointed, and ſomewhat flatted. The noſtrils are long, and placed tranſverſely to the length of the noſe. The ſockets of the eyes are of an elliptic figure; but the eyes themſelves are exactly round, and have a membrane which at times the fiſh draws over them, and there are no cavities behind the eyes. The teeth are not ſo numerous as in the white ſhark, there being only two rows of them, but theſe are very large and triangular, exactly of the ſhape of the gloſſopetræ. The tail is bifid, and one portion of it is much larger than the other. It is very voracious of human fleſh, and will follow cloſe under the ſhore if there is depth enough, and a man is walking there. It is ſometimes found on the Engliſh ſhores, and has been caught on the Cornwall coaſt. See Tab. of Fiſhes, N° 4. and *Willoughby*, Hiſt. Piſc. p. 49.

GALEUS *lævis*, the *ſmooth hound fiſh*, in zoology, the name of a fiſh of the ſame genus with the *galeus ſpinax*; but differing in ſize and many other particulars. It is called the ſmooth hound fiſh, not from any peculiar ſmoothneſs of the ſkin, for all the *galei* are rough in that particular, but by way of diſtinction from the *galeus ſpinax*, as it has no prickles. Its back and ſides are aſh coloured; its belly white; its body long and round, the end of its ſnout is obtuſe, and runs out a great way beyond the mouth and eyes. It has two fins on the back, and two pair of fins on the belly. It has properly ſpeaking no teeth, but the jaws are both rough and ſharp like a file. *Geſner*. de Piſc. p. 717.

GALEUS *rhodius*, in ichthyology, a name given by Albenæus and ſome other of the old writers, to a very large and delicate fiſh. Schoneveldt is of opinion, that they meant by it the ſturgeon, and brings many good reaſons for his opinion.

GALEUS *ſpinax*, in zoology, the name of a fiſh of the ſhark kind, called in Engliſh the hound fiſh. It has a long and round body, and has no ſcales, but is covered with a rough ſkin, us'd by ſeveral artiſts for poliſhing their works. Its back is of a browniſh aſh colour. Its belly white and leſs rough, its noſe conſiderably long, ſomewhat flatted, and rounded at the end. The pupil of the eye is black, of an elliptic form, and ſtands tranſverſely. The mouth is placed about the middle of the ſnout, and in its lower part; and it has two rows of ſmall teeth. It is common in the Mediterranean and Engliſh ſeas. *Geſner* de Aquat. p. 716.

GALEUS *ſtellatus*, the *ſtar'd hound fiſh*, in zoology, a kind of hound fiſh, remarkably ſpeckled with white ſpots in from of ſtars. *Salvian* de Aq. p. 29.

GALEXIA, in ichthyology, a name given by Galen and ſome of the other antient writers, to the common lamprey. See LAMPETRA and PETROMYZON.

GALGULUS, in zoology, a name by which many have called a bird of the thruſh kind, of a find gold yellow, with black wings, more commonly known by the name of Galbula, and ſuppoſed to be the chloreus of Ariſtotle, and the icterus, or jaundice bird of Pliny. *Ray*'s Ornitholog. p. 147. See the article GALBULA.

GALI, in the materia medica, a name given by ſome to the indigo, or fæculæ of the plant anil uſed in dying, *&c.* Garcias gives us this name, and ſays, that the plant is like the mangirique; but Cluſius tranſlating this word by ocymum or baſil, has ſtrangely perplexed the caſe. The anil or indigo plant not having any reſemblance of that herb.

GALL, or BILE (*Cycl.*)—After all that has been ſaid about the *bile* by ancient and modern writers, there ſeems yet a doubt as to its true origin, and where it is generated. The commonly eſtabliſhed opinion is, that the *bile* contained in the *gall* bladder has been ſiltrated into it by certain glands which are found on its inner cavity. Theſe glands however, have been rather ſuppoſed than demonſtrated, and if writers mean by them, thoſe little protuberances found ſometimes within the cyſt, there is no certainty of their ſeparating the *bile*, ſince theſe glands, as they are called, are wanting in many, nay in the greater part of perfectly ſound bodies, where the viſcera are in a good ſtate, and not affected by any obſtructions. When the world was beginning to believe that there were in reality no ſuch glands as theſe, it was ſaid that there were certain veſſels and canals which collecting the *bile* from the ſubſtance of the liver, carry'd it to the inner ſurface of the *gall* bladder, where they opened and emptied their contents into its cavity; but theſe veſſels have in reality been no more demonſtrated to exiſt than the beforementioned glands, and there have ſometimes appeared caſes, where demonſtration has in a manner appeared on the contrary ſide, to prove, that the *bile* is not ſeparated in the *gall* bladder, but is brought into it from elſewhere: of this kind there is one very remarkable one mentioned in the memoirs of the academy of ſciences of Paris.

Mr. Lieutaud, on diſſecting a morbid body, found the *gall* bladder ſo extremely ſhrunk up in ſize, that he could ſcarce at firſt believe that it was the *gall* bladder; its neck was wholly filled, and as it were plugged up with a blackiſh matter, formed into a body of a ſpherical ſhape, and compoſed of ſeveral beds, or layers, in the manner of thoſe ſtones which are not unfrequently found in the *gall* bladders of different animals; and the other part of this body of it, which was alſo much the largeſt, was contained in a bag made by the ſeparation of the two membranes of which the *gall* bladder is naturally compoſed; this contained no fluid matter, except a few drops of a very clear water; and its inner ſurface, which was perfectly white, did not appear ever to have contained any *bile*; the cyſtick canal, and the biliary pore, were very much dilated, and the canal as full of *bile* as it could hold, and the whole ſubſtance of the liver was very ſound, and in a ſtate of perfect health. Now if either the glands in the inner membrane of the *gall* bladder ſeparated the bile, or if any veſſels ſeparated it from the liver, and convey'd it immediately into that reſervoir by apertures in its inner ſurface; in either of theſe caſes all this might have been done in the bladder, though its neck were thus ſtopped up, but on the contrary there was no *bile* found there, and it ſhould appear very plainly from this, that the *bile* muſt have ſome other origin, ſince it ſeems to be conveyed into the *gall* bladder no other way than through its neck. Mem. Acad. Scienc. Par. 1735.

The human *bile* taken out of the bodies of thoſe who died of the plague at Marſeilles, was always found to be of a blackiſh, or deep green colour. On the mixing ſpirit of vitriol with it, it always became of a fine green, which colour never changed in it: and when ſalt, or oil of tartar were mixed in it, it always became yellow. Spirit of nitre added to it turned it black, but the colour ſoon faded. This *bile* poured into a wound made in the leg of a dog, would always render him drowſy, dull, and not caring to eat, and all the dogs on which the experiment was tried, died within about four days, with all the circumſtances of a genuine plague upon them.

A dram of the ſame *bile*, diluted with three ounces of water, and injected into the jugular vein of a dog, killed him in two or three hours; and when opened, the heart was found ſtuffed full of black blood, the liver ſwelled, and the *gall* bladder full of green *bile*. The ſame quantity of diſeaſed *bile* injected in the ſame manner into the crural vein of a dog, has made him drowzy in an hour afterwards, he would then refuſe his food; and in three days peſtilential buboes would appear, and the creature die. A dog which belonged to one of the ſurgeons of the hoſpital of Mail, uſed to attend at all the dreſſings of the plague ſores, and eat up the glands, blood, pus, *&c.* which was thrown

out

but from thoſe ulcers, yet he lived and continued briſk after doing this every day for three months. But on injecting the ſolution of the *bile* in the ſame manner into the crural vein, he died on the fourth day with a large bubo on the wounded thigh, on which alſo there were two carbuncles and a gangreen'd part.

The *bile* being collected after this from one of the dogs dead of the plague, and in the ſame manner diluted with water, and injected into the crural vein of another dog, the creature was immediately convulſed, a carbuncle appeared on the breaſt the ſecond day, and the day afterwards the dog died with a bubo under his ſhoulder. The *bile* taken from this dog, was in the ſame manner injected into a third dog, and he died in the ſame manner. Philoſ. Tranſ. N°. 170.

If half an ounce of alum in powder be added to a pound of ox *gall*, and the whole ſtirred a little together, there riſes immediately an ebullition with a conſiderable effervescence, and the whole becomes thick and turbid like dung, and of a greeniſh yellow colour; but after a while, the *gall* will be precipitated, and its thicker parts ſeparating themſelves and falling to the bottom, the remainder will become of a clear hue and a rediſh colour.

After this has ſtood five or ſix days, ſeparate the clear liquor from the fæces at bottom, and from what foulneſs ſwims at the top, and ſet it in the ſun for three or four months in a vial well ſtopped; there will at the end of this time be found another precipitate at the bottom of the vial, and on the ſurface of the liquor, there will gradually gather together a white and hard fatty matter, and the red colour of the liquor finally will change into its primitive yellow again; and what is very remarkable, the whole will have the ſmell of boiled crayfiſh.

The obſervation that there is contained in this red liquor of the *gall*, though ſeemingly perfectly clear, a white fatty matter like ſuet, and that on the ſeparating of this white matter, the red liquor loſes its colour, and regains its primitive yellow together, prove that the ſubſtance naturally contained in the *gall* bladder, is a kind of liquid ſoap. We very well know that the ſoap we uſe is no other than oil, or other fatty ſubſtances united by boiling to the alkaline ſalt called pot aſhes. In the colder countries where theſe ingredients are more ſcarce, they ſubſtitute the fat of animals for oil, and common aſhes for the alkali; and the ſoap is as good for all the purpoſes as the other. In the conſtituting the *gall*, nature has uſed a ſolid animal fat, and inſtead of a fixed alkali, ſhe has employed that common volatile one with which all the parts of animal bodies abound: in this operation this fat has been ſeen to ſeparate its ſelf by little and little, and as it amaſſed itſelf together, to appear in its native form white and hard like the fat of animals; and the cauſe of this ſeparation has been the deſtroying the alkali by means of the acid of alum, the fat having ſeparated itſelf on that admixture in the ſame manner, as the fatty part of our common ſoap does on the mixing any acid with it.

The liquor of the *gall* appears red after its firſt precipitation, and loſes this colour again by degrees as the fat becomes ſeparated from it; the reaſon of this is, that almoſt all ſolutions of oily or fatty bodies are red, be the menſtruum what it will, and this being one of thoſe ſolutions muſt be red ſo long, as it continues ſuch, that is, ſo long as the fat remains ſuſpended in it; but as ſoon as that fat is ſeparated, the cauſe of the red colour ceaſes, and the liquor becomes yellow.

This depurated liquor of *gall*, is one of the greateſt of all remedies for freckles in the face: the manner of uſing it is this, mix together equal parts of it, and of oil of tartar per deliquium, to a dram and a half of each of theſe, add an ounce of river water, mix them well by ſhaking, and keep them in a viol well ſtopped: the end of the finger being wetted with this, is to be touched upon the freckled part, and this repeated three or four times a day letting it dry on, at length the part will look red, and there will be a ſort of tickling ſenſation felt in it; and after that, the ſkin will become ſcurfy and both that and the freckles will fall off. If this does not ſucceed the firſt time, it is to be repeated, and it will clear the face for ſix or eight months, at the end of which time it is to be uſed again. Mem. Acad. Par. 1709.

GALL *bladder*. Mr. Petit, gives us the marks by which a diſtention of the *gall bladder* from the bile, making an external tumor with fluctuation, may be known and diſtinguiſhed from an abſceſs in the liver. See Mem. de l'Acad. de Chirurg. Tom. 1. & Med. Eſſ. Edinb. Abr. Vol. 2. p. 491.

GALL is alſo uſed by naturaliſts to expreſs any protuberance, or diſtortion of a part of a leaf, or ſtalk on a tree, or plant, occaſioned by an inſect living and growing within it. Theſe are all monſtrous and unnatural productions of the vegetables that bear them; but they often are ſo regular in their formation, that they have the appearance of fruits and flowers. On examination however it will always appear, that they are fruits containing no ſeed, and flowers the product of which is animals. Among the ſmaller inſects, there are many which either in their whole ſtate of the worm, or in a part of it, are of ſo tender and delicate a ſtructure, that they cannot bear the contact of the air; and others that are continually expoſed to the ravage of a number of deſtroyers; ſo that by one or other of theſe means they could never live to arrive at maturity, or to propagate their ſeveral ſpecies. Provident nature has therefore allotted for the habitation of theſe, the *galls* of trees and plants; they never however find excreſcences ready formed, but by their own action make them for themſelves. Some of theſe inſects are produced from eggs laid by the parent animal on the ſtalks of leaves or plants, and as ſoon as ever they are hatched from theſe, make their way into the leaf, or ſtalk, and find a ſafe lodging in this receſs, and neceſſary food in its juices; others are lodged even in the egg ſtate within the ſubſtance of the leaves and branches, and have no occaſion for eating their own way in. The parents of theſe are a peculiar race of flies, which have at their tail an inſtrument prepared for this purpoſe; with this they pierce the ſurfaces of vegetables, and lay their eggs in the holes they have made; ſo that the worms hatched from theſe have nothing to do, but to gnaw the tender fibres of the vegetable, and feed on the juices extravaſated from the apertures they make in them. *Reaumur*, Hiſt. Inſ. Vol. 6. p. 176.

The puccrons make their way into the leaves and tender parts of the branches of trees, and form a ſort of *galls*, depoſiting their young in the place where they are. Theſe are tender *galls*, by ſome called bladders, which often grow to a very conſiderable ſize on the leaves of trees; and were never well known or underſtood, till Mr. Reaumur explained their nature. The worms of ſome flies, and ſome ſpecies of ſmall caterpillars, live alſo within the ſubſtance of leaves, and feed in great ſafety and comfort to themſelves; but theſe are continually changing place, and deſtroy the part they feed in; on the contrary, the worms which inhabit the common *galls*, never move out of the place where their parent depoſited the egg, but there eat and ſuck their nouriſhment. This is ſo far from deſtroying, or injuring the part of the plant, that their feeding occaſions a new derivation of juices to it, and it always grows larger and ſtronger in proportion, as the creature eats within.

The *galls* cauſed by different inſects have a very different internal ſtructure, ſome of them have only one large cavity within, in which a number of the animals live in community, others have ſeveral ſmall cavities with communications between each, and others have different numbers of little cellules each ſeparate, and having no communication with the others: there are ſometimes a hundred of theſe cellules in one *gall*, ſometimes only two or three; and finally, there are others in which there is only one cavity inhabited by one inſect. The creatures of theſe two laſt kinds, live in perfect ſolitude during the worm ſtate, and can have no knowledge of any other living creature beſides themſelves, till they have paſſed through the intermediate ſtate of chryſalis, and become winged animals like thoſe to which they owed their origin, and are ready to lay eggs themſelves. The general diviſion of *galls* into theſe claſſes, admits of a vaſt number of ſubdiſtinctions under each, from the different figure and conſiſtence of the ſeveral ſpecies. Some of them are ſo hard, that they equal, or exceed the hardneſs of the wood of the tree they grow upon; and when cut, appear compoſed of fibres, much more denſely and cloſely arranged: Others are ſoft and ſpongy, and reſemble ſome of the tender fruits in appearance. The firſt kind are uſually called *gall* nuts, and the latter apple *galls*, or berry *galls*. The common *galls* uſed in dying, are of the firſt kind, and what are called oak apples, and oak grapes are of the latter. The oak produces ſeveral of this laſt ſpecies of *galls*, ſome of which are oblong, and others round reſembling grapes, gooſeberries, and other fruits; theſe are alſo uſually beautifully coloured, ſome being of a bright red, others of a bright yellow. Theſe *galls* of the oak, are of the auſtere taſte of the juices of that tree; but thoſe of other plants, are often well taſted. There is a ſpecies of ſage, well known by the name of apple ſage, the leaves of which afford a lodging to the worm of a peculiar ſpecies of fly, and this *gall* grows to a very conſiderable ſize, ſo as to have obtained the name of an apple from its reſemblance to this fruit; theſe are eaten by the people of the eaſtern nations, and are commonly ſold in the markets of Conſtantinople, and other places. A plant very common with us, the ground ivy, has the ſame property: its leaves are often loaded with *galls* on their underſide, which are very green and juicy, and of no diſagreeable taſte. Mr. Reaumur gives us an account of their being one year ſo plentiful in the neighbourhood of Paris, that the poor people eat them both raw and boiled as food. See Tab. of Inſects, N° 25, ſeq. *Reaumur*, Hiſt. Inſ. Vol. 6. p. 182.

The round *galls* are by far the moſt numerous claſs of all others; but theſe have great differences in their appearance: ſome are perfectly ſmooth on the ſurface; others are very rough and knobby; ſome adhere immediately to the leaf or ſtalk of the vegatable; and finally others are placed on a longer or ſhorter pedicle.

There are however, other very ſingular figures among the *galls*, and of theſe ſome are ſo ſtrangely irregular, that it is very difficult to conceive to what mechaniſm they owed them.

Among the ſeveral ſpecies, there are ſome which ſeem to be only the part tumified on which they are placed: theſe reſemble varixes of the veins in animals, and are therefore by authors called varicous *galls*. The leaves of the willow, and ſome other trees afford us a vaſt number of the *galls* of this kind;

kind; others appear to be extremely ſingular productions of the trees on which they are produced and could not at firſt ſight be ſuppoſed to be *galls*: of this kind is the hairy or filamentous *gall* of the briar, or wild roſe, called by the French cheveleau, and by the medical writers bedeguar. The oak affords a *gall* of a very ſingular ſtructure, reſembling the ſquammoſe cup of a flower of ſome of the headed plants, as the jacea or the like; or to expreſs it by a more known thing, the common artichoke, the French from this call it the artichoke *gall*; other ſpecies are covered with longer or ſhorter ſpines or protuberances, ending in a more or leſs ſharp point; theſe are called the prickly *galls*; and the common *galls* of the oak brought from the Levant, and uſed in dying, are diſtinguiſhed by the workmen, by the name of rough or prickly *galls*, from the European ones, particularly thoſe of France; which are uſually very round, and of a perfectly ſmooth and even ſurface, and gloſſy on the outſide. Beſide theſe there is a very beautiful ſpecies of *galls* that always grow in the figure of the common muſhroom.

The leſſer diſtinctions are too minute to be entered into here; but the curious will find them accurately treated of in the excellent treatiſe of Malpighi on this ſubject, to which the accounts given by Reaumur are a ſort of commentary and ſupplement.

Obſervations ſhew that there is no part of a plant on which *galls* are not ſometimes formed; the young ſtalks ſeem the moſt natural parts, and are the moſt commonly of all others affected by them; but they are alſo found on the leaves, the pedicles of the leaves, the eyes or buds of young leaves, the buds of flowers, and the petals of full blown flowers, and finally on the roots. Every *gall* ſerves for the nidus of ſome one or more inſects, and there are vaſt variety of theſe ſmall animals which inhabit them, even thoſe of different claſſes at times forming them; and it ſeems equally certain, that the ſhape and ſtructure of the *gall*, depend on the inſects which form it. This appears very evident from this, that the leaves of the ſame tree will ſometimes afford *galls* inhabited by different inſects, and ſome of theſe will be hard and woody, while others are ſoft and ſpungy. We may always ſee from the outer ſurface of a *gall*, what is its ſtate within: If it is whole throughout, and there appear no perforations or apertures, it is a certain proof that the animal which occaſioned it is yet within it; but if there are found one or more holes in the ſurface, penetrating into the ſubſtance, theſe are the apertures through which the inſect or inſects have eſcaped, and the *gall* will be found empty. It is often neceſſary to uſe a magnifying glaſs on this occaſion, in order to determine with any degree of certainty; becauſe many of the inſects which inhabit *galls* are ſo ſmall that the apertures through which they have eſcaped are not viſible to the naked eye. When, however, the glaſs does not ſhew any ſuch perforations, on opening the *gall* with a knife, we always find the inſect or inſects within, either in their worm ſtate, or in that of the chryſalis; for the generality of the inhabitants of *galls* are to undergo a metamorphoſis, being worms, maggots, or caterpillars in their firſt ſtate, and becoming finally either four winged or two winged flies, of the firſt ſort of which there are very numerous varieties; or elſe butterflies of peculiar kinds, or finally beetles. *Reaumur* Hiſt. Inſ. Vol. 6. p. 186.

As the origin of theſe creatures is from the eggs of the parent inſect in this form, we find accordingly all the varieties of worms and maggots within them; ſome having legs, ſome not, ſome having hard and ſcaly heads, others only ſoft and membranaceous ones; and finally, we often find creatures different from all theſe in them; theſe have been deſtroyers and murderers, having killed and eaten the proper inhabitants and ſeized on their habitations.

It was an opinion of Malpighi, that all the *galls* on the various parts of vegetables had but one origin, which was from the puncture of an ichneumon fly, who depoſited her egg there for her future progeny. It is pretty certain indeed, that all theſe unnatural productions of vegetables are owing to injuries done by inſects; but various other creatures beſide this fly are capable of doing them, and Mr. Reaumur has obſerved that a viviparous creature, the pulex arboreus, or puceron, is frequently the occaſion of them. Theſe excreſcences of trees are of ſuch a diverſity of figures, that they can never be the ſubject of a regular deſcription; ſome are wholly irregular in ſhape, while others repreſent fruits or flowers. They may in general be divided, however, into three claſſes. Thoſe of the firſt claſs have only one cavity, which contains one inſect and never more. Thoſe of the ſecond contain many inſects all living together in the ſame cavity. And finally, thoſe of the third claſs are divided within into ſeveral cellular cavities; in each of which their lives one worm or other inſect, which has no ſociety with, nor entrance into the dwellings of the reſt. Some *galls* are found reſembling apples, others cherries hanging on long ſtalks, others cluſters of grapes, others pine cones, and others the rough fruit of the cheſnut tree, containing the cheſnuts; they are found principally on trees, though not unfrequently on plants. It is eaſy to ſee by the outſide of theſe *galls*, whether they actually contain an inſect at the time of inſpection, or whether they only have contained one which is ſince eſcaped. If they are whole on the ſurface, it is a proof that the creature is yet within them, waiting the time of its change; but if they have a hole in any part, they ſhew that the creature has paſſed into its perfect ſtate, and has eſcaped out at that aperture. Thoſe *galls* which have only one internal cavity, have only one aperture on the ſurface, whether it be only one or more of the animals that is to eſcape at it; but if there are ſeveral cells, each inhabited by a ſeparate inſect, then there are on the ſurface ſo many apertures, one correſponding to every cell. All the inhabitants of theſe *galls*, do not however wait the time of their change within them; but ſome ſpecies crawl out when their change is approaching, and paſs their previous ſtate of reſt in the form of nymphs elſewhere. It is not unfrequent alſo to find a two winged fly, and a four winged one, both coming out of the ſame *gall*. It is eaſy to ſee that theſe could not be produced of worms hatched by the eggs of the ſame parent. One of them only is the proper inhabitant of the excreſcence, whoſe origin is from the puncture of its parent fly: the other is an interloper, and an enemy, who often eats up the proper inhabitant, and then comes out alone as if the whole *gall* had been made for him; but if the proper inhabitant has by any accident eſcaped, they both come out, either together, or ſucceſſively according to the time allotted by nature for their remaining in their ſeveral ſtates. *Reaumur*. Hiſt. Inſt. Tom. 1.

The *galls* which have only one cavity, are uſually inhabited by a pſeudo eruca, or baſtard caterpillar; but it often happens that the carnivorous worm of ſome other fly, makes its way into the *gall*, and the proper inhabitant is not known from the ſtranger on opening the excreſcence. This is a miſchief that often happens in the ſweet ſcented hairy *gall* of the wild roſe, called bedeguar in the ſhops. From theſe, though produced only by the puncture of one ſpecies of fly, and meant for the reception of its young, it is common to ſee ſeveral different ſpecies produced from the worms of other invaders, fly out at the time of their hatching, from the chryſalis ſtate. It is not eaſy to find out among theſe, which is the proprietary of the *gall*, and which are the invaders of his territory; but the gold colour'd fly, admired by many for its beauty, which often is ſeen to come out from theſe galls, is not the proper inhabitant; but is produced from a worm, which is a general tyrant and devourer of whatever it meets with leſs or weaker than itſelf in this ſtate.

Mr. Reneaume in the year 1711, communicated a diſcovery of the common oak *galls*, being a febrifuge not inferior in many caſes to the Peruvian bark, and greatly preferable in many, as wanting ſome of its ill qualities. He found it a certain remedy in all intermittent fevers, and that it required to be given in much ſmaller doſes than the bark, and its uſe to be continued a much ſhorter time; he is not ſo fond of his diſcovery however, as to deny the ſuperior merit of the bark in ſome caſes, but allots to each its peculiar ſphere in the following manner. He ſuppoſes that fevers in general are cauſed either by the ſharpneſs of an indigeſted chyle, occaſioned by the fibres of the ſtomach not having done their office; whether through over tenſion, or too great a relaxation, or by there not being a due quantity of bile, mixed with that chyle to attemperate, and take off its acrimony. In caſes where the miſchief is originally owing to a relaxation of the fibres of the ſtomach, the *galls* by their aſtringency work on the fibres, and reſtore them to their due tone; therefore in theſe caſes the *galls* are to be preferred to the bark. But in thoſe which proceed from a want of a due quality of the bile in the admixture of the juices, the bark he acknowledges is to be preferred, its bitterneſs producing the ſame good effect in the chyle that the bile itſelf would. Some of the French academicians tried this with all the ſucceſs the diſcoverer aſcribes to it, and ſome with leſs, the fever having been found to return afterwards and then to yield only to the bark. Theſe gentlemen however are of opinion, that the galls very well deſerve to be continued in practice, as there is often much good done by them, and they have the advantage of not being attended with any ill conſequences.

In general, galls are found to be very aſtringent, and good under proper management in diarrhœas, dyſenteries, and hæmorrhages of all kinds. They have alſo a great virtue as a febrifuge, and are often found to cure an intermittent. In fevers half a dram or more of the powder of Aleppo *galls* may be given for a doſe. They are alſo uſed externally as a ſtrengthner, and aſtringent: a decoction of them is applied with ſucceſs by way of fomentation in *procidentiæ of the anus*, and has been injected in the fluor albus with great ſucceſs.

Galls may be made a very uſeful teſt for iron in the ſeveral ſpecies of vitriols, for it is certain that an infuſion of galls will become black with a ſolution of any vitriol that contains iron, and not at all ſo with ſuch as contain only copper, as the common blue vitriol and the like.

Box GALLS, in natural hiſtory, the name given by authors to a very ſingular kind of *galls*, of a conic figure, with a conic top, or cover reſembling a wooden box, and encloſing a white worm in the manner of the other vegetable lodgments of the ſame kind; this ſort of *gall* is found only on the leaves of the lime tree. It is common to obſerve the leaves of this tree in the month of July, to be pierced through with ſeveral round holes of about a tenth of an inch in diameter, and

as exactly circular, as if a round piece of the leaf had been taken out in each place by an inſtrument. Mr. Reaumur, to whom the world owes the diſcovery of this ſingular ſpecies of *gall*, was led to the obſerving it by meeting with leaves thus pierced, and then examining others, till he found ſome which had on them the *box galls*, which give origin to theſe holes.

Theſe are very frequently found in conſiderable numbers, twenty or thirty being not uncommon on a ſingle leaf. There are obſerved in theſe places round ſpecks, or parts of the leaf, of the ſame ſize with the holes in the others, which are of a browniſh colour, looking very different from the reſt of the leaf, and are ſurrounded by an edge, or border, ſome what thicker than the leaf, and of the ſame browniſh colour; in the midſt of theſe little brown ſpots there always ſtands a ſmall protuberance, which riſes above the ſurface of the leaf, as well on the under as on the upper ſide; this is the *gall*; it is of the figure of a conic box, with a conic cover, and is of the hardneſs of wood.

The place where this box is largeſt, is where the lid joins on to the body, and this is always in that part where it touches the leaf. If this *gall*, or box, be opened, there is always found in it a ſmall white worm, produced from the egg of a fly. The manner in which this gall detaches itſelf from the leaf, is this: when the creature has ſucked its nouriſhment from the leaf for a conſiderable time, the little brown ſpot, in the midſt of which the *gall* is placed, grows dry, and ſhrinks, ſo as to loſen itſelf in a great meaſure from the ring, or border, which is fixed to the reſt of the leaf, and every way ſurrounds it. While it is in this ſtate, the creature makes ſome violent motions toward the eſcaping out of it, in order to getting under ground, to paſs into the chryſalis ſtate; the conſequence of theſe motions is the looſening the *gall* wholly from the leaf, ſo that it falls out with the circular dry'd piece of the leaf, and the animal finds itſelf on the earth, into which it immediately creeps, as ſoon as it has diſengaged itſelf from its cover.

As this is the caſe, it is no wonder that the worm is always found in its own form, not in that of the chryſalis, when the *gall* is fixed in the leaf; and the conſequence of the falling out of ſeveral of theſe circular pieces from the leaf is, that there are left ſo many circular holes in it, each ſurrounded with a brown and thick ring, which connected the leaf to the ſmall piece which held the *gall*, while that remained freſh and ſucculent. *Reaumur*, Hiſt. Inſ. Vol. 6. p. 207.

Bramble GALLS, a ſpecies of *galls* found on the branches of the common wild bramble. Theſe are often no other than tumefactions of the ſtalk, for the ſpace of an inch, or thereabout, which ſometimes form only ſo many thick cylindric pieces; at other times they are of the ſhape of an olive, and ſometimes they affect only one ſide of the branch: in all caſes, however, the tumid part, or *gall*, is much harder than the other parts of the branch, which are in their natural ſtate. Theſe *galls* are very common in June and July, and in the other ſummer months, and when cut, either longitudinally or tranſverſly, they are found to be inhabited by a great number of worms of an oblong figure, and yellow colour; theſe live in the interſtices, which they make between the woody fibres, and theſe interſtices they alſo make themſelves, by eating away the ſubſtance of the wood; for if the *galls* are opened when old, they are found to have a large cavity filled with the fragments of the woody fibres, which the worms have eat to pieces; and there are uſually twenty or thirty worms in every *gall*.

Theſe differ extremely from the worms of the common oak *galls*, not only in colour, but in ſtructure and parts. The common ones have all two little hooks at the head, in the manner of many of the maggots of the common flies; but theſe, on the contrary, have a ſharp point of a brown colour, and of the hardneſs of horn, coming from the extremity of the head, with this they tear and break the woody fibres, and there is near its end a ſlit, which is evidently the mouth of the creature, and which ſerves for the receiving and conveying into the ſtomach the fragments of wood, which it breaks off with the point.

In ſome of theſe *galls* there are frequently found another ſort of inſect, which is a white worm, ſomewhat different from the former, and is not the proper inhabitant of the *gall*, nor intended to feed on the wood, but has hooks and teeth, in the manner of many of the common fleſh eating maggots. This is a deſtroyer, that gets by accident into the lodging of the other worms, and feeds on them. Mr. Reaumur is of opinion, that the yellow worms, which are the proper inhabitants of the *gall*, turn into two winged flies, and the devourers of them into ſome of the four winged kind; but this is only a conjecture founded on analogy, as he acknowledges that he never actually ſaw the changes of either. The proper inhabitants of this *gall* are evidently the progeny of a fly, which has a power of lodging her eggs in the ſubſtance of the wood, by means of the borer in her tail. *Reaumur*, Hiſt. Inſect. Vol. 6. p. 194.

GALL-*inſect*, in natural hiſtory, the name of a claſs of inſects, ſo called, from their reſemblance to ſmall *galls*, or vegetable protuberances of a like kind upon trees. They are indeed ſo like theſe ſubſtances, as to have been by many miſtaken for them, and thought not of the animal, but of the vegetable kingdom. Theſe inſects paſs a very great part of their life, even many months together, faſtened againſt the leaves or ſtalks of plants, without any appearance of life or motion, and this is the time in which they acquire their ſtated growth. They are in this ſtate as immoveable as the branch they are fixed on, and ſeem to make a part of it. Their exterior form is remarkably plain, and ſimple, and the more the creature increaſes in growth, the leſs appearance of life it ſhews; and even when it has acquired its maturity, and is in a condition to depoſit its eggs for the propagation of its ſpecies, it then appears leaſt of all of an animal form, and more, than in any other ſtate, reſembles a *gall*, or ſuch vegetable protuberance. Not only the vulgar and incurious have been deceived by this appearance, but the accurate count Marſigli, among others, after very attentively examining the *gall-inſects* of one ſpecies, remained ſeemingly convinced that they were real vegetable excreſcences.

The *gall-inſects* are uſually found on the ſtalks and branches of trees, ſhrubs, and perennial plants. There are ſo far from being particular trees or plants allotted for their production, that very few are without them, and even the ſame ſpecies are found on very different ſpecies of vegetables. The figures and colours of theſe animals enable us to diſtinguiſh ſeveral diſtinct kinds of them; they are all very ſmall, even at their full growth, and ſome of them, in their perfect ſtate, reſemble little round balls, faſtened to the branches of trees, *&c.* by a very ſmall part of their ſurface. Of theſe round ones ſome ſpecies never arrive at a ſize beyond that of a pepper corn; others acquire that of a large pea; other ſpecies of them are of the figure of a ſphere, part of which has been cut off, and theſe are fixed on the trees by the part ſeemingly cut; others are of the figure of elongated ſpheres, the greater axis of which is raiſed above the branch; others are ſomewhat flatted, and more pointed at one end than at the other; others are of the figure of a kidney, and theſe are fixed by the part where the cavity is; others reſemble in figure, the half of an oblong ſpheroide, and theſe alone furniſh a large number; theſe are divided, as it were, along their larger axis, and have ſome ſort of reſemblance to a boat turned upſide down.

There is nothing ſingular or ſtriking in their colour; frequently they are of a paler, or deeper cheſnut brown; ſome of them are rediſh; and others have ſomething of a violet tinge; ſome alſo are of a good black, and others of a yellow ground, undulated and ſtreaked with brown; ſome are alſo brown, veined with white.

Theſe creatures have ſo little to attract the obſervation even of the curious, that they might probably have remained much longer unregarded, were it not that they multiply ſo exceſſively faſt on ſome fruit trees. The peach trees, in particular, are ſometimes in a manner covered with them, and theſe of more than one ſpecies; ſome of the globular kind, and others of the boat figure. The branches thus covered look rough and ſcabby, and the gardeners, ſenſible that whatever the things were, they muſt be nouriſhed at the expence of the juices of the tree, have attempted to deſtroy them. The leaves and fruit of theſe trees is often blackened by the wet that has run off from theſe inſects; and our orange trees, which are frequently full of them, firſt ſtirred up the attention of the more careful obſervers of them to clear them away: theſe are principally of that kind, whoſe form is that of the inverted boat. Meſſrs. de la Hire and Sedileau, were at the pains of making a ſet of obſervations, of a very curious kind, concerning them: theſe gentlemen call this ſpecies the *orange tree bug*, a name by which the gardeners alſo call them, tho' they have nothing in common with any known ſpecies of that animal. See the Memoirs of the Academy of Paris, 1692.

If many of the ſpecies of theſe little animals, however, do miſchief to our fruit trees, there are ſome other kinds of them, the value and uſe of which may very well make us amends; ſince it is from one ſpecies of theſe little creatures, that the inhabitants of many places make ſuch great gains, gathering a harveſt of them without the trouble or expence of ſowing or cultivating. The kermes, ſo well known by name, though ſo little truly underſtood, is of this kind, to which both the phyſician and the dyer are ſo greatly obliged.

The greater part of the animals of this claſs acquire their full growth about the middle of May, or beginning of June at the utmoſt; at which time of the year the branches of peach trees, eſpecially ſuch as are but ill taken care of, are found to abound with two kinds of them, the one round like a pepper corn, the other of the boat ſhape. They are ſometimes brown,

brown, ſometimes rediſh, and ſometimes black and ſhining. *Reaumur*, Hiſt. des Inſ. Vol. 4. p. 1.

Dr. Liſter, who was very curious in his obſervations of inſects, was perhaps beforehand with any of the authors, celebrated as the firſt diſcoverers of the *gall-inſect*, and *progall-inſect* claſſes; he found theſe animals on the plum, cherry, vine, lawrel, and many other trees, and calls them patellæ of theſe trees. He was well informed of their animal origin; and in the Year 1671, diſcovered that they would ſome of them ſtrike a carnation red colour with ley of aſhes, which was not only a good, but a permanent tinge. The principal kind on which he made the experiment was the ſemiglobular ſort, which he deſcribes as being round every where, except where they are applied to the tree. They were of the ſize of half a large pea of a cheſnut colour, and of a ſhining ſurface, faſtning themſelves to the bark of the tree, as the limpetts do to the rocks, and generally were ſought after by ants, and other vermin.

Peach GALL-*inſect*. See the article PEACH.

Shell GALL-*inſect*. See SHELL.

Vine GALL-*inſect*. See VINE.

GALL-*inſect fly*, the male of the *gall-inſect* ſpecies. It is a two winged fly of a very particular kind. There ſeems a great reſemblance between theſe flies in all the *gall-inſect* claſs, and that of the *peach gall-inſect* may give a proper idea of all the reſt. This little creature, examined with the help even of the beſt glaſſes, ſhews, on the under part of its head, nothing analogous to the organs of other flies, deſtined to convey their nouriſhment; nothing that at all reſembles the trunks of the other two winged flies, nor any thing that can be compared to teeth. Where the teeth, if any, ought to be placed, nothing is to be ſeen but two hemiſpheric, or more than hemiſpheric bodies, black and ſhining, and in all reſpects reſembling eyes. If theſe are eyes, they are very remarkably ſituated; and juſt over againſt them, on the other ſide of the head, and near the baſes of the antennæ, there are two other ſimilar bodies, which indeed cannot be taken for any thing but eyes. It ſhould ſeem that this fly has therefore no organs to receive aliments, but has two eyes in the place of ſuch. The want of theſe organs is nothing ſingular in the inſect world, ſince the moths and butterflies afford us inſtances of it. Many of theſe may be ſeen, as ſoon as produced from their cryſalis, in a ſtate to propagate their ſpecies, and depoſit their eggs; and this great end atchieved, they have no farther occaſion for life, nor any means for its ſupport; and probably the caſe is the ſame with theſe flies, which, as ſoon as looſe from their ſhell, ſeek out and fecundate the females, and have after this no farther uſe for life. It is another ſingularity in this ſpecies, that they are produced from their ſhell by their hinder part firſt, whereas all other ſpecies of the two winged flies are produced with the forepart of their body firſt; and if we cannot ſay what may be the reaſons for this ſingularity in the production of this fly, we can however eaſily perceive that every thing is prepared and deſtined accordingly for it. In the nymphs of other flies, all the legs are conſtantly apply'd cloſe to the body, whereas, on the contrary, in the nymph of the *gall-inſect fly*, the legs placed next the head, or the firſt pair, are conſtantly ranged upwards, and each of them embraces one ſide of the head; the conſtant poſition of theſe legs in this direction, is a proof that it is the order and courſe of nature in the production of the animal; nor is it without reaſon that they are thus placed in a ſpecies which, contrary to all the others, is to force itſelf backward out of its ſhell, ſince they ſerve very properly for the creature to puſh himſelf backward by: and as the anterior part of the caſes of other flies naturally and eaſily opens, to give paſſage to the animal, ſo the poſterior part of this does. They ſeem alſo to be more than ordinarily ſlow in their getting out, ſome of them having been obſerved to be ten or twelve hours, from the time of the firſt appearance of a piece of each wing, to their perfect enlargements. *Reaumur*, Hiſt. Inſect. Vol. 4. p. 40.

GALLANTES, among the Romans, a ſurname given to the prieſts of Cybele; whence the modern terms of *gallant*, and *gallantry*, have been formed. See Mem. Acad. Inſcript. Vol. 5. p. 427.

GALLERICA *Lapis*, a name given by the writers of the middle ages to a ſpecies of emerald, which was larger than the finer gems of that kind, and of a pleaſant green, but debaſed by an admixture of white.

GALLERIES *(Cycl.)* in gardening, are to be made in the following manner. A line is firſt to be drawn to the length the *gallery* is to be, and this is to be planted with hornbeam, which is to be the foundation of the *gallery*. Theſe require no farther care than to be ſheared a little, and ſometimes digged about, as there may be occaſion. But the chief curioſity is in the ordering the fore part of the *gallery*, and forming the arches. The pillars of the porticoes, or arches, muſt be placed at four foot diſtance from one another, and the *gallery* muſt be twelve feet high, and ten feet wide, that there may be room for three perſons to walk abreaſt in it. When the hornbeams are grown to the height of three feet, the diſtance of the pillars well regulated, and the ground work of the *gallery* finiſhed, the next thing is to form the frontiſpiece. To perform which, the hornbeam muſt be ſtopt between two pillars at the height, and a trellis, made for that purpoſe, muſt be run up, which forms the arch. As it grows up, thoſe branches which out top the others muſt be levelled with the ſhears; and in time they will grow very ſtrong, and may be kept in regularity by the ſhears. Portico *galleries* may be covered with lime trees.

Galleries in general have been always but lightly eſteemed in England; they were once very much in repute in the gardens of Italy, and other hot countries, but now they are got out of credit even there. *Miller*'s Gardner's Dict.

GALLERY *Ladder*, in a ſhip. See LADDER.

GALLIANA, in natural hiſtory, a name given by ſome authors to the turquoiſe ſtone. It is only a corruption of the word *callaina gemma*, a name of this ſtone common among the Roman authors. Pliny has deſcribed the callais, and the callaina, or callaica gemma, in two different parts of his work, but it ſeems too haſty a concluſion to infer from this, that the callais and callaica gemma were two things. Pliny ſays nothing that ſeems to prove them different; and as he collected his accounts from different authors, there is no great wonder that the ſame ſubject, with the name a little varied, ſhould come in his way twice, in the different parts of his great work. We find, in the ſame manner, the ſame ſtone, *lapis arabicus*, deſcribed in two parts of his book, once under the former name, and once under that of *arabica gemma*; and many other inſtances of the ſame kind of inaccuracy in this author might be produced to prove that only the turquoiſe may be meant by both theſe names. Solinus tells us that this ſtone is found in Germany; but no turquoiſes being ever heard of there, ſome doubts have ariſen from this of its being the turquoiſe that the ancients meant by this word. Theſe all ariſe only from the not knowing that Solinus is the moſt inaccurate writer in the world, and that he takes his accounts of things from Pliny. This author tells us, that the callais was found in Caramania, as it ſtill is, but Solinus read this Germania, and thence gives us a country for the torquoiſe, that does not, nor ever did produce it.

GALLIARDA, in the Italian muſic, the name of a tune that belongs to a dance called a galliard. *Broſs. Dict.* Muſ. in voc. See GALLIARD, *Cycl.*

GALLIGASKINS, in our old writers, denoted wide hoſe or breeches, having their name from their being uſed by the Gaſcoigns.

GALLIHALPENCE, a kind of coin, which with *Suſkins* and *Doitkins*, were forbidden by the ſtatute 3 Hen. V. 1.

It is ſaid they were brought into this kingdom by the Genoeſe merchants, who trading hither in galleys, lived commonly in a lane near Towerſtreet, and were called *galley-men*; landing their goods at *Galley-key*, and trading with their own ſmall ſilver coin, termed *galley-half-pence*. *Stow*'s Survey of Lond. p. 137.

GALLINÆ, in the Linnæan ſyſtem of zoology, the name of a large order of birds, the general character of which is, that their beak is conic and bent. The oſtrich, caſſowary, peacock, *&c.* are of this order. *Linnæi*, Syſtem. Naturæ, p. 47.

GALLINA *Guinea*, the *Guinea hen*, in zoology, the name of a ſpecies of gallinaceous fowl, of the ſize of the common hen, but with a longer neck. Its body is ſloped like that of a partridge, and its colour is all over a dark grey, very beautifully ſpotted with ſmall white ſpecks; there is a black ring round the neck; its head is rediſh, and has on its top a hard horney protuberance of a brown colour; it is blue under the eyes, and has a red fleſhy appendage hanging down from thence. They naturally herd together in large numbers, and breed up their young in common; the females taking care of the broods of others, as well as of their own. They breed very well with us. *Ray*'s Ornitholog. p. 115.

GALLINA *Mozambicana*, in zoology, a name under which Nieremberg has deſcribed a ſort of hen, which he ſays has not only black feathers, but black fleſh and black bones; a hiſtory Mr. Ray ſufficiently explodes. *Ray*'s Ornithol. p. 299.

GALLINA *Piſcis*, in zoology, the name of a fiſh of the cuculus kind, more uſually known by the name of the *corax piſcis*. *Willoughby*, Hiſt. Piſc. p. 280. See the article CORAX.

GALLINACEUS, in zoology, the name of a genus of birds of the cock and hen kind, the characters of which are theſe. The beak is ſhort, ſtrong, and a little crooked, proper for the picking up of corn, which is the food of the whole genus; the body is large, thick, and fleſhy; the wings are ſhort and hollowed, and not calculated for much flying; they all breed a numerous progeny; they build on the ground; the young are not fed by the parent, but immediately ſhift for themſelves; and ſome have long ſpurs behind their legs. *Ray*'s Ornitholog. p. 112.

GALLLINAGO, a general name for heath fowls, as the wood cock, ſnipe, *&c.* See WOOD *Cock*.

GALLINAGO *minor*, in zoology, the name uſed by authors for the ſnipe, a bird well known among the ſportſmen, and which, though in general a bird of paſſage, yet ſometimes remains with us the whole year, and builds and breeds here. It lives in marſhy places, and builds among reeds; it lays four or five eggs at a time.

Its

its breaſt and belly are white; its back covered with long feathers, which are variegated with black and a rediſh brown; its tail is ſhort, and hid by the wings when folded; it has a line of a rediſh white running along the middle of the head; its beak is about three fingers breadth long, and is black at the end, and has ſeveral rough tubercles on it. *Ray*'s Ornitholog. p. 214.

GALLINE, in ichthyology, a name given by the Maſſilians to the flying fiſh called by authors, milvus and lucerna. It is a ſpecies of trigla, and is diſtinguiſhed by Artedi, by the name of the trigla, with the ſnout ſomewhat bifid at the end, and the lateral lines forked towards the tail. See the article TRIGLA.

GALLING *(Cycl.)* Good horſes are often ſubject to *gall* upon their backs, and the utmoſt care ought to be taken to prevent or cure it. The beſt methods of prevention is to take a hind's ſkin, well furniſhed with hair, and fit it neatly beneath the pannel of the ſaddle, ſo that the hairy ſide may be next the horſe; this does not harden by ſweat, but keeps the horſe from *galling*. This is alſo a method that ſhould never be omitted with horſes that are newly cured of ſuch a hurt, as it will prevent their falling into it again. In long journeys, and in horſes that are ſubject to *gall*, it is always proper to take off the ſaddle, as ſoon as the horſe is brought in, and examine whether the back be at all preſſed, or pinched in any part: it will be well to re-examine it after an hour or two, to ſee what effect the ſtanding has had, for often the part hurt will not ſhew it at firſt, but will ſwell very violently afterwards. In this caſe, where the ſkin is not fretted, but a ſwelling comes on, a bag of coarſe cloth ſhould be filled with warm dung, and ty'd upon the ſwelling, which will not only prevent it from growing worſe, but will take it often quite down; or the ſwelling may be well rubbed with good brandy, laying on a paper ſoaked in it. If the ſkin be broken, a mixture of red wine and ſallad oil is a good remedy.

GALLINULA, in zoology, the name of a genus of birds which ſwim on the water, and yet have not webbed feet, nor any membranes joined to their toes, to augment their breadth. The common moorhen, and a great number of other birds, both Engliſh and exotic, are of this genus, as the water rail, the grinetta, the ochropus, and ſeveral Braſilian birds.

GALLINULA *ærythropus*, in zoology, a name given by many authors to the bird commonly called in Engliſh the red-ſhank. *Aldrovand* de Avib. l. 28. c. 96. See RED-SHANK.

GALLINULA *hypoleucos*, in zoology, a name given by ſome authors to the becaſſine, or, as we call it in Engliſh, the ſandpiper. *Geſner* de Avib. See SANDPIPER.

GALLINULA *melampus*, in zoology, a name given by Geſner, and ſome others, to the bird more uſually known by its German name, rotknuſſel. *Aldrovand* de Avib. l. 20. c. 45. See ROTKNUSSEL.

GALLINULA *rhodopus*, *phœnicopus*, and *ochropus*, names by which Geſner, and ſome others, have called the common tringa; a bird in which the legs are, at different ages, and in the different ſexes, greeniſh, yellowiſh, or rediſh. *Geſner* de Avib. See TRINGA.

GALLINULA *ſerica*, in zoology, a name given indiſcriminately by many authors to the grinetta, and the water rail; both birds of the moorhen kind, but ſmaller than the common moorhen. *Geſner* de Avib. *Aldrovand* de Avib. See RALLUS *Aquaticus*, and GRINETTA.

GALLITRICHUM, in botany, a name by which ſeveral authors call the *horminum ſativum*, or garden clarey. *J. Bauhin*, Vol. 3. p. 309.

GALLIUM, *ladies bedſtraw*, in the Linnæan ſyſtem of botany, a genus of plants taking in the *gallium*, or ladies bedſtraw, and the *cruciata*, or croſswort of other authors. The characters of it are theſe. The calyx is an extremely ſmall perianthum, divided into four ſegments, and ſituated on the germen; the flower is compoſed of one petal, which forms no tube, but is placed flatwiſe, and is divided into four ſegments at its edge; the ſtamina are four pointed filaments, ſhorter than the flower; the antheræ are ſimple; the germen of the piſtillum is doubled, and is placed below the receptacle of the flower; the ſtyle is ſlender, ſomewhat bifid, and of the ſame length with the ſtamina; the ſtigmata are globoſe; the fruit is compoſed of two dry, globoſe bodies, growing together, which do not adhere to things, as thoſe of the aparine; the ſeeds are ſingle, large, and kidney faſhioned. *Linnæi* Gen. Plant. p. 24.

The characters of *gallium*, according to Tournefort, are theſe. The flower conſiſts of one leaf, ſhaped like a bell, open at the mouth, and divided into ſeveral ſegments; the cup changes into a dry fruit, conſiſting of two ſeeds, uſually of a lunated figure; the leaves are neither rough, nor ſo much as hairy, and are placed in form of ſtars round the ſtalks, at certain intervals, fewer or more of them, at each joint.

The ſpecies of *gallium* enumerated by Mr. Tournefort are theſe. 1. The broad leaved branched mountain *gallium*. 2. The common white flowered *gallium*. 3. The common yellow *gallium*. 4. The pale yellow flowered *gallium*. 5. The narrow leaved mountain *gallium*, with blackiſh purple flowers. 6. The blue flowered upright field *gallium*. 7. The yellow annual Portugal *gallium*. 8. The Portugal *gallium*, with ſmall verticillate yellow flowers. 9. The blueiſh green leaved rock *gallium*. 10. The ſmalleſt, low, or dwarf rock *gallium*. 11. The leaſt moſslike *gallium* of the Pyrenean mountains. 12. The white fine leaved French *gallium*. 13. The narrow leaved French *gallium*, with blackiſh purple flowers. *Tournef.* Inſt. p. 115.

The common *gallium*, or *yellow ladies bedſtraw*, which grows common every where with us under hedges, is an excellent aſtringent.

GALLOPADE, in the manege. See GALLOP, *Cycl.*

GALLOWS *(Cycl.)*—GALLOWS *of a plow*, a name given by our farmers to a part of the common plow, from its reſembling a *gallows* made for the execution of malefactors, in its form; being compoſed of three pieces of timber, one placed tranſverſely over the heads of the other two. The *gallows* are a part of the plow head; they are fixed into the box of the plow, or that part through which the axis of the wheels paſſes. They make an angle with the box inclining upwards. The upper, or tranſverſe piece is notched in ſeveral places, and ſerves to ſuſtain the wilds, a pair of irons to which a ring and hooks are faſtened, and to theſe the chains of the harneſs, by which the whole plow is drawn along.

In ſome other parts of England they call this whole part of the plow the three pieces, being iron inſtead of timber, by the name of the wilds; and the *gallows* of the plow is then the tranſverſe piece at the top of the crowſtaves. *Tull*'s Huſbandry. See the articles CROWSTAVES and PLOUGH.

GALLUS, the *cock*, in the Linnæan ſyſtem of zoology, makes a diſtinct genus of birds of the general order of the gallina; the diſtinguiſhing characters of which are, that the feet have each four toes, the front of the head has a comb, and the wattles are two, and are naked and flat. *Linnæi* Syſtem. Nat. p. 48.

GALLUS *Grunniens*, in zoology, the name of an Eaſt Indian fiſh, approaching to the nature of the *ſcorpius marinus*, and called by the Dutch *knone haen*. Its body is thick, and rounded; its ſkin is free from ſcales, but is very uneven, full of tubercles, ſpotted, and variegated with ſhort ſtreaks of a blackiſh hue; its head is large and thick, and very full of tubercles; its noſe large, its eyes red, and its tail obtuſe; its belly fins are red. It is a very well taſted fiſh, and much valued there. When firſt taken out of the water, it makes a very remarkable grunting noiſe. *Ray*'s Ichthyog. p. 3.

GALLUS *marinus*, in zoology, a name given by many writers to the fiſh called in Engliſh the *doree*, and more commonly known in Latin by the name *faber*. *Geſner* de Aquat. p. 439. See the article FABER.

GALLUS *marinus* is alſo a name by which ſome have called the fiſh, more frequently known by the name of the *orbis piſcis*. See the article ORBIS.

GALLY *Worm*, in zoology, an inſect known by moſt writers under the name *julus*. It is a land inſect with a long body, compoſed of a great number of rings, and furniſhed with a great number of feet. It is found very frequently in gardens, and when touched, has the power of rolling itſelf up into a ball. *Ray*'s Hiſt. Inſ. p. 46.

It is eſteemed a valuable medicine in the jaundice, and in ſuppreſſion of urine. *Charlt.* Exer. p. 51.

This animal is very common with us among rubbiſh, and is by ſome referred to the ſcolopendræ, but improperly; for tho' they agree in the great number of legs, ours is a harmleſs animal, and the ſcolopendræ are miſchievous creatures, armed with dangerous forceps. It is ſuppoſed by Liſter, that this creature, common with us, would on diſtillation yield the ſame ſort of animal acid, that is procured from the ant. The reaſon of the conjecture is, that the ant and this creature both agree in emitting a ſharp and pungent ſmell on being bruiſed; but theſe are not eaſily procured in plenty enough to make the experiment, as they are not a gregarious inſect like the ant. Poſſibly ſome more of the inſects may be found, on trial, to have the ſame acid. Philoſ. Tranſact. N° 68.

GAMBETTA, in zoology, the name of a bird ſomewhat reſembling the common redſhank. Its head, neck and breaſt are grey, full of brown ſpots: theſe are larger on the back, and ſmaller on the breaſt and belly, and ſmalleſt of all on the head. Its whole back is of a grey, a little inclining to a rediſh brown on the lower part of the back, and on the wings; its belly is white, and its beak black. It is common in Italy, and ſome other places, but is not known in England. *Aldrovand* de Avib. l. 20, and 26.

GAMBOGE. This gum, as it is uſually called, appears to be wholly reſinous, or ſulphureous; ſince ſpirit of wine diſſolves it almoſt entirely, and water, though it ſeparates its parts, and keeps them ſuſpended, yet does not diſſolve them at all, nor is by any means a ſolvent for it: it is alſo inflammable, and eaſily melts with a very gentle heat. If mixed with an equal quantity of ſalt of tartar, it readily diſſolves in common water, in a few hours digeſtion; this ſolution, if kept over the fire, ſoon becomes a ſort of ſmooth glue, or jelly; and this, by adding a large quantity of water is eaſily reduced into a red clear liquor in a warm digeſtion; this liquor evapo-

evaporated over a gentle fire, yields a greyiſh ſalt, which eaſily imbibes moiſture from the air, if not kept in a glaſs well ſtopped; and this extract purges in a ſmaller doſe, than the gum itſelf, and yet with leſs irritation; its taſte, however, is extremely acrimonious and fiery, and it muſt therefore be well diſguiſed before it is given. There is, however, another method of giving it, yet more to be recommended than this for general uſe; this preparation is as follows. Tye up the gum in a piece of linen cloth, and put it into a loaf juſt drawn from the oven; the loaf muſt be cut open for this purpoſe, and afterwards ty'd cloſe together, and ſet in ſome place where it will remain warm four and twenty hours; after this the gum is to be taken out and reduced to powder, and this powder ty'd up again, and put into another loaf, and ſo on to the fourth or fifth time; after which it is to be powdered and kept for uſe. By this eaſy preparation this medicine loſes its violent operation, both as a purgative and emetick, and may be given with great ſafety, and the crumb of the firſt loaf, if eaten, proves purgative. Mem. Acad. 1701.

GAME *(Cycl.)*—GAME *Cock.* In the choice of the *game*, or *fighting cock*, four things are principally to be conſidered; theſe are, the ſhape, colour, courage, and ſharpneſs of the heel. As to the ſhape, ſuch a one ſhould be choſen, as is neither too ſmall nor too large; the very large ones are always clumſy and unwieldly, and the ſmall ones are ſlow and tedious in fighting, and are generally too weak to ſtand a very tight battle: another diſadvantage in theſe extremes is, that both are very difficult to be matched; the middle ſized one ought therefore ever to be preferred, as he is generally the moſt nimble and active with his ſtrength, and the matching him is eaſy. The head ought to be ſmall, the eyes large and briſk, and the beak ſtrong, and hooked at the ſetting on; its colour ought alſo to anſwer to that of the principal or general colour of the feathers, whether that be yellow, rediſh, or grey. The beam of his leg ought to be very ſtrong, and according to his plumage, either blue, grey, or yellow; and the ſpurs ought to be rough, long, and ſharp, a little bending, and pointing inward. The three colours eſteemed in the *game cock* are grey, yellow, and red, with a black breaſt. The perfection of a cock is not, however, ty'd down abſolutely to theſe colours, experience has ſhewn, that there are cocks of other colours which have proved excellent ones, but theſe are in general the beſt; the pied cock ſometimes turns out good, but the white and dun are ſeldom of any value.

If the neck of a cock be inveſted with a circle of a ſcarlet complexion, it is a ſign that he is ſtrong, vigorous, and has great courage; but, on the contrary, if it be pale and wan, it denotes him to be defective in theſe material particulars. The courage of the cock may be in ſome meaſure gueſſed at by his proud ſtately manner of walking, and it is a token of great ſpirit to crow frequently in the pen. What the gameſters in this way call a narrow or ſharp heel, is only to be known by obſervation of the bird while fighting; the cock that has this, at every riſing ſtrikes his adverſary in the proper place, he always draws blood, and at every ſtroke threatens immediate death.

It is generally allowed, that a ſharp heeled cock, though he be ſomewhat falſe, is yet to be preferred to a good cock with a dull heel; the one fights a long time, but ſeldom wounds, while the other gives expectation, every moment, of the end of the battle; and though he will not ſtand all the hewing that the firſt will, yet it is ſeldom found neceſſary, he bringing the battle to a ſhorter concluſion: if therefore a cock be found which is middle ſized, hardy, and ſharp heeled, he is the beſt that can be.

In order to prepare a cock for fighting, his mane is to be clipped off with a pair of ſhears cloſe to the fleſh, all the way down the neck, from the head to the ſhoulders; the feathers are alſo all to be clipped off cloſe to the rump, and the reder that appears, the better condition the cock is in. The wings are to be ſpread by the length of the firſt riſing feather, and all the others are to be cut ſloping with ſharp points, that in riſing he may endanger the eyes of his adverſary; there muſt be no feathers left on the crown of the head, that the opponent can take hold of, and his head ſhould be moiſtened with ſpittle; then the ſpurs being put on, and he is to be turned into the pit to try his fortune.

For the well breeding of *game cocks*, the *game hen* ſhould be of the right and ſtaunch breed; her colour ſhould be black, brown, ſpeckled, grey, or grizzled, or ſhe may be yellowiſh, this laſt colour being by many preferred to all the reſt: if ſhe be tufted on the crown ſhe is the more to be eſteemed, for this is a promiſe of courage and reſolution in the chickens; if ſhe have ſpurs, it is alſo a very good ſign. Her body ſhould be large, and particularly behind, that ſhe may be able to lay large eggs; her behaviour among the other hens is alſo to be noted, for if ſhe be found of a tame ſpirit, receiving abuſes from them without revenge, or ſhewing any token of courage, it may be depended on that her chickens will be good for nothing.

A right *game hen* from a dunghill cock will bring good chickens, but the beſt *game cock*, in the world, with a dunghill hen, will never bring a chicken worth a farthing; but the cocker who would have a breed of the very beſt chickens, is to find a match of the beſt cock and beſt hen he can any where meet with, few from theſe will prove bad.

The beſt ſeaſon for the breeding the *game cocks* is from the beginning of February to the middle or latter end of March; the neſt for the hen is to be made of ſweet and clean ſtraw, and ſhould be placed in ſome warm corner, out of the way of diſturbance from other fowl, for this ſort of interruption provokes this quarrelſome bird in ſuch a manner, as to endanger the eggs. That ſhe may never have occaſion to leave the neſt, and cool her eggs, it will be proper to lay all ſorts of food, that ſhe is likely to approve of, before her, and to put clean water every day, not only for her to drink, but to waſh and trim herſelf in; ſome aſhes, ſand, and gravel ſhould alſo be ſifted on about the neſt. The chickens are hatched in about three weeks, and the neſt is to be carefully watched about this time, for there are always ſome of the chickens hatched before the others; theſe ſhould be taken away as ſoon as out of the ſhell, and laid before the fire, or in ſome warm place in wool, and as ſoon as the reſt are hatched, theſe ſhould be given back to the hen. They are not to be ſuffered to go abroad for the firſt fortnight, and the room they are kept in muſt be boarded, all other floors being too cold and too moiſt. At about a month old the chickens may be turned out into a walk of ſome freſh graſs, that they may feed at liberty, and eat worms and other inſects; but there muſt be no puddle of water near the place, for they are apt to get into ſuch, and it occaſions them a number of diſeaſes. As ſoon as the comb and wattles appear on the cocks, they muſt be cut away, and the ſore place anointed with freſh butter till it is well. The chickens may all be ſuffered to run together till they begin to peck one another, then the cocks are to be ſeparated; each muſt have his particular walk, and the more free from diſturbance this is, the better. The place of feeding them muſt either be a boarded floor, or a very ſoft and dry piece of ground. If the place be hard, as a ſtony pavement, or a plaiſtered floor, the taking up their food will injure and blunt their beaks, ſo that they will never be able to hold faſt afterwards. Any white corn is good for the young *game cock* in his walks, and ſo is a white bread toaſt ſteeped in ale; at times this may be given him ſteeped in urine, which will ſerve to ſcour and cool him very well. There never ſhould be more than three hens allowed to one cock in his walk, for if there are more, he will conſume his ſtrength in the treading; and though his courage may *not* fail, yet he will never have the ability to go through a battle. Care is to be taken alſo as to his rooſting place, that the perch be not too ſmall in the gripe, and be ſo placed, that he may ſit on it without ſtradling; if the perch be crooked it is alſo very diſadvantageous, for it will accuſtom the cock to ſuch an uneven diſpoſition of his feet, that he will be no good ſtriker in the battle. The beſt method of contriving the rooſting place is to have a row of ſhort perches, about eight inches long, and the loweſt ten inches from the ground, that he may aſcend with the more eaſe, and when he is come to the rooſting perch, be conſtrained to ſit with his legs cloſe together. A cock bred in this manner may be fought young, but the beſt method is not to hazard a battle till he is ſomewhat more than two years old.

Game cocks are commonly brought to the ſtate of their greateſt ſtrength and activity in about ten days, which Dr. Robinſon calls their athletic weight; but they will ſcarce remain twenty four hours in this condition; nay, ſome have been known to change for the worſe in twelve hours. See *athletic* WEIGHT.

GAMELION, Γαμηλιων, in antient chronology, the eighth month of the Athenian year. It contained twenty nine days, and anſwered to the latter part of our January, and the beginning of February.

This month had its name from being ſacred to Juno Γαμηλιος, the goddeſs of marriage.

GAMITES *Lapis*, the *marriage ſtone*, a ſtone of a very ſingular kind deſcribed by Pliny, and ſome other of the antients; he ſays it was of a white colour, and that it had in it the figure of two hands mutually infolding one another, which made it a ſymbol of that ſtate. We know nothing of any ſuch ſtone at preſent in the world; and it is eaſy to conjecture, that in Pliny's time either the ſtone muſt have been factitious, or elſe fancy muſt have been very far ſtretched to make the reſemblance.

GAMMADIUM, a triangular veſtment uſed in the primitive church. *Hoffm.* Lex. in voc.

GANACHES, in the manege, are the two bones, one on each ſide of the hinder part of the head, oppoſite to the neck, or onſet of the head, which form the lower jaw, and give it motion. It is in this place that the glands, or kernels of the ſtrangles, and the glanders, are placed.

GANG *(Cycl.)* GANG *fiſh*, a name given by ſome authors to a ſmall fiſh caught in the German lakes, and ſent in pickle into many parts of the world. The more uſual name of this fiſh among writers is *lavaretus*. *Willoughby*, Hiſt. Piſc. p. 183.

The *gang fiſh* is a ſpecies of the coregonus, diſtinguiſhed by Artedi by the name of the coregonus, with the upper jaw longeſt

longeſt and flat, and with fourteen rays in the back fin. See COREGONUS and LAVARETUS.

Ox GANG. See OX.

GANGILES, or GANGALES, a name given by ſome to the *lapis aetites*, or eagle ſtone. *Hoffm.* Lex. in voc. See AETITES.

GANGLIO, or GANGLION *(Cycl.)*—Authors in general who have treated of the *ganglion*, have referred it to the claſs of encyſted tumors, ſuppoſing it to be encloſed in a membranous ſack, in the manner of the atheromatous, and ſteatomatous encyſted tumors. Mr. Eller, in the memoirs of the Berlin academy, gives a very different account of this tumor; he obſerved, that very bad ſymptoms often ſucceeded the extirpating the *ganglion*, in the way of the common encyſted tumors by the knife, and thence concluded, that they muſt be of a different nature, and origin from thoſe tumors. The matter contained in the *ganglion* is uſually found to be of a gelatinous texture, like the jelly of hartſhorn, and of no bad ſmell, or ſharp taſte, and the membrane which contains it always contracts itſelf at the baſe into a kind of neck, and is there intimately joined to, and united with the tendon on which it is placed. The appearance of the tendon however, in the place where the *ganglion* adheres, never appears vitiated, nor any way different from other parts of it. Memoirs de Berlin Ann. 1748. p. 109.

In order to underſtand rightly the origin of the *ganglion*, we are to conſider, that every fibre of the muſcle to which the tendon is affixed, and of whoſe fibres it indeed is only an elongation in a more ſtraitened form, is, while in the muſcle, covered with a delicate fine membrane, which leaves it as ſoon as it leaves the muſcle to enter the compoſition of the tendon; and that all theſe membranes together form the general covering of the tendon, which loſes itſelf in the joining of that part to the bone. This membrane would be rather an incumbrance than a uſeful covering to the tendons, if it did not ſeparate a limpid and viſcous juice, which coats over the whole ſurface of the tendon, and facilitates its common motions. Anatomiſts in general have neglected to enquire into the nature and uſe of this membrane which covers the tendons, and therefore they have miſtaken the origin of the *ganglion*, which is not to be underſtood without this previous knowledge of the part to which it is wholly owing.

When this membrane ſuffers with the tendon, any external violence from blows, or violent extenſions, it often burſts in ſome part; and it neceſſarily follows, that the liquor it before contained, muſt eſcape through the aperture, and it after this naturally lodges itſelf in the tunica adipoſa of the ſkin; and as the liquor by degrees encreaſes in quantity, this tunic, or membrane, forms a part of a ſack for the reception of it. As the viſcous liquor continues to be voided through the aperture, the more ſubtil parts of it by degrees eſcape, and the remainder forms the viſcous and tough matter, which is found in opening the *ganglion*. In ſome caſes, where the rupture of the membrane has been incomplete, the ſurface of it riſes and forms the covering of the ſwelling; and in this caſe repreſents the aneuriſm in an artery.

GANGRENE *(Cycl.)*—Wherever this ſeizes a part, the great care to be taken is to prevent, if poſſible, its terminating in a ſphacelus. In ſtrong habits it is always proper in this caſe firſt to bleed largely, and repeat it as occaſion ſhall require; and it is a moſt neceſſary ſtep in theſe caſes, to be very careful in the beginning, to remove all violent external cauſes of inflammation; as too ſtrict a bandage in wounds and fractures, all foreign bodies, which are accidentally lodged in the parts, as thorns, ſplinters, needles, and the like; and all improper external applications, ſuch as oils and plaſters, with cooling and aſtringent things; and eſpecially in old or weak people, to keep up the failing ſtrength by ſuch diet, as afford good and ſuitable juices for nouriſhment. If the patient is weak, and in years, and naturally of a cold habit; eſpecially if he has loſt much blood, and abounds in crudities, the moſt ſuitable diet for him will be ſoops and brooths, made of chicken, or meat, with mace and other ſpices boiled in them; alſo draughts of cordial liquors, with yolks of eggs, cinnamon and ſugar; eggs themſelves poached, and eaten ſoft; ſtrong jellies of calves feet, hartſhorn, and ivory ſhavings, and old and rich wines; or where the patient's circumſtances will not afford theſe, and nothing particular forbids the uſe of malt liquors, fine ales not too ſtale may ſerve very properly. With reſpect to medicines, the proper ones are the cordial tinctures, waters and electuaries, as the confection of alkermes with ſpices, and other cordial ingredients mixed in it; and teas, made of ſage, ſcordium, and the like herbs, with the ſpices, or a few ſhavings of ſaſſafras, or yellow ſanders; for by theſe means, the ſtagnating blood will be greatly reſolved and attenuated, and its ſound and healthy parts will be retained in a due circulation, and its noxious ones diſcharged and diſſipated. It is alſo of ſome ſervice in theſe caſes frequently to apply a ſpunge dipt in hungary water to the noſe, or to bind it to the wriſts, or temporal arteries: the crumbs of rye bread, mix'd with powdered cloves, and ſteeped in ſtrong vinegar, and afterwards made up into a ball, and held frequently to the noſe, is alſo a thing of no little ſervice. For patients who are of a more warm, ſanguine, and bilious habit, ſoops and decoctions mixed with the acid juices of lemons, or other vegetable acids, are very proper ſtrengtheners; as alſo barley gruel, mixed with ſyrrup of lemons, or mulberries, or with jelly of currants, to be taken daily for the common drink. But in theſe caſes, when the heat is ſmall, and the patient weak, or before accuſtomed to wine, it may be allowable to mix a little wine with the gruel: rheniſh is of all wines the moſt proper on this occaſion, and a glaſs of that, or if neceſſary of a richer wine, may be given at proper intervals.

The temperate, or cooling medicines, commonly given in fevers, may alſo be adminiſtered very properly in theſe caſes; but above all others, the bark is generally eſteemed the great internal remedy in this diſorder. To theſe muſt be added, the ſurgeon's utmoſt attention in the diſcharging the ſtagnating and corrupted blood from the parts, as ſoon as poſſible, and to prevent the neighbouring parts from being affected thereby; the principal methods of doing this are, while the proper internal medicines are given, to make ſcarifications as occaſion ſhall direct upon the parts affected with the ſcalpell; theſe inciſions are to be made all lengthwiſe, and very numerous on the part, and are to be opened to a ſufficient depth; that not only the ſtagnating blood may be by that means diſcharged; but free way may be made by thoſe openings, for the ingreſs of the medicinal applications. And laſtly, diſcutient, balſamic, and ſtimulating fomentations and cataplaſms are to be with great care applied to the affected parts, and frequently renewed. A very excellent fomentation on theſe occaſions is made by mixing with a pint of lime water, three ounces of camphorated ſpirit of wine, with half an ounce of ſpirit of ſal armoniac, or of ſpirit of wine, with myrrh, aloes, and ſaffron infuſed in it, or ſpirit of wine camphorated, with a ſmall quantity of venice treacle, and elixir proprietatis. A decoction of rue, wormwood, ſouthernwood, and camomil flowers alſo, with an admixture of four ounces of venice treacle, and two ounces of caſtile ſoap, and half an ounce of ſal gem to the quart makes a very valuable fomentation; this ſhould be applied hot ſeveral times in a day, by means of doubled linen, or woollen cloths dipped in it, and a laſting warmth may often be ſerviceably kept, by means of a brick made hot, by boiling water, and applied afterwards wrapped up in a linen cloth.

The poor may find a cheap domeſtic remedy in the pickle of cabbages, or in horſe or cow dung, boiled in vinegar, or wine if that can be had; theſe ſhould be applied warm, on linen or woollen cloths, and it is much better to ſteep them hot, by means of a hot brick or tile, than to be frequently opening and expoſing the part to the air to renew them.

The more deſperate a *gangrene* is, and the nearer it approaches to a ſphacelus, the longer and deeper the ſcarifications muſt be made; they may now alſo if on the legs, arms, *&c.* be made tranſverſely, as well as longitudinally, down to the quick; and afterwards the injured parts are to be well rubbed and wetted with warm and ſtimulating medicines; and afterwards a penetrating and diſcutient cataplaſm is to be applied, that the blood in the vitiated parts may be reſtored as much as poſſible to its free and proper motion. A proper cataplaſm for this purpoſe may be made of a few handfuls of ſcordium, wormwood, feverfew, mallows, mint, and ſouthernwood, boiled in oxycrate to the conſiſtence of a cataplaſm and pultice, with half an ounce of ſal armoniac, and two ounces of linſeed meal, with half an ounce of the infuſed oils of rue and camomil added afterwards to it; before this cataplaſm is applied to the part, it is always proper to mix with it a little venice treacle, or elſe of ſpirit of wine comphorated to encreaſe its virtue.

Theſe applications are beſt renewed about three times a day, if they are oftner, it expoſes the parts too much to the injuries from the external air by ſo frequent uncovering them; if more ſeldom, it is poſſible changes may happen between, with which the ſurgeon ought to have been timely acquainted. Care however muſt be taken, either by hot bricks, or ſome like means, to keep the applications warm all the time they are on, for when ſuffered to cool upon the part, they are not only uſeleſs but very hurtful. *Heiſt.* Surgery, p. 215.

GANGRINOS, in the materia medica of the antients, a word uſed for foſſile ſalt; Myrepſius plainly uſes it in this ſenſe, and Fuchſius explains it by foſſile ſalt, called by the barbarous authors ſal gemmæ.

GANGYA, in the materia medica, a name by which ſome authors call the ſeſamum, or oily purging grain. *Marcgr.* p. 21.

GANIMEDES, in chemiſtry, a name given by ſome to white ſulphurs, raiſed by frequent ſublimation; theſe affected writers gave it this name from its being elevated by fire in the proceſs, as Ganimede is ſaid by the poets among the antients to have been taken up from the earth, and raiſed to heaven. *Johnſon.*

GANNANAPERIDE, in botany, a name by which ſome authors have called the tree, which produces the famous Jeſuits bark. *Ray's* Hiſt. Pl. Vol. II. p. 796.

GANNETT, in zoology, the name uſed in Cornwall, and ſome other parts of England, for a large ſpecies of larus, or ſcalpell, called by authors *cataractes*. It is one of the largeſt birds of the larus kind, being larger than the common duck. Its beak is ſhorter, ſtronger, and more crooked than that of any other bird of this kind; it is web-footed, but has the ſtrongeſt,

ſtrongeſt and ſharpeſt claws of all the birds of that kind. Its back is of a duſky, browniſh, or ferrugineous gray, like that of the buzzard; its belly and breaſt are paler, but of the ſame dye, and its long wing feathers are black; its tail alſo is all black. It is a very bold and voracious bird; it follows the ſhoals of pilchards and other fiſh, and picks up vaſt numbers of them. It is very common in the weſtern coaſts of England. *Ray*'s Ornitholog. p. 26.

GAONS, a certain order of jewiſh doctors, who appeared in the eaſt, after the cloſing of the talmud. The word *gaons* ſignifies excellent, ſublime, as in the divinity ſchools, we formerly had irrefragable, ſublime, reſolute, angelic, and ſubtle doctors. The *gaons* ſucceeded the Seburæans, or Opiners, about the beginning of the ſixth century. Chanan Meiſchtia was the head, and firſt of the excellents; he reſtored the academy of Pandebita, which had been ſhut up for the ſpace of thirty years. *Calm.* Dict. Bibl. *Baſnag.* Hiſt. des Juifs. Tom. 6. l. 9. c. 5. Art. 3.

GARAB, and ALGARAB, names given by Avicenna to the ægilops, or wild oat.

GARAGAY, in zoology, the name of a rapacious bird of Mexico, of the ſize of our kite; its head and the tips of its wings are white, it makes but ſhort flights, it is very fond of the eggs of tortoiſes and crocodiles, and hunts the places where they have buried them in the ſands. *Ray*'s Ornitholog. p. 252.

GARANHA, in zoology, a name by which ſome have called a large Braſilian fiſh, of the ſhape of our carp, more uſually known among authors, by its Braſilian name acaraaya. See the article ACARAAYA. *Willoughby*, Hiſt. p. 329.

GARATRONIUM, in natural hiſtory, the name of a foſſile body, commonly ſuppoſed the ſame with the bufonites, but very improperly; the only juſt account of it is that of Ferrante Imperato, who tells us, that it is a purple ſtone with variegations of a gold yellow, diſpoſed in the manner of the veins of many ſorts of marble; and that the Perſians, and many other of the eaſtern people, cut it into the handles of their ſabres. It appears by this deſcription to be a kind of jaſper; and is very improperly confounded with the bufonites, a ſmall ſtone fit only to be worn in rings.

GARB, a name given by the Moors, to an African ſpecies of willow. *Ray.*

GARBOARD-*ſtrake*, in a ſhip, is the firſt ſeam next to the keel.

GARBOARD-*plank*, in a ſhip, the firſt plank faſtened on the keel.

GARCINIA, in botany, the name of a genus of plants, called by Garcias *Magoſtans*; the characters of which are theſe. The perianthium is compoſed of four roundiſh, hollow, obtuſe leaves, which remain after the flower is fallen. The flower conſiſts of four roundiſh and hollow petals, which ſtand expanded, and are twice as large as the leaves of the cup. The ſtamina are ſixteen erect and ſimple filaments, placed together in form of a cylinder, and longer than the cup. The antheræ are roundiſh, the germen of the piſtill is of an oval figure; there is ſcarce any ſtyle, the ſtigma is flat and peltated, and divided into eight obtuſe ſegments; the fruit is a large coriaceous globoſe berry, having only one cell, in which are eight hairy and fleſhy ſeeds, convex on one ſide, and angular on the other. *Linnæi*, Gen. Pl. p. 212. *Garc.* AA. 431. t. 1.

GARDEN (*Cycl.*)—The principal things to be conſidered in the forming a *garden*, are the ſituation, form, ſoil, aſpect, and expoſure; as to the form, a ſquare, or rather an oblong, is the moſt eligible; if the ground be irregular, it may be made uniform by art. A triangle is a beautiful figure, as well as a ſquare, and the moſt irregular ſpots of ground may, by borders and walks, be brought to one or other of thoſe figures.

The ſituation ought to be neither too high nor too low, for the winds in one of theſe extremes, and the damps in the other are equally to be avoided. The ſides of a hill are always the moſt eligible, and if the declivity be eaſy, and there are ſprings of water, the ſituation is as happy as any thing can be. *Gardens* on level ground have their advantages, and are leſs expenſive; but they want proſpect, and ſeveral other very agreeable things in thoſe on the ſides of hills not too ſteep. The ſoil is greatly to be regarded, as it is not poſſible to make a good *garden* when this is bad. Great expences may be incurred in meliorating the ground, and when that is done, the advantages of it will be loſt in a little time; nay, where three feet of good earth have been laid over the whole ſurface of a *garden*, when the trees have been rooted enough to ſtrike into the natural bottom, the whole plantation has been known to dwindle away. Places naturally producing heath and thiſtles are to be rejected, and where the trees are ſeen to be ſtubbed, and ſtunted, it is an ill omen. When the graſs grows well, and there is not leſs than three feet earth, *gardens* are ſure to ſucceed. The ground muſt not be too ſtoney, nor of all things, a hard ſtiff clay, which is moſt to be avoided of all ſoils for *gardening*. A third requiſite is water, without which a *garden* muſt ſuffer extremely in droughts. And to theſe may be added, a very advantageous and pleaſing, though not abſolutely neceſſary thing, the proſpect of a pleaſant country. The area of a handſome garden may take up thirty or forty acres, not more, and the following rules ſhould be obſerved in the diſpoſition of it. There ſhould always be a deſcent from the houſe to the *garden* of not fewer than three ſteps; this will render the houſe more dry and wholeſome, and the proſpect on entering the *garden* more extenſive. *Miller*'s Gard. Dict.

The firſt thing preſenting itſelf to view in a *garden*, ſhould be a fine level piece of graſs, full as broad as the front of the building, and this ſhould be ſurrounded with a gravel walk, for the convenience of walking in damp weather. On the outſide of theſe gravel walks ſhould be borders of three or four feet wide for flowers. And from the back of theſe a ſlope of ever-green ſhrubs will terminate the proſpect very agreeably: but whenever there are good proſpects, or agreeable buildings to terminate the view, there then ſhould be left open viſtas.

Groves make the moſt agreeable part of a *garden*, ſo that there cannot be too many of them; only they muſt not be too near the houſe, nor be ſuffered to block up agreeable proſpects. To accompany parterres, groves opened in compartments, quincunxes, and arbour work with fountains, *&c.* are very agreeable. Some groves, all of evergreens, ſhould be planted in proper places, and ſome ſquares of trees of this kind among the other wood.

The head of the parterre ſhould be adorned with baſons and waterworks; and behind them ſhould be a circular line of paliſades, or woodwork, cut into a gooſe foot, and leading into the principal walks. The principal walk muſt be in front of the houſe, and ſhould extend from the graſs plat next the houſe, to the end of the garden, and at the end terminated by a foſſe to continue the view.

The ſeveral parts of every piece in the *garden* ſhould alſo be diverſified; if a baſon be round, the walk ought to be octangular; and the ſame is to be obſerved in graſs plats, and bowling greens, which are the midſt of groves. In places where the eye takes in the whole at once, the two ſides ſhould be always the ſame; in all others they ſhould be varied, and above all things, ſmall baſons, narrow walks, and other littleneſſes in contrivance, are to be avoided.

Before a *garden* is plan'd out, it ought alſo ever to be conſidered, what it will be when the trees have had twenty years growth. The corners and angles of every part of a *garden* ought to be ſloped, or cut hollow.

The ſeveral ſorts of *gardens* may be properly enough ranged under three general heads. 1. *Gardens* on a perfect level. 2 *Gardens* on an eaſy aſcent. 3. *Gardens*, whoſe ground and level are interrupted by falls and terraces, banks, ſlopes, or flights of ſteps. *Gardens* on a perfect level have the advantages of leſs expence, and an eaſy walking. Thoſe on an aſcent fatigue people in walking, but they entertain the eye with an agreeable proſpect. Thoſe with frequent terraces have the advantage of preſenting, in different places, ſo many different views of the compartments, as to give the pleaſure of ſeveral gardens. *Miller*'s Gard. Dict.

Kitchin GARDEN. See KITCHIN.

Pendant GARDENS. See PENSILES *horti*.

GARDECAUT, or GARD DU CORD, in a watch, that which ſtops the fuſee, when wound up, and for that end is driven up by the ſtring; ſome call it *guard-cock*; others *guard du gut*.

GARDON, in zoology, the name of a fiſh of the roach kind, ſuppoſed by many not to differ in any thing eſſential from the common Roach of the Engliſh rivers; ſome authors call it the *gardon* ſargus, and cephalus; others leuciſcus. *Willughby*'s Hiſt. Piſ. p. 260. See LEUCISCUS and SARGUS.

GARDUS, in ichthyology, a name given by ſome writers on fiſhes, to that kind of cyprinus, called by Geſner and others, the ſargus. See GARDON and CYPRINUS.

GARE, in our old writers, a coarſe wool, full of ſtaring hairs, ſuch as grows about the ſhanks of ſheep. 31 Edw. 3. c. 8. *Ruſt.* Dict. in voc.

GARGANEY, in zoology, the name of a freſh water fowl of the duck kind; it is ſomewhat larger than the teal, but very like it in ſhape. Its beak is black, and its legs and feet livid with a faint mixture of green; the upper part of the head is almoſt wholly black, but it has on each a white ſtreak drawn from the eyes to the back part of the head, the throat and lower part of the neck are variegated with white and a rediſh brown; juſt under the beak it has a black ſpot, the breaſt is beautifully variegated with tranſverſe undulated lines of black, and a duſty brown; the belly is white, or yellowiſh. The female is ſmaller than the male, and has not the bright colours about the head, which are ſo beautiful in that.

GARICON, in the materia medica, a name given by the Arabian writers to the drug called agaric by the antients. The Arabians have ſaid nothing of this drug, but what they have tranſcribed from the Greek of Dioſcorides and others; it is certain however from the concurrent teſtimony of all the antients, as to the form, nature, and virtues of agaric, that theirs was not the ſame ſubſtance which we call by this name. See AGARIC.

The antients knew two kinds of what they called agaric; they diſtinguiſhed theſe by the common terms of male and female.

female; the male was a root reſembling the ſilphium of a cubit long, and of an inch or two in diameter; the female was the corrupted *wood* of certain trees, particularly of the cedar, and other odoriferous woods.

Pliny makes it indeed the decayed wood of the oak, which ſhines like fire in the dark, and calls it a fungus, but this was not the agaric of the Greeks.

The female agaric, or the decayed wood of the cedar, was what they gave as an antidote and cordial; the male, or as others called it, the black agaric, was poiſonous. Dioſcorides places it among the poiſonous roots, and Aviſenna condemns it, as hard and unfit for internal uſe; the other, or female agaric, being ſoft, friable and tender. When it was thus in a great degree however, it was condemned by the more accurate writers; and Dioſcorides, in particular, condemns the agarics of Cilicia and Galatia as too friable, and of no value: ſo that they ſeemed to fix upon a proper ſtage in the decay, as the neceſſary qualification of good agaric.

GARIDELLA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of a number of arched leaves, each bifid at the end, and all diſpoſed in a circular form; the cup is divided into ſeveral ſegments, and from it ariſes a piſtil, which finally becomes a ſort of head compoſed of ſeveral oblong bivalve capſules, which contain roundiſh ſeeds.

There is only one known ſpecies of this plant, which is the *garidella* with finely divided leaves, commonly called the fennel leaved cretic nigella. *Tournefort*, p. 625.

GARLICK, *Allium*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the liliaceous kind, and conſiſts of ſix leaves, with a piſtil in the center, which finally becomes a roundiſh fruit, divided into three cells, and containing roundiſh ſeeds. To this it is to be added, that the flowers are always collected into round heads, and the roots are tunicated, and uſually made up of ſeveral ſmall nuclei; and finally, that the leaves are not tubular. The ſpecies of *garlick* enumerated by Mr. Tournefort are theſe. 1. The common cultivated *garlick*. 2. The cultivated *garlick*, with the twiſted top of the ſtalk, called by many alliopraſum, ophioſcordon, and Rocambole. 3. The broad leaved round headed *garlick*. 4. The leek leaved wild *garlick*, with red flowers and red roots. 5. The narrower leaved globular headed *garlick*. 6. The broad leaved wild *garlick*, called *bears garlick*, and ramſons. 7. The broad leaved ſpotted mountain *garlick*. 8. The leſſer broad leaved mountain *garlick*. 9. The narrow leaved ſpotted mountain *garlick*. 10. The greeniſh yellow flowered *garlick*, called moly with green flowers. 11. The two horned purple proliferous mountain *garlick*. 12. The two horned wild *garlick*, with a greeniſh white flower, with three purple ſtreaks in each petal. 13. The two horned mountain *garlick*, with a duſky coloured flower. 14. The two horned mountain *garlick*, with pale yellow flowers. 15. The two horned ruſh leaved yellow flowered mountain *garlick*. 16. The round headed mountain *garlick*. 17. The purple flowered Pyrenean *garlick*, called by ſome the purple moly. 18. The great narciſſus leaved mountain *garlick*. 19. The narciſſus leaved mountain *garlick*, with ſoft leaves and pale coloured flowers. 20. The leſſer narciſſus leaved mountain *garlick*. 21. The narciſſus leaved mountain *garlick*, with narrow leaves and pale flowers. 22. The long rooted mountain *garlick*. 23. The purple flowered rock *garlick*, with roots like acorns. 24. The little mountain *garlick*. 25. The broad leaved lily flowered mountain *garlick*. 26. The broad leaved *garlick*, with red lily like flowers. 27. The broad leaved Spaniſh *garlick*. 28. The broad leaved yellow flowered *garlick*. 29. The broad leaved ſtrong ſcented yellow flowered *garlick*. 30. The purple flowered African *garlick*. 31. The whitiſh green flowered *garlick*. 32. The leſſer mountain *garlick*, or moly with a large roſe coloured flower. 33. The narrow leaved *garlick*, with pale red umbellated flowers. 34. The low *garlick*, with groſſy leaves. 35. The triangular ſtalked *garlick*. 36. The large flowered narrow leaved *garlick*. 37. The narrow leaved *garlick*, with twiſted leaves: and 38. The little ruſh leaved, ſweet ſcented wild *garlick*. *Tourn.* Inſt. p. 383.

Garlick is an extremely active and penetrating medicine. It is of the number of thoſe roots which ought always to be uſed freſh and full of juice, not dried; ſome eſteem it the greateſt of all alexipharmics. The German phyſicians frequently carry a clove of *garlick* in their mouths, when they viſit patients in malignant fevers: with us it is more in uſe among country people, than in the ſhops. They give a decoction of *garlick* in milk, as a remedy for worms, and alſo in the cholic, and in ſuppreſſions of urine. Its moſt conſtant uſe, however, is in aſthma's, and catarrhous diſorders of the breaſt, in which it promotes expectoration.

Whatever may be the virtues of *garlick*, it ought to be uſed in ſmall doſes, and that not too frequently, becauſe, if long continued, it is apt to heat and inflame the viſcera. Vid. *Hill*'s Hiſt. Mat. Med. p. 660, ſeq.

GARNET, in natural hiſtory. See GRANATUS.

GARNET, aboard a ſhip, is a tackle having a pendant coming from the head of the main maſt, with a block ſtrongly ſeized to the main ſtay juſt over the hatch way; in which block is reeved the runner, which hath an hook at one end, in which is hitched the ſlings; and at the other end is a double block, in which the fall of the runner is reeved; ſo that by its means any goods, or caſks, that are not over heavy, may be haled and hoiſed into, or out of the ſhip; when this *garnet* is not uſed, it is faſtened along by the ſtay at the bottom of it.

GARNET *colour*. To give this colour to glaſs the workmen take the following method. They take equal quantities of cryſtal and rochetta frit, and to every hundred weight of this mixture they add a pound of manganeſe, and an ounce of prepared zaffer; theſe are to be powdered ſeparately, then mixed and added by degrees to the frit while in the furnace: great care is to be taken to mix the manganeſe and zaffer very perfectly, and when the matter has ſtood twenty four hours in fuſion, it may be worked. *Neri*'s Art of Glaſs, p. 91.

GARNET *paſte*. The making the counterfeit *garnet* in paſte is done in three different proportions of the ingredients, which are theſe.

Take prepared cryſtal two ounces, common red lead ſix ounces, manganeſe ſixteen grains, zaffer three grains; mix all well together, and put them into a crucible, cover it with a lute, and ſet it in a potter's kiln for twenty four hours.

Or take cryſtal two ounces, minium five ounces and a half, manganeſe fifteen grains, zaffer four grains; mix them well together, and leave room for their ſwelling in the pot; bake them twenty four hours in a potter's kiln.

The laſt method is this: Take cryſtal prepared two ounces, minium five ounces, mix them, and add manganeſe fifty two grains, zaffer ſix grains; mix them well together, and let all be baked, in a pot well luted, in a potter's kiln for twenty four hours.

The firſt of theſe makes a very handſome *garnet* of the common tinge, the ſecond a deep one with ſomething of a violet tinge, as many of the natural garnets have, but the third makes infinitely the fineſt and brighteſt. *Neri*'s Art of Glaſs, p. 134.

Clew-GARNET, on board a ſhip. See CLEW-*Garnet*.

GAROSMUS, in botany, a name uſed by ſome authors for the atriplex olida, or ſtinking orach, a very ſtinking low plant common on dunghills. *Ger.* Emac. Ind. 2.

GARRULUS *Bohemicus*, the *Bohemian magpie*, a name given by ſome to the bird more uſually called *ampelis*, from its love of grapes. See AMPELIS.

GARRULUS *Argentoratenſis*, in zoology, the name given by authors to the ſpecies of magpie commonly called the roller, a very beautifully variegated bird, brought to market in Italy, and ſome other places. *Ray*'s Ornitholog. p. 89.

GARTH (*Cycl.*) is uſed in ſome parts of England for a little backſide or cloſe. It is an antient Britiſh word. *Gard*, in that language, ſignifies garden, and is pronounced and written *garth*.

This word is alſo uſed for a dam, or wear, *&c.*

GARTH-*men*, is uſed in our ſtatutes for thoſe who catch fiſh by means of fiſh-garths, or wears.

By ſtatute it is ordained, that no fiſher, nor *garth-man*, ſhall uſe any nets or engines to deſtroy the fry of fiſh, *&c.* 17 Rich. II. c. 9. The word is ſuppoſed by ſome to be derived from the Scotch word *gart*, which ſignifies forced or compelled; becauſe fiſh are forced by the wear to paſs in a loop, where they are taken.

GARUM, a word in very common uſe among the old writers on medicine; they expreſſed by it a pickle, in which fiſh had been preſerved. The principal kind of fiſh they preſerved in this manner was the mackarel.

The *garum* principally conſiſted of the juices of the fiſh and ſalt; but we find the old writers ſpeaking of ſeveral kinds of it: one they called Spaniſh *garum*, from the place whence they had it; another kind, from its colour, was termed the black *garum*; this laſt kind ſeems to have been that called *fæcoſum* by the Latin poets, as if the fæces and remains of the fiſh were left among it: and by others *garum ſanguineum*, from its being ſometimes tinged with their blood to a rediſh colour. The Romans ſometimes called the Spaniſh kind, which was eſteemed the beſt, *garum ſociorum*; and Galen ſays, that the black *garum* was called oxyporum, but he only means by this, that it was uſed in the preparations called oxypora. It ſerved to dilute them, and thence took the name of them to itſelf, by way of diſtinction from the Spaniſh, and other kinds, not uſed to this purpoſe. Pliny tells us, that *garum* was compoſed of all the offals of fiſh, of every kind, macerated in ſalt; it had its name, he ſays, from its being originally made of a fiſh called by the Greeks *garos*, but in his time the beſt ſeems to have been made with the mackarel; but that there were ſeveral other kinds uſed, both in food and medicine, ſome of which muſt have been made from ſcarce fiſh, for they were of great price. They were uſed in glyſters, and externally applied in ſeveral kinds of cutaneous eruptions: the antients had a great opinion of them in glyſters, for removing the pain in the ſciatica, and other like caſes; and the coarſer ſorts were their common medicine for curing cattle of the ſcab, by making inciſions in the ſkin, and laying over the part cloaths wetted with it.

The true way in which the antients prepared their *garum*, which they ſo much valued as a delicacy at their tables, is unknown to us; but it appears that ſome kinds of *garum* had no fiſhy matter in them, from Aëtius, who gives the following preſcription of a liquor, which he calls by this name. Take of common water thirty one pints, of ſea ſalt two pints, and of dried figs fifty; let theſe all macerate together, and afterwards be ſtrained clear for uſe. All the *garums* were eſteemed hot and drying by the antients, and were ſometimes given as laxatives before food. The modern writers underſtand the word *garum* in a much more limited ſenſe, meaning no more by it than the brine or pickle in which herrings or anchovies are preſerved.

GARYOPHYLLUS, or CARYOPHYLLUS, the *clove ſpice*. There is great room to doubt whether the *caryophyllus* of the antient Greeks and Romans was the ſame with the ſpice we now know by that name. Pliny's account of it is, againſt the general opinion, that it was. He ſays it was of the ſhape of a pepper corn, but larger, and more brittle, and that it was brought over for the ſake of its ſmell. This deſcription of the *caryophyllus* of the antients does not at all agree with our clove ſpice, but much better with the pimento, or, as we call it, Jamaica pepper. Pliny adds, that it was ſaid to grow in ſome part of the Indies. The copies differ in theſe words, ſome have it in *indico luce*, others in *indicato*, and the moſt correct in *indica Tynde*. Tyndis was a famous market of the Eaſt Indies in old times, and, according to Peutinger's tables, it was the very utmoſt limits of the Roman traffick in this part of the world: and the author of the Periplus of the Red Sea mentions Tyndis and Muziris, as two of the moſt remarkable and flouriſhing marts of the Indies, where merchants of all nations reſorted to purchaſe the products of the Eaſt. The cloves, or *caryophylli* of our times, grow in the Molucca iſlands, and in Ceylon, which was the Taprobatane of the antients.

The *caryophyllus* of Pliny muſt be allowed to be different from our clove, but Paulus Ægineta ſeems plainly to have known our clove by this name; he ſays, that it was a ſpice brought from the Indies, and ſeemed a ſort of flower, but compoſed of a woody ſubſtance, and bore its fruit on the top. The flower itſelf he alſo, in another place, compares to a nail, a compariſon adopted by many who have written ſince his time, and very appoſite to the cloves now in uſe, but by no means to the cloves of the antients, which, as deſcribed by Pliny, muſt have been round, and in ſize between a pepper corn and a pea, its ſize and ſhape very well agreeing with our pimento. Paulus Ægineta finds fault with the name *caryophyllus*, which ſignifies having leaves like the nut tree. It is very certain that the clove july flower, with which we make a ſyrup in the ſhops, is by no means entitled, by the ſhape of its leaves, to this name, and has only obtained it from its flower, ſomewhat reſembling, in ſmell, the clove ſpice. Some ſay that it is applicable to the clove tree, but this will ſcarce hold, for the clove tree is, by all modern writers, agreed to have leaves like the bay, and the bay leaf has no great reſemblance to any thing of the nut kind. Theophraſtus indeed compares the citron leaf to the leaf of the bay, the nut, and the andrachne; but though we allow that the andrachne had leaves very like the bay, we can ſcarce come into the opinion, that the nut leaf is like the bay. Upon the whole, the quarrel that Ægineta makes to the name, and the name being received as a proper one among all the Greek writers, ſeems a farther proof that their clove was not the ſame with ours: the tree that produced their clove, if different from ours, might perhaps have leaves like a nut tree, though the leaves of our clove tree are like the bay.

GAS *(Cycl.)*—GAS *ſylveſtre*, a term uſed by Van Helmont to expreſs a ſubtile and floating ſpirit, which is ſcarce abſent from any place, but impregnates the air; and though it is of no harm when in an open place, yet when ſhut up, and cloſe confined in a cavern, has power to extinguiſh a candle, and even in a more potent ſtate will ſuffocate animals. Neuman obſerves that this *gas* always remains, in ſome portion, in fermented liquors, though it is not to be ſeparated from them, any more than from any other body which it impregnates in a ſenſible form. Ale is obſerved by this author always to retain a conſiderable portion of it, to which it owes its inebriating and narcotic quality, more than to the common ſpirit which it contains.

GAST *hound*, a term uſed in the north of England for a ſort of hound, called alſo, more expreſſively, the gaze hound. This dog is more beholden to the ſharpneſs of his ſight in hunting, than to his ſmell. He will ſeldom loſe ſight of the fox, when once he has found him, and makes very good ſport with the hare. As to the buck, he will always ſingle out a plump and good one from the herd, and if after a time he joins them again, and they ſuffer it, this dog will ſoon pick him out again by his eye, and never leave him till he is worried. Theſe ſort of hounds do better in champaign even ground, than where there are buſhes and briars; and they are better for people who follow them on horſeback, than for thoſe who hunt on foot. If this ſort of dog takes a wrong way, he is not obſtinate in it, but begins the chace afreſh from a ſignal made him by the maſter, and follows with as much courage and nimbleneſs as at firſt.

GASTEROSTEUS, in ichthyology, the name of a genus of the acanthopterygious fiſhes, the characters of which, according to Artedi, are theſe. The brancheoſtege membrane on each ſide contains three ſmall and ſlender bones; the belly is almoſt all over covered with bony ſcales; the belly fins have only two rays, the one of which is much larger than the other, and is prickly. The ſpecies of this fiſh are theſe. 1. The *gaſteroſteus*, with three prickles on the back; this is the common piſciculus aculeatus, or common ſtittleback. 2. The *gaſteroſteus*, with ten prickles on the back; this is the pugnitius minor of authors. 3. The *gaſteroſteus*, with fifteen prickles on the back; this is the ſteinbicher of the Germans. The body is ſquare, and the fiſh is five or ſix inches long.

The name is of Greek origin, and is derived from the words γαστηρ, *the belly*, and οστεον, *a bone*; the greater part of the belly of this fiſh being fortified by bony plates. *Artedi* Gen. Piſc. p. 37. See alſo *Linnæi* Syſt. Nat. p. 53.

GASTRIC *(Cycl.)*—GASTRIC *juice*, a name given by ſome authors to the proper juices of the ſtomach. This is a thin, pellucid, ſpumous, and ſaltiſh liquor, which continually diſtils from the glandulous kernels of the ſtomach for the diſſolution, mixture, and dilution of our food, and is of great ſervice in digeſtion.

GASTROCNEMII, *(Cycl.)* in anatomy, two thick pretty broad and oblong muſcles, ſituated laterally with reſpect to each other, in the ſame plane, under the *poples*, and forming a great part of what is called the calf of the leg. That which lies next the tibia is called internus, and that next the fibula, externus. Each muſcle is fixed above, by a flat tendon to the poſterior part of the lower extremity of the os femoris, behind the lateral tuberoſity of each condyle, adhering cloſely to the poſterior ligaments of the point of the knee: from thence they run down, each forming a large and pretty broad fleſhy body, irregularly oval. The externus covers the poplitæus, being larger and broader, ſpreading more laterally, and running lower down than the internus; the fleſhy body of which begins higher up than the other. About the middle of the leg they end in a ſtrong, broad, common tendon, which contracts a little in breadth as it deſcends, and is inſerted in the poſterior extremity of the os calcis, together with the tendon of the ſolæus. The ſuperior tendons of theſe muſcles become gradually cartilaginous in aged perſons; and at length oſſify near the condyles, the bony portions looking like ſeſamoide bones. It is ſometimes very late before they are hardened in this manner, and often one of them is hardened before the other. *Winſlow*'s Anat. p. 218.

GASTRORAPHY, in ſurgery, expreſſes the operation of the ſuture, or ſowing up wounds in the abdomen.

The word is derived from γαστηρ the belly, or abdomen, and ῥαφη, a ſuture.

This operation is generally much dreaded by the patient, and is unneceſſary in ſeveral caſes where the wound is only in the muſcular part, and 2. where it is not very large, eſpecially if it be made lengthwiſe: for if the wound ſhould penetrate into the cavity of the abdomen, and even let out a part of the omentum, or inteſtines; yet in caſes where it is very ſmall, as wounds generally are, which are made by puncture, or have happened lengthways; in theſe caſes, upon returning the parts which are puſhed out, ſtopping the wound with a ſoft tent, and ſecuring all with a proper bandage, it may be healed without the help of the needle. Beſides in fat perſons, this operation is very difficult: and it would be an act of great cruelty in a ſurgeon, to perform this operation upon a man, when he might be cured after an eaſier method.

But there are two caſes in which this operation is abſolutely neceſſary; the firſt is, where the wound is ſo large, that there is no poſſibility of retaining the inteſtines by any other method; for as the inteſtines are continually puſhed forward in the act of inſpiration, by the action of the diaphragm and the abdomen, the falling down of the inteſtines in this caſe is unavoidable, and therefore the operation is neceſſary; the other is in large tranſverſe wounds of the abdomen, where the muſcles are divided, but the peritonæum is not concerned.

In wounds of the abdomen the chief inquiry is, whether the omentum or inteſtines are let out; if none of theſe have burſt through the wound, the lips of the wound muſt be kept as cloſe together as poſſible with the hands, and the patient kept with his head lying downwards, till the wound is ſufficiently ſecured from letting out the contents of the abdomen: but when the inteſtines are already fallen out, they muſt be returned with the greateſt expedition, leſt they ſhould receive any injuries from the external air. It is firſt to be examined however, whether they have received any wound, or not; and whether they preſerve their natural warmth and colour: for where they are cold, livid, or dry, or wounded, they are not to be returned ſuddenly, but fomented with warm milk and water, or wrapped up for ſome time in the cawl of ſome animal newly killed, till they have in ſome degree recovered their native warmth and condition.

You will eaſily perceive, that there is ſome hurt in the in-

teſtines, though the wound does not immediately appear, if there is a more than ordinary flaccidity in them; and when this is the caſe, the reſt of the inteſtines muſt be pulled gently forward till you find the wound. If nothing of this ſort is the caſe, but the inteſtines are in their natural ſtate and condition, they muſt be returned in the following manner. The patient muſt be placed in a ſupine poſture, and laid on that ſide that is oppoſite to the wound, and the inteſtine muſt be returned by the aperture of the wound, with the two fore fingers, taking care never to take off one finger, till the other is on the gut; the patient is to be adviſed all the while to hold his breath, and the lips of the wound muſt be then brought together.

If the inteſtines have been forced through a ſmall wound, and are afterwards ſo diſtended with wind, that they cannot eaſily be returned; it is neceſſary to pull the inteſtine gently forward, that more of it may come out, and the wind take up by that means leſs room in any one part; an aſſiſtant muſt then gently dilate the wound as far as may be, either with his hand, or with two hooks fixed in the internal membrane, while the ſurgeon returns the inteſtines; when this is done, the wound muſt be ſecured firſt with the hand, and then with the proper dreſſings, and in this caſe the ſurgeon may avoid the uſe of this painful operation.

When it is found neceſſary to perform the operation, it muſt be done in the following manner; firſt paſs a ſtrong double, or quadruple thread well waxed through two crooked needles, and with theſe ſtitch up both ends of the wound, beginning at one end with the upper lip of the wound, paſſing the needle through the peritoneum, muſcles of the abdomen, and the common integuments, from within outwards, leaving only the breadth of a thumb between the ſtitches, and the mouth of the wound, obſerving the ſame method in paſſing the other needle through the lower lip; while you are paſſing the needle with one hand, it will be proper to ſupport the lips of the wound with the other, to prevent the inteſtines from being wounded. In a wound of two fingers breadth, one ſtitch in the middle will be ſufficient; but in larger wounds the ſtitches muſt be repeated in proportion to their ſize, leaving a thumb's breadth between each of the ſutures, the extremities of the thread are to be left hanging down on each ſide; and when the ſuture is finiſhed, while an aſſiſtant holds the lips of the wound together, theſe ends are to be tied in knots, in the following manner. Both ends of the threads are to be taken up, and to be tied in a double knot, paſſing a ſmall boulſter between the two knots to prevent the ſkin from being hurt. Where there are more ſutures than one, you muſt begin at the upper part of the wound, tying them down in order; that before the laſt is tied, a ſoft tent of the ſize of a finger, with a thread faſtened to the end of it, may be introduced into the lower part of the wound. This tent will keep a paſſage open for the evacuation of grumous blood, or matter, which may be collected in the cavity of the abdomen. The wound, when all this is done, muſt be anointed with ſome vulnerary balſam, and covered with pledgits of lint, a ſticking plaiſter, and boulſters, ſecuring all with the ſcapulary bandage. Large wounds alſo extending to the peritoneum, but not penetrating it, require this operation to prevent bad ſymptoms, and dangerous herniæ from a diſtenſion of that membrane; but in this caſe the needle muſt paſs only through the muſcles, and common integuments.

GASULON, in the materia medica, a word uſed by Aviſenna and Serapion, to expreſs ſometimes the plant hyſſop, and ſometimes nitre. Theſe are two very different things to be known under the ſame name, but the proper interpretation of the word being the cleaning of clothes, it was uſed probably at ſome time to ſignify every thing of an abſterſive quality; but among the many things of this kind once called by it, the two above mentioned are all that we find recorded. And when they are named, it is always eaſy to ſee which is meant, ſince the ſalt and the plant are ſo very different, that there can be no miſtaking the one for the other in the context.

GATE (*Cycl.*)—Gate, in the manege, called in French *train*, is uſed for the going, or pace of a horſe.

Gate *of the ſea*, or a *ſea gate*, is uſed when two ſhips lie a board one another in a wave or billow, and by that means, ſometimes become *rib-broken*.

GATHER, in the ſea language. A ſhip is ſaid to *gather* on another, when ſhe gets the wind of her.

GATVISCH, in zoology, a name given by ſome to an American fiſh, a ſpecies of the turdus or wraſſe, of a yellow colour, and beautifully variegated with red, called by moſt authors by its Baſilian name, pira pixanga. *Willoughby*, Hiſt. Piſc. p. 321. See Pira.

GAVALI, in the materia medica, a name given by ſome of the old writers to Bdellium, particularly to the Arabian kind, which was the pureſt, and was uſually in form of ſmall tears, and of a pale yelloviſh colour.

GAVELET, in London, a writ uſed in the huſtings of London,—*Breve de* Gaveleto *in London*, pro *reditu ibidem quia Tenementa fuerunt indiſtringibilia*. And the ſtatute of *Gavelet*, 10 Edward II. gives this writ to lords of rents in the city of London, as well as in Kent. Here the parties, tenant and demandant, appear by *ſcire facias*, to ſhew cauſe why the one ſhould not have his tenement again, on payment of his rent, or the other recover the lands, on default thereof. Practiſ. Solic. 419.

GAVELMED, the duty or work of mowing graſs, or cutting of meadow land, required by the lord from his cuſtomary tenants. *Conſuetudo falcandi quæ vocatur* Gavelmed. *Somner*.

GAVELRIP, bedreap, or duty of reaping, at the command of the lord—*de conſuetudine metendi* 40 *acras & dimid. de* Gavelrip *in autumno* 40 ſol. & ſex denar.

GAVELSESTER, *ſextarius vectigalis*, a certain meaſure of rent ale. Among the articles to be charged on the ſtewards and bailiffs of the manors belonging to the church of Canterbury in Kent, according to which they were to be accountable, this of old was one: *de* Gavelſeſter *cujuſlibet bracini braciati infra libertatem maneriorum, viz. Unam lagenam & dimidiam vereviſiæ*. This duty elſewhere occurs under the name of *Tolſeſter*, in lieu whereof, the Abbot of Abingdon was wont of cuſtom to receive the penny mentioned by Selden, in his diſſertation annexed to *Fleta*, c. 8. Nor doth it differ from what is called *oakgavel* in the gloſſary at the end of the *Laws* of Henry I. Sax. Dict.

GAVELWERK, was either *manu-opera*, by the hands and perſon of the tenant, or *carropera*, by his carts or carriages.

GAUGING (*Cycl.*)—For the ready computation of the contents of veſſels, or of any ſolids in the meaſures in uſe in Great Britain, we ſhall here inſert the following rules, taken from a treatiſe of practical geometry, publiſhed at Edinburgh in 1745. 8°. Vid. pag. 137. ſeq.

1°. To find the content of a cylindric veſſel in Engliſh wine gallons, the diameter of the baſe and altitude of the veſſel being given in inches and decimals of an inch: ſquare the number of inches in the diameter of the veſſel; multiply this ſquare by the number of inches in the height, then multiply this product by the decimal fraction 0.0034, and you'll have the contents of the veſſel in gallons, and decimals of a gallon. For example, let the diameter be $=D=$ 51.2 inches, the height $=H=$ 62.3 inches, then will the content be $DDH \times 0.0034 = 51.2 \times 51.2 \times 62.3 \times 0.0034 = 555.27342$ wine gallons.

2°. Suppoſing the Engliſh ale gallon to contain 282 cubical inches, the content of a cylindric veſſel is computed in ſuch gallons, by multiplying the ſquare of the diameter of the veſſel by its height as before, and their product by the decimal fraction 0.0027851. that is, the ſolid content in the gallons will be $DDH \times 0.0027851$.

3°. If the Scotch pint contains 103.4 cubical inches, the content of ſuch a veſſel in Scotch pints, will be $DDH \times 0.0076$.

4°. Suppoſing the Wincheſter buſhel to contain 2178 cubic inches, the content of a cylindric veſſel is computed in thoſe buſhels, by multiplying the ſquare of the diameter of the veſſel by the height, and the product by the decimal fraction 0.0003606. But the legal Wincheſter buſhel containing only 2150.42 ſolid inches, the content of a cylindric veſſel is computed in ſuch buſhels, by multiplying the ſquare of the diameter by the height, and their product by the decimal 0.0003652. Or the content will be $DDH \times 0.0003652$. See Bushel.

5°. Suppoſing the Scotch wheat firlot to contain $21\frac{1}{4}$ Scotch pints, or about 2197 cubical inches, the contents of a cylindric veſſel in ſuch firlots will be $DDH \times 000358$.—And if the bear firlot contain 31 Scotch pints, the contents of ſuch a veſſel in bear firlots will be $DDH \times 0.000245$. See Firlot.

6°. It is to be obſerved, that when the ſection of the veſſel is not a circle, but an ellipſis, the product of the greateſt diameter by the leaſt is to be ſubſtituted in theſe rules, for the ſquare of the diameter.

7°. To compute the content of a veſſel, which may be conſidered as the fruſtum of a cone in any of thoſe meaſures. Let A repreſent the number of inches in the diameter of the greater baſe, B the number of inches in the diameter of the leſſer baſe. Compute the ſquare of A, the product of A by B, and the ſquare of B. Take the third part of the ſum of all theſe, and ſubſtitute it in the preceding rules for the ſquare of the diameter, and then proceed in all reſpects as before. Thus for example, the content in wine gallons will be $\overline{AA + AB + BB} \times \frac{1}{3} H \times 0.0036$. Or thus, to the ſquare of half the ſum of A and B add one third of the ſquare of half their difference; and ſubſtitute this ſum in the preceding rules for the ſquare of the diameter of the baſe of the veſſel. For the ſquare of $\frac{1}{2} A + \frac{1}{2} B$ added to $\frac{1}{3}$ of the ſquare of $\frac{1}{2} A - \frac{1}{2} B$ gives $\frac{1}{4} AA + \frac{1}{2} AB + \frac{1}{4} BB + \frac{1}{12} AA - \frac{1}{6} AB + \frac{1}{12} BB = \frac{1}{3} AA + \frac{1}{3} AB + \frac{1}{3} BB$.

8°. When the veſſel is a fruſtum of a parabolic conoid, meaſure the Diameter of the ſection at the middle of the height of the fruſtrum; and the content will be the ſame as of a cylinder of this diameter, of the ſame height with the veſſel.

9°. When a veſſel is a fruſtum of a ſphere, if you meaſure the diameter of the ſection at the middle of the height of the

the fruſtum, then compute the content of a cylinder of this diameter, and of the ſame height with the veſſel, and from this ſubſtract $\frac{1}{3}$ of the content of a cylinder of the ſame height, on a baſe, the diameter of which is equal to that height; the remainder will give the content of the veſſel. That is, if D repreſent the diameter of the middle ſection, and H the height of the fruſtum, you are to ſubſtitute $DD - \frac{1}{3}HH$ for the ſquare of the diameter of the cylindric veſſel in the firſt ſix rules.

10° When the veſſel is a fruſtum of a ſpheroid, if the baſes are equal, the content is readily found by the rule given in the cyclopædia from Oughtred. In other caſes, let the axis of the ſolid be to conjugate axis, as n to 1; let D be the Diameter of the middle ſection of the fruſtum, H the height or length of the fruſtum, and ſubſtitute in the firſt ſix rules $DD - \frac{HH}{3nn}$ for the ſquare of the diameter of the veſſel.

11°. When the veſſel is an hyperbolic conoid, let the axes of the ſolid be to the conjugate axis, as n to 1, D the diameter of the ſection at the middle of the fruſtum, H the height or length, compute $DD + \frac{HH}{3nn}$ and ſubſtitute this ſum for the ſquare of the diameter of the cylindric veſſel in the firſt ſix rules.

12°. In general, it is uſual to meaſure any round veſſel, by diſtinguiſhing it into ſeveral fruſtums, and taking the diameter of the ſection at the middle of each fruſtum; thence to compute the content of each, as if it was a cylinder of the mean diameter; and to give their ſum as the content of the veſſel. From the total content computed in this manner they ſubſtract ſucceſſively the numbers which expreſs the circular areas that correſpond to thoſe mean diameters, each as often as there are inches in the altitude of the fruſtum to which it belongs, beginning with the uppermoſt; and in this manner calculate a table for the veſſel, by which it readily appears how much liquor is at any time contained in it, by taking either the dry, or the wet inches; having regard to the inclination, or drip of the veſſel, if it has any.

This method of computing the content of a fruſtum from the diameter of the ſection at the middle of its height, is exact in that caſe only when it is a portion of a parabolic conoid; but in ſuch veſſels as are in common uſe the error is not conſiderable. When the veſſel is a portion of a cone or hyperbolic conoid, the content by this method is found leſs than the truth; but when it is a portion of ſphere or ſpheroid, the content computed in this manner exceeds the truth. The difference or error is always the ſame in the different parts of the ſame, or of ſimilar veſſels, when the altitude of the *fruſtum* is given. And when the altitudes are different, the error is in the triplicate ratio of the altitude. If exactneſs be required, the error in meaſuring the *fruſtum* of a conical veſſel, in this manner, is $\frac{1}{5}$ of the content of a cone, ſimilar to the veſſel, of an altitude equal to the height of the *fruſtum*. In a ſphere it is $\frac{1}{5}$ of a cylinder of a diameter, and height equal to the *fruſtum*. In the ſpheroid and hyperbolic conoid, it is the ſame as in a cone, generated by the right angled triangle contained by the two ſemiaxes of the figure revolving about that ſide which is the ſemiaxis of the *fruſtum*. Theſe are demonſtrated in a treatiſe of fluxions by Mr. Mac Laurin [d], where thoſe theorems are extended to *fruſtums* that are bounded by planes oblique to the axis in all the ſolids, that are generated by any conic ſection revolving about either axis. [Vid. pag. 25. and 715.]

In the uſual method of computing a table for a veſſel, by ſubducting from the whole content the number that expreſſes the uppermoſt area, as often as there are inches in the uppermoſt *fruſtum*, and afterwards the numbers for the other areas ſucceſſively, it is obvious that the contents aſſigned by the table, when a few of the uppermoſt inches are dry, are ſtated a little too high, if the veſſel ſtands on its leſſer baſe, but too low when it ſtands on its greater baſe; becauſe, when one inch is dry, for example, it is not the area at the middle of the uppermoſt *fruſtum*, but rather the area at the middle of the uppermoſt inch, that ought to be ſubducted from the total content, in order to find the content in this caſe.

GAVIAON, in zoology, the name by which the Portugueze called the caracara, a ſpecies of Brazilian hawk, of the bigneſs of our kite. *Ray*'s Ornitholog. p. 42. See CARACARA.

GAVILAN, in natural hiſtory, a name given by the Spaniards to a ſpecies of hawk, common in the Philippine iſlands; it is ſomewhat larger than our ſparrow hawk, and is of a yellowiſh colour on the back and wings, and whitiſh under the belly; it is the moſt common of all the birds of prey in that part of the world, and is very voracious, and miſchievous.

GAVIOTA, in zoology, the name given by the Portugueze to a water fowl of the gull kind, common in Braſil, and called by the natives *Guaca guacu*. It is of the ſize of a common hen, its beak is long, ſtrait, and yellow, its head is black on the top, as is alſo the farther half of the wings and tail: the throat, breaſt and belly are white, it lays in the ſand, and its eggs are of the ſize of thoſe of the hen, and are accounted very good, but the fleſh is not valued.

GAULONITÆ, among the Jews, the name of a faction rather than a religious ſect, the ſame with the *Galilæans*, *Hoffm.* Lex. in voc. See GALILÆANS, *Cycl.*

GAULUS, in antiquity, a ſhip of a roundiſh form, moſtly uſed by the people of Phœnicia.

GAULUS, alſo ſignified a kind of cup. *Pitiſc.* Lex. Ant. in voc.

GAVOTTA, or GAVOTTE, in the Italian muſic, is a kind of dance, the air whereof has two ſtrains, briſk and lively, and in common time; each of its ſtrains are played twice over, the firſt has uſually four or eight bars, and the ſecond contains eight, twelve, or more. The time begins with a minim, or two crochets, or notes of equal value, and the hand riſing; and ends with the fall of the hand upon the dominant, or mediant of the mode, never upon the final, unleſs it be a rondeau. And the laſt begins with the riſe of the hand, and ends with the fall upon the final of the mode. *Broſſ.* Dict. Muſ. in voc.

Tempo di GAVOTTA, in the Italian muſic, is when only the time or movement of a *gavotte* is imitated, without any regard had to the meaſure or number of bars, or ſtrains. We often find parts of ſonnatas, which have this phraſe to regulate their motions. *Broſſ.* Muſ. Dict. in voc.

GAYTICPUA, in zoology, the name of an American ſpecies of ſerpent, found as it is ſaid only in the kingdom of Razim. It grows to a vaſt ſize, and ſtinks ſo intolerably, that no creature can bear to be near it. *Ray*'s Syn. anim. p. 329.

GAZA *giovane*, in zoology, the name of a ſmall ſpecies of *heron*, of a fine white colour, called by other authors *ardea alba minor*, or the *ſmall white heron*. It is ſo ſmall as not to weigh a pound. Its whole body is of a pure and perfect ſnow white, and it has a ſhort creſt on the hinder part of its head, and a naked ſpace which is greeniſh about its eyes. Its feet alſo are green, but are ſometimes covered with blackiſh ſcales. The feathers of the creſt are very ſoft and white, and are much valued. It is eaten in Venice and Italy, and is common enough in the markets there. The creſt feathers however are uſually pulled off before it is offered to ſale. *Ray*'s Ornithol. p. 205.

GAZAR, a name uſed by ſome authors for the bay tree. *Johnſon.*

GAZELLA, the *antelope*, in zoology, the name of an animal of the goat kind of which there are three known ſpecies.

1. The *Gazella Africana Strepſicheros Plinii*. This is the ſpecies we uſually ſee under the name of the *antelope*; it is called the *addace* in Africa, and is the *dorcas lybica* of Ælian. Its horns are ſlender and erect, they are black, tranſverſely radiated, and twiſted into the appearance of ſpiral lines; though theſe are in reality ſo many annular circles, they are toward the middle bent a little outwards, and thence they turn in again, ſo that they in ſome meaſure repreſent the antient lyre.

2. The *Gazella Indica*, or Indian antelope, with very long ſtrait horns, which are annulated only in that part near the head. The horns of this creature are ſometimes three feet long, and are perfectly ſmooth and gloſſy, except near the head, and black. The creature is of the ſize of our common deer, and is of a greyiſh colour; its tail is a foot long, and has longer hairs on it than thoſe of the reſt of the body. The horns of this ſpecies are very common in the muſæums of the curious. This creature ſeems to be the animal which produces the bezoar ſtone ſo much valued in medicine.

3. The African kind, which has flat horns annulated to the very top, and crooked near the middle; this has been ſeen alive ſometimes in England. It was much ſmaller than our deer, and of a ſandy colour; its belly white, and its ſides where the white and ſand colour met, of a duſky appearance. Its tail is black and longer than that of the deer, black covered with a ſmaller number of hairs than thoſe of our deer, and white on that part next the body. Its horns grew out of the middle of the forehead near the eyes and are very long, ſharpening at the ends, and all the way marked with tranverſe ſtriæ of furrows, and a little bent upwards. Its ears are large, and its legs very ſlender.

GAZOPHYLACIUM, in the Jewiſh antiquities: this word, according to the Greek etymology, ſignifies the treaſury-chamber. There were ſeveral places in the temple of *Jeruſalem*, where the rich preſents conſecrated to God by kings, princes, or private perſons were kept. But the ſignification of this word *Gazophylacium*, has been farther inlarged, ſo as to comprehend the rooms where the proviſions of the temple were laid up, both for ſacrifices, and for the ſupport and ſuſtenance of the prieſts, and in general this word is uſed for all the apartments of the temple. In the goſpel, by *Gazophylacium* is meant the cheſt into which people caſt their offerings at the entrance of the temple. It has been alſo uſed by naturaliſts for a collection of figures of curious ſubjects. *Mark.* c. xii. ỳ 41, 43. *Luk.* c. xxi. ỳ 2. *Calm.* Dict. Bibl.

GAZOPHYLAX, Γαζοφυλαξ, in antiquity, an officer who had the care and management of the treaſure belonging to the kings of Perſia. *Hoffm.* Lex. in voc.

GAZZA, in zoology, the name of a ſpecies of *heron* common in Italy, and called by many authors *ardea alba major*, the *greater white heron*. Its whole body is of a ſnow white, its beek yellow, and the membranes about its eyes green, though called large in compariſon of the leſſer white one;

it is ſmaller than the common grey heron. Its tail alſo is much longer, and it has no creſt. It is ſometimes ſeen in England, and has been miſtaken for a common heron become accidentally white, as ſparrows and other birds ſometimes are. *Ray*'s Ornithol. p. 205.

GAZZETTA, in zoology, a name given by Geſner and others to a ſpecies of ſmall white heron, ſold in the markets of Italy, and ſeeming to be the ardea alba minor of authors, or gaza giovane of the Venetians. *Geſner*, de Avib. See GAZA *Giovane*.

GAZZETTO, in ichthyology, a name of a fiſh of the turdus, or wraſſe kind, caught in the Mediterranean, and ſold in the markets of Italy. It is of a fine green colour, and is conſiderably thick, though broad; its fins are ſpotted, and it has a large purple tubercle near the anus. It has only one back fin which has twenty four ribs or nerves, the firſt fifteen of which are rigid and prickly, the reſt ſmooth and flexile. *Ray*'s Ichthyolog. p. 320. See the article TURDUS.

GEANNIDES, in natural hiſtory, a name given by ſome authors to the ſtone called by others encymonites. It ſeems to have been the ſame with our ſparry incruſtations on the tops of caverns, *&c.* but the word has been generally underſtood to mean the eagle ſtone. It was ſuppoſed to poſſeſs great virtues in helping delivery, and was given to women in their labours.

GEAR, or *about your gear*, at ſea, a command to work on all hands.

GEASTER, in botany, the name of a genus of fungus's: or according to Linnæus, of ſome ſpecies of the genus of the Lycoperdon. Theſe fungus's have a radiated bottom like a ſtar, and in the center of this there grows a round ball which opens at the top when ripe, and is found to be full of impalpable ſeeds in form of powder. See LYCOPERDON.

GECCO, in natural hiſtory, a name given by the Indians to their terrible poiſon, which kills in ever ſo ſmall a quantity when mixed with the blood. They ſay that this *gecco* is a venomous froth or humor, vomited out of the mouths of their moſt poiſonous ſerpents, which they procure in this fatal ſtrength, by hanging up the creatures by the tails, and whipping them to enrage them: they collect this in proper veſſels as it falls, and when they would uſe it, they either poiſon a weapon with it, or wounding any part of the fleſh, introduce the ſmalleſt quantity imaginable of it, and this is ſaid to be immediate death. *Sympſon*'s Zymol. Chym.

GECHYTON, a name given by ſome authors to the external covering of the earth, commonly called garden mould, which is ſoft and not ſtony. *Ruland.*

GECOLITHUS, a corrupt way of ſpelling the word *tecolithus*, the name of the lapis judaicus among the Romans. The writers of the middle ages often write it *gecolithus*.

GED, in zoology, an Engliſh name for the ſmall ſpecies of ſnipe, uſually called the juddock, and by authors gallinago minima. See JUDDOCK.

GEGENES, Γηγενεις, in antiquity. The antients generally called themſelves Γηγενεις, *ſons of the earth*, as Heſychius informs us. Alluding to the ſame original, the Athenians ſometimes ſtyled themſelves, Τεττιγες, *graſshoppers*; and ſome of them wore graſshoppers of gold, faſtened to their hair as badges of honour, to diſtinguiſh them from others of leſs antiquity, and leſs noble extraction, becauſe thoſe inſects were believed to be generated out of the ground. *Pott.* Archæol. Græc. l. 1. c. 1.

GEISON. See GISON.

GELÆOPACHIA, in natural hiſtory, the name of a claſs of mineral fluids, which are inflammable, and of a ſomewhat thick texture, and opake.

The word is derived from the Greek γη the earth, ελαιον oil, and παχυς thick. The bodies of this claſs are the Barbadoes tar, oil of earth, and the common piſſaſphaltum of the ſhops, which ſee under their ſeveral heads. *Hill*'s Hiſt. of Foſſ. p. 421.

GELÆOPSILA, in natural hiſtory, the name of a claſs of foſils. The word is derived from the Greek γη earth ελαιον oil, and ψιλος thin, and expreſſes a thin oily ſubſtance naturally found in the earth. Theſe are thin and pellucid inflammable liquid ſubſtances, commonly known by the name of liquid bitumens, but by that denomination confounded with the thicker and coarſer kinds. The only bodies of this claſs are thoſe commonly diſtinguiſhed by the names of Naphtha, and Petroleum. See NAPHTHA. *Hill*'s Hiſt. of Foſſ. p. 419.

GELASINI *Dentes*, a term uſed by ſome authors to expreſs the four middle fore teeth, both of the upper and under jaw. They have this name from the Greek γελως laughter, becauſe they are ſhewn when people laugh.

GELATINA, *jelly*, a form of food, or medicine prepared from the juices of ripe fruits, boiled to proper conſiſtence with ſugar, or of the ſtrong decoctions of the horns, bones, or extremities of animals boiled to ſuch a height as to be ſtiff and firm when cold, without the addition of any ſugar.

The *jellies* of fruits are cooling, ſaponaceous, and aceſcent, and therefore are good as medicines in all diſorders of the primæ viæ, ariſing from alcaleſcent juices, eſpecially when not given alone, but diluted with water: on the contrary, the *jellies* made from animal ſubſtances are all alcaleſcent, and are therefore good in all caſes in which an acidity of the humours prevails: the alcaleſcent quality of theſe is however in a great meaſure taken off, by the adding lemon juice and ſugar to them. There were formerly a ſort of *jellies* much in uſe, called *compound jellies*; theſe had the reſtorative medicinal drugs added to them, but they are now ſcarce ever heard of. *Hoffm.*

GELATINA *Avenæ*, *oat jelly*, a preparation of common oats recommended by many of the German phyſicians, in all hectic diſorders, to be taken with broth of ſnails or crawfiſh.

It is made by boiling a large quantity of oats with the huſk taken off, with ſome hartſhorn ſhavings, and currants together, with a leg of veal cut to pieces, and with the bones all broken; theſe are to be ſet over the fire with a large quantity of water till the whole is reduced to a ſort of *jelly*, which when ſtrained and cold will be very firm and hard. A few ſpoonfuls of this are to be taken every morning, diluted with a baſon of either of the above mentioned broths, or any other warm liquor.

GELATIO, properly ſignifies freezing, but is alſo uſed for that rigidity of the body and limbs, which comes on in the cataleplis, and other diſorders of that kind.

GELBUM, a name given by the Hungarian miners to a ſort of marcaſite or mundick, which contains a conſiderable quantity of ſilver.

GELDING (*Cycl.*)—In *gelding* of horſes there are two things principally to be regarded, which are the age of the creature, and the ſeaſon of the year; if it be a colt that is to be gelt, it may be done at nine days old, or at fifteen, or as ſoon as the teſticles come down; for the ſooner this is done the better it always is for ſtrength and courage in the creature afterwards. But a farrier may geld a horſe at any age that he pleaſes, if he will be careful as to the cure. The ſecond thing is the time of the year, as to this, the months of April and May are always eſteemed the moſt proper, but it ſhould by no means be done later than in June for the ſummer time; if this is paſſed by, it ought to be deferred till the fall of the leaf, or end of September. The farriers generally add a third conſideration, which is always to do it in the wane or decreaſe of the moon.

The manner of *gelding* is this. Whether it be a foal, colt, or horſe it is to be caſt, or thrown on its back in a ſoft place, then the legs are to be faſtened ſo as to prevent miſchief from ſtruggling, and the operator is to take hold of the teſticles between the fingers, and ſlit the ſcrotum or cod, and ſqueeze out the teſticles at the ſlit. Then take hold of the veſſels with a pair of fine ſteel or box nippers, and hold them ſo tight that there may be no flux of blood on the cutting them; they are then to be cut off below the nippers, and the ends ſeared with a hot iron, or they may be burnt off with a thin drawing cauteriſing iron, and the whole operation performed at once. There muſt be in readineſs a plaiſter made of wax, roſin, and waſhed turpentine. The hot iron muſt be applied to this, and it muſt be made to melt and drop upon the ends of the veſſels where they were cut or burnt off, then the iron is to be applied to ſear them again, and after this more of the plaiſter melted on. This is to be repeated till there is ſuch a cicatrix formed, and ſuch a thickneſs of the ſalve left on, that there is no danger of the veſſels burſting out into a bleeding.

When this is thoroughly done, the nippers, which all this while held the veſſels faſt above the cutting, are to be looſened, and the other teſticle is to be taken off, and the veſſels ſeared up in the ſame manner. When this is done, the ſlit of the cod is to be filled with white ſalt, and the outſide rubbed over with hogs lard. After all is over the horſe is to be ſuffered to riſe, and led into a warm ſtable, where he is not to be tied up, but left looſe to walk about, for nothing is better for him than moderate exerciſe. If the parts ſhould ſwell, he muſt be trotted up and down an hour or two every day, and this alone will generally make all right.

This is a very coarſe operation, but it is ſafe, and generally ſucceeds very well.

GELDING, in the manege, is alſo uſed for a horſe, whoſe teſticles are cut out. Vid. Supra.

GELDUM, a name given by ſome to the philoſophers ſtone.

GELFUM, or *Gelbum*, a Hungarian name for a kind of mundick which contains ſilver.

GELLOSIA, in natural hiſtory, a name by which ſome of the writers of the middle ages call the chalazias.

GEMELLI, (*Cycl.*) two ſmall flat narrow muſcles, ſituated almoſt tranſverſely one above another, between the tuberoſity of the iſchium, and the great trochanter; immediately below the pyriformis, and parted by the tendon of the obturator internus.

The ſuperior or ſmaller *gemellus* is fixed to the lower part of the ſpine of the os iſchium, to the ſuperior part of the ſmall iſchiatic notch, and to a rough line which runs croſs the outſide of the iſchium, beginning at the ſpine, and continued under the acetabulum where it is bent downward.

The inferior and largeſt *gemellus*, is fixed to the ſuperior and back part of the tuberoſity of the iſchium, and to a rough impreſſion, which runs croſs the outſide of the iſchium, from the lower extremity of the iſchiatic

tic notch, and is bent upward toward the other line, together with which it forms a ſort of irregular ſemicircle. Both theſe muſcles have alſo a ſmall inſertion in the inſide of the iſchium, where being united together, by a particular membrane, one of them joins the upper ſide, and the other the lower ſide of the *obturator internus* a little after it has paſſed over the notch. They encloſe it as in a bag, and continue to be fixed to it by fleſhy fibres all the way to its extremity. The ſuperior muſcle terminates wholly with the tendon of the *obturator internus*, but the inferior being broader, is inſerted likewiſe by fleſhy fibres, in the orbicular ligament, and under the tendon of the ſame obturator. *Winſlow*'s Anat. p. 210.

GEMS (*Cycl.*)—Mr. Boyle ſpeaks of tinctures from *gems*, and of his having diſſolved them; and ſeems to think it not improbable, that they may have medicinal uſes exhibited in ſubſtance. *Boyle*'s Works, Abr. Vol. 1. p. 62.

GEMS of *the antients*. The *gems*, on which the antients engraved, and which are commonly called intaglios, are uſually of a long oval figure inclining to a point at each end, convex as well upon the engraved ſurface as on the others, and having a ridge running from end to end on the underſide, which is thereby as it were divided into two faces; both which are alſo, though not ſo diſtinctly, parted from the upper face by another ridge running quite round the oval. The ſtone moſt frequently engraved on, is what the jewellers call the beryl, a ſtone very different from that called the beryl by the antients, which was the *gem* we call the aquamarine.

This beryl of the jewellers is only a finer kind of cornelian, and is of three kinds; the red, the yellow, and the white. The firſt is much the moſt valuable of theſe, and is of the greateſt luſtre; that which is moſt frequent next this beryl, is the praſius, or as ſome call it, the *plaſma de ſmaraldo*. This our jewellers call the preme or prime emerald. It is of a ſomewhat duſky green, and is ſometimes tolerably clear, but moſt uſually it is full of black and white ſpecks, and rather opake.

The moſt frequent next to this is the jacynth or hyacinth. This alſo is not the *gem* known by the antients under this name, that having been a ſort of amethyſt, but the ſtone we now call the hyacinth, which is of a tawny red, or a ſort of fire colour, and is very bright and tranſparent.

The chryſolite is ſometimes but rarely found engraved on. It is of a greeniſh colour, and is tranſparent but not lively. Sometimes there are alſo met with the oriental pebble cryſtal, which is much more tranſparent and lively than the common cryſtal, and indeed but little inferior in beauty to the white ſapphire: the garnet which is of a deep red, and not ſo lively as the hyacinth; and finally the amethyſt which is of a deep purple, and is very lively and tranſparent. Theſe ſeem to have been all the ſtones uſed in the earlier times of the Roman empire. There are indeed ſometimes found ſome other ſpecies, but theſe are rarely of any time but the latter ages of the empire, when the art itſelf was greatly upon the decline. The beforementioned ſtones are ſaid to have been brought to Rome from the borders of the Nile or of the Ganges. The onyx agate, onyx ſardonyx, and alabaſter of two colours were alſo engraved on by the Romans in a different manner. Theſe, as alſo certain ſhells of different coats, were frequently engraved in relief, and theſe ſort of engravings are commonly called cameos; they alſo ſometimes engrafted a head or ſome other figure in relief of gold upon a bloodſtone. Philoſ. Tranſ. N°. 483.

Beſide theſe there are alſo ſome antiques, moſtly cornelians, which are covered with a ſtratum of white. This ſtratum has by ſome been looked on as natural; but it was really only a ſort of coat or enamel that was laid on: this was uſed only in the times of the lower empire. The antients engraved many of their ſtones juſt as they were found with their native poliſh, and in their native ſhape; but the beauty of the ſeveral ſpecies of the onyx could only be ſhewn by a proper cutting. The antique *gems* of Greek work are of all others the moſt eſteemed, and next to them the Roman in the time of the higher empire. Philoſ. Tranſ. N° 483.

Imitation of antique GEMS. There has been at different times a method practiſed by particular perſons of taking the impreſſions and figures of antique *gems*, with their engravings in glaſs of the colour of the original *gem*. This has always been eſteemed a very valuable method, and greatly preferable to the more ordinary ones of doing it on ſealing wax or brimſtone; but to the misfortune of the world, this art being a ſecret only in the hands of ſome particular perſons, who got their bread by it, died with them, and every new artiſt was obliged to new invent the method, till at length Mr. Homberg having found it in great perfection, gave the whole proceſs to the world to be no more forgotten or loſt, and ſince that time it has been very commonly practiſed in France, and ſometimes in other places.

Mr. Homberg was favoured in his attempts with all the engraved *gems* of the king's cabinet, and took ſuch elegant impreſſions, and made ſuch exact reſemblances of the originals, and that in glaſſes ſo artfully tinged to the colour of the *gems* themſelves, that the niceſt judges were deceived in them, and often took them for true antique ſtones. Theſe counterfeit *gems* will ſerve as well as the original ones to make more copies from afterwards; ſo that there is no end of the numbers that may be made from one; and there is this farther advantage, that the copy may be eaſily made perfect, though the original ſhould not be ſo, but ſhould have ſuſtained ſome damage from a blow or otherwiſe. Mem. Acad. Par. 1712.

The great care in the operation, is to take the impreſſion of the *gem* in a very fine earth, and to preſs down upon this a piece of a proper glaſs ſoftened or half melted at the fire, ſo that the figures of the impreſſion made in the earth, may be nicely and perfectly expreſſed upon the glaſs. In general, the whole proceſs much reſembles that of the common founders. But when it is brought to the trial, there are found a number of difficulties which were not to be foreſeen, and which would not at all affect the common works of the founder. For his purpoſe every earth will ſerve, that is fine enough to receive the impreſſions, and tough enough not to crack in the drying; theſe all ſerve for their uſe, becauſe the metals which they caſt are of a nature incapable of mixing with earth, or receiving it into them, even if both are melted together, ſo that the metal always eaſily and perfectly ſeparates itſelf from the mould; but it is very difficult in theſe caſts of glaſs. They are compoſed of a matter which differs in nothing from that of the mould, but that it has been run into this form by the force of fire, and the other has not yet been ſo run; but is on any occaſion ready to be ſo run, and will mix itſelf inſeparably with the glaſs in a large fire; and conſequently if there be not great care uſed, as well in the choice of the glaſs, as in the manner of uſing it, when the whole is finiſhed, there will be found great difficulty in the ſeparating the glaſs from the mould, and often this cannot be done without wholly deſtroying the impreſſion.

All earths run more or leſs eaſily in the fire, as they are more or leſs mixed with ſaline particles in their natural formation. As all ſalts make earths run into glaſs, and as it is neceſſary to uſe an earth on this occaſion for the making a mould, it being alſo neceſſary to the perfection of the experiment, that this earth ſhould not melt or run; it is our buſineſs to ſearch out for this purpoſe ſome earth, which naturally contains very little ſalt. It might be ſuppoſed, that earths artificially diveſted of their ſalts by means of fire or water, or by whatever other proceſs, might ſerve this purpoſe; but experiment proves this not to be the caſe. Theſe earths, though diveſted of their ſalts, yet retain thoſe cellules where their ſaline particles were once lodged, and are therefore ready to receive them on occaſion again; and glaſs being only a compoſition of earth, and ſalts run together as ſoon as it becomes hot, its ſaline parts are leſs firmly united than before to its earth, and readily run into the cellules of a foreign body, which are open to receive them; and thence when ſuch earths are employed as mould, the glaſs and the moulds are always found ſo blended together that the whole is ſpoiled. Whereas on the other hand, thoſe earths which naturally contain little or no ſalt, have no pores, or cellules ready to receive any, and never blend themſelves with the glaſs, unleſs the whole is kept too long over a great fire, in which caſe the ſalts of the glaſs will get looſe and ſerve as a flux to the reſt, and ſo deſtroy the whole. Of all the ſpecies of earth which Mr. Homberg examined on this occaſion, none proved ſo much diveſted of ſalts, or ſo fit for the purpoſe as the common tripela, or tripoly, uſed to poliſh glaſs and ſtones. Of this earth there are two common kinds, the one reddiſh, and compoſed of ſeveral flakes or ſtrata; the other yellowiſh, and of a ſimple ſtructure. Theſe are both to be had in the ſhops. The latter kind is from the Levant, and the former is found in England, France, and many other places. This tripela muſt be choſen ſoft and ſmooth to the touch, and not mixed with ſandy or other extraneous matter. The yellow kind is the beſt of the two, and is commonly called Venetian Tripoli. This receives the impreſſions very beautifully, and never mixes with the glaſs in the operation, which the red kind ſometimes does. Mr. Homberg uſually employed both kinds at once in the following manner. Firſt powder a quantity of the red tripela in an iron mortar, and ſifting it through a fine ſieve, ſet it by for uſe; then ſcrape with a knife a quantity of the yellow tripela into a ſort of powder, and afterwards rub it till very fine in a glaſs mortar with a glaſs peſtle. The finer this powder is, the finer will be the impreſſion, and the more accurately perfect the caſt. The artificer might naturally ſuppoſe that the beſt method to obtain a perfectly fine powder of this earth, would be by waſhing it in water; but he muſt be cautioned againſt this. There is naturally in this yellow tripoly a ſort of unctuoſity, which when it is formed into a mould keeps its granules together, and gives the whole a uniform gloſſy ſurface: now the waſhing the powder takes away this unctuoſity, and though it render it much finer, it makes it leave a granulated ſurface, not this ſmooth one in the mould, and this muſt render the ſurface of the caſt leſs ſmooth. Mem. Acad. Par. ibid.

When the two tripelas are thus ſeparately powdered, the red kind muſt be mixed with ſo much water, as will bring it to the conſiſtence of a paſte, ſo that it may be moulded like

a lump of dough between the fingers: this paſte muſt be put into a ſmall crucible of a flat ſhape, and about half an inch or a little more in depth, and of ſuch a breadth at the ſurface as is a little more than that of the ſtone, whoſe impreſſion is to be taken. This crucible is to be nicely filled with this paſte lightly preſſed down into it, and the ſurface of the paſte muſt be ſtrewed over with the fine powder of the yellow tripela not wetted. When this is done, the ſtone, whoſe impreſſion is to be taken, muſt be laid upon the ſurface, and preſſed evenly down into the paſte with a finger and thumb, ſo as to make it give a ſtrong and perfect impreſſion; the tripela is then to be preſſed nicely even to its ſides with the fingers, or with an ivory knife: the ſtone muſt be thus left a few moments for the humidity of the paſte to moiſten the dry powder of the yellow tripela, which is ſtrewed over it; then the ſtone is to be carefully raiſed by the point of a needle fixed in a handle of wood, and the crucible being then turned bottom upwards, it will fall out, and the impreſſion will remain very beautifully on the tripela. Mem. Acad. Par. ibid.

If the ſides of the cavity have been injured in the falling out of the ſtone, they may be repaired, and the crucible muſt then be ſet, for the paſte to dry, in a place where it will not be incommoded by the duſt.

The red tripoli being the more common and the cheaper kind, is here made to fill the crucible only to ſave the other, which alone is the ſubſtance fit for taking the impreſſion. When the ſtone is taken out, it muſt be examined to ſee whether any thing be lodged in any part of the engraving, becauſe if there be any of the tripela left there, there will certainly be ſo much wanting in the impreſſion. When the crucible and paſte are dry, a piece of glaſs muſt be choſen of a proper colour, and cut to a ſize proper for the figure; this muſt be laid over the mould, but in ſuch a manner, that it does not touch the figures, otherwiſe it would ſpoil them. The crucible is then to be brought near the furnace by degrees, and gradually heated till it cannot be touched without burning the fingers; then it is to be placed in the furnace under a muffle, ſurrounded with charcoal. Several of theſe ſmall crucibles may be placed under one muffle, and when they are properly diſpoſed, the aperture of the muffle ſhould have a large piece of burning charcoal put to it, and then the operator is to watch the proceſs, and ſee when the glaſs begins to look bright: this is the ſignal of its being fit to receive the impreſſion. The crucible is then to be taken out of the fire, and the hot glaſs muſt be preſſed down upon the mould with an iron inſtrument, to make it receive the regular impreſſion: as ſoon as this is done, the crucible is to be ſet at the ſide of the furnace out of the way of the wind, that it may cool gradually without breaking. When it is cold, the glaſs is to be taken out, and its edges ſhould be grated round with pincers, which will prevent its flying afterwards, which is an accident that ſometimes happens when this caution has been omitted, eſpecially when the glaſs is naturally tender. The different coloured glaſſes are of different degrees of hardneſs, according to their compoſition, but the hardeſt to melt are always the beſt for this purpoſe, and this is known by a few trials.

If it be deſired to copy a ſtone in relief, which is naturally in creux; or to take one in creux, which is naturally in relief, there needs no more than to take an impreſſion firſt in wax or ſulphur, and to mould that upon the paſte of tripela inſtead of the ſtone itſelf: then proceeding in the manner before directed the proceſs will have the deſired ſucceſs. Mem. Acad. Par. 1712.

Semipellucid GEMS. Theſe are defined to be ſtones, compoſed of a but ſlightly debaſed cryſtalline matter, of great beauty and brightneſs, of a moderate degree of tranſparence, and uſually found in ſmall maſſes. The bodies of this claſs are divided into two general orders, and under theſe into eight diſtinct genera. Of the firſt order are thoſe of but few variegations, and frequently of one plain ſimple colour, though ſometimes veined. Of the ſecond are thoſe remarkable for their veins, zones, and variegations. The genera of the firſt order, are the cornelians, chalcedonies, hydrophanæ, and pramnion. Thoſe of the ſecond, are the agates, onyxes, ſardonyxes, and cameæ. See each of theſe under its proper head. *Hill*'s Hiſt. Foſſ.

Indian GEM, *Indica Gemma*, a name given by Pliny, and ſome other of the antients, to a *gem* of a reddiſh colour, which according to their accounts, afforded a purple ſweat on being rubbed: another kind of it is alſo mentioned, which was white and looked duſty.

GEMMA *Veneris*, in natural hiſtory, a name given by ſome of the Latin poets, and other authors in that language, to a *gem*, which was much eſteemed by the Romans, and ſet in rings. It was called by the Greeks aphrodites. Many have ſuppoſed this to be the opal; but it is certain from the oldeſt accounts, that the moſt beautiful kind of the amethyſt was the *gem* they called by this name. They diſtinguiſhed the amethyſt as all the other *gems* into ſeveral kinds, according to the degrees of the colour, and to the moſt eminent of theſe they gave peculiar names, as is evident in the ſeveral kinds of the emerald and beryl. The worſt amethyſts were thoſe which had very little colour beyond that of cryſtal, and the very beſt were thoſe which had the fine red of the carbuncle, mixed with the purple of the violet; and the whole ſo pale, that a roſe colour ſeemed blended with them, and predominating over the reſt. Theſe Pliny tells us were called pæderotes, and anterotes, and were the *gems* called from their beauty *aphrodites lapis*, and *gemma veneris*; but all theſe names have been ſince given by others to the opal.

GEMMEUM, an epithet uſed by the Latins to expreſs ſuch veſſels, as were called dialitha and lithocolla by the Greeks. The more correct Roman authors however call this *gemmatum poculum*, and not *gemmeum*; the word *gemmeum*, ſignifying properly a vaſe or cup, cut out of a ſingle ſtone, as an agate or the like; but *gemmatum* expreſſing thoſe five vaſes of gold, which were ornamented with emeralds, and other precious ſtones.

GEMONIDES, a name by which ſome of the antients have called the peantides; probably the ſame with our ſtalactites, a ſtone famous with them for its ſuppoſed virtue, in promoting delivery. *Plin.* Hiſt. Nat.

GEMURSA, a word uſed by the antient writers on medicine, for a diſtemper which was an excreſcence of fleſh between the toes; a diſeaſe not known with us. *Caſt.* Lex. Med. in voc.

GENECANTHE, in botany, a name uſed by ſome authors, for the black bryony. *Ger.* Emac. Ind. 2.

GENERATION (*Cycl.*)—The act of *generation* is very differently performed in different animals, and is not leſs wonderful in the ſmaller than in the larger creatures.

GENERATION of *Butterflies*. The *butterfly*, whoſe whole life in that ſtate is employed only in the propagation of its ſpecies, gives the curious obſerver much cauſe of wonder in the manner of it. In all the ſpecies, the male, in the time of coupling, throws out from the laſt ring of his body a part which enters into the hinder part of the female. This organ may be ſeen on preſſing lightly with the fingers the body of a male *butterfly*. The end of the body where this is ſituated is extremely flexile, and the creature turns it with great facility upward or downward, or to either ſide; and to this it is owing, that there are many different attitudes in the *generation* of different *butterflies*. In many ſpecies the male lays his body in a parallel beſide the body of the female, and their wings being ſpread horizontally, make a ſort of cloſe covering for both their bodies, and the hinder part of the body of the male being capable of turning ſideways, is now able to perform all its functions. In other ſpecies the male gets upon the body of the female, and the work is then performed by means of his power of bending the end of his body downwards. In this ſtate, if any thing diſturbs them, the female ariſes from her ſeat, and flies away with the male upon her back; and this ſeems almoſt the only uſe the female has for wings, for ſhe is too heavy to fly with any pleaſure. The power the male has of bending this part of his body upwards, is of uſe when he meets the female on the wing; but this is ſeldom the caſe, and that only in a few ſpecies. But beſides all theſe forms of *generation*, they are not unfrequently ſeen joined tail to tail, with their bodies in a ſtrait line, and their heads ſtanding oppoſite ways. The act of *generation* in moſt ſpecies of *butterflies*, paſſes without any emotion, and ſeemingly in a ſtate of reſt and perfect tranquillity; but this is not the caſe in all, for in the *butterfly* bred of the ſilkworm caterpillar, the male raiſes and falls his wings all the time with great celerity. Mr. Malpighi has had the patience to count the number of theſe vibrations of the *butterfly* of this ſpecies wings, and found them 130 in number; after this the creature falls into a languor and faintneſs, which laſts about a quarter of an hour, and ſometimes ſeparates himſelf from the female; if not, at the end of this time he recovers himſelf and renews the agitations of his wings, but for a leſs number of times. The ſame author uſually counted at this latter time thirty ſix, and after this he becomes languid again, and afterwards revives ſeveral other times, but the intervals are longer and the clappings of the wings leſs numerous. Memoirs Acad. Scient. Par. 1736.

Unnatural GENERATION. One of the moſt ſingular accounts ever publiſhed as to the unnatural *generation* of animals, is that recorded in the Philoſophical Tranſactions, under the names of Mr. Roberts and Mr. Halley of Cheſter, of a male greyhound, which voided by the anus a whelp, reſembling a greyhound puppy. They ſay that the creature came into the world alive, and after a few hours died; but that it was preſerved in ſpirit of wine. A white mucous matter was voided with it, and it had a ſhot on one ſide exactly in the ſame part where the greyhound had, which voided it. The dog was killed and diſſected, but nothing particular was found in the internal parts. Many people atteſted the truth of this ſtrange ſtory, but if true, by whatever accident it happened, it is odd that hiſtory ſhould have produced no one inſtance of ſuch an accident before, nor the world have met with any thing like it ſince. Philoſ. Tranſ. N°. 222.

We read alſo in the ſame book of *generation* performed, notwithſtanding that a ſtone ſo filled the urethra, that for ſeveral years the urine did not paſs, but by the introduction of a knitting needle. The author of the relation does not pretend to account for the difficulty of the caſe; he only

increaſes it by telling us, his patient's wife had the character of a very virtuous woman. See Phil. Tranſ. N°. 480. p. 218.

There is no part of the hiſtory of animals ſo difficult to account for as their *generation*, in many particulars, and this is in none ſo abſtruſe, as in thoſe which are produced in places to which there is no viſible way for them to arrive. The animalcules diſcovered by Lewenhoek, in the *ſemen maſculinum* of animals, and the worms in the human bowels are of this kind. The firſt of theſe are too minute for our obſervation in regard to the clearing of this point; but as to the others, Valliſnieri has proved, that they are not produced from the eggs ſwallowed down our throats in our drink or otherwiſe, but that they really do propagate their ſpecies within us, and are owing to parents of the ſame kind hid in ſome parts of our inteſtines. Redi has given ſuch deſcriptions of the lumbrici rotundi, or common worms, that the thing is rendered paſt all doubt in regard to them; and this author taking up the ſubject where he dropped it, has proved as much in regard to the tænia, or tapeworm.

The bowels are evidently the true and proper ſeat and habitation of theſe creatures, but they are alſo ſometimes voided by urine, and thence conceived to have lived in the urinary paſſages. Valliſnieri gives an account of a worm in the form of a ſerpent voided by urine by a prieſt, from one Landus; and from Alghiſi another caſe of great numbers of worms of the ſize and ſhape of barley corns, voided in the ſame manner after terrible pains. Our tranſactions alſo give an account of a large and long worm, taken out of the penis of a youth by a ſurgeon of reputation. It is poſſible that worms different from thoſe uſually found in the body, may be ſometimes *generated* there, but as to their inhabiting the urinary paſſages, there is great reaſon to ſuſpect the fact. That they have been voided by urine is certain, but in perſons who have died ſoon after, and been diſſected, it has been found that the colon has been exulcerated, and that theſe creatures had eaten their way from thence into the bladder; and this is probably the caſe in all thoſe ſtories, where the fact is certain. And the opinion of Valliſnieri as to the reſt is, that they were concreated with the human frame, and that our bowels are their natural and proper nidus. *Valliſnieri* Obſer. Med.

The polypus, or polype, being neither male nor female, but producing its young, as plants do their ſhoots, only that at laſt the young polypes drop from their parent, ſhews a remarkable anology between animal and vegetable nature. See POLYPE.

Mr. Demours [a] affords us another fact to illuſtrate this analogy. It is in the act of propagation of water ſalamanders, the male of which has no penis, but ſquirts out his ſemen at a little diſtance from the female; and though it could not be obſerved that any of it is received into her body, yet her ova are fecundated. [a] *Obſervat. concern. L'Hiſt. naturelle.*

Some animals may be *generated* from the cuttings, or pieces of another of the ſame ſpecies, in the ſame manner as trees and plants are produced, by ſetting ſmall pieces of the ſame plant. See POLYPE.

GENERATION of *plants*. The *generation* of *plants* bears a near analogy to that of ſome animals, eſpecially ſuch as want local motion, as oiſters and ſome other ſhell fiſh. The flower is the container of the parts of *generation*, and each performs its peculiar office for the propagation of the ſpecies.

The flower of a lilly, for inſtance, conſiſts of ſix petals, or flower leaves, from the bottom of which, at the middle ariſes a kind of tube, called the piſtil, and round this there are diſpoſed ſeveral ſmall threads called the ſtamina or chives, which ariſe alſo from the bottom of the flower, and terminate at their tops in ſmall bodies called the apices, which contain a fine duſt called the farina. *Miller*'s Gard. Dict.

This is the general ſtructure of flowers, and though in many, ſome of theſe parts ſeem wanting; yet probably they are there, only leſs apparent. The fruit is uſually at the baſis of the piſtil, ſo that when the piſtil falls with the reſt of the flower, the fruit is ſeen in the place of it, though in ſome this is not the caſe, but the piſtil itſelf becomes the fruit. The petals ſeem only an outer covering to defend the piſtil and ſtamina, and the duſt which the apices at the ends of theſe are full of, was by many great men believed to be only an excrementitious matter ſeparated from the plant, by the chives, which they ſuppoſed tubes deſtined to carry off this abundant nutriment from the fruit. Later diſcoveries however have ſhewn this to be a very eſſential part of the flower, and to ſerve the office of the male ſperm of animals, and that the piſtil is properly the female organ of *generation*.

The ſeeds which come up in their proper involucra, ſeem of the nature of the unimpregnated eggs of animals; alſo that the farina ſeminalis, or duſt contained in the apices, is a congeries of plantules, each of which is to be lodged in one of thoſe ſeeds, which are only a proper matrix for its reception; that the ſtyle or upper part of the piſtil is a tube deſtined to convey theſe ſeminal plants into the uterus, or bottom of the piſtil where theſe ſeeds are lodged; and finally it appears, that the vaſt quantity of this farina is only becauſe of the multitudes that muſt miſcarry, for one that finds its way into this narrow paſſage.

To exemplify theſe conjectures by obſervation. It may be ſeen that in the crown imperial, the uterus, or vaſculum ſeminale of the plant, ſtands upon the center of the flower; and from the top of this ariſes the ſtyle, the vaſculum ſeminale and ſtyle together making the piſtil. Round this are placed ſix ſtamina, the apices of which are ſo artfully fixed, that they play about with every wind; and are in height almoſt equal to the ſtyle, round about which they are continually in motion, and which in this plant is manifeſtly open at the top, and hollow all the way down; and to this it muſt be added, that on the top of this ſtyle there is a tuft of pinguid villi, or ſmall tendrills, which ſeem deſtined to catch hold of the farina, or male duſt, as it is diſlodg'd from the apices when they burſt, and from theſe it may very eaſily find its way through the hollow to the ſeeds it is deſtined to impregnate. *Miller*'s Gard. Dict.

The tube or ſtyle of the piſtil always dies away as ſoon as the apices have diſcharged all their powder, having then ſerved the purpoſes it was deſigned for.

The ſeminal plant is always lodged in that part of the ſeed which lies neareſt the aperture of the tube, through which this farina is conveyed; and in beans there is an evident perforation to be diſcovered by ordinary glaſſes juſt above the eye, which probably has been the paſſage by which the plantula ſeminalis entered. In theſe and the other leguminous plants alſo, if we carefully take off the petala of the flower, we ſhall diſcover the pod cloſely covered by an enveloping membrane, which near the top ſeparates into ſeveral ſtamina, each loaded with its apex and farina, and theſe ſtamina are all bound cloſely to that bruſh which ſhews itſelf at the end of the pod.

In roſes there ſtands in the middle a column conſiſting of many tubes, which though cloſely clung together, yet are eaſily ſeparable, and each leads to its particular cell, the ſtamina being in great abundance placed all round the orifices of theſe tubes. In ſtrawberries and raſberries, the hairs growing on the outſides of thoſe fruit are ſo many tubes leading to the ſeeds, and in the firſt opening of the flowers of theſe plants, theſe hairs ſtand in a thick wood as it were at the bottom of the flower, and are every where ſurrounded by ſtamina with apices on their tops; and it is not till after theſe apices have diſcharged their farina, that the fruit ſwells out of the huſk. In flowers which naturally hang down, as the imperial crown and the like, the piſtil is much longer than the ſtamina, that it may receive the farina as it falls from the apices.

Mr. Geoffroy obſerved, that the cutting off the piſtil of a flower before the apices were ripe, always made the fruit abortive, and the plant barren for that ſeaſon. In ſome plants, whether male and female flowers ſtand on different ſtalks from the ſame root, or on different plants of the ſame ſpecies, the wind is the vehicle of this farina; and if it does not reach the female flowers, they ever remain barren. *Miller*'s Gard. Dict.

GENERATION of plants from pieces or cuttings of the ſame plant. See PIECES.

GENERATION, in mathematicks, is uſed for formation or production. Thus we meet with the *generation* of equations, curves, ſolids, &c.

GENERATION *of ſtone*. See LITHOGENESIA.

GENERICAL *name*, in natural hiſtory, the word uſed to ſignify all the ſpecies of natural bodies, which agree in certain eſſential *and peculiar* characters, and therefore all of the ſame family or kind; ſo that the word uſed as the *generical* name, equally expreſſes every one of them, and ſome other words expreſſive of the peculiar qualities or figures of each are added, in order to denote them ſingly, and make up what is called the ſpecific name.

Thus the word roſa, or roſe, is the *generical* name of the whole ſeries of flowers of that kind, which are diſtinguiſhed by the ſpecific names of the red roſe, the white roſe, the apple roſe, &c. The ignorance of former ages in the true principles of natural hiſtory, has occaſioned the bodies, which are the objects of it, to be arranged into very unnatural ſeries under the name of *genera*; and theſe have been called by names as improper, as the characters they were diſtinguiſhed by. Linnæus has done a great deal in the exploding the bad *generical* names in Botany, and Artedi has applied his rules about the formation of theſe names with very little difference to the ſubjects of ichthyology. See BOTANY.

Many of the *generical names* of fiſhes till the time of this author, were ſo barbarous and obſcure, that it was not eaſy to trace them to their original; or to find whether they were truly Teutonic, Engliſh, Dutch, Swediſh, French, Italian, Spaniſh, Portugueſe, Latin or Indian. The ignorance of the writers on theſe ſubjects, or their too ſcrupulous adherence to the cuſtoms of their predeceſſors, ſeem to have been principally the cauſes of this, and often an entire negligence. Artedi's rules for *generical* names for fiſhes are theſe.

Whatever

Whatever fiſhes there are which agree in the ſame *generical* characters, and are properly of the ſame genus; theſe ought all to be called by the ſame *generical* name, their differences being only expreſſed by ſpecific ones. This appears ſo plain, ſo juſt, and ſo neceſſary a rule, that it is almoſt a ſhame to lay it down; yet the writers on fiſhes, till the time of this author, had very ſeldom kept up to it: but in many different parts of their works, fiſhes of the ſame genus were found deſcribed under different *generical* names, and in other parts, on the contrary. The greateſt confuſion imaginable was brought on by the deſcribing fiſh of really and truly diſtinct genera under the ſame *generical* name. Thus the alburnus, the barbus, bubulca, brama, capito, caraſſius, carpa, erythrophthalmus, fundulus, gobius, griſlagine, leuciſcus, mugil, naſus, orfus, phoxinus, pigus, rutilus, ſqualus, tinca and varius, are all uſed as ſo many diſtinct *generical* names; yet they are all the names of the different ſpecies of only one genus, the cyprini. In the ſame manner, the agonus, alauſa, celerinus, and chalcis, the encraſicholus, harengus, lycoſtomus, pilchardus, ſardanus, ſprattus, ſparlingus, thriſſa, *&c.* are a parcel of barbarous names uſed as diſtinct *generical* terms; yet the fiſh they are applied to, are all ſpecies of the ſame genus, *viz.* the clupeæ. Numerous other inſtances of this kind might be brought.

On the other hand, fiſhes of the moſt different genera have been confounded under the ſame *generical* name. Thus we have two fiſh deſcribed under the ſame name tinca, as if of the ſame genus, but diſtinguiſhed by the ſpecific additions of their places of abode, the one called tinca lacuſtris, and the other tinca marina. The firſt of them is truly a ſpecies of cyprinus, and the other a ſpecies of as different a genus as can be well conceived.

Another barbariſm and impropriety in the *generical* names of fiſhes among the old authors, is the uſing the ſame words to expreſs them, which are alſo the names of other animals, quadrupeds, birds, and reptiles. Theſe are ſubject to great objection; becauſe when they are uſed it is not eaſy to ſee, in ſome caſes, whether the author is ſpeaking of a bird, a beaſt, or a fiſh. It is therefore one of the general rules of Artedi, that all theſe names are to be aboliſhed, as alſo all thoſe which are common to fiſhes, and to plants, minerals, and to the tools of huſbandry, or other ſervices. *Artedi* Ichthyolog. p. 10, 69.

Among the names common to fiſh, and to quadrupeds, we have the aper, the aſellus, the canis, the caper, the elephas, the gottorugine, or felis, the hyæna, the hyſtrix, the lepus, the lupus, the porcus, the monoceros, the muſtela, the oniſcus, the ſimia, the veſpertilio, and the vulpes. Who would think of boars, aſſes, dogs, and elephants among fiſhes? Or enquire into thoſe names common to the fiſhes and birds, who would expect to find in the ſea, the alauda, the aquila, the capo, the corvus, the cuculus, the gallus, the galerita, the gracculus, the hirundo, the larus, the merula, the milvus, the paſſer, the pavo, the ſcolopax, the turdus?

Among the names common to the amphibious animals, and to the fiſhes, we find the cecilia, draco, dracunculus, ophidion, lacertus, rana, ſaurus, ſerpens, tarantula, and typhle. Among thoſe common to inſects, and to fiſhes, we have the araneus, the aſellus, the gryllus, the ichneumon, the iulis, the libella, the ſcarabæus, the ſcorpio, the tænia, and the lumbricus. Among the names common to plants and fiſhes, we find the adonis, ammogloſſus, bugloſſus, cynogloſſus, erica, hippurus, holoſteum, papaver, paſtinacha, ſpinacha, thymus, and viola. It has been pretended that the old authors have given to fiſh the names of beaſts, as ſuppoſing their internal ſtructure the ſame with theirs; but this is an analogy almoſt entirely imaginary; and if it could have any ſhare in the comparing fiſh to quadrupeds, yet it leaves the comparing them to ſpinage, poppies, parſnips, and violets, wholly without excuſe.

Among the ſeveral names common to fiſhes, and to the inſtruments of huſbandry and other arts, the offices, trades, and employments of men and other things, as foreign to the nature of the ſubject as theſe, we find the following. The acus, bubulus, carbonarius, citharus, faber, gladius, huſo, hippogloſſus, hippuris, lingula, lucerna, lyra, maltha, mola, naſus, novacula, orbis area, quadratulus, rhaphis, remora, rhombus, ſerra, ſolea, umbra. To theſe alſo may be added the names taken from ſpiritual beings, to which the nameſake fiſhes can certainly have no reſemblance or affinity: ſuch are the angelus, and the diabolus.

Another rule of this excellent author is, that *generical* names that are compoſed of two whole words unnaturally tied together are to be aboliſhed, it being eaſy to contrive names leſs barbarous, and as expreſſive; among theſe we find the araneus marinus, aſper piſciculus, gobioni perſimilis, muſtelæ affinis, piſcis cornutus, veſpertilio aquaticus, and a great number of others formed upon the ſame plan with every one of theſe. Next to theſe are to be exploded thoſe names which are formed of two *generical* words before in uſe, the one broken, or cut ſhort, the other preſerved intire: of this kind are the ſquatino-raia, the lucio-percæ, the rhino-batus, and the like. *Artedi* Ichthyolog. p. 73.

Another general rule in regard to theſe names is, that all ſuch as are not of either Latin, or Greek origin, are to be proſcribed and wholly rejected. This rule cuts off a prodigious number of barbarous words, with which we find the books of authors of former ages on theſe ſubjects crowded. Among the barbarous names of German origin, are the caraſſius from karas, carpa from carpe, orfus from urff, triſſia from truſchen, *&c.* Among thoſe of Belgic origin are theſe, coretta from coret, and the hayen, lumpen, *&c.* which are all Belgic words. Among thoſe of Engliſh origin are the braulinus from brauling, gornatus from gurnard, graia from grey, and huitingo-pollachus from whiting pollach. Among thoſe of Swediſh origin are ſicus from ſilk or ſik, ſtromingus from ſtroming, *&c.* Among thoſe of Gallic origin are theſe, barbotta from barbott, celerinus from celerin, *&c.* Among thoſe of Portugueſe origin are theſe, tiburo from tiberaon, and linguado and pudiano, both Portugueſe words. Among thoſe of Italian origin come the fragolinus from fragolino; and the fiatola, rayna, and many others which are true Italian words. Amongſt thoſe of American origin are the paru, tamaota, narinari, and a multitude of other ſuch barbarous and unintelligible ſounds copied from Piſo, Marcgrave and others. And finally among thoſe of Aſiatic origin, or borrowed from the modern Greek, wholly differing from the antient, are the corcovada, cheriſcaria, liſſa, *&c.*

A ſixth rule for the regulating *generical* names is, that all ſuch are to be aboliſhed as terminate in *oides*, as expreſſing a reſemblance often imaginary, and often alluding to ſomething unknown, or rendered difficult to trace from the changing the names of other things ſince the time when it was formed. Theſe words convey no idea of the character of the genus expreſſed by them, except that they are like the other thing alluded to in ſome external, though perhaps not eſſential character: of this kind are the rhomboides, ſcorpoides, *&c.*

A ſeventh rule in regard to theſe names is, that all ſuch are to be rejected as are barely diminutives and terminate in *ulus* or *ula*. Theſe convey no other idea, but that of the fiſh being like ſome other fiſh, only leſs: now bigneſs is no *generical* character; therefore if this genus, and that referred to, differ only in ſize, they have no *generical* difference at all; if they do differ otherwiſe that ſhould be expreſſed. What makes many of theſe names alſo the more intolerable is, that they allude not to fiſhes, but to other things ſo different in their nature, that there muſt needs be many other more eſſential varieties between them, beſide ſize: of this kind are the lingula from lingua, capriſcus from caper, ſpinarolla from ſpina, ſardella, from ſarda, and ſo on to the anguella, dracunculus, albula, *&c.*

Another general rule is, that ſuch *generical* names as are pure Latin, but are mere adjectives are to be exploded, there being no reaſon for uſing them as ſubſtantives: the names of things of this ſort, are coracinus from corax, latulus from latus, aculeatus, centrine glaucus, and the like. *Artedi* Ichthyolog. 10, 79.

A ninth general rule is, that ſuch names as are formed of Latin words, unknown to the antient Romans, and formed by the later writers are to be expelled as barbarous, and others of better credit placed in their ſtead. Of the number of theſe new names are theſe, alburnus, lucius, ſalar, tinia, lampetra, *&c.*

Finally, ſuch *generical* names as have been given to fiſh from the places where they are caught, are to be rejected; of this kind are the ſardella and ſardina from the iſland of Sardinia, and the ſturio from Aſturia, a province of Spain. Theſe ſorts of names can convey no idea of the nature of the fiſh, and may belong as well to one genus as to another. *Artedi* Ichthyolog. p. 10, 79.

Theſe rules of proſcription baniſh ſo many of the received *generical* names of fiſhes, that it might be ſuppoſed the whole number was exhauſted, and all the fiſh in the world to be named anew. But this is not the caſe, the *genera* are in reality much fewer in number than they have been uſually ſuppoſed, and therefore fewer words will ſerve to expreſs them, and there yet remains many truly Latin words uſed by the antient Romans, by which the far greater part of the *genera* may be expreſſed, and the few remaining may be beſt denominated by compound Greek words, expreſſive of their real characters.

Among the true and genuine Latin and Græco-Latine names of the *genera* of fiſhes are theſe, accipenſer, amia, anthias, balæna, blennus, clupea, cobites, cyprinus, delphinus, elops, eſox, exocœtus, gobius, labrus, lamia, liparis, mugil, mullus, muræna, perca, phyſeter, priſtis, raja, ſalmo, ſalpa, ſcarus, ſcomber, ſilurus, ſparus, ſqualus, thynnus, torpedo, triton, turſio, uranoſcopus, xiphias, zeus. Theſe will go a great way toward the naming the true *genera*. Artedi has merited greatly of the world, in thus reforming the names of fiſhes, and the rules he has laid down, thus given at large, may with little variation be made to ſerve to any other author, in whatever branch of knowledge he has occaſion to write.

GENESIS, *(Cycl.)* in mathematics, is uſed for formation, or production. Thus authors ſpeak of the geneſis of equations, figures, *&c.*

GENETHLIA, Γενεθλια, in antiquity, a ſolemnity kept in memory of ſome perſon deceaſed. *Potter.* Archæol. Græc. l. 2. c. 20. Tom. 1. p. 375.

GENE-

GENETIDES, in natural hiſtory, a name given by the antients to the ſtone, more generally known under the name enchymonites. This was the ſpar incruſted on the tops and ſides of ſubterranean caverns, which they ſuppoſed daily to bring forth more, and therefore gave the powder of it to women at the time of their lying in, to promote their ſpeedy delivery. *Boetius* de Boot.

GENETTA, a ſmall animal of the weaſel kind. See the article GINETTA.

GENETTE, in the manege, a Turkiſh bit, the curb of which is all of one piece, and made like a large ring, and placed above the liberty of the tongue. When they bridle a horſe, they make his chin paſs through this curb, which ſurrounds his beard. This ſort of bit was much uſed at the court of France when Guillet wrote.

GENETTE is alſo uſed for the particular way of riding practiſed in Spain, which being ſo ſhort, that the ſpurs bear upon the horſe's flank, would be reckoned an indecency in France and England, but among the Spaniards, it paſſes for a piece of gallantry and handſome carriage when they ride upon their *genettes*, in going to court before the ladies.

GENETYLLIS, Γενετυλλις, in antiquity, a ſolemnity celebrated by women in honour of *Genetyllis*, the goddeſs of that ſex. *Potter*, Arch. Græc. l. 2. c. 20.

GENEVA *(Cycl.)*—There never was ſo great a quantity of the liquor vulgarly called by this name made as at preſent; but it is wholly different from what the liquor ſo called was at firſt. The beſt *geneva* we now have, is made from an ordinary ſpirit, diſtilled a ſecond time with an addition of ſome juniper berries; but the original liquor of this kind was prepared in a very different manner. It was a cuſtom in the diſtilling of ſpirits from wort, or other fermented liquors, to add in the working ſome aromatic ingredient; ſuch as ginger, cortex winteranus, or grains of paradiſe to take off the bad flavour, and to give a pungent taſte to the ſpirit. Among other things uſed with this intent, ſome tried the juniper berries, and finding that they gave not only an agreeable flavour, but very valuable virtues alſo to the ſpirit, they brought it to a general cuſtom, and the liquor ſold under this name. The method of adding the berries was to the malt in the grinding: a proper proportion was allowed, and the whole was reduced to meal together, and worked in the common way. The ſpirit thus obtained was flavoured *ab origine* with the berries, and exceeded all that could be made by any other method. Our common diſtillers leave out the juniper berries entirely from the liquor they now make and ſell under that name. Our raſcally chemiſts have let them into the ſecret, that the oil of juniper berries, and that of turpentine are very much alike in flavour, though not in price; and the common method of making what is called *geneva* in London, is with common malt ſpirit, and a proper quantity of oil of turpentine diſtilled together. *Shaw*'s Eſſay on Diſtill. p. 7.

GENICULARIS, in botany, a name uſed by ſome authors for the great garden valerian called phu. *Ger.* Emac. Ind. 2.

GENIPA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the monopetalous kind, and is ſhaped like a bell, and very wide at the mouth. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower. The cup finally becomes an oval fleſhy fruit, divided into two cells, and containing a number of flatted ſeeds. There is only one known ſpecies of this genus, which is the oval fruited *genipa* or *genipat* of authors. *Tourn.* Inſt. p. 658.

GENISTA, *Broom*, in Botany, the name of a genus of plants, the characters of which are theſe: the flower is of the papilionaceous kind; the piſtil which ariſes from the cup finally becomes a flat pod, which when ripe ſplits into two parts, and is found to contain kidney-ſhaped ſeeds. To this it is to be added, that the leaves ſtand either in an alternate or verticillate order. See Tab. 1. of botany, Claſs 22.

The ſpecies of *geniſta*, enumerated by Mr. Tournefort, are theſe. 1. The common Spaniſh *broom*, or ruſhy ſtalked *broom*. 2. The dwarf, ſweet ſcented Spaniſh *broom*. 3. The dyers weed, or German dyers *broom*. 4. The dyers weed with narrower leaves. 5. The ſhrubby dyers *geniſta*, with hoary leaves. 6. The broad leaved dyers *broom*. 7. The great Portugal dyers *broom*. 8. The Portugal *broom* with ſmall yellow flowers. 9. The low Dutch *broom*. 10. The branched *broom* with hypericum leaves. 11. The radiated or ſtarry *broom*. 12. The purging *broom* or ſpartum. 13. The ſhrubby African *broom* with nervous butchers *broom* leaves. 14. The ſhrubby African *broom* with narrower butchers *broom* leaves. 15. The African *broom* with lavender leaves. 16. The African ruſhy ſtalked *broom* with very ſmall leaves, and blue flowers. 17. The ſmalleſt African *broom* with myrtle like leaves, ending in a fine point. 18. The roſemary leaved African *broom* with bright yellow flowers. 19. The African tree *broom* covered with a ſilvery hoarineſs. 20. The ſhrubby African *broom* with very narrow leaves, and purple ſpiked flowers. 21. The broader leaved purple flowered ſhrubby African *broom*. 22. The African *broom* with hairy larch like leaves. 23. The African *broom* with thick and hairy larch like leaves. 24. The larch leaved ſhrubby African *broom* with ſpiked flowers. 25. The larch leaved ſhrubby African *broom* with glomerated heads. 26. The larch leaved ſhrubby African *broom* with yellow ſpiked flowers. 27. The ſhrubby African *broom* with woolly heads, and very ſhort larch like leaves. 28. The ſhrubby African *broom* with hoary larch like leaves. 29. The African *broom* with ground pine leaves, and very ſmall yellow flowers. 30. The gallium leaved African *broom*, and 31. The dorychnium leaved African *broom*. *Tourn.* Inſt. p. 644. *Broom*, is an attenuant, abſtergent, and aperient. The juice of the green ſhoots of *broom*, or a ſtrong infuſion of them in wine, is an excellent diuretic, and cleanſes the ureters and kidneys. If taken in large doſes it purges by ſtool, and therefore is doubly proper in dropſical caſes. The ſeed of *broom* is alſo a purge, and that of no weak kind, a dram and half of it being a ſufficient doſe. The young buds are frequently pickled in the manner of capers, and make a very agreeable addition to our food. The *Lixivium* of *broom* with white wine is a powerful diuretic, but muſt be taken with caution.

GENISTA *ſpartium*, in botany, the name of a genus of plants, agreeing in all reſpects with *broom*, but that the ſtalks are prickly.

The ſpecies of *geniſta ſpartium*, enumerated by Mr. Tournefort, are theſe. 1. The great yellow flowered *geniſta ſpartium*. 2. The great *geniſta ſpartium*, with pale yellow flowers. 3. The great hairy *geniſta ſpartium*. 4. The great ſmooth leaved *geniſta ſpartium*, with ſlender branches. 5. The ſmaller *geniſta ſpartium*. 6. The very prickly ſmall ſtone *geniſta ſpartium*. 7. The great *geniſta ſpartium* with ſome longer, and ſome ſhorter thorns. 8. The leſſer common, or German *geniſta ſpartium*. 9. The ſmaller Engliſh *geniſta ſpartium*. 10. The Spaniſh very woolly ſmall *geniſta ſpartium*. 11. The woolly Spaniſh *geniſta ſpartium* with very long and ſlender three pointed thorns. 12. The woolly Portugal *geniſta ſpartium* with very long three pointed thorns. 13. The Portugal *geniſta ſpartium* with ſhort three pointed prickles 14. The Portugal *geniſta ſpartium* with ſhort thick and crooked three pointed thorns. 15. The Portugal *geniſta ſpartium* with very ſhort blueiſh prickles. 16. The Portugal *geniſta ſpartium* with very thick ſet prickles and tufted flowers. 17. The ſilvery Portugal *geniſta ſpartium*, with very ſtrong thorns and numerous flowers. 18. The great prickly ſpiked flowered *geniſta ſpartium*. 19. The dwarf *geniſta ſpartium* with ſmall flowers. 20. The ſmall Portugal *geniſta ſpartium* with ſpiked flowers. 21. The Portugal *geniſta ſpartium* with crooked or falcated pods. *Tourn.* Inſt. p. 645, 646.

GENISTELLA, in botany, the name of a genus of plants, the characters of which are theſe. The flowers and fruit are the ſame as in the broom, but the leaves are jointed, or grow to one another by a ſort of articulation.

The ſpecies of *geniſtella*, enumerated by Mr. Tournefort, are theſe. 1. The narrow leaved herbaceous *geniſtella*, or chamæſpartium. 2. The broad leaved herbaceous *geniſtella*. 3. The broad leaved ſhrubby Portugal *geniſtella*, and 4. The narrow leaved ſhrubby Portugal *geniſtella*. *Turn.* Inſt. p. 646.

GENITURA, in botany, a name given by ſome authors to the anethum or dill, a plant common in gardens, and uſed in medicine and cookery. *Ger.* Emac. Ind. 2.

GENOA *Balſam*, in medicine, the name of a famous compoſition, called alſo the balſam of aquapendente. Its great virtues are the curing pains in the extremities of the body, and allaying the violent pain in the bowels to which many women are ſubject after delivery. The preſcription is given at large in Velſcius, but the medicine is now grown out of uſe. *Velſc.* Med. Obſ.

GENTIANA, *Gentian*, in botany, the name of a genus of plants of which there are ſeveral ſpecies. The characters of the genus are theſe. The flower conſiſts only of one leaf faſhioned like a bell, in ſome ſpecies long and tubular, in others broader and open, and uſually divided into ſeveral ſegments. From the bottom of the cup there riſes a piſtil, which perforates the bottom of the flower, and ripens into a fruit of a membranaceous texture, and pointed oval figure, this is formed of two valves, and contains only one cell, in which are a number of ſeeds uſually flat, of a rounded form and marginated, or rim'd round the edge.

The ſpecies of *gentian* are theſe. 1. The great yellow flowered kind. 2. The great purple flowered kind. 3. The great white flowered kind. 4. The great kind with a ſpotted flower. 5. The ſwallow-wort leaved *gentian*. 6. The great flowered alpine *gentian*. 7. The large dwarf ſpring *gentian*. 8. The leſſer dwarf ſpring *gentian*. 9. The centaury leaved ſpring dwarf *gentian*. 10. The ſhort leaved alpine dwarf kind. 11. The blue flowered kind with hoary edges. 12. The croſs leaved kind. 13. The branched autumnal kind. 14. The meadow *gentian*, with woolly flowers. 15. The ſhort and large flowered meadow *gentian*. 16. The bladder *gentian*. 17. The broad leaved marſh kind with ſpotted flowers. 18. The great narrow leaved autumnal kind, called pneumonanthe. and 19. The little dwarf *gentian*. *Tourn.* Inſt. p. 81. See GENTIAN, *Cycl.*

GENTIANA *nigra*, a name given by ſome botanical authors to the mountain daucus or black libanotis. *Rump.* Flor. Gen. 221. See DAUCUS.

GENTIANELLA, *Little Gentian*, a diminutive of the name *gentiana*, commonly applied to the ſmaller ſpecies of *gentian*. See GENTIANA.

GENTILITIA *ſacra*, among the Romans. See SACRA.

GENTILITIUS, an epithet uſed by ſome authors, to expreſs diſeaſes propagated from father to ſon, and running through whole families, ſuch as are more uſually called hereditary diſorders. Such is the gout very frequently, and often many others. See DISEASE.

GENTLE *Pit Ore*, in mineralogy, a name given by our miners in Suſſex to a kind of iron ore found in conſiderable plenty in that county, and very readily running in the fire, though not over rich in metal. It is a ſtrong ſubſtance, and lies in ſeveral parts of that county in form of a moderately thick ſtratum. It is of a duſky brown colour, and in ſome places much paler than in others. It has always a great number of glittering ſpangles in it, and very often contains foſſile ſhells, and other extraneous ſubſtances in it. *Woodw.* Cat. Foſ. Vol. 1. p. 225.

GENUS *(Cycl.)*—By the word *genus*, in natural hiſtory, we underſtand a certain analogy of a number of ſpecies making them agree together in the number, figure, and ſituation of their parts in ſuch a manner, that they are eaſily diſtinguiſhed from the ſpecies of any other *genus*, at leaſt by ſome one article. This is the proper and determinate ſenſe of the word *genus*. Some have extended it to the claſſes under which theſe *genera* are formed, calling the claſs *genus ſummum*, and this *genus ſubalternum*.

A *genus* in ichthyology, for inſtance, is a certain agreement between ſeveral ſpecies founded on the ſimilitude of their eſſential external parts, generally regarding their ſituation, number, figure, and proportion. On this foundation, if only one fiſh ſhould be found differing from all the known *genera* in ſome eſſential point, the ichthyologiſt is not to force this into the ranks of ſome former *genus*, but allow it one to itſelf, and it is extremely probable that ſome other fiſhes hereafter may be diſcovered belonging to the ſame *genus* with it, and no more than it reducible to any of the formerly eſtabliſhed ones. *Artedi* Ichthyolog.

GENUS, in the antient muſic, was a diviſion of the *diateſſaron*, or fourth [a], containing four ſounds, into three intervals [b].—[a *Euclid.* Introd. Harm. p. 1. Ed. Meibom. b Phil. Tranſ. N°. 481. p. 271. *Gaudent.* p. 5. Edit. Meibom.]

The Greeks conſtituted three ſuch *genera* known by the names of *enharmonic*, *chromatic*, and *diatonic*. See ENHARMONIC, *&c.*

The enharmonic was not ſubdivided, but the chromatic was divided into three ſpecies, and the diatonic into two; ſo that the antients had ſix ſpecies, or different diviſions of the fourth in uſe. The moderns know but four [c], and one of theſe, the enharmonic, is ſcarce ever met with. It does not appear that the antients themſelves could accurately define theſe ſeveral ſpecies. Ariſtoxenus left it to the ear and practice, and did not pretend to aſſign any true proportions in numbers. However he has attempted to convey ſome idea of theſe *genera* and ſpecies, by ſuppoſing the fourth divided into thirty parts. That is (as Ptolemy underſtands him) he ſuppoſes the difference of a chord and its fourth to be divided into 30 parts; and then aſſigns a certain number of theſe parts to each interval, or diviſion of the various ſpecies. Hence the fourth [d] containing two tones and a half, the tones will each have twelve parts, and the ſemi-tone ſix. —[c Philoſ. Tranſ. N°. 481. p. 272. d *Wallis* Append. and *Ptolem.* Harm. p. 164.]

In the enharmonic, he makes the interval between the hypate and parypate, as alſo, between the parypate and the lichanus, to be a *dieſis quadrantalis*, or $\frac{1}{1\frac{1}{2}}$; and from the lichanus to the nete he makes a ditonus or $\frac{2\frac{1}{2}}{3\frac{1}{2}}$. So that the enharmonic diviſions will be $3 + 3 + 24 = 30$.

In the chromaticum molle [e], he makes the interval between the hypate and parypate, as alſo from the parypate to the lichanus a triental dieſis, or $\frac{1}{1\frac{1}{2}}$; and from the lichanus to the nete $\frac{22}{1\frac{1}{2}}$, that is, an undivided interval equal to a tone, a ſemitone, and a triental dieſis. Hence the intervals of this ſpecies will be repreſented by the numbers, $4 + 4 + 22 = 30$ [f]. [e μαλακον. f *Wallis* Ibid.]

In the chromaticum hemiolium [g], or ſeſquialterum [h], he makes the interval from the hypate to the parypate, and from thence to the lichanus, a dieſis ſeſquialtera, that is $\frac{1}{2}$ of the enharmonic dieſis, or $4\frac{1}{2}$ parts of his diviſion of the fourth. The remaining undivided interval is of 21 parts; being equal to a tone, a hemitone, and quadrantal dieſis. This ſpecies will be repreſented by the numbers, $4\frac{1}{2} + 4\frac{1}{2} + 21 = 30$. [i]. or to avoid fractions, $9 + 9 + 42 = 60$.—[g ἡμιολιον. h Phil. Tranſ. N°. 481. pag. 272. i *Wallis* ibid.]

In the chromaticum tonicum or toniæum [k], he makes the interval between the hypate to the parypate, and from thence to the lichanus, a hemitone or $\frac{6}{1\frac{1}{2}}$, and from thence to the nete, a tone and an half or $\frac{18}{1\frac{1}{2}}$. Hence the ſpecies will be expreſſed by the numbers, $6 + 6 + 18 = 30$ [l].—[k τονιαιον. l *Wallis* ibid.]

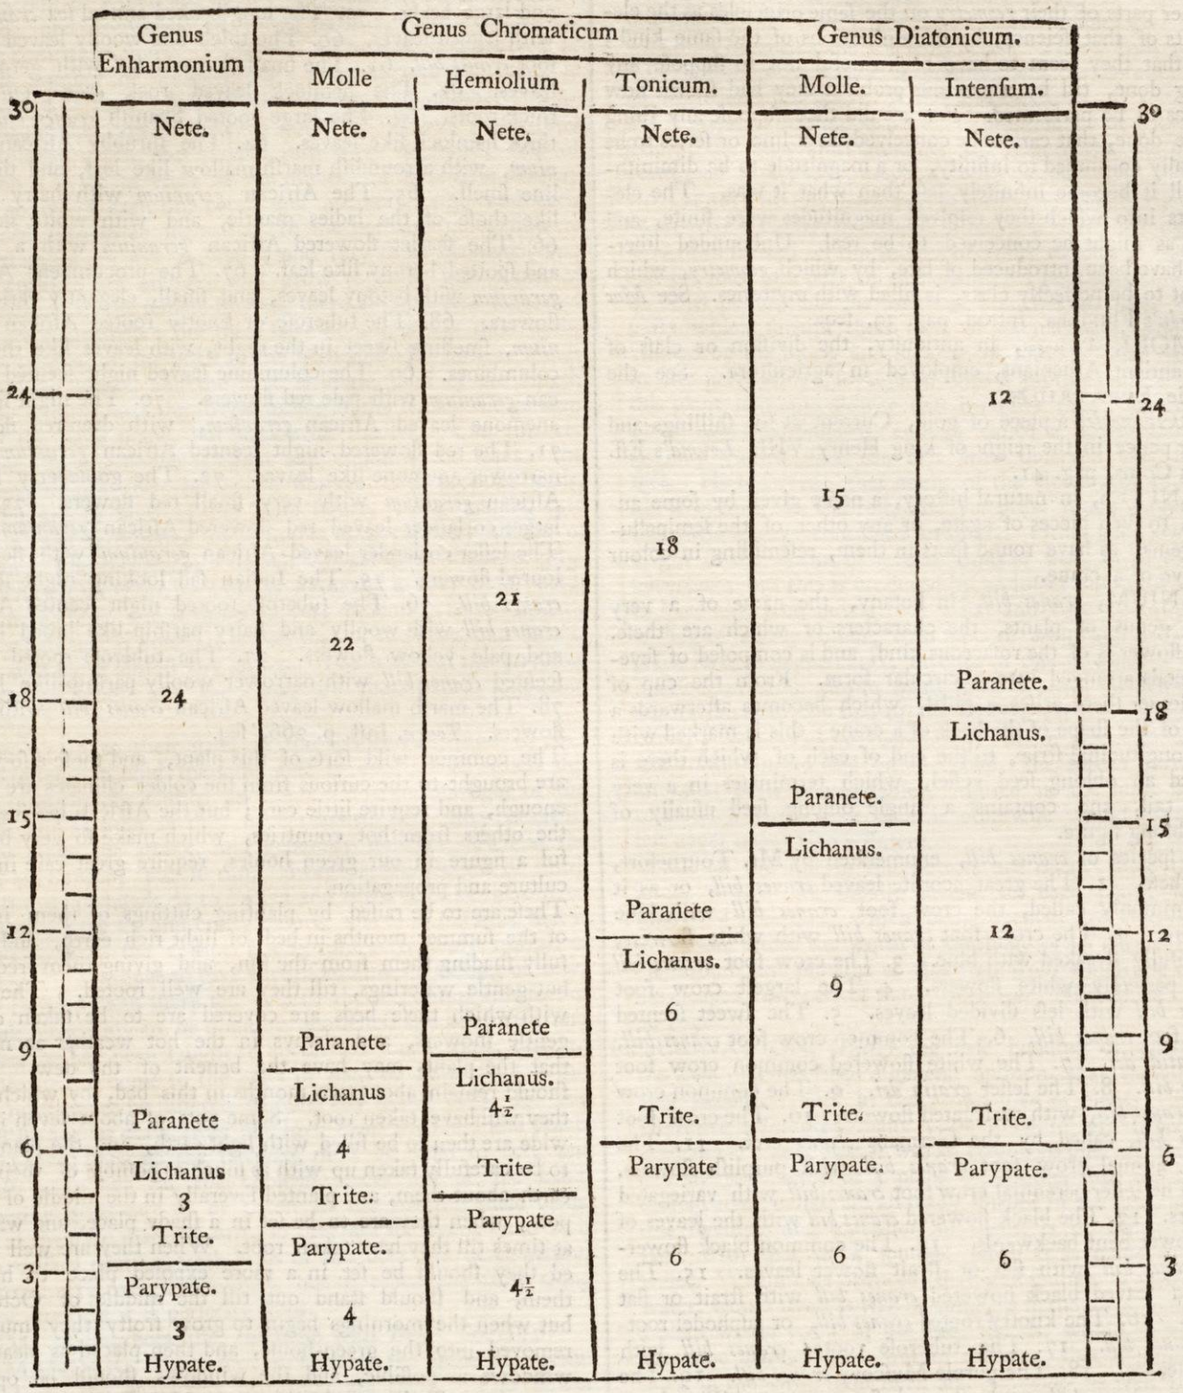
In the diatonicum molle [m], he makes the interval between the hypate and parypate a hemitone or $\frac{6}{1\frac{1}{2}}$, from hence to the lichanus $\frac{9}{1\frac{1}{2}}$, and from this to the nete $\frac{15}{1\frac{1}{2}}$; ſo that this ſpecies will be repreſented by the numbers $6 + 9 + 15 = 30$ [n]. —[m μαλακον. n *Wallis* ibid.]

In the diatonicum intenſum or ſyntonum [o], the interval between the hypate and parypate, is according to him a hemitone; and between the parypate and lichanus, as alſo between the lichanus and nete, is a tone. Hence the expreſſion of this ſpecies will be $6 + 12 + 12 = 30$ [p].—[o συντονον. p *Wallis* ibid.]

The ſame diviſions are in Euclid [q], and Ptolemy [r] gives the like proportions from Ariſtoxenus, only doubling the numbers to avoid fractions.—[q Introd. Harm. p. 10, 11. Edit. Meibom. r *Harmon.* Lib. 1. c. 12.]

Ariſtoxenus does not pretend that the diviſions he propoſes are accurate. He ſeems to doubt of the diateſſaron being two tones and an half; and of its being at all meaſurable by any ſmall interval, as the hemitone or dieſis. He queſtions whether the enharmonic dieſis be preciſely the fourth part of a tone; or if the chromatic dieſis be its third part. All which doubts are very well grounded. And it ſeems as if this famous muſician had only propoſed his diviſions of the tetrachord, as approximations to convey ſome idea of the different ſpecies to the imagination; and not as an accurate ſtandard to guide the voice, and hand, in ſinging and playing. *Wallis* Append. and *Ptolem.* Harm. pag. 169.

This is the doctrine of the antients concerning their ſix ſpecies of fourths. How to reconcile this to modern notions, and with the true principles of muſic, might be a work of ſome difficulty. Dr. Pepuſch has given us his opinion as to what theſe ſix ſpecies ought accurately to be. How far his opinion is deducible from the remains of the antient muſicians, has not yet been publicly ſhewn. We have mentioned his doctrine under the heads CHROMATIC, DIATONIC and ENHARMONIC, and ſhall here give them in one ſhort view. Phil. Tranſ. N° 481. pag. 266. ſeq.



Intervals of the

Enharmonic, $\text{IV} = s + d + \text{III}$.
Cromaticum molle, $\text{IV} = s + s + (3 + d.)$
Chromaticum ſeſquialterum, $\text{IV} = S + s + 3$.
Chromaticum toniæum, $\text{IV} = S + S + (T + s.)$
Diatonicum molle, $\text{IV} = S + 2s + (T + d.)$
Diatonicum intenſum, $\text{IV} = S + t + T$.

To underſtand which, obſerve, that d ſtands for the dieſis enharmonica, s for the ſemi-tone minor, S for the ſemi-tone major, t for the tone minor, T for the tone major, 3 for the third minor, III for the third major, IV for the fourth; and when two intervals are placed within a parentheſis, it ſignifies a ſingle interval equal to the two joined by the ſign of addition $+$. Thus $(3 + d)$ is an interval equal to the third minor and dieſis enharmonica; $(T + s)$ is equivalent to the tone major & ſemitone minor, commonly called a ſuperfluous tone; and laſtly $(T + d)$ ſignifies a tone major and dieſis enharmonica, which interval, no more than $(3 + d)$ has no particular name. Phil. Tranſ. N° 481. pag. 272.

Dr. Wallis has given us a ſynopſis of the *genera* and ſpecies according to Ariſtoxenus, we ſhall here inſert it, as it gives light to the doctrine of the antient tetrachords. *Wallis.* Append. ad *Ptolem.* Harm. pag. 164.

Generum Synopſis ſecundum Ariſtoxenum.

The gradual approach of the paranete, in the different ſpecies to the nete, ſhews why this chord was called lichanus. The length of this ſcheme, or the ſide divided into thirty parts, is ſuppoſed to be the difference of any chord, and its fourth. Ptolemy takes theſe diviſions in an aſcending fourth; that is, the longeſt of the two chords, or the whole of one chord, is terminated at hypate; and the termination of the ſhorter chord, or of that part of the long chord, ſounding a fourth to the whole, is at nete. So that we muſt imagine ninety parts added upwards to this ſcheme beyond nete; and then, for inſtance, the lengths of the chord, or parts of a chord repreſenting the *diatonicum intenſum* of Ariſtoxenus, according to Ptolemy, will be, 120, 114, 102 and 90. *Ptolem.* Harmon. pag. 92. Edit. *Wallis* in Oper. Tom. 3.

But we muſt obſerve, that the ninety parts might be added downwards in the foregoing ſcheme, from hypate; and then we ſhould have a deſcending fourth expreſſed by the following numbers, 90, 96, 108 and 120, which is moſt perfectly in tune, and gives us the ſemitone major, the tone major, and the tone minor. For $\frac{90}{96} = \frac{15}{16}$ is the proportion of lengths of chords expreſſing the ſemitone major; $\frac{96}{108} = \frac{8}{9}$ is in like manner a tone major; and $\frac{108}{120} = \frac{9}{10}$ is the expreſſion of the tone minor. On the other hand, Ptolemy's numbers are much out of tune, and ſuch as a muſician like Ariſtoxenus dividing a ſtring by his ear could not fall upon. We do not know that any commentator of the antients ever made this obſervation; but if we purſue it through all the ſpecies, we ſhall find a very ſenſible difference in the expreſſions of the proportions of the various intervals found according to Ptolemy's manner, and thoſe found in the way here mentioned, and exemplified in the diatonicum intenſum. Ariſtoxenus and his followers determined the ſeveral ſpecies, or diviſions of the fourth by intervals, making the whole diateſſaron equal to two tones and an half. But the Pythagoreans ſetting aſide this method, took another, whereby they ſought for three ratios, which added together would produce the ratio of 4 to 3, being the expreſſion of the fourth or diateſſaron. And as this might be variouſly done, ſo they conſtituted various differences of *genera*. *Ptolem.* L. 1. c. 9. Edit. *Wallis* Oper. Tom. 3.

But they did not admit all ratios indiſcriminately. They chiefly regarded ſuch as were multiple and ſuperparticular; and did not admit of the ſuperpartient, but through neceſſity, and much leſs of incommenſurable expreſſions. *Wallis* Append. ad. *Ptolem.* Harm. pag. 166. Oper. Tom. 3.

Ptolemy [b] gives us ſeveral diviſions of the tetrachord, partly his own and partly of others, which we ſhall here place in one ſhort view from Dr. Wallis's Appendix to Ptolemy's harmonics [c].—[[b] Ibid. Lib. 1. c. 13, 14, 15 and 16. [c] Pag. 166. Oper. Tom. 3.]

$\frac{28}{27} \times \frac{36}{35} \times \frac{5}{4} = \frac{4}{3}$	Enharmonic	of Archytas.

GEOME-

GEOMETRICAL *(Cycl.)*—GEOMETRICAL *method of the antients.* It is to be obſerved that the antients eſtabliſhed the higher parts of their *geometry* on the ſame principles as the elements of that ſcience, by demonſtrations of the ſame kind; and that they ſeem to have been careful not to ſuppoſe any thing done, till by a previous problem they had ſhewn how it was to be performed. Far leſs did they ſuppoſe any thing to be done, that cannot be conceived, as a line or ſeries to be actually continued to infinity, or a magnitude to be diminiſhed till it become infinitely leſs than what it was. The elements into which they reſolved magnitudes were finite, and ſuch as might be conceived to be real. Unbounded liberties have been introduced of late, by which *geometry*, which ought to be perfectly clear, is filled with myſteries. See *Mac Laurin*'s Fluxions. Introd. pag. 39. ſeq.

GEOMORI, Γεωμοροι, in antiquity, the diviſion or claſs of the antient Athenians, employed in agriculture. See the article EUPATRIDÆ.

GEORGE *noble*, a piece of gold, Current at ſix ſhillings and eight pence in the reign of king Henry VIII. *Lownd*'s Eſſ. upon Coins, pag. 41.

GERANITES, in natural hiſtory, a name given by ſome authors to ſuch pieces of agate, or any other of the ſemipellucid gems, as have round ſpots in them, reſembling in colour the eye of a crane.

GERANIUM, *cranes bill*, in botany, the name of a very large genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, and is compoſed of ſeveral petals arranged into a circular form. From the cup of the flower there ariſes a piſtil, which becomes afterwards a fruit of the ſhape of the beak of a crane; this is marked with five longitudinal ſtriæ, to the end of each of which there is affixed an oblong ſeed veſſel, which terminates in a very long tail, and contains a ſingle oblong ſeed uſually of an oblong figure.

The ſpecies of *cranes bill*, enumerated by Mr. Tournefort, are theſe. 1. The great aconite leaved *cranes bill*, or as it is commonly called, the crow foot *cranes bill* with blue flowers. 2. The crow foot *cranes bill* with white flowers, beautifully ſtreaked with blue. 3. The crow foot *cranes bill* with perfectly white flowers. 4. The largeſt crow foot *cranes bill* with leſs divided leaves. 5. The ſweet ſcented crow foot *cranes bill*. 6. The common crow foot *cranes bill*, or *gratia dei*. 7. The white flowered common crow foot *cranes bill*. 8. The leſſer *gratia dei*. 9. The common crow foot *cranes bill*, with variegated flowers. 10. The crow foot *cranes bill*, called by the Germans *cranes neck*. 11. The leſſer annual crow foot *cranes bill* with purpliſh flowers. 12. The leſſer perennial crow foot *cranes bill* with variegated flowers. 13. The black flowered *cranes bill* with the leaves of the flower bent backwards. 14. The common black flowered *cranes bill* with flat or ſtrait flower leaves. 15. The ſpotted leaved black flowered *cranes bill* with ſtrait or flat petals. 16. The knotty rooted *cranes bill*, or aſphodel rooted *cranes bill*. 17. The tuberoſe rooted *cranes bill* with trifid leaves. 18. The purple Muſcovy *cranes bill*. 19. The Roman *cranes bill* with ſtriated flowers. 20. The large flowered bloody *cranes bill*. 21. The bloody *cranes bill* with variegated flowers. 22. The bloody *cranes bill* with paler coloured and more deeply divided leaves. 23. The bloody *cranes bill* with more upright ſtalks and ſmaller flowers. 24. The greater tuberoſe rooted *cranes bill*. 25. The ſilvery alpine *cranes bill*. 26. The thick rooted aſh-coloured-leaved Pyrenean *cranes bill*, with large variegated flowers. 27. The ſhining leaved ſtone *cranes bill*. 28. The little ranunculus leaved *cranes bill*. 29. The roundiſh mallow leaved *cranes bill*, or dove's foot *cranes bill*. 30. The greater blue flowered dove's foot *cranes bill*. 31. The dove's foot *cranes bill* with ſmaller blue flowers. 32. The white flowered dove's foot *cranes bill*. 33. The greateſt perennial Pyrenean dove's foot *cranes bill*. 34. The round leaved mountain *cranes bill* with large purple flowers. 35. The greateſt dove's foot *cranes bill* with diſſected leaves. 36. The dove's foot *cranes bill* with diſſected leaves, and with flowers on long footſtalks. 37. The finely divided dove's foot *cranes bill*. 38. The finely divided dove's foot *cranes bill* with white flowers. 39. The leſſer dove's foot *cranes bill* with a larger flower compoſed of bifid petals. 40. The large finely divided dove's foot *cranes bill* with bifid petals. 41. The common marſh mallow leaved *cranes bill*. 42. The marſh mallow leaved *cranes bill* with deep purple flowers. 43. The ſmaller mallow leaved *cranes bill*. 44. The mallow *cranes bill* with thick, wrinkled, and undivided leaves. 45. The little procumbent ſea *cranes bill* with marſh mallow or betony leaves. 46. The *cranes bill* with leaves like thoſe of the bladder alcea. 47. The common or green leaved *herb robert*. 48. The red leaved *herb robert*. 49. The white flowered *herb robert*. 50. The ſhining ſtone *cranes bill* with *herb robert* leaves. 51. The hemlock leaved *cranes bill* with very long beaks. 52. The hemlock leaved *cranes bill* with the ſmell of muſk. 53. The ſcentleſs hemlock leaved *cranes bill*. 54. The ſmall procumbent hemlock leaved *cranes bill*. 55. The little procumbent hemlock leaved *cranes bill* with white flowers. 56. The upright hemlock leaved Roman *cranes bill*. 57. The Neapolitan *cranes bill*, with the Cretic corn marygold leaf. 58. The broad leaved Candy *cranes bill* with extremely long and large beaks. 59. The long beaked annual ſea *cranes bill* with jagged leaves. 60. The thick and woolly leaved crows foot *cranes bill*. 61. The ſmalleſt *cranes bill* with germander leaves. 62. The hemlock leaved rock *cranes bill* with thick roots. 63. The large rooted Spaniſh *cranes bill* with thick hemlock like leaves. 64. The ſhrubby African *geranium*, with a roundiſh marſh mallow like leaf, and the carline ſmell. 65. The African *geranium* with hairy leaves like thoſe of the ladies mantle, and with white flowers. 66. The ſcarlet flowered African *geranium* with a jagged and ſpotted betony like leaf. 67. The procumbent African *geranium* with betony leaves, and ſmall, elegantly variegated flowers. 68. The tuberoſe or knotty rooted African *geranium*, ſmelling ſweet in the night, with leaves like thoſe of columbines. 69. The columbine leaved night ſcented African *geranium* with pale red flowers. 70. The night ſcented anemone leaved African *geranium*, with deep red flowers. 71. The red flowered night ſcented African *geranium* with narrower anemone like leaves. 72. The gooſeberry leaved African *geranium* with very ſmall red flowers. 73. The larger coriander leaved red flowered African *geranium*. 74. The leſſer coriander leaved African *geranium* with fleſh coloured flowers. 75. The Indian ſad looking night ſcented *cranes bill*. 76. The tuberoſe rooted night ſcented African *cranes bill* with woolly and hairy parſnip-like broad leaves, and pale yellow flowers. 77. The tuberoſe rooted night ſcented *cranes bill* with narrower woolly parſnip-like leaves. 78. The marſh mallow leaved African *cranes bill* with ſmall flowers. *Tourn.* Inſt. p. 266, ſeq.

The common wild ſorts of this plant, and thoſe alſo which are brought to the curious from the colder climates are hardy enough, and require little care; but the African ſpecies, and the others from hot countries, which make ſo very beautiful a figure in our green houſes, require great care in their culture and propagation.

Theſe are to be raiſed by planting cuttings of them in any of the ſummer months in beds of light rich earth, and carefully ſhading them from the ſun, and giving them frequent, but gentle waterings, till they are well rooted. The mats with which theſe beds are covered are to be taken off in gentle ſhowers, and always in the hot weather at nights, that the plants may have the benefit of the dew. They ſhould remain about two months in this bed, by which time they will have taken root. Some pots of about ſeven inches wide are then to be filled with light earth, and the plants are to be carefully taken up with as much as poſſible of their own earth about them, and planted ſeverally in the middle of theſe pots; when they are to be ſet in a ſhady place, and watered at times till they have taken root. When they are well rooted they ſhould be ſet in a more expoſed place to harden them, and ſhould ſtand out till the middle of October; but when the mornings begin to grow froſty they muſt be removed into the green-houſe, and then placed as near the windows as poſſible, and the windows ſhould be opened upon them till the weather is very cold. During the winter they muſt be frequently watered a little at a time, and their dead leaves ſhould be pulled off. They muſt not ſtand under the ſhade of other plants, nor need any artificial heat. Some raiſe them alſo from ſeeds, which muſt be carefully preſerved and ſown on fine light earth, and when they come up be tranſplanted into other beds of rich earth, with dung at the bottom. They muſt be ſet here at about ſix inches aſunder, and in July they ſhould be tranſplanted into pots, and from that time managed exactly as thoſe raiſed by cuttings. *Miller*'s Gard. Dict.

Geranium ſtands recommended as one of the greateſt vulneraries and abſtergents of the vegetable world; and is highly extolled for its power of ſtopping profluvia of the menſes, and hæmorrhages of all kinds. Experience confirms the truth of this, eſpecially among the poor people in the country; and it were to be wiſhed that the plant could be brought into more eſteem in the ſhops, where at preſent it is diſregarded.

GERANOS, Γερανος, in antiquity, a remarkable dance performed in the feſtival called *delia*. See DELIA.

GERARDIA, in botany, the name of a genus of plants the characters of which are theſe. The perianthium is compoſed of one leaf divided into five ſegments, and remains after the flower is fallen. The flower is of the labiated kind, and compoſed only of one leaf. The tube is longer than the cup, and of a cylindric figure. The upper lip is erect, plain broad, obtuſe and emarginated. The lower lip is bent backwards, and divided into three ſegments. The two ſide ones are long and emarginated, and the middle one ſhorter and bifid. The ſtamina are four filaments ſomewhat ſhorter than the flower, and two of theſe are a little ſhorter than the other two. The antheræ are ſmall. The germen of the piſtil is ſmall and oval. The ſtyle is ſimple and ſhort, and the ſtigma is obtuſe. The fruit is an oval bivalve capſule, containing two cells, and opening at the bottom; when ripe the ſeeds are ſingle and oval. *Linnæi* Gen. Plant. pag. 289. *Plumier*, Gen. 12.

GERBERA, in botany, the name of a genus of plants, the characters of which are theſe. The common cup is imbricated, and compoſed of long, narrow, and erect leaves. The compound flower is radiated. The diſk is compoſed of a vaſt number of hermaphrodite flowers, and the radius is compoſed of female flowers about twenty in number. The hermaphrodite flowers are each compoſed of one petal, and are tubular, erect, and divided into three ſegments, one of which is twice as wide as the others. The female flowers alſo conſiſt of each one petal, and are very long, and each divided into three ſegments. In the hermaphrodite flowers the ſtamina are five capillary, and very ſhort filaments, and the antheræ are oblong, and grow together into a ſort of cylinder. In the female flowers there are alſo five ſubulated and erect filaments; but theſe have no antheræ at their ends. The germen of the piſtil in the hermaphrodite flowers ſtands below the flower, and the ſtyle is ſingle, and of the length of the ſtamina, and the ſtigma bifid; in the female the germen is of the ſame ſhape, but ſomewhat ſmaller. The cup remains after the flower is fallen and contains the ſeeds: the hermaphrodite and the female flowers both produce ſeeds, which are in both of the ſame figure, being oblong and ſingle, and terminated by a ſimple long capillary thread of down. The receptacle is naked. *Linnæi* Gen. Plant. p. 385.

GERFALCON (*Cycl.*)—This is naturally a very bold, wild, and fierce bird, and is therefore very difficult to be reclaimed; but when that is done, it proves one of the very beſt kinds, and will fly at almoſt any thing. The beak of the *gerfalcon* is always blue, and the claws are remarkably long and ſtrong.

In going up to their gate, as the ſportſmen expreſs it, this bird does not hold the ſame ſort of courſe that others do, but immediately climbs up upon the train on ſight of the bird, and as ſoon as they have reached her, they immediately make the attack, and generally pull her down at the firſt encounter; but if not, always at the ſecond or third. This ſort of hawk is to be fed and rewarded like the others. It is of a very ſly and crafty nature, and is ſo ſlothful, that it loves to keep the caſting a long time; therefore inſtead of cotton, it is proper to give them ſometimes a caſting of tow, and to keep them ſharp ſet. As to the reclaiming this ſort of hawk, it is only to be done by gentleneſs and kindneſs; and when ſhe has been taught to be turned looſe, ſhe is next to be learned to come to the pelts of hens or other fowl. But ſhe muſt never be ſuffered to taſte any living fleſh, for that will be apt to draw away her love from the hand and voice. Whenever ſhe eats the falconer muſt be cloſe to her, and muſt make her eat the choiceſt pieces out of his hand. There is great care to be taken in the making theſe birds, for as they are made at firſt, ſo they are for ever; and it is a neceſſary caution, with birds of this bold and fierce nature, not to hurry over the buſineſs, but to repeat the ſame thing very often till it is perfectly fixed.

GERM, among botaniſts, the ſame with *Bud*. See BUD.

GERMANDER, *Chamædrys*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of the labiated kind, but wants the upper lip, the ſtamina ſupplying its place. The lower one is divided into five ſegments, the middle one of which is hollowed like a ſpoon, and uſually bifid, the others ſtand oppoſite to one another in the neck of the flowers. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and is ſurrounded with four embryos, which are finally ripened into as many ſeeds in the cup of the flower. To theſe marks it may be added, that the flowers of the *germanders* grow in the alæ of the leaves, and that the cups are tubular.

The ſpecies of *germander*, enumerated by Mr. Tournefort, are theſe.

1. The great creeping *germander*, eſteemed the true *chamædrys*. 2. The great creeping *germander* with flowers, ſome red, and ſome white on the ſame plant. 3. The ſmall creeping *germander*. 4. The ſmall creeping *germander* with ſnow white flowers. 5. The hairy alpine *germander*. 6. The hoary marſh *germander*, which is the ſcordium of the ſhops. 7. The ſhrubby baum-leaved wild *germander*. 8. The variegated ſhrubby baum-leaved wild *germander*. 9. The ſhrubby balm-leaved *germander* with ſmaller leaves, and a ſmell like that of apples. 10. The purple flowered ſmall baum-leaved ſhrubby *chamædrys*. 11. The ſhrubby *germander*, commonly called teucrium, or tree *germander*. 12. The ſhrubby alpine *germander* with ſhining leaves. 13. The Spaniſh ſhining ſhrubby *germander*. 14. The purple flowered Cretic ſhrubby *germander*. 15. The narrow leaved, many flowered Spaniſh *germander*. 16. The ſmall, hoary, ſtone, Spaniſh *germander*. 17. The Canada *germander* with nettle like leaves hoary underneath. 18. The hoary, ſhrubby ſea *germander* with ſpear pointed leaves. 19. The jagged leaved *germander*. 20. The ſweet ſcented prickly *germander* with divided leaves. *Tourn.* Inſt. p. 204.

Authors have added ſome other plants, but that very improperly, to this genus. Such are, 1. The alpine *germander*, with cyſtus like flowers of Caſpar Bauhine, which is a ſpecies of caryophyllata. 2. The ſtone alpine *germander* of the ſame author, which is a ſpecies of Veronica. 3. The ſpiked ſingle ſtalked *germander* of the ſame author, which is a ſpecies of pedicularis, and ſome other plants called baſtard *germanders*, which all belong to the Veronica claſs. *Tourn.* Inſt. p. 205. The common *germander* is diuretic and diaphoretic. It is an ingredient in many of the compoſitions of the ſhops, and is given in infuſion in fevers, in ſuppreſſions of urine in the ſcurvy, the gout and jaundice, and where the uſe of it is continued ſufficiently, generally with ſucceſs.

Water GERMANDER, *ſcordium*, in medicine. See SCORDIUM.

GERMANDER *Galls*, in natural hiſtory, a term uſed by thoſe who have treated on the ſubject of *galls*, to expreſs a peculiar vitiated ſtate of a part of this plant. The ſtalks and leaves of other plants, and the bark and branches of trees, are the parts which furniſh theſe ſorts of excreſcences, and being vitiated by the biting and ſucking of ſome inſects, ſwell out in the parts where ſo injured into a protuberance; but in this plant it is the flower that becomes thus vitiated, and forms what is properly enough called a flower-gall. Mr. Bernard Juſſieu was the firſt who obſerved this ſingular fact. He obſerved, that many of the flowers of this plant never opened like the reſt, and yet grew much larger, and that theſe always contained an inſect. Other galls owe their origin to the worms of ſeveral kinds of flies, or to the little pucerons; but this is produced by an inſect not known before to have any ſuch power. A ſmall and very beautiful kind of bug of a grey colour, with ſpots of white and brown, depoſits its eggs in the calyx, or cups of this flower.

Theſe ſoon hatch into ſo many ſmall worms, which feeding on the juices of the bud of the flower, eat their way into its cavity; when lodged there they remain perfectly at eaſe, and continuing to feed on the petal, the flower grows like all other parts of vegetables, injured in the ſame manner, to a much larger ſize than it otherwiſe would have done, but never opens into a flower.

While all the reſt of the flowers are open, thoſe thus injured, which are uſually ſeveral on each plant, form ſo many red tubercles, which being opened, are always found to contain either the worm of the bug, or its chryſalis, or at the utmoſt, the remains of that ſtate from which the creature has eſcaped in its perfect ſtate. *Reaumur*, Hiſt. Inſect. Vol. 6. p. 195.

GERMINATION, (*Cycl.*) the firſt budding of plants from the ſeed. It has been a general opinion, that the air was a very neceſſary agent in the *germination* of plants; but Mr. Homberg attempted many years ſince to prove before the academy at Paris, that it was an erroneous one. He obſerves, that the *germination* of a plant is no other than the ſwelling of its parts, which are all ready formed in the ſeed, and that this ſwelling and extenſion of them, is no other than the ſame with that of a ſponge, when it is made to imbibe water. Whence he deduced, that as a ſponge, if wetted with water, would ſwell as well *in vacuo*, as in the air; ſo doubtleſs a plant would ſwell in the ſeed, that is, would *germinate* in the ſame manner in or out of the air: that therefore ſeeds ſown in the earth muſt ſwell and *germinate* as well *in vacuo*, as in open air; and conſequently, that the air contributed nothing to the effect.

Reaſon thus far anſwering for his ſentiments on this ſubject by analogy, he determined to bring the fact to experiment, which he did thus. He procured a wooden box, four inches long and two wide, he made five compartments in this box, filled all of them with garden mould, and ſowed in them five ſeveral ſorts of ſeeds, *viz.* Purſlain, creſſes, lettice, chervil and parſley; he put forty ſeeds into each compartment. On the firſt day of May 1693. he put this box into the receiver of an air pump, emptied of its air in the moſt careful manner poſſible; he every third day took out the box to water the earth, and returned it into the receiver as quick as poſſible, and every time emptied out all the air again as nicely as poſſible; and beſide this, he every morning emptied out the air that had come in with the water uſed to moiſten the earth.

That he might be able to judge perfectly of the *germination* of theſe ſeeds, and of others which had the common advantage of air, he ſowed the ſame number of the ſame ſeeds in a box of the ſame dimenſions, which he left expoſed to the open air, and watered it every third day as he did the others; he alſo expoſed this laſt box at times to the ſun, but this could not be often done, the May that year proving a very cloudy one. In the box expoſed to the air the *germination* of the creſſes appeared on the fifth day of May, that of the lettice on the ſeventh, of the purſlain on the eighth, of the chervil on the eleventh, and that of the parſley on the fourteenth. All the ſhoots continued to grow, except thoſe of the purſlain, which the uncommon cold of that ſeaſon killed. In the box kept in the receiver, there appeared no *germination* during the nine firſt days; but on the tenth there appeared ſome germs of the creſſes and ſome of the purſlain. The lettice did not appear to *germinate* till the fifteenth, and there were but four germs of all the ſeeds which were ſown; but in three days time theſe grew to an inch in height, yet the two firſt leaves never expanded themſelves, nor encreaſed in bulk. The caſe was the ſame with the creſſes and

and the purſlain, but with this difference, that the lettice leaves were not nearly of the ſize of thoſe growing in the open air; whereas thoſe of the purſlain and creſſes were of the ſame ſize. The purſlain lived only one day in the receiver, and the creſſes only five; after this their leaves became black, and flaccid; the lettice continued vigorous fifteen days. In all this time the chervil and parſley had not *germinated* at all, on which Mr. Homberg was deſirous to ſee what was the ſtate of thoſe ſeeds, which had not *germinated*, under the ſame circumſtances in which others had, and whether they would *germinate* in the open air after they had refuſed to do it in the exhauſted receiver; but that the trial might be confined to the ſame circumſtances only, he determined to keep them cloſed up in the ſame receiver, only filling it with air. He let in the air on the twenty fifth of May, and carefully cloſed the veſſel; and on the twenty ſeventh, there appeared ſome *germinations* of chervil, and ſome freſh ones of purſlain and creſſes, and on the thirty firſt of the ſame month there appeared above twenty *germinations* of the parſley. The following days produced no new *germinations*; and Mr. Homberg, to try whether thoſe ſhoots which had appeared in a cloſe air would live in an open one, removed the box out of the receiver into the open air, when in a few days all the ſhoots withered and decayed, though carefully watered every evening.

There happened alſo a remarkable change in the earth in the box on this expoſure; it was of the fine mould from the king's garden, and for the firſt five days it ſhewed no appearance of change, but on the ſecond watering on the ſixth day, when the air came to be exhauſted from among that water, the earth fermented as new leavened paſte or dough, and ſwelled over the ſides of the box, part of it falling into the receiver. The ſame thing after this happened from every watering and exhauſting, and what is very remarkable, the earth after this felt ſoft and fatty in the handling; whereas before it was rough and coarſe to the touch. This propably happened from the diſuniting of certain particles in the earth, which while held together made large granules, and gave a coarſeneſs to the touch.

Another remarkable change in the earth was, that on the eighth day after its being put into the receiver, it appeared to have changed colour, and when held in ſome lights appeared grey, and of a ſhining gloſſy look. On examining into the cauſe of this appearance by the microſcope, the whole ſurface of the earth was ſeen to be covered with fine ſlender filaments like thoſe of the ſpider's web. The whole earth appeared as it were mouldy, by means of this covering of the threads, ſome of which aroſe from little eminences on the ſurface, others from other parts, and croſſing one another they formed a web of ſuch ſort, that when the earth was watered, the wet would often roll about upon them in large drops for ſome time before it broke their texture to get in. This was at firſt ſuſpected to be nitre ſhooting out of the earth, but in reality it at length appeared to be a fungous ſubſtance which vegitated there, and which when once cleared off, never renewed itſelf again. So long as the ſhoots of the ſeeds in the exhauſted receiver continued to be kept there, there always ſtood a drop of water upon the top of each, which as it encreaſed in ſize from time to time, run down the ſides of the ſhoot and entered into the earth; but as ſoon as this was done, there was always another immediately formed on the top of the ſhoot.

Though theſe experiments did not ſucceed ſo far as might have been expected in the growth of the ſhoots, yet they prove ſufficiently, that neither the elaſticity, nor the weight of the air, are neceſſary to the *germination* of ſeeds, for here were plainly ſome ſeeds which did *germinate in vacuo*. It muſt be allowed that the air however, though not abſolutely an eſſential agent, proves an accidental one in this effect, ſince a great number of ſeeds which had not *germinated* in the exhauſted receiver, did afterwards *germinate* when the air was admitted to them. The reaſon Mr. Homberg gives for the number of ſeeds miſcarrying, ſeems a very juſt one: he obſerves, that there is always a little air contained in every ſeed, that this expands and dilates itſelf much more readily *in vacuo*, where there is nothing to reſiſt its motions than in the open air, by which it is preſſed on every ſide. If therefore a ſeed be ſown in the open air, this excluded air meeting with reſiſtance from without, can only expand itſelf in a ſlow and regular manner, ſo as to aſſiſt in the explicating the fibres of the included plant; whereas when the ſeed is ſown *in vacuo*, the included air burſts out at once with great violence, and uſually eſcapes without doing its office in vegetation. If in the violence of its getting out it tears the principal veſſels of the young plant, which doubtleſs is often the caſe, then the ſeeds muſt periſh; but if it eſcapes without injuring them, then the ſeeds may *germinate* without it. Thus it is that ſome ſeeds *germinate* in the exhauſted receiver. This is the reaſon that they *germinate* but weakly; and that ſo few of the general number do *germinate* at all. Mem. Acad. Par. 1693.

Metallic GERMINATION. Borrichius, in his hiſtory of chemiſtry, gives us ſome very remarkable accounts of theſe ſort of *germinations*, and of one in particular, for which he quotes a witneſs, as he ſays, of ſo great veracity and ſo little credulity, that he might be abſolutely depended on. This perſon he tells us living at Bruſſels, was viſited by a ſtranger, who entruſted him with a ſmall quantity of powder of about the weight of a barley corn, with which the operation of one of theſe *germinations* was to be performed, and which was afterwards to be returned to him. Three or four pound of river water was to be put into a glaſs, and this powder being put into it, the whole was to be ſhaken together that ſome part of the powder might be diſſolved in the water; after this the water was to be decanted into a clear veſſel, and the powder dried. The ſtranger came again for his powder, and bidding the perſon who had the water thus impregnated, to put ſome ounces of crude mercury into it, he took his leave. The mercury was put in, eight ounces of it, and immediately after there was ſeen the beginning of the *germination*. The quickſilver on all parts ſhot out multitudes of filaments, or thread like branches of ſilver, which by degrees extended themſelves all over the veſſel, and even roſe above the ſurface of the water; the liquor being poured off, the quickſilver was all found to be converted into pure ſilver, which ſtood the ſevereſt teſts of fire, and was acknowledged ſilver by the ſilver-ſmiths of the place. *Borrichius* de Ortu Chemiæ.

More quickſilver was added to the water, and procured a ſecond wood of pure ſilver, and ſo on to the ſixth time; but the liquor grew more languid every time, and at length had no more of this virtue. Stories like this have deluded many people into the ſacrificing their whole time and fortunes in the ſearch of ſuch *germinations* and tranſmutations; but there is yet no proof of the truth of any thing of this kind ever having been performed. We ſee that Borrichius, who is one of the ſtrongeſt advocates for this opinion among the chemical writers, gives the ſtory only at ſecond hand; and had he ſaid that himſelf had ſeen it, it would have ſcarce been credible without ſome further proofs. Phil. Tranſ. N°. 39.

GEROCOMIA, a term uſed by the antients for that ſort of medicinal practice, which treated of the proper regimen to be obſerved in old age.

GERRES, GERULI, or GIROLI, in ichthyology, names given by the Venetians to a fiſh common in that part of the world. It is the Smaris, or Mæna alba of authors. Artedi very judiciouſly makes it a ſpecies of the ſparus, and diſtinguiſhes it from the others, by its having a black ſpot on each ſide, and the pectoral and tail fins red.

GERRHA, γερρα, among the Greeks, wicker hurdles, reſembling the Roman *vineæ*, which the ſoldiers held over their head to ſhelter themſelves. *Potter*, Tom. 2. p. 93.

GERSA, a word uſed by ſome authors for ceruſs, or white lead. See CERUSS.

GERYON, a name given by ſome of the affected chymical writers to quickſilver.

GESOR, a name uſed by ſome of the Arabian writers for galbanum. See GALBANUM, *Cycl.*

GESTATION, *Cycl.* the ſtate of a woman with child. See PREGNANCY.

GESTU *&* *fama*, an antient writ, where a perſon's good behaviour was impeached, now out of uſe. *Lamb.* Eiren. Lib. 4. c. 14.

GET-*off*, among bowlers. See BOWLING.

GETHYLLIS, in botany, the name of a genus of plants, deſcribed by Linnæus, the characters of which are theſe. The cup is a ſpatha of a lanceolated form, compoſed of one membranaceous inflated leaf, and containing only one flower. The flower conſiſts of one petal. Its tube is extremely ſlender and long. The limb is plain, and is divided into ſix equal ſegments of a lanceolated form, which are of about a third part of the length of the tube. The ſtamina are either twelve or eighteen ſetaceous filaments ſtanding in the cup. They are ſhort and erect, and the antheræ are oblong. The Germen of the piſtil is oblong, and ſtands low in the ſpatha under the baſe of the flower. The ſtyle is capillary, and of the length of the ſtamina, and the ſtigma is trifid and obtuſe. The fruit is an oblong, inflated, triangular capſule, containing three cells in which are numerous ſeeds. *Linnæi* Gen. plant. p. 206.

GEUM, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral petals or leaves diſpoſed in a circular form. From the cup there ariſes a two pointed piſtil which afterwards becomes an oblong and double headed fruit, bicapſular and filled with very ſmall ſeeds.

The ſpecies of *geum* enumerated by Mr. Tournefort are theſe. 1. The larger round leaved *geum*, called by ſome round leaved mountain ſanicle. 2. The ſmaller round leaved *geum*. 3. The rounded leaved *geum* with the piſtil of the flower of a pale colour. 4. The rounded and finely crenated leaved *geum* with the piſtil of the flower of a fine red. 5. The larger rounded leaved *geum* with the piſtil of the flower red. 6. The ſmaller roundiſh leaved *geum* with the piſtil of the flower red. 7. The *geum* with the ſmalleſt rounded leaves. 8. The ſmaller marſh *geum* with oblong crenated leaves. 9. The ſmall branched Portugueze marſh

geum,

GERBERA, in botany, the name of a genus of plants, the characters of which are these. The common cup is imbricated, and composed of long, narrow, and erect leaves. The compound flower is radiated. The disk is composed of a vast number of hermaphrodite flowers, and the radius is composed of female flowers about twenty in number. The hermaphrodite flowers are each composed of one petal, and are tubular, erect, and divided into three segments, one of which is twice as wide as the others. The female flowers also consist of each one petal, and are very long, and each divided into three segments. In the hermaphrodite flowers the stamina are five capillary, and very short filaments, and the antheræ are oblong, and grow together into a sort of cylinder. In the female flowers there are also five subulated and erect filaments; but these have no antheræ at their ends. The germen of the pistil in the hermaphrodite flowers stands below the flower, and the style is single, and of the length of the stamina, and the stigma bifid; in the female the germen is of the same shape, but somewhat smaller. The cup remains after the flower is fallen and contains the seeds: the hermaphrodite and the female flowers both produce seeds, which are in both of the same figure, being oblong and single, and terminated by a simple long capillary thread of down. The receptacle is naked. *Linnæi* Gen. Plant. p. 385.

GERFALCON (*Cycl.*)—This is naturally a very bold, wild, and fierce bird, and is therefore very difficult to be reclaimed; but when that is done, it proves one of the very best kinds, and will fly at almost any thing. The beak of the *gerfalcon* is always blue, and the claws are remarkably long and strong.

In going up to their gate, as the sportsmen express it, this bird does not hold the same sort of course that others do, but immediately climbs up upon the train on sight of the bird, and as soon as they have reached her, they immediately make the attack, and generally pull her down at the first encounter; but if not, always at the second or third. This sort of hawk is to be fed and rewarded like the others. It is of a very sly and crafty nature, and is so slothful, that it loves to keep the casting a long time; therefore instead of cotton, it is proper to give them sometimes a casting of tow, and to keep them sharp set. As to the reclaiming this sort of hawk, it is only to be done by gentleness and kindness; and when she has been taught to be turned loose, she is next to be learned to come to the pelts of hens or other fowl. But she must never be suffered to taste any living flesh, for that will be apt to draw away her love from the hand and voice. Whenever she eats the falconer must be close to her, and must make her eat the choicest pieces out of his hand. There is great care to be taken in the making these birds, for as they are made at first, so they are for ever; and it is a necessary caution, with birds of this bold and fierce nature, not to hurry over the business, but to repeat the same thing very often till it is perfectly fixed.

GERM, among botanists, the same with *Bud*. See BUD.

GERMANDER, *Chamædrys*, in botany, the name of a genus of plants, the characters of which are these. The flower consists of one leaf, and is of the labiated kind, but wants the upper lip, the stamina supplying its place. The lower one is divided into five segments, the middle one of which is hollowed like a spoon, and usually bifid, the others stand opposite to one another in the neck of the flowers. The pistil arises from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and is surrounded with four embryos, which are finally ripened into as many seeds in the cup of the flower. To these marks it may be added, that the flowers of the *germanders* grow in the alæ of the leaves, and that the cups are tubular.

The species of *germander*, enumerated by Mr. Tournefort, are these.

1. The great creeping *germander*, esteemed the true *chamædrys*. 2. The great creeping *germander* with flowers, some red, and some white on the same plant. 3. The small creeping *germander*. 4. The small creeping *germander* with snow white flowers. 5. The hairy alpine *germander*. 6. The hoary marsh *germander*, which is the scordium of the shops. 7. The shrubby baum-leaved wild *germander*. 8. The variegated shrubby baum-leaved wild *germander*. 9. The shrubby balm-leaved *germander* with smaller leaves, and a smell like that of apples. 10. The purple flowered small baum-leaved shrubby *chamædrys*. 11. The shrubby *germander*, commonly called teucrium, or tree *germander*. 12. The shrubby alpine *germander* with shining leaves. 13. The Spanish shining shrubby *germander*. 14. The purple flowered Cretic shrubby *germander*. 15. The narrow leaved, many flowered Spanish *germander*. 16. The small, hoary, stone, Spanish *germander*. 17. The Canada *germander* with nettle like leaves hoary underneath. 18. The hoary, shrubby sea *germander* with spear pointed leaves. 19. The jagged leaved *germander*. 20. The sweet scented prickly *germander* with divided leaves. *Tourn.* Inst. p. 204.

Authors have added some other plants, but that very improperly, to this genus. Such are, 1. The alpine *germander*, with cystus like flowers of Caspar Bauhine, which is a species of caryophyllata. 2. The stone alpine *germander* of the same author, which is a species of Veronica. 3. The spiked single stalked *germander* of the same author, which is a species of pedicularis, and some other plants called bastard *germanders*, which all belong to the Veronica class. *Tourn.* Inst. p. 205. The common *germander* is diuretic and diaphoretic. It is an ingredient in many of the compositions of the shops, and is given in infusion in fevers, in suppressions of urine in the scurvy, the gout and jaundice, and where the use of it is continued sufficiently, generally with success.

Water GERMANDER, *scordium*, in medicine. See SCORDIUM.

GERMANDER *Galls*, in natural history, a term used by those who have treated on the subject of *galls*, to express a peculiar vitiated state of a part of this plant. The stalks and leaves of other plants, and the bark and branches of trees, are the parts which furnish these sorts of excrescences, and being vitiated by the biting and sucking of some insects, swell out in the parts where so injured into a protuberance; but in this plant it is the flower that becomes thus vitiated, and forms what is properly enough called a flower-gall. Mr. Bernard Jussieu was the first who observed this singular fact. He observed, that many of the flowers of this plant never opened like the rest, and yet grew much larger, and that these always contained an insect. Other galls owe their origin to the worms of several kinds of flies, or to the little pucerons; but this is produced by an insect not known before to have any such power. A small and very beautiful kind of bug of a grey colour, with spots of white and brown, deposits its eggs in the calyx, or cups of this flower.

These soon hatch into so many small worms, which feeding on the juices of the bud of the flower, eat their way into its cavity; when lodged there they remain perfectly at ease, and continuing to feed on the petal, the flower grows like all other parts of vegetables, injured in the same manner, to a much larger size than it otherwise would have done, but never opens into a flower.

While all the rest of the flowers are open, those thus injured, which are usually several on each plant, form so many red tubercles, which being opened, are always found to contain either the worm of the bug, or its chrysalis, or at the utmost, the remains of that state from which the creature has escaped in its perfect state. *Reaumur*, Hist. Insect. Vol. 6. p. 195.

GERMINATION, (*Cycl.*) the first budding of plants from the seed. It has been a general opinion, that the air was a very necessary agent in the *germination* of plants; but Mr. Homberg attempted many years since to prove before the academy at Paris, that it was an erroneous one. He observes, that the *germination* of a plant is no other than the swelling of its parts, which are all ready formed in the seed, and that this swelling and extension of them, is no other than the same with that of a spunge, when it is made to imbibe water. Whence he deduced, that as a spunge, if wetted with water, would swell as well *in vacuo*, as in the air; so doubtless a plant would swell in the seed, that is, would *germinate* in the same manner in or out of the air: that therefore seeds sown in the earth must swell and *germinate* as well *in vacuo*, as in open air; and consequently, that the air contributed nothing to the effect.

Reason thus far answering for his sentiments on this subject by analogy, he determined to bring the fact to experiment, which he did thus. He procured a wooden box, four inches long and two wide, he made five compartments in this box, filled all of them with garden mould, and sowed in them five several sorts of seeds, *viz.* Purslain, cresses, lettice, chervil and parsley; he put forty seeds into each compartment. On the first day of May 1693. he put this box into the receiver of an air pump, emptied of its air in the most careful manner possible; he every third day took out the box to water the earth, and returned it into the receiver as quick as possible, and every time emptied out all the air again as nicely as possible; and beside this, he every morning emptied out the air that had come in with the water used to moisten the earth.

That he might be able to judge perfectly of the *germination* of these seeds, and of others which had the common advantage of air, he sowed the same number of the same seeds in a box of the same dimensions, which he left exposed to the open air, and watered it every third day as he did the others; he also exposed this last box at times to the sun, but this could not be often done, the May that year proving a very cloudy one. In the box exposed to the air the *germination* of the cresses appeared on the fifth day of May, that of the lettice on the seventh, of the purslain on the eighth, of the chervil on the eleventh, and that of the parsley on the fourteenth. All the shoots continued to grow, except those of the purslain, which the uncommon cold of that season killed. In the box kept in the receiver, there appeared no *germination* during the nine first days; but on the tenth there appeared some germs of the cresses and some of the purslain. The lettice did not appear to *germinate* till the fifteenth, and there were but four germs of all the seeds which were sown; but in three days time these grew to an inch in height, yet the two first leaves never expanded themselves, nor encreased in bulk. The case was the same with the cresses

might be to the people at that time, it was greatly confirmed afterwards by the diſcovery of two entire ſkeletons of elephants, found near the ſame place, which had both ſuch teeth fixed in their jaws. A ſecond ſkeleton of an imaginary *giant* was dug up near Tunis in 1630, and a tooth of it being ſent to the learned Pireſc, he took the impreſſion of it in wax, and upon comparing it with the tooth of an elephant ſhewn near the place, he found it to be of the very ſame ſhape and ſize. Philoſ. Tranſ. N°. 404. p. 514.

Lambecius gives an account of a tooth of a *giant*, ſent from Conſtantinople to Vienna, and offered to ſale to the emperor, at the price of two thouſand rix dollars. It was ſaid to have been found in a large ſubterranean cavern, over which was an inſcription in the Chaldaic language, ſignifying here lies the *giant* Og. This was pretended therefore to be a tooth of the *giant* Og, king of Baſhan, mentioned in the ſcriptures, but the whole ſtory being found to be a fable, the tooth was ſent back again. This was doubtleſs the tooth of an elephant like all the others. Sir Hans Sloane gives a very accurate and learned account of ſeveral other miſtakes on this ſubject, which we refer to in the above-mentioned Tranſaction.

GIANT's *Cauſeway*, a name given by the common people of the county of Antrim in Ireland, to a vaſt quantity of that kind of black marble, called baſaltes, which ſtands in columns, as is natural to that marble, and runs out a great way into the ſea.

The ignorance of the vulgar in the nature of this ſtone, has occaſioned this great pile of it to be ſuppoſed artificial, and the work of I know not what *giants*, once inhabitants there. But the truth is, that the baſaltes, in whatever part of the world it is found, is always naturally of this figure. See the article BASALTES.

Whoever conſiders this amazing ſeries of columns in Ireland, will be ſoon convinced no human hands could have formed them; and will find an accuracy in their figures, greater than could have been expected from the moſt curious hand. The length of the ſeveral columns, and their joints ſo regularly placed in ſeries, and the niceneſs of their articulations, by which no ſpace or vacuity is left between, is wonderful.

Nature has been abundantly curious in the ſtructure and formation of animal and vegetable bodies, but the foſſils in general are leſs curiouſly put together; but this *cauſeway* of *baſaltes* ſeems one of the works in this part of the creation, in which her greateſt accuracy has been employed.

The ſingle columns of which this maſs of piles conſiſts are ſometimes octangular, ſometimes of ſeven, or fewer ſides, and when examined, they are found juſt ſuch as muſt neceſſarily be required in the places where they ſtand to fill up between others, ſo as to leave no vacuity. Each of theſe columns is compoſed of a great many ſeries of joints, each of which is ſo well fitted to the place, that the joining appears only a crack, or crevice in the ſtone. Yet theſe are regularly articulated, there being always a ball on one part, and a ſocket in the other to receive it, ſo that the joints cannot ſlip off from one another. The triangular and ſquare columns are fewer in number than the others, but they ſtand principally in the inner part of the large ſeries, and are ſeldom ſeen unleſs ſearched after by a curious eye.

The regular figure of the ſtone compoſing this *cauſeway* is not more wonderful than its quantity. Other figured ſtones, as cryſtals, ſpars, and the remains of animals, ſuch as *entrochi* and *aſteriæ*, are found only ſcattered thinly up and down, but nature has been profuſe in this part of her workmanſhip, the whole country for many miles being full of it, and a vaſt maſs running no one knows how far into the ſea. For beſides what vulgarly goes by the name of the *giant's cauſeway*, which is itſelf of vaſt extent, there are great numbers of the ſame pillars at diſtances in other places.

There are two other ſmaller and imperfect *cauſeways* to the left hand of the great one, and farther in the ſea, a great number of rocks ſhew themſelves at low water, which appear plainly all to conſiſt of the ſame ſort of columns. In going up the hill from the *cauſeway* there are found, in different places, a vaſt number of the ſame columns; but theſe do not ſtand erect, but are laid ſlanting upwards in different angles and directions. Beyond this hill eaſtward alſo, at ſeveral diſtances, there ſtand a great number of the ſame pillars placed ſtrait and erect, and in cluſters of different ſizes. Theſe are ſeen ſcattered as it were over the ſeveral parts of the hills. One parcel of them is much admired, and called by the country people the looms or the organs. It ſtands in an elegant form, and faces the bottom of the hill. The columns, of which this cluſter conſiſts, are fifty in number, and they are ſo nicely put together, that the talleſt ſtand in the middle, and the ſhorter gradually on each ſide of it to the end, ſo that they look like the pipes of a church organ viewed from the front. The talleſt one of all theſe, which ſtands exactly in the center, is forty feet high, and conſiſts of forty four diſtinct joints.

Four miles weſtward of the *giant's cauſeway* ſeveral ranges of tall pillars, of the ſame kind with thoſe of the *cauſeway*, ſhew themſelves in cluſters, and ſmaller piles ſtanding for a long way on the ſides of the rocks. A neighbouring church was built of the ſtone of ſome like pillars found thereabout, and this ſtone on examination proves to be the very ſame with that of the pillars of the *giant's cauſeway*.

The inland pillars differ from thoſe which run into the ſea, and are called the *cauſeway* only in the following particulars; ſome of the inland pillars are much larger than thoſe of the *cauſeway*, being two feet and a half in diameter, and among theſe there are only found ſuch as have three, four, five, and ſix ſides, none of them having yet been found to have ſeven or eight ſides, as many of thoſe of the *cauſeway* itſelf have. And finally theſe inland pillars, though compoſed of as many joints as thoſe of the *cauſeway*, yet have not that curious articulation of the ball and ſocket, but are only joined by the laying one ſmooth ſurface on another; ſo that a joint of a ſingle column may be ſlipped off from the reſt by a conſiderable force preſſing againſt it. There is ſomething like this obſervable alſo in ſome of the columns of the *cauſeway* itſelf; for among the numbers which are jointed by the ball and ſocket, there are ſome which only adhere by being applied ſurface to ſurface. This is found only in a few of the columns, however, and they always ſtand within the cluſters, and are compoſed of leſs than ſeven ſides. In theſe alſo the joint is not made by the application of two horizontal planes, but by ſuch as ſlant, ſo that it looks very like the breaking of an entrochus, or aſteria, or ſome other ſuch ſparry body, of extraneous or animal origin.

Great numbers of the upper ends of the columns which compoſe the *cauſeway* itſelf are hollowed at the top, as if intended to receive another joint with a ball at its end, or as if ſuch a joint had fallen off from them. Theſe hollows are of great uſe to the neighbouring poor, for they make a kind of ſalt pans of them; and thus very eaſily procure themſelves a kind of bay ſalt in ſummer. They fill theſe little baſins with ſea water at high tides, and the heat of the ſun and of the ſtone contributing greatly to the evaporation, as well as the ſhallowneſs of the baſin, the whole humidity is found evaporated in the time of four tides, and they take out the ſalt ready for uſe. The joints, of which theſe pillars conſiſt, are generally convex at one end, and concave at the other; the firſt part ſerving as a ball for the ſocket of the joint next below, and the other as a ſocket for the ball of the joint next above. But this is not an unalterable law in their formation; for there are ſome joints found which are convex at both ends, and others which are concave at both ends, to receive balls, or enter ſockets both ways.

The vaſt height of theſe ſtrait jointed pillars, eſpecially of the more ſlender and perfect ones, is amazing. Forty foot is a very conſiderable height for a pillar, of perhaps leſs than a foot in diameter, yet this is far from being the whole real length of the pillar, for this appears above ground, but what is buried in the earth is not yet known. Some curious people have dug down eight feet at the baſe, and found the column run in the ſame ſhape and regularity to that depth; and there has appeared no room to doubt of its having gone in reality much farther.

The joints, as we ſee the pillars above the ſurface, are uſually as many in number, as the pillar is feet high; but they are not regularly each of a foot long, for they are ſhorteſt at the upper part of the columns, and run gradually longer and longer as they approach the baſe. This is obſerved both in the inland columns, and in thoſe of the *cauſeway*; but though the length of the joints differs, their convexities and hollows are much the ſame in all parts of the column.

It is to be obſerved, that where the top of any pillar ſeems compleat, and no part to have been broken off, the ſummit of the topmoſt joint is uſually flat and ſmooth, nature having provided no convexity or cavity in a part where it had no uſe.

There ſeems a very great difficulty to conceive by what means the ſtony joints, ſo bulky and ponderous, and ſo perfectly diſtinct, and diſcontinued bodies from one another, could arrive at the places where they now are placed, or be carried to the tops of ſuch high columns; but when we conſider many other natural phænomena, we ſhall find ſo many things equally wonderful, that this will not appear the leſs a work of nature becauſe beyond our comprehenſion.

The internal ſubſtance of the ſtone compoſing theſe columns, is extremely hard and compact. Its greet, or grain is ſo very fine, that the eye does not perceive it, unleſs examined very nicely, and that in the ſurface of a piece newly broken. It then ſhews itſelf like a very fine glittering ſand, thickly interſperſed among a more opake matter; the whole is heavier than almoſt any other ſimple ſtone; yet it contains not the leaſt particle of any metal ſo far as has been yet diſcovered. It is the pureſt and moſt homogene of any ſtone of this country; having no extraneous matter, no foſſils of the animal kind in it, ſuch as ſhells, entrochi, and the like; which are well known to be very common in the various ſtrata of ſtone, in Ireland, and in many other parts of the world. Marbles, in general, are very ſubject alſo to cracks, which when filled up as they uſually are with ſparry matter,

matter, make a ſort of white veins; but ſuch cracks and veins are not to be ſeen in the marble of theſe columns.

Theſe obſervations naturally lead us to an analogy between this marble and cryſtal in their origin and formation, as the columns of cryſtal are alike pure and homogeneous, alike of a regularly angular figure, and both are alike free from veins, cracks, and extraneous ſubſtances. See Philoſ. Tranſ. N°. 199, 212, 241. *Lowth.* Abrid. Vol. 2. p. 511. ſeq. See alſo the article TOUCHSTONE.

GIAR *Alnabar*, in botany, a name given by Aviſenna, Serapio, and the reſt of the Arabian writers to the potamogeiton of thoſe times. This is tranſlated by ſome the water ruſh, but that is founded on an error; it is certain that the plant thus called by the Arabians, was very different from the potamogeiton of our times. Aviſenna tells us it had flowers reſembling thoſe of the water lily; and it ſeems either to have been the ſagitta aquatica or water arrow head, or elſe the butomus, or ſome of the ſmaller ſpecies of nymphæa.

GIAROLA, in zoology, the name of a bird of the lark kind, remarkable for its very long heel. It is of the ſize of the common lark. Its head, neck, back, and wings, are of a mottled colour reſembling that of the quail. The general colour of the feathers is a cheſnut brown, and their edges are variegated with white, yellow, and red; the back part of its head has a ſort of crown or ring of white feathers. Its belly is white; its tail is ſo ſhort that it ſeems to have none; it is biſid however, and is elegantly variegated with cheſnut colour and white. *Aldrovand.* de Avibus. Lib. 17. Cap. 39.

GIAROLO, in zoology, a name by which a ſmall bird of the ſnipe kind, remarkable for its white tail, is known in the markets of Italy. It very much reſembles the bird we call in Engliſh the ſtint, but its beak is broad at the baſe, and tapers to a point, and its legs are thicker and ſhorter. It is not known among authors by any Latin name, except that Aldrovandus has called it the *cinclus tertius*, and cinclus is a very indeterminate name, being applied by different authors to ſeveral different birds. *Aldrovand.* Lib. 20. Cap. 56. See CINCLUS and STINT.

GIBBOUS, (*Cycl.*) crooked or hump-backed. *Gibboſity* is a preternatural incurvation of the *ſpina dorſi* either backward, or on one ſide. Infants are more ſubject to this diſorder than adults, and it oftner proceeds from external, than from internal cauſes. A fall, blow, or the like violence frequently thus diſtorts the tender bones of infants. When it proceeds from an internal cauſe, it is generally from a relaxation of the ligaments that ſuſtain the ſpine, or a caries of its vertebræ; though the ſpine may be inflected forward, and the back thrown out, by a too ſtrong and repeated action of the abdominal muſcles; and this if not timely redreſſed, uſually grows up and fixes as the bones harden, till in adults it is totally irretrieveable: but when the diſorder is recent, and the perſon young, there are ſome hopes of a cure. The common method is by a machine of paſtboard, wood, or ſteel, which is made to preſs principally upon the *gibbous* part, and this by long wearing may ſet all right. The ſurgeons however have a different inſtrument which they call a croſs, much more efficacious though not quite ſo convenient in the wearing; by the uſe of this, the parts are always prevented from growing any worſe, and are often cured. During the application of theſe aſſiſtances, the parts ſhould be at times rubbed with Hungary water, ſpirit of Lavender, and the like, and defended with a ſtrengthening plaſter of oxycroceum, opodeldoc or the like. *Heiſter*'s Surg. P. 2. p. 21.

GIBBOUS *fiſh*, *Gibboſus Piſcis*, in zoology, a name given by Mr. Ray to the fiſh called by the Dutch kromrugh. It is a ſmooth fiſh without ſcales, its belly is white, its fins and tail black. It grows to a conſiderable ſize, ſometimes to four feet. It is caught all over the Eaſt Indies, near the ſea ſhores, and is very firm, and much eſteemed at table. It has its name from the remarkable riſing of its back, which is like that of the pearch, but much higher. *Ray*'s Ichthyolog. Append. p. 4.

GIBUR, a general name given by ſome chemical writers, to all medicines drawn by their art from metallic or mineral ſubſtances.

GIFFT MEHL, the name given by the German chemiſts and metallurgiſts, to the firſt appearance of arſenic, or the grey flowers ariſing from the roaſting of cobalt, and ſticking to the long wooden funnel, which they carry from the furnaces. The grey colour of theſe flowers is occaſioned by the ſmoak of the fuel; and when they are afterwards ſublimed in a cloſe veſſel, the arſenical flowers begin to grow clammy in that part of the veſſel which is laſt made hot by the continuation of the fire, and there form themſelves into a ponderous thick ſublimate.

Nevertheleſs this ſublimate neither runs out, nor gets to the bottom of the veſſel when the fire is encreaſed. A tenacious doughy clammineſs is indeed communicated to arſenic by the fire; but fire alone cannot make it melt, but reſolves it into a ſmoak, which when it can find no way to eſcape, often burſts the veſſels in which it is confined. The yellow arſenic, which has one tenth part ſulphur, is by that mixture much more eaſily formed into a ſolid ſublimate than the white arſenic alone; but the red arſenic, which contains double that quantity of ſulphur, cannot eaſily be formed into a ſublimation by aſcent, becauſe of its extream readineſs to fuſe. The beſt way of preparing this is therefore to raiſe it out of a retort in the large and long neck of which it may be condenſed, and thence fall while yet fluid into the receiver. Arſenic of this kind may be immediately produced out of ſome ſpecies of pyrites without any previous addition; or by mixing a ſulphureous pyrites of the common kind with one of the white ones, or with any other ore of arſenic; and by this proceſs there will be ſeparated an arſenic either yellow or red, according to the ſmaller or larger proportion of the ſulphur in the mixture of the whole. *Cramer*'s Art. of Aſſay. p. 408.

The word *gifft mehl* is German, and ſignifies poiſonous meal or flower.

GIFT, *Donum*, in law, is a conveyance which paſſeth either lands or goods, and is of a larger extent than a grant, being applied to things moveable and immoveable; yet as to things immoveable, when taken ſtrictly, it is applicable only to lands and tenements given in tail; but *gift* and grant are often confounded.

GIGAROS, in botany, a name given by ſome writers to the dracontium.

GIGARTON, the ſtone or kernel of a grape or raiſin. Ægineta obſerves, that grape-ſtones are drying and refrigerating; and the ſtones of raiſins, on analyſis, afford an acid ſpirit, and empyreumatic oil, and as ſome ſay, a very conſiderable quantity of a volatile ſalt.

GIGERIÆ, a term uſed by ſome writers, to expreſs the offals of poultry of any kind, including the inteſtines, extremities, and whatever elſe is thrown away before the dreſſing.

GIGMILLS, a kind of fulling mills, for fulling and burling of woollen cloth, prohibited, *anno* 5 *and* 6. *Ed.* 6. c. 22.

GIGOT, in the manege. A branch after the form of a *gigot* or leg, is a branch, the lower part of which is round, and called in French *gargouille*.

GILAM-HIO, in the materia medica, a name uſed by ſome authors, for a peculiar ſort of the lignum aloes, which is ſoft, whitiſh, and very ſweet ſcented. *Camell.* Syll. p. 87.

GILARUM, in botany, a name uſed by Marcellus, for the ſerpyllum.

GILDING (*Cycl.*)—To *gild* iron with water gold, that is by means of quick ſilver, has formerly been thought difficult, if not impracticable; but Mr. Boyle tells us, it may be done by caſing the iron when bright, with copper, by frequently immerſing it in a ſtrong ſolution of good vitriol containing copper, in warm water; and letting the iron dry of itſelf, each time, till copper enough remains upon it; and then the iron may be gilt like copper, with the amalgam of gold and mercury. *Boyle*'s works Abr. Vol. 1. p. 152. See GILDING, *Cycl.*

GILDING *on china ware*. The gold is very much valued on *china ware*, and would be much more ſo, were it not that it is very liable to loſe its luſtre, and to rub off. The Chineſe at preſent have a method of preventing both theſe accidents in a great meaſure, by means of a ſort of poliſhing, which they give it after it is laid on. They prepare for this purpoſe a fine piece of agate, which they poliſh on one ſurface in as perfect a manner as poſſible. With this they rub over the gold as it lies on the porcelain ſeveral times, when it firſt comes from the baking.

This gives the gold a luſtre which it would not otherwiſe have, and fixes it down to the ware in ſuch a manner, that it cannot eaſily be got off. The principal miſchief that gold thus laid on is ſubject to, is the tarniſhing, or growing dull; this is remedied by the ſame ſort of means. They wet the veſſel upon which they would revive the luſtre of the gold, in common clean water, and while it is wet, they rub it with the ſame poliſhed agate, adding a little fair water at times to keep it moiſt. If the gold has not been laid on well at firſt, this may poſſibly raiſe it or take it off in ſome places; but if it was originally put on with the help of this ſtone, as all the gold on porcelain now is, the rubbing it with it a ſecond time never gives it any ſcratches, but recovers its priſtine luſtre and beauty. It muſt be obſerved, that the rubbing with this ſtone muſt be all done one way, both in the firſt laying on the gold, and in the brightning it up afterwards. This may ſerve as a method for us as well as the Chineſe, not only to recover the beauty of our tarniſhed gilt *china ware*, but alſo to lay gold upon ſome of our home manufactures of this kind. Obſer. Sur les Coutumes de l'Aſie.

GILDING *on wood*. This is performed two ways; the firſt called plain, the other burniſhed *gilding*. In the firſt, the leaf gold is laid upon a coat of whiting, which is laid ſeveral times over upon the wood, and allowed to dry each time; after which it is watered, and then the gold is laid gently on with a piece of cotton or otherwiſe; as the whiting dries the gold adheres, and the looſe pieces being afterwards taken off, the work is finiſhed; for this will not bear burniſhing.

The other method is by making a coat or two of gold ſize, and letting it dry; they wet it when the gold is to be laid on, and cover it with the leaf gold, wetting it again when the gold is on, and add freſh where there are any blemiſhes. When all is thoroughly dry, this is burniſhed with a dog's tooth, or other ſmooth ſubſtance. This is the ſhort method of *gilding* now practiſed. See the article GOLD *ſize*.

GILLS *of fiſhes*, (*Cycl.*) the parts which ſerve to their taking and throwing out again proper quantities of water, impregnated with its due and natural portion of air. The *branchiæ*, or *gills* of fiſh, therefore, are the organs which in them correſpond to the lungs in quadrupeds and birds, as alſo of frogs, ſerpents, and lizards, creatures too much confounded with fiſh by the old authors; all fiſhes therefore have theſe *branchiæ*, except the cetaceous and the petromyzum. The *gills* in all fiſh are eight in number, four being placed on each ſide the throat. The loweſt *gill* is always much ſmaller than either of the others; the other three on each ſide are gradually larger to the top one, which is in all fiſh the largeſt. Every one of theſe *gills* is compoſed of a bony ſubſtance formed into a ſemicircle, in moſt kinds, or bent into the ſhape of a bow. On the convex ſide of which there is formed a ſort of plume, or the reſemblance of a leaf.

Each leaf (to uſe that word) is compoſed of a double row of bony lamellæ, formed like ſo many ſickles, and each of theſe lamellæ is fixed to the convex part of the bow, by means of the membrane with which that bow is covered. Theſe lamellæ have one part convex, and the other concave. The convex ſide is covered with numerous hairs in all parts, and theſe are longeſt near the baſe, and ſhorteſt toward the apex. They are leſs hairy on the concave ſide; the hairs there being ſhorter, and continued only to the middle of the lamellæ, not running all the way along it. Theſe hairs are all the way connected to the *gill* by a very tender membranous ſubſtance, which covers the lamellæ, but they are each ſingle at the baſe. *Artedi*, Ichthyolog.

The concave part of every lamina is applied to the convex part of the next oppoſite lamina, and the laminæ are all connected one with another, by means of a membrane which ariſes at their baſe, and is continued up half their length; at this part the membrane becomes ſtronger and forms a ſort of cord. The reſt of the lamina is free and terminates in an extremely fine and flexile point. Every one of theſe laminæ is inveſted with a fine and thin membrane, and each ſerves to receive the ramifications of the veſſels which are brought into the branchia. The inſide of every bow or bony ſemicircle which makes one *gill*, gives place to one artery, one vein, and one nerve. The conformation of this hollow part of each *gill* is different in different fiſh; in ſome it contains a number of ſmooth tubercles, which are ſhort and ſcarce ſtand out beyond the ſurface: this is the caſe in the *gills* of the cyprinus, &c. In ſome it is in this manner beſet with very rough tubercles as in the cotti; in ſome others theſe tubercles are rough, and reſemble teeth, as in the ſalmons, &c. In ſome alſo this ſurface, inſtead of tubercles, is beſet with a ſort of long hairs reſembling rays as in the clupeæ; and finally in ſome this part is beſet with real, but ſhort prickles, as in the eſoces. The uſe of the *gills* in fiſh ſeems to be to receive the blood which is protruded from the heart into the aorta, and derive it to the utmoſt parts of the lamina, from whence it is returned by veins which diſtribute it to every part of the body and to ſerve for the office of reſpiration.

The motion of the *gills* of fiſh is no way ſo beautifully ſeen as in the viewing thoſe of a ſmall eel with a microſcope. Two rows of theſe are always bended roundiſh one againſt the other, while their ends play againſt one another, touching and going back again very regularly and ſucceſſively, and imitating the opening and ſhutting of a pair of bellows, in a regular ſucceſſion; and in the generality of fiſh, one pair does this, while another pair only continues advanced, ſo as to cloſe with their baſe, and this is done alternately by one and another pair all the time that the obſervation is continued. Philoſ. Tranſ. N°. 222.

Apertures of the GILLS. See BRANCHIARUM *foramina*.

Leaf of the GILLS. See FOLIUM *Branchiarum*.

GILT *head*, *Aurata*, in zoology, the name of a broad and flat ſea fiſh, not unlike the bream in ſhape, and by ſome called the ſea bream, a name too looſely uſed and ſometimes applied alſo to the ſparus, cantharus, and other flat fiſhes. It ſometimes grows to eight or ten pound weight, its ſcales are moderately large, its back is of a blackiſh green, and its ſides of a duſky brown, with a faint caſt of yellow. At the upper angle of the coverings of the *gills* it has uſually a black ſpot, and under that often a purple one between its eyes. It has a fine gold coloured, arched or lunated mark, the convex or gibboſe part of which is toward the mouth, the points toward the eyes.

The eyes are large, the mouth moderately wide, and the tongue pointed. It has ſix or eight teeth in each jaw with ranges of tubercles behind them, and theſe are covered by thick lips. Its back is ridged and ſharp, and its fins have ſome of their anterior rays prickly, the others ſoft. It is common in the markets of Rome, Venice, &c. and caught in great plenty in the ſummer months in different parts of the Mediterranean; in winter it is more ſcarce, but more valued. *Rondelet.* de Piſc. Lib. 5. Cap. 2. p. 115. *Bellon.* de Piſc. p. 118.

GIN. See the article GENEVA.

GIN, in mechanics. See CRABB.

GINGER (*Cycl.*)—The two ſorts of *ginger*, the one of which is cultivated in great plenty in the warm parts of the Weſt-Indies, and the root of which is what we uſe in the kitchen; the other a wild plant in ſome parts of the Eaſt Indies, and whoſe root is called *zerumbeth*, and uſed in medicine, are both kept in the gardens of the curious with us.

They are progagated by parting the roots, the beſt ſeaſon for doing which is early in ſpring before they begin to ſhoot. Every large part of the root may then be divided into ſeveral ſlips with two or three eyes to each, all which will ſucceed: theſe are to be planted ſeparately in pots of a light rich earth, and plunged into a hot bed of tanners bark, where they muſt be frequently watered, and in hot weather muſt often have the glaſſes raiſed with a brick to give them air. They will encreaſe greatly at the root, and ſometimes flower with us, but they muſt be kept in the hot bed all the ſummer, and in winter be removed into the back ſtove. *Miller*'s Gard. Dict.

GINGIBRACHIUM, a name given by ſome medicinal authors to the ſcurvey, when it affects the arms and other extremities.

GINGIPEDIUM, a name given by ſome authors to the ſcurvy when it affects the feet.

GINETTA, or GENETTA, the name of a ſmall animal of the weaſel kind, of a mixed colour, between yellowiſh and blackiſh, and ornamented with ſeveral black ſpots in different parts of the body. It is naturally a very tame and inoffenſive creature. It is uſually found about rivers feeding on what it finds about their banks. It is found in ſome parts of Spain, and at Conſtantinople, and in ſome other parts of the Turkiſh dominions. It runs looſe about the houſes like a cat, its tail is variegated with circles of darker and paler colours, and its ſkin is of a ſomewhat perfumed ſmell. *Ray*'s Syn. Quad. p. 101.

GINGRA, in antiquity, a kind of dance uſed at funerals, *Pitiſc.* Lex. Ant. in voc.

GINGRINA, in antiquity, a name given to a ſmall kind of flute fit for beginners.

GIOAR, in the materia medica of the antient Arabians, a word applied to ſeveral different ſubſtances, and ſometimes uſed as the diſtinct names of them; ſometimes only as an epithet to them. It is generally uſed by Aviſenna as a name for arſenic, ſometimes for antimony; and in Serapio, we often find it ſtanding for any of the mineral poiſons. The original meaning of the word is no more than what the Greeks expreſſed by the word οσια, ſubſtance, but it became applied to ſeveral things moſt eminent in their way, as to arſenic the moſt fatal of poiſons; to antimony, ſuppoſed at that time the moſt valuable of medicines; and to pearls, as the moſt valuable of gems.

GIOMELU, a body of the ſpahis, or horſe in the ſervice of the Grand Signior. *Pocock*'s Egypt. p. 166.

GIR, a name by which ſome of the chemical writers have called quick-lime.

GIRANDOLE, a large kind of branched candleſtick. See BRANCH and JESSE.

GIRDING-*girt*, at ſea. The ſeamen ſay a ſhip is *girt*, or hath a *girding-girt*, when her cable is ſo tight or ſtrained, that upon the running of the tide, ſhe cannot go over it with her ſtern part, but will lie acroſs the tides.

GIRDLE, among jewellers, the line which encompaſſes the ſtone, parallel to the horizon; or, which determines the greateſt horizontal expanſion of the ſtones. *Jeffries* on Diamonds.

GIRGILIM, in the materia medica, a name given by ſome authors to the ſeſamum, or oily purging grain.

GIRGITES, a name uſed by ſome chemical writers for a ſort of white ſtones found in rivers, of which they make a peculiarly ſtrong lime. The ſtones are of the ſparry kind worn into roundneſs by the motion of the water, and they have their name *Girgites*, from the word Gir, uſed by the chemiſts for lime.

GIRMER, a word uſed by ſome of the chemical writers, to ſignify tartar.

GIRROCK, the common Engliſh name of the fiſh called the lacertus, a larger ſpecies of gar fiſh, caught in the Mediterranean and Engliſh ſeas. *Willoughby*'s Hiſt. Piſc. p. 232. See LACERTUS.

GIRT, in meaſuring timber, is uſed for the circumference of a tree. See *Coggeſhall*'s SLIDING-*Rule*, *Cycl.*

Some call the fourth part of the circumference the *girt*, and ſuppoſe the ſquare of this equal to the area of the ſection of the tree. Treat. Pract. Geom. p. 150. See TIMBER, *Cycl.* and Suppl.

GISARMS, or GUISARMES, in our old writers, an halbert or hand ax; it comes from the latin *bis arma*, becauſe it wounds on both ſides. *Shene.—Eſt armorum genus longo manubrio*

manubrio & porrecta cuſpide. Spelm. It is mentioned in the ſtatute 13 Ed. I. c. 6.

GISCARA, a name uſed by ſome botanical authors for the *palma conifera minor Braſilienſis*, a ſmall palm common in the Braſils.

GISON, or GEISON, in the Jewiſh antiquities, a little wall about breaſt high, made round the temple properly ſo called, and the altar of burnt ſacrifices, to keep the people at a diſtance. Joſephus, in his book of antiquities, makes it to be three cubits high; and but one, in his hiſtory of the Jewiſh war. *Joſeph.* Antiq. l. 8. c. 2. p. 262. & de Bello Jud. l. 6. p. 918. *Calm.* Dict. Bibl.

GITHAGO, in botany, a name uſed by ſome authors, particularly by Pliny, for the lolium or darnel graſs. *Ger.* Emac. Ind. 2.

GITTITH. This word occurs frequently in the Pſalms, and is generally tranſlated *wine preſſes*. The conjectures of interpreters are various concerning this word *gittith*. Some think it ſignifies a ſort of muſical inſtrument; others, that the Pſalms, with this title, were ſung after the vintage; laſtly, others, that the hymns of this kind were invented in the city of *Gath*. Calmet is rather of opinion, that it was given to the claſs of young women, or ſongſtreſſes of *Gath* to be ſung by them. Pſ. viii. 1. lxxxi. 1. lxxxiv. 1. Dr. Hammond thinks that the Pſalms, with this title, were all ſet to the ſame tune, and made on *Goliah* the *Gittite*. See *Hammond* on Pſ. viii. *Calm.* Dict. Bibl.

GIZEIR, in the materia medica of Galen and the antients, a name given to the fineſt and beſt kind of caſſia fiſtula. The antients had ſeveral ſorts of this drug, ſome collected ſeparate from the wood, ſome with it; the young ſhoots, being cut bark and all, and preſerved together.

GLABELLA, a term uſed by ſome writers to expreſs the ſpace between the two eye-brows; it is ſo called from its ſmoothneſs, being uſually without hair.

GLACIATION is ſometimes uſed to ſignify congelation.

GLADIOLUS, *gladiole*, in botany, a plant which in the Linnæan ſyſtem of vegetables, makes a diſtinct genus. The characters of which are, that the flower cup is only compoſed of certain looſe ſpathæ or films. The flower is divided into ſix petals, which are all obtuſe and oblong. The three upper ones, which are next one another, cloſing together, and the inferior ones bending backward; all of them having their points growing together at their inſertion, and forming a ſhort tube. The ſtamina are three pointed filaments, one ariſing from every other ſegment of the flower, and all hid under the converging part of it. The antheræ are of an oblong form. The piſtillum has its germen placed beneath the receptacle. The ſtyle is ſingle, and of the ſame length with the ſtamina, and the ſtigma is trifid and concave. The fruit is an oblong, bellied capſule, irregularly three cornered, obtuſe, conſiſting of three cells, and having three valves. The ſeeds are numerous, roundiſh, and ſurrounded, being incloſed in a membrane. *Linnæi* Gen. Plant. p. 10.

GLADIOLUS, according to Tournefort, is characteriſed thus: the flower is of the liliacious kind, and is at the bottom of a ſort of funnel ſhape: it is compoſed only of one leaf, but from the bottom tube becomes greatly enlarged, and divides into two lips; the upper one is imbricated, and the lower is divided into five ſegments. The cup of the flower becomes afterward an oblong fruit divided into three cells, and filled with roundiſh ſeeds, covered with a ſort of hood.

To this, it is to be added, that the root is a double bulb, or compoſed of two thick and fleſhy parts, which lie the one over the other. See Tab. I. of Botany, Claſs 9.

Mr. Tournefort enumerates the following ſpecies of *gladiole*: 1. The great Indian *gladiole* with red flowers. 2. The great Conſtantinople *gladiole* with blackiſh purple flowers. 3. The great, tall, rediſh purple flowered *gladiole*, with the flowers all placed on one ſide the ſtalk. 4. The great tall *gladiole*, with white flowers placed all on one ſide the ſtalk. 5. The *gladiole* with fleſh coloured flowers. 6. The ſmall low *gladiole*, with flowers placed all on one ſide the ſtalk. 7. The leaſt *gladiole*, with flowers placed all on one ſide the ſtalks. 8. The little fleſh coloured flowered *gladole*, with flowers placed on one ſide the ſtalk. 9. The purpliſh blue *gladiole*, with flowers on both ſides the ſtalk. 10. The bright red *gladiole*, with flowers on both ſides the ſtalk. 11. The white flowered *gladiole*, with flowers on both ſides the ſtalk. 12. The narrow or graſſy leaved *gladiole*. *Tourn.* Inſt. p. 365.

GLADIUS *Piſcis*, in zoology, a name uſed by many for the ſword fiſh, called more frequently the xiphias. *Willoughby's* Hiſt. of Piſc. p. 161. See the article XIPHIAS.

GLAMA, in natural hiſtory, the name of a ſpecies of camel, called alſo *elaphocamelus*, by many authors, and by many erroneouſly accounted a ſheep; its length from head to tail is about ſix feet; its height about four feet; its head, neck, and the general appearance of the upper part of the body, greatly reſembles the camel; and its upper lip is divided, in the ſame manner, as in that creature. Its parts of generation are alſo the ſame as in the camel; and it is deſtitute of the fore teeth, and chews the cud like other animals that are ſo. It has no horns, and its feet are divided into two portions, which terminate in a ſort of claws, and are faſtened by a ſkin round the anterior part of the foot; and the ſole of the foot is tender, and covered over only with a thick ſkin, as in the camel.

It has at the place where the breaſt joins to the belly a protuberance, like that which the camel and dromedary have in the ſame part, and in this animal there is a continual diſcharge of a ſort of liquid excrement from it. It is a very tame animal, and fit for domeſtick uſes. It never offends any creature; but when provoked, revenges itſelf by diſcharging the contents of its ſtomach, by vomit, upon whatever injures it, and this it will do to a great diſtance.

It is a native of Peru, and is of vaſt uſe to the inhabitants for carrying burthens; the weaker of them very eaſily carrying a hundred and fifty pound weight, and the ſtronger two hundred and fifty. *Ray's* Syn. Quad. p. 143.

GLAMA, in the old writers of medicine, is ſometimes uſed to ſignify the ſordes of the eyes in lippitudes, and other diſorders attending them.

GLANDES *Terræ*, a name uſed by ſome authors for the tuberous roots of a plant of the lathyrus kind, called the *lathyrus repens tuberoſus*. See LATHYRUS.

GLANDS (*Cycl.*)—In all the moveable articulations, eſpecially of thoſe perſons who end their lives by ſudden or violent deaths, we find a viſcid liquor in ſome meaſure reſembling a liquid mucilage, or the white of an egg well beat, which is commonly called *ſynovia*, a name given at firſt to a diſeaſe. This liquor is contained, together with the articulations, in the ligamentary capſulæ, which hinder it from running out. It is furniſhed chiefly by ſmall bundles of *glands* more or leſs flat, which are contained in the ſame capſulæ, and known by the name of mucilaginous *glands*; theſe being the organs through which this mucilage is conveyed from the blood. It may likewiſe partly tranſude through the pores of the internal ſurface of the capſular ligaments, and partly be made up of an unctuous matter ſqueezed from the fatty ſubſtances lying near the *glands*, by the motion and friction of the articulated bones. Theſe *glands* are of a more or leſs red colour, and of a very ſingular ſtructure, reſembling ſmall floating fringes, of different thickneſſes made up of pelliculous or veſicular grains, and furniſhed with a great number of veſſels, running in different directions. In ſome places they appear like diſtinct grains fixed immoveably; they are proportioned to the bones and joints, and lodged ſo as to be ſecured from violent frictions, chiefly near the edges of the capſulæ, or in particular cavities contrived on purpoſe to receive them.

The liquor continually furniſhed by theſe *glands*, mixed with that which ſweats through the pores of the capſulæ, and perhaps with that which comes from the fatty moleculæ, is diffuſed between the articulated bones, and its uſe is to facilitate their motions, to prevent them from bruiſing each other, and to keep their cartilages from drying or wearing out. *Winſlow's* Anatomy, p. 117.

Some ſuppoſe and endeavour to prove the neceſſity of veſicles to the conglomerate *glands*, in order to receive all the different particles required in the compoſition of ſecerned liquors, which muſt be conveyed in different ſeries of veſſels, to be intimately blended in the veſicle, which will be conſiderably aſſiſted by the ſyſtole and diaſtole, which it is ſuppoſed the veſicle undergoes. See Acad. Bonon. Com. p. 336.

The *glands* are liable to be ſo altered by accidents as to be ſcarce known for what they really are; and their diſtemperatures are too often productive of the moſt miſchievous conſequences. The Paris memoirs give an account of a woman, who attempting to lift a large weight, had a ſwelling that appeared the ſame day on the lower part of her arm, which continued increaſing in ſize for eighteen months. After this there appeared a hole in the inner part of the hand, from which there was diſcharged a quantity of matter daily, but yet the ſwelling continued to increaſe. At the end of two years ſhe conſented to have it laid open. There was very little matter diſcharged, the whole not amounting to more than two ſpoonfuls of a thick viſcous fluid; all the reſt of the tumor was ſolid, and contained about two hundred white bodies, of a roundiſh, but ſomewhat oblong figure, and not unaptly reſembling ſome of the kinds of kidney beans. Theſe were covered with a ſolid membrane, and had no cavity within; and ſome of them had at one end a ſort of ſtalk, or pedicle, by which they ſeemed to have been faſtened to ſome other body. Theſe were the *glands* which had loſt their natural uſe, and were become hard, and what ſeemed a pedicle or ſtalk to ſome of them was their excretory duct which had not periſhed. Mem. Acad. Par. 1708.

The *glands* which have no particular ſecretory ducts, are called *glandulæ cæcæ*, or *clauſæ*.

Dr. Quietſchius argues for theſe *glands* being deſigned to prepare nouriſhment for the other parts, from the obſervation that they decreaſe after birth to full growth, then continue in the ſame condition till old age comes on; after which they gradually ſhrivel. Select. medic. Francofurt. Tom. 2. Vol. I. §. 3.

Renal GLANDS, *glandulæ renales*—Mr. du Vernoy remarks the *glandulæ renales* to be very variable in their magnitude, figure, &c. but that they are always contiguous, and firmly connected to the kidneys. In ſome fœtus's they appear ſolid, without any cavity, in others, they are diſtended with thin blood; in adults, they are always flat: they are readily diſtended, by blowing air into them by their vein. When the *glands* are opened, and quickſilver is injected, a great many ducts are ſeen, at which the mercury runs out. Two arteries and a vein belong to each *gland*, and a great many ducts, like rays, make a circle round it. An artery ariſing from the aorta, is ſent down from the lower edge of the *gland* to the teſtes of men, and ovaria of women, which Valſalva miſtook for ducts. Comment. Acad. Petrop. tom. 5.

GLANIS, in zoology, the name of a fiſh, called in Engliſh the ſheat fiſh, and in Latin, *ſilurus*. *Aldrovand.* de Piſc. l. 5. c. 25. See the article SILURUS.

GLANS *Marinus*, in natural hiſtory, a name given to a genus of ſhell fiſh, more uſually called balanus, and in Engliſh the center ſhell.

GLANS (*Cycl.*)—GLANS *Penis*. We read of a *glans penis* regenerated after amputation in the medical Eſſ. Edinb. vol. 5. art. 35.

GLANS *Trochitifera*, in natural hiſtory, a name given by Geſner, and ſome other writers, to a kind of figured foſſil, found uſually among the trochitæ and entrochi, and evidently appearing to have in ſome manner belonged to them. All the writers who have themſelves examined the places where the trochitæ are found, have mentioned theſe under the names of glandes trochitiferæ, others under leſs determinate ones. Agricola calls them lapides informes; and Liſter after him *rude ſtones*, having impreſſions of the entrochi.

Theſe ſtones are found bedded in clay or marble among the entrochi; they are uſually of the bigneſs of a middle-ſized walnut, and have the impreſſions of entrochi in many places upon their ſurfaces in conſiderable number, ſo that the trochitæ and entrochi in general ſeem to have grown from theſe, and thoſe who make the trochitæ a kind of rock plants, generally eſteemed theſe to be the bulbous roots of them. On cleaning theſe ſtones with vinegar the impreſſions appear more fair on them; they are round holes radiated, and exactly reſemble the holes in the main ſtones of the entrochi, out of which the ſmaller branches have been broke. The greater number of theſe *glandes* or roots of the entrochi are ſo ſhattered and broken, that they may very well be called *lapides informes*, or rude ſtones; but this is not the caſe with them all, for they are ſometimes found perfect and uninjured, and are then very elegant and regular bodies. *Geſner* de Foſſ.

Some of them are of the exact ſhape of a pine apple, or cone, with a hollow bottom, about half an inch deep, and as much over; on the tops of theſe are found the impreſſions of ſingle entrochi, and round their bottoms, at equal diſtances, there ſtand five ſingle feet in figure of creſcents. Theſe ſtones are formed of angular plates: the bottom is compoſed of five which are called feet, the middle of five more, all of a ſex-angular figure. Others of theſe *glandes* are found of the ſize of a walnut, of the ſame ſort of conic figure with the other, but the bottom convex. Theſe have alſo at the top generally the figure of one entrochus, and the bottom is edged with five double points, or feet all broken off, and reſembling ſo many creſcents. This, as well as the other kind, is uſually covered with incruſtated ſcales or plates, and they reſemble nothing more than the ſkin of ſome of the fiſh of the piſcis triangularis kind; the ſkin of the ſame fiſh, in theſe ſpecies, being covered in its ſeveral parts with ſcales of the moſt different figures, as trigonal, tetragonal, pentagonal, and hexagonal. The angular plates which cover theſe *glandes* or roots of the entrochi, are often found looſe among the clay, and in the rocks where the entrochi are found. They are of various figures, and many of them extremely elegant, and they are often heaped up together in ſuch vaſt numbers in the clay, that on waſhing it vaſt multitudes are ſeparated from the ſame ſmall lump. *Agricola* de Metall. Phil. Tranſ. N° 100.

The pentagonal ones are ſometimes half an inch long and near as much in breadth; they are convex on the one ſide, and concave like a little diſh on the other; on the convex ſide there are uſually ſeveral knots ſet in a regular ſquare order. Theſe plates grow thin toward the extremities, but very ſeldom form a ſharp edge; ſome of theſe are alſo found with but a little convexity on the outſide, and with no hollow at all within: theſe are uſually ſmooth all over, and have not the leaſt appearance of ever having had any knots, and are very blunt at the edges in ſome, but others of them go off ſo fine as to be as ſharp as a knife. There are ſometimes found alſo another kind of theſe, which have one edge indented and the reſt plain; theſe are ſmaller than the others, and their convex ſide riſes higher, though the concave is not more hollow than in the firſt kind: in theſe the indented ſide is always the thinneſt, and the ſtone is always moſt ſloped toward that ſide. Some of this laſt ſort are alſo found channelled on the concave ſide in a very regular and orderly manner. Dr. Liſter alſo mentions one very ſingular ſpecimen of this kind, found near Wansford-bridge in Northamptonſhire; they had one end notched or indented as the others, and the convex part had in the middle a round umbo like ſome of the antient ſhields, and round about the ſides of this a liſt of ſmaller ſtuds.

The ſexangular plates found looſe in the beds of the entrochi, and which have alſo made part of the coverings of ſome of theſe *glandes*, are uſually ſmall; they are convex on one ſide and a little hollowed on the other. The hollow ſide is uſually plain, ſometimes highly furrowed, but the convex ſide is uſually very elegantly wrought with a kind of ſtudded and emboſſed work. The figures expreſſed by this work are uſually an equilateral triangle, embracing each corner or angle of the plate, and a ſingle right line in the midſt, or two triangles one within the other. Another kind of the ſexangular plates are ſmooth on the convex ſide, or only irregularly ſcabrous. Theſe are but little hollowed on the under ſide, and ſome of them are ſo thick that they do not deſerve the name of plates. The ſides of theſe are very unequal, as the planes in cryſtals are; ſometimes there are five large and one ſmall plane, ſometimes two are broader than the reſt, and ſometimes more. Theſe are the moſt common of all the plates, a thouſand of them being generally found for one of the others. Phil. Tranſ. N° 100.

GLANUS, or GLANIS, in ichthyology, a name given by Pliny and many other of the old writers to that ſpecies of the ſilurus, which we in England call the ſheat fiſh, the *glanus* and ſilurus, of authors, diſtinguiſhed by Artedi by the name of the ſilurus, with four beards on the chin. See the article SILURUS.

GLAREANA, in zoology, the name of a bird deſcribed by Geſner from a figure, and ſuſpected to be no way different from the ſpipoletta, called tordino by the Venetians, a kind of lark. See SPIPOLETTA.

GLASS (*Cycl.*)—A *glaſs* much harder than any prepared in the common way, may be made by means of borax in the following method: take four ounces of borax, and an ounce of fine ſand; reduce both to a ſubtile powder, and melt them together in a large cloſe crucible ſet in a wind furnace, keeping up a ſtrong fire for half an hour; then take out the crucible, and when cold break it, and there will be found at the bottom a pure hard *glaſs*, capable of cutting common *glaſs* like a diamond. This experiment, duly varied, may lead to ſeveral uſeful improvements in the arts of *glaſs*, enamels, and factitious gems, and ſhews an expeditious method of making *glaſs*, without any fixed alkali, which has been generally thought an eſſential ingredient in *glaſs*, and it is not yet known whether calcined cryſtal, or other ſubſtances, being added to this ſalt inſtead of ſand, it might not make a *glaſs* approaching to the nature of a diamond. *Shaw*'s Lectures, p. 426.

Annealing of GLASS—The operation of annealing of *glaſs* is performed in a peculiar furnace called the *leer* which conſiſts of two parts, the *tower* and the *leer*. The veſſels as ſoon as made, are placed by the ſervitors on the floor of the former, to anneal; which done, they are drawn ſlowly in a ſort of pan called *fraches*, by an operator called the *ſarole-man*, all along the *leer*, the ſpace of five or ſix yards, to give them time to cool gradually; ſo that when they reach the mouth of the leer, they are found quite cold [a].

The particles of *glaſs* by annealing are ſuppoſed to loſe part of their ſpringineſs, and their brittleneſs at the ſame time. A gradual heating or cooling of *glaſs*, according to Dr. Hook, *anneals* or reduces its parts to a texture more looſe, and eaſy to be broke; but withal more flexible than before [b]. And hence in ſome meaſure the phænomena of *glaſs* drops.[—[a] *Merret*, Not. to Neri, p. 243. *ſeq.* [b] *Hook*, Microgr. obſ. 7. p. 37.—]

Borrichius, in his chymiſtry, ſeems to think that the rendering *glaſs* ductile or malleable, is not ſo impracticable as it is uſually thought; in ſupport of this, he alledges the inſtance of the luna cornea, which is a ſort of ſalt made of ſilver diſſolved in an acid, and which is in ſome degree ductile, and ſo far altered from the nature of ſilver that it may be melted at a candle, and reduced into ſmall tranſparent leaves; and adding to this the proceſs for making a ductile ſalt out of common ſal armoniac, diſſolved in a large *glaſs* and cryſtallized a vaſt many times; the cryſtals of this ſalt, he ſays, at laſt became half a foot long, and were flexile and elaſtic, and in ſome degree ductile under a hammer. From theſe changes in bodies naturally brittle as ſalts are, he judges, that the ſame changes may be made in *glaſs*. Phil. Tranſ. N° 39.

Glaſſes unannealed, are ſo exceſſively brittle, as to fly and break of themſelves, even frequently before they are well cold. Hence, the practice of nealing or annealing was deviſed.

Some of the phænomena depending on the fragility of unannealed *glaſs* deſerve the attention of the curious. Thoſe of the lacrymæ, or glaſs drops, were among the firſt taken notice of; and it has alſo been obſerved, that hollow bells made of unnealed *glaſs*, with a ſmall hole in them, will fly to pieces, by the heat of the hand only, if the hole by which the internal and external air communicate be ſtopped with a finger. Phil. Tranſ. N° 477. Sect. 3.

But

But lately ſome veſſels made of ſuch unannealed *glaſs* have been diſcovered, which have the remarkable property of reſiſting very hard ſtrokes given from without, though they ſhiver to pieces by the ſhocks received from the fall of very light and minute bodies dropped into their cavities. Thoſe *glaſſes* may be made of any ſhape; all that needs be obſerved in making them, is to take care that their bottoms may be thicker than their ſides. The thicker the bottom is, the eaſier do the *glaſſes* break. One whoſe bottom was three fingers breadth in thickneſs, flies with as much eaſe at leaſt as the thinneſt *glaſs*. Some of theſe veſſels have been tried with ſtrokes of a mallet, ſufficient to drive a nail into wood tolerably hard, and have held good without breaking. They alſo reſiſt the ſhock of ſeveral heavy bodies let fall into their cavities, from the height of two or three feet. For inſtance, muſket balls, pieces of iron, or other metal; pyrites, jaſper, wood, bone, *&c.* but this is not ſurpriſing, as other *glaſſes* of the ſame ſize do the ſame. But, the wonder is, that taking a ſhiver of flint of the ſize of a ſmall pea, and letting it fall into the *glaſs* only from the height of three inches, in about two ſeconds the *glaſs* flies, and ſometimes the very moment of the ſhock: nay, a bit of flint no larger than a grain dropt into ſeveral *glaſſes* ſucceſſively, though it did not immediately break them, yet they all flew, being ſet by, in leſs than three quarters of an hour. Phil. Tranſ. ibid. p. 509.

Some other bodies produce a like effect with flint: for inſtance, ſapphire, porcelain, diamonds, hard tempered ſteel, as alſo marbles, ſuch as boys play with[i], to which add pearls from the animal kingdom[k].[—[i] Phil. Tranſ. ibid. p. 510. ſeq. [k] ibid. p. 512.—]

The experiments ſucceeded alſo when the *glaſſes* were held in the hand, reſted on a pillow, put in water, or filled with water. It is alſo remarkable, that the *glaſſes* broke, upon their bottoms being ſlightly rubbed with the finger, though ſome of them did not fly till half an hour after the rubbing.

If the *glaſſes* be every where extremely thin they do not break in theſe circumſtances.

Some have pretended to account for theſe phænomena, by ſaying, that the bodies dropped into theſe veſſels cauſe a concuſſion, that is ſtronger than the coheſion of the parts of the *glaſs*, and that conſequently a rupture of the ſame muſt enſue. But, why does not a ball of gold, ſilver, iron, copper, or ſeveral other bodies, even a thouſand times heavier than a ſhiver of flint, equally cauſe this concuſſion, and break the *glaſſes*? Is it becauſe they are not elaſtick? But ſurely iron is more ſo than the end of one's finger[l].[—[l] Ibid. p. 513. and ſee p. 514, 515. the experiments of this kind made before the Royal Society.]

Mr. Euler has endeavoured to account for theſe appearances from his principles of percuſſion. He thinks this experiment entirely overthrows the opinion of thoſe who meaſure the force of percuſſion by the *vis viva* [d], and he thinks the principles he has eſtabliſhed [e], give a clear ſolution of this phænomenon. According to theſe principles, the extreme hardneſs of the flint, and alſo its angular figure, which makes the ſpace of contact with the *glaſs* veſſel extremely ſmall, ought to cauſe an impreſſion on the *glaſs*, vaſtly greater than lead or any other metal [f]; and this may account for the flint's breaking the veſſel, though the bullet, even falling from a conſiderable height, does no damage.—[c Mem. Acad. Berlin. 1745. p. 47. [d] See FORCE. [e] Mem. Acad. Berlin. 1745. p. 22, *ſeq.* [f] See FORCE.]

Hollow cups made of the green bottle *glaſs*, ſome of them three inches thick at bottom were inſtantly broken, by a ſhiver of flint weighing about two grains, though they had reſiſted the ſhock of a muſket ball from the height of three feet. Phil. Tranſ. Ibid. p. 515.

Colouring of GLASS. That the colours given to *glaſs* may have their full beauty, it muſt be obſerved, that every pot when new, and firſt uſed, leaves a foulneſs in the *glaſs* from its own earthy particles; ſo that a coloured *glaſs* made in a new pot can never be bright, or perfectly fine. For this reaſon, the larger of theſe when new may be glazed with white *glaſs*, but the ſecond time of uſing the pots loſe this foulneſs.

Thoſe pots which have ſerved for one colour muſt not be uſed for another, for the remainder of the old matter will ſpoil the colour of the new. The colours muſt be very carefully calcined to a proper degree, for if either too much or too little they never do well; the proper proportion, as to quantity, muſt alſo carefully be regarded, and the furnaces muſt be fed with dry, hard wood. And all the proceſſes ſucceed much the better if the colour be uſed dividedly, that is a part of it in the fritt, and the reſt in the melted metal. *Neri*'s Art of Glaſs, p. 44.

Balas coloured GLASS is made thus: put into a pot cryſtal fritt thrice waſhed in water; tinge this with manganeſe prepared into a clear purple; to this add *alumen cativum* ſifted fine, in ſmall quantities, and at ſeveral times: this will make the *glaſs* grow yelloviſh, and a little rediſh, but not blackiſh, and always diſſipates the manganeſe. The laſt time you add manganeſe give no more of the *alumen cativum*, unleſs the colour be too full. Thus will the *glaſs* be exactly of the colour of the *balas* ruby. *Neri*'s Art of Glaſs, p. 183.

Red GLASS. A blood red *glaſs* may be made in the following manner: put ſix pound of *glaſs* of lead, and ten pound of common *glaſs* into a pot glazed with white *glaſs*; when the whole is boiled and refined, add by ſmall quantities, and at ſmall diſtances of time, copper calcined to a redneſs, as much as on repeated proofs is found ſufficient; then add tartar in powder by ſmall quantities at a time, till the *glaſs* is become as red as blood; and continue adding one or other of the ingredients till the colour is quite perfect. Ibid. p. 182.

Yellow GLASS. It is a neceſſary remark in *glaſs* making, that the cryſtal *glaſs* made with ſalt, that has an admixture of tartar, will never receive the true gold yellow, though it will all other colours; for yellow *glaſs*, therefore, a ſalt muſt be prepared from polverine or pot-aſhes alone to make the *glaſs*. *Neri*'s Art of Glaſs, p. 12.

GLASS *of Antimony* may be deprived of its emetic quality, by digeſting it with pure ſpirit of vinegar till the menſtruum be highly tinged. *Boyle*'s Works Abr. Vol. I. p. 74. Where he ſays, that if you abſtract this liquor, and digeſt good rectified ſpirit of wine on the remaining powder, an excellent tincture againſt ſeveral diſeaſes may be obtained.

GLASS-*Chalcedony*. A mixture of ſeveral ingredients, with the common matter of *glaſs*, will make it repreſent the ſemi-opake gems, the jaſpers, agates, chalcedonies, *&c.*

The way of making theſe ſeems to be the ſame thing with the method of making marbled paper, by ſeveral colours diſſolved in ſeveral liquors, which are ſuch as will not readily mix with one another when put into water, before they are caſt upon the paper which is to be coloured. There are ſeveral ways of making theſe variouſly coloured *glaſſes*, but the beſt is this: diſſolve four ounces of fine leaf ſilver in a *glaſs* veſſel in ſtrong aqua fortis, ſtop up the veſſel, and ſet it aſide.

In another veſſel diſſolve five ounces of quickſilver in a pound of aqua fortis, and ſet this aſide.

In another *glaſs* veſſel diſſolve in a pound of aqua fortis three ounces of fine ſilver, firſt calcined in this manner: amalgamate the ſilver with mercury, mix the amalgama with twice its weight of common ſalt well purified, put the mixture in an open fire in a crucible, that the mercury may fly off, and the ſilver be left in form of powder. Mix this powder with an equal quantity of common ſalt well purified, and calcine this for ſix hours in a ſtrong fire; when cold, waſh off the ſalt by repeated boilings in common water, and then put the ſilver into the aqua fortis. Set this ſolution alſo aſide. *Neri*'s Art of Glaſs, p. 79.

In another veſſel diſſolve in a pound of aqua fortis three ounces of ſal armoniac, pour off the ſolution, and diſſolve in it a quarter of an ounce of gold. Set this alſo aſide.

In another veſſel diſſolve three ounces of ſal armoniac in a pound of aqua fortis, then put into the ſolution, cinnabar, crocus martis, ultramarine, and ferretto of Spain, of each half an ounce. Set this alſo aſide.

In another veſſel diſſolve in a pound of aqua fortis three ounces of ſal armoniac, then put into it crocus martis made with vinegar, calcined tin, zaffer, and cinnabar, of each half an ounce; let each of theſe be powdered very fine, and put gently into the aqua fortis. Set this alſo aſide. *Neri*, p. 80.

In another veſſel diſſolve three ounces of ſal armoniac in a pound of aqua fortis, and add to it braſs calcined with brimſtone, braſs thrice calcined, manganeſe, and ſcales of iron which fall from the ſmith's anvil, of each half an ounce; let each be well powdered, and put gently into the veſſel. Then ſet this alſo aſide.

In another veſſel diſſolve two ounces of ſal armoniac in a pound of aqua fortis, and put to it verdigreaſe an ounce, red lead, crude antimony, and the caput mortuum of vitriol, of each half an ounce; put theſe well powdered leiſurely into the veſſel, and ſet this alſo aſide. *Neri*, p. 81.

In another veſſel diſſolve two ounces of ſal armoniac in a pound of aqua fortis, and add orpiment, white arſenic, painters lake, of each half an ounce: keep theſe nine veſſels in a moderate heat for fifteen days, ſhaking them well at times. After this pour all the matters from theſe veſſels into one large veſſel, well luted at its bottom; let this ſtand ſix days, ſhaking it at times, and then ſet it in a very gentle heat, and evaporate all the liquor, and there will remain a powder of a purpliſh green. Ibid. p. 82.

When this is to be wrought, put into a pot very clear metal, made of broken cryſtalline and white *glaſs*, that has been uſed; for with the virgin fritt, or ſuch as has never been wrought, the chalcedony can never be made, as the colours do not ſtick to it, but are conſumed by the fritt. To every pot of twenty pound of this metal put two or three ounces of this powder at three ſeveral times; incorporate the powder well with the *glaſs*, and let it remain an hour between each time of putting in the powders. After all is in, let it ſtand twenty-four hours; then let the *glaſs* be well mixed, and take an eſſay of it, which will be found of a yelloviſh blue; return this many times into the furnace; when it begins to grow cold, it will ſhew many waves of different colours very beautifully. Then take tartar eight ounces, ſoot of the chimney two ounces, crocus martis made with brim-

brimſtone half an ounce; let theſe be well powdered and mixed, and put them, by degrees, into the *glaſs* at ſix times, waiting a little while between each putting in; when the whole is put in, let the *glaſs* boil and ſettle for twenty four hours, then make a little *glaſs* body of it, which put in the furnace many times and ſee if the *glaſs* be enough, and whether it have on the outſide veins of blue, green, red, yellow, and other colours, and have beſide theſe veins, waves like thoſe of of the chalcedonies, jaſpers and oriental agates, and if the body kept within looks as red as fire. *Neri*'s Art. of Glaſs, p. 73.

When it is found to anſwer thus it is perfect, and may be worked into toys and veſſels, which will always be beautifully variegated; theſe muſt be well annealed, which adds much to the beauty of their veins. Maſſes of this may be poliſhed at the lapidary's wheel as natural ſtones, and appear very beautiful. If in the working the matter grow tranſparent, the work muſt be ſtopped, and more tartar, ſoot, and crocus martis, muſt be put to it, which will give it again the neceſſary body and opacity, without which it does not ſhew the colours well. *Neri*, p. 74.

GLASS *of lead*, a *glaſs* made with the addition of a large quantity of lead, of great uſe in the art of making counterfeit gems. The method of making it is this. Put a large quantity of lead into a potter's kiln, and keep it in a ſtate of fuſion with a moderate fire till it is calcined to a grey looſe powder, then ſpread it in the kiln, and give it a greater heat, continually ſtirring it to keep it from running into lumps; continue this ſeveral hours till the powder become of a fair yellow, then take it out and ſift it fine; this is called calcined lead.

Take of this calcined lead fifteen pound, and cryſtalline, or other fritt, twelve pound, mix theſe as well as poſſible together, put them into a pot, and ſet them in the furnace for ten hours; then caſt the whole, which will be now perfectly melted, into water; ſeparate the looſe lead from it, and return the metal into the pot, and after ſtanding in fuſion twelve hours more, it will be fit to work. It is very tender and brittle, and muſt be worked with great care, taking it ſlowly out of the pot, and continually wetting the marble it is wrought upon. *Neri*'s Art of Glaſs, p. 110.

Glaſs of lead is capable of all the colours of the gems in very great perfection. The methods of giving them are theſe: for green, take polverine fritt twenty pound, lead calcined ſixteen pound, ſift both the powders very fine, then melt them into a *glaſs* ſeparating the unmixed lead, by plunging the maſs in water; after this return it into the pot, and add braſs thrice calcined ſix ounces, and one penny weight of crocus martis made with vinegar; put this in at ſix different times, always carefully mixing it together, let it finally ſettle an hour, then mix it together and take a proof of it; when the colour is right, let it ſtand eight hours, and then work it. If inſtead of the calcined braſs the ſame quantity of the caput mortuum of the vitriolum veneris be uſed, the green is yet much finer. *Neri*'s Art of Glaſs, ibid. and p. 112.

For topaz colour, take cryſtal fritt fifteen pound, calcined lead twelve pound, mix them well together by ſifting the powders through a fine ſieve, then ſet them in a furnace not too hot, and ſeparate the ſuperfluous unmixed lead, by caſting the whole into water; repeat this twice, then add half gold yellow *glaſs*, and let them incorporate and purify, and they will be of the true and exact colour of the oriental topazes. *Neri* p. 113.

For ſea green, take cryſtal fritt ſixteen pound, calcined lead ten pound, mix and ſift them together, and ſet them in a pot in a furnace, in twelve hours the whole will be melted; then caſt it into water and ſeparate it from the looſe lead, put them into the furnace again for eight hours, then ſeparate the looſe lead by waſhing a ſecond time, and return it to the pot for eight hours more. *Neri*, p. 114.

GLASS *porcelain*, the name given by many to a modern invention of imitating the china ware with *glaſs*. The method given by Mr. Reaumur, who was the firſt that carried the attempt to any degree of perfection, is delivered by that gentleman in the memoirs of the academy of ſciences of Paris to this effect. Memoirs Acad. Paris 1739.

The mixing *glaſs* reduced to powder, with other leſs eaſily vitrifiable ſubſtances for the forming a paſte to be afterwards made into a ſort of porcelain, has been a contrivance long practiſed, but it is very troubleſome, and the reſult ſubject to many faults; but this new ware is made of *glaſs* alone, and that with much leſs trouble, and without the reducing it to powder. By this art, veſſels of *glaſs* are changed into veſſels of a ſort of porcelain, without altering their form, and the meaneſt *glaſs* ſerves as well as the beſt for that purpoſe; our common coarſe green quart bottles, or the great bell *glaſſes* with which gardeners cover their melons, *&c.* being by this means changeable into a beautiful white ſort of porcelain ware; and this is to be done in ſo eaſy a manner and with ſo ſmall expence, that it requires no more trouble or charge, than that of baking a common veſſel of our courſe earthen ware, and for this reaſon the veſſels of this ſort of ware may be afforded extremely cheap.

It is very certain that all procelain ware is a ſubſtance in the ſtate of ſemivitrification; and in order to bring *glaſs*, which is a wholly vitrified ſubſtance, into the condition of porcelain, there requires no more than to reduce it to a leſs perfectly vitrified ſtate.

The queſtion which would naturally be ſtarted on this occaſion, is, whether it be poſſible to reduce *glaſs* to a leſs vitrified ſtate, it having already undergone what is eſteemed the laſt change by fire. But when we conſider that the *glaſs* of antimony, the vitrifications of many of the metals, as the *glaſs* of lead, and the counterfeit gems coloured by the metals, are more or leſs eaſily reduced again by chymiſtry to metals, *&c.* the reducing ſand, flints, *&c.* after they are vitrified, at leaſt a little way back toward their native or priſtine ſtate, may appear not wholly impracticable; and the attempts which Mr. Reaumur made on this occaſion, were what gave him the firſt hints of the *glaſs* porcelain.

The method of making it is this. The *glaſs* veſſels to be converted into porcelain, are to be put into a large earthen veſſel, ſuch as the common fine earthen diſhes are baked in, or into ſufficiently large crucibles; the veſſels are to be filled with a mixture of fine white ſand, and of fine gypſum or plaiſter ſtone burnt into what is called plaiſter of Paris, and all the interſtices are to be filled up with the ſame powder, ſo that the *glaſs* veſſels may no where touch either one another, or the ſides of the veſſel they are baked in. The veſſel is to be then covered down and luted, and the fire does the reſt of the work; for this is only to be put into a common potter's furnace, and when it has ſtood there the uſual time of the baking the other veſſels, it is to be taken out, and the whole contents will be found no longer *glaſs*, but converted into a white opake ſubſtance, which is a very elegant porcelain, and has almoſt the properties of that of China. Memoirs Acad. Sciences Par. 1739.

The powder which has ſerved once, will do again as well as freſh, and that for a great many times; nay it ſeems ever ſo often.

GLASS-*balls*, a term uſed to expreſs circular or otherwiſe ſhaped hollow veſſels of *glaſs*, coloured within ſo as to imitate the ſemipellucid *gems*. The method of doing it is this; make a ſtrong ſolution of ichthyocolla or iſinglaſs in common water by boiling, pour a quantity of this while warm into the hollow of a white *glaſs* veſſel, ſhake it thoroughly about, that all the ſides may be wetted, and then pour off the reſt of the moiſture. Immediately after this, throw in red lead, ſhake it and turn it about, throw it into many places with a tube, and the moiſture will make it ſtick and run in waves and pretty figures. Then throw in ſome of the painter's blue ſmalt, and make it run in waves in the ball as the red lead, then do the ſame with verdigreaſe, next with orpiment, then with red lake, all well ground; always caſting in the colours in different places, and turning the *glaſs* that the moiſture within may run them into the waves. Then take fine plaiſter of Paris, and put a quantity of it into the ball, ſhake it alſo nimbly about, this will every where ſtick firmly to the *glaſs*, and give it a ſtrong inner coat, keeping all the colours on very fairly and ſtrongly. Theſe are ſet on frames of carved wood, and much eſteemed as ornaments in many places. *Neri*'s Art of Glaſs, p. 167.

GLASS *Pots*, the veſſels in the *glaſs* trade uſed for melting the *glaſs*. Thoſe for the white *glaſs* works are made of a tobaccopipe clay, brought from the Iſle of Wight, which is firſt well waſhed, then calcined, and afterwards ground to a fine powder in a mill; which being mixt with water, is then trod with the bare feet till it is of a proper conſiſtence, to mould with the hands into the proper ſhape of the veſſels. When theſe are thus made, they are afterwards annealed over the furnace. Thoſe for the green *glaſs* work are made of the nonſuch, and another ſort of clay from Staffordſhire; they make theſe ſo large as to hold three or four hundred weight of metal. And beſides theſe, they have a ſmall ſort called piling pots, which they ſet upon the larger, and which contain a finer and more nice metal fit for the niceſt works. *Neri*'s Art of glaſs, p. 245.

GLASS *Tubes*, laid before the fire in an horizontal poſition, and their extremities ſupported, have been obſerved to have a rotatory motion about their axis; and alſo a progreſſive motion towards the fire, even when their ſupports are inclining from the fire, ſo that the tubes will move a little up hill. See Phil. Tranſ. N°. 476. § 1.

When the progreſſive motion of the tube is ſtopped by any obſtacle, its motion about its axis will ſtill continue. When the tubes are placed in a nearly upright poſture leaning to the right hand, the motion will be from eaſt to weſt; but if they lean to the left, the motion will be from weſt to eaſt; and the nearer they are placed to the perfectly upright poſture the leſs the motion will be either way.

If the tube be placed horizontally on a *glaſs* plane, the fragment for inſtance of coach *window glaſs*, inſtead of moving towards the fire, it will move from it, and about its axis, in a contrary direction to what it had done before. Nay it will recede from the fire and move a little up hill, when the

the plane inclines towards the fire. Vid. Phil. Tranſ. ibid. p. 343, 344.

Neither the draught of air up the chimney, nor attraction or repulſion are the cauſe of theſe phænomena. It ſeems rather owing to the ſwelling of the tube towards the fire; for allowing ſuch ſwelling, gravity muſt pull the tube down, when ſupported near its extremities horizontally; and a freſh part being expoſed to the fire, and ſwelling out again, muſt fall down again, and ſo on ſucceſſively; which will produce a rotatory motion towards the fire.

If the tube be ſupported by two other tubes, and theſe be brought near to each other and to the center of the ſupported tube, then its parts hanging over on each ſide, being larger than the part which lies between the ſupporters, will by their weight, pull downwards, and conſequently force the middle part, reſting upon its two props, upwards; and being leſs advanced towards the fire, as being leſs heated, will, by their oblique ſituation, pull the middle part backwards alſo from the fire, which will cauſe a rotatory regreſſive motion quite contrary to what the tube had when ſupported near its extremities. And when a ſingle tube lies inclining oppoſite to the fire, either to the right hand or to the left, out of a plane perpendicular to the ſurface of the fire, gravity will not permit the curved part to reſt, but pull it down till it coincides with a plane perpendicular to the horizon; and conſequently, as new curves are generated, new motions will be ſo too; that is, the tube will be made to move about its axis, with this difference, when the tube inclines to the right hand, the motion will be from eaſt to weſt; when to the left hand, from weſt to eaſt. The juſtneſs of this reaſoning is made manifeſt, by bending a wire and ſupporting it firſt near its extremities, then near its center on each ſide, afterwards inclining it to the right and to the left; the bending in every caſe repreſenting the curved part of the tube next the fire. This ſolution of the phænomena is rendered the more probable from hence, that when four ſupporters were made uſe of, one at each extremity, and two near the middle, there was no motion at all either backward or forward. Nor does the increaſe of contact hinder the motion, becauſe the plate of *glaſs* was ſo broad as to have a much greater contact with the tube, and yet both the rotatory and regreſſive motions were manifeſt. Philoſ. Tranſ. ibid. p. 347, 348.

The experiments ſucceeded beſt with tubes about twenty or twenty two inches long; the diameter about $\frac{1}{10}$ inch; and they had in each end a pretty ſtong pin fixed in cork, for an axis to roll with on the ſupporting tubes.

GLASS, how to cement the cracks of *glaſs* receivers. See RECEIVER.

GLASS. To take the impreſſion of antique gems in *glaſs*. See GEM.

GLASS-*wort*. See KALI.

GLAUCEDO, a term uſed by ſome medical writers, for the diſeaſe more uſually called glaucoma. See the articles GLAUCOMA and CATARACT, *Cycl.*

GLAUCIDIUM, in zoolygy, the name uſed by ſome authors, for the ſmaller ſpecies of glaucus, the ſecond ſpecies of Rondeletius. *Ray*'s Ichthyolog. p. 296. See the article GLAUCUS.

GLAUCIUM, in zoology, the name given by Bellonius to a ſpecies of duck, ſeeming by his deſcription to be the ſame with the *capo roſſo*, or *anas fera fuſca minor*, the ſmall brown wild duck of authors. See CAPO *Roſſo*.

GLAUCIUM, *horned Poppy*, in botany the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being uſually compoſed of four leaves diſpoſed in a circular order. The cup conſiſts of two leaves, and from it there ariſes a piſtil, which finally becomes a long ſlender unicapſular pod, or ſeed veſſel, of a cylindric form, containing a number of roundiſh ſeeds.

The ſpecies of *glaucium* enumerated by Mr. Tournefort are theſe. 1. The ſmooth yellow flowered *glaucium*. 2. The hairy ſcarlet flowered *glaucium*. 3. The ſmooth ſcarlet flowered *glaucium*. 4. The *glaucium* with violet coloured flowers. *Tourn.* Inſt. p. 254.

GLAUCUS, in zoology, the name of a genus of fiſhes, of which Rondeletius has deſcribed three ſpecies. The firſt, or more common kind, is a broad fiſh approaching to the figure of the turbut, but very thin; its colour on the back and ſides is a duſky olive, and on the belly white, and it has on each ſide three or four black ſpots. Its ſcales are very ſmall and rounded, its mouth is moderately large, but its teeth are extremely ſmall; the whole inſide of its mouth is tinged with blue. Its gill fins are ſmall, and its back fins two in number, but the anterior ſcarce deſerving the name of a fin, being only a ſeries of looſe prickly rays or nerves; theſe are ſeven in number, and the foremoſt of them bends forward pointing toward the head, the other all ſtoop toward the tail. The tail is extremely large, and more forked than almoſt in any other fiſh; the tips of the forks are tinged black. This is caught in the Mediterranean. *Willugh.* Hiſt. Piſc. p. 298.

The ſecond kind has much of the figure of the firſt, and is called by ſome *glaucidium*, as being a diminutive of *glaucus*; it never arriving at the ſize of the former. This has alſo an undulated line running on each ſide from the membrane of the gills, to the middle of the body, from whence it is continued ſtrait to the tail; whereas in the common *glaucus*, this line runs ſtrait all the way. The fins alſo of this are ſpotted with black, and its body is ſomewhat leſs broad in proportion to its length. *Rondelet.* de Piſc. p. 460.

The third kind differs from the former in its having very ſtrong and ſharp teeth, and having its ſide lines from the gills much more ſinuous, and waved, reſembling the curling of a ſerpent in motion. The back, to this line, is of a deep bluiſh black, below this line it is perfectly white. *Rondelet.* de Piſc. p. 400.

GLAUX, *milk wort*, in botany, the name of a genus of plants. the characters of which are theſe. The flower conſiſts of one leaf, formed into the ſhape of a bell, ſometimes open at the end, and ſometimes ſhut, and divided into ſeveral ſegments. From the middle of the flower there riſes a piſtil which afterwards ripens into a fruit or ſhell, which is uſually of a globular figure, and opening at the extremity, ſhews a great number of ſmall ſeeds fixed to a placenta. The ſpecies of *glaux* enumerated by Mr. Tournefort are theſe.

1. The common ſea kind. 2. The white flowered ſea kind, and 3. the marſh *glaux* with leaves like thoſe of purſelain and a ſtriated ſhut flower. *Tourn.* Inſt. p. 88.

GLAZING. The Roman method of *glazing* ſome of their urns, might give our workmen a hint toward a method greatly ſuperior to any thing now in practice for the *glazing* earthen ware. There are a ſort of red urns found in Yorkſhire, which are, inſtead of *glazing*, covered all over inſide and out with a fine coral coloured varniſh, which gives them a beauty, no earthen ware of our times can come up to; and is not only far more durable than our way of doing it with lead, which is apt to crack and fly, both with wet and with heat, but far more ſafe and wholſome. Lead being well known to be a vapourable metal, and its fumes very noxious, there is great reaſon to ſuſpect that it muſt be unwholeſome when brought to the fire. This antient *glazing* ſeems to have been done either by the bruſh, or elſe by dipping, for both inſide and out are varniſhed with equal regularity; and ſomething may be gueſſed at as to the materials they uſed in it from what Pliny has left us. This author occaſionally obſerves, that ſuch earthen ware as was painted with bitumen, never loſt its beauty; and afterwards that it was a cuſtom to cover over whole ſtatues with this ſort of *glazing*, which he obſerves did not only make a ſmooth coat, but ſunk into the matter of the ſtone or earth, and therefore this could not be likely to crack and fly off like our lead coat on plates, *&c.* which is merely a cruſt laid over them. *Hook*'s Philoſ. Collect. p. 89.

Black GLAZING is made of lead aſhes eighteen meaſures, iron filings three, copper aſhes three, and zaffer two meaſures. This when melted will make a brown black; and if you want it blacker, add more zaffer to it.

Blue GLAZING is thus prepared: take lead aſhes one pound, clear ſand or pebble two pound, ſalt two pound, white calcined tartar one pound, venice or other glaſs ſixteen pound, zaffer half a pound; mix them well together, and melt them for ſeveral times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glaſs furnace for a day or two.

Brown GLAZING is made of common glaſs and manganeſe or brown ſtone, of each one part, and lead glaſs twelve parts.

Fleſh-colour GLAZING is made of twelve parts of lead aſhes, and one of white glaſs.

Gold coloured GLAZING. To make gold coloured *glazing*, take of litharge parts iij. of ſand or calcined flint, p. i. pound, and mix theſe very well together, then run them into a yellow glaſs with a ſtrong fire. Pound this glaſs and grind it into a ſubtile powder, which moiſten with a well ſaturated ſolution of ſilver, make it into a paſte; which put into a crucible, and cover it with a cover. Give at firſt a gentle degree of fire, then increaſe it, and continue it till you have a glaſs, which will be green. Pound this glaſs again, and grind it to a fine powder; moiſten this powder with ſome beer, ſo that by means of an hair pencil you may apply it upon the veſſels, or any piece of earthen ware. The veſſels that are painted or covered over with this *glazing*, muſt be firſt well heated, then put under a muffle, and as ſoon as the glaſs runs, you muſt ſmoak them, and take out the veſſels. Mr. Heinſius of Peterſburg, who ſent this receipt to the Royal Society, uſes the words *afflare debes fumum*, which is rendered *ſmoak them*, in the Tranſactions. Phil. Tranſ. N°. 465. § 6.

Green GLAZING may be prepared of eight parts of litharge, eight parts of venice glaſs, four parts of braſs duſt; or, of ten parts of litharge, twelve of flint or pebble, and one of *æs uſtum*, or copper aſhes.

Iron-

Iron-colour GLAZING is prepared of fifteen parts of lead aſhes, fourteen of white ſand, five of copper aſhes, one of manganeſe, one of zaffer, and one of iron filings.

Liver coloured GLAZING is prepared of 12 parts of litharge, eight of ſalt, ſix of pebble or flint, and one of manganeſe.

Purple brown GLAZING conſiſts of lead aſhes 15 parts, clear ſand 18 parts, manganeſe one part, white glaſs 15 meaſures, and one meaſure of zaffer.

Red GLAZING is made of antimony two pounds, litharge three, and ruſt of iron calcined one; grind them to a fine powder.

Sea-green GLAZING is made of five pound of lead aſhes, one pound of tin aſhes, three pound of flint, three quarters of a pound of ſalt, half a pound of tartar, and half a pound of copper duſt.

White GLAZING. A fine white *glazing* for earthen ware is thus prepared. Take two pounds of lead, and one of tin; calcine them to aſhes: of this take two parts, calcined flint or pebble one part, and ſalt one part, mix them well together, and melt them into a cake for uſe.

The white *glazing* for common ware is made of 40 pound of clear ſand, 75 pound of litharge or lead aſhes, 26 of pot-aſhes, and ten pound of ſalt: theſe are three times melted into a cake, quenching it each time in clear cold water. Or, it may be made of 50 pound clean ſand, 70 of lead aſhes, 30 of wood aſhes, and 12 of ſalt.

Yellow GLAZING is prepared of red lead, three pints; antimony and tin, of each two pound. Theſe muſt be melted into a cake, then ground fine; and this operation repeated ſeveral times. Or, it may be made of 15 parts of lead ore, three parts of litharge of ſilver, and 15 parts of ſand.

Citron yellow GLAZING is made of ſix parts of red lead, ſeven parts of fine red brick-duſt, and two parts of antimony. Vid. *Smith*'s Laboratory.

GLECHOMA, in botany, the name by which Linnæus calls ground-ivy. See IVY.

GLECHONITES, a name given by the antient phyſicians to a ſort of wine impregnated with penny-royal, much recommended in all obſtructions. It takes its name from *glechon*, the Greek name of penny-royal or pulegium. See PULEGIUM.

GLEDISTIA, in botany, a name given by Clayton to the plant called ceſalpinoides, by the author of the Hortus Cliffortianus, and others. The characters of the genus are theſe: it produces ſeparate male and female flowers; the male are cloſe and compact *amenta*, and the females more open and looſe ones, but both are pendulous. In the male amentum, the peculiar cup of every flower is erect, and open, and is compoſed of one leaf, divided into four concave ſegments. The flower conſiſts of four petals, of an oval figure, but very narrow, and ſomewhat hollowed; the ſtamina are ſix ſlender filaments longer than the flower, and the antheræ lie upon them. *Linnæi* Gen. Plant, p. 481.

In the female flower the cup is of the ſame ſtructure with that of the male; the flower is alſo compoſed of four like petals, but they are much larger, and there are in the baſe of this flower two ſlender nectaria-like filaments; the germen of the piſtil is broad, and compreſſed, and is longer than the flower; the ſtyle is long, the ſtigma lies upon it, and is large and crooked: the fruit is a very large and broad pod, of an extremely compreſſed figure; there are ſeveral tranſverſe ſepta in it, and the cells between them are filled with pulp; in each of theſe there is alſo contained a ſingle ſeed which is roundiſh and very hard. Hort. Cliffort. p. 489.

GLESUM, or *glæſum*, in natural hiſtory, a name given by many of the antients to the common yellow amber or ſuccinum. The word ſeems to have been originally German, and to have been adopted by the Romans in their conqueſts in that part of the world. They ſeem to have uſed the word in general for any tranſparent ſubſtance, and thence to have applied it to amber as a tranſparent ſtone. The iſland Auſtravia of the Germans afforded a very great quantity of fine amber on its ſhores, and the Roman ſoldiers thence gave it the name of *Glæſaria*. This is a proof of the word *gleſum*, being received into common uſe as the name of amber. Pliny tells us, that this iſland was called by the Roman ſoldiers *Glæſaria*, becauſe of the great quantity of ſuccinum found in it; and that by the barbarous natives, that is the Germans of thoſe times, it was called Auſtravia. The finding amber in plenty on this iſland, on which there grew alſo a great number of pines of a ſpecies not known to the Romans before, gave origin to an opinion that prevailed a long time among them; that is, that the amber was the condenſated reſin of this tree. Pliny ſays, that the reſin of this tree ſweating out of its cracks and chinks in the heat of the autumn, and falling into the ſea, was there toſſed about and hardened by the water; and finally, ſo concreted by the cold weather, as to acquire the ſtony hardneſs we ſee in it; and it is in this ſenſe that the Roman authors tell us, that the diſcovery of the true nature of amber was owing to Cæſar Germanicus, who diſcovered this new ſort of pine in the amber country.

Pliny alſo tells us, that the *gleſum*, or amber, was produced in India, and relates a ſtory of Archelaus, a governor of a province, who ſent from thence a rude or rough maſs of amber to Rome, with the bark of the pine tree, from which it had exſudated, yet remaining affixed to it. This might ſeem a proof of its being the gum or reſin of a tree; but when we conſider the inaccuracy of the writers of that time, it will have but little weight againſt the modern ſyſtem of amber being a true and genuine mineral. The ſtory might poſſibly not be true; or if ſo, the amber might be only adhering to that ſort of cortical ſubſtance reſembling the barks of trees, among which it is found foſſile in Pruſſia at this time. This ſubſtance is not the bark of any tree, though it much reſembles it. Finally, it might not be amber which this governor ſent to Rome; but ſome Indian gum, of which there are two or three ſo like amber, that nothing but experiments can ſhew that they are not ſo, and this might very naturally be ſent with the bark of the tree, which produced it, yet adhering to it. Tacitus tells us, that the amber brought from Germany was rough or rude, but he does not ſay any thing of its having any bark adhering to it.

GLEUCINUM, a term uſed by the old Greek writers, to expreſs a compoſition made of the oil of unripe olives, in which there were infuſed ſchænanth, ſpikenard, and many other of the aromatic drugs, with a conſiderable quantity of muſk; all theſe were put together into a veſſel, which was ſurrounded with the preſſings of grapes, the fermentation of which gave it a gentle heat; and it was left thus thirty days, being well ſtirred about every day: at the end of this time it was ſtrained off, and the clear oil reſerved for uſe. It was eſteemed warming, emollient, and relaxing, and was uſed externally in many caſes.

GLINUS, in zoology, a name by which Bellonius and ſome other authors have called a ſmall ſea fiſh, more commonly known by the name of the *dracunculus*.

GLIS. In the common acceptation of the word, this only ſignifies the dormouſe. But Linnæus has uſed it in a larger ſenſe; and, in his ſyſtem of zoology, makes it the claſſical name of a ſet of animals. The characters of the creatures of this claſs are, that they have only two fore teeth in each jaw, they have no dentes canini or dog teeth, and have all eight paps placed on their belly. The animals of this claſs are the ſeveral ſpecies of the porcupine, the hare, the ſquirrel, the beaver, and the mouſe and rat. *Linnæi* Syſtem. Natur. p. 38.

GLIS is commonly uſed as the name of an animal of the mouſe kind; but ſo differently deſcribed by different authors, and ſo imperfectly and erroneouſly by many, that it is a queſtion whether we can properly call any known animal by the name.

Geſner deſcribing it by hearſay, ſays, that it is larger than a ſquirrel, and either black, or brown on the back, and white on the belly, its tail ſhort, and its general figure ſomewhat approaching to that of the bear. *Ray*'s Syn. Quad. p. 230.

GLIS *Volans*, the *flying dormouſe*, in zoology, the name of an animal, properly of the veſpertilio or bat kind; it is diſtinguiſhed, by Linnæus, by the name of *veſpertilio caudatus naſo foliato obverſe cordato*. *Seba*, Vol. I. p. 9. *Linnæi* Syſt. Nat. p. 37.

GLISCHROCOLOUS, an epithet uſed by ſome writers, to expreſs excrements which are at once viſcid, and very highly ſated with gall.

GLISCHROMICTHES, in natural hiſtory, the name of a genus of compound earths. The word is derived from the Greek γλισχρὸς tough, and μικθὶς mixed. The bodies of this genus are loams compoſed of ſand and a more viſcid clay, and are of a tough and firm texture.

The earths of this genus are uſed in making bricks, and on ſome other occaſions, and are of ſeveral diſtinct ſpecies. 1. A greyiſh white one, dug in many counties of England, and making a very firm brick. 2. A pale yellow one, dug plentifully in the neighbourhood of London, and making a fine red brick. 3. A yellowiſh brown one, frequent at ſmall depths in all parts of the kingdom. 4. A rediſh brown one, dug in Staffordſhire, and ſome other counties, and ſhewing itſelf in ſome places on the ſurface in the roads. *Hill*'s Hiſt. of Foſſ. p. 429.

GLISOMARGA, a word uſed by ſome authors as a name for chalk. See CHALK.

GLISSA, in zoology, the name of a ſea fiſh of the tunny kind, but of a perfectly ſmooth ſkin, and wholly free from ſcales. It uſually grows to the length of two cubits, and the thickneſs of a man's body. It is of a very round body, and has very rough jaws, but no diſtinct teeth; its tail is forked, but not ſo arched or lunated as that of the tunny; it lives in deep water, and is a fiſh of very delicate taſte. *Geſner* de Piſc. p. 1158.

GLOBE (*Cycl.*)—Our common *globes*, though inſtructive inſtruments for explaining the firſt rudiments of geography, and the ſpherical doctrine of aſtronomy, yet labour under ſeveral defects, as they do not ſhew how the phænomena ariſe from the motion of the earth, which is one of the chief points beginners ſhould have in view. Mr. Joſeph Harris has therefore contrived to remedy theſe defects, in the Philoſophical Tranſactions, N° 456. Sect. 7.

He places two horary circles under the meridian, one at each pole, ſo that the *globe* ſerves equally well for ſolving of queſtions in ſouth, as in north latitudes. He alſo divides the braſs meridian, at one of the poles, into months and days according to the ſun's declination, reckoning from the pole. If then the day of the month be brought to the horizon, and the *globe* rectified according to the time of the day, the horizon will repreſent the circle ſeparating light and darkneſs; and the upper half of the *globe*, the illuminated hemiſphere, the ſun being in the zenith. Mr. Harris alſo gives an account of a cheap machine for ſhewing the annual motion of the earth in its orbit, without the great expence of an orrery. See Phil. Tranſ. N° 456. Sect. 7. p. 323.

GLOBULARIA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the floſculous kind, and is compoſed of a number of ſmall floſcules of an unilabiated figure, divided into many ſegments, and each contained in its proper and peculiar cup: from the bottom of each ariſes a piſtil, which is fixed in the manner of a nail to the hinder part of the floſcule; and this, finally, becomes a ſeed, which remains till ripe in a capſule made of what was before the cup of the flower; and all theſe capſules are affixed to a placenta, which ſtands in the center of the general flower.

The ſpecies of *globularia* enumerated by Mr. Tournefort are theſe. 1. The common daiſy leaved *globularia*, called by many the blue daiſy, with foliaceous ſtalks. 2. The long leaved pyrenæan *globularia* with naked ſtalks. 3. The low, procumbent, creeping mountain *globularia*. 4. The ſhrubby *globularia*, with tridentated myrtle-like leaves. 5. The ſhrubby African *globularia*, with woolly leaves like the thymelæa. 6. The prickly *globularia*; and 7. The ſmalleſt origanum leaved alpine *globularia*. *Tourn.* Inſt. p. 466.

GLOKEN *ſpeiſſe*, in mineralogy, a term uſed by the Germans to expreſs a ſort of impure regulus of biſmuth, obtained by accident, ſometimes in the making of ſmalt. The biſmuth ores are often ſo intimately mixed with the cobalt, that they cannot be ſeparated from them. In this caſe, the arſenic being raiſed in flowers, there remains at the bottom, inſtead of the fixed vitrifiable earth of the cobalt, a ſort of impure regulus of a reddiſh colour. This is biſmuth, with an admixture of the earth of cobalt, and other extraneous matter. They ſometimes call this whole matter by the common name of *ſpeiſſe*, but more uſually they ſeparate it into two parts; and call the under part, which is moſt ſolid, *gloken ſpeiſſe*, and the upper part they diſtinguiſh by the name of *æs caldarium*.

GLOMERELLS, in our old writers, commiſſaries appointed to determine differences between ſcholars of a ſchool or univerſity, and the townſmen of the place. In the edict of the biſhop of Ely, anno 1276, there is mention of the maſter of the *glomerells*.

GLOSSOCATOCHOS, a word uſed by ſome writers to expreſs a chirurgical inſtrument, uſed to depreſs the tongue for examining the mouth. See GLOSSOSPATHA.

GLOSSOGRAPHE, in botany, a name uſed by ſome authors for the fumaria, or common fumitory. *Ger. Emac.* Ind. 2.

GLOSSOIDES, in natural hiſtory, a name given by ſome authors to a ſpecies of ſtone, reſembling the figure of the human tongue. This is a mere accidental configuration of a common flint, or pebble, perfectly indeterminate in ſize and colour, and owing its form to no animal mould, as the ſtones found in ſhells uſually do, but is a mere *luſus naturæ* in the concretion of the ſtone.

GLOSSOPETRÆ. See the article LAMIODONTES.

GLOSSOSPATHA, a chirurgical inſtrument, called by ſome *ſpeculum linguæ*, and uſed to depreſs the tongue, in order to look into the fauces.

There are many inflammatory diſorders of the mouth, fauces, and palate, which require a depreſſion of the tongue, while they are inſpected, and treated with proper remedies. The handle of a ſilver ſpoon is made to ſupply the place of this inſtrument in moſt caſes, and anſwers the purpoſe very well. Whichever is uſed, care ſhould be taken to depreſs very gently, to avoid giving the patient pain, as alſo to avoid irritating the mouth and inflamed parts.

When injections are to be made into the mouth, this inſtrument or the ſpoon ſhould alſo be applied, and the ſyringe ſhould be conveyed into the mouth over it. *Heiſter* Surgery, p. 464.

GLOTTIS, in zoology, a name given by many authors to a bird of the long leg'd kind, approaching to the nature of our redſhank, but larger and longer legg'd, and generally known by the name *limoſa*. See LIMOSA.

GLOVE. The delivery of a *glove* was in frequent uſe formerly, as a ſymbol of inveſtiture. See *Du Cange* Gloſſ. Lat.

Gloves was alſo uſed to ſignify the ſteward's or bailiff's fee, or part of the price of the inveſtiture, or purchaſe money of the land. *Si aliquam territorii partem venundari contigerit, domini venditiones habebunt; ſcilicet, tot denarios quot venditor inde habuerit ſolidos. Major vero terræ illius pro* wantis *accipiet duos denarios.* Where *wanti*, ſignifies *gloves*, or in French, *gants*. *Du Cange* Gloſſ. Lat.

Hence the common cuſtom in many bargains of giving ſervants money for a pair of gloves.

GLOUTIUS, in anatomy, a name given by Riolan, and ſome others, to the muſcles of the thigh, generally called *glutæi*, or ſingly *glutæus major*, &c.

GLOW-*worm*, *cantharis*, in zoology, a claſs of inſects, the antennæ of which are ſetaceous, the exterior wings flexile, the thorax ſomewhat flatted, and the ſides of the abdomen plicated and papilloſe.

The ſpecies of *cantharis* enumerated by Dr. Hill are theſe. 1. The *cantharis*, the female of which has no wings, and is the common *glow-worm*. 2. The *cantharis*, with blackiſh exterior wings, and with a red thorax, with a black ſpot. 3. The red winged *cantharis*, with a red thorax and black ſpot. 4. The *cantharis*, whoſe exterior wings are black, with two red tranſverſe lines. 5. The large, yellowiſh, or orange-coloured *cantharis*, without ſpots. 6. The black-winged *cantharis*, with a red thorax, and black ſpot on it. 7. The red-wing'd *cantharis*, with a black thorax, and red ſpot on it. 8. The braſſy-green *cantharis*, with the exterior wings reddiſh toward their edges. 9. The braſſy-green *cantharis*, with the exterior wings red at the tips. 10. The black *cantharis*, with the exterior wings yellow at the extremities. 11. The brown *cantharis*, with the exterior wings yellowiſh at the extremity, and the breaſt reddiſh. 12. The black *cantharis*, with livid wings. *Hill*, Hiſt. of Animals, p. 53. ſeq.

The common *glow-worm* is frequently met with under our hedges, and, if carefully taken up, may be kept alive many days on freſh turfs of graſs; all which time it will continue to ſhine in the dark.

The light of this little inſect is ſo ſtrong, that it will ſhew itſelf through ſeveral ſubſtances, in which the creature may be put up; a thin pill box eaſily ſhews it through, and even though lined with paper, the light is not impeded in its paſſage by both. The creature is ſluggiſh, and appears dead in the day-time, and its light is not diſtinguiſhable, even if carried into a darkened room, unleſs the creature be turned upon its back, and diſturbed, ſo as to be put in motion, and then it is but very faint: after ſun-ſet the light begins to return, and with it the life and motion of the animal. The motion and light of this creature ſeem, in ſome meaſure, to depend upon one another: it never ſhines but when its body is in ſome ſort of motion; and when it ſhines moſt the body is extended to one third more than its length in the day-time. In the time of brighteſt ſhining, it will ſometimes of a ſudden turn its body about, and the light will not be larger than the head of a pin; and, on being touched, ſhe will then immediately extend herſelf, and the light will become as large and as bright as ever. Phil. Tranſ. N° 71.

Flying GLOW-*worm*, *Cicindela volans*. In the warmer months of the year, this creature is ſometimes caught in our houſes flying to the flame of a candle, and when examined in the dark it is found luminous at theſe times, though perhaps leſs, or not at all ſo, at others; which may be a reaſon of its not being known though caught in the fields: and to this it may be owing, that many who have deſcribed it have thought it not a native of England. See Tab. of microſcopical Objects, Claſs 1. Without wings it is frequently enough found in form of the common *glow-worm*, and then always ſhines. Aldrovand has very well deſcribed the *cicindela volans*; and ſays, that it lays eggs which hatch into ſmall worms, and that theſe after a time become flies, by the ſame ſort of change which happens to caterpillars and other reptiles which become butterflies, and other ſpecies of winged inſects. Mouffett, and Thomas Bartholine, both deſcribe the animal much as Aldrovand has done, but they allow only the male to have wings; but Julius Scaliger contradicts this, and ſays, that he has caught them both winged in the act of generation; this is a plain proof that both ſexes are winged; yet it has not happened that both have been acknowledged to be ſo even by thoſe who have quoted this paſſage. And Mr. Waller, who gives an account of them in the Philoſophical Tranſactions, obſerved them in the ſame manner in the act of copulation both winged, and with no other difference between them, but that the female was the larger of the two, which is the caſe in regard to many inſects. *Julius Scalig.* Exerc. 191. Phil. Tranſ. N°. 167. p. 841.

The male and female in this winged ſtate, both ſhine in hot weather, and their light is ſo vivid as to be eaſily ſeen even while there is a candle in the room; the vibrations of it are irregular, and its colour greeniſh. The luminous parts are two ſmall ſpecks under the tail at the end, and the light continues in theſe ſome time after the tail is cut off, but then gradually goes out.

The parts of inſects continue alive in ſome degree for a conſiderable time after they are cut off, and probably the light in the tail of this animal continues juſt as long as that ſort of life remains in it. *Mouffett*, Cap. 15.

The uſe of this light ſeems to be to direct the animal in its courſe, and in the taking of its prey, and to this purpoſe it is admirably placed. The tail is eaſily bent under the belly, and then throws the light full upon any object about, or under the head of the animal, and the eyes are placed not on the upper part, but on the under ſide of the head; ſo that they have all the advantages of it, while the light in this part is not offenſive to the eyes, as it naturally would have been, if carried before the head. The creature can

upon occaſion cover this light ſo as not to be known, or purſued by it, by its enemies. *Thomas Barthol.* de Luce Anim. Lib. 2. Cap. 12.

This inſect is of the beetle kind, of a brown and duſky colour. It has hard caſe or ſhell wings as the other beetles have, and when theſe are expanded, there appear a pair of very large membranous ones; its head is covered with a ſort of ſhield or broad brim'd hat; under this hat are placed the eyes, which are black and large, and are moveable; ſo that the creature can upon occaſion thruſt them forward to the ſides of the hat, or covering of the head; it has two hairy antennæ, and its legs are like thoſe of the common fly, hard, ſhelly, and hairy. Its eyes afford an elegant object for the microſcope, being compoſed of an infinite number of lenſes, as thoſe of the libellæ and other inſects. *Aldrovand.* de Inſect. Lib. 1. Cap. 8.

GLUE *(Cycl.)*—A ſtrong and fine *glue* may be prepared with iſinglaſs and ſpirit of wine, thus; ſteep the iſinglaſs for twenty four hours in ſpirit of wine or common brandy. When the menſtruum has opened and mollified the iſinglaſs, they muſt be gently boiled together, and kept ſtirring till they appear well mixed, and till a drop thereof ſuffered to cool, preſently turns to a ſtrong jelly. Then ſtrain it while hot through a clean linnen cloth, into a veſſel to be kept cloſe ſtopped. A gentle heat ſuffices to diſſolve this *glue* into a tranſparent and almoſt colourleſs fluid, but very ſtrong; ſo that pieces of wood *glued* together with it, will ſeparate elſewhere, than in the parts joined. *Boyle*'s works, Abridg. Vol. 1. p. 130.

GLUME, *gluma*, among botaniſts, a ſpecies of cup conſiſting of two or three membranous valves, which are often pellucid at their edges. This kind of cup belongs to the graſſes. See the article GRASS.

GLUTTA, a name given by ſome authors to the gutta gamba, or gamboge. See GAMBOGE.

GLYCOPICROS, in botany, a name by which ſome authors have called the ſolanum lignoſum, or dulcamara. *J. Bauhin.* Vol. 2. p. 109.

GLYCYCALAMUS, a word uſed ſingly as the name of a vegetable ſubſtance, by ſome of the Greek writers; but by the moſt antient, it is only uſed as an epithet for a peculiar kind of lotus. This *lotus glycycalamus*, is a name given by Myrepſus and others to the caſſia fiſtula, but by other of the antients, it ſeems to have been made the name of the ſugar cane. See LOTUS.

GLYCYNE, in botany, the name given by Linnæus to a genus of plants, ſome of the ſpecies of which are deſcribed by Boerhaave under the name of *apios*, the characters are theſe. The cup is a one leaved compreſſed perianthium, divided at the extremity into two lips, the upper of which is emarginated and obtuſe, the under one is long, obtuſe, and divided into three ſegments, the intermediate one of which is longer than the others. The corolla is of the papilionaceous kind. The vexillum is obtuſely cordated, the ſides are bent back, and the back gibbous, the end ſtrait and marginated. The alæ are oblong, oval toward the end, ſmall and bent downwards. The carina is ſlender, falcated, and bent upwards, and is broadeſt toward the apex, where it riſes up to the vexillum. The filaments are diadelphous, and the apices ſimple. The germen of the piſtil is oblong. The ſtyle is cylindric, and twiſted into a ſpiral form, and the ſtigma is obtuſe. The fruit is an oblong bilocular pod. The ſeeds are kidney ſhaped. *Linnæi* Gen. Pl. 370. *Boerhaave* Ind. ult. 146.

GLYCYRRHIZA, *liquorice*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the papilionaceous kind, and from its cup there ariſes a piſtil, which finally becomes a ſhort pod, which uſually contains a number of kidney ſhaped ſeeds. To this it may be added, that the leaves are placed oppoſite to one another, many of them on a long middle rib which has a ſingle one to terminate it at the end.

The ſpecies of *glycyrrhiza* mentioned by Mr. Tournefort are two. 1. The *glycyrrhiza* or liquorice with echinated heads, and 2. the german or podded *liquorice*. See LIQUORICE.

GNAPHALIUM, *cudweed*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the floſculous kind, being compoſed of many ſmall floſcules, ſtanding on the embryo ſeeds, each divided into ſeveral ſegments at the end, and among theſe are intermixed many imbricated leaves, all comprehended in a general cup of a foliacious ſtructure and hemiſpheric figure. The embryos become hard ſeeds covered with a ſort of hood.

There is only one known ſpecies of this genus, which is the plant commonly called *Gnaphalium maritimum*, the ſea *cudweed*. *Tourn.* Inſt. p. 461.

The common *cudweed* is deſiccative and aſtringent, and is of great efficacy in hæmorrhages of all kinds. In dyſenteries, and in floodings of the menſes, it has been known to do great cures. Some have recommended the diſtilled water of it in cancers, but this ſeems to have no very great foundation. A decoction of it in ſmall beer is a common medicine among country people for quinſies, and is ſaid ſometimes to have done remarkable cures in them.

GNAPHALOIDES, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the floſculous kind, being compoſed of a number of ſmall floſcules which are barren. The embryo ſeeds conſtitute the cup of the flower, which afterwards becomes a creſted fruit containing uſually an oblong ſeed.

There is only one known ſpecies of this plant, which is called by ſome, the ſmall procumbent *cudweed* from Portugal with echinated ſeed. *Tourn.* Inſt. p. 439.

GNAPHEUS, in ichthyology, a name given by Athenæus and other of the Greek writers to the tench. See the articles TINCA and CYPRINUS.

GNATS. There is no ſpecies of inſect that we have ſo much reaſon to diſlike in regard to the injury it does us as the *gnat*. Others indeed give us more pain with their ſtings, but 'tis but by accident that we are ſtruck by them; the *gnats* thirſt for our blood, and follow us about in whole companies for it. There are many marſhy places where the legs and arms are all the ſummer ſwelled to an enormous ſize by the repeated bitings of theſe inſects, and in many other countries they are yet greatly more troubleſome than with us. *Reaumur* Hiſt. Inſ. Vol. 4. p. 574.

But as troubleſome enemies as theſe little creatures are to us, there is that about them which is extremely worthy our admiration, nor can we indeed fail greatly to admire even the very inſtrument of the miſchief they do. They have beſide this many very obſervable particulars in the courſe of their lives, and there is one moment of that in which forgetting the trouble they are likely to give us we cannot but be ſolicitous for their ſafety.

All the naturaliſts of late years have applied the microſcope to the examination of the parts of this little animal, and Swammerdam, Hook, Bonanni, Lewenhoek, *&c.* have given very good accounts, and very valuable drawings of the creature.

The external figure of the *gnat* is well known, yet not enough to prevent ſome miſtakes about it, as it is frequently confounded with the tipula, or *father long legs* as we vulgarly call it in England. There are many marks indeed which they have in common, they both have ſuch long legs, that they look as if mounted upon ſtilts. Both have long ſlender bodies, and both prominent corcelets, which make them look hump backed; but when either of theſe inſects is taken into the hand it is very eaſily known, the *gnat* having a very long trunk, and the tipula no trunk at all.

There is a great number of very ſmall ſpecies of *gnats*, and though ſome are conſiderably large, yet none even of theſe approaches to the ſize of the tipula. The larger tipulæ are therefore eaſily diſtinguiſhed from the *gnats*, but Swammerdam, Goedart, Liſter, and others have very often given us the ſmaller tipulæ among the ſpecies of *gnats*.

There is a prodigious number of ſpecies of the *gnat* kind taking in the ſmaller ones, but of thoſe of a ſize to be remarked with eaſe, and without the help of glaſſes, there are three principal kinds; the one has its body variegated with white and black; this is the larger kind, and its corcelet is ſtreaked with black or deep brown, and white lines or greyiſh ones; theſe have brown eyes. Another is ſmaller than this ſpecies, and has a plain brown body, the colour of the corcelet, and that of the eyes is the ſame as in the larger or firſt ſpecies. The third kind is the ſmalleſt of the three and the moſt common, has its corcelet reddiſh, or of a faded reddiſh yellow, and the body whitiſh, and on the under part of the belly, every ring has one ſingle brown ſpot; the reſt is grey. The eyes of this ſpecies are of a very pleaſant green.

All the *gnats* have a long cylindric body compoſed of eight rings; their corcelet is ſhort, but large in proportion to the ſize of the fly, and to this are fixed the leg, the wings, and the balancers; four ſtigmata are alſo found here as is the caſe in other flies. The two firſt of theſe are placed near the head, and have been miſtaken for ears.

When the *gnat* is in a ſtate of reſt, it holds one wing ſomewhat croſſed over the other, in ſuch a manner, as that they cover the body. It has a multitude of little oblong ſcales on its wings, and not only there, but on its corcelet and body; and they are ſo thick laid on the body, that one cannot touch it without rubbing them off, and leaving the part naked. Beſide theſe, they have alſo very long and extremely fine hairs, and ſome of the ſpecies have ranges of theſe on each ſide the body appearing like fringes. The antennæ of the *gnats* are extremely worth obſervation, and differ much from one another. Some of them are elegantly feathered, theſe belong to the males of certain ſpecies, for the antennæ of the females are not ſo beautiful.

Theſe feathered antennæ of the male *gnats*, examined by the microſcope, ſhew at every junction of two of the rings, a ſmall cluſter of hairs in form of a pencil on each ſide; the hairs of which theſe are compoſed ſeparate, and ſpread toward their extremities; theſe cluſters of them grow ſhorter as they approach the upper part of the antennæ, and toward the extremity of each, there is a vacant ſpace where they are wholly wanting; this part however is covered with ſingle ſhort hairs.

The antennæ both of the males and females of ſome ſpecies have alſo their ſtalks covered with ſingle hairs and at certain diſtances, or at every articulation theſe have four hairs longer than the reſt, and eaſily diſtinguiſhable by the naked eye.

The *gnats* have no ſmall or gloſſy eyes as moſt of the other flies have, but in recompence for the want of theſe, they have reticular eyes ſo large as to ſurround, and in a manner cover the whole head. Thoſe of many ſpecies are extremely beautiful, of a fine changeable green in ſome lights, and of a bright red in others.

Many of the ſpecies of *gnats* have before their heads two ſmall oblong cylindric bodies, ſomething reſembling the antennæ of the ſhort bodied flies; theſe we may not improperly call the beards of the *gnat*, for immediately below them is placed the trunk, and they ſeem to have ſome analogy with the beards of the butterfly claſs, which are placed in the ſame manner. *Reaumur*, ibid. and p. ſeq. For the trunk and wings of the *gnat*, ſee the articles TRUNK and WINGS.

GNAT-*worm*, in natural hiſtory, a ſmall water inſect, produced of the egg of a *gnat*, and which is after its ſeveral changes transformed into a *gnat* again.

Theſe worms do not frequent rivers, but ditches, ponds, and other ſtanding waters afford them in vaſt abundance, from the middle of May, till toward the beginning of winter. This is the reaſon why watery and marſhy places are found moſt to abound with *gnats*, and why the wet ſummers are found to produce the greateſt numbers of them; becauſe in dry ſeaſons, the ponds and ditches, where they are to paſs their worm ſtate, are dried up, and the worms killed. Theſe are a creature however, that one need not go far to ſeek, ſince one need only expoſe a veſſel of water in a garden, or any open place in the ſummer months, and ſooner or later it will not fail to afford plenty of theſe worms.

Before theſe worms are arrived at their full growth, though they are then but ſmall, they are eaſily found, becauſe they are under a neceſſity of coming frequently to the top of the water, by having occaſion for frequent reſpiration; and to do this, they are obliged to keep the end of a ſmall pipe they are furniſhed with, from the laſt ring of their body, above water. The end of this pipe is hollow and indented, and forms a ſort of funnel on the ſurface of the water: it is of the length of about three rings of the body, and is ſomewhat thicker at its inſertion than at its extremity.

As there is a vaſt number of ſpecies of *gnats*, there is no leſs of the worms from whence they are produced, and to this is in a great meaſure owing the variety in the figures given of the worms by the authors who have treated of them; which may alſo be not a little added to by the particular views in which thoſe draughts have been taken. Notwithſtanding all the variations of theſe figures, the general form of the animal is however the ſame in all, and the ſpecies cannot but be known from any of them.

The worm is of the third claſs of thoſe which are transformed into two winged flies; that is, it has no legs, and has a head of a conſtant and invariable figure, and has no teeth or moveable jaws formed to play againſt one another. Their body is ſomewhat long, and the head is detached from the firſt ring, to which it is faſtened by a ſort of neck. This firſt ring is the longeſt and largeſt of all, and ſeems a ſort of corcelet to the worm. The creature has eight rings beſide this, theſe grow ſmaller as they approach the hinder extremity.

The tube of reſpiration which is ſent off from the laſt ring, uſually makes an angle with it, and is ſeldom ſeen in a right line with the reſt of the body; but beſide this there is ſent off from the ſame ring, another pipe or tube as wide as this, though much ſhorter; this is affixed to the lower part of the laſt ring near the belly, and is placed almoſt perpendicularly to the length of the body; this is the paſſage for the excrements of the worm, which is often ſeen to void green ones through it.

This whole tube is ſurrounded with long hairs, and from its end, from within the hollowed part, there are propagated four very tranſparent, thin, and ſcaly oval bodies, which ſeem intended as ſo many oars; they are placed by pairs, one pair going out from the right hand ſide, and the other from the left, and the creature has a power of drawing them toward, or ſeparating them from one another. Every ring of the body has on each ſide about the middle of its length a pencil of fine hairs, but the firſt ring which may be compared to the corcelet of flies, is furniſhed with three of theſe pencils.

While the worm is young, the body is whitiſh or greeniſh, but when it is at its full growth, and draws near the time of its changes, it becomes greyiſh. The great tranſparence of the body of this worm, gives a fine view of what paſſes within it; it is at any time eaſy to ſee into the motion of the inteſtines, by which the food is puſhed on towards the anus. The two principal tracheæ are alſo ſeen very diſtinctly in this creature, they are two white tubes placed in a parallel direction one to another, and run from the firſt ring to the tube of reſpiration.

The head is of a browner hue than the reſt of the animal, and is ſomewhat flatted; on each ſide one may eaſily diſtinguiſh a brown ſpot which are the eyes. There are no teeth diſcoverable in the mouth, but all about it there are placed a number of ſmall beards; two of theſe are much larger than the reſt, and are ſomething of the figure of two creſcents; theſe are fringed within, and the creature has a power of moving them very ſwiftly, and by that means makes a current of water about its mouth, which brings with it the proper food for the animal.

The head of this creature is adorned alſo with a ſort of antennæ; theſe are bent into a ſort of circle, and the concave ſide of one is turned toward the concave ſide of the other. Theſe are antennæ of a very different ſtructure from thoſe of the winged inſects, for they have no articulation except that of their baſe. Their concave ſide is ſmooth and poliſhed, and all along the convex ſide, there are placed at certain diſtances ſmall hairs, which look like ſo many weak thorns or prickles. And at ſome diſtance from the end of each antenna, is a ſmall cluſter of long and fine hairs.

The *great worm*, ſeveral times changes its ſkin in the courſe of its life. After three changes of this kind, which uſually happen in the ſpace of three weeks, or thereabout, it undergoes a fourth, where the old ſkin is as eaſily thrown off as in the reſt, but the animal now appears in a new form, that of a nymph: it is now ſhorter and rounder than before, and the body is ſo bent that the tail is applied to the under part of the head; this, however, is only its form in a voluntary ſtate of reſt, for it can yet move, and when it pleaſes extends its tail, and ſwims about as ſwiftly as when in its other ſtate.

All the parts of the future *gnat* may be ſeen in this nymph; the ſkin of it is extremely thin and tranſparent, yet ſufficiently tough and firm for the uſe it is intended for. It is uncertain how long exactly the animal lives in this nymph ſtate; but after the time is accompliſhed, its change into the *gnat* is very quick, and is attended with great danger to the animal, ſince multitudes are drown'd, and periſh in the act of getting out. *Reaumur*, Hiſt. Inſect. Vol. IV.

GO, in ichthyography, a name given by ſome to the common rock fiſh, or ſea gudgeon. *Willoughby*'s Hiſt. Piſc. p. 206. See the article GOGET.

GOACONEZ, in botany, the name of an American tree which affords a white balſam, but little known in Europe; it is called by ſome authors *balſamum album*, and by others *balſamum purius*.

GOAN, the name of a Perſian tree, of the aſhes of which they make a ſort of antiſpodon, or medicinal powder for diſeaſes of the eyes. *James*, Med. Dict. in voc.

GOARING, on ſhip-board. The ſeamen ſay a ſail is cut *goaring*, when it is cut ſloping by degrees, and is broader at the clew than at the earing, as all top-ſails and top-gallant ſails are.

GOAT, *capra*, in zoology, a genus of animals; the characters of which, according to Mr. Ray, are theſe. That it is covered with hairs, not with wool; that its horns are leſs crooked than thoſe of the ſheep, and that it has a beard hanging down from its chin, and is of a ſtrong ſmell.

It is very ſingular, that this genus of animals are all able to run and climb about the rugged parts of mountains without falling, though their feet ſeem by no means contrived by nature for any ſuch purpoſes. There are eleven known ſpecies of this animal. 1. The common kind ſufficiently known. 2. The *capra mambrina* or Syrian *goat*. This is remarkable for the length of its ears, which reach almoſt to the ground; the horns are two or three hand's breadth long, and are very little inflected backwards; it is of the ſhape of the common *goat*, but larger; its colour is that of the fox; its horns are black, and its ears very like thoſe of the common hunting hound; it has two appendages hanging from under its throat, and is a creature eaſily tamed, and feeds on hay and other vegetables. 3. The *capra Africana*, or African *goat*, deſcribed in the German ephemerides, which is of a duſky grey colour, and has a bundle of erect hairs growing on the middle of its head; and on each ſide, between the eyes and noſe, it has two cavities, which contain a thick, fat, yellowiſh liquor, which afterwards congeals into a black ſubſtance, of a mixed ſmell, between thoſe of muſk and caſtor. As ſoon as the matter contained in theſe cavities is taken away there returns more in its place, which is in like manner dried and hardened by the air. Theſe cavities have no communication with the eyes, and therefore the matter deſcribed here is nothing of the nature of the *lachryma cervi*, mentioned in the catalogues of the materia medica: this creature is figured without horns, in which it agrees with the muſk animal. The other ſpecies are, 4. The *ibex*, 5. The *rupi capra*, 6, 7, 8. The three ſpecies of *gazella*. 9. The *buſelaphus*, and 10, 11. The two *tragelaphi*, each of which ſee under its proper head. *Ray*'s Syn. Quad. 180. Ephem. Germ. ann. 14. obſ. 57.

Goats may be of great advantage to the farmers in ſome parts of the kingdom, as they will live in rocky barren countries, where nothing elſe can get a ſupport for life. They will climb

climb the ſteepeſt rocks, and there browſe upon briars, heath, and ſhrubs, of various kinds, which other creatures will not taſte of. They will feed on graſs in paſtures, but as they love browſing on trees much better, great care muſt be taken to keep them from valuable plantations. *Mortimer*'s Huſbandry, p. 246.

The greateſt advantage of theſe creatures is their milk, which they yield in large quantities, and which is accounted the beſt milk of all animals. They mix this and cow's milk together in many parts of the kingdom, and a very valuable kind of cheeſe is made of it. Beſide this, the kids or young *goats* are very fine food, and the beſt kinds bring forth theſe two or three at a time, and that twice a year. See MILK.

Goat's hair alſo is of value, it may be ſheared as the wool from ſheep, and is excellent for making ropes that are to be uſed in the water, as they will laſt a great while longer than thoſe made the common way. A ſort of ſtuff is alſo made of it in ſome places. The beſt kind of *goats* for keeping to advantage ſhould be choſen in this manner: the male ſhould have a large body, his hair ſhould be long, and his legs ſtrait and ſtiff; the neck ſhould be plain and ſhort, the head ſmall and ſlender, the horns large, the eyes prominent, and the beard long. The female ſhould have a large udder, with large teats and no horns, or very ſmall ones. They ſhould be kept in flocks, that they may not ſtraggle, and they ſhould have good ſhelter both in ſummer and in winter, the heat and cold being both prejudicial to them. They ſhould be coupled in December. They ſhould have no litter in winter, but only a paved floor kept clean. The kids are to be brought up for the table in the ſame manner as our lambs are. They are recommended to lie among horſes, their ſmell, as is ſuppoſed, preventing many diſtempers in thoſe cattle. Ibid. p. 247.

GOAT *of Greenland*, *Caprea Greenlandica*, in zoology, the name of an animal of the northern parts of the world. We are not perfectly acquainted with the ſhape or figure of the creature, but its horns are preſerved in the muſæum of the Royal Society, and in ſome other collections, and are uſually an ell long, very much branched, and the branches not flat but rounded, covered all over with a velvety down, compoſed of ſhort filaments ſtanding erect every way, and about a quarter of a finger's breadth long.

GOAT-*fiſh*, *Capriſcus*, in ichthyography, the name of a fiſh called alſo by ſome *caper*. Its head is very much flatted both ways, its eyes are placed very high in the head, its mouth is ſmall, but well furniſhed with teeth, each jaw having eight of them, and all ſtrong, broad, and not ſerrated, but much reſembling the human ones. The gills are four on a ſide, covered only with a membrane, and opening by a ſmall ſlit as in the mola. In the middle of its back it has three very ſtrong and large prickles, the firſt of which is three times as large as any of the others, and all are connected by a membrane. Behind theſe is a furrow in the back, into which at pleaſure the animal can depreſs theſe. Behind theſe there begins a fin, which runs down the back to the tail. It has another thorn running along under the ſkin of the lower part of its body, and at length appearing externally in a very ſtrong and ſharp prickle; and behind that ſeveral other ſmaller and more feeble ones, which are ſerrated at their edges. From the anus to the tail there runs another fin, and there are two ſmaller ones at the gills. See Tab. of Fiſhes, N° 22.

The whole fiſh is covered with a ſcaly ſkin, but the ſcales have more the appearance of thoſe of a ſerpent, than thoſe of a fiſh; for they are placed in cancellated lines interſecting one another, and are ſo well fixed, that they with difficulty come off; and wood or ivory may be poliſhed with the ſkin, as with the common fiſh ſkin uſed by the turners, &c. It is of a blueiſh green colour, ſpotted with a fine blue, and the back and belly fins are black, with ſome blue and red ſpots. Its whole figure is very broad and flat, as well as ſhort, ſo that it approaches to a round form. It ſeldom exceeds two pound in weight. It is caught in the Mediterranean ſea, but not commonly. The ſkin of it is frequently found in the cabinets of the curious. *Salvian.* p. 207.

GOAT-*ſucker*, in zoology, a name by which the *caprimulgus* is called in ſome parts of England, but its more uſual name with us is the *churn owl*. It is a very beautiful bird, ſeeming rather to approach to the cuckow than the owl kind, and has had its common Latin name and this Engliſh one from an opinion, there ſeems to be no foundation for, of its ſucking the *goat*'s dugs in the night time. *Ray*'s Ornitholog. p. 70. See the article CAPRIMULGUS.

GOATS *Beard*, in botany. See TRAGOPOGON.

GOATS *Thorn*, in botany. See TRAGACANTH.

GOBEMOUCH, the *fly-catcher lizard*, a ſpecies of American lizard that is always employed in catching of flies. It is the ſmalleſt of all the lizard kind, and is very beautiful, its ſkin often appearing as if covered with leaf gold, or leaf ſilver, and in ſome others of a green, or red and gold, wonderfully bright and beautiful. They are not at all ſhy or fearful of men, but as they do no hurt, ſo they ſeem to dread none; they enter chambers and cloſets, and do no ſort of damage, but deſtroy the flies and other troubleſome vermin they find there. Their whole lives ſeem ſpent in the chace of theſe inſects, and it is a very pleaſing thing to obſerve the various ways they have of catching them. They are a very cleanly creature, and may be ſuffered to run over the table at meal time; where if they ſee a fly, they will purſue it over the very hands or cloaths of people, or over the diſhes, without doing the leaſt hurt.

Notwithſtanding their great beauty while alive, they are only of a duſky grey when dead, all their other colours immediately vaniſhing, *Rochefort*, Hiſt. Antill.

GOBIO *capitatus*, a name by which many writers in zoology have called the cottus, a ſmall fiſh called in Engliſh the bull head, or miller's thumb. *Aldrovand*, de Piſc. Lib. 5. c. 27. See COTTUS.

GOBIONARIA, in ichthyology, a name given by Gaza and others to the little fiſh called cobitis, and aphya cobitis by the antient Greeks, and by many of the modern authors; and by ſome marſio, or ſimply cobitis. See the article APHYA.

GOBIUS, in ichthyology, the name of a genus of fiſhes of the acanthopterygious, or prickly finned kind, the characters of which are theſe. The branchioſtege membrane contains on each ſide five very diſtinct bones. Theſe are very irregular in their ſize, the firſt and fourth being much broader than the others. The belly fins grow together ſo as to form one ſingle fin, of the ſhape of a funnel. Theſe, and the pectoral fins, are placed at the ſame diſtance from the head. There are two fins on the back, the anterior of which conſiſts of ſomewhat rigid bones. The ſcales are rough, the body is oblong, the head compreſſed, and the eyes covered with the common ſkin of the head. It is eaſy to ſee from theſe characters, that the common river gudgeon is no *gobius*, as thus diſtinguiſhed. The ſpecies properly belonging to this genus are theſe. 1. The blackiſh variegated *gobius* with fourteen ribs in the ſecond back fin. This is the *gobius niger* of authors. The *go*, and *goget* of the Venetians, called by us the rock fiſh, or ſea gudgeon. 2. The *gobius* with a yellow tranſverſe line in the top of the anterior back fin. This is the *gobius ſecundus* and *paganellus* of authors. 3. The inch *gobius* with ſeventeen bones in the ſecond back fin. This is the *aphua cobitis* of authors. 4. The *gobius* with the blue belly fin, and with the rays of the anterior back fin riſing above the membrane. This is the white *gobius* of authors, and the *jozo* of the Roman markets. *Artedi*, Gen. Piſc. p. 23.

According to Willughby, there are only three kinds of this fiſh. 1. The common kind, caught about the ſhores of the Mediterranean, and called by the Venetians *goget*. See GOGET. 2. The large yellow kind, called by authors the *gobius marinus maximus flaveſcens*, and by ſome *paganellus*. See the article PAGANELLUS. And 3. the white kind, called the *gobius albus* by authors, but more commonly known by the name *jozo*. *Willughby*, Hiſt. Piſc. p. 206. See the article JOZO.

GOBIUS *aſper*, in ichthyology, a name given by Geſner and others to a ſpecies of pearch called by many *aſper piſciculus*, a name confounding it with many other very different fiſhes. It is diſtinguiſhed among the pearch tribe by Artedi under the name of the pearch with eight or nine black lines on each ſide. See PEARCH.

GOBIUS *fluviatilis*, in zoology, the freſh water *gudgeon*, a ſmall river fiſh, of which there are two ſpecies. The firſt, our common river *gudgeon*, known by its long and rounded body, the ſmallneſs of its ſcales, and its brown colour, with the variegations of its black ſpots. The ſecond is the leſſer river *gudgeon*, differing from the former not only in ſize, but in being of a more tapering ſhape, growing very ſmall toward the tail, and being of a whiter colour and leſs ſpotted. The firſt is common in our rivers, the ſecond in thoſe of Germany, where it is commonly called a *wapper*. *Geſner*, de Aquat. p. 474.

GOD (*Cycl.*)—Monſieur de Maupertuis having aſſerted the principle of the leaſt quantity of action, as the univerſal principle of all the laws of motion and of reſt, thinks this principle ſo wiſe and ſo worthy of the ſupreme being, that a better argument may be drawn from hence for his exiſtence, than any that has been hitherto framed from the courſe of nature. See Mem. de l'Acad. de Berlin. Tom. 2. p. 268, ſeq. But this principle is either abſolutely neceſſary, or contingent. If the former, it cannot prove the exiſtence of the deity. If the latter, it has no privilege beyond other regular contingencies. See *Quantity of* ACTION.

GOGET, in zoology, a name frequently uſed for the *gobius niger*, the ſea gudgeon or rock fiſh, and by which it is known in moſt parts of the world.

This is a long and ſlender fiſh, of a rounded not flat body, and ſeldom exceeds ſix inches in length. Its colour is very various, being either a brown variegated with white and yellow, or a blueiſh white with lines of a faint olive colour, and black ſpots. Its fins and tail are of a pale blue, but the ribs or nerves in them are ſpotted with black; the coverings of the gills and the belly are yellow. The head is large, and the jaws look tumid, and the eyes ſmall, placed very near one another, and bent or directed upwards. The mouth

is large, and the jaws have each two rows of teeth. The belly fins join together into one, and make a ſort of funnel ſhaped hollow, by which the fiſh is ſuppoſed to apply itſelf, and ſtick faſt to the rocks, whence it has its name of rock fiſh. It is very ſoft and ſlippery, yet is covered with ſcales, but they are very ſlender and ſoft. It is caught about the Engliſh and Italian ſhores, and lives in ſhallow water. It is conſtantly in the markets of Rome, *&c.* *Willughby*, Hiſt. Piſc. p. 206.

GOHDAKADURA, in botany, a name given by ſome authors to the tree which produces the *nux vomica*. *Herm.* Muſ. Zeyl. p. 41.

GOHKATHU, in botany, a name given by ſome authors to the tree which produces the gamboge, or *gutta gamba* of the ſhops. *Dale*, Pharm. p. 327.

GOING, in the manege, called in French *alleure*, is the pace or gate of a horſe.

GOLD *(Cycl.)*—This metal is found in many places mixed in ſmall grains among the ſand of rivers. The way of ſeparating it is this: They have a long trough made with a declivity, and lined at the bottom with flannel; the ſand is received into this, and while it is ſtirred about in the water by the hand, the ſand is waſhed off, and the ſmall particles of *gold* left in the pores, and among the woolly matter of the flannel, and is afterwards waſhed out from thence.

This is the method where the ſand is fine, but when it is mixed with large gravel, they ſift it through wire ſieves, whoſe meſhes are of one determinate ſize; by which means all the *gold* is ſure to go through with the ſand, and the gravel or larger ſtones are left behind, and thrown away. The ſand thus ſeparated is treated as before, and there is no danger of any *gold* being thrown away with the gravel, becauſe it is extremely rare to meet with any one grain of *gold* in this ſtate ſo large as a barley corn; and therefore as the meſhes of their ſieves are kept to more than that ſize, there is no fear of loſing any of the metal. *Shaw*'s Lectures, p. 253.

Mr. Boyle mentions an artiſt in Holland, who by digeſting *gold* with aqua fortis, had ſeparated the tincture, or yellow ſulphur from it, and made it volatile; the remaining body growing white; and that with this *golden* tincture he had turned ſilver into very perfect *gold*, with conſiderable profit. Mr. Boyle [a] ſeems to credit this account; and ſince that Monſieur Homberg [b] declares, he has actually converted ſilver into *gold* by heat.—[[a] Works Abr. Vol. 1. p. 166. [b] Mem. de l'Acad. des Sciences 1709.]

Monſieur Homberg is of opinion, that there is in ſilver ſome parts, which, though not yet *gold*, eaſily become ſo by means of fire; and he thinks that in *gold* naturally pale, there is a whitiſh matter, which fire brings to the true colour of *gold*. He obſerves, that this pale *gold* does not afford ſilver, and therefore thinks there is a mean metal between *gold* and ſilver. See Mem. de l'Acad. Loc. cit.

Mr. Boyle mentions an anti-elixir he tried, that is, one that would debaſe *gold*, and which changed its malleability, colour, homogeneity, and ſpecific gravity, ſo that tho' the powder did not weigh the thouſandth part of the *gold*, yet the ſpecific gravity of the metal to which it was debaſed was to that of water, but as $15\frac{2}{3}$ to 1. inſtead of 19 to 1. See his Works Abr. Vol. 1. p. 78.

The ſolution of *gold* in vegetable acids has not yet ſucceeded according to Mr. Marggraf, but he thinks it poſſible, as well as that of ſilver and mercury. See the articles SILVER and MERCURY.

It is the received opinion, that whatever has been done to this metal, the common way of purifying it by the copel reſtores it eaſily to itſelf again; but this is not always ſo certain, or ſo eaſy, as is generally imagined. Mr. Homberg put into the copel an ounce of *gold*, which he had uſed in ſeveral chemical experiments, in order to reſtore it to its original ſtate; but after four times copelling it, he found, that whatever quantity of lead he uſed, ſtill the metal, tho' of the right and beautiful colour, was brittle, and not at all in the ductile ſtate of pure *gold*. Finding therefore that lead would not anſwer his purpoſe, he incorporated the *gold* with four times its quantity of ſilver, and having performed the operation of the depart in the common manner, he fuſed it with borax; but after all this the *gold* was as brittle as before, though ſtill of the ſame beautiful colour. He then melted it again without any addition, but ſtill it remained in the ſame brittle ſtate. His next trial was by antimony, not doubting but that the particles, whatever they were, that had ſtood the operation of the depart, and of lead, would be abſorbed by this powerful ſemi-metal, and the *gold* left in its natural malleable ſtate: He melted it twice to this purpoſe with eight ounces of antimony; but after ſeparating the antimony, and then melting the *gold* ſeveral times with ſalt petre, and many times without any mixture, it was found of the moſt perfect and beautiful colour imaginable, but ſtill brittle, and not in the leaſt malleable. Surpriſed to ſee all the common methods fail, he melted it again with ſix ounces of antimony, and afterwards melted this regulus with three times its own weight of lead, and ſet the whole in a copel in a proper degree of fire, to evaporate both the antimony and the lead. But when the fire was out, he was ſurpriſed to find the *gold* covered with a browniſh ſubſtance, reſembling a muſhroom, which fell to powder on being touched by the fingers. The *gold* itſelf was become of a grey colour, and was full of wrinkles on the upper ſurface, from whence this fungous matter had been thrown out; but on the under ſurface, where it ſtuck to the copel, it was ſtill of a fine and beautiful *gold* colour. He then melted ſeveral times the *gold* and the fungous ſubſtance together, and every time there appeared the ſame ſort of fungous cruſt at the top. At laſt he gathered this fungous ſubſtance carefully off from the *gold*, and then melting the metal by itſelf, there was no more any fungous matter thrown out upon it, but only a thin layer of a powder of the ſame nature and colour with the former. Three times it was melted, and at every time threw off a quantity of this powder; and after this being fuſed with borax, it at length became perfect malleable *gold*.

He then fuſed together the fungous matter, and all the quantities of powder which he had ſaved, there appeared a new fungus on the matter, and that for ſeveral times melting; but at laſt this diſappeared, and there was found a ſmall lump of pure *gold* in the copel. It is not eaſy to gueſs at the cauſe of this obſtinate brittleneſs of the *gold*, becauſe it had paſſed ſeveral experiments, and been mixed with ſeveral ſalts and ſeveral metals, particularly at laſt with iron and with emery. The emery ſeemed moſt to be ſuſpected as the cauſe, but this brittleneſs cannot be given to *gold* by emery alone, and muſt have been owing to the mixed effect of ſome of the ſalts and emery together, as by means of the ſalts, the particles of emery are thrown farther, and more intimately mixed with thoſe of the *gold* than they could otherwiſe be. We have been told of the degradation of *gold*. This *gold* would have been declared degraded, and robbed of one of its greateſt qualities, its malleability, had it fallen into any hands but thoſe of ſo great a chemiſt; and it is much to be doubted, whether Mr. Homberg would not have been able to reduce the degraded *gold* of any other chemiſt, and reſtore it to its natural ſtate and purity, though the common methods of operating on it ſhould all have failed, as they did in this caſe. Mem. Acad. Par. 1693.

The method of rendering *gold* perfectly pure from ſilver, by means of aqua regia, is as follows. The mixture of *gold* and ſilver muſt firſt be copelled with lead in the uſual way, which ſeparates from it all other metals. Out of the remaining regulus hammer thin plates, and when the metal grows rigid under the hammer, make it red hot in a gentle fire, by which means its ductility will be reſtored. When the plates are ſufficiently thin, make them red hot for the laſt time, and then cut them into ſmall pieces with a pair of ſheers. Put theſe pieces into a cucurbite of clear glaſs ſet in a warm place, and pour on them a ſufficient quantity of pure and ſtrong aqua regia, ſtopping the orifice of the cucurbite with a cornet of paper, to keep out duſt.

When the diſſolution is finiſhed the ſilver will remain at the bottom, in form of a white powder. Pour off the clear ſolution, and put on the remaining calx ſome phlegm of the ſpirit of ſalt; make the whole boil a good while, to incorporate all the remaining ſolution of *gold*, and pour it off clear to the former ſolution: This done, inſpiſſate the whole over a very gentle fire till quite dry; put what remains into a crucible, cover it with powder of borax, melted beforehand with a little nitre, cover the crucible cloſe with a tile, and when the fuſion is perfect, pour it into an ingot. *Cramer*'s Art of Aſſaying, p. 260.

The purifying of *gold* by cementation is to be performed in this manner. Chuſe ſome tiles or bricks not vitrified by an exceſſive fire, nor too much tempered with ſand; the oldeſt alſo are the beſt; clean them well from lime and all other filthineſs, pound them in an iron mortar, and then ſift them through a coarſe ſieve; take four parts of this powder, and one part of colcothar not waſhed, and the ſame quantity of common ſalt; mix theſe thoroughly together, grind them in a mortar, and wet them with a little water or urine, ſo that they may cohere when preſſed between the hands. Then take a clean earthen veſſel of a proper ſize (it muſt be quite round) ſufficiently thick, and not glazed; ſtrew the bottom of this with the moiſtened powder, or cement, and diſtribute it evenly all over with a finger, and preſs it down very gently, ſo that the thickneſs of the cement may be half an inch all about; put upon this the *gold* in ſmall pieces, and in thin plates, made perfectly clean by heating them red hot in the fire; cover the ſurface of the cement with theſe pieces, then lay ſuch another bed of cement over theſe, and over that another of *gold*, and ſo on alternately, till the veſſel is full within the breadth of a finger; let this laſt ſpace be filled with cement; lute well a tile upon the veſſel, and keep it moderately red hot in a furnace for ſixteen or twenty hours, then open the pots and waſh the purified *gold*. *Cramer*'s Art of Aſſaying, p. 271.

A ſolution of *gold* in aqua regia affords a very curious object for the microſcope. Mr. Lewenhoek took great pains to obſerve the configurations it would put on in its concretions: He found that in warm weather, if a drop of the ſolution

was laid on a clean glaſs, and examined by the microſcope, the ſalts ſoon coagulated, but appeared very irregular in their manner of concretion. They ſometimes aſſumed a regular hexangular form, but more frequently they were rendered irregular, by the application of other ſubſtances, in form of ſmaller cryſtals upon them. One thing in this is very remarkable, that is, the cryſtals formed at different times ſeem very differently impregnated with the metal, thoſe which concrete firſt being uſually large, and perfectly clear and tranſparent, and thoſe which afterwards form themſelves upon theſe, and alter and injure their figures, being ſmaller and ſeemingly much more impregnated with the metal, as being all of a fine *gold* yellow. Sometimes alſo it happens, that the ſmall ſalts ſated with the particles of the *gold* ſhoot firſt, and when the other clear and tranſparent cryſtals of ſalt form themſelves afterwards, it not unfrequently happens that they form about the others, and encloſe them within their own bodies. Thus it is not uncommon to ſee one of theſe large and tranſparent cryſtals with a ſmall *gold* coloured cryſtal immerſed in its center.

This is a very elegant and entertaining ſight by the microſcope, but it is only to be obſerved in dry ſeaſons, for in moiſt weather the cryſtals either do not form themſelves at all, or elſe it is done but very confuſedly, and they melt and diſſolve away on the acceſs of freſh damp air.

If a ſmall piece of copper be put into this ſolution of *gold* in aqua regia, the liquor immediately operates upon it, and not only diſſolves the copper, but precipitates the *gold* it had before held in a ſtate of ſolution upon the ſurface of the copper, in the place of what copper it had taken away. The ſame thing happens when a piece of copper is put into a ſolution of ſilver in aqua fortis, but in this laſt caſe the effect is more beautiful; for the ſilver particles precipitated on the copper arrange themſelves in the form of trees and ſhrubs, like the arbor Dianæ; [ſee DIANÆ *Arbor*] but in the caſe before us, the *gold* is only precipitated in form of irregular filaments, or ſmall granules, and ſeems rather to imitate that proceſs obſerved in the famous water of the Ziment, or Cement Springs in Hungary; where the water being highly impregnated with a ſolution of blue vitriol, containing a very large portion of copper, if a piece of iron be put into it, immediately it works upon the iron, and diſſolving it, precipitates copper in ſmall irregular granules in its place: So that in the opinion of the vulgar, the copper is made of the iron, but in reality the iron is all diſſolved, and the copper left in a ſolid form by the menſtruum which diſſolved it; as in this experiment, the copper put into the ſolution of *gold* is diſſolved, and taken up into the liquor, and the *gold* which was before diſſolved is precipitated in its place. Philoſ. Tranſ. N° 286. p. 1438.

If the aſſiſtance of art be called in, and the ſolution of *gold* be made according to the rules of chemiſtry in a ſand heat, and the menſtruum ſo ſated with it, that it can diſſolve no more, then it readily ſhoots into cryſtals, on being expoſed to dry in drops before the microſcope on plates of glaſs; and the cryſtals which it forms are in this caſe all of one kind, all ſated with *gold*, of a regularly angular figure, and their angles very ſharp.

Theſe cryſtals appear only like ſo many pieces of pure *gold*, of a fine luſtre and brightneſs, and ſeem maſſes of native *gold* of this form juſt taken from ſome mine. In order to procure theſe *gold* cryſtals as regularly formed as can be, the ſmall drop, laid on the plate of glaſs, muſt be poured off again at one ſide, and by this means the liquor being ſpread extremely thin, the cryſtals will be formed extremely regular; but then they will be ſo ſmall, that they are only viſible through very powerful glaſſes; when thus managed, however, they ſhew their true form, which is regularly hexangular, but that not in form of a column, as in the hexangular cryſtals; but in a ſhort and thick maſs, reſembling a die, only more long ſhaped, not ſo exactly ſquare. Notwithſtanding that theſe ſmall cryſtals are yellow, they are as tranſparent as cryſtal, and the liquor remaining about them is alſo yellow and tranſparent. Some of theſe cryſtals, though of the ſame figure with the others, appear not of the ſame even and plain ſtructure, but are plainly ſeen to be formed of a great number of rings, or concentric circles, extended round each other. Copper being put into this ſolution, ſo highly ſated with *gold*, is not preyed upon ſo faſt as in a weaker ſolution; ſome few air bubbles, however, are driven to the ſurface, but without any great effect; but if the ſolution be diluted with a little water, the acid then preys with violence upon a piece of copper put into it. A part of the copper is ſoon diſſolved, and the liquor becomes green, and a ſmall portion of the *gold*, out of the ſolution, is precipitated on the copper, in the place of that part of it which was diſſolved. In this caſe alſo the *gold*, in ſome meaſure, emulates the appearance of the ſilver in its concretion; for though it does not form regular trees and branches, it forms long and ſlender filaments, and theſe do not look of a pure fine yellow, or like pure *gold*, but ſeem duſky, and to have ſome copper among them.

If a ſmall parcel of this ſolution be evaporated on a glaſs plate over a gentle heat, the nature of the metal, and its effects on vitrified bodies, are more eaſily diſcovered than one would expect in ſuch ſmall quantities. Where the liquor has lain the thinneſt in this caſe, the glaſs is tinged red by the entrance of the particles of *gold* into its ſurface, which they do eaſily; becauſe in thoſe places where the liquor lay thin, they formed themſelves into extremely minute concretions, according to the foregoing obſervations; and it is well known, that red is the colour which *gold* imparts in the earth to cryſtals and other ſtones, and in the experiments of the chemiſts, to glaſs of any kind. In ſuch places as the liquor has lain thicker in, and has been conſequently evaporated in larger quantity, and from a larger portion of the *gold*, the glaſs is not tinged red, but there is ſeen a remainder of the ſolution ſticking to it: This however is not formed into cryſtals, but is in this caſe pure *gold*, left from the evaporation in its proper metalline form. This however was in ſuch minute concretions, that where they lay ſingle, or ſeparate, they were not viſible, according to Mr. Lewenhoek's account, to the naked eye, and he computes that many thouſand millions of them were not equal in ſize to a ſingle grain of ſand: In moſt places they were not however thus ſeparate, but were formed into oblong and ſlender concretions, which were ſometimes ſimple, and ſometimes ramoſe, and the microſcope ſhews theſe concretions very elegantly, ſome in form of ſimple threads, ſome of branches of trees or plants. Philoſ. Tranſ. N° 286. p. 1441.

The denſity of *gold* is no way better ſeen than in this experiment; for though it may eaſily be conceived, that ſuch particles of theſe as were but of a thouſand millionth part, or much leſs than that, of the bigneſs of a grain of ſand, muſt needs be of an almoſt inconceivable thinneſs, yet not the ſmalleſt of theſe would tranſmit any light through it, but all were as perfectly opake as a piece of ſheet lead. A ſmall drop of a ſolution of *gold* in aqua regia being laid over a ſtrong fire, approaching it by degrees, till being expoſed to its utmoſt fury, both the *gold*, and the glaſs on which it lies, begin to melt; in this caſe the *gold* is found concreted in like manner into filaments compoſed of globules, or of particles nearly round; and if it be taken from the fire juſt at that time, when the glaſs only begins to run, it affords to the microſcope a very diſtinct way of obſerving the ramifications of the *gold* and ſilver ores in their firſt ſtate, and ſhews how they are formed. *ibid.*

Mr. Homberg found by experiment, that *gold* properly managed in the focus of the great burning glaſs, after the evaporation of ſome of its conſtituent parts, was vitrifiable, like other metals. That part of this metal which flies off in fume, he ſays, is the mercury which entered its compoſition, and what then remains, which is an earth penetrated by ſulphurs, runs into glaſs, as all other ſubſtances of a like kind muſt with a like fire. As the ſubſtances expoſed to the focus of the burning glaſs are laid upon a piece of charcoal, and that charcoal is always in part reduced to aſhes about the body in trial, and theſe aſhes often fly over and all about it; it had been objected to Mr. Homberg, by ſome who ſaw his experiments, that it was theſe aſhes alone which vitrified on the *gold*, and not any part of the *gold* itſelf; but Mr. Homberg very judiciouſly anſwers, that if this were the caſe, theſe aſhes would alſo be vitrified upon ſilver in the like trials and circumſtances, and give an appearance of the ſilver's vitrifying; but often repeated experiments have proved, that ſilver expoſed to the focus of the burning glaſs, gives not the leaſt ſign of vitrification in any circumſtance, unleſs it has been refined with antimony; that is to ſay, unleſs there has been given to it by art more ſulphurs than it is naturally poſſeſſed of; but in that caſe, theſe unnatural abundant ſulphurs will always vitrify a part of its earth. Mem. Acad. Par. 1707.

Mimic GOLD. See AURUM *ſophiſticum*.

GOLD, in medicine, is now of little other uſe, than as a covering for pills. Some mechanical phyſicians have had a notion, that if the particles of *gold* could be rendered fine enough, ſo as to circulate with the blood, that it would prove more effectual in the cure of diſeaſes than mercury. But this is mere hypotheſis. The *aurum fulminans* has been uſed, and other preparations of *gold* are to be met with in authors; but they ſeem to meet with little credit among modern practitioners.

GOLD *colour*. The manner of giving this colour to glaſs is this. Take cryſtal fritt two parts, and rochetta fritt one part, both made with tarſo, not ſand; mix theſe well, and to every hundred weight of this add of tartar in lumps, but well powdered afterwards, and of manganeſe prepared, each one pound, mix theſe well together and put them into the fritt; when this is done put all into the furnace, and let it ſtand there four days in a common fire not too violent, and at the end of this time work it. It will be thus very beautiful, but if all cryſtal fritt be uſed, it will be yet much finer. It may be made deeper or paler, by adding to, or diminiſhing the quantity of the ingredients, in proportion to that of the fritt. *Neri's* Art of Glaſs, p. 89.

GOLD *coloured glazing*. See GLAZING.

GOLD *on china-ware*. The *gold* on this ware is never laid on alone, but managed in the following manner: they grind it in water to a fine powder, and leave it to dry in the ſhade.

They then mix with every ten grains of *gold* one grain of ceruſs, and incorporating the whole with gum water, they lay it on in the manner of other colours.

There have been many methods of imitating the colour and appearance of *gold* in the baſer metals, but none of them come up to that of Mr. Homberg, which is performed in this manner: make an amalgame of one part pure copper and three parts quickſilver, boil this in river water for two hours, then diſtil off the quickſilver, and cohobate it once; take out the copper, and fuſe it, and it will be found of a beautiful gold colour, and more ductile than common copper under the hammer, and is extremely fitted for watch-work, gilding, and the finer machines and utenſils. *Shaw*'s Lectures, p. 282.

GOLD *ore*. They have one way of working this ore at Chremnitz in Hungary, which is very ſingular, as no lead is employed in the whole courſe of the work. They waſh the pounded ore very often, and lay it in powder upon cloths, and by the gentle and oblique deſcent of the water over it, and their continual ſtirring of it, the earthy, clayiſh, and lighter parts are all clean waſhed away, while the heavier and metalline remain in the cloth. Not much unlike to this proceeding is that with ſheeps ſkins and wool, which they place either in the water that comes from the works, or in the ſtreams of rivulets, which have their origin in hills where there is much gold; ſo that while the water or fluid parts paſs through or over them, the more ſolid, heavy, and metalline are inſnared and detained, and by this means the ſkin becomes a golden fleece. The cloths which are by the Chremnitz works in this manner impregnated with *gold*, are waſhed in large tubs of water, and after ſettling, the water is decanted ſlowly off; the ſediment which is left behind is, after this, waſhed in three or four other waters, and to the clean remainder they add quickſilver, which they then work and knead into an amalgam, like dough or paſte. When they have worked this together for an hour or two, they throw it into water, and waſh off the quickſilver, which did not adhere, and then there remains a pure and perfect maſs of the amalgam. They ſqueeze as much of the quickſilver as they can from this, firſt through coarſe cloths and then through fine ones, they then put the remainder on a perforated plate, which they place over a deep pan, ſet in the earth, in the bottom of which there is put ſome quickſilver; they then cover with a hollow earthen lid, luting it carefully on, and when the lute is dry they make a charcoal fire over it. By this means the quickſilver yet remaining with the *gold* in the amalgam is driven off, and runs down through the holes of the plate, mixing itſelf with the reſt in the bottom of the pan, and the *gold* is left alone in a ſpungy maſs, which only needs once melting in the common way to be pure and malleable *gold*. *Brown*'s Travels, p. 67.

GOLD-*finch*. This bird is particularly fond of the buds of the gooſeberry tree. They often come in whole droves at once into gardens, and will clear away all the buds from the trees in a few days; they are eaſily ſhot, but the trees are uſually injured by this, ſo that it is better to lime the twigs. *Mortimer*'s Huſbandry.

GOLD *fiſh*, in zoology, a name by which ſome authors have called the alauſa or ſhad, from the yellow colour it frequently has on the covering of the gills. See the articles ALAUSA and AGONUS.

GOLD *ſize*. The method of making *gold ſize* for burniſhed gilding or wood is this: take a pound and a half of pipe clay, half an ounce of red chalk, a quarter of an ounce of black lead, forty drops of ſweet oil, and three drachms of pure tallow; grind the clay, chalk, and black lead, all ſeparately, very fine in water, then mix them together, and add the oil and tallow, and grind all to a due conſiſtence. This is the ſize now in uſe, and is accounted the better the older it is.

GOLD-*ſmith*, or as ſome chuſe to expreſs it *ſilver-ſmith*, the artiſt, who makes veſſels, utenſils, and ornaments in *gold* or ſilver. The *goldſmiths* work is either performed in the mould, or beat out with the hammer, or other engine. All works that have raiſed figures are caſt in moulds, and afterwards poliſhed and finiſhed; plates or diſhes of ſilver or *gold* are beat out from thin flat plates, and tankards and other veſſels of that kind are formed of plates ſoldered together, and their mouldings are beat, not caſt. The buſineſs of the *goldſmith* formerly required much more labour than it does at preſent, for they were obliged to hammer the metal from the ingot to the thinneſs they wanted: but there are now invented flatting mills, which reduce metal to the thinneſs that is required at a very ſmall expence. The *goldſmith* is to make his own moulds, and for that reaſon ought to be a good deſigner, and have a taſte in ſculpture: he alſo ought to know enough of metallurgy to be able to aſſay mixed metals, and to mix the alloy.

The *goldſmith* in London employs ſeveral hands under him for the various articles of his trade. In this great city there are always hands that excel in every particular branch of the trade, and there is commonly employment enough for every one in his particular branch. The jeweller, the ſnuff-box and toy maker, the ſilver turner, the gilder, the burniſher, the chaſer, the refiner, and the *gold* beater, are all employed by and under the *goldſmith*.

GOLDEN *(Cycl.)*—GOLDEN *eye*, in ornithology, the Engliſh name of a ſpecies of ſea duck, called by authors *clangula*. It has its Engliſh name from the beautiful yellow of the iris's of its eyes. See Tab. of Birds, N°. 50. the article CLANGULA.

GOLDEN *eye*, is alſo uſed for a ſpecies of fly. See CHRYSOPIS.

GOLDEN *fleece*: Suidas imagines that the *golden fleece* which Jaſon and the Argonauts carried over the Pontic Sea from Colchis, was only a book written on ſkins, which taught the manner of making *gold* by the chemical art. This, if proper vouchers could be given for it, would carry back the antiquity of chemiſtry very far indeed, even thirteen centuries before Chriſt, in which time the ſcience muſt have been both known, practiſed, and even written of, ſo as to prove the occaſion of this painful and hazardous expedition. But what diſcredits all theſe accounts, is, that Moſes and the other ſacred writers, as alſo Sanchoniatho, Orpheus, Homer, Pindar, Heſiod, Herodotus, Thucydides, Hippocrates, Ariſtotle, Theophraſtus, Dioſcorides, Galen, and Pliny, are all utterly ſilent on this head; when the ages they lived in, muſt have given them opportunities to have ſpoken of it in their works. The malleable glaſs mentioned by Pliny, and Caligula's extracting *gold* from orpiment, are only proofs that they were great maſters in the art of glaſs and aſſaying. *Boerhaave*'s Chem. p. 17.

GOLDEN *head*, in zoology, a name by which ſome have called the anas artica cluſii, a web footed fowl, common on our ſhores. See DUCK.

GOLDEN *rod*, *virga aurea*. We have ſeveral very beautiful ſpecies of this plant cultivated in our gardens, where they are very great and laſting ornaments, beginning to flower in May, and one kind or other of them continuing flowering till October. See VIRGA *aurea*.

They are all eaſily propagated by parting their roots in ſpring, before they begin to ſhoot; they will grow in any ſoil, or ſituation, but they ſucceed beſt in a light freſh earth and an open expoſure, and ſhould be planted in the middle of large flower beds: they are perennial plants, dying down to the ground, as ſoon as they have ripened their ſeeds, but riſing again the following ſpring. Theſe ſeeds ſown will very freely grow, and often produce varieties in the flower. *Miller*'s Gardners Dict.

GOLDEN *Saxifrage*, in botany. See CHRYSOSPLENIUM.

GOLTBERGENSIS *terra*, in the materia medica, a whitiſh earth, uſed in the ſhops of Germany and Italy as an aſtringent, a cordial, and a ſudorific, but little known among the Engliſh apothecaries. It is dug in many parts of Germany, but particularly at this time in the neighbourhood of Hoſſel, in the biſhopric of Liege, in the circle of Weſtphalia. It is taken up there in conſiderable quantities, and uſually is ſealed with the impreſſion of an eagle, and with its old name *goltbergenſis terra* under it. It is imagined to contain ſome particles of ſilver, and thence to derive ſome of its virtues. It is a denſe compact earth, of a dull greyiſh white, ſoft and friable, and adheres firmly to the tongue, and makes no efferveſcence with acids. *Hill*'s Hiſt. of Foſſils, p. 4.

GOMARA, or GOMARIS, in natural hiſtory, a name given by ſome of the old authors to *talc*; ſome have alſo called it *gamara*: this laſt ſeems only a corruption of the word *gomaris*, and that of *comaros* or *comaris*, a name this ſtone was often called by among the Greek writers of the middle ages. Some have alſo called the ſelenites by this name, and it ſeems to have originally belonged to that foſſile; but both being foliaceous foſſils, both were often confounded together.

GOMATUS, in zoology, a name uſed by many for the *gurnard*, more frequently called by authors *gurnardus*. *Ray*'s Ichthyog. p. 279. See the articles GURNARD and CUCULUS *Piſcis*.

GOMPHASIS, a word uſed by the old Greek phyſicians for a pain in the teeth, and ſometimes for their being looſe in their ſockets.

GOMPHII, a word uſed by the old Greek writers for the *dentes molares*.

GOMUTTRA *ſelagitta*, in natural hiſtory, the name given by the Indians to a kind of foſſil, found in great plenty on the mount Vindy in the Eaſt-Indies, in places, as they obſerve, where the cows frequently urine. It is a bituminous ſubſtance, and after calcination the reſiduum is given in caſes of internal ulcers and in gonorrhœas. The Indians ſuppoſe it is formed by the drying up of the cow's urine.

GONAMBUCH, in zoology, a name by which many called the *guainumbi*, or humming bird; the ſmalleſt of all birds. See the article GUAINUMBI.

GONANDINA, the name of a Braſilian tree, remarkable for its great height.

GONDOLA *ſhell*, in natural hiſtory, a name given by authors to a peculiar kind of *concha globoſa*; ſuppoſed, in ſome degree, to repreſent the ſhape of a Venetian boat. It is of the genus of the dolium, and there are ſeven ſpecies of it. 1. A grey thick one. 2. A long ſhaped greeniſh one. 3. An oblong reddiſh one. 4. A thin white papyraceous one. 5. A yellow one, with four brown circular lines. 6. A browniſh one, with capillaceous lines. 7. A white one umbilicated on each ſide. Theſe are called by the Latin writers

writers *cymbium*, and the firſt is generally known by the name of *nux maris*.

GONGOLARA, in botany, a name by which Imperatus has called a very beautiful ſea plant, known among botanical writers by the name of *fucus ericæ foliis*, or *erica marina*, the ſea heath. See ERICA *Marina*.

GONGRONA, a word uſed by many authors to expreſs a round and hard tubercle in the trunk of a tree: it is alſo uſed in medicine to expreſs any round and hard tumour of the nervous parts, but principally a bronchocele.

GONGRUS, in ichthyology, a name given by Elian, Appian, and ſome other of the Greek writers to the *conger*, or ſea eel.

GONIOMETRICAL *lines*, in geometry, lines uſed for meaſuring or determining the quantity of angles. Such are, ſines, tangents, ſecants, verſed ſines, &c.

We have a paper by Mr. Jones in the Philoſophical Tranſactions, containing a commodious diſpoſition of equations for exhibiting the relations of *goniometrical* lines. From whence a multitude of curious theorems may be derived. See Phil. Tranſ. N° 483. Sect. 26.

GONION, in ichthyology, a name given by the French to the common gudgeon.

GONIOSIS, a term uſed by Archigenes, to expreſs a peculiar ſort of pulſe, which ſeems to ſtrike, not with the whole circle of the artery, but with an angle of it; or when the elevated artery is not felt like the curve of a circle, but like the vertex of a triangle. The cauſe of this is an imbecillity in the motion of the blood, which renders it incapable of elevating the whole artery.

GONYALGIA, a termed uſed by ſome authors to expreſs a violent pain in the knee.

GOODS, among diſtillers. See SPIRITS.

GOOLE, a breach in a ſea bank or wall; or a paſſage worn by the flux and reflux of the ſea. Vid. 16 and 17 Car. 2. c. 11. The word comes from the French *goulet*, the gullet or neck.

GOOSANDER, in zoology, the Engliſh name for the male *merganſer*; the female of that ſpecies having been univerſally eſteemed a different bird, and called the *dundiver*, and *mergus cirratus longiroſter*. *Ray*'s Ornitholog. p. 253. See MERGANSER and DUNDIVER.

GOOSE, *Anſer*, in the Linnæan ſyſtem of zoology, the term uſed to denote one of the orders of the feathered kingdom, the general character of which is, that the mouth is dentated or toothed, and jagged or ſerrated. The *gooſe* is a well known bird in the common ſpecies, but of which there are beſide that ſeven other kinds. 1. The *anſer ferus*, or wild *gooſe*, of the ſame ſhape with the tame kind, and of the ſame ſize, but of a browner and greyer colour. 2. The *bernacle*. See the article BERNICLA. 3. The brent *gooſe*. See the article BRENTA. 4. The *anſer hiſpanicus*, or ſwan *gooſe*, which always moves in a ſtately manner, and with its head erect like the ſwan. Its back is of a browniſh grey, its belly white, and its breaſt a little tinged with a reddiſh brown, and it has a line of blackiſh brown running ſtrait down the middle of the neck to the back. 5. The *anſer gambenſis*, or gambo *gooſe*, which in figure and ſize reſembles the Muſcovy duck, but has very long red legs, and a fine ſhining purple back; its belly is white, its beak red, and its head has a red caruncle, but its moſt obſervable character is, that it has a ſtrong ſpur ſtanding out from the firſt joint of the wings, as ſome of the Braſilian birds deſcribed by Marggrave have. 6. The *anſer canadenſis*, or Canada *gooſe*; this is of the ſhape of the common *gooſe*, but a little longer bodied. Its back is of a browniſh grey, and its rump black, and its neck black at the bottom, and white in every other part, its belly is white, and its tail and wings black, and 7. The *rat gooſe*, or *road gooſe*, which is but of about half the ſize of the common *gooſe*, and is of a blueiſh grey on the back, and white at the belly. This is wild in the northern counties of England. *Linnæi* Syſt. Nat. p. 46. *Ray*'s Ornitholog. p. 272, to 276.

Soland GOOSE, the Engliſh name of a large water fowl, called by authors *anſer baſanus*.

It is of the ſize of the common *gooſe*, and its wings are very long and capable of extending to a very remarkable breadth; its beak is long and ſtrait, and of a duſky grey, and a little hooked at the end. It has alſo near the hooked part, two ſmall appendages like teeth. It is naked behind the eyes. Its mouth opens to a great width, and it ſeems to have no noſtrils; but in the place of them, has a long furrow running nearly the whole length of the bill, it has alſo a row of ſerratures or indentings all along, provided by nature for its holding fiſh more firmly. Its feet are black, and all the four toes are connected by the ſame membrane. It is all over of a clear white when full grown, except that the larger wing feathers have ſome blackneſs, and the head with age is apt to become yellow. Its ſkin adheres but looſely to its fleſh, and the young are mottled with grey and brown. It flies well, but if it fall on the ground does not eaſily raiſe itſelf. They are a bird of paſſage, and build in the iſland of the Baſs in Scotland, in vaſt numbers. Each female lays only one egg. The young *geeſe* are eſteemed a great delicacy, and ſell at a great price. *Ray*'s Ornitholog. p. 247.

Magellanic GOOSE, *anſer magellanicus*, in zoology, the name given, though improperly by Cluſius, to a bird of the diver kind. It is a ſea bird, and is uſually very fat; it is of the ſize of the largeſt *geeſe*, and is black on the back, and white on the belly. The neck is ſhort and thick, and has a ring or circle of white feathers round it. Its ſkin is thick and tough like that of a hog, and it has only two coriaceous or leather-like fans in the place of wings, hanging from its ſides like two arms, covered with a few feathers which are ſhort and partly black, partly white, and by no means of any uſe to fly with, but very ſerviceable to the creature in ſwimming. It lives continually in the water, except at its breeding time; the tail is very ſhort, and the beak as large as a raven's, but not protuberating on the top, but flatted. *Cluſius* Exot.

GOOSE *dung*, in agriculture and medicine. See the articles DUNG and CHENOCOPRUS.

GOOSE *wing*, at ſea, a certain manner of fitting a ſail; which is thus performed: when a ſhip ſails before a wind, or with a quarter wind, and in a freſh gale, the ſeamen ſometimes, to make the more haſte, unparal the miſſen-yard, and then they launch out both ſail and yard over the quarter on the lee-ſide, fitting guyes at the further end, to keep the yard ſteddy with a boom, and this booms out the miſſen-ſheet. This they do to give the ſhip the more way, which otherwiſe, with theſe winds, the miſſen-ſail could not do; and this ſail ſo fitted, is called a *gooſe wing*, and ſometimes a *ſtudding ſail*.

GOOSEBERRY-*buſh*, in botany. See GROSSULARIA.

The *gooſeberry-buſh* is propagated either by ſuckers or cuttings, but the latter way is preferable, as the roots are leſs ſubject to ſhoot out ſuckers afterwards.

The beſt ſeaſon for planting the cuttings is in February, juſt before the buds begin to open; obſerving always to take the handſomeſt ſhoots, and to pick them from ſuch branches as produce the greateſt quantity of fruit. The cuttings ſhould be about eight inches long, and ſhould be planted in a bed of light earth expoſed to the morning ſun; they muſt be planted about three inches deep, and watered to help their taking root. The ſhoots ſhould all be rubbed off from theſe plants as they put out, except thoſe at the top, that there may be a regular ſtem. In the September following, they ſhould be removed to a bed of fine light earth, and planted at two feet diſtance. They ſhould remain here two years, and the croſs branches at times be cut off, as alſo the lower ones, ſo as to keep a clean ſtem about a foot above the ground. They will be then fit to plant out where they are to ſtand; which ſhould be in a light ſandy loam. They ſhould be kept from the ſhade of other trees; and to have the fruit in its utmoſt perfection ſhould be ſet in an expoſed place in rows of eight feet a ſunder, and each of the ſhrubs, ſix feet from the others in the rows. The beſt time for tranſplanting them is in October, after the leaves are fallen. *Miller*'s Gard. Dict.

GOOSEBRRY-*galls*, in natural hiſtory, the name given by authors to a ſpecies of protuberances of the *gall* kind, found very frequently on the oak. They are of a roundiſh figure, and ſometimes adhere to the tree by a ſhort pedicle, but more frequently by a part of their ſpheric ſurface. They are uſually found on the underſide of the leaves of the oak, but ſometimes on the young ſhoots, and ſometimes on the pedicles of the leaves.

They are moſt frequent in ſpring, but they are found at all times when the leaves are upon the trees. Theſe *galls* are greeniſh at firſt, and afterwards become yelloviſh, and finally red; in which laſt ſtate, they very much reſemble the ſmall red *gooſeberry*. They are very ſoft to the touch, and when opened are found to contain a juicy ſubſtance, with a cavity in the midſt, in which there is lodged a ſingle inſect. This, according to the time in which the *gall* is opened, is found in the form of a white worm, or elſe of a white chryſalis, or finally of a ſmall ſhort bodied four winged fly, of a black colour. For the creature does not leave the *gall* to go through any of its changes, but paſſes all its ſtates in it. The *gall*, in all theſe caſes, is found whole and unhurt; but if one is opened in which there is a hole pierced, this is ſure to be found empty, that being the paſſage by which the fly has made its way out. *Reaum.* Hiſt. Inſ. Vol. 6. p. 214.

GOOSEBERRY *worm*, in natural hiſtory, the name of an inſect, found very frequently on the *gooſeberry* buſhes, and uſually ſuppoſed to be a caterpillar, but differing eſſentially from that genus of animals, and being one of thoſe which the French call *fauſſe chenilles*. It has a round head, and has twenty two legs, and finally becomes not a butterfly, but a common four winged fly. This worm is at firſt of a greeniſh colour, with ſome yellow variegations, and ſeveral black tubercles; but on the laſt change of its ſkin it becomes whitiſh or cream coloured, and loſes its tubercles. *Reaum.* Hiſt. Inſ. Vol. 9. p. 18.

GOR, a name given by ſome writers to a very lofty tree, which bears a fruit like a cheſnut; it grows principally on the banks of the river Niger, and that not near the ſea, but far up the country.

GOR-*cock*, in zoology, the name of a bird of the gallinacious kind, called by authors the lagopus altera, and by many the moor cock, or red game; it is of the ſhape of the partridge, but is half as large again. Its beak is black and ſhort, and it is very remarkable for the bare ſpace over its eyes, which is very broad and of a fine bright red, and in the cock is ſurrounded by a prominence of the ſame bright colour, bare of feathers, and fimbriated like a cock's comb. The male is alſo diſtinguiſhed from the female, by having a black plumage at the baſe of the bill interſperſed with frequent white ſpots, and ſome large white ſpots near the origin of the under chap. The male is alſo redder than the female in all parts, and on his throat and breaſt is of a fair red without the mixture of any other colour. The head, neck, back, and wings are all variegated with red and black. The breaſt and belly are of the ſame colours with the back, but on the breaſt there are ſome variegations of white. The legs and feet are covered with a very long and thick plumage to the very ends of the toes. The wings are browniſh, with ſome reddiſh variegations, and the tail is almoſt wholly black. It is ſeldom found but on the tops of very high hills, and is very common in Derbyſhire, Yorkſhire, and Wales. It lays ſeven or eight eggs, which are of a mixed red, and black colour, and are all over covered with ſmall ſpots, except for one or two ſpaces, which are clear near the ſmall end. It feeds on worms and other inſects. It is a very well taſted bird. *Ray*'s Ornitholog. p. 128.

The Italians call this as well as the lagopus, by the common name of *francolino*, and there is much reaſon to ſuſpect that the lagopus and this, are indeed the ſame ſpecies of bird, tho' different in colour.

GORAIS, in zoology, a name uſed by ſome authors for the more common ſpecies of the *caraſſius*. The third ſpecies, as it is called by Geſner, *&c.* *Willughby*'s Hiſt. Piſc. p. 249. See the article CARASSIUS.

GORCE, or GOURT, denotes a wear. By ſtat. 25. Ed. 3. c. 4. it is ordained, that all *gorces*, mills, wears, *&c.* levied or ſet up, whereby the king's ſhips and boats are diſturbed, and cannot paſs in any river, ſhall be utterly pulled down, without being renewed. Sir Edward Coke [a] derives this word from *gurges*, a deep pit of water, and calls it a *gors* or gulf; but this ſeems to be a miſtake, for in domeſday it is called *gourt* and *gort*, the old French word for a wear. [[a] Co. Litt. 5.]

GORGET, in military affairs, a piece of braſs or ſilver, worn by officers upon their breaſts when on duty. The *gorget* hangs round the neck by a ribband; they are ſometimes gilded, and have commonly ſome device engraved on them; as the ſovereign's, or even the colonel's coat of arms, creſt or cypher.

GORGONIAS, in natural hiſtory, a name given by ſome old writers, to coral, on occaſion of its ſuppoſed change from a ſoft ſubſtance, to an abſolute ſtone, on being brought out of the water into the air; but this is known now to be a fabulous opinion, coral being as hard while growing to the rocks, as when it has been ever ſo long out of the ſea.

GORGONEI *fontes*, an affected term uſed by ſome of the writers in chemiſtry, to expreſs thoſe ſprings or waters, which turn things into ſtone. We have ſeveral ſprings in England, which cover over things with a ſtony matter, without introducing it into their inner ſtructure; but there are very few certain inſtances of waters, which at this day abſolutely petrify wood, that is, fill its bores with true ſtony matter. The famous water of Lough Neagh in Ireland, is much diſputed by ſome as to its having this quality, and many fruitleſs experiments have been made in attempting to prove that it has.

GORGONEUM, Γοργονειον, in antiquity, a kind of maſque uſed on the antient theatre to repreſent hideous and frightful figures, in imitation of the *gorgons*. Mem. Acad. Inſcrip. T. 5. p. 184. See GORGONS.

GORGONIUM, in botany, a name given by ſome authors, to the common eryngium, or eryngo, the roots of which we uſe candied.

GORGONS, in antiquity. Authors are not agreed in the account they give of the *Gorgons*. Diodorus Siculus will have the *Gorgons* and Amazons to have been two warlike nations of women, who inhabited that part of Libya, which lay on the lake Tritonidis. We may well imagine, ſays that author, that they had frequent quarrels together, as being women and neighbours. He goes on to give an account of a moſt bloody engagement between them, wherein the Amazons had the better, three thouſand of the *Gorgons* being made priſoners, and the reſt obliged to take ſhelter in a wood, to which the Amazons ſet fire, with an intention to deſtroy the whole nation of *Gorgons*; but as the wind did not prove favourable, they were obliged to deſiſt, and retire to their own territories. Here the Amazons, intoxicated with their victory, gave themſelves up to feaſting and mirth; and as the guard was very negligently kept in the night time, the three thouſand priſoners laid hold on the opportunity, and ſeizing the ſwords of theſe imprudent females, maſſacred a great many of them, but were themſelves at laſt overpowered and cut to pieces. Myrine the queen of the Amazons, cauſed monuments to be erected to her female warriours, who had been ſlain on this occaſion; which monuments were to be ſeen, ſays our author, in his days. The extermination of theſe female nations was not effected till Hercules undertook and performed it.

Pauſanias's account of the *Gorgons* is much to the ſame purpoſe. They were, ſays he, the daughters of Phorbus, after whoſe death, Meduſa his daughter reigned over the people dwelling near the lake Tritonidis. The queen was paſſionately fond of hunting and war, ſo that ſhe laid the neighbouring countries quite waſte. At laſt Perſeus having made war on them, and killed the queen herſelf; when he came to take a view of the field of battle, he found the queen's corpſe ſo extremely beautiful, that he ordered her head to be cut off, which he carried with him to ſhow his countrymen, the Greeks, who could not behold it without being ſtruck with aſtoniſhment.

Theſe accounts appear ſomewhat credible, but others repreſent them in a very incredible manner, making them to be a kind of monſtrous women, all covered over with hair, who lived in woods and foreſts. Others again make them a kind of animal, reſembling wild ſheep, with ſuch long hair on their faces, that it required their utmoſt efforts to remove it before they could ſee any thing; but when once they had effected this, they killed all that they ſaw, with the poiſonous influence of their eyes. For a further account of them, ſee Mem. Acad. Inſcript. Vol. 4. p. 72. ſeq.

GOSHAWK, in zoology, the Engliſh name for the *accipiter palumbarius*, a very large hawk, which preys on pheaſants, geeſe, and hares, and is remarkable for the ſhortneſs of its wings. *Ray*'s Ornitholog. p. 51.

GOSSAMPINUS, a name given by Pliny and the antients to a tree growing in the Eaſt Indies, which produced a ſort of cotton, the threads of which were too ſhort to be ſpun or corded; ſo that it ſerved only for the ſtuffings of beds and the like, for which it was very proper, being very light and ſoft. It was in ſome eſteem in medicine alſo, to recall the heat and ſpirits into parts to which it was applied. It is called by Piſo *arbor lanigera*, the wool tree, and had its antient name from the words *goſſipium* cotton, and *pinus* the pine tree, being ſomewhat like the pine in external appearance, yet bearing a ſort of cotton.

GOTTORUGINE, in zoology, the name of a ſmall fiſh common in the Mediterranean, and brought to market at Rome, Venice, *&c.* It has no ſcales, but is ſoft and lubricous to the touch, large toward the head, and ſmaller toward the tail, and of a flatted ſhape. Its colour is motled with olive colour and a browniſh red, diſpoſed in lines running half lengths, and parted by other lines of a pale blue. The lower part of the fiſh toward the belly is variegated with the ſame colours, but they are ſomewhat paler and fainter. It is uſually of about ſix or ſeven inches long; it has one back fin running from near the head to the tail; the tail is not forked but ſtrait, and of a redder colour than the reſt of the body. The eyes ſtand very prominent, and are placed in the ſummit of the head, very near one to the other. And near them are two extremely ſmall fins, thick at their baſes, and ending very thin. Its mouth is of a moderate ſize, and its teeth are like thoſe of the blennus. It has no ſwimming bladder, and the anus is ſituated nearer the head than the tail.

GOVERNOUR (*Cycl.*)—*Governours of the cheſt at Chatham*, are officers appointed to take care of, and relieve the poor and maimed ſeamen belonging to the navy royal. Vid. 22 and 23 Car. 2.

GOUMA, in mineralogy, the name given by the natives of the iſland of Samos, to the Samian earth, called *Terra Samia* by the old writers. *Pocock*'s Egypt. Vol. 2. P. 2. p. 29.

GOURD, *Cucurbita*, in botany the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, faſhioned like a bell, very open at the mouth, and ſo deeply divided into five ſegments, that it appears to be a five leaved flower. Some of the flowers in this plant are male and ſteril, others are female, and have an embryo which ripens into a large fruit, in ſome ſpecies long and ſlender; in others reſembling a bottle, uſually divided into five cells, and containing flat and oblong ſeeds; obtuſe at one end, and very broad at the other, and ſeemingly ſurrounded with a ring or circle within the edge.

The ſpecies of *gourds* enumerated by Mr. Tournefort are theſe. 1. The long fruited *gourd* with ſmooth leaves and white flowers. 2. The crooked or falcated *gourd* with ſmooth leaves and white flowers. 3. The broader *gourd* with ſmooth leaves and white flowers. 4. The long *gourd* with a white flower and protuberant belly. 5. The very long cylindric American *gourd*; this grows to three or four feet long. 6. The bottle *gourd* with ſmooth leaves and white flowers. 7. The white flowered ſmooth leaved *gourd* with a turbinated fruit. 8. The larger variegated bottle *gourd*, and 9. the ſmaller variegated bottle *gourd* with a rough fruit.

Gourds are eſteemed cooling and diuretic, are uſed in emulſions, and eſteemed good in fevers, and all diſorders ariſing from the acrimony of the blood or humours. Emulſions of theſe, and the other cold ſeeds, are anodyne, and are generally uſed to take off ſtranguries occaſioned by bliſters.

GOURY *Paſhnum*, in natural hiſtory, a name given by the people of the Eaſt Indies, to a kind of orpiment of a deep yellow colour, veined with red in ſeveral places, and in ſome with white. It is found principally at the bottoms of mountains. They calcine it ſeveral times, and afterwards give it internally in intermitting fevers, and uſe it externally in ointments for the itch.

GOUT (*Cycl.*)—As this diſeaſe receives different appellations, according to the places it affects, the following diſtinctions will be found neceſſary, to prevent confuſion on this head.

Arthritis is a word very differently underſtood by different authors, ſome expreſſing by it only what we call the *gout*, others making it the general name of that and many other diſeaſes of the ſame nature and origin, and diſtinguiſhing that particular ſpecies of it which we call the *gout* by the term *podagra*. Stahl, and from him Junker, define the *arthritis* to be a ſpaſtic affection of the joints in any part of the body, afflicting the patient with a violent and laſting pain, and never coming to that ſalutary end, which nature ſeemed to intend by her motions in it. The *podagra* in particular is thus defined to be a ſpaſtic and painful affection of the foot, taking its origin from a congeſtion of blood, which ſhould have been voided by the hæmorrhoidal veſſels, and which finding no means of evacuation there, becomes very painful in its emotions, and growing into a habit afterwards recurs on any light occaſion.

When the *arthritis* is taken in its general ſenſe, it comprehends ſeveral diſeaſes ſubdiſtinguiſhed by their ſeveral ſpecific names, as the hemicrania, the ſpurious pleuriſy, the ſciatica, the chiragra, the gonagra, and finally the podagra, or *gout* in the feet.

Some authors take the word *arthritis* in a more ſpecific ſenſe than this, and yet diſtinguiſh it ſufficiently from the *podagra*; theſe expreſs by it thoſe ſpaſtic affections which happen in the upper limbs and parts of the body; it is then made of the ſame genus with the *podagra*, and diſtinguiſhed from it, as one ſpecies from another by the following particulars.

The *arthritis* affects young perſons, the *podagra* thoſe more advanced in years. The *arthritis* is naturally the firſt of theſe two diſeaſes in perſons who have them both, and as people afflicted with it grow into years, it very naturally degenerates into a *podagra*. This is a diſtinction of ſome very judicious authors, yet in reality the ſeveral appearances of the *arthritis*, as taken in its moſt general ſenſe, differ no otherwiſe than as to the place they affect, and the times at which they happen; for they all agree in their eſſential conditions and general cauſes. The true *arthritis* is however to be carefully diſtinguiſhed from what is called the *arthritis vaga*, the wandering, ſimple, or ſcorbutic *arthritis*. This very ſuddenly flies from one part of the body to another, and changes place from the feet to the thorax, from thence to the hips, and ſo on. *Junker*'s Conſp. Med. p. 615.

The rheumatiſm and *arthritis* are diſeaſes alſo not greatly different from, but properly ſubordinate to one another, and a light *arthritis* is very often called a fit of the rheumatiſm. The rheumatiſm is no other than a ſtagnation of the maſs of blood about particular parts of the body; taking its origin from a copious congeſtion of the blood, particularly directed by nature to that part. The rheumatiſm has its ſeat in the muſcular parts of the body, the *arthritis* principally affects the joints of the ſeveral limbs. The rheumatiſm naturally precedes the *gout*, and very often degenerates into it; it is even certain that the rheumatiſm and *arthritis* often are complicated together. Simple congeſtions and commotions of the blood differ extremely from the *arthritis*; firſt in regard to their effects, for they uſually terminate in an eruption of the blood by ſome means, but the *arthritis* never arrives at that end.

Secondly in their duration, for they are uſually terminated ſome way within a very ſhort period; but this diſeaſe is of very long and terrible duration, they differ thirdly in regard to the parts they affect. The ſimple congeſtions affect the internal parts and the blood veſſels; but the *arthritis* affects the external, and the muſcular fibres. Finally they differ not leſs in regard to the event, for the ſimple congeſtions bring on inflammations and ulcerations, but the *arthritis* contractions and extenuations of the limbs.

The ſigns of the ſciatica are a vehement and excruciating pain in the hip, which remains a long time, and is felt principally in the tendons, and in the junctures of the bones. This ſpaſm ſo violently affects the muſcles of the whole ſide, that the patient is compelled to walk in a crooked poſture.

The other *arthritic* complaints, as the hemicrania, *&c.* are deſcribed under their ſeveral heads, and the general method of cure is the ſame in all of them, and the following is the proper treatment.

Method of cure. The material cauſe, which is a plethoric habit, is to be removed by bleeding at proper times, and by applying leeches to the hæmorrhoidal veins to promote a diſcharge that way; and in perſons of a moiſt habit, cupping is very proper. After this, the crudities of the primæ viæ, eſpecially ſuch as are of a bilious nature are to be abſterged, and gently carried off as they always are the occaſion of all ſpaſtic pains, being greatly exaſperated. The digeſtive ſalts, ſuch as *tartarum vitriolatum*, *arcanum duplicatum* and the like, are very good abſtergents; and the proper method of evacuating the matter is by gentle laxatives, ſuch as purging draughts of ſena and rhubarb, with a little ſoluble tartar. Glauber's ſalt or the common purging ſalt, called Epſom ſalt, ſucceeds alſo very well; and great ſervice is done by the medicated wines, impregnated with the abſtergent diuretic and purging ingredients. The violent emotions of the blood and its ſulphureo-ſaline acrid quality are to be attemperated, and the rigors of the ſolids ſoftened and taken off. This is excellently done by nitrous medicines with ſaline abſorbents; and in the more robuſt habits, ſometimes the ſtronger acids are neceſſary: after this nature is to be aſſiſted in making an equal and regular diſtribution of the humors. This is to be done in perſons of choleric habits, by means of the neutral ſalts, and the drinking large draughts of warm and diſcutient decoctions, ſuch as a tea made of the herb veronica, which has of late years been celebrated as a medicine able to cure all the diſeaſes of this kind alone. In other habits, the temperate alexipharmics are to be added on this occaſion, ſuch as decoctions of the woods of ſaſſafras and guaiacum, and of china and ſarſaparilla, and pimpernel root. *Junker*'s Conſp. Med. p. 623.

Finally, the vehement ſpaſtic and painful ſtate of the parts is to be mitigated and taken off. To this purpoſe, ſmall doſes of cinnabar, with the powder of earth-worms are to be given, and with theſe the gentle diaphoretics; at the ſame time that theſe are given internally, there may be applied externally ſpirit of wine with camphor mixed with tincture of ſaffron. The acid ſpirit diſtilled from ants, and the ſpirit of earth-worms. Tincture of caſtor may alſo be applied in this manner, and in ſome caſes Venice ſoap diſſolved in ſpirit of wine or our famous opodeldoc ointment. A cerate with a large portion of galbanum has alſo been known to have good effect, and ſome have applied with ſucceſs the common ſoap plaiſter; others prefer bags with the warm vegetables, ſuch as the leaves of germander, ground pine, origanum, and ſerpyllum, with the roots of pimpernel, angelica, and ſolomon's ſeal, and the ſeeds of aniſe and daucus ſylveſtris; others make theſe bags in a ſhorter way, uſing only oat-meal, elder flowers, and ſaffron, and ſprinkling the bag over with camphorated ſpirit of wine, or elſe dipping it all over in hot wine, and applying it immediately to the part. Some greatly recommend alſo the applying cheeſe beaten to a ſort of paſte to the part, covering it with a piece of a hare-ſkin; and many ſpeak largely of the effects of ſuffumigations made by burning under the part the flowers of ſtæchas, or of maſtic and olibanum, with the woods of ſaſſafras and guaiacum, with rhodium and yellow ſaunders. The vapour of the decoctions of warm and aromatic herbs is alſo greatly recommended, and ſome preſcribe gentle rubbing on the parts with a fleſh bruſh, or with flannels which have before been thoroughly impregnated with the fumes of the before mentioned dry fumigations. Theſe are the principal means of a cure; but there is not leſs judgment required in the time and manner of giving and applying them, than in the ſelecting them. In the time of the fits, it will be proper for the patient to take three or four times a day, a powder prepared of nitre and tartar vitriolated, each half an ounce, crabs eyes ſaturated with lemon juice three drams, cinnabar four ſcruples; theſe are to be all perfectly mixed together, and a ſcruple weighed out for every doſe, and after theſe it will be proper to take ſome gently diaphoretic draught; during the internal uſe of theſe, rags dipped in camphorated ſpirit of wine, impregnated with ſaffron, are to be applied to the parts: and to keep the bowels lax and ſoluble, a glyſter of the common emollient kind is to be given as occaſion ſhall require, with a ſmall quantity of nitre diſſolved in the decoction; and afterwards ſmall doſes of the common Epſom ſalt will be very proper for the keeping them in a due lax ſtate. After a fortnight's continuance in the uſe of the nitrous powders, it will be proper to take every day two or three doſes of a mixture of tincture of ſalt of tartar, and ſpirit of ſal armoniac, of which twenty five drops are a doſe, and every night a ſmall doſe of the ſtorax pill may be taken when the violence of the fit is abated. The gentle alexipharmics are to be taken without keeping up a hot regimen, and the frequent waſhing the feet in warm water, impregnated with an alkaline ſalt from the aſhes of vegetables, or otherwiſe, proves of the greateſt ſervice to compleat the carrying it off, and reſtore the parts to their natural tone. *Junker*'s Conſp. Med. p. 623. When the fits are thoroughly off, bleeding ſhould never be omitted ſpring and autumn, and in people of ſucculent habits, cupping upon the parts is often very uſeful; with women, the menſes are to be conſidered before all things, and brought to their regular periods before any hope of a

cure

cure can be had. In men, the application of leeches to the hæmorrhoidal veins is of ſervice, and four times, at leaſt, in the year purging medicines, ſuch as rhubarb, ſena, and the like, are to be taken in decoctions, or infuſions, mixing with them ſuch things as are known to ſweeten the blood. And in the general regimen, a ſufficient quantity of weak liquors is to be always drank, and a moderate exerciſe of the body is to be kept up. And finally, as the ſpring and autumn are the times at which the fits of all *arthritic* diſeaſes uſually return, it will be proper, by way of prevention, to take at ſuch times decoctions or infuſions of ſaſſafras, or the other woods, in the manner of tea, and with them a few moderate doſes of ſome of the nitrous medicines.

It is a general obſervation in all *arthritic* caſes, that all kinds of excretion, moderately promoted, leſſen the pains, and, on the contrary, that the ſuppreſſion of any of them render them much more violent and intenſe. Hence opiates are to be as much as poſſible avoided in the height of the fits, for tho' they give ſome eaſe for the preſent, they always encreaſe the pain afterwards. The aſtringent ſteel preparations, with the boles and other medicines of this claſs, ſuppreſs the excretions, conſtringe the viſcera, and ſometimes bring on dropſies. Volatile ſalts given imprudently, and in too large doſes, conſtringe the viſcera, and at the ſame time excite a violent emotion in the humours: hence they are often the occaſion of great miſchiefs, and it is very unhappy that the preſent practice is ſo free in the uſe of them in theſe caſes.

Among the external applications, thoſe which are aſtringent, cooling, ſaturnine, and the like, all give a temporary relief; but they are of very dangerous, and often of fatal conſequences, as they bring on nodes, tophs, and contractions of the parts in ſome caſes, and in others forcibly repel the matter to the internal parts, and bring on fatal ſymptoms, which no other medicines can relieve.

The acrid, hot, and nervine medicines uſed externally, ſuch as the chemical oils, and the natural balſams, all exaſperate the ſymptoms, and bring on intolerable pains and inflammations; for there is in theſe caſes no weakneſs of the parts to be ſtrengthened by ſuch medicines, but a too great ſtricture and tenſion of them, which all medicines of this kind, by their acrid qualities, muſt neceſſarily add to.

Strong purges given in the time of the fit have often proved fatal, by drawing in the morbid matter to the internal parts; and bleedings in the time of the fits always make them more violent, ſubject the patient to more frequent returns, and bring on a neceſſity of repeating the bleedings every time, before any medicines can take effect. But bleeding in the very beginning, or at the coming on of the fit, as alſo at its decline, have their real uſe; eſpecially the applying four or five leeches to the hæmorrhoidal veins, or in the ſciatica the cupping with deep ſcarification on the part: by this means alone this diſeaſe has ſometimes been abſolutely cured, ſo as never to return again. Camphorated ſpirit of wine, and the bags of dry ingredients ſprinkled with it, are proper in all ſtages of the diſeaſe, and in all conſtitutions.

A cerate of galbanum and camphor often gives immediate relief. This ſhould be applied after bleeding in the acceſs of the fit, and if it does not take effect in three hours time, it ſhould be taken off again. The ſoap plaiſter, with a large portion of camphor, is often alſo found of great ſervice in the beginnings of theſe caſes. The waſhing the feet in warm water, if uſed juſt before the coming on of a fit of the *gout*, always makes it much more ſevere, but if uſed afterwards, it often proves of ſervice. The proper time for it is in the decline of the fits.

Above all things, when a fit is gone off, the occaſional cauſes of its returning are to be avoided; theſe are, a too rich diet, the drinking too much wine, an immoderate uſe of venery, violent emotions of the mind by anger, or other paſſions, and violent and immoderate exerciſes; if theſe are not reſtrained, the return of eaſe will probably be of but very ſhort duration.

The uſe of ſalivation has been recommended by ſome in theſe caſes, but was never found to be of any real uſe.

Dr. Stahl commemorates a very remarkable caſe, proving the *gout* in the feet to be contagious or catching. It is, that a certain gentleman, ſubject to the *gout*, giving his footman a pair of boots which he had been uſed to wear, the man, after a ſhort time wearing them, became gouty.

A total milk and ſeed diet will, it is ſaid, cure the *gout*. See *Cheyne*'s Nat. Meth. of Curing, p. 266.

Dr. Dover ſays, a *gouty* patient will be free in two or three hours at fartheſt, after taking a doſe, from forty to ſeventy grains, of the following powder. Take ſalt petre, and tartar vitriolated, each four ounces, put them into a red hot mortar, ſtir them with a ſpoon till they have done flaming, then powder them very fine, and after that ſlice in an ounce of opium; grind thoſe to powder, then mix it with an ounce of the powder of ipecacuanha, and as much of the powder of liquorice. This is to be taken going to bed in a glaſs of white wine poſſet drink, covering up warm, and drinking a quart or more of poſſet drink while ſweating.

The doctor is alſo of opinion, that Mynſicht's elixir of vitriol often taken, though it may cauſe pain for ſome time, yet moſt certainly deſtroys the *gouty* matter in the end. Med. Eſſ. Edinb.

Dr. Stevens endeavours to prove the *gouty* humours to be rather of an alkaline than acid nature.

Dr. Cajetanus Tacconus tried many experiments with the mucilage of the joints of brutes, and of men, both ſound and *gouty*, in order to diſcover whether the *gouty* matter is acid or alkaline, and concludes, that its matter is ſometimes of the one, and ſometimes of the other nature. If the *gout* produces no *tophi*, or knots, or does it very ſlowly, and eſpecially if it is attended with œdematous ſwellings, he pronounces it to depend on an alkaline humour; but if the knots are large, and quickly formed, it is owing to an acid.

Monſieur de Sault being of opinion that the *gout* depends on the want of perſpiration, propoſes warm baths, exerciſe, keeping always warm, and defending from cold; clean clothes, moderate eating, abſtaining from ſupper, tranquillity of mind, friction, and milk diet, as preſervatives from it. Garlic being obſerved by Sanctorius to increaſe perſpiration, is recommended; as are *cortex Peruvianus* and ſteel in winter. When the ſtomach is attacked he lets blood at the ankles, and applies epiſpaſtics of different kinds to the feet, and then endeavours to procure a general ſweat. When the pain is very violent he blunts it, by applying a cloth dipped in liquid laudanum to the pained part, and exhorts the patient to uſe exerciſe after this. Medic. Eſſ. Edinb.

GOUTY *land*, in agriculture, a term uſed by the farmers to denote a hollow fuzzey black earth with little ſprings, that have no free outlet, and therefore ſwell and elevate the ſurface in many places. *Moreton*'s North. p. 39.

GRACILIS (*Cycl.*)--GRACILIS *rectus*, in anatomy, a name given by Riolan to one of the muſcles of the leg called by Winſlow the *rectus cruris anterior*, and by Cowper the *rectus femoris*. Albinus calls it the *rectus cruris*.

GRACULUS, in the Linnæan ſyſtem of zoology, a diſtinct genus of birds, of the order of the *anſeres*. The diſtinguiſhing character of which is, that the beak is of a conic figure, and has a crooked point. *Linnæi* Syſt. Nat. p. 46.

GRACULUS *palmipes*, in zoology, a name given by ſome to a bird called in England the *ſhagge*, and by Mr. Ray the *corvus aquaticus minor*, or leſſer cormorant, being regularly a ſpecies of that bird. *Ray*'s Ornith. p. 249. See the article CORVUS *aquaticus minor*.

GRADATION, *Gradatio* in rhetoric. See CLIMAX, *Cycl.*

GRADO, in the Italian muſic, ſignifies *degree*; thus *di grado* is uſed to denote *conjoint degrees*, which is when the notes riſe or fall from ſpace to line, or from line to ſpace, without making any leap of a third, fourth, or other interval. See SALTO.

Di grado aſcendente intimates, that all the notes riſe by *conjoint degrees*, as *ut*, *re*, *mi*, *fa*, &c.

Di grado deſcendente, is when all the notes deſcend or fall by *conjoint degrees*, as *ſol*, *fa*, *mi*, *re*, *ut*. *Broſſ.* Muſ. Dict. in voc. See DEGREE and CONJOINT.

GRÆA, a name uſed by the old Greek writers for the wrinkled pellicle which ariſes upon milk in the boiling.

It was alſo uſed in a figurative ſenſe for the wrinkles in the ſkin of old people.

GRAFFER, from the French *greffier*, i. e. *ſcriba*, a notary, or ſcrivener; it is uſed in the Stat. 5 Hen. VIII. c. 1.

GRAFFIO, or GRAVIO, in our old writers, denotes a *landgrave*, or *earl*.—*Nec princeps nec* graffio, *hanc lenitatem mutare audeat*. Blount.

GRAFFIUM, in old writers, is uſed for a writing book, regiſter, or cartulary of deeds and evidences.

GRAFTING (*Cycl.*)—Many have talked of changing of ſpecies, or producing mixed fruits by *engrafting* one tree on another of the ſame claſs; but as the *graft* carries the juices from the ſtock to the pulp of the fruit, there is little hope of ſucceeding in ſuch an expectation by ever ſo many repeated *grafts*; but if after changing the *graft* and ſtock ſeveral ſucceſſive times, you ſet the ſeed of the fruit produced on the *graft* in a good mould, it is poſſible that a change may happen, and a new mixed plant may be produced. Thus the almond and peach may, by many changes in the *graftings*, and by interrations of the ſtones of the peaches, and of the ſhells of the almonds, and by terebrations of the ſtem of the root here and there, alter their nature ſo much, that the coat or pulp of the almond may approach to the nature of the peach, and the peach may have its kernel enlarged into a kind of almond; and on the ſame principle the curious gardiner may produce many things of ſuch mixed kinds. Philoſ. Tranſ. N° 46.

Mr. Du Hamel of the Academy of Sciences of Paris has obſerved, that in *grafting* of trees there always is found at the inſertion of the *graft* a change in the directions of the fibres, and a ſort of twiſting or turning about of the veſſels, which greatly imitates that in the formation of certain of the glands in animal bodies; and he very judiciouſly infers from thence, that a ſort of new viſcus being formed by this means, the fruit may very naturally be ſo far influenced by it, as to be meliorated on the new branch; but that no ſuch ſudden and eſſential changes can be effected by this means, as too many

of the writers in agriculture pretend. This author obſerves, however, that this anatomical obſervation alone would not have convinced him of the falſity of too many of theſe relations, had not experiment joined to confirm it; he tried many *grafts* on different trees, and, for fear of error, repeated every experiment of conſequence ſeveral times, but all ſerved only to convince him of the truth of what he at firſt ſuſpected. He *grafted* in the common way the peach upon the almond, the plum upon the apricot, the pear upon the apple, the quince, and the white thorn, one ſpecies of plum on other very different ſpecies, and upon the peach the apricot and the almond; all theſe ſucceeded alike, the ſpecies of the fruit was never altered, and in thoſe which would not come to fruit, the leaves, the wood, and the flowers, all were the ſame with thoſe of the tree from which the *graft* was taken.

Authors in agriculture have mentioned alſo a very different ſort of *grafting*, that is the ſetting *grafts* of one tree on ſtocks of a different genus of trees; ſuch as the *grafting* the pear upon the oak, the elm, the maple, or the plum; the mulberry upon the elm, the quince, and the fig; the cherry upon the laurel; the peach upon the hazel; the vine upon the cherry tree, and upon the hazel; and the like unnatural conjunctions. Mr. Du Hamel tried all theſe ſeparately, and carefully, and the event proved very plainly, that thoſe who had mentioned them had never tried them; and a natural concluſion from this was, that there muſt be a natural alliance between the *graft* and the ſtock which receives it, otherwiſe it will either never grow at all, or elſe very ſoon periſh. Memoirs Acad. Par. 1727.

The facility with which *grafts* take place, and grow on proper ſubjects, is well known; there are, however, many accidents and uncertainties attending them in their different periods. Some periſh immediately, ſome after appearing healthy for many months, ſome even after years of health. Of theſe laſt ſome die without the ſtocks ſuffering any thing; others periſh together with it. It is very certain, that the greater part of *grafted* trees do not live ſo long as they would have done in their natural ſtate, yet this is no unexceptionable rule, for there are ſome which evidently live the longer for this practice; nay there are inſtances of *grafts*, which being placed on ſtocks naturally of ſhort duration, live longer than when placed on thoſe which are more robuſt and laſting. Theſe are irregularities which have been little conſidered hitherto, though they happen in a practice, the advantages of which are very great. One great requiſite for the ſucceeding of any *graft* is, that it be in its own nature capable of ſo cloſe and intimate an union with the ſubſtance of the ſtock, that it becomes as it were a natural branch of it. If all trees reſembled one another in their ſtructure and juices, if their ſolid parts were all of the ſame figure, and their ſap all of the ſame nature and conſiſtence, their veſſels all of the ſame diameters, and their elaſticity, and the number of the tracheæ equal in all, and in all filled with the ſame quantities of air; if trees were alike in theſe particulars, probably *grafts* of all trees would ſucceed upon one another, but this is by no means the caſe.

Trees are well known to be compoſed of numerous arrangements of hollow fibres, and theſe are different and unequal in every ſpecies of tree. In order to the ſucceeding of a *graft*, it is evident that there muſt be a mutual conformity in its veſſels and juices with thoſe of the ſtock, and the more nearly they agree in this, probably the better they ſucceed; and the farther they differ, the worſe.

If there be, however, ſome difference in the ſolid parts of trees, there are evidently many more in their juices. The ſap in ſome trees is white as milk, in others it is reddiſh, and in others clear and limpid as water; in ſome it is thin and very fluid, in others thick and viſcous. In the taſte and ſmell of theſe juices there are alſo not leſs differences; ſome are ſweet, ſome bitter, ſome inſipid, ſome acrid, and ſome fœtid; the differences in one or other claſs are varied almoſt to infinity, and the ſucceſs of *grafts* may very rationally be ſuppoſed owing to the agreement between the juices as well as ſtructure of the *graft* and of the ſtock. The quality of the ſap thus makes a very great difference in the nature of trees, but its quantity, and readineſs of derivation to the parts, is ſcarce leſs obſervable. In this we have familiar inſtances in the willow and the box, one of which will puſh out longer ſhoots in a year than the other in twenty.

Another difference yet more ſtriking, and indeed more eſſential in regard to the growth of *grafts* than all theſe, is the different ſeaſon of the year at which different trees ſhoot out their leaves, or ripen their flowers. The almond tree is in flower before other trees in general have opened their earlieſt buds, and when other trees are in flower, this is full of leaves, and has its fruit ſet before the mulberry begins to puſh out its buttons. When we conſider all theſe differences in trees, we cannot but wonder how it is poſſible for a branch of one to live upon another; and it becomes a much more perplexing queſtion, how any *graft* can ſucceed, than how ſuch numbers come to miſcarry. A *graft* of one pear upon the ſtock of another of a different kind, ſhall be ſeen to grow immediately, as if upon its own tree, and in a fortnight to gain ſix inches in length, and ſo of ſome others. This muſt be owing to the great ſimilarity between the ſtock and the *graft* in all reſpects; and a great contrariety, or difference in the ſtructure of parts, will make as remarkable a want of joining on the other hand. An inſtance of this may be had in the plum and the elm, which no art can ever make to ſucceed with one another, whether the plum be *grafted* on the elm, or the elm on the plum ſtock. Theſe are examples of the extremes of eaſy growth, and of abſolute decay; but there are many conjunctions of trees which ſeem of a middle nature between the two, and neither immediately periſh, nor totally ſucceed. Of theſe, ſuch as were *grafted* in autumn uſually remain green the whole winter without puſhing, and thoſe which are *grafted* in ſpring remain green a month, or longer, but ſtill without ſhooting. Some particular ones have been alſo known to make ſome ſhoots the firſt, or even the ſecond ſap ſeaſon after the operation, but all periſh at the end of theſe times. Of this kind are the *grafts* of the pear tree upon the elm, the maple and the hornbeam, and the mulberry upon the elm, and upon the fig, with many others.

When we come to enquire into the cauſe of this, we find that theſe *grafts*, though unnatural, have yet had a communication with the ſtock by means of a few ſmall veſſels, which has been ſufficient to keep them green, or even to make them ſhoot a little during the great aſcent of the ſap: But the far greater number of the fibres have had all the while no communication, and are found putrified, dried up, or covered with a putrid juice. This has evidently happened, by means of the diſproportion in ſize between the veſſels of the ſtock and of the *graft*, and the great difference between their natural juices, which are obſtacles abundantly ſufficient to prevent either an union of the fibres, or the introduction of new ſap.

The *grafts* of the almond on the plum, and of the plum on the almond, always grow very vigorouſly for the firſt year, and give all the appearance imaginable of ſucceeding entirely, yet they always periſh in the ſecond, or elſe in the third year. The almond *graft* upon the plum ſtock, always puſhes out very vigorouſly at firſt, but the part of the ſtock immediately under the *graft* grows ſmaller, and periſhes; the *graft* abſorbing too much of its juices, and the *graft* neceſſarily periſhes with it. The decay of the whole generally happens early in the ſpring, and that plainly from the different ſeaſon of the natural ſhooting of the two trees, the almond puſhing very vigorouſly, and conſequently draining the ſtock of its juices, at a time when, according to its nature, the juices are but in ſmall quantity in it, and the ſap does not begin to aſcend. The *grafts* of the plum on the almond are, from the ſame cauſe, furniſhed with an abundance of ſap, which they have at that time no occaſion for, and conſequently they as certainly periſh of repletion, as the other of inanition. Mem. Acad. Par. 1730.

The peach *grafted* on the plum ſucceeds excellently, and lives longer than it would have done in its natural ſtate. The reaſon of which is this: the peach is a tender tree, it ſhoots with great vivacity, and produces more branches than the root is able to maintain, which is the reaſon why peach trees are uſually full of dead wood, and often their large branches periſh, and ſometimes their whole trunk; on this occaſion, the plum being a ſlow ſhooting tree, communicates its virtue to the *graft*; and the peach conſequently ſends out ſhoots, which are more robuſt, and ſtrong, and are no more in number than the root is able to ſupply with nouriſhment; and conſequently the tree is more ſtrong and laſting. Ibid.

Tools neceſſary for GRAFTING. In order to *grafting*, a perſon muſt be provided with the following tools. 1. A neat and ſmall hand-ſaw to cut off the heads of large ſtocks. 2. A ſtrong knife with a thick back, to make clefts in the ſtocks. 3. A ſharp penknife to cut the *grafts*. 4. A *grafting* chiſſel and a ſmall mallet. 5. Braſs ſtrings, or elſe woollen yarn to faſten on the *grafts* with, and finally, a quantity of clay, which ſhould be prepared a month before it is uſed, and kept turned and worked about every day like mortar. The beſt mixture for this matter is: a quantity of ſtrong, fat and viſcous loam muſt be got, and into this muſt be well beat and mixed ſome ſtone-horſe dung, and ſome chopp'd ſtraw cut very ſhort and ſmall; finally, a quantity of common ſalt muſt be thrown in, this muſt be mixed up and beat together into a paſte with water, but it muſt not be expoſed to the froſts. This is equally proper to be employed for all the different ſorts of *grafting*. *Miller*'s Gardners Dict.

Principal kinds of GRAFTING, are, 1. *Grafting* in the rind, called alſo ſhoulder-*grafting*, and by ſome crown-*grafting*; this is only fit for large trees, and the *grafts* in this are ſet in form of a circle or crown. This is moſt properly performed in the latter end of March or beginning of April.

2. *Cleft-grafting*, which is alſo called by ſome ſtock and ſlit-*grafting*. This is proper for ſtocks or trees of a leſſer ſize, and not exceeding two inches in diameter. This *grafting* is to be performed in the months of February and March, and ſupply the failure of the eſcutcheon way, which is uſually performed in June, July, and Auguſt.

3. *Whip-grafting*, which is alſo called tongue-*grafting*; this is proper for ſmall ſtocks of an inch, or an inch and half diameter, and from this down to the ſmalleſt ſize; this is found the moſt effectual way of any, and is what is now almoſt univerſally practiſed.

4. *Grafting* by approach or ablactation. This is performed when the ſtock to be *grafted* on, and the tree from which the bud is taken, are ſo near together that they may be joined. This is beſt performed in the month of April, and is called by ſome inarching; and is chiefly uſed for jaſmines, oranges, and the tenderer exotic trees.

All thoſe trees which are of the ſame tribe, that is, which agree in their flower and fruit, will take upon one another; thus all the nuts may be engrafted on one another; as may alſo all the plums, and all that are allied to them; as the almond, peach, nectarine, and the like: but as theſe generally loſe a great deal of gum in the *grafting*, the operation of inoculation is greatly more proper for them.

All the trees which bear cones will ſucceed very well on one another, even though ſome ſhed their leaves in winter, and others do not. Thus the cedar of Lebanon and the larch tree do very well on one another; but theſe, becauſe they abound ſo greatly in reſin, muſt be *grafted* by approach, becauſe the reſin of the *graft* being loſt from it before it is ſet into the ſtock, makes it otherwiſe often miſcarry.

Bad weather will often deſtroy the hopes of the beſt operator; otherwiſe with theſe regulations the whole generally ſucceeds very well; and is not only of uſe for the propagating many exotic plants, but even will make very tender ones bear our climate, by placing them on the hardier ſtocks of the ſame kind. *Miller*'s Gardners Dict.

The antients were very fond of *grafting*, and if we are to underſtand their writings as they now ſtand, we muſt acknowledge that they had an art greatly ſuperior to ours, as they could make the moſt unlike trees ſucceed upon one another. Thus they *grafted* the mulberry on the fig, the plum upon the cheſnut, and ſo on: but it ſhould ſeem that either the authors who have affirmed theſe things wrote upon hearſay, without any knowledge of experiments, or elſe that they called other plants by theſe names; ſince experience abundantly ſhews us, that no tree, however like another in leaf, or any other particular, will ever be made to ſucceed upon another, unleſs they have both the ſame fructification. Id. Ibid.

GRAILE, *gradale* or *graduale*, a gradual, or book containing ſome of the offices of the Roman church.—Gradale, *ſic dictum, à gradalibus in tali libro contentis. Lyndewod.* Provincial. Angl. l. 3.

It is ſometimes taken for a maſs-book, or part of it, inſtituted by Pope Celeſtine, *anno* 430. See Stat. 37 Hen. 6. c. 32.

GRAIN (*Cycl.*)—*Structure of* GRAIN. There are three particulars obſervable in every *grain*, whether it be wheat, barley, oat, or whatever elſe of that kind. Theſe are, 1. The outer coat or pellicle which contains all the reſt. This in the ſame ſpecies of *grain* is found to be very different in thickneſs in different years, and as it has grown in different ſoils. 2. The germ or bud. This is always hid within the ſeed or *grain*, and is the plant in miniature that is to ariſe from it; and 3. The meal, or that farinaceous matter which is incloſed in the ſkin, and which ſurrounds the germ, and ſerves to give it nouriſhment when firſt put into the earth, before it is capable of drawing it from the earth itſelf. Dr. Grew, in his anatomy of plants, has treated of this at large. See VEGETATION, &c.

The whole ſtructure of the plant which produces theſe ſeeds is equally admirable. The chaffy huſk is admirably adapted to ſhield and defend the ſeed as long as that is neceſſary, and then to let it fall; and the ſtalk formed hollow and round is neceſſarily at once light and ſtrong, capable of ſuſtaining the ear, without abſorbing too much of the juices deſtined to its nouriſhment; and the beards of many kinds are a defence againſt the birds, that would otherwiſe deſtroy the ſeed before its ripening. The covering of the ſeed is formed of two membranes, which meeting in a line on one part of the ſeed, form together that furrow we ſee on it. This is the place at which the ſeed is to burſt open on being moiſtened. Had not nature provided this means of the germ's coming out, the toughneſs neceſſary to the coat of the ſeed, as a defence from injuries, would have ſuffered the farinaceous matter and the germ to rot together, within it, before it would have given them way to come out, and for the germ to grow.

Nor is this the only uſe of this place of opening. The great Creator of all things has provided theſe ſeeds, not only for a ſupply of the ſame ſpecies of plant, but for our food, and for that of birds, *&c.* We have art enough to erect machines for the reducing the farina to powder, and the freeing it from its covering membrane, but the birds eat it as it is, and it would paſs through them whole, and without doing them any good, were it not that the juices of the ſtomach ſwelling it up, it burſts open at this furrow, and all the nutritive matter pours itſelf out. *Des Landes* Trait. Phyſ. p. 62.

This farinaceous matter is compoſed of an infinite number of white and tranſparent bodies, of a globular figure: theſe every way ſurround and incloſe the young plant, and by their figure being eaſily put in motion, as ſoon as the heat and humidity of the earth act upon them, they, by degrees, force themſelves into the veſſels of the plant, and give it increaſe from time to time till they are received into it; and they then have ſo far given it ſtrength, that it is in a condition to feed on the juices in the earth. The ſame proceſs of nature is obſervable in the caſe when *grains* of corn grow out of time, on being thrown too careleſsly together in a moiſt place.

When the corn is ground into powder, it is theſe farinaceous globules, that make what we call the flower. The germs are always leſs white, and leſs tranſparent than they, but they are of great uſe: ſince it is principally to them, that we owe the agreeable flavour of bread, and almoſt wholly to them, that the fermentation of dough is owing. Their little parts being, of all others, of the *grain* the moſt eaſily put in motion. And it is alſo to theſe, that the rotting of wheat, preſerved in damp granaries, is to be attributed, their natural tendency being to motion and to corruption, if that motion be given without the neceſſary accidents. That the obſervation of the fermentation of dough, and the lightneſs of bread, being owing to theſe germs, may not ſeem advanced at random; it may be proper to confirm it, by the obſervations of the people employed in the making bread for the army. Theſe people always find, that fine flour, if well dried, and put up in dry barrels, will keep good a long time; but that after it has been thus kept long, though it will make biſcuit, and ſerve for many other neceſſary uſes, it will never make the fine light bread eaten at table; and this they attribute to the life of the flower being ſpent; that is, to theſe germs being deſtroyed, as to their vegetative power, by having been a long time broken to pieces.

GRAIN *of iron.* Even iron has its *grain* as well as wood, and that not the ſame in all iron, though all iron is very evidently the ſame ſpecies of body. The common caſt iron has a *grain* very different from that which has been hammered, or wrought, the granules which compoſe the maſs, being in this laſt ſtate forced as it were into combinations with one another, by the repeated blows of the hammer: the tempering of iron into ſteel alſo alters its *grain*, partly by means of the ſalts and ſulphurs, which are by that operation introduced into it, and partly by the ſtopping the effect of the fiery particles received into it at a certain time.

But beſide theſe differences, the common wrought iron has in its ſeveral pieces, or ſometimes in the ſeveral parts of the ſame piece, different *grains*. Firſt a laminated one, ſecondly a granulated one, and thirdly a fibroſe or ſtringy one. Theſe, however, are not ſo different, in reality, as they appear to be; for the laminæ, as they become ſmaller, become granules; and arrangements of theſe granules, in long lines, make the fibres of the thready kind. The artificers, however, know by theſe marks of the *grain*, what iron is fitteſt for tempering into ſteel; and they find the laminated pieces to be the worſt of all, and the granulated ones the beſt. Mem. Acad. Scien. Par. 1722.

The world has talked much about the different *grains* of lead ores, but theſe are three, juſt as in iron, and are owing only to the ſize and arrangement of the ſame ſhaped particles as in the iron. The broad grained lead ore being analogous to the laminated kind of iron, the ſteel grained being equally analogous to the granulated iron, and what is called the antimoniated lead ore, being in the ſame manner analogous to the fibrous grained iron, and all in the ſame manner ariſing out of one another.

GRAIN *weight.* The *grain weight* in uſe among jewellers is one fourth of a carrat; and the carrat is about the one hundred and fiftieth part of an ounce troy; according to Mr. Jeffreys, in his treatiſe on diamonds and pearls.

Hence, the jewellers *grain* is to the troy *grain*, inverſely, as 600 is to 480, that is directly as 4 to 5.

GRAMINIFOLIA, in botany, a name given by Dillenius to a genus of plants, called by Micheli and Linnæus *zannichellia*. *Dillen.* Gen. 169. See ZANNICHELLIA.

GRAMMELOUC, in natural hiſtory, the name of an Eaſt-Indian ſhrub, very common in the woods and foreſts. It grows to five or ſix feet high. Its leaves are very long and narrow, and terminate in a point; they are of a lively green. The fruit is carried in a bag of a triangular ſhape, of the ſize of a hazel-nut, but ſomething longer: on opening this there appear three cells, in each of which is contained one fruit, reſembling the ſeed of the palma chriſti, but covered with a tranſparent pellicle, and a black one under that. The inſide of the fruit is white, and is of a ſharp and pungent taſte. It is a very violent medicine, operating both by ſtool and vomit, and that often, ſo as to endanger the life of the perſon, who has taken it. They allay its operation by eating betle. Mem. Acad. Par. 1699. See BETLE.

GRAMPUS, in ichthyology, an Engliſh name given to one of the cetaceous fiſhes, properly of the genus of the *delphinus*, or dolphin, according to the new Artedian ſyſtem, and diſtinguiſhed from the others of that genus by the name of the dolphin, with the ſnout bending upwards, and with broad

ſerrated teeth. This is the orca of almoſt all the antient as well as modern writers, and is called the loper and north caper by the people of Scotland. Sibbald gives it the name of the *balæna*, but he diſtinguiſhes it from the common whale by its ſmaller ſize, and having teeth in both the jaws. Paulus Jovius calls it alſo *capidolius*. Theſe are all the names it is known by; and that of *porpeſſe* is ſometimes ignorantly given to it, but properly belongs to another ſpecies of the ſame genus, the *phocæna*. See PHOCÆNA.

GRANA *regia*, in the materia medica, the ſeeds of the common ricinus, called by ſome *palma chriſti*. See RICINUS.

GRANA *figlia*, in the materia medica, the fruit of a ſpecies of ricinus. See RICINUS.

GRANADILLA, *paſſion flower*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral petals diſpoſed in an orbicular form. The cup conſiſts of many leaves, and from this there ariſes a piſtil which has a fringed crown at its baſe, and at its apex a tender embryo, adorned with three bodies of the ſhape of nails, and with a great number of ſtamina underneath. The embryo ripens afterwards into a globular or oval fruit which is fleſhy, unicapſular, and furniſhed with ſeeds covered with a ſort of hoods, and adhering to the ribs of the fruit as to ſo many placentæ.

The ſpecies of *granadilla* enumerated by Mr. Tournefort are theſe: 1. The common *granadilla* called the maracot and paſſion flower. 2. The *granadilla* with three pointed leaves, and blackiſh purple flowers. 3. The *granadilla* with tricuſpidate leaves, and large yellow flowers. 4. The *granadilla* with tricuſpidate leaves, and ſmall yellow flowers. 5. The *granadilla* with tricuſpidate leaves, and an olive faſhioned fruit. 6. The *granadilla* with narrower tricuſpidate leaves, and olive ſhaped fruit. 7. The *granadilla* with ſmooth narrow tricuſpidate leaves, and very ſmall green flowers. 8. The ſtinking *grandilla* with a tricuſpidate hairy leaf and white flower. 9. The ſtinking *granadilla* with tricuſpidate hairy leaves, and variegated purple flowers. 10. The many leaved *granadilla* with an oval fruit. 11. The many leaved *granadilla* with fruit of the ſhape of the colocynth. 12. The many leaved *granadilla* with curled flowers. 13. The ivy leaved *granadilla* with very ſmall flowers and fruit. 14. The ivy leaved *granadilla* with white flowers, and hairy globoſe fruit. 15. The ivy leaved *granadilla* with variegated leaves. 16. The *granadilla* of Surinam with oblong ſerrated leaves. 17. The elm leaved *granadilla* of Surinam. 18. The *granadilla* with two pointed leaves, and beautiful red flowers. 19. The apple fruited broad leaved *granadilla*. 20. The long leaved citron fruited *granadilla*. 21. The *granadilla* with ſmall corymboſe fruit. 22. The *granadilla* with androſæmum leaves, and fruit like the jujube.

GRANARY (*Cycl.*)—In the care of public *granaries*, or magazines of corn, one great caution neceſſary, is, the laying up in them ſuch corn as will be leaſt ſubject to decay, and the ſingle thing to be conſidered in this, is the laying up only ſuch as is the product of hot and dry countries. In France the corn of the ſouthern provinces keeps many years longer than that of the other parts of the kingdom; and antient and modern hiſtory both inform us, that the corn which is the produce of Africa, particularly of the country about Algiers and Tunis, will keep much longer than that of any other country. The Romans, in old time, annually imported vaſt quantities of corn from Egypt; this they found not only to produce much larger crops than ſuch as was the produce of their own country, but to keep many years in their public *granaries* without injury. The Marquis of Santa Cruz, the author of many excellent obſervations on the politic and military ſtate of different nations, obſerves, that in Galicia and the Aſturias the corn will hardly keep in the *granaries* from one year to another, and that it is the humidity it contains that rots and decays it; and that the corn brought from Caſtile will keep good many years. This corn, he tells, is the only kind they ever venture to lay up in the public *granaries* of Spain, and that the whole difference between this and the other, is, that it grows in a country where there is leſs rain in ſummer. *Des Landes* Trait. Phyſ.

It would be eaſy to import corn from Barbary in ſufficient quantity, for all the ſeed corn of the kingdom; and in countries where the people are ſubject to famine, even for the ſupport of the nation; and the advantage this African corn would have over the European, would be much greater than that of Caſtile is obſerved to have over the produce of the other parts of Spain. Flat bottomed veſſels, of conſiderable burthen, yet not made to draw much water, would be very proper for this ſort of ſervice; and the voyage through the ſtraits of Gibraltar would, at a proper ſeaſon of the year, be ſhort, and performed at ſmall expence. We might thus be furniſhed with ſeed corn, vaſtly better than any we can purchaſe at preſent; and France with corn that would guard ſufficiently againſt the miſeries of a famine, which a long war generally brings upon that nation; and if the public magazines for receiving and laying up this corn, were erected near the mouths of the ſeveral larger rivers, the water carriage would eaſily diſperſe it in time of want to all parts of the kingdom.

The kingdoms of Fez and Morocco might be alſo as good marts for us, though the French are forbid trading for corn in them, on any other condition than that of exchanging military ſtores for them, which they make a point of it not to do. The keeping up a good underſtanding with Algiers and Tunis, is however of ſo much conſequence to us, that we do not ſcruple purchaſing their friendſhip at this price; and we therefore might, if we pleaſed, as well traffic for corn with fire-arms in Fez and Morocco, as with any other of the commodities of our country. Id. Ibid.

The choice of the *grain* being made, and the manner of procuring it regulated, the next conſideration is how to preſerve it; for this purpoſe, we have the concurrent teſtimony both of the antients and moderns, that ſubterranean caverns made in a dry ſoil, and preſerved from the ingreſs of damp air, are the propereſt places. Pliny tells us, that in his time they kept corn a long time in theſe ſort of ſtore rooms, covering the bottom with ſtraw, and laying upon that the corn in the ear. We find that corn will be preſerved thus very well, for five, ſix, or ſeven years. And an accident, ſome years ago, diſcovered a parcel of corn thus preſerved at Amiens, which, though it had been laid up a great number of years, was found to be freſh and good, not worm eaten, not rotten, nor even mouldy. This is certainly owing to the moiſt air having been kept out, and with it the eggs of animals, and ſeeds of thoſe minute vegetables, which we ſee in form of mouldineſs on ſuch corn, as has been leſs carefully defended from the acceſs of them.

Experimental philoſophy has proved that the air is the great ſource of corruption; keep out that, and all is kept out; and the moſt corruptible ſubſtances, ſuch as meal, butter, milk, and the like, have been preſerved freſh four months in the exhauſted receiver of an air pump.

The only objection to this ſcheme for public *granaries* is the expence, but it is not proper that any but a monarch ſhould undertake them; and there does not appear any way in which the public money could be better employed, than in ſo general a good. They have near Grand Cairo a magazine of this kind, defended with good walls, and called Joſeph's *granaries*. It is not probable, that they are quite ſo old as the days of that patriarch, but they abundantly proved the utility of ſuch ſtorehouſes, by the vaſt quantities of *grain* annually preſerved in them.

Many parts of Africa abound with *granaries* of this kind. They are ſo many deep pits made in the ſolid rock, the deſcent into them is but juſt large enough for a man to go down into them by, but they grow larger as ſoon as the perſon is in, and are uſually ſquare, and from thirty to forty feet in diameter. In theſe the great men of the country preſerve their corn; they firſt ſtrew over the floor with ſtraw, then they lay on the corn; ſtill as the heap riſes, placing a thin bed of ſtraw between the corn and the ſides, as they did at the bottom. In this manner they proceed till the whole cavity is filled: when this is done, they cover the mouth of the entrance with a ſort of hurdle of green boughs of trees, interwoven one with another. This they cover with about two feet thickneſs of ſand, and over this they raiſe a ridge of earth, well beat together, in order to throw off the rain both ways, that none may ſettle on the place and ſoak into the magazine.

The corn thus ſtored up always keeps three, four, or more years very good; and not unfrequently the proprietor being taken off by the ſeverity of the eaſtern governments, under which they live, the magazine is forgotten, and ſome accident diſcovering it many years afterwards, the corn is almoſt always found perfectly good in it. All the care they take, in regard to the corn, is to expoſe it two or three days to the ſun's heat, to dry it thoroughly before they carry it into the magazine.

In the dutchy of Lithuania, and in the Ukraine, the people always preſerve their corn in the ſame manner in wells or pits made in dry places; but in theſe countries great care is to be taken in the opening theſe ſtore rooms; for if people deſcend into them, before they have had ſufficient communication with the freſh air, they are often killed by the damps; this, however, is eaſily guarded againſt, and by theſe and numerous other inſtances of the practice of other countries, it appears evident that the advantage of theſe ſubterranean *granaries* over all others is very great. Id. Ibid. p. 30.

Though theſe are to be recommended before all others, yet the common *granaries* may, with proper care, be rendered greatly more uſeful than they are at preſent. The grand caution neceſſary to this purpoſe is to guard againſt the too great humidity, which there always is in places, where there is a great number of doors and windows. A too free acceſs of the external air is alſo to be carefully guarded againſt; for this brings in with it the eggs of a vaſt number of different inſects, which prey upon and deſtroy the corn. A third caution is, when the corn is the produce of the country, where it is preſerved, not to fill the place with the crop of one place only, but to mix the harveſts of

cure can be had. In men, the application of leeches to the hæmorrhoidal veins is of ſervice, and four times, at leaſt, in the year purging medicines, ſuch as rhubarb, ſena, and the like, are to be taken in decoctions, or infuſions, mixing with them ſuch things as are known to ſweeten the blood. And in the general regimen, a ſufficient quantity of weak liquors is to be always drank, and a moderate exerciſe of the body is to be kept up. And finally, as the ſpring and autumn are the times at which the fits of all *arthritic* diſeaſes uſually return, it will be proper, by way of prevention, to take at ſuch times decoctions or infuſions of ſaſſafras, or the other woods, in the manner of tea, and with them a few moderate doſes of ſome of the nitrous medicines.

It is a general obſervation in all *arthritic* caſes, that all kinds of excretion, moderately promoted, leſſen the pains, and, on the contrary, that the ſuppreſſion of any of them render them much more violent and intenſe. Hence opiates are to be as much as poſſible avoided in the height of the fits, for tho' they give ſome eaſe for the preſent, they always encreaſe the pain afterwards. The aſtringent ſteel preparations, with the boles and other medicines of this claſs, ſuppreſs the excretions, conſtringe the viſcera, and ſometimes bring on dropſies. Volatile ſalts given imprudently, and in too large doſes, conſtringe the viſcera, and at the ſame time excite a violent emotion in the humours: hence they are often the occaſion of great miſchiefs, and it is very unhappy that the preſent practice is ſo free in the uſe of them in theſe caſes.

Among the external applications, thoſe which are aſtringent, cooling, ſaturnine, and the like, all give a temporary relief; but they are of very dangerous, and often of fatal conſequences, as they bring on nodes, tophs, and contractions of the parts in ſome caſes, and in others forcibly repel the matter to the internal parts, and bring on fatal ſymptoms, which no other medicines can relieve.

The acrid, hot, and nervine medicines uſed externally, ſuch as the chemical oils, and the natural balſams, all exaſperate the ſymptoms, and bring on intolerable pains and inflammations; for there is in theſe caſes no weakneſs of the parts to be ſtrengthened by ſuch medicines, but a too great ſtricture and tenſion of them, which all medicines of this kind, by their acrid qualities, muſt neceſſarily add to.

Strong purges given in the time of the fit have often proved fatal, by drawing in the morbid matter to the internal parts; and bleedings in the time of the fits always make them more violent, ſubject the patient to more frequent returns, and bring on a neceſſity of repeating the bleedings every time, before any medicines can take effect. But bleeding in the very beginning, or at the coming on of the fit, as alſo at its decline, have their real uſe; eſpecially the applying four or five leeches to the hæmorrhoidal veins, or in the ſciatica the cupping with deep ſcarification on the part: by this means alone this diſeaſe has ſometimes been abſolutely cured, ſo as never to return again. Camphorated ſpirit of wine, and the bags of dry ingredients ſprinkled with it, are proper in all ſtages of the diſeaſe, and in all conſtitutions.

A cerate of galbanum and camphor often gives immediate relief. This ſhould be applied after bleeding in the acceſs of the fit, and if it does not take effect in three hours time, it ſhould be taken off again. The ſoap plaiſter, with a large portion of camphor, is often alſo found of great ſervice in the beginnings of theſe caſes. The waſhing the feet in warm water, if uſed juſt before the coming on of a fit of the *gout*, always makes it much more ſevere, but if uſed afterwards, it often proves of ſervice. The proper time for it is in the decline of the fits.

Above all things, when a fit is gone off, the occaſional cauſes of its returning are to be avoided; theſe are, a too rich diet, the drinking too much wine, an immoderate uſe of venery, violent emotions of the mind by anger, or other paſſions, and violent and immoderate exerciſes; if theſe are not reſtrained, the return of eaſe will probably be of but very ſhort duration.

The uſe of ſalivation has been recommended by ſome in theſe caſes, but was never found to be of any real uſe.

Dr. Stahl commemorates a very remarkable caſe, proving the *gout* in the feet to be contagious or catching. It is, that a certain gentleman, ſubject to the *gout*, giving his footman a pair of boots which he had been uſed to wear, the man, after a ſhort time wearing them, became gouty.

A total milk and ſeed diet will, it is ſaid, cure the *gout*. See *Cheyne*'s Nat. Meth. of Curing, p. 266.

Dr. Dover ſays, a *gouty* patient will be free in two or three hours at fartheſt, after taking a doſe, from forty to ſeventy grains, of the following powder. Take ſalt petre, and tartar vitriolated, each four ounces, put them into a red hot mortar, ſtir them with a ſpoon till they have done flaming, then powder them very fine, and after that ſlice in an ounce of opium; grind thoſe to powder, then mix it with an ounce of the powder of ipecacuanha, and as much of the powder of liquorice. This is to be taken going to bed in a glaſs of white wine poſſet drink, covering up warm, and drinking a quart or more of poſſet drink while ſweating.

The doctor is alſo of opinion, that Mynſicht's elixir of vitriol often taken, though it may cauſe pain for ſome time, yet moſt certainly deſtroys the *gouty* matter in the end. Med. Eſſ. Edinb.

Dr. Stevens endeavours to prove the *gouty* humours to be rather of an alkaline than acid nature.

Dr. Cajetanus Tacconus tried many experiments with the mucilage of the joints of brutes, and of men, both ſound and *gouty*, in order to diſcover whether the *gouty* matter is acid or alkaline, and concludes, that its matter is ſometimes of the one, and ſometimes of the other nature. If the *gout* produces no *tophi*, or knots, or does it very ſlowly, and eſpecially if it is attended with œdematous ſwellings, he pronounces it to depend on an alkaline humour; but if the knots are large, and quickly formed, it is owing to an acid.

Monſieur de Sault being of opinion that the *gout* depends on the want of perſpiration, propoſes warm baths, exerciſe, keeping always warm, and defending from cold; clean clothes, moderate eating, abſtaining from ſupper, tranquillity of mind, friction, and milk diet, as preſervatives from it. Garlic being obſerved by Sanctorius to increaſe perſpiration, is recommended; as are *cortex Peruvianus* and ſteel in winter. When the ſtomach is attacked he lets blood at the ankles, and applies epiſpaſtics of different kinds to the feet, and then endeavours to procure a general ſweat. When the pain is very violent he blunts it, by applying a cloth dipped in liquid laudanum to the pained part, and exhorts the patient to uſe exerciſe after this. Medic. Eſſ. Edinb.

GOUTY *land*, in agriculture, a term uſed by the farmers to denote a hollow fuzzey black earth with little ſprings, that have no free outlet, and therefore ſwell and elevate the ſurface in many places. *Moreton*'s North. p. 39.

GRACILIS (*Cycl.*)--GRACILIS *rectus*, in anatomy, a name given by Riolan to one of the muſcles of the leg called by Winſlow the *rectus cruris anterior*, and by Cowper the *rectus femoris*. Albinus calls it the *rectus cruris*.

GRACULUS, in the Linnæan ſyſtem of zoology, a diſtinct genus of birds, of the order of the *anſeres*. The diſtinguiſhing character of which is, that the beak is of a conic figure, and has a crooked point. *Linnæi* Syſt. Nat. p. 46.

GRACULUS *palmipes*, in zoology, a name given by ſome to a bird called in England the *ſhagge*, and by Mr. Ray the *corvus aquaticus minor*, or leſſer cormorant, being regularly a ſpecies of that bird. *Ray*'s Ornith. p. 249. See the article CORVUS *aquaticus minor*.

GRADATION, *Gradatio* in rhetoric. See CLIMAX, *Cycl.*

GRADO, in the Italian muſic, ſignifies *degree*; thus *di grado* is uſed to denote *conjoint degrees*, which is when the notes riſe or fall from ſpace to line, or from line to ſpace, without making any leap of a third, fourth, or other interval. See SALTO.

Di grado aſcendente intimates, that all the notes riſe by *conjoint degrees*, as *ut*, *re*, *mi*, *fa*, &c.

Di grado deſcendente, is when all the notes deſcend or fall by *conjoint degrees*, as *ſol*, *fa*, *mi*, *re*, *ut*. *Broſſ.* Muſ. Dict. in voc. See DEGREE and CONJOINT.

GRÆA, a name uſed by the old Greek writers for the wrinkled pellicle which ariſes upon milk in the boiling.

It was alſo uſed in a figurative ſenſe for the wrinkles in the ſkin of old people.

GRAFFER, from the French *greffier*, i. e. *ſcriba*, a notary, or ſcrivener; it is uſed in the Stat. 5 Hen. VIII. c. 1.

GRAFFIO, or GRAVIO, in our old writers, denotes a *landgrave*, or *earl*.—*Nec princeps nec* graffio, *hanc lenitatem mutare audeat*. Blount.

GRAFFIUM, in old writers, is uſed for a writing book, regiſter, or cartulary of deeds and evidences.

GRAFTING (*Cycl.*)—Many have talked of changing of ſpecies, or producing mixed fruits by *engrafting* one tree on another of the ſame claſs; but as the *graft* carries the juices from the ſtock to the pulp of the fruit, there is little hope of ſucceeding in ſuch an expectation by ever ſo many repeated *grafts*; but if after changing the *graft* and ſtock ſeveral ſucceſſive times, you ſet the ſeed of the fruit produced on the *graft* in a good mould, it is poſſible that a change may happen, and a new mixed plant may be produced. Thus the almond and peach may, by many changes in the *graftings*, and by interrations of the ſtones of the peaches, and of the ſhells of the almonds, and by terebrations of the ſtem of the root here and there, alter their nature ſo much, that the coat or pulp of the almond may approach to the nature of the peach, and the peach may have its kernel enlarged into a kind of almond; and on the ſame principle the curious gardiner may produce many things of ſuch mixed kinds. Philoſ. Tranſ. N° 46.

Mr. Du Hamel of the Academy of Sciences of Paris has obſerved, that in *grafting* of trees there always is found at the inſertion of the *graft* a change in the directions of the fibres, and a ſort of twiſting or turning about of the veſſels, which greatly imitates that in the formation of certain of the glands in animal bodies; and he very judiciouſly infers from thence, that a ſort of new viſcus being formed by this means, the fruit may very naturally be ſo far influenced by it, as to be meliorated on the new branch; but that no ſuch ſudden and eſſential changes can be effected by this means, as too many

It is common in Egypt and Arabia, and is found in many parts of the world beſide. We have of it in the weſt of England very little inferior to the Oriental.

The whitiſh red granite is ſometimes found in form of large ſtrata, but much more frequently in large looſe nodules. It is very little inferior in beauty to the Oriental *granite*, and is of a leſs coarſe and rude texture; it's ground colour has different degrees of its red tinge, and is ſometimes even whitiſh. This is beautifully ſpangled with black, white, and yellow; much in the ſame manner as the Oriental kind, and it is equally hard, and capable of as elegant a poliſh. It is very plentiful in many parts of the iſland of Minorca, from whence we might have it in abundance, and it would make very beautiful tables, *&c.* The rough maſſes of it are ſometimes found alſo on the ſhores of our iſland of Guernſey, whence they are taken up for ballaſt for ſhips, and are ſometimes by this means brought among us and uſed in the pavements of our ſtreets. *Hill*'s Hiſt. of Foſſ. p. 500.

GRANULATION *of metals* (*Cycl.*) in aſſaying, is the reducing metals into very ſmall particles, that they may the more readily fuſe, and the more equally mix with other bodies in ſome of the nicer operations.

This is done more coarſely in the wet way, by means of running them into water through a new broom, or rolling them about in a hollow cylinder contrived on purpoſe; but the nicer and finer way is the dry method, by means of a wooden box chalked within. Lead is very nicely granulated this way, and it is to be done in the following manner.

Put a quantity of lead into an iron ladle, and melt it ſlowly over a gentle fire; ſo ſoon as it is perfectly liquid, pour it into a round wooden box, with a wooden cover well fitted to it, and both that and the cavity of the box well rubbed over with chalk; ſhut the box immediately when the melted metal is in, and ſhake it violently, ſo that the metal within may be agitated forcibly againſt all parts of the box; continue this agitation till the metal is cold; and on opening the box, you will find the greater part of it finely granulated, or comminuted into very ſmall porous grains. Let the chalk that adheres to theſe grains be waſhed off, and then ſift them to make them of an equal ſize.

Lead, tin, and braſs, are the moſt proper metals for this proceſs, ſince theſe, when ready to melt, are always extremely brittle, in ſome degree like wetted ſand. The chalk with which the inſide of the box is rubbed over gives the ſurface a great reſiſting force, and keeps it from being burnt; while the metal daſhed againſt its ſides, being extremely brittle juſt as it becomes ſolid, is broken into a minute powder, not to be obtained any other way than by this operation.

There are however ſome cautions neceſſary in the management of this. The lead muſt not be melted at too fierce a fire; for this occaſions a ſkin upon the ſurface, which however often it be taken away, is always immediately ſucceeded by another; and the matter of theſe ſkins mixing with the metal during the ſhaking, makes the whole tenacious, and much obſtructs the operation. Though the fire is not to be fierce, the lead however muſt be all perfectly fluid; otherwiſe it will concrete almoſt as ſoon as poured into the box, and little powder will be produced.

This ſort of *granulation* cannot be obtained from ſuch metals as are the more tenacious, the nearer they come to fuſion, as gold, ſilver, *&c.* Theſe therefore can only be *granulated* the other and coarſer way, by means of water. *Cramer*'s Art. Aſſ. p. 70.

GRANULOSE *Roots*, are thoſe compoſed of ſmaller knobs than the grumoſe ones, and reſembling ſo many grains of corn; of this ſort is the white ſaxifrage.

GRANUM *Viride*, in botany, a name given by ſome authors to the turpentine tree. The fruit of this tree is reddiſh while unripe; but as it ripens it becomes of a deep blueiſh green colour, and hence the name.

GRAPES (*Cycl.*)—Thoſe kinds of *grapes* which are thin ſkined, grow ſooner ripe than others, and will thrive in a temperate climate where the others will not. If it happen that *grapes* are ſtruck with hail at the time that they are large and near ripening, they never become ripe at all, but harden and ſo remain. *Portzius* de Vin. Rhen.

We have in the Philoſophical Tranſactions a remarkable account of the change of colour in *grapes* of the ſame tree. A muſcadine *grape* tree was raiſed from a cutting of a parent vine of this kind, whoſe fruit was white; it was planted againſt an eaſtern wall, where it had the benefit of the ſun from its riſing, to half an hour after twelve. The ſoil a ſtiff clay, but rendered fitter for the growth of this ſort of tree, by a mixture of rubbiſh of an old wall.

At about five years ſtanding it was ſo pruned, as to make it ſhoot two principal branches, one to the right, the other to the left hand; from hence it ſhot twenty two inches on each ſide, before it came to a joint. That on the right was a very luxuriant branch, as thick as the body of the tree, the other about half that bigneſs. The leaves on the right hand were alſo of twice the bigneſs of thoſe on the left, and indeed larger than the leaves of the parent tree; but what is moſt ſingular is, that the luxuriant branch produced annually fine black *grapes* in large bunches, and the left hand branch white ones. But the white were often in the greateſt quantity, though the black grew on the much ſtronger branch. It is obſervable, that in all thoſe vines which bear black and blue *grapes*, that the leaves die red; but in this tree, whoſe origin was from a white *grape*, the leaves on that branch which bore black *grapes* died white, as well as thoſe on the other. The ſucceeding year, the number of the branches on the right hand ſhoot were greatly encreaſed in number, and the ſucceeding year all bore fine deep black *grapes* in very large numbers. Phil. Tranſ. N° 366. p. 102.

Wolf-GRAPES. See LYCOSTAPHYLA.

GRAPE *galls*, in natural hiſtory, a name given by authors to a ſpecies of protuberances reſembling cluſters of *grapes*, and when ripe of a reddiſh colour, which are found hanging from the oak at ſome ſeaſons of the year. Theſe are genuine *galls*, though of a peculiar kind; and owe their origin to a very ſmall four winged black fly. This little creature depoſits its eggs either on the ſurface, or within the ſubſtance of thoſe pedicles of the oak which nature has deſtined for producing the catkins, or ſmall flowers of that tree. The biting and ſucking of the worms, which are produced from theſe, occaſion a wrong derivation of the juices to the part, and the conſequence of this is, that inſtead of flowers, there appears a protuberance over the part where each of theſe inſects is lodged. This tubercle at firſt is ſmall, and of a pale greeniſh colour, but it finally becomes yellowiſh, or reddiſh, and is juicy and large. A number of theſe ſtanding cloſe together upon the ſtalk, give the appearance of a cluſter of *grapes* on the bunch, and when any one of theſe is opened, there is found in it either a worm, a chryſalis, or a fly, the animal never quitting its habitation till in its perfect ſtate, but paſſing through all its changes in it. *Reaumur*, Hiſt. Inſect. Vol. 6. p. 16.

GRAPES, in the manege, is uſed to ſignify the *arreſts*, or mangy tumours that happen in a horſe's legs. See ARREST.

GRAPHIDA, in natural hiſtory, a name by which ſome authors have called the *morochthus*, or French chalk. *Worm.* Muſ. p. 71. See the article MOROCHTHUS.

GRAPHISCUS, in the writings of the antients, a name given to an inſtrument uſed for the extracting darts from wounds. It is ſaid to have been the invention of Diocles, and is deſcribed by Celſus.

GRAPLINGS, in a ſhip. See GRAPNEL.

GRAPNEL, on ſhip board, a kind of anchor for boats or gallies to ride by. It differs from other anchors, as having four flukes and no ſnack, though there are ſome with three flukes, with which they uſe to ſweep for hawſers or ſmall cables. In men of war alſo, the *grapnels*, or at leaſt a lighter kind of them, are uſed to be thrown into an enemy's ſhip, in order to catch hold of ſome of her gratings, rails, gunwales, *&c.* this is done in order to boarding of her.

GRASS (*Cycl.*)—The Engliſh *graſs*, when good in its kind, is much ſuperior to that of all other nations, and in our *graſs* plats, and turfed walks, our gardens excel thoſe of all the world.

The common way of making theſe is by laying on turfs from a common, and the plats thus made are greatly ſuperior to thoſe made by ſowing, there being great nicety and art required in bringing the latter to good order, and in the procuring the proper ſeed, that from common hay-lofts being of a mixture of good and bad kinds, and by no means fit for the purpoſe, as containing the ſeeds of weeds, as well as very improper *graſſes*.

In order to ſow *graſs*, the ground muſt be dug up with the ſpade, then finely and evenly raked over, all the clods and ſtones taken off, and an inch thickneſs of good mould ſifted on to facilitate the growing of the ſeed. This done, the ſeed muſt be ſown very thick, that the blade may come up cloſe and ſhort; and the ground muſt be then raked over again to bury the ſeed, otherwiſe, if it ſhould happen to be windy weather, a great part of it may be blown away.

The beſt ſeaſon for ſowing of *graſs* is the latter end of Auguſt, and it is beſt to ſow it in a mild day, when there is a likelyhood of rain. When it is come up to any height, it muſt be mowed, and this repeated very frequently, for the oftener it is mowed, the thicker it grows. It ſhould be rolled alſo frequently with a wooden roller. In autumn, wherever there are naked patches, the ground ſhould be ſown with freſh ſeed. *Miller*'s Gard. Dict.

Everlaſting GRASS, a name given by ſome of our farmes to the plant more properly called *ſaint foin*. It ſerves as *graſs* for the food of cattle, and dries into hay; and a crop of it once well rooted in the ground, will continue forty years without renewing. See the article SAINT-*Foin*.

Rey GRASS. See REY *graſs*.

GRASS-*hearth*, in our cuſtoms, *graſing*, or turning up the earth with a plough. Hence the cuſtomary ſervice for the inferior tenants of the manor of Amerſden in Oxfordſhire, to bring their ploughs to do one day's work for their lord, was called *graſs-hearth*, or *graſs-hurt*. *Kenn.* Paroch. Antiq. p. 496, 497.

GRASS *walks*. Theſe are a great ornament in the Engliſh gardens, our turf being, like our gravel, ſuperior to that of any other country.

They are either made by turfing them with turf cut off from a common, or by ſowing with hay ſeed, and will be always handſome with good rolling and frequent mowing. If the ſoil be dry, it is beſt to lay theſe quite even, and level, but if damp, they may be laid a little rounding, but that not more than an inch in twenty feet. The oftener theſe walks are mowed and rolled in ſummer, the thicker their bottoms will be, and in autumn they ſhould be kept ſhorter than at any other ſeaſon, for if the blade runs up high at that ſeaſon, the bottom will be bare in winter. All *graſs walks* ought alſo to be frequently polled, as the gardeners call it. This operation is the diſperſing the worm-caſts all over the walks with long aſh poles; this, beſide deſtroying the worm-caſts, is very beneficial to the *graſs* of the walk. *Miller*'s Gard. Dict.

GRASSA, a name given by ſome authors to native *borax*.

GRASSETTE, in botany, the name given by the French to the *pinguicula*, or butter-wort, called alſo in Yorkſhire *ſanicle*. See PINGUICULA.

GRASSHOPPERS. Theſe animals are of the locuſt kind, and ſometimes come in ſwarms to particular places, in the ſame manner as that devouring creature does. They appeared ſome years ago in Languedoc, and ſome other places, in very formidable ſwarms, and eat up all the harveſt of ſeveral years. They took their flight like birds, and were about an inch long, and of a grey colour, in ſhape wholly like the common *graſshoppers*. They were found in many places covering the whole ſurface of the earth four or five inches deep, and uſed to lie quiet till toward noon; but when the ſun then ſhone warmly upon them they uſed to ariſe and take wing, and ſettling on the corn-fields, they would in a few hours eat up the whole produce, ears, leaves, and even the more tender parts of the ſtalks.

When they had deſtroyed one field in this manner, they uſed to take wing and fly to another. They uſually flew very high in the air, and directly againſt the wind; but as ſoon as they ſaw a new crop of corn, they dropped together in a ſwarm, and cleared it as they had done the firſt. This practice they continued the whole day, and toward evening they ſettled upon the ground, where they remained quiet till the heat of the following day raiſed them again. When they had deſtroyed all the corn in the country, they ſeized upon the vines, garden herbs, and willows, and at laſt upon the hemp, whole fields of which they eat up, notwithſtanding its great bitterneſs. Toward autumn they left off feeding, and were found in copulation, and ſoon after this the females were every where ſeen laying their eggs, which they depoſited in the ground, making a hole with their tail large enough to receive a gooſe quill.

In theſe holes every female would lay forty or fifty eggs, each of the ſize of a millet ſeed, and when they had finiſhed the laying, they covered up the hole to keep out the water; after this they died apace, and the multitudes of their carcaſſes ſtunk intolerably, poiſoning the air. The next year they hatched in April, and from this one ſwarm there were ſuch prodigious numbers hatched, that fifteen tuns of them were deſtroyed, while no bigger than flies, and nine tuns of their eggs before the hatching, and yet there remained enough of them to deſtroy, in a great meaſure, the ſucceeding harveſt. After this they gradually decreaſed for ſeveral years, till they were not more numerous there than elſewhere. This was attributed to the induſtry of the farmers in killing them; but it is more probable, that unfavourable ſeaſons deſtroyed them. Philoſ. Tranſ. N° 182. p. 146.

GRATINGS, in a ſhip, are ſmall ledges of ſawed plank, framed one into another like a lattice, or priſon grate, lying on the upper deck, between the main-maſt and fore-maſt, ſerving for a defence in a cloſe fight; and alſo for the coolneſs, light, and conveniency of the ſhip's company.

GRATIOLA, in botany, the name of a ſmall plant not unfrequent in watery places. It is a ſpecies of the *digitalis*. See DIGITALIS.

Mr. Geoffroy has obſerved, that the leaves of this plant are a very ſtrong purge, and that in the dry extract, a method he is very fond of, for the extracting the virtues of many medicines. A briſk purge may be prepared from the *gratiola*, which operates in a ſmall doſe, and without any diſagreeable taſte. The manner of preparing it is this. The leaves are to be infuſed in water, till they have communicated their virtue to it by the means of heat, and this liquor is to be evaporated over a balneum mariæ to a perfect dryneſs; when it leaves a dry pulveriſable extract, that operates in a doſe of eight or ten grains. Mem. Acad. Scienc. 1738. p. 287.

This is a very rough purgative, it often operates by vomits as well as by ſtool, and carries off a great quantity of water in dropſical caſes. It alſo deſtroys worms, and opens obſtructions of the viſcera. Its operation, however, is ſo violent, as to be only fit for perſons of robuſt conſtitutions. The *gratiola* is uſually given in decoction in water or ale, half an handful being a ſufficient doſe for a very ſtrong man. Its operation is rendered more mild, by being boiled in milk, and the decoction drank. It purges very well in the form of glyſters, but care muſt be taken not to give it when the bowels are in an inflamed ſtate.

Externally, it is ſaid to be a vulnerary, a cataplaſm of the bruiſed herb being ſometimes applied to wounds with ſucceſs.

GRAVE, (*Cycl.*) in the Italian muſic, ſerves to denote a ſlow motion, ſomewhat faſter than *adagio*, and ſlower than *largo*. *Broſs*, Muſ. Dict. in voc. See ADAGIO, and LARGO.

GRAVEDO (*Cycl.*)—The ſigns of a *gravedo* are a dizzineſs and heavineſs of the head, attended with tenſive and preſſing pains, which ſometimes become violently pungent and as it were burning, a remarkable turgeſcence of the veſſels, thirſt, and a dryneſs of the mouth, and unſound ſleep; and finally the breaſt is drawn into conſent, and is afflicted with a tenſive and oppreſſive pain.

The *gravedo* is a ſpecies or rather ſymptom of the head-ach, and conſequently is removed by the ſame means uſed againſt it. See HEAD-ACH.

GRAVEL (*Cycl.*)—The *gravel* of England as much excells that of France, Holland, Flanders, *&c.* as the graſs does. This and graſs are the natural ornaments of a country ſeat. We have ſeveral ſorts of *gravel* in the different parts of England, but that which is common on black heath is the moſt valuable ſort for garden walks, as it conſiſts of round, even, and beautiful pebbles, and when mixed with a ſtiff loam, binds well, and keeps in order the longeſt of all kinds of *gravel*.

GRAVEL *walks*. Theſe are deſervedly eſteemed a vaſt advantage, which our gardens have over thoſe of all other nations. The method of laying ſuch walks is this.

The bottom ſhould be laid with lime rubbiſh, or large flint ſtones, or any other hard matter, for eight or ten inches thick, to keep weeds from growing through, and over this the *gravel* is to be laid about ſix or eight inches thick: This ſhould be laid rounding up in the middle, by which means the larger ſtones will run off to the ſides, and may be raked away, for the *gravel* ſhould never be ſcreened before it is uſed, that ſpoiling it. It is a common miſtake to lay theſe walks too round, which not only makes them the more uneaſy to walk on, but takes off from their apparent breadth. One inch in five feet is a ſufficient proportion for the riſe in the middle; ſo that a walk of twenty feet wide ſhould be four inches higher in the middle than at the edges, and ſo in proportion. As ſoon as the *gravel* is laid it ſhould be raked, and the large ſtones thrown back again; then the whole ſhould be rolled both lengthwiſe and croſswiſe, and the perſon who draws the roller ſhould wear ſhoes with flat heels, that he may make no holes, becauſe holes made in a new walk are not eaſily remedied. The walks ſhould always be rolled three or four times in very hard ſhowers, after which they will bind more firmly than they could ever be made otherwiſe to do.

Gravel, with ſome loam among it, binds much more firmly than the rawer kinds, and when *gravel* is naturally very harſh and ſharp, it is very proper to add a mixture of loam to it. The beſt *gravel* for walks is ſuch as abounds with ſmooth round pebbles, which being mixed with a little loam, binds ſo firmly, as never to be injured after, either by wet or dry weather. Theſe are not ſo liable to be turned up by the feet in walking, as the more irregular ſhaped pebbles, and remain much more firmly in their places after rolling. *Miller*'s Gard. Dict.

GRAVELY *land*. The farmers obſerve, that *gravely* and ſandy lands eaſily admit of heat and moiſture, but that they have leſs advantage from the laſt than any other lands, becauſe they let it paſs too ſoon, if they have a looſe under ſtratum; or retain it too long, if they have a firm one, ſuch as clay, or a cold ſolid ſtone. From theſe accidents it either parches, or chills too much; but when *gravely* ground has a thin coat of good mould at top, and a bottom of looſe ſtone, it will produce excellent crops of *graſs*, for it will receive heat and moiſture enough; and if at any time it parches up the roots, the leaſt rain refreſhes it again, and the growth is quicker than before. *Mortimer*'s Huſbandry. Tom. 1. p. 69.

GRAVITAS, Βαρυτης, in the antient muſic, was uſed to ſignify a ſound produced by the remiſſion, or falling of the voice. *Gravitas* differs from remiſſion, as the effect from its cauſe. Vid. *Ariſtoxen*, p. 10—13. Edit. Meibom.

GRAVITAS is alſo uſed to denote the ſtate of a woman going with child. See PREGNANCY.

GRAVITATION (*Cycl.*) is ſometimes diſtinguiſhed from gravity. Thus Monſieur Maupertuis takes gravity for that force, whereby a body would fall to the earth, ſuppoſed at reſt; and *gravitation* for the ſame, but diminiſhed by the centrifugal force. See Fig. of the Earth determ. p. 206. of Mr. Murdoch's tranſlation.

It is only *gravitation*, or gravity thus blended with the centrifugal force, that we can meaſure by our experiments. However, methods have been found to diſtinguiſh what remains of primitive gravity, and what has been deſtroyed by the centrifugal force. See *Maupertuis* loc. cit.

GRAUPEN, a term uſed by the German miners to expreſs the reſiduum of any ore after the regulus, or metalline part is run from it. Thus the ores of biſmuth leave behind them, after the regulus is melted off, an earthy ſubſtance called *biſmuth graupen*, with which, mixt with flints and an alkali, they make a kind of ſmalt, not diſtinguiſhable from the true ſmalt made from cobalt. Philoſ. Tranſact. N° 390.

GRAY, in zoology, a name given in ſome counties of England to the badger. See the article TAXUS.

GRAY is alſo uſed in ſome places for a ſpecies of wild duck, more commonly known by the name of the *gadwall*. See the article GADWALL.

GRAYLING, or UMBER, the Engliſh name for the fiſh called by authors *thymallus*, and *thymus*, and by Artedi made a ſpecies of coregonus. See THYMALLUS and COREGONUS.

GREEN (*Cycl.*)—The fineſt method of giving this beautiful colour to glaſs is this. Take five pound of cryſtalline metal, that has been paſſed ſeveral times through water, and the ſame quantity of the common white metal of polverine, four pound of common polverine fritt, and three pound of red lead; mix the red lead well with the fritt, and then put all into a pot in a furnace. In a few hours the whole maſs will be well purified; then caſt the whole into water, and ſeparate, and take out the lead; then return the metal into the pot, and let it ſtand a day longer in fuſion; then put in the powder of the reſiduum of the vitriol of copper, and a very little crocus martis, there will be produced a moſt lively and elegant *green*, ſcarce inferior to that of the oriental emerald. There are many ways of giving a *green* to glaſs, but all are greatly inferior to this. *Neri*'s Art of Glaſs, p. 55.

GREEN *fiſh*, in the fiſh trade, a name given to the cured cod fiſh which has been caught and preſerved in Greenland. *Willughby*, Hiſt. Piſc. p. 166. See the article COD *fiſh*.

GREEN-*hew*, or *Green-hue*, in our old writers, the ſame with *vert* in foreſts, &c. *Manwood*, Par. 2. cap. 6. num. 5. Vid. Terms of Law.

GREEN-*houſes*. The length of *green-houſes* muſt be proportioned to the number of plants intended to be preſerved in them, and cannot therefore be reduced to rule; but their breadth ſhould never be more than twenty feet in the clear, and the length of the windows ſhould be at leaſt equal to the breadth, or depth of the houſe; and theſe muſt be carried quite up to the cieling, that there may be no dead air in any part of the houſe, and they ſhould come down within ten or twelve inches of the floor. In a ſmall *green-houſe* they ſhould not be leſs than four feet broad, and in a large one they ought to be ſix. The piers between the windows muſt be as narrow as may be to ſupport the building, for which reaſon they ſhould either be of ſtone, or of hard burnt bricks.

If the piers are made of ſtone, they ſhould be twenty inches wide in front, and ſloped off behind to ten inches, by which means there will be no corners to take off the rays of the ſun. If they are of brick, they will require to be at leaſt two feet in front, but they ſhould be in the ſame manner ſloped off behind. Over the *green-houſe* may be rooms for drying and preſerving ſeeds, roots, &c. and behind it a place for tools and other purpoſes; and both theſe behind, and the rooms above, will be of great uſe in keeping off the froſts, ſo that the wall between theſe need not be of more than two bricks in thickneſs.

The floor of the *green-houſe*, which ſhould be laid either with marble, ſtone, or flat tiles, muſt be raiſed two feet above the ſurface of the adjoining ground, or if the ſituation be damp, at leaſt three feet; and under the floor, about two feet from the front, it will be very adviſeable to make a flue of ten inches wide, and two feet deep; this ſhould be carried the whole length of the houſe, and then returned back along the hinder part, and there be carried up into funnels adjoining to the tool-houſe, by which the ſmoak may be carried off. The fire place may be contrived at one end of the houſe, and the door at which the fuel is put in, as alſo the aſh grate, may be contrived to open into the tool-houſe, and the fuel being laid in the ſame place, the whole will be out of ſight. The uſe of fires muſt, however, be very ſparing in this place, and it is not one winter in three or four that will require them in any part, only when the weather is very ſevere, and the froſt cannot well be kept out any other way, this is an expedient that is good to have in readineſs, as it may ſave a whole houſe of plants. There muſt be a number of truſſels, with forms of wood upon them, to ſupport the pots of plants, the talleſt to be placed hindmoſt, the loweſt within four feet of the windows; and all the inſide of the *green-houſe* ſhould be white-waſhed, or painted white, to reflect as much as poſſible the ſun's rays. The placing the euphorbiums, cereus's, and other ſucculent plants among orange trees, and other common *green-houſe* plants, is always deſtructive of them, by making them receive an improper ſort of effluvia, which plants of that kind imbibe very freely. They ſhould therefore be placed in two wings built at each end of the *green-houſe*, which, if well contrived, will be a great beauty, as well as uſe, to the building. Theſe wings may be made capable of a greater warmth alſo, by more flues, and may be made to contain a hot-bed of tanners bark for the raiſing many of the tender plants, natives of warm climates. *Miller*'s Gard. Dict.

GREEN *muſtard*, an Engliſh name for the herb dittander, or pepperwort. See LEPIDIUM.

GREEN *ſilver*, the name of an antient cuſtom within the manor of Writtel in the county of Eſſex; which is, that every tenant, whoſe fore-door opens to Greenbury, ſhall pay an halfpenny yearly to the lord, by the name of *green ſilver*. *Blount*.

GREEN *wax*, is uſed where eſtreats are delivered to the ſheriffs out of the Exchequer, under the ſeal of that court, made in *green wax* to be levied in the ſeveral counties. This word is mentioned in the ſtat. 43 Ed. 3. c. 9. And 7 Hen. 4. c. 3. Terms of Law.

GREGARIOUS *birds*, are ſuch as do not live ſolitarily, but aſſociate in flights or coveys, a great many together in company.

GRENAILLE, a name given by the French writers to a preparation of copper, which the Chineſe uſe as a red colour in ſome of their fineſt china, particularly for that colour which is called oil red, or red in oil. The china ware coloured with this is very dear. The manner in which they procure the preparation is thus: they have in China no ſuch thing as ſilver coined money, but they uſe in commerce bars, or maſſes of ſilver; theſe they pay and receive in large bargains, and among a nation ſo full of fraud as the Chineſe, it is no wonder that theſe are often adulterated with too great an alloy of copper. They paſs, however, in this ſtate in the common payments. There are ſome occaſions, however, ſuch as the paying the taxes and contributions, on which they muſt have their ſilver pure and fine: on this occaſion they have recourſe to certain people, whoſe ſole buſineſs it is to refine the ſilver, and ſeparate it from the copper and the lead it contains. This they do in furnaces made for the purpoſe, and with very convenient veſſels. While the copper is in fuſion, they take a ſmall bruſh and dip the end of it into water, then ſtriking the handle of the bruſh, they ſprinkle the water by degrees upon the melted copper; a ſort of pellicle forms itſelf by this means on the ſurface of the matter, which they take off while hot with pincers of iron, and immediately throwing it into a large veſſel of cold water, it forms that red powder, which is called the *grenaille*; they repeat the operation, every time they in this manner ſeparate the copper; and this furniſhes them with as much of the *grenaille* as they have occaſion for in their china works. Obſervations ſur les Coutumes de l'Aſie, p. 309.

GRESLING, in ichthyology, a name given by the Germans to the *gobius fluviatilis*, or common gudgeon, which is very frequent in their ſmaller rivers.

GRESSURA, a word uſed by ſome writers, to expreſs the part between the pudenda and the anus. See the article PERINÆUM.

GREWIA, in botany, the name given in the *hortus malabaricus*, and continued by Linnæus to a genus of plants, the characters of which are theſe: the cup is a perianthium, compoſed of five oblong, erect, lanceolated leaves ſtanding open, and coloured within. The flower is compoſed of five petals, ſomewhat ſmaller than the leaves of the cup, and edged with a foliacious rim at the baſe. The nectarium is compoſed of certain little ſcales, inſerted one in the baſe of each petal; theſe are thick, and ſomewhat incurvated, and ſurround the ſtile. The ſtamina are very numerous filaments inſerted in the baſe of the germen, and of the length of the flower; the apices or antheræ are roundiſh. The piſtil is a long columnar receptacle, erect and edged with a pentangular rim; it is terminated with a roundiſh germen. The ſtile is capillary, and is of the length of the ſtamina; the ſtigma is obtuſe and quadrifid; the fruit is a quadrangular berry with four cells; the ſeeds are globoſe. *Linnæi* Gen. Plant. 439. Hort. Mal. Vol. 5. p. 46.

GREWT, in mineralogy, a word uſed by our miners to expreſs earth, but particularly that earth found in the flat countries, and in the banks of rivers in their ſearches after mineral veins, which is different in colour and nature from the reſt of the bank or bottom. This they always underſtand to have been waſhed off from the neighbouring hills, in the time when the ſhoad ſtones, by which they train their new mines, were alſo waſhed down, that is at the univerſal deluge; and this wherever found, proves of great uſe to them in theſe reſearches, as it ſhews which way the waſh from the hill has run, and directs them how to trace the reſt, and where to look for the ſhoad ſtones with any probability of ſucceſs.

They generally examine the banks of rivers, where they have been worn away by land floods, in order to find theſe *grewts*, and then examine, in a ſtrait line with the next hill,

hill, though four or five miles off; and, if there be any mine there, they generally meet with ſhoad ſtones, as tokens of it in the way. Phil. Tranſ. N° 69.

GREY (*Cycl.*)—GREY, in zoology, an Engliſh name for a truttaceous fiſh, caught in many of the rivers of England. It is a very large fiſh, often growing to the full ſize of the larger ſalmon, but differing from that ſpecies, in the body being broader, and all over covered with immenſe numbers of *grey* ſpots; from theſe ſpots it has its name. Its tail is not forked, and its fleſh is much finer taſted than the ſalmon, and in the places where both are to be had, the *grey* ſells at the larger price. It comes up into the freſh waters in the month of Auguſt, and is a very ſcarce fiſh. *Willughby*'s Hiſt. Piſc. p. 193.

GREY-*hound* (*Cycl.*)—Among a litter of *greyhound* puppies, the beſt are always thoſe which are lighteſt. Theſe will make the lighteſt and nimbleſt dogs as they grow up. The *greyhound* is the beſt uſed in open countries where there is little covert; in theſe places there will ſometimes be a courſe after a hare of two miles or more, and both the dogs and the game in ſight all the while. It is generally ſuppoſed that the *greyhound* bitch will beat the dog in running; but this ſeems to be an error, for the dog is both longer made, and conſiderably ſtronger than the bitch of the ſame kind. In the breeding theſe dogs the bitch is principally to be regarded; for it is found, by experience, that the beſt dog, with a bad bitch, will not get ſo good puppies as an indifferent dog with a good bitch. The dog and bitch ſhould be as nearly as can be of the ſame age, and for the breeding of perfect and fine dogs, they ſhould not be more than four years old; an old bitch may be uſed with a young dog, but the puppies of a young bitch and an old dog will never be good for any thing.

The general food of a *greyhound* ought to be chippings or raſpings of bread, with ſoft bones and griſtles, and theſe chippings ought always to be ſoaked in beef or mutton broth; and when it is nearly cool, ſome milk ſhould be added; this given the dog morning and evening will keep him in good heart and ſpirits; he muſt never have any hard bones given him, becauſe they harden his mouth and hurt his teeth. If the dog grow ſick and weakly upon this diet, then take ſheeps heads with the wool on, waſh them clean, and boil them in a ſufficient quantity of water, to make a very rich and ſtrong broth, and add a large quantity of oat-meal to it; when the meat is very tender, and the broth rich, it is good and fit for the dog; and giving him ſometimes the one, and ſometimes the other, will very ſoon recover him.

If one of theſe dogs is to run for a wager, or on any particular occaſion, he may be dieted with the following bread. Take half a peck of good wheat, and the ſame quantity of the fineſt and drieſt oat-meal, grind theſe together, and let the meal be ſifted very fine, then add as much liquorice and anniſeeds, in powder, as will not give it too diſagreeable a flavour, and knead the whole into dough with the whites of eggs. This ſhould be baked in ſmall loaves conſiderably hard, and when the dog is to be fed with it, it is to be ſoaked in beef or other broth. He is to be led out to walk half an hour after ſun riſe every morning, and half an hour before ſun ſet every evening, and at his coming in fed with this ſoaked bread.

The proper exerciſe for a *greyhound* is the courſing him three times a week, and rewarding him with blood, which will animate him in the higheſt degree, and encourage him to proſecute his game. But the hare alſo ſhould ever have fair play; ſhe ſhould have the law, as it is called, that is, have leave to run about twelve ſcore yards before the dog is ſliped at her, that he may have ſome difficulty in the courſe, and not pick up the game too eaſily. If he kill the hare he muſt never be ſuffered to tear her, but ſhe muſt be taken from him, his mouth cleaned of the wool, and the liver and lights given him by way of encouragement. Then he is to be led home, and his feet are to be waſhed with butter and beer, and about an hour after he is to be fed.

When the dog is to be taken out to courſe, he ſhould have nothing in the morning but a toaſt and butter, and then he is to be kennelled till taken out to the field. The kennelling theſe dogs is of great uſe, always giving them ſpirit and nimbleneſs when they are let looſe; and the beſt way of managing a fine *greyhound* is never to let him ſtir out of the kennel, except at the times of feeding, walking, or courſing.

GRIEF. The influence of this paſſion on the body is very great, ſo as often to deſtroy all appetite, and deſire of meat, either by inſpiring men with a diſreliſh for life, or by a mechanical inſtinct; becauſe food taken at ſuch a time makes but bad nouriſhment, fitter to corrupt the blood than prolong life: on which account it is aſſigned as a phyſical cauſe for the faſting practiſed among the heathens. [See FASTING.] The influence of this paſſion extends itſelf even to beaſts; which when indiſpoſed, not only take no pains to provide themſelves food, but alſo refuſe it when laid before them. Vid. Mem. Acad. Inſcript. Tom. 5. p. 50. ſeq. This paſſion has been found to leſſen perſpiration and urine. See PERSPIRATION.

GRINDERS, *molares dentes*. See MOLARES.

GRINETTA, in zoology, the name of a water fowl of the gallinula, or moor hen kind, having open feet, and no membranes annexed to them. It is ſmaller than the moor hen, and the water rail. Its legs are of a duſky greeniſh colour, and its toes very long; its beak very ſhort, compreſſed ſideways, and pointed at the end, and is covered at the origin with a deep yellow ſubſtance, looking like a plaiſter put on it. Its neck and beak are variegated with an irregular mixture of a blackiſh, greeniſh, and whitiſh, but none of the colours are clear or bright. It is common in Italy and Germany, as well as in England. Aldrovand has twice deſcribed this bird, once under the name of *gallinula alia chloropus fulicæ ſimilis*, and another time under that of *gallinula ſerica*. *Ray*'s Ornitholog. p. 235. *Aldrovand*, Lib. 3. p. 340.

GRISLAGINE, in zoology, the name of a freſh water fiſh of the gudgeon kind, common in rivers of Germany. It ſomething approaches to the common roach in ſhape. Its back is of a duſky blue, and its belly and ſides, below the ſide lines, are of a ſilvery whiteneſs. The ſide lines are yellow and dotted, and over this there is an interrupted blackiſh line running in ſeveral oblong ſtreaks from the gills to the tail. *Willughby*, Hiſt. Piſc. p. 263.

GRISLEA, in botany, the name of a genus of plants, the characters of which are theſe. The perianthium conſiſts of one leaf, and is of a tubulated bell-faſhioned ſhape. It ſtands erect, and is divided into four ſegments at the end. The flower conſiſts of four oval petals extremely ſmall, ſcarce indeed exceeding in ſize the ſegments of the cup. The ſtamina are eight ſubulated, erect, and extremely long filaments. The antheræ are ſimple and erect. The germen of the piſtil is oval. The ſtyle is capillary, and of the length of the ſtamina. The ſtigma is ſimple. The fruit and ſeeds are not known. It is an American tree, extremely well diſtinguiſhed from all others by the flower alone. *Linnæi* Gen. Pl. p. 160.

GRISOLA, in zoology, the name of a bird of the lark kind deſcribed by Aldrovandus, and ſuppoſed by Mr. Ray to be the ſame with the *ſpipoletta*, or *tordino* of the Venetians. See the article SPIPOLETTA.

GRITHBRECHE, in our old writers, the ſame with breach of the peace. In this ſenſe we find it mentioned in *leg.* Hen. I. c. 36. *In cauſis regiis* grithbreche 100 *Sol. emendabit.* Terms of Law.

It comes from the Saxon, *grithbryce*, which ſignifies the ſame.

GRITHSTOLE, in our old writers, a place of ſanctuary. Blount. See FRIDSTOLE, *Cycl.*

GROMA, among the Romans, a way-wiſer, or ſurveying inſtrument; whence thoſe who uſed it were called *gromatici*, and the place in the camp where it was kept, *groma*. *Pitiſc.*

GROMETS, in a ſhip, are ſmall rings faſtened to the upper ſide of the yard of a ſhip by ſtaples, to tie unto it, or to faſten the laſkets.

GROMPHENA, in botany, a name uſed by ſome authors, particularly by Pliny, for the common garden marygold. *Ger.* Emac. Ind. 2.

GROMWELL, in botany. See LITHOSPERMUM.

GRONDEUR, a name given by the French in America to a fiſh which is commonly eaten there; the jaws of which have been brought into Europe, and being examined by Mr. Juſſieu, were found beſet in a remarkable manner with teeth, which perfectly reſembled the buſonitæ called crapandines, and by ſome, ſerpents eyes; and which, in their foſſile ſtate, had been for many ages accounted gems. The arrangement of theſe teeth is ſuch, that the whole flat ſurfaces of the upper and lower jaw are in a manner paved with them. They are of different ſhape and ſize in the different parts; thoſe placed toward the edges were of the ſmall and flat kind, commonly found in Malta, and called ſerpent's eyes; and the larger toad-ſtones, as they are called, were placed more toward the middle; the largeſt of all being placed in two ſtrait rows, or lines, along the center of each jaw.

Each of theſe teeth is articulated by gomphoſis in the jaw, and when taken out, they all have that natural cavity which is found in the hinder part of the foſſile ones. The ſockets of theſe teeth have much the appearance of thoſe from whence teeth have been frequently changed, and probably the fiſh ſheds them often in the courſe of its life. Mem. Acad. Par. 1723.

GRONNA, in our old writers, a deep pit, or bituminous place, where turfs are dug for burning. Hoved. 438. Mon. Angl. Tom. 1. p. 243. *Blount.*

GROOVE, in mining, is the ſhaft, or paſſage into the lead mines, by which they draw up their ore. They are ſometimes ſunk in the vein, and ſometimes out. *Houghton*'s compl. Miner, in the Explan. of the Terms.

GROOZDISHYS, in botany, a name given by the Ruſſians to a ſpecies of muſhroom reſembling our pepper, or milky muſhroom, deſcribed by Liſter, Ray, &c. but larger. The *groozdiſhys* is very broad and thick, and abounding with an acrid juice. The Ruſſians preſerve them in pickle, and eat them

them with their meats. When eaten freſh they inflame the mouth and throat, and endanger ſuffocation. Phil. Tranſ. N° 89.

GROSSBEAK, in zoology, a name by which we commonly call the coccothrauſtes, called alſo at other times the hawfinch. See COCCOTHRAUSTES.

GROSSULARIA, the *gooſeberry* and *currant buſhes*. Theſe in botany make together but one genus of trees, under the common name *groſſularia*; the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals placed in a circular order, between the ſegments of a one leaved cup, which is hollowed into the form of a baſon; the hinder part of which finally becomes a globoſe or oval ſoft fruit, containing ſmall ſeeds.

The ſpecies of *groſſularia*, enumerated by Mr. Tournefort, are theſe. 1. The common wild prickly *gooſeberry*. 2. The cultivated prickly *gooſeberry*. 3. The broad leaved prickly *gooſeberry* with duſky purple fruit. 4. The ſmooth *gooſeberry* with blueiſh fruit. 5. The common great white *gooſeberry*. 6. The great oblong fruited yellowiſh white *gooſeberry*, commonly called the *amber gooſeberry*. 7. The double fruited *gooſeberry* without ſeeds. 8. The common *red currant*. 9. The great fruited *red currant*. 10. The great white garden *currant*. 11. The ſingle fruited *currant*. 12. The ſower *white currant*. 13. The ſweet Alpine *currant*. 14. The *black currant*. 15. The ſmooth *groſſularia* with ſmall black fruit. 16. The American *groſſularia* with large plantain-like leaves. 17. The broad plantain-leaved American *groſſularia* with ſmall blue fruit. 18. The American *groſſularia* with narrow hairy plantain-like leaves. 19. The ſmooth plaintain-leaved American *groſſularia* with roſe coloured flowers. See the article GOOSEBERRY.

GROTTO *(Cycl.)*—The famous *grotto* of our own country, known by the name of Ookey Hole, lies on the ſouth ſide of Mendip Hills, within a mile of Wells. The entrance of it is in the fall of thoſe hills, which is beſet all about with rocks, and has near it a precipitate deſcent of near twelve fathom deep, at the bottom of which there continually iſſues from the rocks a conſiderable current of water. The naked rocks above the entrance ſhew themſelves about thirty fathom high, and the whole aſcent of the hill above is about a mile, and is very ſteep. As you paſs into this vault, you go at firſt upon a level, but advancing farther, the way is found to be rocky and uneven, ſometimes aſcending, and ſometimes deſcending. The roof of this cavern, in the higheſt part, is about eight fathom from the ground, but in many particular places it is ſo low, that a man muſt ſtoop to get along. The breadth is not leſs various than the height, for in ſome places it is five or ſix fathoms wide, and in others not more than one or two. It extends itſelf in length about two hundred yards. People talk much of certain ſtones in it, reſembling men and women, and other things, but there is little matter of curioſity in theſe, being only ſhapeleſs lumps of a common ſpar. At the fartheſt part of the cavern there is a good ſtream of water, large enough to drive a mill, which paſſes all along one ſide of the cavern, and at length ſlides down, about ſix or eight fathom, among the rocks, and then preſſing through the cleſts of them, diſcharges itſelf into the valley.

The river within the cavern is well ſtored with eels, and has ſome trouts in it; and theſe cannot have come from without, there being ſo great a fall near the entrance. In dry ſummers, a great number of frogs are ſeen all along this cavern, even to the fartheſt part of it; and on the roof of it, at certain places, hang vaſt numbers of batts, as they do in almoſt all caverns, the entrance of which is either level, or but ſlightly aſcending or deſcending; and even in the more perpendicular ones they are ſometimes found, provided they are not too narrow, and are ſufficiently high. The cattle that feed in the paſtures, through which this river runs, have been known to die ſuddenly ſometimes after a flood; this is probably owing to the waters having been impregnated, either naturally or accidentally, with lead ore. Philoſoph. Obſerv. N° 2. p. 2.

In the Philoſophical Tranſactions [a], we have an account of a ſubterranean *grotto*, or cavern, near Weredale, about twenty miles ſouth weſt of Newcaſtle. The entry into this *grotto* is by a little hole in the ſide of a vaſt mountain, by this you enter a ſpacious cavity, chambered with walls and pillars of deſcending lapideſcent waters. The hollowneſs is pervious farther than any yet has adventured to diſcover, the darkneſs of theſe caverns requiring the help of candles, which are often extinguiſhed by the dropping water. [[a] Numb. 480. p. 223.]

GROUND *(Cycl.)*—GROUND *angling*, the art of catching fiſh under water without a float, only with a plumb of lead, or a bullet. This method is moſt expedient in cold weather, when the fiſh ſwim low. The bullet is to be placed nine inches from the baited hook; the top of the rod is to be very gentle, that the fiſh may more eaſily run away with the bait, and not be ſcared with the ſtiffneſs of it. The angler in this way is not to ſtrike as ſoon as he feels the fiſh bite, but ſlacken his line a little, to give the fiſh an opportunity to ſwallow the hook.

The tackle here is to be fine and ſlender, ſtrong and big lines being apt to fright the fiſh. Morning and Evening are the chief ſeaſons for the *ground* line for trout, but in a cloudy day, or a muddy water, you may fiſh at *ground* from morn to night. Dict. Ruſt. in voc. *Ground*.

GROUND, among bowlers. See BOWLING.

GROUND, in the manege. See TERREIN.

GROUND *ivy*. See the article IVY.

GROUND *pine*, in medicine, &c. See CHAMÆPITYS.

GROUND *plates*, in architecture, are the outermoſt pieces of timber lying on, or near the *ground*, and framed into one another with morteſſes and tennons. In theſe alſo are morteſſes made to receive the tennons of joiſts, the ſummers, and girders; and ſometimes the trimmers for the ſtair caſe and chimney way, and the binding joiſts.

GROUND *timbers*, in a ſhip, are thoſe timbers which lie on her keel, and are faſtened to it with bolts through the keelſon. They are ſo called, becauſe the ſhip lies at reſt upon them when ſhe is aground.

GROUNDAGE, a cuſtom, or tribute, paid for the ſtanding of a ſhip in a port. *Blount*.

GROUNDLING, an Engliſh name for that ſmall ſpecies of the cobitis more commonly called the loach, and by Artedi, the ſmooth ſpotted cobitis with the body cylindric. See the article COBITIS.

GROUNDSEL. See ERIGERUM.

GROUSE, in zoology, the name of the *tetrao*, or *urogallus minor*, called alſo the black game, and the heath hen, and by Turner, the moor hen. It is a large bird of the gallinaceous kind. The male is all over black, but the edges of his feathers, eſpecially on the neck and back, have a blueiſh gloſs mixed among the black, and its thighs are grey. The female is of the colour of the partridge, and is variegated with tranſverſe black lines on the back, and the breaſt and belly are grey. Its beak is black and crooked. It is found in the mountainous and heathy parts of the kingdom, and is a very well taſted bird. The male and female differ ſo much in colour, that ſome very accurate writers on theſe ſubjects have been deceived into an opinion of their being two different ſpecies of bird; and Geſner has diſtinguiſhed them in this manner, calling the female of this the *grygallus minor*, and that of the great *urogallus*, or cock of the mountain, the *grygallus major*. *Aldrovand*, de Avib. Lib. 14. c. 16. *Ray*'s Ornithol. p. 125. See UROGALLUS.

GROWAN, in natural hiſtory, a word uſed by the miners in Cornwall to expreſs a ſort of coarſe and gritty ſtone, which they are uſually obliged to dig through before they come at the veins of ore. This is uſually grey or whitiſh, but ſometimes it is of various colours, often yellowiſh, and ſometimes ſpotted with iron colour, and an inky black; and often its texture is ſo looſe and ſpungy, that there are holes in it of the ſize proper to receive a pea, or a horſe bean; theſe are ſometimes empty, but more uſually they are filled up either with chalk, or with ſpar. Beſide the ſtrata of this ſtone that lie over the ore, there is alſo a large quantity of it often placed by its ſide. They have this, and two other ſorts of ſtone, lying in their way to the tin ore in Cornwall. The firſt of the others they call *moor ſtone*; a very uncertain name, as it is alſo given by ſome to the common white granite of that country; but the miners only mean by it a looſe ſort of freeſtone, ſomewhat ſofter than that uſually employed in building. The other ſtone is called *killos*. This is a grey ſtone of the ſlate kind, eaſily ſplitting into thin plates, and is very full of talcky flakes. This *killos* is, however, a very indeterminate name, as well as the other, for the ſame people ſometimes uſe it alſo to ſignify a white earth, common among them; this laſt, however, they ſometimes diſtinguiſhed by the epithet white. The word *growan* ſeems the only name they have kept to any determinate ſignification, for they never expreſs by this word any other ſubſtance, than the ſtone above deſcribed.

GROWME, in our old writers, an engine to ſtretch woollen cloth after it is woven; it is mentioned in the ſtatute 43 Ed. 3. c. 10. *Cowel*.

GROWTH. The *growth* of animals, nay even of the human ſpecies is ſubject to great variations as to the time and manner of it in particular inſtances. We have lately had in England, an account of a boy at Willingham, who though he lived but a few years, grew ſo faſt as to be accounted a prodigy; but in the Memoirs of the Academy, there is recorded a much more memorable inſtance in France, in the year 1729. The French Academy of Sciences examined a country youth born in Normandy, whoſe name was Noel Fichet, who was not only remarkable for ſtature, but for ſtrength alſo greatly beyond his age. He was then only ſeven years old, and the account his mother gave of him was, that he *grew* in a very uncommon manner in the firſt year, and that afterwards, he encreaſed ſix inches in height every year to the fourth year; that at that time the people of the place meaſured him exactly, and found him three feet ſix inches high; and at the time the Academy meaſured him he was, at ſeven years old, four feet eight inches and four lines high without his ſhoes.

His mother obſerved the ſigns of puberty on him at two years old, which continued to encreaſe very quick, and ſoon arrived at the uſual ſtandard. At four years old, he was able to lift and toſs the common bundles of hay in ſtables into the horſes racks; and at ſix years old, could lift burthens which were as much as a ſturdy fellow of twenty could well manage. The mother had had four children before him, which were no way remarkable, and he was no larger than other children when brought into the world. It was remarkable, that this youth, though a man in ſtature, was but a child in underſtanding; he was no greater a proficient in knowledge than children of his age; and the boys plays, ſuch as other children diverted themſelves with at his age, were alſo his favourite amuſements. This is no way ſurpriſing, ſince knowledge is only acquired by a ſucceſſion of ideas which neceſſarily require time; while on the other hand, the encreaſe of the body and its ſtrength depend only on the continual addition of matter which many accidents might cauſe to be made more readily, and more abundantly than uſual. Memoirs Acad. Scien. Par. 1736.

Nor is it peculiar to boys to *grow* ſometimes in this extraordinary manner; there are not wanting inſtances of a like nature in the other ſex. There is an account in the Paris Memoirs, of a girl who at three months old had the menſes regularly come on, and *growing* very faſt in her younger time, was, at the age of four years, three feet ſix inches high, and had her limbs well proportioned to that height; her breaſts large and plump, and the parts of generation like thoſe of a girl of eighteen; ſo that there is no doubt but ſhe was marriageable at that time, and capable of being a mother of children. Theſe things are more ſingular and marvellous with us, than they would appear in ſome other places, where the females come ſooner to maturity. In the Eaſt Indies, there are ſome places where the girls have children at nine years old.

GROWTH *Half-penny*, a rate ſo called, and paid in ſome places for the tithe of every fat ox, or other unfruitful cattle. *Blount.*

GRUARII, in our old writers, the principal officers of the foreſt in general. The word comes from the old French *gruyer*, which ſignifies the ſame.

GRUB, the Engliſh name of the hexapode worms, or maggots, hatched from the eggs of beetles. See SCARABÆUS. *Grubs* are an excellent bait for many kinds of fiſh. In angling for the grayling, the aſh *grub* is to be preferred to all others. This is plump, milk white, but round from head to tail, and has a red head. There is alſo another *grub*, which is very common, and is longer and ſlenderer than the aſh *grub*. It is yellower and tougher, and is known by having a red head, and two rows of legs all along the belly. The trout and grayling uſually frequent the ſame places, and it is not uncommon to take the trout while fiſhing for the other. Theſe *grubs* are to be kept in bran, in which they will grow tougher than they were at firſt; but the aſh *grub* is always ſo tender, that it is difficult to make a good bait of it. The beſt method is to wrap it in a piece of ſtiff hair with the arming, leaving it ſtanding out about a ſtraw's breadth at the head of the hook, ſo as to keep the *grub* from totally ſlipping off when baited. The horſe hair that the hook is faſtened to ſhould be as white as poſſible, that it may reſemble the colour of the bait, and not be ſuſpected.

GRUB *of the box*, or *box puceron*, in natural hiſtory, a name given to a ſort of inſect approaching to the nature of the *puceron* of the elder and other trees, but differing from that animal in ſome eſſential characters, and being more properly of the ſame genus with the fig-inſect or falſe *puceron*. *Reaumur*'s Hiſt. Inſ. Vol. 6. p. 100. See FIG-*inſect*.

In the months of March and April the leaves of box are often found forming a ſort of ball at the extremities of ſome of the branches. Theſe balls are hollow, and are form'd of the two outer leaves bent each into the half of a ſphere and joined at their edges, and of ſeveral other ſmaller inner ones rounded in the ſame manner. All theſe balls are the places of abode of inſects of the falſe *puceron* kind; they have flat bodies in the manner of the fig inſect; but the caſes of their wings are leſs obſervable. There are different numbers of theſe animals found in different balls of the plant: ſome containing twenty or thirty, others only three or four, and theſe are ſometimes found crawling about looſe in the cavity, ſometimes between the outer and the inner leaves. Among theſe inſects there is always found a great quantity of a yellowiſh white matter of a tolerably firm conſiſtence; but ſuch that it may eaſily be flatted by preſſing it between the fingers. This is ſometimes found in looſe and regular grains, reſembling ſmall ſeeds, and ſometimes in long and flat pieces. This is the dung of the animal, it is often ſeen hanging in part out of the anus, while they are voiding it in the round grains; and often the long pieces hang out to a great length from the anus, making a ſort of tail twice or tree times as long as the body of the animal. This very much reſembles the common vermicelli, and is of a ſweet and very agreeable taſte; for it is the juices of the plant very little altered, retaining yet their ſaccharine nature, and greatly reſembling the common manna. Mr. Reaumur ſuppoſes this might be of great uſe in medicine, and obſerves that it would eaſily be gathered in the neceſſary quantity for experimenting, as the box affords theſe animals in vaſt abundance, and every ball of the leaves would yield the quantity of the bigneſs of a pea of the matter. As the common *puceron* therefore voids by ſtool a ſaccharine water, this creature voids a kind of manna, and this when newly excluded from the body of the animal is not firm and hard, but ſoft and viſcous. It dries as it becomes expoſed to the air, and ſometimes it is a diſeaſe in the animal to have it dry too quickly, or be too hard before it is voided; and it is in this caſe that it forms a long tail to the creature. Theſe animals have the ſame ſort of trunk with the *pucerons*, and ſuck the juices of trees in the ſame manner; and as the wounds given by the true *pucerons* of the poplar occaſion its leaves to fold themſelves together, and make a ſort of caſe; ſo probably it is the biting or wounding of the leaves of the box by theſe animals, that makes its leaves form theſe balls at the end of the branches. It is to be obſerved however, that the balls of the preſent year only are to be ſearched for theſe creatures; thoſe of former years having been long abandoned by them, and being uſually inhabited by ſmall ſpiders, or other minute inſects. *Reaumur*'s Hiſt. Inſ. Vol. 6. p. 107.

Theſe inſects change their ſkin ſeveral times in the manner of the *pucerons*, and they change their colour at the ſame time. They are at firſt reddiſh, but they are then extremely ſmall; after this they throw off a ſkin and become yellowiſh; after this they are of a deeper yellow, ſpotted with black; and finally when at their full growth they are greeniſh, and have black antennæ. The exuviæ which theſe creatures leave behind them, have often a grain of the excrement remaining fixed to them.

Mr. Reaumur, who took great pains to know the hiſtory of theſe minute animals, found that they finally became flies of a peculiar kind, reſembling thoſe of the fig-inſect; they hopped in the manner of graſshoppers, but only a little way at a time, and he was able to diſcover the parts peculiar to the male and female ſex, in the different individuals, but never could find any eggs, or embryo animals in the latter.

Vine GRUBS, in the hiſtory of inſects. See VINE.

GRUBBING, the term uſed by our farmers to expreſs the taking up the roots of trees out of the ground. Several occaſions offer for the doing this; as when trees are old and paſt growing to any uſe, the roots muſt be taken up, that young trees may be planted in their place. This is a chargeable operation in moſt places, but in ſome countries the farmers have deviſed a machine, which does a great part of the work in a much ſhorter time than in any other way can be done. It is a hook of iron, of about two feet and a half long, with a large iron ring faſtened to its ſtrait end or handle. The whole inſtrument may be made for about three or four ſhillings, and is to be uſed in this manner. The ground is firſt to be cleared away about the root, and any ſtraggling ſide roots found running horizontally are to be cut off. They then faſten the point of the hook to ſome part of the ſtump or root, and putting a long and ſtrong lever through the ring, two men at the end of it go round forcing it every way, 'till they tear the root out, twiſting the top roots off at ſome diſtance under ground. The digging down to which in the common way is one great article of the expence. It is very effectual in ſtubbing up the roots of the underwood, but when large tree roots are to be taken up by it, it is beſt to cleave them firſt with wedges into ſeveral pieces, and then pull them out ſeparately. *Mortimer*'s Huſbandry.

GRUINA, the *crane fly*, a name given by ſome authors to the tipula, or father long legs, from its legs being like thoſe of a crane.

GRUMOSE *Roots*, are thoſe which are compoſed of ſeveral ſmall knobs, ſuch are thoſe of the anemones, and of the little celandine.

GRUNDEL, or GRUNDLING, in zoology, a name uſed by ſome for the common loach, or loche, a ſmall freſh water fiſh, known among writers by the names of cobitis and fundulus. *Geſner* de aq. p. 486. See the article COBITIS.

GRUNDLING, in ichthyology, a name given alſo by the Germans to the *gobio fluviatilis*, or common gudgeon. Theſe fiſh, though of different genera, the one being a cyprinus, and the other a cobitis, yet are ſo perplexed by this common name, that the Germans in general do not diſtinguiſh their difference. They have beſide this, however, their peculiar names for each of the two, the loach or cobitis being called the ſmerle and ſmerling, a name never applied to the gudgeon; and that being called a gobe and a greſſling, names never given to the loach. When there are ſo many diſtinct names for each of theſe fiſhes, it is ſtrange to find the authors of that nation, who write in their own language, ſo often uſing, inſtead of either, this name *grundling*, which is common to both.

GRUNDULUS, in ichthyology, a name given by Figulus and others, to the fiſh called by us the loach, or grundling; it is a ſpecies of cobitis, called by authors in general

cobitis barbatula, and *cobitis fluviatilis*. Artedi has diſtinguiſhed it by the name of the ſmooth ſpotted cobitis, with the cylindric body. See the article COBITIS.

GRUMA, a word uſed by ſome chemical writers, as a name for crude tartars.

GRUNNIENS *Piſcis*, *the grunting fiſh*, the name of a fiſh caught in many parts of the Eaſt Indian ſeas, and called by the Dutch there *knorre pot*. It ſeems of the gurnet or gurnard kind, and nearly related to the guabi-coara of the Braſilians. When it is firſt taken out of the water, it makes a remarkable *grunting* noiſe. It has two ſide lines on each ſide, running from the gills to the tail; the one of which is brown, and the other yellow. It is covered with very ſmall ſcales, and is a very fat and fleſhy fiſh. It grows to about ſix or ſeven inches long, and its head is large and ill ſhaped. It is a very well taſted fiſh. *Ray*'s Ichthyolog.

GRUS, *the crane*, the name of a genus of birds very tall and remarkable for the length of their legs and neck, of which there are three known ſpecies. 1. The common *crane*, the body of which is ſo large, as ſometimes to weigh ten or twelve pounds, and when meaſured from the tip of the beak to the toes extended, is five feet long. Its beak is of a greeniſh black and is long and pointed, its wings are large, and its legs and feet black, its toes very long. But what is moſt obſervable in this bird, is the conſtruction of its wind pipe or aſpera arteria, which runs deep into the breaſt, by means of a foramen prepared for it, and there ſuffering ſome windings and turnings, goes out again at the ſame paſſage, and then deſcends into the lungs. It is a very common bird in Italy, and other places, and ſometimes comes over to us in England, large flocks of them being ſometimes ſeen in Lincolnſhire, and Cambridgſhire in ſummer. It has been ſaid that they build here, but this wants confirmation. It is ſuppoſed by many, that this bird eats fiſh, but erroneouſly, the ſtructure of its ſtomach plainly ſhows it a granivorous bird, and its fleſh is very delicate, and much valued in the Italian markets.

2. The *Indian crane*. This is ſmaller than ours, and of the ſame gray colour; its tail is ſo ſhort that the wings hide it, and it is not ſeen. Its beak is longer than that of our *crane*, but its moſt obvious diſtinction is, that it has on the top of its head, from the inſertion of the beak to the crown, a rough red ſkin, beſet with a few looſe hairs.

3. The laſt ſpecies is the *grus Balearica*, the Majorca *crane*; this is of the ſhape of the ſtork, but has not its long beak, but that of the *crane*, and is diſtinguiſhed by a fine thick ſhewy creſt which it carries on its head. This is not made up of feathers, but of hairs like hogs briſtles. It runs very ſwiftly, and feeds on herbs and corn like the hens and turkeys. *Ray*'s Ornithol. p. 200, 201.

The general diſtinctions of the *crane* kind from the herons are theſe. 1. The claw of the middle toe is not ſerrated. 2. They are much larger. 3. Their beak is ſhorter. Beſide theſe, the make of their ſtomach, guts, and above all, of their aſpera arteria, greatly diſtinguiſh them.

GRUS, the *crane*, in the Linnæan ſyſtem of zoology. This is made a diſtinct genus of the order of the macrorynchæ, or long beaked. The characteriſtic of this genus is, that the head is criſtated or creſted, and almoſt bare of feathers. *Linnæi* Syſt. Nat. p. 45.

GRYGALLUS, in zoology, the name of the female of the urogallus. It obtained this name as if another ſpecies of bird, being ſo unlike the male in colour, as not to be ſuppoſed to belong to the ſame ſpecies. See the article GROUSE.

GRYLLOTALPA, the *mole cricket*, a creature approaching to the locuſt kind, and very properly called by this name by Mouffett, as it has much of the form of the *cricket*, and makes a noiſe like it in the evening, and is like the mole, continually employed in digging the ground. It is an inſect of a very unpleaſant form. It is of the length and thickneſs of a man's little finger, and is of a brown colour, which is darker in the male than in the female. There are on each ſide of the anus two hairy proceſſes, reſembling the tails of mice; its belly is compoſed of eight joints, and is covered with as many ſcales which are of a pale fleſh colour, and are covered with ſhort hair. The back is covered by a pair of pointed wings, along each of which there runs a black ſtreak or line. Theſe wings fold any way at the creature's pleaſure, and when fully expanded are very large. Over theſe lye the antennæ; theſe are variegated alſo with black, and reach about half the length of the wings. It has only four legs; the hinder pair are long and fit for hopping; the anterior pair are ſhort, and furniſhed with a ſort of hands for digging in the manner of the mole. The breaſt is covered with a cruſtaceous ſubſtance which is blackiſh, and hairy on the outſide, and ſmooth and pale within. The eyes are very bright and black, and are very hard, and the mouth is wide and has two tonſils, and teeth in both jaws. This creature lives under ground, and is principally found in damp and boggy places. There has for many years been a breed of them in the gardens of lord Burlington at Chiſwick, under the graſs walk toward the lower end of the canal, where they are now very numerous. They come out in the duſk of the evening, and make a very lowd noiſe of the nature of that of the *cricket*.

The *mole cricket* moves very ſlowly, and Goedartius is of opinion, that its wings were given it rather as an ornament, than as a thing of uſe; or if they have any real uſe, that it is the covering and defending the tender body of the creature, which is very ſoft, and eaſily liable to accidents; and Mouffett ſays, that its flights are no more than long leaps. But we have a very different account of the uſe this creature makes of its wings in the German ephemerides. Mentzelius, in a paper there, declares this to be one of the moſt miſchievous inſects of the creation. He ſays it lives equally well under ground, in the air, or under water; that while it is under ground, it does infinite miſchief by burrowing under the beds of a garden, and eating the roots of flowers, and that in the night it comes out, and taking wing ſettles upon the fruit trees, where it does little leſs miſchief; and all this the author affirms from his own experience, in the gardens where he lived. *Mouffett*'s Hiſt. Inſ. *Ray*'s Hiſt. Inſ. p. 64. *Goedartius* de Inſ. Ephemerid. Germ. Anno. 10. Obſ. 48.

This creature is very nice in the conſtruction of its neſt. This is always under ground, and it chooſes a ſolid clay for the purpoſe; in this it makes a large cavity, with a ſmall paſſage to go in and out at, and in this it depoſits a hundred and fifty or more eggs. When the whole number of eggs is laid, the creature ſtops up the hole at which it was uſed to go in and out, with a large piece of firm clay, and then burrows away all round, and all under the neſt. By this means ſhe keeps the ſides of the neſt firm and cloſe, ſo that no inſect can get in to eat the eggs; and the whole neſt being thus rendered looſe and moveable, ſhe is at the pains of raiſing it toward the ſurface in warm weather, that the eggs may have the advantage of the ſun towards their hatching; and in cold weather ſhe ſinks it deeper into the ground to defend it from froſts. This has been obſerved by Goedartius, and is recorded in his hiſtory of the creature. Swammerdam obſerves, that this creature, while young, has four ſmall protuberances on its back, and has no wings over the body, and that theſe are the rudiments of the wings, which by degrees become expanded afterwards. The creature in this ſtate being of the ſame nature with the graſshopper found without wings, and thence called bruchus and attebalus. It is remarkable of this creature, that it can move backward as faſt as forward, and often does ſo when frighted. *Goedart.* de Inſ. *Ray*'s Hiſt. Inſ. p. 66.

GRYLLUS, *the cricket*, in natural hiſtory, the name of a genus of inſects nearly allied to the locuſt claſs. The two principal kinds are the houſe and field *cricket*. The firſt of theſe is ſmaller, and is of a brown colour ſpotted with black. The latter is more than an inch long, and has a great head and very large eyes. The antennæ in this ſpecies have no articulations.

GRYLLUS, in ichthyology, a name given by ſome to the conger, or ſea eel. Ritterſhuſius, who has given commentaries on Oppian's Halieutics, has given this word as the tranſlation of the gongros of that author, which is the name of the ſame fiſh with the congrus of Ariſtotle, and the other antient Greeks. Artedi has avoided the occaſion of any ſuch errors for the future, by not allowing it any generical name at all. He makes it a ſpecies of his genus of muræna, and diſtinguiſhes it from all the others by the name of the muræna with the rim of the back fin black. *Ritterſhuſius* in Oppian. See MURÆNA.

GRYLLUS *vulgaris*, in ichthyology, a name given by Geſner, Bellonius, and others, to the ophidion of the generality of authors; diſtinguiſhed by Artedi by the name of the ophidion with four cirri, or beards, at the lower jaw. Pliny has mentioned this under the name of the *piſciculus congro ſimilis*. See OPHIDION.

GRYPHITES, in natural hiſtory, the name of a very common foſſile ſhell, the recent, or living fiſh, to which it belongs, not being known, either on our own or other ſhores.

It is an oblong ſhell, very narrow at the head, or cardo, and gradually becoming wider to the extremity, where it ends in a circular limb. The head or beak is very crooked, or very much bent inward. It has been called by ſome the *conchites anomius rugoſus*, by others they are called *conchæ rugoſæ*, and they are commonly known among us by the name of *crow ſtones*. They are very frequent in many parts of the kingdom in our gravel-pits and clay-pits, and we ſeem to have three or four diſtinct ſpecies of them. Some are extremely rounded and convex on the back, others are leſs ſo, and the plates of which they are compoſed are in ſome ſmaller and thinner, in others much larger and thicker, in ſpecimens of the ſame bigneſs. *Hill*'s Hiſt. of Foſſ. p. 650.

GRYPHIUS *pes*, the *griffons claw*, a name of a chirurgical inſtrument deſcribed by Ambroſe Parêy, and uſed for extracting moles from the uterus.

GRYPHUS, one of the many names uſed by chemiſts for the philoſophers ſtone.

GRYPHUS, in ſurgery, a ſort of crooked pincers uſed by ſurgeons.

GRYPOSIS, in medicine, the name of a diſtemperature of the toe nails, in which they bend inwards, and make their way deep into the fleſh.

GUACAGUACA, in zoology, the Braſilian name of a bird of the larus, or gull kind, the eggs of which are much valued in America, but the fleſh not at all. It is called by the Portugueſe there, the *gaviota*. See GAVIOTA.

GUACARI, in zoology, the name of an American fiſh of a roundiſh, or in ſome ſort a pyramidal figure, and of a foot or more than that in its common length. Its head is flat below, and roundiſh on the upper part. Its mouth is ſmall and round, and is placed in the under part of the head, and is furniſhed with a ſort of beard, of ſlender, but ſtiff bodies, reſembling ſhort ſegments of hogs briſtles. Its back fin is ſomewhat prickly, as in the pearch, and its tail is ſupported by ſtrong nerves, and is very forked. Its head is covered with a hard ſhelly cruſt, which feels rough to the touch; and its body with triangular ſcales, which are larger toward the tail than near the head; and all of them are rough, as if they had been cut and ridged, and have a ſort of tubercle in their middle; ſo that the whole fiſh ſeems covered with a coat of armour, and has a quadruple arrangement of tubercles on each ſide. It is all over of a pale ſaffron colour, but ſomewhat deeper on the belly than on any other part, and is all over variegated with brown ſpots, of the ſize of muſtard ſeeds.

There is alſo another kind of this fiſh which differs in colour, being all over of a duſky brown, ſpotted with ſmall ſpecks of a fine deep black. They are both eaten, but the firſt kind has very little fleſh; the latter has more, and it is alſo better taſted. *Marcgrave*'s Hiſt. Braſil.

GUACUCUA, in zoology, the Braſilian name of a kind of water bat. *Barlæus*, p. 224.

GUACUIA, the name of a very remarkable Braſilian fiſh, called alſo by ſome the *veſpertilio aquaticus*, or water bat, and by others the *monoceros piſcis*. The anterior part of the body of this fiſh is like a plough; the head is eight fingers long, and five wide in the broadeſt part; the hinder part of its body is round, and pointed toward the tail. It is broad and flat, and the head ſcarce appears beyond the rim of the body; and has between the eyes a ſingle horn, which is very hard, of a conic ſhape, and near two fingers long. It has a tolerably wide mouth, but no teeth; and it has on each ſide, in the middle of the body, an arm, and under theſe, on the belly, has two fins, which ſeem to ſerve as feet. It has a tough ſkin, and no ſcales. It is brown on the back, and full of tubercles, and is red on the belly. It, moſt of all fiſh, approaches to the *rana piſcatrix*. *Marcgrave*, Hiſt. Braſ. p. 39.

GUADUM, *woad*, a name given by the people of ſome parts of France in common to the glaſtum, or iſatis, properly called *woad*, and uſed in dying a blue colour; and to the *geniſtella tinctoria*, or dyers weed, uſed in dying yellow.

We alſo have the ſame confuſion of names in the Engliſh language, many of our Herbals calling the geniſtella *wold*, *weld*, or *woad*. The Latins alſo called both this and that by the ſame name, *cymene*, properly the Greek name of the geniſtella. See ISATIS.

GUAIAC (*Cycl.*)—Decoctions of this wood taken internally, as alſo applied in fomentations externally, have been found of ſervice in cancerous diſorders. See Medic. Eſſ. Edinb. Vol. 5. Art. 9.

It is a very remarkable quality in *guaiac*, that the ſalt it yields has very little of the alkaline quality of other ſalts of that kind.

GUAIACANA, in botany, the name of a genus of trees, the characters of which are theſe. The flower conſiſts of one leaf, and is of the bell-faſhioned kind. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the under part of the flower; this finally becomes a roundiſh, ſoft, and multicapſular fruit, containing a number of hard ſeeds.

The ſpecies of *guaiacana* enumerated by Mr. Tournefort are theſe. 1. The *guaiacana*, called by authors the broad leaved African lotus; and 2. the *guaiacana*, called the narrow leaved African lotus. *Tourn.* Inſt. p. 600.

GUAIAVA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular form. The cup is of the ſhape of a funnel, and finally becomes a ſoft coronated fruit of an oval figure, in the pulpy part of which there are encloſed ſeveral ſmall ſeeds. There is only one known ſpecies of this plant, which is the pomiferous *guaiava* of America, deſcribed by Gaſpar Bauhine, and others. *Tourn.* Inſt. p. 660.

GUAIBI *Coara*, in zoology, the name of an American fiſh, called by the Portugueze *burace de velha*. It is flat bodied, with a riſing back, and is uſually caught between five and eight inches long, and of about a third part of its length in breadth. Its noſe is pointed, and its head very large, and in each jaw it has one row of very ſmall teeth: its tongue and palate are red, and its eyes are large, and of a browniſh yellow. Its tail is forked, and it has only one fin on the back; the anterior rays of which are prickly, the others ſoft to the touch. Its ſcales are of the ſize of thoſe of the pearch, they are of a ſilvery white, with duſky edges, and on the back are all over of a blueiſh hue. It is caught among the rocks and about the ſhores, and is eaten in conſiderable plenty in the Braſils, both by the natives and Portugueſe. *Marcgrave*'s Hiſt. Braſil.

GUAIMINIBIQUE, in zoology, a name by which many authors have called the humming bird, or *guainumbi*. *De Laet*'s Hiſt. Ind. Occ. l. 15. c. 7. See the article GUAINUMBI.

GUAINUMBI, in zoology, the name of an American bird, called the *humming bird*, and by ſome authors *tomineus*. It is a large genus of birds, many ſpecies of it having been deſcribed by authors, and many which they have not deſcribed, having been ſent into Europe by the curious. It is the ſmalleſt of all birds, but of the moſt beautiful and lively colours of all others. It flies very ſwiftly, and in flying makes a noiſe exactly like the humming of a bee, and is not much larger than the humble bee. It can ſuſtain itſelf a long time on the wing, and in that poſture thruſts its little beak into flowers, the juices of which it ſucks and feeds on. As it has no other food but this, there is no keeping it alive, but all die that are taken; and they are preſerved and ſent over as curioſities to us. Many have reported ſtrange ſtories of their ſleeping all the winter months, and reviving at the approach of ſpring; but Marcgrave ſaw them in great plenty, in the woods in all ſeaſons. The Indians make pictures with the feathers of theſe birds, which are ſo brightly coloured, as to vie with the fineſt paint, and ſo thin as to be as cloſe as colours on canvas. *Ray*'s Ornithol. p. 165.

The *humming bird* is ſo ſmall, that its leg and foot together meaſure but half an inch, and its whole trunk not an inch. The body weighs only $\frac{1}{10}$ of an ounce, which is about equivalent to a ſilver ſix-pence; whereas a titmouſe, the ſmalleſt bird among us, weighs two ſhillings, or half a crown [a]. Its neſt, which is made of cotton, is much of the ſize and figure of the thumb of a man's glove; its egg about the bigneſs of a pea. Some of the Indians wear them in their ears for pendants [b].[—[a] Phil. Tranſ. N° 200. p. 760. [b] Phil. Tranſ. N° 206. p. 993.—]

GUALACLING, in natural hiſtory, the name given by the people of the Philippine Iſlands, to a ſpecies of bird of the ſtarling kind. It is of the bigneſs of the turtle, it feeds on fruits, and is a very briſk and lively bird. It appears to be of a plain black colour, except when viewed in the ſun, and then is ſeen to be of a vaſt variety of bright colours.

GUAMAJACU *ape*, in zoology, a name by which Marcgrave, and ſome other writers, have called the *piſcis triangularis*. *Willughby*'s Hiſt. Piſc. p. 149. See TRIANGULARIS *piſcis*.

GUAMAJACU *Atinga*, in zoology, the name of a fiſh of the orbis or globe fiſh kind; which is thorny, and has the mouth of the ordinary frog-mouthed ſpecies. It is uſually about ſeven fingers breadth long, and in the place of teeth has a hard bone above and below in its mouth. The holes for its gills are large enough to admit one's finger, and near theſe there are two ſquare, broad, and ſhort fins. Near the tail it has another ſmall oblong fin, and one oppoſite to it on the belly. Its tail is a ſimple fin, of a finger and a half long, and a finger broad. Its head is covered with a hard bony ſhell, and all its body with prickles, except on the belly, where it is ſoft as the belly of a frog; the prickles are ſo many ſmall pointed bones. The head, back, and ſides are of a browniſh grey, the belly is of a yellowiſh white, as are alſo the prickles. It has about its gills, mouth, and back fin ſome ſmall black ſpots. It can, at pleaſure, inflate its whole body into the reſemblance of a bladder. It is not eatable, but eſteemed poiſonous. *Piſo*, Hiſt. Nat. l. 5. c. 16.

GUAMAJACU *Guara*, in zoology, a name by which ſome call that ſpecies of the *hiſtrix*, or ſea porcupine, called by Marcgrave *Diabe*. *Willughby*'s Hiſt. Piſc. p. 147. See the article DIABE.

GUANABANUS, a name by which Plumier, and other authors, have called ſeveral ſpecies of the anona. *Plumier* 10. See the article ANONA,

GUAPERVA, in zoology, the name of an American fiſh, of the toad fiſh or rana piſcatrix kind, but different from that in many things, and remarkably ſmall. It is ſeldom found of more than four finger's breadth long, and its more uſual ſize is but two fingers. It has no gills; its mouth is large, projected like that of a dog, and furniſhed with extremely ſmall teeth. It has a bone, ſupplying the place of a tongue. Its eyes are extremely ſmall, and of a fine pale blue, like that of the turquoiſe. Between its eyes, or in the middle of its upper lip, it has a little horn, ſtanding upright, but bending a little backward, and before that horn is a ſlender filament, half a finger long, turned backward, and with a little button at its end. It has one large fin upon its back, and two ſmaller on his belly or breaſt, and in the middle of its body, but rather neareſt the head. It has on each ſide an arm, which toward the extremity degenerates into a fin, and is prickly at the end. It has no ſcales, but a

tough

tough ſkin, rough on the back, and ſmooth on the belly. It is of a reddiſh brown colour, and ſpotted all over with large black ſpots. *Marcgrave* Hiſt. Braſ. p. 131.

GUARA, in zoology, the name of a Braſilian bird, called by Cluſius, *Numenius Indicus*, or the *Indian Curlew*. It is a large bird, of the ſize of the platea, or ſpoonbill, and lives about waters: its beak is long, and of a whitiſh grey, figured like a Poliſh ſword: the tail is ſhort, and is hid by the wings when they are cloſed. It is all over of a fine gay red, only that the long-wing feathers are tipped with black at their extremities, and there is ſomething very remarkable in its growth, for it is black when firſt hatched from the egg, from this it becomes greyiſh, and from this at length changes to its fine red. *Marcgrave*'s Hiſt. Braſil.

GUARACAPEMA, in zoology, a name uſed by ſome for the fiſh more uſually called the *dorado*, or *auratus piſcis*. *Marcgrave*'s Hiſt. Braſil. See the article DORADO.

GUARA TEREBA, in zoology, the name of an American fiſh of the cuculus kind, approaching to the nature of the trachurus, and which Mr. Ray thinks may properly be called the trachurus Braſilienſis, or the Braſilian ſcad. It is uſually of about four or five inches in length, its head is obtuſe, and its mouth furniſhed with very ſmall teeth. The ſide lines towards the tail are armed with prickly hooks, all pointed backwards. The tail is divided into two horns. Its ſcales are of a triangular figure, and are ſo ſmall, that it is very ſmooth to the touch. It is of a greeniſh gloſſy hue, very bright and glittering; the lower parts of its ſides and its belly are yellow, but with a white gloſs among it. The belly fins are white, the tail and the reſt of the fins are yellow. It is eaten in Braſil and other American countries. *Ray*'s Ichthyog. p. 291.

GUARAUNA, in zoology, the name of a ſmall Braſilian bird common in watery places, and of the ſize of our ſnipe. Its bill is ſtrait, but a little hooked at the end, and is between four and five fingers breadth long. Its body is about the ſame length, and its legs ſix fingers long. It is all over of a duſky brown, with an admixture of a caſt of greeniſh. It is a well taſted bird. *Marcgrave*'s Hiſt. Braſil.

GUARIBA, in natural hiſtory, the name of a ſpecies of monkey found in the Weſt-Indies. It is of the ſize of a fox; its face is raiſed high, its eyes are black and ſhining, and its ears ſmall and round. Its tail is very long, naked toward the end, and extremely moveable; the creature frequently twiſting it round things to faſten itſelf by it. It is covered all over with fine black ſhining hairs, except on the legs and part of the tail where they are brown. The hairs are ſo nicely diſpoſed all over the body, that the creature appears perfectly ſmooth; and they are much longer under the chin and throat, ſo that they form a ſort of beard there. *Ray*'s Syn. Quad. p. 152.

This ſpecies is found in prodigious numbers together in the woods, and makes a very loud and frightful noiſe; and it is very common for one only to make a noiſe, and all the reſt to form a mute aſſembly round him. Marcgrave relates a very ſingular thing of this creature, in this reſpect, which he ſays he has frequently been an eye-witneſs to. They meet in great numbers before and after mid-day, when they form a large circle, and one placing himſelf above the reſt, begins to make a loud noiſe; when he has ſung thus by himſelf for ſome time, the reſt all remaining in perfect ſilence, he lifts up his hand, and they inſtantly all join in a ſort of chorus; this intolerable yell they keep up inceſſantly, till the ſame monkey, who gave the ſignal for their beginning, lifts up his hand a ſecond time, on which they all ceaſe and become ſilent again in a moment. He then exalts his pipe alone again, and ſo finiſhes the buſineſs of the aſſembly.

Theſe creatures carry their young upon their backs, and ſkip very nimbly with them from tree to tree, the young ones claſping faſt round their body with their arms. They are a very fierce animal, and can never be tamed. There is a ſpecies of this kind alſo much larger than theſe, which have a very long black hairy beard. Theſe, as Marcgrave aſſures us, on his poſitive knowledge, will often attack the negro women as they go through the woods, and lie with them by force.

GUARUGUARU, in zoology, the name of a ſmall American freſh water fiſh, ſeldom exceeding an inch and half in length, and of a very ſlender body: its head is flatted, its eyes very ſmall, with very black pupils, and yellow iris's. It has only five fins, two at the gills, two under the belly, and one on the hinder part of the back. Its tail is ſmall and rounded. It is covered with extremely minute ſcales, and all its upper part, both back and head, are of a duſky olive colour, till near the tail; where, as alſo on the ſides, it is of a fine yellow, and on the edges of the ſcales of a duſky amber colour. The belly and under part of the head are of a ſilvery white; near the tail it has alſo on each ſide a large black ſpot. It is eaten, though very ſmall, being very well taſted. It is caught in abundance in lakes and ponds. *Marcgrave*'s Hiſt. Braſil.

GUASSEM, a word uſed by Avicenna, and ſome other authors, to expreſs certain black ſcorbutic ſpots and blotches appearing on the ſkin.

GUATUCUPA, in zoology, the name of a ſea fiſh caught about the Braſilian ſhores. It grows to about two feet long; its back is a little elevated, its mouth ſmall, and beſet with ſharp teeth. It has only one long fin upon the back, the rays of which are rigid and prickly. Its ſcales are of a fine ſilvery white, and its back and ſides are variegated with ſtreaks of a fine browniſh yellow, and others of a gloſſy ſilvery red; theſe are not tranſverſe, but run from the head to the tail; and beſide theſe, there is the common line on each ſide, reaching from the gills to the tail, which is elevated above the ſurface of the body. Its head is of a mixt colour, of white, yellow, and a reddiſh brown. Its fins all white, except the tail, which is of a reddiſh brown. Its belly is white. It is caught among the rocks, and is an extremely well taſted fiſh. *Ray*'s Ichthyog. p. 338. *Marcgrave*, Hiſt. Braſ. *Willughby*, Hiſt. Piſc. p. 338.

GUATUCUSA, in zoology, the name of an American fiſh, approaching to the nature of the *coracinus* of the Mediterranean, and called by ſome *corvina*. It is of an oblong ſhape. Its back is a little prominent, but its belly perfectly flat and even. Its uſual length is from twelve to twenty inches. Its mouth is large; its noſe pointed, and the lower jaw longer than the upper. Its teeth are very ſmall. It has ſeven fins; two behind the gills, two on the belly, one long one behind the anus, and one long, high, and triangular on the back. This is ſupported by very rigid nerves, and behind this there is a long and low one, extended to the tail. Its tail is large and broad, and of a ſomewhat ſquare figure. Its ſcales are very ſmall, and it appears ſoft to the touch. It is all over of a ſilvery whiteneſs, except that on the back there is a ſlight admixture of yellow. Its belly, its tail, and all its fins, are of a pure white; and its ſide lines, which run ſtrait from the gills to the tail, are of a ſilvery whiteneſs. It is caught on the Braſilian ſhores, and is a very delicate fiſh. *Marcgrave*, Hiſt. Braſ.

GUAZAMA, in botany, the name of an American tree, deſcribed by Plumier as of the nature of the cacao. They are both ſpecies of the theobroma of Linnæus, but the *guazama* is peculiar in the ſtructure of its fruit, which is of a ſomewhat globular figure, full of tubercles and perforations on the ſurface, and yet divided into five lodgments for ſeeds within. *Plum.* Nov. Gen. 18.

GUDGEON, in ichthyology, the Engliſh name of the fiſh called by authors the *gobio*, and *gobius fluviatilis*. According to the new Artedian ſyſtem, the word *gobius* is made the name of another genus of fiſhes, and the *gudgeon* is reduced to the genus of the cyprini; of which, according to the diſtinctions and characters of that author, it is a true ſpecies. See GOBIUS and GOBIO.

GUDGEONS, in a ſhip, is uſed for the eyes driven into the ſtern poſt, into which the pintles of the rudder go, to hang it on.

GUEBUCU, in zoology, the name by which ſome have called the fiſh more uſually known by the name of the bicauda, a kind of ſword fiſh. *Marcgrave*'s Hiſt. Braſ. See the article BICAUDA.

GUESDA, in botany, is properly the name of woad, but it is alſo uſed by ſome for the lutum, or *lutea herba* of the Romans, and cymene of the Greeks. This is an error in too many of the old authors, though ſo palpable, that one would have thought no body could have run into it; the lutum, or cymene, having been always uſed to dye yellow, and the glaſtum, or *gueſda*, to dye blue; and the characters of the lutum, or, cymene, plainly ſhewing it to be our *geniſtella tinctoria*, or dyers weed, but not at all agreeing with the glaſtum, or woad.

GUEST-*rope*, on ſhip-board, is that rope by which the boat is kept from *ſteeving*, or going too much in and out, as ſhe lies in the tow of a ſhip.

GUIANA *bark*, in the materia medica, the ſame with what is otherwiſe called *ſima-rouba*. See SIMA-*rouba*.

GUIDA, in the Italian muſic, the guide, or leading voice or inſtrument, in fugues. The parts, that are to imitate and follow, are ſaid to be *in conſequenza*. *Broſs*, Muſ. Dict. in voc. See FUGUE, *Cycl.*

GUIDONIA, in botany, the name given by Plumier to the plant, called afterwards by Linnæus, ſamyda, and ſuppoſed to be allied to the melia. See SAMYDA.

GUILANDINA, in botany, the name of a genus of plants called *bouduc* by Plumier, who firſt gave the deſcription. The characters are theſe. The ſeveral plants are ſome male, others female. The male has a one-leaved perianthium lightly divided into five ſegments, and falling off with the flower. Its lower part is a cylindric tube, marked with ten ſtriæ. The margin is concave, and the ſegments very ſmall. The flower is compoſed of five petals, which are equal in ſize, and are hollow, ſeſſile, and inſerted into the mouth of the calyx, and are a little larger than its ſegments. The ſtamina are ten erect pointed filaments; they are inſerted into the cup, and are ſhorter than it, and are alternately ſmaller one than another. The apices are obtuſe, and incumbent. The fruit, which ſucceeds the female flowers, is a pod of a rhomboidal form, with a convex ſuture on the upper part; it is ſmooth, inflated, but ſomewhat compreſſed, and contains,

tains only one cell, which is divided into ſeveral lodgments by their ſepta. The ſeeds are numerous, of a bony hardneſs, of a globoſe, but ſomewhat compreſſed form, and are placed one in every lodgment. The dry fruit is common in the Muſeums of the curious, who collect fruits and ſeeds. *Plumier*, 39. *Linn.* Gen. Pl. 518.

This plant is eſteemed good in colics, and hernias; and is ſaid to diſcuſs flatulencies, comfort a weak ſtomach, provoke the menſes, and expel the ſtone.

GUILLEM, in zoology, the name given in many parts of England to the bird called by authors *lomwia*, and in ſome places the *kiddaw*. See LOMWIA.

GUINEA *corn*. See the article CORN.

GUINEA *pig*, the name given by our common people to a ſort of animal, diſtinguiſhed by authors by the name of *mus porcelli pilis et voce*, the rat with the hair and voice of a hog.

It is a very ſingular kind of animal, and there are three ſorts of it, all very different from one another. 1. The *porcellus indicus*, or common *Guinea pig*. 2. The *aguti*: and 3. The *paca* of the Americans. This creature ſeems to partake of the nature of ſeveral animals. Its hair and voice are like the hog's; its teeth and head reſemble the rabbit's, as does alſo its general ſize; and its ears are wholly like thoſe of the mouſe and rat kind. See PORCELLUS, AGUTI, and PACA.

GUINIAD, in zoology, a name given by ſome to the fiſh, known among authors by the name of *ferra*, a fiſh of the truttaceous kind, common in the lakes of Wales, and ſome of the northern counties of England; and in the laſt of theſe places called the ſchelley. *Willughby*, Hiſt. Piſc. p. 184. See the article FERRA.

GUIRA ACANGATARA, in zoology, the name of a Braſilian bird of the woodpecker kind, and of the ſize of our larger ſpotted woodpecker. Its tail is remarkably long, and conſiſts of eight feathers. Its head feathers are brown in the middle, and yellowiſh at the ſides, ſo that the bird looks creſted; and on the contrary, the feathers of the wings and neck are yellow in the middle, and brown at the edges; its belly, and great part of its back, are of a pale yellow; its feet and legs are of a blueiſh green. It is common in the woods in ſeveral parts of America, and, like our woodpeckers, makes a very loud yelling. *Marggrave*, Hiſt. Braſil.

GUIRACENOIA, in zoology, the name of a ſmall Braſilian bird of the parus, or titmouſe kind. Its head, throat, breaſt, belly, and the lower half of its back, are all of a fine blue; its neck, and the upper half of its back, black; its wings are black, variegated with blue; its tail is black; and its legs brown. *Marggrave*, Hiſt. Braſ.

GUIRACOEREBA, in zoology, the name of a Braſilian bird of the ſize of a greenfinch. Its head is ornamented with a large ſpot of ſea-green feathers; the reſt of its head, its throat, its breaſt and belly, and the lower half of its back, are of a fine ſhining blue, with white variegations. There runs a fine blue line acroſs the wings. The upper half of the back is of the deepeſt black imaginable, and is very gloſſy and ſhining; the tail is black, and the wings are large, and have a great deal of yellow in them; but that is not ſeen, unleſs when the bird is flying. *Marggrave*, Hiſt. Braſ.

GUIRA GUAINUMBI, in zoology, the name of a bird of the king-fiſher, or merops kind, of the ſize of a pigeon in appearance, being very thick covered with feathers, but its body is really not larger than that of a thruſh; the bill is longiſh and black, a little crooked, and notched at the edges like the teeth of a ſaw; its legs are very ſhort; its tail very long, and very narrow. It is a very beautiful coloured bird; its head is of a very fine blue, and has a large black ſpot in the middle; its breaſt, throat, and belly, are of a duſky yellow, and its back of a fine graſs green; and the neck and wings have a blueiſh caſt with the green, like that on the necks of the drake, the peacock, and ſome other birds. *Marggrave*, Hiſt. Braſ.

GUIRANHEEMGATU, in zoology, the name of a Braſilian ſparrow of the ſize of our common ſparrow. Its head and throat are yellow, and its neck, breaſt, and belly, of a deep ſaffron colour. The wings are variegated with green and yellow. The male of this ſpecies ſings very ſweetly, but the female is much leſs beautifully coloured, and has no other note but *tſchrip*, *tſchrip*. *Marggrave*, Hiſt. Braſ.

GUIRAPANGA, in zoology, the name of a Braſilian bird of the thruſh kind, remarkable for the loudneſs of its voice. It is the largeſt of all the thruſh kind, approaching to the ſize of a ſmall pigeon. Its beak is a finger's breadth long, broad at the baſe, and very ſharp, and a little hooked at the point. Its mouth opens very wide. Its throat is very broad, and it has ſeveral black fleſhy protuberances hanging down from it of a finger long, and the ſhape of a ſpear point. Its head is of a duſky brown; its neck, breaſt, belly, back, and thighs, are of a duſky greyiſh hue, and the back ſpotted with black, and toward the origin of the tail a little alſo with brown. Its tail is ſhort, and is variegated with black, grey, and green; and its wings are black, ſhaded and variegated with green. Its breaſt is, as it were, bifid, and gives place for a very large wind-pipe, by means of which it is able to make a very loud noiſe. Its only ſounds are *cick cock kur kur kur*, which it repeats almoſt inceſſantly during the ſeaſon when it cries, which is only for ſix or ſeven weeks about Midſummer. *Marggrave*, Hiſt. Braſ.

GUIRAPEREA, in zoology, the name of a Braſilian bird. It is of the ſize of a lark, and has a ſhort, thick, black beak. Its head, neck, back, and belly, are of a pale yellow, like that of wax; and the lower part of the head, the throat, and the breaſt are black; the wings and tail are brown and black, with a ſlight variegation of ſea green. *Marggrave*, Hiſt. Braſ.

GUIRAGUACUBERABA, in zoology, the name of a Braſilian bird of the ſize of a goldfinch. Its throat and the extremity of the belly are of a fine pale yellow, as is alſo the back. Its head, the outſide of its neck, and the anterior half of its back are of a pale green, as are alſo its wings and tail; but the wings have ſome brown feathers intermixed. It has a large black ſpot under its throat, reaching almoſt to its eyes. Its beak is ſtrait, ſlender and pointed. Its feet are brown. *Marggrave*'s Hiſt. Braſ.

GUIRAQUEREA, in zoology, the name of a Braſilian bird of the caprimulgus, or goat-ſucker kind, a ſort of ſmall owl, approaching to the figure of the cuckow. It is about the ſize of the lark, but its wings and tail are very long, which make it look much larger than it is. It has a large flat head, a ſhort beak, a very wide mouth, and ſome briſtles about the origin of the bill. It is of a browniſh grey colour, variegated with yellowiſh and whitiſh ſpots; and about its head and neck has a ſort of ring of a deep yellow. Its legs are very ſhort, and its toes are connected by a membrane, but not webbed like the ducks. It is not ſaid whether this be a night bird, or one that flies by day light, but probably it is of the firſt kind, as its whole figure reſembles the caprimulgus. *Ray*'s Ornitholog. p. 71.

GUIRARA NHAENGETA, in zoology, the name of a Braſilian bird of the œnanthe or wheat ear kind. Its beak and legs are black, its head, neck, breaſt, and belly are of a very pale grey, its back of a pale aſh colour; on each ſide of the head, from the angle of the beak, there is a long black ſtreak; the wings are black, and the tail of an extremely deep and gloſſy black, with a fine white tip and ſome white ſpots on ſeveral parts of it. *Marggrave*'s Hiſt. Braſ.

GUIRATANGEIMA, in zoology, the name of a Braſilian bird of the woodpecker kind. It is of the ſize of a lark, its head and neck are black; it has a broad black ſpot on its back, and its wings are alſo black, but have a long white ſpot in the middle. Its general colour, excepting theſe marks, is a deep and ſomewhat reddiſh yellow. Its legs are blue. There is a great deal of beauty in the contrivance of the neſt of this bird; it is of a long cylindric figure, and is very nicely hung down from the firm twigs of trees. *Marggrave*'s Hiſt. Braſ.

GUIRATINGA, in zoology, the name of a Braſilian bird of the heron kind, but ſmaller than the common heron; it walks very erect, its neck is long, and its feet and legs of a greeniſh yellow; it is all over of a pure ſnow white, and its neck feathers are whiter and ſofter than thoſe of the oſtrich. It is always ſeen about waters. *Marggrave*'s Hiſt. Braſ.

GUIRATIRICA, in zoology, the name of a Braſilian bird of the bulfinch kind, called by Mr. Ray *rubicilla Americana*. It is of the ſize of a lark, and has a very ſtrong beak. Its head, throat, and the middle and lower part of its neck are of a fine ſhining blood red. The ſides of its neck, its breaſt, and its belly are white, the upper part of the neck is black with a ſlight variegation of white. Its back is grey ſpotted with black, and its wings and tail black with a little whiteneſs at the edges. *Marggrave*'s Hiſt. Braſ.

GUIRAUPIAGARA, in zoology, the name of a ſpecies of ſerpent found in America, and ſo called from its love of eggs, the word expreſſing a devourer of eggs. It is a long ſlender ſnake, black on the back, and yellow on the belly. It is a great climber of trees, and rolls about among their upper branches, as ſwiftly as if ſwimming in water: it is a great enemy to birds, deſtroying vaſt quantities of their eggs. *Ray*'s Syn. Anim. p. 329.

GUITARRA, in the Italian muſic, the name of a muſical inſtrument of the ſtring kind, with five double rows of ſtrings, of which thoſe that form the baſs are in the middle; unleſs it be one for the burden, an octave lower than the fourth. *Broſs.* Muſ. Dict. in voc.

This inſtrument was firſt uſed in *Spain*, and the Italians give it the particular denomination of *Spagnuola*. It is found in Italy, and other countries, but more frequently in Spain. Id. ibid.

GUITGUIT, in zoology, the name under which Nieremberg has deſcribed a bird, which he ſays is no larger than a wren, and of a beautiful green colour; and much eſteemed for the table. This bird he ſays has great courage though ſo very ſmall, and often attacks whole flights of ravens, which it perſecutes till they ſeek ſhelter among reeds and in thickets, to hide themſelves from it. *Ray*'s Ornitholog. p. 297.

Mr. Ray eſteems the whole to be an entirely fabulous and

alſe account, contrived as an imitation of the antient tradition of the wren's fighting the eagle.

GULASISI, in natural hiſtory, a name given by the people of the Philippine iſlands, to a very ſmall and very beautiful ſpecies of parrot.

GULBE in architecture, the ſame as *gorge*. See the article GORGE, *Cycl.*

GULE *of Auguſt*, the day of St. Peter ad vincula, which is celebrated on the firſt of Auguſt.

It is called the *gule of Auguſt*, from the Latin *gula*, a throat, for this reaſon, that one Quirinus a tribune, having a daughter that had a diſeaſe in her throat, went to pope Alexander, the ſixth from St. Peter, and deſired of him to ſee the chains that St. Peter was chained with under Nero, which requeſt being granted, and ſhe, kiſſing the chains, was cured of her diſeaſe: whereupon the pope inſtituted this feaſt in honour of St. Peter; and, as before, this day was termed only the calends of Auguſt, it was on this occaſion called indifferently either the day of St. Peter ad vincula, from what wrought the miracle, or the *gule of Auguſt*, from that part of the virgin whereon it was wrought. *Durand.* Rationale Divinorum. lib. 7. c. 19. Terms of law.

GULL, in zoology, properly the common name of all the larus kind, but generally underſtood only as the name of the common black and white kind. This is the largeſt of all the *gull* kind; it uſually weighs between four and five pounds. Its beak is yellow, flatted ſideways, and three fingers breadth long, and a little hooked at the end. Its head is large and flatted at the top, and its back, breaſt, belly, and tail white, but with a little blackneſs juſt in the middle of the back, and in the long feathers of the wings. Its legs and feet are white, and its hinder toe very ſhort. Its mouth opens to a great width; it feeds on fiſh, and is common on ſome of our coaſts. *Ray*'s Ornitholog. p. 261.

GULYAVAN, in natural hiſtory, a name given by the people of the Philippine iſlands, to a very beautiful bird, common in that part of the world; it is of the ſize of a turtle dove, and is very beautifully variegated with black and gold coloured feathers. It feeds on fruits.

GUM-*Apples*, in Languedoc, and ſome other parts of France. The juice of apples will ſometimes exſudate thro' their rind, and congeal all about them in form of a clear white *gum*, hard like ice, by reaſon of its being ſoon dried in the ſun into a thin cake. The people call ſuch an apple, *pomme gelée*, or a frozen apple. It is very common to ſee apples covered in part with this *gum* in ſeveral ſpecks; but it is more rare to meet with them wholly ſo. The *gum* is inſipid to the taſte.

We have one plant cultivated in ſome gardens, which yields in the heat of ſummer ſuch another white icy and taſteleſs *gum*. This is the common rhubarb, of the ſtalks of the leaves of which tarts are made. The ribs of the larger leaves of this plant, in June and July, are covered with large tranſparent drops of this *gum*, and an ounce of it may be ſometimes collected from a ſingle plant. Philoſ. Tranſ. N°. 224.

The common plums and ſloes in our hedges alſo afford the ſame clear and taſteleſs white *gum*. If they are wounded on purpoſe for it, they uſually throw more or leſs of it out at the wound; but this is after ſome time, and is not in ſo large quantity as what they naturally throw out. The common laurel alſo affords a little tranſparent white and taſteleſs *gum* of no ill effect, though its leaves are poiſonous. And it ſeems upon the whole, that this clear juice is not peculiar to apples or to two or three plants only; but that a great number, even moſt of them, do contain it, if we knew by what means to get it of them.

GUM-*Boils*, a morbid affection of the *gums*, called by the writers of ſurgery *parulides*. Theſe are of different degrees, and uſually ariſe from pains in the teeth. They are to be treated by diſcutients or other inflammatory tumors, but if theſe fail, or the diſorder is neglected, it uſually terminates in an abſceſs or fiſtula. Sage, camomile and elder flowers, boiled in milk and water, make a good gargariſm to be held in the mouth, and the remaining herbs may be ſowed up in a bag to be kept hot to the cheek. A half roaſted fig is a very good internal application, and when the ſoftneſs of the tumor ſhews that the matter is ſuppurated, it ought immediately to be opened by the lancet, to prevent the matters lodging there, and eroding the bone, and producing a fiſtula or caries. After it is opened, the matter ſhould be gently preſſed out with the fingers, and the mouth frequently waſhed with red wine mixed with a decoction of vulnerary herbs till it is well. When the ulcer has penetrated deep, it will be neceſſary to inject the ſame liquors with a ſyringe, and compreſs the part by a proper external bandage, to make the bottom part heal firſt; and when it is already become fiſtulous, and has callous edges, it may then often be cured by injecting tincture of myrrh, and elixir proprietatis, continuing this for ſome time. If all theſe prove ineffectual, the fiſtula muſt be laid open by inciſion, and the caries removed by medicines, cauſtics, or the actual cautery. If this proceeds, as ſometimes it does, from a carious tooth, this is firſt to be drawn before any thing elſe can be done; and it is a good rule in theſe caſes always to be rather too ſoon than too late in laying them open. *Heiſter*'s Surg. p. 463. See alſo *Schelhammer* de Epulide.

GUM *Lacc.* See the article LACCA, *Cycl.* and *Supplem.*

GUMMA, a ſort of venereal excreſcence on the perioſteum of the bones.

GUMMI *Olivæ*, *olive gum*, in the materia medica of the antients. We meet with this name given to a drug they ſometimes uſed in coughs, and diſeaſes of the lungs. Many have been of opinion, that the antients expreſſed no other than the common oil of olives by this name, and ſome things which they have ſaid about it, ſeem to give countenance to this opinion, though a very ſtrange name be warranted by it for a very common thing. But there are many paſſages in other of the antient writers, which are wholly incompatible with this opinion, and ſhew that ſomething elſe, not oil, was meant by it. Aviſenna deſcribing the common ſtorax tells us, that ſome called the *gummi olivæ* by its name. It could not be that any could call oil and ſtorax by the ſame name.

There is no ſort of reſemblance or affinity between the two things; but the Greek authors ſeem to ſet us right in this matter: they all deſcribe a ſubſtance under the name of δάκρυα Ελαίας, the tears of the olive tree, which ſeems to have been a thing wholly different from oil, and rather a concreted gum thus called; as the galbanum, ammoniacum, and other gums in common uſe with us, are called the ammoniacum in tears, &c.

The Greek authors meant the ſame ſubſtance by this name, that the Latins, or at leaſt the generality of them did by *gummi olivæ*; and they expreſsly deſcribe this as a gum, and diſtinguiſh it from the oil by ſaying, that it is not the expreſſed juice of the fruit of the *elaia*, or olive, but the ſpontaneous exſudation of the tree.

This *gummi oleæ*, or *olivæ*, might very well be compared to the *ſtorax ſtegonius*, or ſtorax in tears, or drops; and the inaccuracy of the early writers among the Arabians might authorize its being called by the ſame name; that it is not likely that any ſhould call a gum and an oil by the ſame name.

GUN *(Cycl.)*—The advantage of large *guns*, or cannon, over thoſe of a ſmaller bore, is generally acknowledged. This advantage ariſes from ſeveral circumſtances, particularly in diſtant cannonading. The diſtance to which larger bullets fly with the ſame proportion of powder, exceeds the flight of the ſmaller ones, almoſt in proportion to their diameters; ſo that a thirty two pound ſhot for inſtance, being ſomewhat more than ſix inches in diameter, and a nine pound ſhot but four inches, the thirty two pound ſhot will fly near half as far again as that of nine pound, if both pieces are ſo elevated as to range to the fartheſt diſtance poſſible. The reaſon of this is, the extreme great reſiſtance of the air, which is ſuch, that the diſtances to which bullets fly, is more regulated by this reſiſtance, than by the velocity they receive from the powder: and the larger bullets are leſs reſiſted in proportion to their weight, than the ſmaller; ſo that their reſpective ranges are found to be nearly in the proportion of their diameters, as before mentioned [a]. [[a] *Robins*, propoſ. for increaſ. the ſtrength of the navy. p. 2, 3.]

This advantage in the range of the heavier bullet, will not eaſily be counterballanced by increaſing the charge of powder allotted for the ſmaller bullet. For though the ſwiftneſs of this laſt, at it's iſſuing from the piece, may be thereby greatly increaſed, yet the diſtance to which the bullet will fly is thereby but little influenced: as all this increaſe of velocity is ſoon taken away by the reſiſtance of the air, which increaſes much faſter [b]. This aſſertion might ſeem a paradox, but it is irrefragably eſtabliſhed by ſome experiments made by the French [c]. [[b] Ibid. p. 4. [c] Ibid. p. 4. not.]

Another and more important advantage of heavy bullets is, that with the ſame velocity they break holes in all ſolid bodies, in a greater proportion than their weight. Thus a twenty four pound ſhot will, with the ſame velocity, break out a hole in any wall, rampart or ſolid beam, in which it lodges above eight times larger than will be made by a three pound ſhot. For the great ſhot will penetrate to above twice the depth that the ſmall one will, and leſs of the cavity it makes will be filled up again by the ſpring of the body pierced [d]. [[d] Ibid. p. 6.]

Large cannon alſo by carrying the weight of their bullet, in grape or lead ſhot, may annoy the enemy more effectually than could be done by ten times the number of ſmall pieces [e]. [[e] Ibid. p. 7.]

The author here quoted, has propoſed to change the fabric of all the pieces employed in the Britiſh navy, from the twenty four pounders downwards; ſo that they may have the ſame or leſs weight, but a larger bore. He thinks the thirty two pounders in preſent uſe, would be a proper model for this purpoſe. Theſe being of fifty two or fifty three hundred weight, have ſomewhat leſs than an hundred and two thirds for each pound of bullet. And that this proportion would anſwer in ſmaller pieces in point of ſtrength, ſeems clear from theſe conſiderations. 1. That the ſtrength of

iron or any other metal is in proportion to its ſubſtance. 2. That the leſſer quantity of powder fired in a ſpace it fills, has proportionably leſs force than a larger quantity. So that if two pieces a large, and a ſmall one, be made in the ſame proportions to their reſpective bullets, and fired with a proportionable quantity of powder, the larger piece will be more ſtrained, will heat more, and recoil more than the ſmaller [f]. [f Ibid. p. 11, 12.]

On this ſcheme, our preſent twenty four pounders will be eaſed of ſix or eight hundred weight of uſeleſs metal; and ſome pieces of a leſs calibre, as 9 and 6 pounders, would be ſometimes eaſed by 14 hundreds. Hence much larger *guns* of the ſame weight might be borne. Thus inſtead of 6, 9, 12, and 18 pounders, our ſhips might carry 12, 18, and 24 pounders [g]. [g Ibid. p. 14.]

Guns would be kept cooler and quieter, and would be of more ſervice in many reſpects, if their uſual charge of powder were diminiſhed. See CHARGE.

The author here quoted is of opinion, from his own trials, that a much greater reduction of the weight of ſhip-guns might ſafely take place, and that one fourth, and even one fifth of the weight of the bullet in powder, if properly diſpoſed, would be ſufficient for naval purpoſes [h]. [h See the ſaid Treatiſe, p. 22. and the note.]

GUN is alſo a name given by the miners, to an inſtrument uſed in cleaving rocks with gunpowder. It is an iron cylinder of an inch and quarter thick, and about ſix inches long, and having a flat ſide to receive the ſide of a wedge, and a hole drilled through it to communicate with the inſide of the hole in the rock. The hole is made of about eight inches deep, and in the bottom of it is put about two or three ounces of gunpowder; then this *gun* is driven forcibly in, ſo as to fill up the hole, and the wedge is driven in on its flat ſide to ſecure it. The priming at the hole is then fired by a train, and the orifice being ſo well ſtopped by this *gun*, the force of the powder is determined to the circumjacent parts of the rock which it ſplits. See MINING.

GUN-*Room*, in a ſhip, is the apartment under the great cabin, where the maſter gunner and his crew rendezvous, get ready their cartridges, &c. and do all things belonging to their buſineſs.

GUNNELLUS, in zoology, the name of a fiſh caught upon the Corniſh ſhores, and there called the butter-fiſh. It is always very ſmall, and is of the anguilliform, or eel like claſs. It ſeldom arrives at ſix inches in length, or above one finger's breadth, and has a flat and thin body; its colour is ſomething various, being either of a reddiſh brown and white, or elſe of an olive colour and white, and is variegated all over with lines of theſe colours. At the root of the back fin it has very beautiful round black ſpots, ſurrounded with a circle of white on each ſide; theſe are ten or twelve in number, and run at equal diſtances all down the back. Its head is ſmall and flatted, its noſe ſhort, its mouth wide, with only one range of teeth. Its eyes are ſmall, and it is covered with fine ſmall ſcales.

GUNNERS-*Tackle*, in a man of war. See TACKLE.

GUNNERY. See the *Appendix*.

GUNPOWDER *(Cycl.)*—It is generally aſſerted by hiſtorians, that *gunpowder* has no exploſion within the vapour of the Grotto del Cane in Italy, and every traveller who viſits that place, returns with the ſame opinion, which he ſuppoſes he has had ocular demonſtration of, as one of the experiments made there by the people who ſhew the grotto, is always the ſnapping a loaded piſtol within the body of the vapour, and this never gives fire. We owe to Lamberti the clearing up this piece of curioſity, and it is found from his experiments, that the vulgar opinion is erroneous. This gentleman on making the experiment ſeveral times himſelf, and that with great care, always found that the piſtol indeed miſſed fire, but that this did not appear a defect in the nature of the *gunpowder*, but in the fire; for he took notice, that all the ſparks ſtruck off by the flint and ſteel, became extinguiſhed by the vapour the inſtant of their appearance, and not one of them ever reached the *powder* in the pan, in its fiery ſtate. It appeared now no wonder that *gunpowder* ſhould not go off in a caſe in which fire never touched it; and to try whether the vapour here would prevent its exploſion when really kindled, he cauſed ſome *gunpowder* to be wetted, and made into a ſort of paſte, in which caſe it does not explode all at once, but burns away gradually. On lighting a parcel of this in the open air, and throwing it while on fire into the body of the vapour, he found it continued to burn under, or within it, as well as elſewhere. After this he carried the experiment yet further, by placing ſeveral heaps of dry *gunpowder* within the vapour on the ground; from one to the other of theſe a train was laid, and then a parcel of the wetted *gunpowder* being fired and thrown into the vapour, near the train of the dry powder, the firſt ſpark from it that touched the train while on fire, ſet fire to the train, and all the heaps exploded at the ſame inſtant. Act. Erudit. Anno. 1717.

As to the theory of *gunpowder*. See the *Appendix*.

GUNSHOT-*Wounds* are attended with much worſe conſequences than wounds made by ſharp inſtruments, for the parts are more ſhattered and torn, eſpecially when the ſhot falls upon the joints, bones, or any conſiderable part. Wounds of this kind have an eſchar formed upon them, and are therefore attended with little or no hæmorrhage at firſt, unleſs ſome conſiderable veſſel is wounded; but as ſoon as this eſchar falls off, the hæmorrhage is ſometimes ſo violent, as to endanger the life of the patient unleſs the ready aſſiſtance of a ſurgeon can be had. For the five or ſix firſt days there is little or no diſcharge of matter from theſe wounds; there is therefore no wonder that *gunſhot-wounds* exceed all others in violence of ſymptoms, ſuch as inflammation, pain, gangrene, &c.

The eſchar which is formed upon theſe wounds, is not occaſioned ſo much by the heat of the bullets, as by the rapidity with which they deſtroy the parts, and the violence of the ſymptoms is owing chiefly to this manner of wounding. Neither is there any thing poiſonous in theſe wounds, as has been by ſome imagined, for nothing poiſonous enters the compoſition, either of powder or ball.

Gunſhot-wounds are ſome deeper than others, and in ſome the muſcular parts alone are hurt; in others the veſſels, bones, or viſcera, are wounded. Sometimes the ball paſſes clear through, and ſometimes it remains fixed in the wound, and frequently carries part of the cloths, or wadding with it. From the difference of theſe circumſtances very different ſymptoms ariſe.

Gunſhot-wounds in the cranium, even the ſlighteſt of them, are attended with very great danger, and frequently bring on terrible ſymptoms, by the concuſſion of the internal parts, which they occaſion; inſomuch, that it is ſurpriſing to ſee how ſmall an external wound upon this part will bring on death, if not prevented by the trepan. Internal wounds of this ſort are alſo extremely dangerous, but if no large veſſel is wounded, they are frequently cured.

When they are inflicted on the bones or joints, they are attended with very bad ſymptoms; for in this caſe it is next to impoſſible to eſcape inflammation, gangrene, caries, and dangerous fiſtulæ, which either require amputation of the limb, or leave it without ſenſe or motion.

If any part of the cloths, wadding, or any other extraneous body, be forced into the wound, it muſt be removed before you can attempt to heal the wound; and the ſame caution is to be obſerved in regard to any ſplinters of bone: When theſe are removed, the hæmorrhage is to be ſtopped, then ſuppuration is to be promoted, and new fleſh encouraged, and care taken to procure an even cicatrix.

Extraneous bodies are much eaſieſt to be removed from theſe wounds at firſt; for after ſome delay, the tumor, and inflammation of the part, renders it difficult and painful: beſide, the bullets will by degrees work themſelves deeper, and be buried under the muſcles, which will occaſion fiſtulæ, rigidity of the limb, and other inconveniences. In extracting balls that lie deep, you muſt take great care not to lay hold of blood veſſels or nerves; which accident will be beſt avoided, by introducing the forceps ſhut, and not opening them till you feel the ball.

Sometimes the orifice of theſe wounds is ſo narrow, that it is impoſſible to come at the body you are to extract, without making a larger opening; this then muſt be done on the moſt convenient ſide, always obſerving that no nerve, blood veſſel, tendon, or ligament, lies in the way. When the parts are very much inflamed, and ſwelled, an opening of this kind is frequently of ſervice; for by this means the obſtructed blood is diſcharged, and the bad conſequences of the inflammation are prevented. When the extraction of the ball is attempted, the patient muſt be put into the ſame poſture and ſituation that he was in when he received the wound. When the ball has penetrated ſo deep, that it may be eaſily felt with the finger on the oppoſite ſide, it is ſometimes better to make an inciſion there, and take it out in that place, than to attempt the getting it back the other way. If the wound cannot ſafely be enlarged, nor the ball extracted at firſt, without great pain and danger, it muſt be left in the wound, either till the pain is abated, or the wound is ſo enlarged by ſuppuration, that it either can work itſelf out, or be extracted with leſs danger. On the other hand, all other extraneous bodies are inſtantly to be removed, where there is danger of their bringing on pain, inflammation, and convulſions, by being left behind. If a ball has paſſed into the cavities of the body, it is beſt not to attempt to extract it, but to heal the wound, leaving it there. Perſons have carried a ball thus in them for many years without inconvenience, and, at one time or other, it frequently happens that it will work itſelf into ſome part of the body, out of which it may be extracted with ſafety.

Balls lodged in the bones, are either to be extracted immediately, or, if fixed firmly in the bone, to be left to be ſet at liberty by the ſuppuration of the parts; but balls that are thrown into the joints, are always to be extracted with all poſſible expedition, for delays are very dangerous; and indeed, in moſt caſes of this kind, the amputation of the limb is found abſolutely neceſſary. In wounds from large guns, the joint or bone are frequently grievouſly ſhattered; and in this caſe, the moſt prudent method is always to take off

the

the limb at once, not to ſpend time in fruitleſs attempts to make a cure.

If a large artery is wounded by the ball, either in the arms or legs, which will be known by the loſs of blood, the tourniquet muſt be applied, and the blood being ſtopt, the veſſel muſt be taken up by a crooked needle; but if this cannot be done, or little hopes of a cure appear from future dreſſings, it will be prudent to take off the limb juſt above the wound. When wounds of this kind have been well cleaned, and the blood ſtopped, the firſt intention is to uſe the utmoſt endeavours to prevent, or aſſwage the tumor and inflammation. The wound ſhould be dreſſed with lint dipped in warm ſpirit of wine, and covered with a compreſs wetted with the ſame liquor, or with camphorated ſpirit of wine, either alone, or diluted with lime water. Having done this, the next intention is to forward the ſuppuration of the bruiſed and torn parts; to which end, it is common to uſe the common digeſtive made of turpentine diſſolved in the yolk of an egg, or a mixture of baſilicon and Arcæus's liniment, ſoftened with ſpirit of wine and oil; and where there is a very great corruption of the parts, a little myrrh and aloes are to be added, as alſo Venice treacle, the brown ointment; and, where the occaſion requires it, and the nerves do not lie bare, a little of the red precipitate.

In deep wounds, where the ball has gone quite through, a ſkein of thread being drawn through the eye of a blunt needle, and well ſaturated with the digeſtive ointment, is to be paſſed through the wound in manner of a ſeton, and kept there till the wound is found in a condition to heal, and then the common methods purſued to heal and cicatrize. *Heiſter*'s Surg. p. 51.

GUNWALE, or GUNNEL *of a ſhip*, is that piece of timber which reaches on either ſide of the ſhip, from the half deck to the fore-caſtle, being the uppermoſt bend, which finiſhes the upper works of the hull in that part, and wherein they put the ſtanchions which ſupport the waſte-trees. This is called the *gunwale*, whether there be guns in the ſhip or not. The lower part of any port, where any ordnance are, is alſo termed the *gunwale*.

GUR, in mineralogy, a word uſed to expreſs a fluid matter looking like milk, but reduced ſometimes, by evaporation, to the conſiſtence of honey, and appearing in form of a white ſediment. It always contains more or leſs ſilver, and is common in the mines of Sweden, and in ſome other places. *Bromell.* de Lapid.

GURGEATIO, a name by which ſome authors have called that peculiar diſeaſe, ſo fatal in England at one time, and commonly called *ſudor Anglicus*, from the violent profuſions of ſweat which appeared immediately on being ſeized with it. See SUDOR, *Cycl.*

GURGULIO, in natural hiſtory, a name given by the antients to a peculiar claſs of *ſcarabæi*, or *beetles*; the characters of which are, that they have not a ſhort head like the other *beetles*, but a long one, forming a trunk in the manner of the common flies: in this the horns, or antennæ of the creature are lodged. Theſe are divided by Liſter into two kinds; the one having only one joint in this promuſcis, or ſnout, and that placed in, or near the middle; the other having ſeveral placed near the end. Of the firſt kind we have only two ſpecies. 1. The great rough grey and black *beetle*. This is a very large ſpecies of *beetle*. Its ſnout, or promuſcis is lodged under the belly, where there is a cavity made to receive it. It is all over covered with a ſort of tubercles. When caught it makes a mournful noiſe; and is a very large creature, never loving to move. It is a very ſcarce animal, but is found in ſome places among willows by river ſides in the beginning of April. 2. The brown hoary *beetle*. This is a middle ſized *beetle*, and is very common in paſtures, in moſt of the ſummer months.

Of the other kind, in which the promuſcis has ſeveral joints at the end, we have five ſpecies; and in all theſe, as well as in the former, the antennæ are inſerted in the promuſcis. 1. The great reddiſh black *beetle*. This is a very large *beetle*; it has long and ſlender antennæ. 2. The ſcarlet *beetle*. This is of about the ſize of a horſe bean, and its colour is all over a bright red. It is a very ſcarce ſpecies. 3. The ſmall blueiſh *beetle*, called the *weevil*. This is too well known, and is much too frequent among corn in granaries. 4. The greeniſh gold *beetle*. This is a middle ſized *beetle*; its promuſcis is ſhort, and its antennæ very long. This is found frequently among nettles in June. 5. The little grey *beetle* with two large black ſpots on its wings. This is a very ſmall ſpecies. It is of a cheſnut colour, ſprinkled over as it were with a whitiſh powder. It is common in June on the leaves of the *verbaſcum album*, or white mullein. *Ray*'s Hiſt. Inſect. p. 395.

GURNARD, a ſea fiſh, of which there are ſeveral ſpecies. See the article CUCULUS.

The *grey* GURNARD is the moſt common kind; it is frequent in the Britiſh ſeas, and elſewhere, and eſteemed a very well taſted fiſh. This is of a long ſlender ſhape. Its back is of a duſky green, marked with black ſpots, and with yellow and white ones. The ſide lines are dotted, and rough; under theſe the ſides are of a pale colour, and variegated with numerous white ſpots. The belly is white. The head is large, and is covered with a ſort of boney plates; the upper one of which runs out behind into two ſharp prickles. The ſnout has alſo two horns, each having four or five little thorns, or teeth, and there are alſo two others before each eye. The mouth is large, and the teeth very ſmall. Its gill fins are not ſo large, as in many others of this kind; and its back has a cavity between two rows of pointed bones. *Willughby*, Hiſt. Piſc. p. 279.

Red GURNARD, an Engliſh name given to the fiſh called by authors in general the *cuculus*, and by ſome, *coccyx*, *lyra*, and *capo*. It is properly a ſpecies of the trigla, according to the new Artedian ſyſtem, and is diſtinguiſhed from all the other ſpecies, by the name of the wholly red trigla with the ſnout lightly divided into two horns, and the opercula of the gills ſtriated. This is an inſtance of the value of the Artedian names: this conveying ſo good an idea of the fiſh, that it cannot be miſtaken, and the others conveying none at all. See Tab. of Birds, N° 46. and the article CUCULUS. This red ſpecies is what we ſometimes ſimply call the *gurnard*, and ſometimes the *rotchet*.

GUROUNDI, in zoology, the name of a ſmall Braſilian bird, frequently kept in cages for its ſinging, and more commonly called *teitei*. See TEITEI.

GUTS. It is obſerved in the diſſections of many of the beaſts of prey, that the *guts* are very remarkably ſhort in compariſon of thoſe of other animals. The lion and the lynx are of this number; the *guts* being in theſe only of three times the length of the body. This argues ſpeedy digeſtion, and great voracity in the creature. Ouvrages, Adopt. Acad. Par. Vol. 1. See INTESTINES.

GUTTA (*Cycl.*)—GUTTÆ *anglicanæ*. See the article DROPS.

GUTTA *roſacea*. See BUTIGA.

GUTTA *ſerena*. The proximate cauſe of a *gutta ſerena* is, according to Hoffman [a], and other eminent phyſicians, a palſy of the optic nerves.—[a Oper. Tom. 3. p. 228.]

The mediate cauſes of this diſorder may, as in other nervous caſes, be referred to two kinds, repletion, and inanition.

To the firſt belong all ſuch cauſes as encreaſe the blood too much, or force it with too much violence into the head. Thus too great motion; immoderate hot bathing; violent fits of anger; deficiency of the menſes; and ſpaſms in the lower parts forcing the humours upwards, as it ſometimes happens to women in labour; and by vomits. All theſe cauſes, as alſo the repulſion of humours appearing on the ſkin, and drying up of ulcers; the tranſlation of morbid matter in malignant fevers, ſmall-pox, or phrenſy; and the improper uſe of mercurials; have been known to bring on a *gutta ſerena*; ſometimes indeed only tranſitory, and ſometimes curable, by evacuations, as bleeding, &c.

To the ſecond kind, belong all immoderate effuſions of the vital juices. Thus great hæmorrhages; bloody vomits; profuſe bleeding; and, above all, early and immoderate venery; have been obſerved to produce blindneſs, extremely difficult, if not impoſſible, to cure. See *Hoff.* Oper. Tom. 3. p. 228. ſeq. See BLINDNESS, *Cycl.* and *Suppl.*

Mercurials, and antimonials, have been known to cure the *gutta ſerena*. Pitcairn recommends calomel; and Hoffman the ſulphur of antimony.

GUTTUROSUS *piſcis*, a ſmall fiſh common in the Mediterranean, and brought to market at Rome, Venice, and elſewhere; and called, in different parts, *gotoroſala*, *gottorugine*, and *gotto di mare*. *Willughby*, Hiſt. Piſc. p. 132.

GUY, in a ſhip, is any rope uſed to keep off things from bearing, or falling againſt the ſhip's ſide, when they are to be hoiſed in. Thus, if any thing is to be haled in over the gunwale, it is gently eaſed in by a *guy-rope*, faſtened uſually to the ſtanchions of the waſte-trees.

That rope alſo which is made faſt to the fore-maſt at one end, and is reeved through a ſingle block, ſeized to the pendant of the winding tackle, and then again reeved through another, ſeized to the fore-maſt, and whoſe uſe is to hale forward the pendant of the winding tackle, is called a *guy*.

GWABR-MERCHED, in our old writers, a Britiſh word ſignifying a payment, or fine, made to the lords of ſome manors, upon the marriage of their tenants daughters; or otherwiſe, on their committing incontinency. *Blount.* See MARCHET, *Cycl.*

GYLPUT, in our old writers, the name of a court held every three weeks, in the liberty or hundred of Pathbew, in the county of Warwick. *Inquiſit. ad quod damn.* 13 Edw. III. *Blount.*

GYLTWITE, in our old writers, a compenſation or amends for treſpaſſes, &c. *Mulcta pro tranſgreſſione.* LL. Edgar. regis, anno 964. *Terms of Law.*

GYMNASTES, Γυμναστης, among the antients, an officer in the antient *gymnaſium*, next in authority to the *gymnaſiarch* and *Xyſtarch*. *Hoffm.* Lex. in voc.

GYMNASTERIUM, Γυμναστηριον. See CORICEUM.

GYMNOCRITHON, in botany, a name given by ſome authors

authors to the zeopyrum, or hordeum nudum, the naked barley. *Chabræus*, p. 175.

GYMNOPODIA, γυμνοποδια, among the antients, a kind of ſhoes which diſcovered the naked feet. They were worn by the Grecian women, who affected them much. *Hoffm.* Lex. in voc.

GYMNOPYRIS, in natural hiſtory, the name of a genus of foſſils, the characters of which are theſe. They are of the claſs of the pyritæ, and are compound, inflammable metallic bodies, found in detached maſſes, of no determinately angular figure; of a ſimple internal ſtructure, not ſtriated; and are naked, or not covered with any inveſtient coat, or cruſt, in which they differ from the pyriplaces. See Tab. of Foſſils, Claſs 5. *Hill*'s Hiſt. of Foſſ. p. 614.

Of this genus there are only two known ſpecies. 1. The green ſmooth variouſly ſhaped *gymnopyris*; and 2. the *gymnopyris* with a botryoide ſurface. The firſt of theſe is the moſt common of all the pyritæ, and appears to be under a great variety of ſhapes. It is a very hard and firm body, of a compact and cloſe texture, and very conſiderably heavy. It is found in maſſes of various ſizes, from half an inch to ten inches, or more, in diameter, and is uſually of a ſomewhat flatted form, and of an undulated, or rigid ſurface, though not unfrequently it emulates the ſhape of the common pebbles, and often is perfectly ſmooth. Its ſurfaces are never very rugged in their native ſtate, and when broken, it appears of a ſmooth even ſtructure, and is both within and without of a pale ſilvery green. It cracks and burſts in the fire, and yields a deep blue flame, and finally burns to a purple powder.

It is very common in the ſtrata of tile clay in all parts of England, and ſhews itſelf there in a number of various ſhapes and forms, very often having formed itſelf in the cavities of ſea ſhells buried there, and ſince periſhed; but moſt frequently of all in the pores of wood, pieces of branches of trees, and even of old boards, being frequently wholly ſaturated with it. All theſe as well as the ſubſtance in its native ſtate, readily moulder away on being expoſed to a moiſt air, and are then found very pregnant with vitriol. It is from theſe, and particularly from the foſſile wood, impregnated with this pyrites, that the green Engliſh vitriol, or common copperas, is made at Deptford, vaſt quantities of foſſile wood thus impregnated, being lodged in the ſtrata of clay in the cliffs of Sheppey iſland and elſewhere, which the ſea at times waſhes out, and leaves ſcattered about the ſhore, and which are there gathered by people employed for that purpoſe.

The ſecond ſpecies, or botryoide *gymnopyris*, is a very elegant and beautiful foſſil. It is very hard and heavy, and is very irregular in ſhape and ſize; but moſt frequently met with either in oblong, or ſomewhat globular pieces of many pounds weight; though ſmaller, and thoſe very elegant flatted ſpecimens, are not uncommon. It has naturally no coat or cruſt, but when it has been long expoſed to the air, it ſometimes acquires a browniſh ruſt, like that of iron which covers it and looks like one. When broken it appears the moſt uniform and regular in its ſtructure of any of the pyritæ, looking like a maſs of ſome melted metal. It is uſually of a pale ſilvery green, though ſometimes of a deeper browniſh one; but what abundantly diſtinguiſhes it from all the other pyritæ, is, that its ſurface is ever beautifully elevated into a number of tubercles, of various ſizes, but of irregularly roundiſh ſhapes; and ſometimes not only its ſurface but its whole ſubſtance is thrown into theſe forms. Hence it is, that it reſembles cluſters of grapes, hanging very thick upon the branches. It is frequent in Yorkſhire, nor leſs ſo in Devonſhire and Cornwall, and there is a great deal of it in the clifts of Sheppey iſland, but there the ſpecimens are uſually ſmall.

GYMNOSPERMIA, in botany, the name given by Linnæus to a certain ſeries of plants of the didynamia claſs. This claſs, according to that author, comprehends the plants with labiated and perſonated flowers: thoſe with labiated flowers always have four ſeeds ſucceeding each flower, and theſe are placed without any capſule or covering in the baſe of the cup. Theſe are therefore called *gymnoſpermia* or naked ſeeded, whereas the others which have perſonated flowers, have the ſeeds incloſed in capſules, and are therefore called *angioſpermia*. See DIDYNAMIA.

GYMNOTUS, in ichthyology, the name of a genus of fiſhes, the characters of which are theſe. It is of the malacopterygious kind. The branchioſtege membrane contains five bones, and it has no fin upon the back. There is only one known ſpecies of this genus. It is an American fiſh, deſcribed by Marggrave, under the name of *carapo*. *Artedi* Gen. Piſc. 22.

GYNÆCOCOSMI, γυναικοκοσμοι, in antiquity, Athenian magiſtrates, whoſe buſineſs it was to regulate the women's apparel, according to the rules of modeſty and decency. See GYNÆCONOMUS, *Cycl.*

GYNÆCOMASTOS, a term uſed by the antients, to expreſs a man, whoſe breaſts are large and turgid like thoſe of women, and afford milk.

It was an obſervation among the antients that ſuch men were naturally impotent. Paulus Ægineta obſerves, that the breaſts of men as well as women ſwell at the time of puberty, but that thoſe of women continue ſwelled, and thoſe of men ſubſide again, except in the caſe of the *gynæcomaſtoi*, where they remain turgid, and become in time more and more ſo, as the fat increaſes under them.

As this ſwelling of the breaſts gave a ſuſpicion of impotency, thoſe who laboured under that deformity, uſually had recourſe to a very painful operation in ſurgery to get rid of it. An inciſion was made in the form of a creſcent in the lower part of the breaſt, then the ſkin being drawn back the fat was taken out, and the lips of the wound healed by means of a ſuture. When the breaſts were very large, and hung down, they made two inciſions, one within the other, meeting at the extremities, and then ſeparating all the ſkin between them they took out the fat: and finally, if the diſeaſe returned, or they had performed the operation imperfectly, leaving ſome behind, they repeated the whole a ſecond time.

GYNÆSIA, a word uſed by the writers in medicine, ſometimes for the menſtrua and ſometimes for the lochia. See MENSTRUA and LOCHIA.

GYNANDRIA, in botany, a claſs of plants, in which the male and female parts of the flower are joined at their origin, the ſtamina or male parts of which grow to the piſtillum or female part, and not to the receptacle of the ſeed.

The word is formed of the Greek γυνη female, and ανηρ male. Among the plants of this claſs are the paſſion flower, birthwort, &c.

The general character of this claſs of plants is very obvious: they are diſtinguiſhed at firſt ſight from all others, by the ſtamina being placed upon the ſtyle; or, in other words, the receptacle is elongated into the form of a ſtyle, and bears on it both the piſtil and ſtamina.

The order of the *diandria*, the firſt of this claſs, is a very natural diſtinction among plants, and its genera differ from one another in no other grand particular, but the nectaria. Botaniſts, in general, have judged the roots of this order of plants, which are either teſticulated, or palmated, to be a very certain mark of diſtinction: but this obſervation, of the difference of the nectaria, which is owing to Linnæus, is much to be preferred, as being both more certain and more obvious. The ſtructure of the fructification, in this order of plants, is very ſingular. The germen of the piſtil is always contorted, and the petals are five in number: the two external ones often form themſelves into a galea, the lower lip of which forms the nectarium, which ſupplies the place of a ſixth petal and a piſtil. The ſtyle is affixed to the interior margin of the nectarium, ſo that it and its ſtigma are ſcarce to be diſtinguiſhed in the flower. The ſtamina are always two filaments, very ſhort, and ſupporting two antheræ, which are of a narrow ſhape below, and are naked, and divided into ſeveral lobes, in the manner of the pulp of an orange. Theſe are covered each with a ſmall cell, which is open downwards, and growing on the inner margin of the nectarium. The fruit or ſeed veſſel is a capſule, containing only one cell, and formed of three valves. The ſeeds are very numerous, and as ſmall as grains of duſt, and are affixed to a ſlender receptacle, which is placed within each valve. All theſe plants are extolled by authors as provocatives. See Tab. 1. of botany, Claſs. 1.

The flowers of all the plants of this claſs have a ſtrange and, as it may be called, monſtrous appearance, very different from that of all other plants in their flowers; but this is only owing to the ſingular diſpoſition of the parts of fructification in theſe flowers, as deſcribed above. *Linnæi* Gen. Pl. p. 451.

GYPSINE *ſtone*, a name given by ſome writers to the *gypſum*, or foſſile ſubſtance, of which the powder called plaiſter of Paris is made by calcination. There are in many parts of Arabia vaſt rocks of this ſtone; it reſembles alabaſter, but is ſofter, and of a more lax texture. It is found to be a very eaſy ſtone to form by tools, and therefore the Arabs build with it in ſome of the places in the neighbourhood of the quarries, but they are forced to make the walls very thick, as the ſtone is ſo ſoft and crumbly. The building called Arſoffa, or Arſoffa Emir, which ſeems the remains of a monaſtery, is built wholly of this ſtone; and when the ſun ſhines upon it, the walls give ſuch a luſtre, that they dazzle the eyes; but the ſoftneſs of the ſtone, and the redneſs of the mortar, have conſpired to make it a very ruinous pile at preſent, though of no great antiquity; the ſtones having ſplit and mouldered away in the walls, and the foundations failed in many places. Phil. Tranſ. N° 218. p. 150. See GYPSUM.

GYPSINUM *metallum*, in the natural hiſtory of the antients, a name uſed for the common *lapis ſpecularis*, of which they often made windows as we do of glaſs. It was by ſome called *cyprinum metallum*, becauſe frequently found in Cyprus. *Hill*'s Theophraſt. p. 142.

GYPSOCHI, artiſts who work in plaiſter. See the article PARADIGRAMMATICE.

GYPSOPHYTON, in botany, a name given by ſome authors to the *ſaxifraga antiquorum*, or ſaxifrage of the antients. *Chabræus*, p. 210.

GYPSUM (*Cycl.*) in natural hiſtory, the name of a claſs of foſſils; the characters of which are theſe. They are compoſed of ſmall flat particles, irregularly arranged, and giving the whole maſſes ſomething of the appearance of the ſofter marbles; they are bright, gloſſy, and in a ſmall degree tranſparent: not flexile nor elaſtic, not giving fire with ſteel, nor fermenting with or diſſoluble in acid menſtruums, and calcine very eaſily in the fire. *Hill*'s Hiſt. of Foſſils, p. 111.

Of this claſs of bodies there are two orders, and under thoſe four genera. The firſt order is of the *gypſums*, which are of a firm compact texture, and conſiderably hard. The ſecond of thoſe which are of a lax or looſe texture, and are accordingly ſoft and crumbly.

The genera of the firſt order of the *gypſums* are theſe. 1. Thoſe which are hard, compoſed of ſomewhat broad particles, and of a bright cryſtaline luſtre; the *pholides*. 2. Thoſe of a ſofter texture, compoſed of very ſmall particles, and of a leſs glittering hue; the *lepra*. Id. Ibid.

The genera of the ſecond order are, 1. Thoſe of a ſofter texture, which are very bright and glittering; the *timachides*. 2. Thoſe of a ſofter texture, which are dull and opake; the *claſmia*. All the ſpecies of this whole claſs burn with a very ſlight degree of fire, to what is commonly called plaiſter of Paris: but the ſofter require the ſmaller degrees of fire; and, in general, the harder and more marbly make the better plaiſter.

The common way of burning this ſtone into plaiſter, is too ſlight to give it all the hardneſs it is capable of. It is reported by many, that a greater degree of heat renders it greatly ſuperior in hardneſs; and, it is ſaid, that the artificial marble, with which the whole palace of Munich is adorned, and which the elector of Bavaria eſteems more than marble, for which it is miſtaken by all that ſee it, is made of the common *gypſum*, firſt burnt in the ordinary way, and afterwards put over the fire again in a copper veſſel, and ſuffered to boil, as it will like water for a long time. When this boiling ceaſes of itſelf, the matter is taken out, and common colours, ſuch as are uſed in painting, are mixed with it in various proportions; which on the wetting it with water, and working it in the common manner of plaiſter of Paris, diffuſe themſelves, and imitate the veins of natural marble. Phil. Tranſ. N° 93.

Gypſum is uſed in the Canaries by way of remedy for their wine, and about Malaga a large quantity is tunned up with the juice of their grapes. *Boyle*'s Works abr. Vol. 1. p. 146.

GYPSY, a name given to a ſet of vagrants. See the article BOHEMIANS.

GYRFALCO, in zoology, the name of a large and fierce ſpecies of falcon, called in Engliſh the jerfalcon. See the article FALCON.

Its name is a compound of the German *gyr* which ſignifies a *vulture*, and *falco* the *falcon*. It is the largeſt of all the falcon kind, its head is flatted and of a greyiſh colour, its beak very thick and ſtrong, but ſhort, and of a blueiſh colour. The iris of its eyes is blue, and its back, wings, belly and tail are white, but moſt of the back and wing feathers are variegated with one black ſpot, of a cordated form, and in ſome degree reſembling the eye ſpots in the peacock's tail. The long wing feathers have alſo a large black ſpot near their extremities. The throat, breaſt, and belly are of a pure white. The tail is ſhort, and variegated with tranſverſe black lines. The legs are thick and ſtrong, and both they and the feet are of a pale blue. *Ray*'s Ornithol. p. 44.

It is a very bold and daring bird, attacking all other fowl without reſerve, and particularly the heron and ſtork kind. The other falcons are all afraid of this.

H.

HABENA, in ſurgery, the name of a bandage contrived to keep the lips of a wound together, and ſave the painful operation of a ſuture. See the articles BANDAGE and SUTURE.

HABHAZZIS, in botany, a name given by Leo Africanus, and ſome other of the writers of geography, to a plant growing in many parts of Africa, which they ſay produces its fruit under the earth in form of ſmall round globules, which are much eſteemed as food, and have the taſte of an almond. The fruit as it is called, is no other than the disjunct tubera of the root, which are connected by fibres or ſtrings, and are in the propagation of the plant very uſeful to its ſpreading over a large ſpot of ground in a little time; all the fibres which ſhoot out horizontally from the root being terminated by theſe tubera, and each of theſe ſending out on the oppoſite ſide ſeveral other fibres, which at due diſtances produce other tubera. The Africans dig up the ground at random near to the place where they ſee any of theſe plants, and never fail of picking up a great number of them. The plant which produces them is the traſi, and they are eaten in many other places beſides Africa. The Spaniards are very fond of them, and call them avellanda from their likeneſs to hazel-nuts in ſhape.

HABIT *(Cycl.)*—The different *Habits* and cloaths that the generality of the world wear, are thro' inadvertency and inattention very frequently the cauſe of very unhappy maladies. Mr. Winſlow, in the memoirs of the royal academy of ſciences at Paris, has obſerved that the greateſt attention and care is neceſſary on ſeveral occaſions in regard to this, as it is ſuppoſed, trifling article; and given many inſtances of the ill effects of it.

The antients have obſeved the inconveniencies of many parts of dreſs, and daily obſervation confirms to us the many miſchiefs the ladies ſuffer from the ſtiff whale-bone ſtays they wear, and the diſorders of the viſcera of the lower belly to which thoſe are ſubject who lace themſelves too tightly; and this is not only of dangerous conſequence to themſelves, but frequently is the death of children in breeding women.

The tight binding of the neck by the men's neckcloths, ſtocks, or the too tight collars of their ſhirts, *&c.* has been very frequently the only occaſion of ſeveral very terrible diſorders of the head, the eyes, and the breaſt; deafneſs, vertigoes, faintings, and bleedings at the noſe, are the frequent conſequences of this practice; and the phyſicians conſulted for relief in theſe caſes, have found all means ineffectual, merely from their not attending to the cauſe of the malady; when a cure might have been, and often has been, made without the help of medicines, only by leaving off thoſe unnatural bandages which had been the occaſion of them, from the not ſuffering the free return of the blood by the jugular veins, which had paſſed up into the head without moleſtation by the carotide arteries.

Mr. Cruger added to theſe relations, that a certain officer in the army of the king of Denmark, always ordered his ſoldiers to tye their cravats very tight, and garter their ſtockings below the knee, tying them alſo very hard; by which means they always looked red and florid in the face and thick leged, ſo that his men always appeared ſtout, robuſt, well fed, and in good caſe. But the conſequence of this was, that after ſome time his men were all ſeized in a very particular manner with diſorders, for which the common methods of treatment gave no relief, and great numbers of them died, after all the internal as well as external methods which could be tried were found ineffectual. Their diſeaſe ſeemed a putrid ſcorbutic infection, and this not only appeared externally, but was found to affect even the internal parts of ſuch of them as were opened after their death. It is unqueſtionable, but that this wholly proceeded from the ligatures they continually wore about their necks and legs by order of their officer, and might have been cured merely by leaving them off; and it has even been proved on animals, as calves, ſheep, *&c.* that extremely tight ligatures on their legs, *&c.* will have ſo great an effect, as to alter the whole maſs of blood, render the animal morbid, and even make the fleſh unwholeſome and unfit for food. Memoirs Acad. Scien. Par. 1740.

Mr. Winſlow has obſerved, that the different motions of the bones of the foot which are very free in their natural ſtate, as is very plainly ſeen in young children, are uſually wholly loſt to us as we grow up, by means of the improper preſſure of our ſhoes. The high heeled ſhoes the women wear, entirely change the natural conformation of the bones of the whole foot. They render the foot elevated and arched, and uncapable of being flatted by reaſon of the unnatural union and ancyloſis they bring on between the bones, which is not unlike that which happens to the vertebræ of people who are humpbacked: for theſe high ſhoes make the extremity of the os calcis, to which the tendo achillis is affixed, to be always unnaturally elevated, and the anterior part of the foot on the contrary is much more depreſſed than it naturally would be. The conſequence of this is, that the muſcles which cover the hinder part of the leg, which ſerve by the attachment of the tendon to ſtrech out the foot, are continually in an unnatural ſtate of contraction, while the muſcles of the anterior part of the leg, whoſe office is to bend the foot forward, are on the contrary kept in a like unnatural ſtate of elongation and diſtention. To this cauſe it is owing, that we very frequently ſee women unable to go down a hill or any declivity without great pain, whereas on the contrary, in walking up hill their high heeled ſhoes make them walk as it were on even ground; the end of the foot being only ſo far elevated as to bring it on a level with the unnatural poſition of the heel. The women who wear theſe ſort of ſhoes find it alſo very troubleſome to walk for a long time, tho' it be on the moſt even ground, and eſpecially if they are obliged to walk quick. They can by no means leap ſo freely and eaſily as thoſe who wear lower heeled ſhoes. The reaſon of which is, that in the human ſpecies as well as in birds and beaſts, the action of leaping is executed by a ſudden lifting up the hinder part of the os calcis, by means of the action of thoſe muſcles to which the great tendon is faſtened.

Low heeled ſhoes by no means ſubject the wearer to any of theſe inconveniencies, but on the contrary, they greatly facilitate all the natural motions of the feet, as we have daily and innumerable inſtances in the labourers, chairmen, porters, and others of the lower claſs of mankind; and the wooden ſhoes worn by the lower claſs of people in France, notwithſtanding their weight and inflexibility, do not ſo much prevent the proper motions of the muſcles whoſe office it is to move the feet. For beſide the lowneſs of their heel, they are rounded at the end downwards, which in ſome degree compenſates for their inflexibility, ſerving in the place of the alternate inflection of the foot on its toes on the one part, while the other is lifted up in walking.

But to return to the miſchiefs done by high heeled ſhoes, there is yet a farther inconvenience from them than what has been mentioned, ſince not only the muſcles of the tendo achillis which ſerve to move the foot in the extenſion, but the anterior muſcles alſo, which ſerve to the extenſion of the toes, are by the height of theſe ſhoes always in an unnatural ſtate; and not only the anterior muſcles which ſerve to the bending of the foot, but the poſterior muſcles alſo which ſerve to the bending the toes, are at the ſame time by means of this height, kept forcibly in an elongated and extended ſtate. This continual unnatural ſhortening of ſome of the muſcles, and as unnatural lengthening of others, cannot but cauſe ſooner or later, a greater or leſſer diſtemperature of their veſſels as well the veins and arteries, as the lymphatics and nerves; nor may this be confined merely to the parts affected, but by the communication of theſe veſſels with thoſe of other more diſtant parts, nay even with thoſe of the abdomen and its viſcera, may bring on diſorders which will be attributed to very different cauſes, and therefore will be treated with medicines which will not only prove uſeleſs, but in many caſes hurtful. It is certain that long cuſtom makes theſe unnatural extenſions and contractions of the muſcles as it were natural to women; inſomuch that thoſe who are accuſtomed to theſe ſhoes would find it painful and diſagreeable to walk in others; but this is no proof that the unnatural ſtate in which the muſcles are continually kept, may not often be the occaſion of all the remote diſorders before hinted at, and which, many of them at leaſt, may appear to have no relation to their original cauſe. Memoires de Acad. Scien. Par. 1740.

HACK, a tool uſed by miners, in ſhape like a mattock. *Houghton*'s Compl. Miner, in the Explan. of the Terms.

HADBOTE, in our old writers, a recompence or amends for violence offered to perſons in holy orders. *Blount*. Sax. Dict.

HADDOCK, in ichthyology, a name given by us to a ſpecies of fiſh of the aſellus kind, according to the generality of writers, and of the genus of the gadi according to the new Artedian ſyſtem. It is called by Salvian, the aſellus major or greater aſellus, and by Willughby, the onos and aſinus of the antients. Charleton tells us that it was the callaris, galeris, or galaxis of the old Romans mentioned by Pliny; but Artedi has ſome doubt about that. It is called by Artedi by a name much more expreſſive than any of the old ones: this is the gadus with a bearded mouth, with three fins on the back, with a whitiſh body, with the upper jaw longeſt, and with the tail a little forked. *Artedi*, Gen. Piſc. 38. See ASELLUS.

HADE, in mining, is where any ſhaft or turn goes deſcending like the ſide of a houſe, or like the deſcent of a ſteep hill. It is then ſaid to *Hade*. *Houghton*'s Compl. Miner, in the Explan. of the Terms.

HADRIANISTS, *Hadrianiſtæ*, in church hiſtory, heretics who followed the errors of Simon Magus. *Hoffm.* Lex. in voc.

HÆMACHATES, *the Blood-coloured Agate*, in the natural hiſtory of the antients, the name of an agate found at this time in the Eaſt Indies and in ſome parts of Germany, and called by Dr. Hill achates ſanguineus variegatus; or the blood-coloured variegated agate.

It is one of the moſt beautiful of the agate kind, and was extremely well characterized by the name the antients gave it, being always of a ſtrong and deep red like that of blood. Often, it is only of this plain and ſingle colour throughout the maſs, but more frequently it is found beautifully variegated with a pale blue, and with brown; the blue in this caſe always ſurrounding the red, and appearing like the ſerum which ſeparates from and floats about the blood, when it has been ſome time out of the body. The brown or hair colour is often the baſis or ground colour of the ſtone, and the red in ſpots only, and variegations, ſurrounded with this thin bluiſh colour; it is very hard, and takes a fine polliſh, and is cut into the tops of ſnuff-boxes and other toys, and much valued by our lapidaries. *Hill*'s Hiſt. of Foſſ. p. 472.

HÆMAGOGOS, the name of a medicinal compoſition deſcribed in Myrepſius, and intended to bring away the lochia, or forward the menſtrual diſcharges; it conſiſts of black hellebore and the fætid gums with honey.

HÆMALOPS, a term uſed by many authors for that blackneſs which appears about the eyes from blows; but Hippocrates uſes it to expreſs a black thick and fæculent blood overſpreading the chorion in the formation of the fœtus, and rejected afterwards as of no uſe, and diſcharged into the ſpace between the uterus and chorion. Some authors alſo uſe the word for ſpitting of blood.

HÆMANTHUS, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the monopetalous lilliaceous kind, and is divided into ſix ſegments. The cup finally becomes a ſeed veſſel compoſed of three cells and containing a number of oblong ſeeds. To this it is alſo to be added, that the flowers are collected into a head, and ſurrounded with little leaves at their baſe. *Tournef.* Inſt. p. 657.

There is only one known ſpecies of this plant, which is the African *Hæmanthus*, called by ſome the cape tulip, and by others the ſcarlet Indian narciſſus.

The ſeaſon for tranſplanting the bulbs of this plant is in May or June, when the leaves are decay'd; they may be kept out of the earth at this ſeaſon three or four months, but it is more adviſeable to plant them ſooner, as they always flower the ſtronger for it. Their ſoil is half a fine hazel earth and half old rotten dung; in September they muſt be removed into a moderate ſtove, and watered gently at times: they flower in the depth of winter.

HÆMATITES, (*Cycl.*) in medicine, is accounted aſtringent and deſiccative. Its doſe in hæmorrhages is from ten grains to five and twenty. It is alſo uſed in diſtemperatures of the eyes. *Hill*, Hiſt. Mat. Med. p. 10.

HÆMATION, a word uſed among the antients, for a ſort of reddiſh garon, made of the inteſtines and blood of fiſhes macerated in ſalt.

HÆMATOCELE, a ſpecies of rupture where the ſwelling contains blood.

HÆMATOCHYSIS, a term uſed by Willis and ſome others for an hæmorrhage.

HÆMATOPUS, in zoology, a bird called by others the *pica marina*, or ſea-pye. This, in the Linnæan ſyſtem of nature, make a diſtinct genus of birds of the order of the ſcolopaces; the diſtinguiſhing characters of which are, that the toes are three in number on each foot, and the apex of the bill in form of a wedge. *Linnæi* Syſtem. Naturæ, p. 47.

HÆMATOPUS *Ardea*, the red-leg'd heron, a very beautiful bird common in Italy, and called by the antients *cirris*; it is one of the ſmalleſt of the heron kind, and is of a yelloviſh cheſnut colour. *Ray*'s Ornithology, p. 206. See the article CIRRIS.

HÆMATOXYLUM, in botany, the name by which Linnæus calls the tree which produces the logwood, called by Sir Hans Sloan *campechia*. The general characters of this tree are theſe: The perianthium conſiſts of one leaf divided into five ſegments of an oval figure, which do not fall with the flower; the flower conſiſts of five oval petals ſomewhat larger than the ſegments of the cup. The ſtamina are ten ſubulated filaments longer than the flower; the antheræ are ſmall; the germen of the piſtil is oval and oblong, the ſtyle is ſimple and of the length of the ſtamina, and the ſtigma is thick and emarginated: The fruit is an obtuſe pointed capſule compoſed of two carinated valves, and containing only one cell in which are ſome oblong flatted ſeeds. *Linnæi* Gen. Plant. p. 184. *Sloan*, Jamaic. V. 2. T. 20.

HÆMIONIUM, in botany, a name by which Dioſcorides calls the aſplenium.

HÆMITYBION, in the writings of the antients, a linnen piece of apparel fringed on both ſides. Others call it a ſoft kind of handkerchief to wipe off ſweat; but Galen makes it ſignify a thick piece of linnen cloth. In this he has an eye to ſome paſſages of Hippocrates where the word ſeems plainly to be uſed in that ſenſe; others of the antients have alſo uſed it exactly in the ſame meaning.

HÆMOCENCHRUS, in medicine, a term uſed by ſome of the old writers for a ſpiting of blood, attended with a ratling noiſe in the noſe and fauces.

HÆMODIA, a ſtupor of the teeth, cauſed by auſtere and acid ſubſtances.

HÆMOPTOE, in medicine. See HÆMOPTYSIS, *Cycl.* and *Suppl.*

HÆMOPTYSIS, or HÆMOPTOE (*Cycl.*)—This diſorder is by ſome confounded with the ſputum cruentum, or bloody ſpit, but very improperly, ſince in this caſe the blood is thrown up pure and florid from the lungs, and that without any violent efforts: Whereas in the other the ſaliva is only thrown out tinged or ſtreaked with blood, and that with much trouble and laborious hauking; and ſometimes a ſlight roſion of the gums or fauces tinging the ſaliva with blood, makes what is thus called. The *Hæmoptyſis* differs alſo from the vomiting of blood, in that the blood is arterial and unmixed and voided without emotion, and with a little cough; whereas in the other caſe there is always a ſtraining to vomit, and the blood is venal, and uſually coagulated, and there is no cough.

Signs of it. The *Hæmoptyſis* is generally preceded by a ſenſation of oppletion and narrowneſs of the breaſt; or more tacitly by a ſort of itching or titillation felt all along the aſpera arteria; and in moſt caſes there is a dry, and not very violent or troubleſome cough, for ſome time before. Sometimes, however, the blood is voided without any of theſe antecedent ſymptoms, and only with a ſenſation of ſomething warm coming up out of the breaſt to the mouth.

Perſons ſubject to it. This is a caſe that more rarely happens than moſt other of the complaints of the lungs, and the perſons afflicted with it are principally young men between eighteen and twenty-five; it very rarely happens after thirty, and principally affects perſons of a plethoric habit, or ſuch as uſe high ſeaſoned food. Women are more ſubject to it than men, from the frequent diſturbances nature meets with in the menſtrual diſcharges; and people who are accuſtomed to loud ſpeaking or ſinging, are ſometimes afflicted with it from the violent diſtentions they give the veſſels of the breaſt. Sometimes alſo it ſeizes perſons who have changed an active life to a ſedentary one; and more than any others thoſe who have had ſome other hæmorrhage, or natural and habitual evacuation, ſtopped upon them, without having the caution to bleed or evacuate properly on the occaſion. *Junker*'s Conſp. Medic. p. 28.

Cauſes of it. Youth and a plethoric habit, with too great a derivation of the blood upon the lungs, are ſometimes the natural cauſes of this; but external accidents frequently concur, or alone bring it on: Such are all violent ſtrainings of the breaſt; violent attempts to lift or carry burthens to which the body is not accuſtomed, blowing vehemently in the playing on trumpets and other wind inſtruments, violent paſſions, as anger, &c. and violent motions in wreſtling, running, jumping, or the like; violent coughing may alſo bring it on; but this is not the caſe ſo often as is ſuppoſed, the cough attending this diſorder and ſuppoſed to be the cauſe of it, being uſually only a ſymptom of it.

Prognoſticks from it. This is a diſorder of the utmoſt conſequence, and is by far the moſt dangerous of all hæmorrhages; and tho' the quantity of blood voided is ſeldom ſo great as to bring on ſudden death, yet what remains extravaſated in the lungs eaſily corrupts there, and brings on a phthiſis of which death is the conſequence. The uſe of violent aſtringents is often the cauſe of this alſo, where nature would have eſcaped it.

The method of cure. When the quantity of blood brought up is ſmall, and the ſymptoms not violent, ſuch things only are to be given as quiet the violent emotions of the blood; ſuch are nitre, and cinnabar made into powders with crabs eyes or any other abſorbent: If the caſe is more violent, a gentle anodyne or opiate may be added, ſuch as the pill de ſtyrace, or de cynogloſſo. In more violent caſes, where the attemperating medicines take no effect, the milder aſtringents are to be uſed; or if the urgency of the ſymptoms make it neceſſary even the ſtronger; but with theſe there ſhould always be given a gentle opiate; the antimonial crocus of ſteel, and the vitriolic colcothars, may then be given with the ſtorax pill. Revulſion muſt alſo be attempted, by diaphoretics, bleeding in the foot, and clyſters, and gentle purges; and finally the cure is to be compleated by pectorals and detergents. *Junker*'s Conſp. Med. p. 30.

If a ſuppreſſion of the menſes, or hæmorrhoidal diſcharges, have been the cauſe of the diſtemper, great care is to be taken to bring them on regularly again, by bleeding in the foot, applying leeches to the hæmorrhoidal veſſels, and the like means. Authors diſtinguiſh an *Hæmoptoe* into a great many ſpecies, ſuch as anaſtomoſis, diaireſis, diapedeſis, rixis, and diabroſis; and write a great deal of the different cauſes of theſe *Hæmoptoes*, and of the ſigns by which they are to be diſtinguiſhed. But a late author thinks this of little importance. He thinks it moſt advantageous to conſider a *Hæmoptoe* ſimply as a præternatural efflux of blood, and as ſuch it agrees with the hæmorrhage

of

of the noſe, vomiting of blood, dyſentery, bloody urine, too great flow of the menſes, &c. all which have the ſame immediate cauſes, the ſame effects and conſequences, and ſuggeſt the ſame indications of cure; which are, in the beginning to diminiſh the quantity of blood, and to make a revulſion by opening a vein in the arm, foot, &c. then to moderate the velocity and rarefaction of the blood by cooling medicines; and laſtly, to contract and ſtrengthen the veſſels by aſtringents. The ſame method muſt take place in all, and therefore the general ſtyle of this claſs of diſeaſes ought to be hæmorrhage. See Medic. Eſſ. Edinb. Vol. I. Art. 25.

HÆMORRHAGES (*Cycl.*)—Theſe are divided, by the medical writers, into natural and preternatural.

Natural *Hæmorrhages* comprehend bleeding at the noſe, ſpitting of blood, the fluxes of the hæmorrhoids and menſes, the lochia in lying-in women, vomiting of blood, and voiding blood by urine.

The preternatural *Hæmorrhages* are ſuch as derive their origin from external accidents, as falls, blows, and wounds. Some alſo comprehend, under this term, the artificial evacuations, by bleeding, cupping, and the like.

Hæmorrhages differ much, according to the age and ſtate of the patient, and other accidents. *Hæmorrhages* from the noſe are moſt frequent in young perſons, thoſe of the hæmorrhoids in people of a middle age, or later in life; the ſpitting of blood, to perſons in a middle age; and voiding blood by urine uſually to older people. Some *Hæmorrhages* are periodical, and others vague or uncertain. The firſt obſerve ſome ſtated period of time for their return upon people; the laſt are wholly uncertain in that particular. Some are alſo termed critical; theſe are ſuch as happen at the criſes of fevers. There are uſually violent pains about the part whence natural *Hæmorrhages* are to proceed; but theſe always go off as ſoon as the bleeding comes on in due quantity.

Perſons moſt ſubject to HÆMORRHAGES. Young perſons of a healthy and florid conſtitution are moſt ſubject to *Hæmorrhages*; people of plethoric habits are alſo much ſubject to them, and eſpecially ſuch whoſe blood is ſound and fluxile, not ſubject to any dyſcracy. Thoſe who drink much wine, or eat high ſeaſon'd foods; and, more than all theſe, perſons who are ſubject to violent paſſions, eſpecially to anger. Hence it is that brutes are very rarely afflicted with them.

Cauſes of HÆMORRHAGES. Among the principal of theſe are to numbered a plethora, violent commotions of the body, hot foods and liquors, a heat of the ſeaſon, a ſudden cooling of the body after violent heat, and paſſion. *Junker*'s Conſp. Med. p. 12.

Prognoſtics from them. *Hæmorrhages* from the lungs, and vomiting, and voiding blood by urine, are all very dangerous. The others, when regulated, and in due proportion, are ſalutary, and often prevent diſeaſes. And the common cuſtom of ſtopping them by aſtringents, or otherwiſe, is often productive of ſtagnations, inflammations, and violent fevers.

Method of Cure. *Hæmorrhages* flowing moderately, and from natural paſſages, require no aſſiſtance of medicine; when they happen to plethoric perſons, they are to be ſuffered to continue a ſufficient time. When the quantity of the blood is leſſened by theſe diſcharges, its quality, if diſtemper'd, is next to be amended by internal remedies; if ſulphureous and acrid, by nitrous medicines and abſorbents, and by gentle acids; to this purpoſe ſal prunellæ, crabs eyes, lemon juice, and the like, are excellent; if the blood be too thick, a ſmaller quantity of food, and a larger of drink, is to be preſcribed, and to this the reſolvent and attenuating medicines are to be added, as the neutral ſalts and diuretic roots. Theſe are the neceſſary things out of the fit; and during the bleeding ſuch things are to be given as repreſs the violent motion of the blood, ſuch as cinnabar, nitre, and crab's eyes, ſated with a vegetable acid. Spirit of hartſhorn and tincture of antimony may next be given, and, after theſe, moderately ſtyptic and anodyne medicines; but the ſtronger ſtyptics and aſtringents are not to be uſed but with great caution.

Mr. Petit, in examining all the different methods employed by ſurgeons for ſtopping *Hæmorrhages*, aſſures us, that in each of them a piece of clotted blood is contained in the veſſel, which ſerves to keep the blood from eſcaping, after the effect of the medicine, firſt employed, ceaſes. Where abſorbents or aſtringents are uſed, that there is not only a cylindrical piece of clotted blood in the veſſel, but there is a covering of it on and round the orifice of the cut veſſel; which cylindrical form makes it eaſily puſhed out. Cauſtics have much the ſame effects, only the covering on the extremity of the veſſel is firmer, by the ſolid parts being confounded with the clotted extravaſation. When a ligature is uſed, there is no clotted covering, and the internal plug is of a pyramidal figure, therefore it is with difficulty that ſuch a clotted piece can be puſhed out. Beſides this advantage, the ſides of the veſſel, which are brought to be contiguous by the ligature, will probably grow together; for which reaſon, and the ſaving both pain to the patient, and loſs of ſubſtance of the ſtump, he prefers compreſſion to all the other methods. In proof of the effects of coagulated blood ſtopping the efflux of blood from large arteries, he relates two hiſtories; in one, the artery was oſſified; and, in the other, it lay in a bony groove: So that, in both, it muſt have been a plug which prevented the *Hæmorrhage*. He endeavours to prove, that the plug is ſtronger and firmer, when formed of coagulated lymph, than when compoſed of red blood. For executing the compreſſion right, after amputation of the larger extremities, he has contrived a machine, compoſed of a large circular belt, to be put round the trunk of the body, or ſuperior part of the member, which is to ſuſtain the bandage, by ſtraps going from it, which are faſtened, at the other end, to a leſſer circular belt, that is put round the part of the member where the tourniquet is commonly applied. This leſſer belt is to have two ſcrews, &c. in the form of his ſcrew-tourniquet. From this leſſer belt four ſtraps go out, to croſs over two plates with their ſcrews, as in the tourniquet, placed on the ſtump. When the operation is performed, he applies thick bolſters of lint on the ſide of each large artery fartheſt from the bone, and placing the interior convex plate of the ſmall tourniquet on them, he ſecures it in the right ſituation with the four ſtraps, and ſcrews down the plate on the bolſters and veſſel, which being preſſed between the inſtrument and the bone, can allow no blood to paſs. See Mem. de l'Acad. des Sciences, 1731 & 1732.

Mr. Morand imagines, that the change which happens to the artery, on being wounded, aſſiſts greatly in ſtopping the flux of blood; and that this and the congelation are uſually joint agents in this caſe. When the artery is either empty, or at leaſt leſs diſtended than uſual with blood, it naturally will collapſe, in ſome degree, and become more or leſs flatted; and if this goes ſo far as that the ſides come to touch one another, they naturally unite, and the whole cure is performed by this alone. And this is very frequently the caſe in wounds of ſmall arteries, and in internal *Hæmorrhages*. Nor is it more difficult for a large veſſel to become flatted and collaſpe in the ſame manner, till its ſides touch, provided that the courſe of the blood thro' it be by any means reſtrained. Mr. Morand gave the academy of ſciences of Paris a very remarkable account of a thing of this kind, which fell within his knowledge. A countryman having received a very violent blow upon his arm, had afterwards no pulſation in the artery, in that part of the arm beneath the place where the blow had been given, tho' he had a plain one in that part of the artery which was above it. There was at firſt ſome fear that the arm muſt have been taken off, but Mr. Morand ſaved it, and, as the cure went on, the pulſe was obſerved gradually to be felt again in the hand, and lower part of the arm. The occaſion of this was plainly, that the artery had become flatted by the blow, and the blood was unable to force the oppoſition, and circulated only thro' the ſmall veſſels, while the injury from the blow remained violent, but gradually made its way again, as the parts reſtored themſelves to their natural ſtate. Memoirs Acad. Scienc. Par. 1736.

A wounded artery, in caſe it be cut quite aſunder, is in the ſame ſtate with a cord which is cut in two while it is on the ſtretch. We well know, that when this is done, the two ends recede a great way from one another, and that in proportion to the tention they had before: The caſe is wholly the ſame with an artery, and that for the ſame reaſon. Its longitudinal fibres are drawn back and ſhortened, and its circular ones are, by this very action, compelled to run together more cloſe than they naturally ſhould, and in conſequence they form thicker rings about the extremities of the divided veſſel; the conſequence of which is, that they make the inner hollow narrower. This is a thing of great importance, as not only the ſides of the veſſel are brought nearer together, and therefore they more eaſily may come to touch; but the diameter of the bore of the artery being leſs, a ſmaller maſs of congealed blood may ſtop it; and this blood, adhering to the ſides of the veſſel on every hand, fills up the paſſage as it congeals, and, by degrees, brings them together.

Mr. Petit, in confirmation of his opinion, that *Hæmorrhages* are ſtoppod by plugs of clotted blood, ſhewed the academy of ſciences, at Paris, ſuch a plug, in an artery which had been opened. See Hiſt. de l'Acad. des Scienc. 1735.

What is remarkable is, that this plug of clotted blood had loſt nothing of its conſiſtency, nor of its adheſion to the aperture of the artery, after lying two months in water, and three years in brandy. This ſhews the plug to be analogous to a ſcar: Nor is this ſtrange, ſince both are formed from the juices deſtined to the nouriſhment of the part. Hiſt. de l'Acad. &c. ibid.

The ſtyptic powder of Helvetius has been found excellent in *Hæmorrhages*. See STYPTIC *Powder of Helvetius*.

The *Vitrum antimonii ceratum* has likewiſe proved very efficacious in uterine *Hæmorrhages*. See VITRUM *antimonii ceratum*.

Soft compreſſion is, by Garengort, thought more effectual to ſtop *Hæmorrhages*, than hard ſubſtances; and its uſe recommended even when ſtitches of arteries give way, in which caſe the uſe of vitriol buttons is condemned.

Internal HÆMORRHAGES. The Omentum itſelf is not free from being the ſeat of fatal internal *Hæmorrhages*, tho' this rarely happens. The Peterſburg commentaries give us an account of a woman, who dying almoſt immediately of a blow ſhe received on the belly, was opened, and the cavity of the abdomen

abdomen was found greatly diſtended with blood, which had plainly been diſcharged from the omentum, as a great number of grumes of blood were found lodg'd between its foliages. It was obſerved alſo, in this ſubject, that the omentum was firmly attach'd to the fundus of the uterus.

The ſame papers give an account alſo of another very remarkable internal *Hæmorrhage*; this was of the ſtomach. In this caſe the patient died inſtantaneouſly; and the blood having been diſcharged into the ſtomach too faſt, either for its being ejected upwards or downwards, when the body was opened, the ſtomach was found greatly diſtended, and compleatly filled with one great grume, or maſs, of coagulated blood. It is remarkable that, in this ſubject, the ſtomach was found in a perfectly ſound ſtate, but the ſpleen was found putrid and rotten. Act. Petropol. vol. 1. p. 382.

HÆMORRHAGE *of the Noſe.* Mr. Le Dran propoſes to make a ſeton, like that mentioned in the article *Polypus*, ſerve for ſtopping *Hæmorrhages* of the noſe; for which purpoſe he faſtens two doſſils to the cord, and, after drawing one out at the noſtril, to bring away the clotted blood, he continues to draw the cord, and ſo fills up the poſterior part of the noſtril with the other, which ought to be larger, and well wet in a ſtyptic liquor; by which not only the *Hæmorrhage* will be ſtopped, but if it ſhould continue, the blood and medicines will be effectually prevented from running down the throat, which commonly occaſions a cough or vomiting, that increaſes the bleeding. Med. Eſſ. Edin.

Unnatural HÆMORRHAGES, a term uſed by ſome medical writers to expreſs ſuch diſcharges of blood as are made from parts not naturally, or, in the common courſe of things, admitting ſuch evacuations. Of theſe we have a very remarkable inſtance, recorded in the philoſophical tranſactions. It is of a young child which bled firſt at the noſe and ears, and afterwards at the hinder part of the head, where there was no ſore, and afterwards at the ſhoulders, waſte, and at the fingers and toes, and the bending of the arms.

HÆMORRHAGES *from Wounds.* Profuſions of blood, from wounds, ariſe from injuries of the veins or arteries, received in the inflicting the wound; and the violence of the *Hæmorrhage* is ever in proportion to the ſize of the wounded veſſel: it is no wonder, therefore, that great weakneſs, fainting fits, and ſometimes inſtant death, are the dreadful conſequences attending this ſymptom, according to the ſize of the wounded veſſel. The ſurgeon ought, for this reaſon, never to be without the proper remedies, to ſtop blood, about him; but there are ſome caſes in which it is by no means proper to ſtop the *Hæmorrhage* inſtantly. In a young plethoric habit, or in a wound got in a drunken fit, or even in a fit of great paſſion, it is beſt to let the blood run as long as it continues to do ſo without inconvenience to the patient; for, by a moderate loſs of blood, the inflammation, tumour, pain, and fever, are either entirely prevented, or much leſſened.

The ſtopping of *Hæmorrhages* is to be done by various ways: If no large veſſel is wounded, dry lint alone is always ſufficient; the wound is to be filled with this, and a proper compreſs and bandage put over it. The wound muſt be filled pretty cloſely with the lint, and a proper degree of preſſure given over the compreſs, with the hand, by which more is done ſometimes than by all the bandages or violent remedies in the world. But if the *Hæmorrhage* is too large to be ſtopped by the application of dry lint alone, the uſe of aſtringent medicines is to be called in. The uſual application, in this caſe, is rectify'd ſpirit of wine applied cold to the wound, filling it up with doſſils dipped in the ſame ſpirit, and covering it with large compreſſes wrung out of the ſame liquor, and making a proper preſſure over all with a bandage. The other aſtringents, uſed on this occaſion, are vinegar, the lycoperdon, or puff-ball oil, and ſpirit of turpentine, alum, vitriol, or ſaccharum ſaturni, diſſolved in water or vinegar, or the dry powders of bole armenic, bloodſtone, dragon's blood, *&c.*

When veſſels of a larger ſize are divided, we are to have recourſe to cauſtic medicines inſtead of aſtringents, the common medicine, in this intention, is the Roman vitriol, which being coarſely powder'd, and ſprinkled upon cotton, is to be applied to the wound, dreſſing up with doſſils, a compreſs and bandage. It is uſually neceſſary to be very greatly cautious in the application of this, that it only be laid to the bottom of the wound, or the part where the veſſel wounded lies, otherwiſe the other parts will ſuffer too great an eroſion from it.

If theſe applications all prove fruitleſs, it will be proper wholly to divide the artery, yet only divided in part; for, by this means alone, it will contract and hide its end under the muſcular fleſh, and its orifice will, by that means, either be entirely choaked up, or at leaſt it will be more ready to yield to the force of the medicines before adviſed to be uſed on ſuch occaſions. This method of treatment is moſt uſually neceſſary in wounds of the temporal arteries, and thoſe of the cubits, and tibiæ.

If this method ſhould fail, you muſt then have recourſe to the hot iron, or actual cautery; the orifices of veſſels being burned, a cruſt is formed over them, and this method is ſo very effectual, that it is ſcarce poſſible for an *Hæmorrhage* to happen in wounds of the external parts, which may not certainly be ſtopped by it. In this caſe, two cauteries ſhould be always ready, that, if one ſhould be extinguiſhed before the operation is finiſh'd, the other may be at hand without waiting for it. Cauteries are made of different ſhapes and ſizes, according to the parts they are intended to be applied to. The great inconvenience attending the uſe of the cautery, is, that after two or three days, the eſchar ſometimes falls off, and then a ſecond, and that commonly a fatal *Hæmorrhage* ſucceeds; to prevent this fatal accident, the wounds muſt be handled very tenderly at the time of dreſſing, and every time the wound is dreſſed, to be provided with a cautery ready heated, to repeat the operation if it ſhould be neceſſary. This caution is to be obſerved, in regard to the larger arteries, for fourteen days; after this there is no great danger of a return of the complaint; but when the crural or axillary arteries are wounded, the cautery is of no uſe.

In very dangerous wounds of the large arteries, ſuch as the crural and axillary, and, in amputations of the limbs, the ſafeſt method is that of making a ligature round the veſſels: If this is performed by paſſing a ſtrong waxed thread under the artery, by means of a crooked needle, the blood is preſently ſtopped, and the orifices of the artery coaleſce.

Inſtruments for the ſtopping of *Hæmorrhages* have alſo been in uſe in all ages, which, by their forcible compreſſion on the part, ſtop the mouths of the veſſels, the moſt convenient of which is thus compoſed: A braſs plate, three fingers long, and two fingers broad, is perforated in the middle to admit a ſtrong ſcrew, which is provided at the lower end with a ſmall round plate; a piece of leather is ſtrongly faſtened to one end of the braſs plate, of equal breadth with it. In violent *Hæmorrhages* this inſtrument is fitted to the wounded part. The end of the leather is brought round the part, and, by means of holes made through it, is faſtened, at the proper part, to two ſmall hooks made on the braſs plate, at the end, oppoſite to that where the leather is faſtened; this is to be adjuſted in ſuch manner, that the ſmall plate at the bottom of the ſcrew is to be brought to preſs exactly upon the compreſſes and dreſſings that cover the wound; the handle of the ſcrew is then to be turned round with a gentle preſſure, till it is found turned far enough to make a preſſure of force, to ſtop the blood: It is then to be left in this condition for a day or two, or till it may ſafely be taken off. *Heiſter's* Surg. p. 45.

HÆMORRHOIDS (*Cycl.*) are diſtinguiſhed, from the manner and time of their return upon the patient, into regular or periodical, and vague or irregular.

Signs of HÆMORRHOIDS. They are generally preceded by a ſenſation of pain, and tenſion in the hypocondria, and vibrative or ſpaſtic motions about the ſtomach, meſentery, and ſpleen; and what is much more obvious than theſe, there is a ſenſation, as it were, of a hard nucleus ſticking in the extremity of the rectum; and the more high up in that inteſtine this is felt, the more difficult will be the eruption of the hæmorrhoidal diſcharge, and the longer before its appearance. With theſe ſymptoms there alſo very frequently comes on a teneſmus. Theſe are the uſual antecedent ſigns; but there are ſome in whom they appear without any previous notice. When preſent, there is a diſcharge of blood, and that uſually very pure and florid in perſons who have them frequently and regularly; in others who have them ſeldom and imperfectly, the blood appears black and grumous; and in ſome caſes, eſpecially in perſons who never have had a genuine and proper flux of this kind, there is excreted a ſanious matter inſtead of pure blood. The evacuation of the blood from them is ſeldom voluntary, but uſually is forced out by the preſſure and hardneſs of the ſtools. *Junker's* Conſp. Med. p. 47.

Perſons ſubject to them. They equally affect both ſexes, but are oftener met with in men than in women. They are moſt frequent in the middle and advanced ages of life, and when they happen to young people, they are uſually hereditary.

Cauſes of them. Among theſe are to be reckoned a plethora, and thickneſs of the blood, for an over thinneſs and acrimony of it is ſeldom the cauſe, tho' very often ſuppoſed to be ſo. Violent concuſſions of the abdomen, as by violent exerciſes of riding or walking, will alſo bring them on, as will a ſedentary life, in which, by the compreſſion of the abdomen, the circulation is impeded at the vena portæ; alſo an omiſſion of any cuſtomary evacuations of blood, an abuſe of hot foods and ſpirituous liquors, and the taking of aloes, or other the like medicines. In Saxony the *Hæmorrhoids* are very frequent, from their taking great quantities of elixir proprietatis; and in Hungary, from their eating large quantities of garlic, violent binding of the bowels, and paſſions of the mind, eſpecially anger and fear, and the venereal infection will alſo frequently bring them on; but this laſt cauſe chiefly brings on the blind piles, or ſuch as do not bleed.

Prognoſticks from them. The *Hæmorrhoids*, when they flow naturally and moderately, are very beneficial to health, and often prevent violent diſeaſes. They are peculiarly the moſt certain of all remedies in hypocondriacal affections; they eaſe deliriums, and very often take off fits of the gout. With all theſe advantages in them, when moderate, they are, however, attended, when immoderate, or when too long continued, with bad ſymptoms, and are often dangerous: They bring on great weakneſs, and, in length of time, induce ca-

chectic

chectic diſpoſitions; but they very ſeldom are attended with ſo copious an hæmorrhage as to endanger life on the ſudden, tho' this has ſometimes happened. The ſudden ſtopping them is always dangerous, and often brings on immediate fatal ſymptoms; ſchirruſes of the viſcera, inflammations, melancholy, madneſs, vomiting of blood, and dropſies, and jaundices, often are the conſequence of ſuch practice. Thoſe perſons who have them while very young, generally are attended regularly with them thro' their lives, and ſeldom live to be very old; on the contrary when they do not appear till perſons are advanced in years, and continue regular and moderate afterwards, they promiſe a long life. Finally, when the *Hæmorrhoids* are continual, and flow without any intermiſſions, there is great cauſe to ſuſpect a ſchirrous or ulcerated ſtate of ſome of the abdominal viſcera.

Method of Treatment. When the *Hæmorrhoids* have never yet appeared, but there are ſigns of their approaching, it is not always adviſeable to forward or promote their diſcharges, for they ſeldom anſwer exactly to expectation; but when there is room to fear the ſucceſs, it is better to endeavour at a revulſion by bleeding in the arm or foot, and at the ſame time to ſtrengthen the tone of the parts by a decoction of yarrow or the like medicines. And the bleeding is to be repeated afterwards at ſtated periods, and the uſe of the internal means continued if neceſſary; but when the *Hæmorrhoids* have already been uſed to flow, as ſoon as the patient feels the ſignals of their approach, their diſcharge is always to be gently promoted, by a moderate uſe of elixir proprietatis, or tincture of black hellebore, or its reſin made with ſpirit of wine; and externally by the application of leeches, or, if that is not ſufficient, by opening the veins with a lancet. *Junker*'s Conſp. Medic. p. 47.

During the time of the flux, if that be moderate, there is no occaſion for any aſſiſtance from medicines, but a proper diet is to be obſerved; all windy foods are to be avoided, as alſo all aſtringent ones; the uſe of ſpirituous liquors is to be reſtrained, and the mind kept quiet and free from the commotions of any of the paſſions. When the diſcharge is too ſmall, it is to be promoted; and when it is really too great, and the ſtrength of the patient cannot bear it, then the nitrous, cinnabarine, and abſorbent medicines are to be given, as powders prepared of ſal prunellæ, cinnabar either native or antimonial; if there be urgent neceſſity ſome gentle opiate may be added to theſe, as the pill de ſtyrace, or de cynogloſſo. After this, gentle clyſters are to be injected, and then the uſe of ſpecifics is to be entered on; among theſe, a decoction of the common yarrow is of ſingular virtue: decoctions of maiden hair alſo and other of the like herbs are of great uſe. After the fit is over, bleeding muſt be repeated at the equinoxes, and gentle purges given at times, eſpecially ſmall doſes of rhubarb, which has an abſtergent virtue that renders it peculiarly proper; and this may be given even in the time of the fit, in ſmall doſes.

Blind HÆMORRHOIDS, *Hæmorrhoides cæcæ*, the name given by medical writers to what are vulgularly called the piles. The *blind* and *external piles* are infarctions of the external *hæmorrhoidal* veſſels about the orifice of the inteſtinum rectum, which ſometimes form ſimply turgeſcent, ſometimes inflammatory tumors; and are meant by nature for the diſcharge of blood from this part to relieve *Hæmorrhages*.

The *blind piles* are of two kinds, either ſimply turgeſcent, or tumid, the latter kind are painful, the former wholly indolent.

The turgeſcent *blind piles* reſemble a ſoft tranſparent veſicle filled with a blackiſh blood, and are attended with no ſenſible uneaſineſs, except at the time of going to ſtool, when they occaſion a ſenſation reſembling that of a bean or plum ſtone, or the like, ſtopping in the paſſage; and at times there is an uncommon heat in the parts.

The tumid *blind piles* are ſituated a little deeper within the verge of the extremity of the inteſtine, and reſemble a hard and inflammatory tumour; theſe are properly indeed no other than furunculi of this part, and occaſion very violent and exquiſite pains from the ſenſibility of the nervous and muſcular coat which lines the inteſtines. Many authors beſide theſe reckon under the name of *blind piles* all the tumid excreſcences and fungous and ulcerated protuberances that happen about the anus: theſe are diſtinguiſhed indeed by the appellation of ſpurious *Hæmorrhoids*; they uſually owe their origin to venereal taints, but ſometimes ariſe from the *turgeſcent piles*, which, in bad habits, and bodies ſubject to ulceroſe ſeroſities, ſometimes degenerate into theſe dry and verrucoſe ſwellings, and are called *thymi*, *mariſci*, and *ficus ani*. *Junker*'s Conſp Med. p. 233.

The external or *blind piles* differ from the internal, in regard to the veſicles to which they owe their origin, the internal ariſing from the vena porta, the external from the vena cava; they differ alſo in their ſize, and in the quantity of blood they diſcharge; the internal ones uſually diſcharge a moderate quantity, and if they are any way diſturbed they will throw off a great deal; whereas the external rarely bleed at all, but only ſhew themſelves in theſe blind tumors. The internal alſo have their regular periods, and very frequently obſerve the monthly diſcharges of the menſtrua in women, returning as regularly in men as theſe in that ſex: the others have no regular periods, but principally appear about ſpring and autumn; and they appear the larger, and have the more blood derived to them, the oftener they have already ariſen in a perſon. Their magnitude is very different in different perſons; in ſome they are of the ſize of a hazel-nut, in others of a walnut, and in ſome they often grow to the ſize of a pigeon's or even a hen's egg.

The *turgeſcent piles* either break naturally, or are to be opened by a ſurgeon; and when this is done, they not only diſcharge the blood they contained, but alſo ſupply a farther quantity afterwards. The tumid ones have all the ſigns of inflammatory tumors, attended with the moſt exquiſite pains.

Perſons ſubject to them. The turgeſcent external piles are principally incident to thoſe of a phlegmatic and pituitous habit; they often indeed appear in women during their going with child, without their being of this temperament, eſpecially toward the latter part of their time, if they ſit much; and ſometimes they happen even during the labour pains, when the fœtus preſſes heavily upon the pelvis.

Cauſes of them. The general cauſe of them is a plethora attended with a thickneſs of the blood; whence nature, attempting to relieve herſelf by an hæmorrhage of theſe veſſels, derives a larger quantity of blood than ordinary into them, where it remains, and according to its different ſtate, forms either ſimple veſicles, or inflammatory tumors. The accidental cauſes which bring them on, are immoderate attritions in theſe parts, from riding long journeys in perſons unuſed to that exerciſe, from an itching or ſharp humour about the part, from the painful voiding of the excrements in perſons very coſtive, and from labour pains in women. Junker ſays that they are ſometimes got by ſitting down in the ſeat in which a perſon has been juſt ſitting, who has the ulcerated piles, while it is yet warm from him. To theſe it is to be added, that they frequently come on from an omiſſion of accuſtomed bleedings, from an improper uſe of aloetic, helleborine, and other hot medicines, and from too high ſeaſoned foods, and the immoderate uſe of ſpirituous liquors.

Prognoſtics in them. The *blind piles* are always in a ſtate of tendency to a ſalutary end, that is to the evacuation of part of the abundant blood in plethoric habits; but from the ſmallneſs of the veſſels where they are formed, they very often miſs of the proper end. When they either burſt naturally or are opened by art, they then afford for ſome time a diſcharge that may ſupply the place of that by the *internal Hæmorrhoids*. When they burſt of themſelves, they eaſily become ulcerated afterwards, but this is not attended with any violent pain. As ſoon as opened, the veſſel which formed the tumor becomes flaccid and rugoſe in that part, and forms a ſort of papulæ or little tubercles, which, if not taken care of in the proper way, often continue to diſcharge a ſmall quantity of blood at every time the perſon has a hard ſtool; and even in ſome caſes theſe papulæ have continued without intermiſſion diſcharging a ſmall quantity of blood for many years; ſometimes alſo they degenerate into ſerpiginous and pruriginous little ulcers, which are called ſerpigo ani, or pruritus ani. This is a troubleſome complaint, and is not unfrequent in people ſubject to the external *Hæmorrhoids*, tho' not much regarded by authors; it never ſpreads far, but often continues many months in the ſame ſpot; and if by unſkilful treatment it be repelled from thence, it ſometimes returns again more violently in the neighbouring parts, and ſometimes occaſions diſorders of a worſe nature in the more diſtant ones. *Junker*'s Conſp. Med. p. 239.

The tumid and *turgeſcent piles* are both without danger to the life of the patient, unleſs in ſuch caſes where they are violently ſuppreſſed, on perſons who have been long ſubject to them. The tumid are however attended with one danger which the turgeſcent are free from; this is, that if unſkilfully managed, they will ſometimes come to a ſuppuration, which terminates often in a fiſtulous ulceration. This too often happens when they are cut too deeply into, during the time of their ripening, and are kept open too long afterwards without being well cleanſed. When *hæmorrhoidal* affections become ulcerous, they are more contagious than almoſt any other diſeaſe; and as this is not commonly known, many ſuffer by it.

Method of cure. The *turgeſcent piles*, if treated in the common way of tumors and little ulcers by a ſkilful ſurgeon, are very rarely attended with any bad conſequences. The tumid give much more trouble. The firſt attempt muſt be to diſcuſs them; and to this end bleeding in the foot is one of the firſt things to be done, in caſes where there is a plethoric habit, and very ſtrong decoctions of yarrow are to be given, ſeveral doſes in a day, and external remedies, ſuch as the unguentum linariæ, and the root of the ſcrophularia, are to be applied; theſe are by ſome eſteemed ſpecifics, and botanical authors boaſt wonders of their effects.

If by theſe means, after three or four days trial, there appears no hope of their being diſcuſſed, then they are to be maturated by all means and with all ſpeed that may be. To this purpoſe a cataplaſm of a roaſted onion with linſeed oil and veal fat, is by many greatly recommended; and when the pains are violent, internal medicines are to be given, ſuch as nitre with the cooling emulſions, and when neceſſary a gentle opiate. Oil of eggs is greatly recommended alſo for external uſe, to allay the pain. When they are brought to maturation, they are to be carefully opened by the hand of a ſurgeon; and the cleanſing and healing them up is then to be forwarded by

all poſſible means. Internally, gently laxative medicines are to be given, ſuch as the lenitive electuary and the like, with manna, ſena, and other gentle purges; then medicines which purify the blood, and ſuch as quiet its too violent emotions. After the cure is completed, the beſt method to prevent a return is bleeding in ſpring and autumn, and applying leeches to the *hæmorrhoidal* veins, at any time when threatened with a relapſe. *Junker*'s Conſp. Med. p. 240.

Suppreſſions of the HÆMORRHOIDS. Phyſicians conſider the ſuppreſſion of the *Hæmorrhoids* in three reſpects: 1. When they have never yet flowed at all, but all the attempts of nature are obſerved toward their appearance, and all the preceding ſymptoms of them ſeen. 2. When they have been uſed to to flow habitually, but their courſe has uſually been impeded by accidents; this is often the caſe in what are called the blind piles. And, 3. When they have been uſed to flow regularly and well, and at ſtated times, for a long courſe of time; the ſuppreſſions in theſe different ſtates are attended with different ſymptoms and different diſorders.

Signs of Suppreſſions of them. Theſe are frequently the common hypocondriacal affections, firſt appearing in pains and tenſion of the left hypocondrium, extending to the region of the loins. Theſe are ſucceeded by ſpaſtic pains, violent colics, inflations of the ſpleen, reachings to vomit, obſtinate coſtiveneſs, a hardneſs of the abdomen, and finally, infarctions and ſchirruſes of the viſcera, melancholy, madneſs, and a vomiting of blood; theſe are the ſucceſſion of ſymptoms, which naturally attend ſuppreſſions of the internal *Hæmorrhoids*. The ſuppreſſions of the external are often violent fits of the gout, nephritic complaints, and the voiding of blood by urine; add to theſe that the moſt frequent ſymptom attending the ſuppreſſion, either of the external or internal, is an aſthmatic difficulty of breathing, often attended with a cough. The perſons moſt ſubject to theſe ſuppreſſions from natural cauſes, are thoſe of a melancholic diſpoſition, ſuch as are eaſily terrified, or grieved at trifles, and ſuch as have ſuddenly changed a life of labour into a ſedentary one. *Junker*'s Conſp. Med. p. 84.

The internal and natural cauſes of theſe ſuppreſſions are principally a thickneſs of the blood, or a violent orgaſtic commotion of it; the external and accidental cauſes of it are the improper uſe of aſtringent medicines, the drinking large draughts of cold liquors when very hot, a thick and heavy diet, and a too great coldneſs of the abdomen. This ſuppreſſion is uſually very difficult to be removed, but in general is found much more eaſily to give way to medicines when owing to natural cauſes than to accidental; and it is to be obſerved, that a ſuppreſſion of them in their firſt attack is leſs dangerous than when they have appeared.

Method of Cure. In caſes where the *Hæmorrhoids* have never yet appeared, but only the antecedent ſymptoms are perceived, great caution is neceſſary to determine, from the habit and conſtitution of the patient, whether it be proper to encourage and promote their appearance, and aſſiſt nature in the way ſhe is endeavouring to eaſe herſelf; or whether it may not be better to carry off the redundant blood ſome other way. If the body be in ſuch a ſtate as to promiſe a ſucceſsful flux from them, it is to be promoted by gentle aperients; but if otherwiſe, the blood is to be derived another way by bleeding in the arm, and the patient is to be ordered to uſe frequent exerciſe. In caſes of ſuppreſſions of uſual and habitual fluxes of the *Hæmorrhoids*, the ſymptoms are to be firſt alleviated by bleeding in the arm, then emollient clyſters are to be adminiſtred, ſuch as chamomile flowers boiled in milk, and after theſe the quality of the blood is to be amended by proper internal medicines, its violent emotions to be taken off by nitre, abſorbents, and the like, and its ſpiſſitude removed by attenuants. After this, its derivation to the proper parts is to be promoted by gently ſtimulating medicines; ſuch are aloes and all its preparations, particularly elixir proprietatis; and ſaffron and borax may alſo be given in ſmall doſes; to this maybe added the uſe of ſtimulating clyſters and acrid ſuppoſitories, and the application of leeches to the parts. *Junker*'s Conſp. Med. p. 87.

HÆMORRHOSCOPIA, an old term uſed by the writers in medicine to expreſs an examination of the blood drawn from a patient by phlebotomy, in order to judge of the nature of the diſeaſe by it.

HÆMORRHOUS, the *blood ſnake*, the name of a peculiar ſpecies of ſerpent; ſo called, becauſe it was ſuppoſed, that on a perſon's being bit by it the blood flowed out of every part of the body. It is a ſmall ſerpent, ſeldom arriving to more than a foot long; its eyes are remarkably vivid, bright, and ſparkling, its ſkin is very gloſſy, and its back variegated with a great number of black and white ſpots, its neck is very ſlender, its tail extremely ſharp, and it has a ſort of ſmall horns placed over its eyes: it is found in Egypt. There is alſo an American kind of this found in the ſouthern parts, and called by the natives ahucyatli, which is larger than the other, and reſembles the rattleſnake in many particulars, but wants the diſtinguiſhing character of the rattle in the tail. See Tab. of Quadrupeds and Serpents N°. 33. and *Ray*'s Syn. An. p. 287.

HÆMOSTASIA occurs in ſome writers as the name of a diſeaſe occaſioning ſudden death; and is ſaid to be a total ſtagnation of the whole maſs of blood from a plethora.

HÆMOSTATICA, a name given, by ſome authors, to medicines uſed to ſtop hæmorrhages, whether for internal taking, or external application.

HÆPHESTITES *Lapis*, in natural hiſtory, a name given, by authors, to a ſtone of a reddiſh colour, and capable of a high poliſh. The antients gave it this name, from its property of ſetting fire to dry ſubſtances by reflection, when formed into a concave ſpeculum. They hence called it the Vulcanean ſtone, or fire-ſtone, not conſidering that the ſhape into which they formed it, and not the nature of the ſtone, was the cauſe of the effect; any ſtone being capable of the ſame, if hard enough to bear a proper poliſh. About Hilderſheim they have, at this time, a ſort of blackiſh-red coarſe jaſper, which they take to be the *Hæpheſtites* of the antients, and uſe it, at this day, for the ſame purpoſes, hollowing large pieces of it into ſpeculums, and ſetting them, when well poliſh'd, in proper frames, and uſing them as burning glaſſes. *Boet.* de Gemmis, 526.

HÆRETULA, in natural hiſtory, a name given, by Mr. Lhuyd, to a ſpecies of foſſile oyſterſhell. See the article *foſſile* SHELLS.

HÆRMIA, an Indian fruit, reſembling pepper, eſteemed good to ſtrengthen the ſtomach, diſperſe flatulencies, and reſtore the uvula when relaxed.

HAFFHERT, in zoology, the name of a bird, deſcribed by Hoier, which is ſeen uſually at ſea, and is ſuppoſed to be a foreteller of ſtorms. It is of the ſize of a common hen, and reſembles the falcon in ſhape. It is all over of a greyiſh colour, variegated with ſpots of white. Its beak is ſtrong and hooked like the falcons, but it is ſhorter. The fiſhermen dread the appearance of this bird, and at ſight of it always make to ſhoar as faſt as poſſible, expecting tempeſts and bad weather. *Ray*'s Ornithol. p. 36.

HAGA, in our old writers, has different ſignifications. In domeſday it is taken for a houſe in a city or borough. An antient anonymous author ſays 'tis a houſe with a ſhop, *Domus cum ſhopa*. See Co. Litt. 56. *Blount*, *Cowel*.

HAGABLUM, in our old writers, the ſame with *gablum* or gabel. *Blount*. See GABEL, *Cycl.*

HAGIAM, in the materia medica, a name given, by ſome of the Arabian phyſicians, to a kind of ſchænanth, or camel's hay. The Greeks made ſeveral kinds of this, according to the places from whence they received it; the ſchænanth of different countries differing in virtue: but the Perſian was, in many ages, eſteemed the beſt kind; and this is probably what the Arabs called *Hagiam*. The interpreters of Aviſenna leave this word wholly unexplained. Garcias, according to what ſkill he had in the Arabic, ſuppoſes it the name of the city Damaſcus, and given to ſuch ſchænanth as came from that part of the world; but this ſeems erroneous. The Arabs called all other nations barbarians; and this term gentiliſm or barbariſm, was, in their language, expreſſed by the word *Hagiam*; they hated the Perſians beyond all other nations in the world, and called them *Hagiam* by way of eminence, and therefore *Hagiam* and Perſian were a ſort of ſynonymous words. It is probable they had their ſchænanth principally from Perſia, and that this, whether better or worſe than the Nabatæan ſchænanth of their own country, was diſtinguiſhed by the epithet of foreign, and that with the word by which they expreſſed Perſian.

HAIHALEM *Maovi*, in botany, a name by which the modern Ægyptians call the plant we name *ſtratiotes* and *ſempervivum aquaticum*, the water ſoldier and water houſeleef. The laſt of theſe names is a verbal tranſlation of the Ægyptian one. Some have ſuppoſed that the niluſar was called by this name by the antient Ægyptians, but this is an error; the plants are ſo perfectly different from one another, that they have nothing but the growing in water in common between them. *Proſper. Alpin.*

HAII, a name uſed, by the Braſilians, for the animal we call the *ſloath*, or *ignavus*. The word ſeems pronounced by the creature itſelf, as its common note, and thence became uſed as its name. *Grew*'s Muſ. p. 11. See SLOATH.

HAIL (*Cycl.*)—The miſchiefs that violent hail-ſtorms are able to do, is ſcarce to be conceived by any but thoſe who have ſeen them. We have, in the philoſophical tranſactions, an account of a ſtorm of this kind in our own country, in which the cloud from which it deſcended was of about two miles in diameter, and for that ſpace immediately below it nothing was ſpared; it happened toward the latter end of April, and all ſorts of fowls were killed by it, and moſt of the ſmaller animals, that happened to be out in it, ſhared the ſame fate; the windows in all the houſes thereabout were broken to pieces, and it plough'd up the earth, and cut down the blade of the green corn, ſo as wholly to deſtroy it. The bowling greens of ſoft mould were all torn up, and had the appearance of beds in a garden, ready for things to be ſown in, and all the ſoft lands ſhared the ſame fate, where the graſs was not ſo high as to prevent it, for the hailſtones came with ſuch force, that they buried themſelves in the ground, and tore up large quantities of it in their way. They were of about five ounces weight each, and were irregular in their ſhapes, ſome being round, and others variouſly angular and crenated; but what was remarkable was, that every one of them had a piece of

ſnow, in the manner of a nucleus or kernel, in the middle. They muſt have fallen from a very conſiderable height, by the force with which they came down; and it was obſerved, that the cloud of them paſſed more than ſixty miles in length undiſperſed. The ſea where it fell was raiſed up into the appearance of a wood of watery trees, and, in leſſer waters, the ſurface was daſhed up to the height of a yard or two in many places. The ſea fowl fared the worſt of all creatures in this ſtorm, and, having no ſhelter to fly to, were deſtroyed in ſuch numbers, that the next tide brought them on ſhore in heaps, and the people in Lancaſhire collected many buſhels of the eatable kinds. Phil. Tranſ. N°. 229. p. 574.

HAIR (*Cycl.*)—It has been ſaid by many, that *Hair*, nails, feathers, *&c.* are not parts of the animal they belong to, but mere vegetable excreſcences; and what argues greatly for this, is, that they are very well known to grow upon the body even after the deceaſe of the animal.

The outer ſurface of the body is the natural place for *Hair*, but both that and teeth have been found in other parts, where the common courſe of nature never produces them. Amatus Luſitanus mentions a perſon who had *Hair* upon his tongue. Pliny and Valerius Maximus concur in their teſtimonies, that the heart of Ariſtomenes Meſſenius was found hairy; and Cælius Rhodiginus relates the ſame of Hermogenes the Rhetorician, and Plutarch, of Leonidas, to omit a great many others. *Amat. Luſitan.* Cent. 6. Can. 65. *Valer. Max.* l. 1. c. 6.

Hairs are ſaid to have been frequently found in the breaſts of women, and to occaſion the diſtemper called trichiaſis; but ſome authors have been of opinion, that theſe are not *Hairs*, but ſmall worms. See TRICHIASIS.

There have been, however, various and indiſputable obſervations of *Hairs* found in the kidneys, and voided by urine. Galen, Actuarius, Braſſavolus, Fernelius, Scultetus, and Tulpius, are among the number of authors who give unqueſtionable inſtances of it.

Hippocrates is of opinion, that the glandulous parts are moſt ſubject to *Hair*; but bundles of *Hair* have been found in the muſcular part of beef, and in ſuch parts of the human body as are as firm as that. *Hair* has often been found in abſceſſes and impoſtumations, as the experience of ſurgeons in all ages has proved. Scultetus opening the abdomen of a woman, found twelve pints of water, and a large lock or bundle of *Hair* ſwimming looſe in it. But of all the internal parts, there is none ſo ſubject to an unnatural growth of *Hair* as the ovaria, or teſticles of females. Dr. Tyſon gives three memorable inſtances of this, from his own obſervation. The firſt in a bitch, which, on diſſecting, appeared to have the omentum larger than uſual, and faſtened very firmly to the inteſtines, to the extremities of the cornua uteri, and to the right ſide: Where the adheſion was, there was an inflammation, and ſeveral ſmall glands, and there was a great quantity of *Hair* growing there, ſome on the omentum, ſome on the cornua uteri, and others in the ovary; ſeveral hairs alſo lay looſe in the veins, and two or three lay in the right ventricle of the heart, and ſeveral were rooted in ſmall glands. The cornua uteri alſo were joined together at their extremities, and both the teſticles made but one large and rude glandule, which had ſeveral ſinuous cavities within, filled with a purulent matter and *Hair*. In the cornua uteri there were the veſtiges of former fœtus's. The creature was much emaciated in her hinder parts, and the *Hair* found in the ſeveral parts of the body was like that of the human ſkin, and was about an inch and half long. The moſt remarkable particular, in this creature, was the *Hair* lying looſe in the veins; but this is not a ſingle inſtance of ſuch a caſe. Cardan mentions his having found *Hair* in the blood of a Spaniard, and Slonacius in that of a gentlewoman of Cracovia; and Scultetus declares, from his own obſervation, that thoſe people who are afflicted with the plica polonica have very frequently *Hair* in their blood. Dr. Tyſon's ſecond inſtance is in the caſe of a young gentlewoman, at the diſſecting of whom he was preſent with many other phyſicians. She had died of a long and tedious illneſs, and, ſearching for what might have been the cauſe of it, they obſerved a tumour in the right teſticle, or ovarium, which was ſwelled into two veſicles, or bags, almoſt as large as a man's head; theſe conſiſted of a thin membrane, and had a free communication one with another within. They were filled with a matter much reſembling curds and whey, for there were ſeveral lumps or pieces of a ſteatomatous or curdy matter ſwimming in a clear lymph. Theſe lumps were fatty and ſoft to the touch, of a pale yellow colour, and of no remarkable ill ſmell, and in part diſſolved in warm water. One of theſe lumps was as large as a man's fiſt, and in this there lay a large quantity of *Hair* of a ſilvery colour, very fine and ſtrong, and ſome of it was two foot long; there were ſmaller parcels alſo of it in ſeveral other of the lumps of fatty matter, and theſe did not grow to any thing, but were quite looſe. On the outſide of the larger bag there was found the remaining part of the ovarium, or teſticle, and in it ſeveral eggs, or hydatides; and beſide theſe, there was a hard and ſolid bony ſubſtance, in all reſpects reſembling an eye tooth. This firmly adhered, at its baſis, to the membranes of the ovary, and had, at its ſides, two other ſmaller, but leſs regularly ſhaped teeth.

The third obſervation was of a gentlewoman who had long complained of all the ſymptoms of a ſtone in the kidneys, as great pains, bloody urine, vomiting, *&c.* which, in all probability, were the principal cauſe of her death: Upon opening her body, there was obſerved, near the uterus, a cyſtis, or bag, of the bigneſs of a large turkey's egg; and in this there was a like fatty ſubſtance, with a large quantity of fine ſoft *Hair*, and a bone reſembling, in ſome ſort, a mandible, with ſeveral ſockets, in which were three dentes molares in a triangle, and a fourth not yet grown out. Beſide theſe, there was alſo found, in one of the kidneys, a large ſtone.

Beſides theſe there are a number of inſtances in the authors of the greateſt credit in phyſic, of *hair* found in the ovaries; but what beyond all other things proves that *hair* may grow without any aſſiſtance of the circulating juices of the body, and be encreaſed merely as an excreſcence of the vegetable kind from it, not as a part of it, is that memorable inſtance, recited in Mr. Hook's philoſophical collections, of a body, which after having been buried forty-three years, was found in a manner wholly converted into *hair*. The woman was buried in a coffin of wood, and lay the loweſt of three in the ſame grave, there being two other coffins over hers; the bones of which being removed, and this coffin appearing, it was obſerved that a great quantity of *hair* had grown out through the cleſts of it. On removing the lid of the coffin, the whole appeared a very ſurpriſing ſight: there was the whole figure of the corpſe reſembling perfectly the human ſhape, exhibiting the eyes, mouth, ears, and every other part, but, from the very crown of the head to the ſole of the foot, covered over with a very thick-ſet *hair*, long and much curled. The people who ſaw this, amazed at the appearance, went to touch the corpſe, but the ſhape fell away as it was handled, leaving only a quantity of ſhapeleſs *hair* without the leaſt remainder of the bones, unleſs a ſmall part of what they judged to be the great toe of the right foot. *Hook*'s Philoſ. Collect. N° 2. p. 10.

Though we meet with ſeveral inſtances of *hairs* being voided by urine in medical authors, yet Dr. Mortimer doubts of their being real *hairs*, and thinks them rather ſlender grumous concretions, formed only in the kidneys by being ſqueezed out of the excretory ducts into the pelvis. See Phil. Tranſ. N° 460, p. 707. in the remark.

HAIR *microſcopically examined.* The *hairs* of different animals are very different in their appearance before the microſcope. Malpighi diſcovered *hairs* to be tubular, or compoſed of a number of extremely minute tubes or pipes; this he diſcovered in examining the *hairs* of the main and tail of a horſe, and the briſtles of a boar; and theſe tubes were much more diſtinguiſhable near the ends of the tubes than elſewhere, as they there appeared more open, and ſometimes above twenty of them might be reckoned in one *hair*. In the hedge-hog's prickles alſo, which are of the nature of *hairs*, theſe tubes are very elegantly diſcovered, and may be ſeen to have a medullary part, and valves, and cells. There are alſo in the *hairs* of many animals, in ſome tranſverſe and in others ſpiral lines, ſomewhat of a darker colour, and running from top to bottom in a very elegant manner; a mouſe's *hairs* are of this ſort, and appear in joints, as it were, like the backbone; they are not ſmooth, but jagged on the ſides, and terminate in the ſharpeſt point imaginable. The *hairs* taken from the mouſe's belly are the leaſt opake, and fitteſt for the microſcope. The *hairs* of men, and of horſes, ſheep, &c. are compoſed of ſmall, long, tubular fibres or ſmaller *hairs*, encompaſſed with a rind or bark; and from this ſtructure a ſplit *hair* appears like a ſtick ſhivered by beating. They have roots of different kinds in different animals, and are always thicker at the middle than at either end. *Baker*'s Microſc. p. 246.

Hairs of the Indian deer are perforated from ſide to ſide, and thoſe of our Engliſh ones ſeem covered with a kind of ſcaly bark or rind. The whiſkers of a cat, cut tranſverſely, have in the middle ſomething which reſembles the pith of elder; and the quills of the hedge-hog and porcupine have ſomewhat of a pith in a ſtarlike form. The *hairs* taken from the different parts of the human body, differ very much in their figures, appearing like different ſpecies of the ſame genus in plants. *Hook*'s Microgr. p. 157.

Diſeaſes of the HAIR. Among the many remedies for diſeaſes of the *hair*, the following are recommended in the philoſophical tranſactions. To make *hair* grow, take a quantity of the largeſt and fineſt roots of the common burdock that can be collected; let them be taken out of the ground in the month of December; bruiſe them in a marble mortar, and boil them in a quantity of white-wine till there only remains as much as will cover them; let this be carefully ſtrained off, and every night, going to bed, let the head be waſhed with ſome of it warm. The other preſcription is this: Burn the ſlender twigs of vines to aſhes, and boil theſe aſhes in ſuch a quantity of common water as will make a ſtrong lye; let this be ſtrained clear off, and the head waſhed every night with ſome of it warm. When the *hair* is good, but in danger of falling off by degrees, the aſhes of the vine branches

are

are to be boiled in red-wine inſtead of water, and this lye is to be uſed inſtead of the other. When the perſon wears powder, let ſome hermodactyls be reduced to fine flour and mixed with it: let this be the only powder uſed, and the liquor conſtantly employed in waſhing the head every night, and the falling of the hair will be wholly prevented. Philoſ. Tranſ. N° 288, p. 90.

HAIR-*Balls*, maſſes of *hair* of different ſhapes and ſizes found in the ſtomachs of cows, oxen, calves, deer, and other animals. Some of theſe are covered with a ſmooth, thin, hard, and ſhining coat or ſhell, and others have no covering at all, but ſhew the naked *hairs* on their ſurfaces. Some are of a cheſnut brown, others of an aſh-colour, and others of yet different colours. They are often found to ten or eleven inches in circumference, ſometimes more, but very often much leſs; ſome of them are pretty exactly ſpherical, others of the figure of a prolate ſpheroide, others oblong and compreſſed, and others regularly oval.

Theſe balls are found in one or other of the four ventricles of the animal, and are ſometimes voided by ſtool. It is very evident that they are formed of the *hair* of the animal, which it has licked off and ſwallowed, and which, by the motion of the ſtomach, which in theſe creatures is very ſtrong and frequent, is wrought and compacted together very firmly, and the thin, ſmooth, and ſhining coat which is found upon ſome of them, ſeems formed of the ſlimy matter of the ſtomach.

Among calves, that ſome have theſe *hair-balls* and others not, ſeems in one reſpect owing to their being the firſt or later offſpring of the creature, ſince thoſe that ſuck of a heifer which never had a calf before, have the taking off of a large quantity of hair from the paps. There is always found more or leſs *hair* in the fourth ventricle of theſe calves that have ſucked young heifers, which has unqueſtionably been licked off from the paps, and waſhed down with the milk, and which at times forms theſe balls. *Moreton*'s Hiſt. Northampt. p. 451.

HAIR-*Cloths*, in military affairs, are large pieces of cloth made with half *hair*; they are uſed for covering the powder in waggons, or upon batteries; as alſo for covering charged bombs, or hand-grenades, and for many other uſes in magazines.

Horſe-HAIR *worms*. See AMPHISBÆNA.

HAIR-*weed*, *conferva*, in botany, the name of a genus of moſſes, the characters of which are theſe: it is a water plant, deſtitute of flower and ſeed, ſo far as has hitherto been obſerved, and compoſed only of ſimple and uniform filaments, which uſually extend to a great length, and are often branched, and uſually of a cylindric figure. The generality of authors have ſuppoſed that theſe are not produced of ſeeds, but are formed of ſome viſcous or gelatinous matter floating in the water, by mere appoſition of parts; but this ſeems erroneous, and probably will be hereafter confuted by the diſcovery of their ſeeds, as has been already the caſe in the ſea fucus's, and in many other genera of plants ſuppoſed formerly to want them. The *confervæ* are uſually divided into ſeveral orders, according to the nature of the filaments they conſiſt of. Some conſiſt of equable and even threads, others are knotted or jointed in the manner of a worm, or other ſuch inſect. Theſe are called the geniculated *confervæ*, to diſtinguiſh them from the other ſimple ones; and, finally, others are compoſed as it were of ſeveral globules joined one to another; theſe laſt are called the knotted *confervæ*. *Dillen.* Hiſt. Muſc. p. 11—17.

Of the firſt kind, or ſimple *confervæ*, there are twenty-four ſpecies: 1. The common ſilky floating *conferva*, called hairy river weed, and crow ſilk. This conſiſts of very long filaments of a ſhining green. 2. The wide ſpreading ſilky *conferva*. The filaments of this are broader and thicker than in the former, and are not ſo long, but more numerous from the root. Theſe are common in freſh waters both in ſpring and ſummer. 3. The ſmall byſſus-like *conferva*. This is the ſmalleſt of all the *confervæ*. Its filaments are ſhort, ſlender, or branched, and of a brown colour. 4. The ſlippery or fleſhy alpine *conferva*. This is common in mountainous places, in all waters, and conſiſts of fine and ſlender filaments ſo cloſely arranged, as to make a ſort of fleſhy moſs. 5. The tender mud *conferva*. This is of a browniſh or greeniſh colour, and lies in form of large cluſters on the mud of ditches. Its filaments are extremely ſmall and ſlender. All theſe are ſimple in their figure as well as ſtructure, and compoſed of ſingle threads. The remaining ſpecies of this order are branched. Theſe are, 6. the common forked *conferva*. This reſembles the common *conferva*, but the ends of the filaments are divided ſometimes into two, ſometimes into three branches. 7. The white ſilky *conferva*. This is of about a hand's breadth long, and is finely divided, and of a ſilky texture and white colour. 8. The fennel-like ſea *conferva*. This grows on the rocks in the ſea, and ſomewhat reſembles the leaves of fennel. It is of a middle texture between the fucus's and *confervas*. 9. The forked briſtly *conferva*. This is of a duſky green colour, and grows to five or ſix inches in length; it is common in ditches about the Thames. 10. The ditch hair *conferva*. The filaments of this are three or four inches long, and uſually thick ſet and expanded every way; they are about the thickneſs of a human hair, and are of a duſky green. 11. The ditch cottony *conferva*. This is of a greeniſh colour, with ſome faint caſt of yellow, and grows to a foot or more in length, ſending off ſhort filaments every where from the main ſtems. 12. The white flock ſea *conferva*. This is of a greyiſh or greeniſh white, and is compoſed of filaments ſo cloſely arranged together, that they are ſcarce diſtinguiſhable. 13. The ruſty flock ſea *conferva*. This is larger, longer, and of a harſher ſtructure than the laſt, and is of a browniſh red colour; it grows very common on rocks about the ſea coaſt. 14. The net-like *conferva*. This is compoſed of ſlender but ſomewhat rigid filaments, arranged into a kind of reticular work; it is of a faint greeniſh colour, and is common in ditches. 15. The velvet mill *conferva*. This is common on the boards and ſides of mill pools, and is uſually very ſhort, and of a blackiſh green. 16. The rough fibrous river *conferva*. This is of a ſomewhat rigid texture, of a browniſh colour, and hairy on the branches; it is common in clear waters in auguſt. 17. The thready and ſpungy amphibious *conferva*. This is found ſometimes in the water, ſometimes at land under old walls. It is of a pleaſant green, and compoſed of ſuch ſlender filaments that it is not eaſy to perceive that they are branched. 18. The ſhort pale-green river *conferva*. This is very ſlender, and of about half an inch long, and very much branched or divided; it is of a pale-green colour, and is covered often with little globules of a whitiſh colour, ſeeming to be the eggs of minute water-inſects. 19. The ſoft long ſea *conferva*. This is of a yellowiſh green, and is ſix or eight inches long; it grows on ſtones about the ſea ſhores. 20. The ſhort ſea-green *conferva*. This is diſtinguiſhed from all the reſt by being of a ſea-green, or bluiſh green; it is ſmall and very much branched. 21. The ſhort-lock ſea *conferva*. This is very ſhort, and its filaments thick ſet together, and is frequent on the branches of fucus's and other ſea plants. 22. The latticed ſea *conferva*. This is of a duſky whitiſh-green colour, and of a cancellated figure; it grows on ſmall ſtones by the ſea ſhores, and is of about an inch and half in length, and very much branched. 23. The feathered ſea *conferva*. This is of a deep green colour, and its branches are ſpread every way, and divided into a number of filaments, and hairy all their length. 24. The jelly ſea *conferva*. This grows to ſome ſmall pebble, and ſpreads its branches every way from it; they are an inch and half long, and ſometimes more, and is of a bright green, and of a gelatinous texture. The ſea-gulls eat this in great quantities. *Dillen.* Hiſt. Muſc. p. 17—29.

Of the ſecond order, or the *geniculated conferva*, there are fourteen kinds. 1. The marſh geniculated thready *conferva*. This is of a yellowiſh white colour, and of the thickneſs of a coarſe thread, and of a foot or more in length. 2. The branched geniculated river *conferva*. This is ſhort and of a fine green. 3. The link-jointed *conferva*. This grows in thick tufts, and affords a lodging for ſmall ſhell-fiſh; the filaments are thick, and the joints long; it grows on ſtones about the Bahama iſlands. 4. The river *conferva* with branched ends, called the river beard. This grows to three inches long, and its filaments ſtand very thick, and are of a duſky browniſh green. 5. The branched hairy ſea *conferva*, called the ſea beard. This reſembles the former, but is of a deeper green, and more branched. 6. The ſpreading *ſea beard*. This is ſometimes of a deeper, ſometimes of a paler green, and is very much branched, and the geniculæ very obvious and evident; it is common on ſmall ſtones on the ſea coaſts. 7. The cluſter *conferva*. This is very full of branches, and of a pale green; it grows in freſh waters. 8. The woolly ſea *conferva*. This is very much branched, and has its filaments divided into numerous ſlender branches, which are ſo interwoven as to reſemble a lock of wool; it is common in ſalt-water ditches. 9. The fine ſilky river *conferva*. This ſeldom exceeds three inches in length, and its filaments are divided at their ends into numerous ſhort and extremely fine threads. 10. The palmated ſea *conferva*. This uſually grows upon the fucus's and other ſea plants, and is of a browniſh green. 11. The larger gelatinous coralline-like ſea *conferva*. This is whitiſh and pellucid, and much reſembles ſome of the corallines in its external figure. 12. The finer ſlippery coralline-like ſea *conferva*. This is of a tougher texture, and finer ramification than the former; it is uſually of a purpliſh-red colour, and ſometimes of a greeniſh or whitiſh. 13. The more branched jointed ſea *conferva*. This grows to about four inches long, and is of a reddiſh colour, and ſhews its joints very remarkably. 14. The hollow ſea *conferva*. This is from two to four inches long, its branches inordinately diſpoſed, and all much branched; it is common on the coaſt of Cornwall.

Of the third order, or the knotted *confervæ*, there are only eight known ſpecies. 1. The ſlippery red ſea-pearl *conferva*. This is a very elegant little plant, and uſually grows upon the fucus's and other ſea plants. 2. The ſlippery coralloide-like ſea *conferva*. This grows like the coralloide moſſes, forming a ſort of ſhrub; it is of a beautiful red colour, and is common on the coaſts of the Iſle of Man, and in ſome other places. 3. The larger mouſe-coloured frog's ſpawn *conferva*. This grows to ſtones and ſticks in freſh-water rivers, and is three

of the noſe, vomiting of blood, dyſentery, bloody urine, too great flow of the menſes, &c. all which have the ſame immediate cauſes, the ſame effects and conſequences, and ſuggeſt the ſame indications of cure; which are, in the beginning to diminiſh the quantity of blood, and to make a revulſion by opening a vein in the arm, foot, &c. then to moderate the velocity and rarefaction of the blood by cooling medicines; and laſtly, to contract and ſtrengthen the veſſels by aſtringents. The ſame method muſt take place in all, and therefore the general ſtyle of this claſs of diſeaſes ought to be hæmorrhage. See Medic. Eſſ. Edinb. Vol. I. Art. 25.

HÆMORRHAGES (*Cycl.*)—Theſe are divided, by the medical writers, into natural and preternatural.

Natural *Hæmorrhages* comprehend bleeding at the noſe, ſpitting of blood, the fluxes of the hæmorrhoids and menſes, the lochia in lying-in women, vomiting of blood, and voiding blood by urine.

The preternatural *Hæmorrhages* are ſuch as derive their origin from external accidents, as falls, blows, and wounds. Some alſo comprehend, under this term, the artificial evacuations, by bleeding, cupping, and the like.

Hæmorrhages differ much, according to the age and ſtate of the patient, and other accidents. *Hæmorrhages* from the noſe are moſt frequent in young perſons, thoſe of the hæmorrhoids in people of a middle age, or later in life; the ſpitting of blood, to perſons in a middle age; and voiding blood by urine uſually to older people. Some *Hæmorrhages* are periodical, and others vague or uncertain. The firſt obſerve ſome ſtated period of time for their return upon people; the laſt are wholly uncertain in that particular. Some are alſo termed critical; theſe are ſuch as happen at the criſes of fevers. There are uſually violent pains about the part whence natural *Hæmorrhages* are to proceed; but theſe always go off as ſoon as the bleeding comes on in due quantity.

Perſons moſt ſubject to HÆMORRHAGES. Young perſons of a healthy and florid conſtitution are moſt ſubject to *Hæmorrhages*; people of plethoric habits are alſo much ſubject to them, and eſpecially ſuch whoſe blood is ſound and fluxile, not ſubject to any dyſcracy. Thoſe who drink much wine, or eat high ſeaſon'd foods; and, more than all theſe, perſons who are ſubject to violent paſſions, eſpecially to anger. Hence it is that brutes are very rarely afflicted with them.

Cauſes of HÆMORRHAGES. Among the principal of theſe are to numbered a plethora, violent commotions of the body, hot foods and liquors, a heat of the ſeaſon, a ſudden cooling of the body after violent heat, and paſſion. *Junker*'s Conſp. Med. p. 12.

Prognoſtics from them. *Hæmorrhages* from the lungs, and vomiting, and voiding blood by urine, are all very dangerous. The others, when regulated, and in due proportion, are ſalutary, and often prevent diſeaſes. And the common cuſtom of ſtopping them by aſtringents, or otherwiſe, is often productive of ſtagnations, inflammations, and violent fevers.

Method of Cure. *Hæmorrhages* flowing moderately, and from natural paſſages, require no aſſiſtance of medicine; when they happen to plethoric perſons, they are to be ſuffered to continue a ſufficient time. When the quantity of the blood is leſſened by theſe diſcharges, its quality, if diſtemper'd, is next to be amended by internal remedies; if ſulphureous and acrid, by nitrous medicines and abſorbents, and by gentle acids; to this purpoſe ſal prunellæ, crabs eyes, lemon juice, and the like, are excellent; if the blood be too thick, a ſmaller quantity of food, and a larger of drink, is to be preſcribed, and to this the reſolvent and attenuating medicines are to be added, as the neutral ſalts and diuretic roots. Theſe are the neceſſary things out of the fit; and during the bleeding ſuch things are to be given as repreſs the violent motion of the blood, ſuch as cinnabar, nitre, and crab's eyes, ſated with a vegetable acid. Spirit of hartſhorn and tincture of antimony may next be given, and, after theſe, moderately ſtyptic and anodyne medicines; but the ſtronger ſtyptics and aſtringents are not to be uſed but with great caution.

Mr. Petit, in examining all the different methods employed by ſurgeons for ſtopping *Hæmorrhages*, aſſures us, that in each of them a piece of clotted blood is contained in the veſſel, which ſerves to keep the blood from eſcaping, after the effect of the medicine, firſt employed, ceaſes. Where abſorbents or aſtringents are uſed, that there is not only a cylindrical piece of clotted blood in the veſſel, but there is a covering of it on and round the orifice of the cut veſſel; which cylindrical form makes it eaſily puſhed out. Cauſtics have much the ſame effects, only the covering on the extremity of the veſſel is firmer, by the ſolid parts being confounded with the clotted extravaſation. When a ligature is uſed, there is no clotted covering, and the internal plug is of a pyramidal figure, therefore it is with difficulty that ſuch a clotted piece can be puſhed out. Beſides this advantage, the ſides of the veſſel, which are brought to be contiguous by the ligature, will probably grow together; for which reaſon, and the ſaving both pain to the patient, and loſs of ſubſtance of the ſtump, he prefers compreſſion to all the other methods. In proof of the effects of coagulated blood ſtopping the efflux of blood from large arteries, he relates two hiſtories; in one, the artery was oſſified; and, in the other, it lay in a bony groove: So that, in both, it muſt have been a plug which prevented the *Hæmorrhage*. He endeavours to prove, that the plug is ſtronger and firmer, when formed of coagulated lymph, than when compoſed of red blood. For executing the compreſſion right, after amputation of the larger extremities, he has contrived a machine, compoſed of a large circular belt, to be put round the trunk of the body, or ſuperior part of the member, which is to ſuſtain the bandage, by ſtraps going from it, which are faſtened, at the other end, to a leſſer circular belt, that is put round the part of the member where the tourniquet is commonly applied. This leſſer belt is to have two ſcrews, &c. in the form of his ſcrew-tourniquet. From this leſſer belt four ſtraps go out, to croſs over two plates with their ſcrews, as in the tourniquet, placed on the ſtump. When the operation is performed, he applies thick bolſters of lint on the ſide of each large artery fartheſt from the bone, and placing the interior convex plate of the ſmall tourniquet on them, he ſecures it in the right ſituation with the four ſtraps, and ſcrews down the plate on the bolſters and veſſel, which being preſſed between the inſtrument and the bone, can allow no blood to paſs. See Mem. de l'Acad. des Sciences, 1731 & 1732.

Mr. Morand imagines, that the change which happens to the artery, on being wounded, aſſiſts greatly in ſtopping the flux of blood; and that this and the congelation are uſually joint agents in this caſe. When the artery is either empty, or at leaſt leſs diſtended than uſual with blood, it naturally will collapſe, in ſome degree, and become more or leſs flatted; and if this goes ſo far as that the ſides come to touch one another, they naturally unite, and the whole cure is performed by this alone. And this is very frequently the caſe in wounds of ſmall arteries, and in internal *Hæmorrhages*. Nor is it more difficult for a large veſſel to become flatted and collaſpe in the ſame manner, till its ſides touch, provided that the courſe of the blood thro' it be by any means reſtrained. Mr. Morand gave the academy of ſciences of Paris a very remarkable account of a thing of this kind, which fell within his knowledge. A countryman having received a very violent blow upon his arm, had afterwards no pulſation in the artery, in that part of the arm beneath the place where the blow had been given, tho' he had a plain one in that part of the artery which was above it. There was at firſt ſome fear that the arm muſt have been taken off, but Mr. Morand ſaved it, and, as the cure went on, the pulſe was obſerved gradually to be felt again in the hand, and lower part of the arm. The occaſion of this was plainly, that the artery had become flatted by the blow, and the blood was unable to force the oppoſition, and circulated only thro' the ſmall veſſels, while the injury from the blow remained violent, but gradually made its way again, as the parts reſtored themſelves to their natural ſtate. Memoirs Acad. Scienc. Par. 1736.

A wounded artery, in caſe it be cut quite aſunder, is in the ſame ſtate with a cord which is cut in two while it is on the ſtretch. We well know, that when this is done, the two ends recede a great way from one another, and that in proportion to the tention they had before: The caſe is wholly the ſame with an artery, and that for the ſame reaſon. Its longitudinal fibres are drawn back and ſhortened, and its circular ones are, by this very action, compelled to run together more cloſe than they naturally ſhould, and in conſequence they form thicker rings about the extremities of the divided veſſel; the conſequence of which is, that they make the inner hollow narrower. This is a thing of great importance, as not only the ſides of the veſſel are brought nearer together, and therefore they more eaſily may come to touch; but the diameter of the bore of the artery being leſs, a ſmaller maſs of congealed blood may ſtop it; and this blood, adhering to the ſides of the veſſel on every hand, fills up the paſſage as it congeals, and, by degrees, brings them together.

Mr. Petit, in confirmation of his opinion, that *Hæmorrhages* are ſtoppod by plugs of clotted blood, ſhewed the academy of ſciences, at Paris, ſuch a plug, in an artery which had been opened. See Hiſt. de l'Acad. des Scienc. 1735.

What is remarkable is, that this plug of clotted blood had loſt nothing of its conſiſtency, nor of its adheſion to the aperture of the artery, after lying two months in water, and three years in brandy. This ſhews the plug to be analogous to a ſcar: Nor is this ſtrange, ſince both are formed from the juices deſtined to the nouriſhment of the part. Hiſt. de l'Acad. &c. ibid.

The ſtyptic powder of Helvetius has been found excellent in *Hæmorrhages*. See STYPTIC *Powder of Helvetius*.

The *Vitrum antimonii ceratum* has likewiſe proved very efficacious in uterine *Hæmorrhages*. See VITRUM *antimonii ceratum*.

Soft compreſſion is, by Garengort, thought more effectual to ſtop *Hæmorrhages*, than hard ſubſtances; and its uſe recommended even when ſtitches of arteries give way, in which caſe the uſe of vitriol buttons is condemned.

Internal HÆMORRHAGES. The Omentum itſelf is not free from being the ſeat of fatal internal *Hæmorrhages*, tho' this rarely happens. The Peterſburg commentaries give us an account of a woman, who dying almoſt immediately of a blow ſhe received on the belly, was opened, and the cavity of the abdomen

red circle, or areola, about the nipple, from its ſimilitude to the circles formed round the ſun and moon at certain times, and called *Haloes*.

HALOSACHNE, in the materia medica of the antients, was a name given to a peculiar ſea ſalt, made by the evaporation of ſmall quantities of ſea water on rocks, by the ſun's heat. It no way differed from the common ſea ſalt in its qualities or properties, except that it did not crackle ſo much in the fire; and this was merely owing to its being compoſed of finer particles, and in form of a ſort of powder, in which ſtate even common ſea ſalt will no more crepitate in the fire than this. *Hill*'s Hiſt. of Foſſ. p. 386.

Tho' this, however, was the common appearance of the *Haloſachne*, it was not its univerſal one; for it was found ſometimes concreted on, or embodied in the alcyonia, and other marine productions, and then appeared in a harder form.

HALOSANTHOS, *Flower of Salt*, in the materia medica of the antients, was a ſubſtance, tho' commonly ſuppoſed only an efflorescence of common Salt, yet really a bituminous matter mixed with ſome particles of ſalt.

It was a tough, viſcous, and fatty ſubſtance, found ſwimming on the waters of ſome ſprings and rivers, and was of a ſoft conſiſtence, and of a yellow colour. And the ſame ſubſtance is ſtill found in the ſame places, and that not only yellow, but of various other colours, as blackiſh, green, or blue. Theſe it takes up, according to the various earths it has waſhed againſt on the ſhores, or the ſubſtances mixed among it at its original concretion. The deſcription Dioſcorides gives of it is very expreſs; he ſays it was found ſwimming on the waters of the Nile, and ſome lakes; and was of a yellow colour, very ſharp to the taſte, fattiſh, and of an unpleaſant ſmell. This, tho' that author did not diſtinguiſh to what claſs of foſſils it properly belonged, is enough, however, to teach us what it truly was; and it is ſomething wonderful, that thoſe who have accounted it a Salt, ſhould not obſerve that the ſame author adds, that it was ſoluble in oil, and not in water. *Hill*, Hiſt. Foſſ. p. 386.

HALTER, in the manege, a head-ſtall for a horſe, of Hungary leather, mounted with one, and ſometimes two ſtraps, with a ſecond throat band, if the horſe is apt to unhalter himſelf.

HALTER-*Caſt*, is an excoriation of the paſtern, occaſioned by the halter's being entangled about the foot, upon the horſe's endeavouring to rub his neck with his hinder feet.

HALTER-*Strap* or *String*, a cord, or long ſtrap of leather, made faſt to the head-ſtall, and to the manger, to tye the horſe.

HALTING (*Cycl.*)—*Halting* in a horſe, happens ſometimes before, and ſometimes behind; if it be before, the ailment muſt neceſſarily be in the ſhoulder, knee, paſtern, flank, or foot. If it be in the ſhoulder, it muſt be toward the withers, or the pitch of the ſhoulder, and this may be known, in that he will a little draw his leg after him, and not uſe it ſo nimbly as he does the other.

If he caſt it more outward than the other in going, it is a ſign of lameneſs, and that the cauſe lies in the ſhoulder; the rider ſhould then take him in his hand, and turn him ſhort, firſt one way, and then the other, and it will be eaſily ſeen which ſhoulder the pain is in, and he will either favour that leg, or trip in the turning. The lameneſs may be ſeen in him alſo while ſtanding in the ſtable, for he will there hold the lame leg out more than the other. If he is worſt when the rider is on his back, it is a ſign that the complaint is in the withers, and this may be ſoon tried, by preſſing down the ſaddle, and pinching him in that part; for if this be the caſe, he will flinch at it, and probably he will offer to bite.

If the complaint be ſeated in the knee, the only way of making this out, is in the going, for he will be ſeen to be ſtiff of this, and not to move it ſo freely as the other.

If the complaint be in the flank, or ſhin bone, it may be ſeen, or felt, being a back ſinew-ſtrain, ſplinter, or the like. If in the bending of the knee, it is a malander, and that alſo is eaſily diſcovered. When the paſtern, or lower joint, is affected, it will be ſeen by his not bending it ſo freely as the other, and generally, if the hand be laid upon the place, it will be found to be very hot.

If the complaint be in the foot, it muſt be ſituated either in the coronet or ſole, and, if in the coronet, it probably came by ſome ſtrain or wrench. If in the hoof, by ſome overreach or diſtemper in or about the fruſh. If it be in the ſole, it probably ariſes from ſome nail or prick.

Theſe are the methods of judging of the cauſe of a horſe's *halting*, and that often leads very directly to the cure, when a great deal of time and coſt might otherwiſe be thrown away in applying remedies, as has often been done to a part a yard or more diſtant from the ſeat of the diſorder.

HAMAMELIS, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is a four-leav'd perianthium, placed in an erect poſture, and compoſed of oblong, obtuſe, and equal leaves. The flower is compoſed of four ſtrait, very long, and equal leaves. The ſtamina are four tapering filaments, of the length of the cup. The antheræ are ſimple. The germen of the piſtil is oval and hairy, and ends in two ſtyles, which are of the length of the ſtamina. The ſtigmata are ſimple. The fruit is a capſule divided into two cells, with two valves. The ſeed is ſingle, ſmooth, but of an oblong oval figure. *Linnæi* Gen. Plant. p. 54.

HAMBLING. See HAMELING, *Cycl.*

HAMFARE, in our old writers, a breach of the peace in a houſe. *Brompton* in Legibus, Hen. 1. c. 80. *Blount*.

HAMMA, a word uſed, by ſome chirurgical writers, for a knot that faſtens a bandage.

HAMMER, in the manege. See SHOEING *Hammer*.

HAMMOCK (*Cycl.*)—Mr. Le Cat has contrived a *Hammock* of Turkey leather, which may be eaſily raiſed, or let down, with a ſick perſon in it, by ropes and pullies. See Phil. Tranſ. N°. 468. §. 3.

HAMMON, in the heathen mythology. See CHAMOS.

HAMMOSTEUS, the oſteocolla of the ſhops. See the article OSTEOCOLLA.

HAMSOKEN, the liberty or privilege of a man's own houſe; alſo a franchiſe granted to lords of manors, whereby they hold pleas, and take cognizance of the breach and violation of that immunity: And it likewiſe ſignifies *quietantiam miſericordiæ intrationis in alienam domum vi & injuſte*. *Fleta*, lib. cap. 47. In Scotland violations of this kind are equally puniſhable with raviſhing a woman. *Skene*. And our old records expreſs burglary under the word *Hamſocne*. *Blount*. *Cowel*. in voc.

HANAB ALTHALEB, in the materia medica, a name uſed, by the antient Arabian writers, to expreſs the lycoperſicum, or pomum amoris. The meaning of the name is the wolfs-grape; and the Greeks have called it by an exactly correſponding term, lycoſtaphylon. We generally call it lycoperſicon, or the wolf's peach. Some have ſuppoſed this the name of a plant differing from the pomum amoris; but it appears, on a ſtrict enquiry, to be wholly the ſame. Some of the Greeks have uſed the word ſtrychnus in this ſenſe alone; and Alexander Trallian, in particular, always makes it the name of an eſculent plant; but Dioſcorides and Theophraſtus uſe it as the common name of the eſculent nightſhade, and of the poiſonous kinds.

HAND (*Cycl.*)—*Cartilages of the* HAND. All the bones of the carpus, metacarpus, and fingers, are cruſted over with cartilages, at thoſe places called cartilaginous ſurfaces, in the deſcriptions of thoſe bones; but in the freſh bones they are much thicker, ſofter, and whiter, than in the ſkeleton. In adult ſubjects, their figure indeed remains the ſame in both ſtates, but it changes in the dried bones of younger ſubjects, particularly thoſe of children. *Winſlow*'s Anatomy, p. 143.

Ligaments of the HAND. The ligaments of the carpus are very numerous. Some of them ſerve to tie each bone of it to the neighbouring bones in the ſame rank; and theſe are ſo very ſhort as to allow theſe bones only a very ſmall degree of motion; ſome of them tie the bones of one row to thoſe of another; theſe are likewiſe made up of numbers of filaments, but are not ſo ſhort as the former, and allow thoſe bones a more manifeſt motion; and laſtly, there are other ligaments of the wriſt, by which the three firſt bones of the firſt row are connected with thoſe of the arm, and to theſe may be added thoſe of the ſecond row, by which its bones are connected to thoſe of the metacarpus, and to the firſt phalanx of the thumb. Beſide all theſe ſhort ligaments belonging to each bone, in both rows, the rough ſurfaces of all the bones, eſpecially of thoſe which form the convexity of the carpus, give inſertion to a great many ligamentary faſciculi, which are ſtretched over, and cloſely united to the former ſmall ligaments, and probably ſerve to ſtrengthen them: There is likewiſe a conſiderable ligament, called the inner tranſverſe ligament of the carpus. It has formerly been called an annular ligament, and may ſtill juſtly enough retain that name.

The bones of the metacarpus, beſide thoſe ligaments by which they are tied to the ſecond row of the bones of the carpus, have ſeveral others by which both their baſes and heads are connected together. The baſes of the third and fourth bones are not ſo cloſely connected as the reſt, and therefore have a very ſenſible motion. The heads of theſe bones are firmly tied to each other by a ſtrong ligament, ſituated tranſverſely in the palm of the hand, and fixed, by diſtinct productions, in the neighbouring parts of the heads. The firſt phalanx of the thumb is fixed to the os trapezium by ſhort ligaments which paſs obliquely over the articulation. The firſt phalanges of the four fingers are joined to the heads of the metacarpal bones by ligaments like the former, and almoſt in the ſame manner. The third phalanx of the thumb is joined to the ſecond, and the ſecond phalanges of the other fingers to the firſt, and the third to the ſecond, by lateral ligaments, almoſt in the ſame manner as the bones of the fore arm to the os humeri; that is, theſe ligaments ſpread from a point fixed in the lateral tubercles of the heads of the phalanges, and are inſerted in their other extremity like radii in the baſes of the neighbouring phalanges. The two firſt phalanges of each finger have a ſtrong ligamentary vagina, inſerted in the rough line or ridges, on their flat ſides; theſe vaginæ are lined with a mucilaginous membrane, which runs like a tube from one phalanx to the other, over the articulation. Theſe ſerve for frænа to the

flexor muſcles of the fingers, the tendons of which paſs thro' them. *Winſlow*'s Anatomy, p. 143.

Luxation of the HAND. Notwithſtanding that the *Hand* is very accurately connected to the ulna and radius, by means of the carpus, and ſtrong ligaments, yet it is liable to luxations, and ſometimes ſuffers them in all directions either outward or inward, or on either ſide, but is generally not ſo eaſy to be luxated ſideways, as in the other directions, becauſe of the two proceſſes of the radius and ulna which guard it on each ſide. The *Hand* is ſaid to be luxated forwards or inwards, when it recedes from the muſcles which bend the fingers, and to be luxated backward, when it departs from the muſcles which extend the fingers. Much in the ſame manner alſo the *Hand* is ſaid to be luxated outwards, when the carpus makes a tumour near the thumb, and a cavity near the little finger, and to be luxated inward, when the contrary of this happens.

To reduce luxations of the *Hand*, it muſt be ſufficiently extended by two aſſiſtants, one of which is to lay hold of the *Hand*, and the other of the humerus, pulling in oppoſite directions; and that part of the extended *Hand* where the ſinus is, muſt be placed on a flat and even table, that whatever ſticks up may be depreſſed into its place; by which method the *Hand*, in whatever part luxated, may be very readily reduced into its natural ſeat. It alſo ſometimes happens, that one or two of the eight little bones of the carpus are luxated and diſtorted from their natural ſeat by ſome external violence. When this happens, there will be perceived a tumour in one part, and a cavity in another, which may be perceived by the feeling, as well as by the ſight, and the patient will feel very violent pains. This is a luxation very readily and eaſily cur'd, by extending the *Hand* as before directed, and replacing the bone. *Heiſter*'s Surg. p. 165.

HAND, in the manege. To make a horſe right upon the *Hand*, and free in the *ſtay* or *reſt*, he muſt be taught to know the *Hand* by degrees, and gentle methods; the horſeman muſt turn him, or change *Hands*; ſtop him, and manage with dexterity the *appui*, or preſſure of his mouth, ſo as to make him ſuffer chearfully and freely the effect of the bit-mouth, without reſiſting or reſting heavy upon the *Hand*. The ſhort, or *Hand* gallop, teaches horſes to be right upon the *Hand*.

HAND is alſo found, in many other terms, or phraſes of art belonging to the manege, as,

To ſlack or yield the HAND, is to ſlacken the bridle.

To hold up, or ſuſtain the HAND, is to pull the bridle in.

To guide a Horſe by the HAND, is to turn or change *Hands* upon one tread.

Appui, or ſtay of the HAND. See APPUI.

Beat upon the HAND. See BEAT and CHACK.

To preſs upon the HAND. See PRESS.

To change the HAND. See CHANGE.

Effects of the HAND. See EFFECTS.

Haſten the HAND. See HASTE.

To feel a Horſe upon the HAND. See FEEL.

Full HAND, *or full Reſt upon the* HAND. See APPUI and MOUTH.

To have Mares covered in the HAND. See STALLION.

To make a Horſe part from the HAND, or ſuffer him *to ſlip from the* HAND, is to put on at full ſpeed.

To make a Horſe part right from the HAND, he ſhould not put himſelf upon his back or reins, but bring down his hips.

All HANDS. A horſe is ſaid to turn upon *all Hands*, that is not reſty for one *Hand*; this is called in French *entier*. See ENTIER.

Fore-HAND and *Hind*-HAND of a horſe, is an expreſſion diſtinguiſhing the parts of a horſe, as divided into the fore and hinder parts, by the ſituation of the horſeman's *Hand*. The parts of the fore-hand are the head, the neck, and the fore quarters. Thoſe of the hind-hand include all the other parts of the body.

HAND, or HANDING, in the ſea language. When a thing is to be delivered away, or paſſed from one to another, or to be brought to any one, then the word is, *hand* it this way, or that way. Alſo, when more men are wanted to do any labour, as hoiſing, &c. they call for more *Hands*, not more men.

HAND *in and out*, in our old writers, the name of an unlawful game, now diſuſed and prohibited by the ſtatute 17 Edw. 4. c. 2. *Blount*, *Cowel*.

HAND-*Barrow*, in the military art, is commonly made of hard light wood. It is of great uſe in fortification, for carrying earth from one place to another, and in a ſiege, for carrying bombs, or cannon ball, along the trenches, and for ſeveral other uſes.

HAND-*Spike*, a leaver, or piece of aſh, elm, or other ſtrong wood, five or ſix feet long, cut thin like a wedge at one end, that it may get the eaſier betwixt things which are to be ſeparated, or under any thing that is to be raiſed; it is better than a crow of iron, becauſe its length allows a better poiſe.

Hand-ſpikes are frequently uſed in ſhips, as to traverſe the ordnance, to heave withal in a windlaſs, to weigh up the anchor, &c.

HANDACOCHA, in botany, a name by which Pliny, and ſome other authors, have called the trifolium bituminoſum, or ſtinking trefoil. *Ger*. Emac. Ind. 2.

HANDFUL, (*Cycl.*) in the manege. Two *Handfuls* are called, in French, *une jointeè*, and is as much grain or bran as two hands will hold, when joined together. A quantity frequently ordered to be given horſes.

HANDGRITH, in our old writers, peace or protection given by the king with his own hand.—*Hæc mittunt hominem in miſericoridia regis, infractio ſeu violatio pacis quam per* Manum *ſuam dabit alicui*. Leg. Hen. 1.

The word is Saxon, from *Hant* or *Hond*, manus, and *grith*, pax. *Blount*. in voc.

HANDY *Warp*, in our old writers, a kind of cloth mentioned in ſtat. 4 & 5 Ph. & Mar. c. 5. *Blount*.

HANG *Benches*, in mining. See STOWS.

HANIG, in our old writers, a term for cuſtomary labour to be performed. *Blount*. in voc.

HANDLES *of a Plough*, the name given, by farmers, to the two pieces of the plough faſtened to the earth-board, and to the ſheat, and ſerving the plowman to reſt his force upon in the guiding of the plow. When they are conſiderably long, the plow is always guided the better, and the land is better tilled; but the lazy plowmen are apt to cut them off ſhorter, that, by bearing their whole weight upon them, they may, in a manner, ride, inſtead of walking. If they ſhould ride, in this manner, on the long handles, they would tilt up the end of the beam, and raiſe the plow out of the ground. *Tull*'s Huſbandry.

HANTELODE, in our old writers, ſignifies an arreſt.

The word is Saxon from *Hant*, hand, and *load*, *i. e.* laid; *Manus immiſſio*, becauſe arreſts are made by laying hold on the debtor, &c. *Du Cange*, *Blount*.

HAQUE, in our old writers, a little hand-gun, prohibited to be uſed for deſtruction of game, &c. by ſtatute 33 Hen. 8. c. 6. and 2 & 3 Ed. 6. c. 14. There is alſo the *half Haque*, or *Demi-Haque*, within the ſaid acts. Terms of Law.

HARACH, in the eaſtern revenues, is a poll tax laid on the Chriſtians and Jews in Ægypt. This had long been in the hands of the janizaries, but of late has got into the power of an officer, called thence the *Harach Aga*, ſent from Conſtantinople. Before this the Chriſtians paid but a trifle, by capitulation with ſultan Selim; and this capitulation the coptis ſay they have in their own hands, it was only two dollars and three quarters a head. The great men conſented to this, and now they pay either two and three quarters, or five and a half, or eleven, according to their ſubſtance, each dollar being about half a crown. The perſons who pay this are thoſe only who have arrived at the age of ſixteen. *Pocock*'s Egypt, p. 173.

HARAHA, in botany, a name uſed, by ſome authors, for the Gourd. *Ger*. Emac. Ind. 2.

HARANKAHA, in the materia medica, a name by which ſome authors have called zedoary. *Herm*. Muſ. Zeylan. p. 50.

HARD *Bodies*, in natural hiſtory. By *hard Bodies* are underſtood ſuch bodies as are abſolutely inflexible by any ſhock or colliſion whatſoever.

This is the common meaning of the term; but Huygens, by *hard Bodies (Corpora dura)* meant what others call perfectly elaſtic bodies; for he thus expreſſes himſelf, *Quæcunque ſit cauſa*, Corporibus duris, *a mutuo contactu reſiliendi cum ſe invicem impinguntur*; *ponimus, cum corpora duo inter ſe æqualia, æquali celeritate, ex adverſo ac directe ſibi mutuo occurrunt, reſilire utrumque eadem qua advenit celeritate. Huyg*. De Motu Corp. ex Percuſſ. Hypoth. 2.

But this hypotheſis is conſiſtent only with perfect elaſticity, and not with the common ſuppoſition of *hardneſs* or inflexibility, which produces no reſilition.

The laws of motion for *hard bodies* are the ſame as for ſoft bodies; and theſe two ſorts of bodies might be comprized under the common name of *unelaſtic*.

Some who follow Leibnitz's doctrine, concerning the meaſure of the moving force of bodies, deny the exiſtence of *hard* or inflexible bodies. And it is ſo far true, that no experience ever taught us, that there are any ſuch. The hardeſt bodies, to appearance, do not preſerve their figures in colliſion, ſuch bodies being only elaſtic, yielding to the ſhock, and then reſtoring themſelves. See *s'Graveſand*. Phyſ. Elem. Math. *Deſaguliers*, Exp. Philoſ. *Muſchenbroek*, &c.

Mr. Bernoulli goes ſo far as to ſay, that *hardneſs*, in the vulgar ſenſe, is abſolutely impoſſible, being contrary to the law of continuity. (See CONTINUITY.) For ſuppoſing two ſuch *hard* bodies of equal maſſes, and with equal velocities to meet directly, they muſt either ſtop or return after the colliſion. The firſt ſuppoſition is commonly admitted; but then it follows, that theſe bodies muſt inſtantaneouſly paſs from motion to reſt, without going thro' ſucceſſive diminutions of their velocities till they ſtop. But this is thought to be contrary to the fundamental laws of nature. See *Bernoulli* Oper. Tom. 3. p. 10.

Hence this author rejects perfectly ſolid and inflexible atoms, which others think a conſequence of the impenetrability of matter. See *Maupert*. Mem. de l'Acad. de Berlin. T. 2. p, 284.

HARD *Horſe*, in the manege, is one that is inſenſible of whip or ſpur.

HARDENING (*Cycl.*)—HARDENING *of timber*. The Venetians are famous for the ſoundneſs of their ſhips, which do not

rot

rot as thoſe of other nations, but will endure many times the common period. Tachenius tells us, that the whole ſecret of this conſiſts in the manner of their *hardening* their timber intended for this ſervice; and that this is done by ſinking it in water while green, and leaving it there many years. This prevents the alkali, or that ſalt which furniſhes the alkali in burning, from exhaling afterwards; and by this means the timber becomes almoſt as incorruptible as ſtone. It is evident that the exhaling of this ſalt, and the rotting of wood, have ſome very great connexion with one another, ſince the more ſound any piece of timber is, the more ſalt it proportionably yields; and the wood which is rotten is found on trial to contain no ſalt at all. *Tachen.* Hippocr. Chym. See the article TIMBER.

HARDNESS *of bodies*. See HARD *bodies*.

HARDWIC. See HERDEWIC, *Cycl.*

HARDY-*Shrew*, a name given by the people in ſome parts of England to the mus araneus, called more uſually the *ſhrew*, or the *ſhrew* mouſe. See MUS *araneus*.

HARDY *Shrubs*. The two *hardieſt ſhrubs* we are poſſeſſed of are the ivy and box; theſe ſtand the ſeverity of our ſharpeſt winters unhurt, while other *ſhrubs* periſh; and trees have their ſolid bodies ſplit and torn to pieces. In the hard winter of the year 1683, theſe two *ſhrubs* ſuffered no injury any where; tho' the yews and hollies, which are generally ſuppoſed very hardy, were this winter in ſome places killed, and in others ſtripped of their leaves, and damaged in their bark. Furze-buſhes were found to be ſomewhat *hardier* than theſe, but they ſometimes periſhed, at leaſt down to the root. The broom ſeemed to occupy the next ſtep of *Hardineſs* beyond theſe; this lived where the others died; and where even this died, the juniper *ſhrubs* were ſometimes found unhurt. This laſt is the only *ſhrub* that approaches to the *Hardineſs* of the box and ivy, but even this does not quite come up to them, for while they ſuffer nothing in whatever manner they are expoſed, the juniper, tho' it bears cold well under the ſhelter of other trees, yet cannot bear the viciſſitudes of heat and cold, inſomuch that ſome juniper *ſhrubs* were found half dead, and half vigorous; that ſide which faced the mid-day ſun, having periſhed by the ſucceſſive thawings and freezings of its ſap; while that which was not expoſed to the viciſſitudes of heat, had bore the cold perfectly well. Such *ſhrubs* as are not *hardy* enough to defy the winter, but appear half dead in the ſpring, may often be recovered by Mr. Evelyn's method of beating their branches with a ſlender hazel wand, to ſtrike off the withered leaves and buds, and giving a free paſſage to the air to the internal parts. Where this fails, the method is to cut them down to the quick; and if no part of the trunk appears in a growing condition, they muſt be taken off down to the level of the ground. Philoſ. Tranſ. N° 165.

HARDER, in zoology, a name given by ſome to a fiſh of the mullet kind, called by Marcgrave paſtor piſcis. *Willughby*'s Hiſt. Piſc. p. 276. See the article PASTOR *piſcis*.

HARE (*Cycl.*)—The ſportſmen diſtinguiſh four ſorts of this animal: the one lives in the mountains; the ſecond kind in open fields; a third kind in marſhy grounds; and the fourth is a rambler, having no particular fixed ſpot of reſidence. It is eaſy to ſee that theſe are no diſtinction in the eye of the naturaliſt; but they have their ſeveral properties according to theſe differences of place, which are of conſequence to the ſportſmen. Thus the mountain *Hares* are the ſwifteſt of all, and the marſh *Hares* the ſloweſt; the field *hares* have a middle degree of ſwiftneſs between theſe; and the rambling *Hares* are the moſt difficult of all others to hunt, for they are not only conſiderably ſwift, but they generally know all the coverts and thickets, and have the art to make a thouſand doublings and eſcapes that the others would not think of.

Hares and rabbits are very miſchievous to new planted orchards, by peeling off the barks of the tender and young trees for their food; they do alſo the ſame ſort of miſchief to nurſeries; for the prevention of which, ſome bind ropes about the trees up to ſuch a height as they are able to reach; ſome daub them with tar; but tho' this keeps off the *Hares*, it is itſelf miſchievous to the trees; but this hurtful property of it is in ſome degree taken off by mixing any kind of fat or greaſe with it, and incorporating them well over the fire. This mixture is to be rubb'd over the lower part of the trees in November, and will preſerve them till that time the next year, without any danger from theſe animals. It is only in the hard weather in the winter ſeaſon, when other food is ſcarce, that theſe creatures feed on the barks of trees.

People who have the care of warrens, pretend to an odd way of making *Hares* fat when they get them there. This is the ſtopping up their ears with wax, and rendering them deaf. The *Hare* is ſo timorous a creature, that ſhe is eternally liſtening after every noiſe, and will run a long way on the leaſt ſuſpicion of danger; ſo that ſhe always eats in terror, and runs herſelf out of fleſh continually. Theſe are both prevented by her feeding in a ſafe place, and that without apprehenſion; and they ſay ſhe will always readily be fattened by this.

HARE, in zoology. See LEPUS.

HARES *Ears*, *Beupleurum*, in botany, the name of a genus of umbelliferous plants, the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral leaves placed in a circular form, and ſtanding on a cup, which afterwards becomes a fruit compoſed of two oblong ſeeds, gibboſe and ſtriated on one ſide, and ſmooth and plain one the other. To this it is to be added, that the leaves are ſingle, not of the compoſite kind, as in the other umbelliferous plants, and that they ſtand alternately on the ſtalk.

The ſpecies of *Beupleurum* enumerated by Mr. Tournefort, are theſe: 1. The broad and rigid leav'd *Beupleurum*. 2. The moſt common, or roundiſh leav'd *Beupleurum*. 3. The narrow leav'd annual *Beupleurum*. 4. The ſmalleſt annual narrow leav'd *Beupleurum*. 5. The ſmall *Beupleurum*, with very long and narrow leaves. 6. The other *Beupleurum*, with extremely narrow leaves. 7. The roundiſh leav'd perfoliate annual *Beupleurum*, commonly called *Thoroughwax*. 8. The double flower'd annual perfoliate *Beupleurum*, called by authors the moſſy flower'd thoroughwax. 9. The long leav'd annual perfoliate *Beupleurum*. 10. The broad leav'd mountain *Beupleurum*. 11. The mountain *Beupleurum*, with extremely ſmall flowers. 12. The ſmaller broad leav'd alpine *Beupleurum*, called by authors the ſmall alpine thoroughwax. 13. The larger narrow leav'd perfoliate alpine *Beupleurum*. 14. The middle ſiz'd narrow leav'd perfoliate alpine *Beupleurum*. 15. The little narrow leav'd perfoliate alpine *Beupleurum*. 16. The graſſy leav'd perfoliate mountain *Beupleurum*. 17. The willow leav'd ſhrubby *Beupleurum*, called by many the Æthiopian ſeſeli. 18. The graſſy leav'd ſhrubby Spaniſh *Beupleurum*. 19. The prickly, graſſy leaf'd ſhrubby Spaniſh *Beupleurum*. 20. The Portugal *Beupleurum*, with long rigid graſſy leaves. *Tournef.* Hiſt. p. 310.

HARENARIA, in botany, a name uſed by ſome authors for the buckſhorn plantain. *Ger.* Emac. Ind. 2.

HARENGIFORMES, in ichthyography, a genus of fiſhes approaching to the herring in ſhape, the principal character of which is, a ſerrated line made up of ſcales running along the bottom of the belly; to which may be added, that the ſides and belly are of a bright ſilver colour, and that the ſcales are large and looſe. *Willughby*'s Hiſt. Piſc. p. 218.

HARENGUS, in zoology, the common *Herring*. The characters by which this fiſh is diſtinguiſhed from the reſt of the fiſhes which approach to it in ſhape, and which are thence called *harengiformes*, are theſe. Its uſual length is ſeven or eight inches, tho' it ſometimes grows to a foot. Its head is flatted, and its mouth placed upwards; its back is a bluiſh brown, and its belly and ſides white, and where the ſcales are off, of a ſilvery brightneſs; the ſcales are large and round; it is not at all ſpotted; and its belly is ſharp, and as it were prickly, a row of denticulated ſcales running all along it; its ſide lines are ſmall, and ſcarce diſtinguiſhable; the lower jaw is longer and more prominent than the upper; its gills are four in number, as in other fiſhes, but their teeth or fibres are remarkably long; it has one fin on its back, which is in the midway between the head and tail; and the tail is forked. *Willoughby*'s Hiſt. Piſc. p. 219.

HARENGUS *Minor Indicus*, in zoology. See the article BLICEA *marina*.

HARMALA, *Harmel*, or *wild rue*, in botony, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, conſiſting of ſeveral leaves arranged in a circular form. The piſtil ariſes from the flower cup, and becomes a roundiſh, tricapſular fruit, uſually containing oblong ſeeds. The leaves in this genus always are placed alternately on the ſtalks; and we have only one known ſpecies of it, which is the plant uſually called *wild rue* and *Harmel*. *Tournf.* Hiſt. p. 257.

HARMONICA, (*Cycl.*) among the antient muſicians, is defined by Ptolemy, a perceptive power of the differences of ſounds, according to acute and grave. Vid. Ptolem. pag. 1. Edit. Wallis.

HARMOS, a word uſed by the old medicinal writers for the fleſh growing between the teeth.

HARP, in the manege. See GRAPPLE, *Cycl.*

HARPAX, a name given by ſome naturaliſts to amber, and by ſome of the chemiſts to quicklime, and by others to ſulphur.

HARPE, in natural hiſtory, the name of a kind of ſhell-fiſh of very great beauty. It is of the genus of the dolium, or concha globoſa. See LYRA.

HARPEGGIATO, or HARPEGGIO, in the Italian muſic, ſignifies the cauſing the ſeveral ſounds of one accord to be heard, not together, but diſtinctly one after the other, beginning with either at pleaſure, but commonly with the loweſt. Vid. *Broſſ.* Muſc. Dict. in voc.

HARRIGATE *Well-water*, a ſtrong ſulphureous water, containing beſides ſulphur, marine ſalt, and nitre, or nitre only and earth. See Dr. *Short*'s Hiſtory of the Mineral Waters of Yorkſhire, &c.

HARSCHEF, in botany, the name by which Aviſenna, Serapion, and the reſt of the Arabian writers call the cinara, or hartichoke. Some who have been puzzled for an etymology for the word hartichoke, or artichoak, as we differently ſpell it, have ſuppoſed that it was derived by corruption from this Arabian word *Harſchef*, which the Engliſh phyſicians, who practiſed according to the rules of Serapion and Aviſenna, might bring into uſe, and adopt in their own language, as the name of the ſame plant.

The

The word *Harſchef* ſeems however like the word cinara, and all the other names of the artichoak, to take in alſo another plant of the ſame kind called by us the chardoon, a ſort of garden thiſtle, the tender ſtalks of which are earthed up and blanched, and are eaten by us, and were ſo by the Greeks. The moſt modern accounts of the Perſians tell us alſo, that they eat the young ſhoots and tender ſtalks of the *Harſchef*, which, as the artichoak plant is not uſed for blanching in this manner, probably ſignifies in this ſenſe the chardoon.

HART (*Cycl.*)—*Harts* at one year old have no horns, but only bunches; and at two years they are very imperfect, being ſtrait and ſingle; at three years old they grow out into two ſpears; at four into three; and ſo increaſe every year in number of branches, till they are ſix years old; but after that their age is not to be known by their heads. February and March are the months in which they caſt their horns; and in general the older ones caſt them ſooner than the young ones. Thoſe that have been injur'd at rut, or which have been gelded, never caſt them at all; if they are gelded while young, they never have any horns; if after their horns are grown, they keep thoſe which they had on at the time, as long as they live. The horns of ſome are reddiſh, thoſe of ſome black, and thoſe of others finally are white. The red horns are generally the largeſt and ſtrongeſt, the black are uſually ſhorter, and the white are worſt of all, being the leaſt ſolid or ſtrong.

This animal is the moſt cunning in its care of itſelf of all the deer-kind. It is the moſt timorous of any, and by its windings and turnings and other ſubtilties, as the running among herds of cattle, often deceives the huntſman, and puts a foil upon the dogs. In the chace, which generally is a long one, he takes over hedge, ditch, or river, or whatever comes in his way, nothing ſtopping him.

This creature loſes its horns in the ſpring time, as the other deer do; but, during the time that it is without them, does not appear, but abides in the thick woods, and only comes out in the night time for food.

HART's *Tongue*. See LINGUA *Cervina*.

HART, or STAG-*Evil*, in the manege, a ſort of rheum or defluxion that falls upon the jaws, and the other parts of the forehand of a horſe, which hinders him from eating: Sometimes alſo this diſtemper affects the parts of the hinder quarters.

HARTANITHE, in the materia medica of the antient Arabs, was one of the names of the ſtruthium, or lanaria herba of the Greeks and Romans, a kind of thiſtle the root of which was uſed in the cleaning of wool. Aviſenna, following the Arabic tranſlation of Dioſcorides extant in his time, gives, under this name, a deſcription of the leontopetalon, and the virtues of the cyclamen, or ſow-bread; but he finds out the error himſelf, and charges it upon the interpreter; acknowledging that in his time *Harthanitha*, or artanita, was not a name either of ſow-bread or of the leontopetalon, but of the ſtruthium. See CYCLAMEN.

HARTSHORN (*Cycl.*)— HARTSHORN *jelly*, in medicine, is nutritive and ſtrengthening, and is ſometimes given in diarrhœas; but a decoction of burnt *Hartſhorn* in water is more frequently uſed for this purpoſe, and is called *Hartſhorn-drink*.

The ſalt of *Hartſhorn* is a great ſudorific, and given in fevers with ſucceſs; its ſpirit is a volatile alkali, and of frequent uſe.

HARVEST-*Fly*, *Cicada*, in natural hiſtory, the name of a large fly, remarkable for the noiſe which it makes in the ſummer months, and particularly about the time of *Harveſt*. The generality of authors have very improperly tranſlated *Cicada* by the Engliſh word graſshopper; but this is extremely erroneous, the *Cicada* having not the leaſt reſemblance to the graſshopper. It is called the Cigale in France in the provinces of Languedoc, *&c.* it is very common in that country: Italy and all the hot countries abound with it; and it is in moſt of theſe places called by the common people by a name expreſſing the *Harveſt-fly*; but in England we have not the inſect, and few of us have any notion of what it is. It is probable, that people who found the *Cicada*, according to the deſcriptition of the antients very noiſy, fancied the graſshopper muſt be the ſame creature, this being of all our inſects the moſt noiſy in the ſummer months.

The *Cicada* is a large four-wing'd fly; its body is ſhort and thick, and its wings long and large: The great or common *Cicada* is by far the largeſt of all the known ſpecies of ſhort-bodied flies, and the ſmaller kinds are larger than the hornet. The head of the *Cicada* is ſhort and obtuſe, the eyes are reticulated as thoſe of other inſects of the winged kind, but they are ſmaller in proportion to the ſize of the body, than thoſe of moſt other ſpecies; they are placed at the two ſides of the back part of the head, and leave a very large naked ſpace of forehead between them, the breadth of this plain ſpace is not leſs than that of the breaſt of the animal, and it therefore makes a very ſingular figure. The reticulated eyes are of an oblong figure, and are cut into a vaſt number of faces, and between theſe there are in the plain ſpace of the forehead three other ſmall and ſhining eyes, reſembling thoſe of ſpiders, and placed in a triangle. The corcelet, or breaſt of this fly is divided into two; the head is fixed to the anterior diviſion, and the body to the other; the anterior has a triangular figure delineated upon it in creux, and the poſterior to which the body is fixed has a ridge in the middle, riſing above the reſt of the ſurface. *Reaumur*'s Hiſt. Inſ. vol. 9. p. 186.

The two pair of wings are of the membranaceous kind: The outer pair are greatly the larger, they are compoſed of an extremely thin membrane, ſupported by ſome ſtrong nerves or ribs; theſe are joined to the poſterior part of the corcelet, near the place where it is joined to the anterior; and the under wings, which are ſmall, are affixed to the other end of this part of the corcelet, near where the body is joined to it. Theſe wings form a ſort of tent or canopy over the body, yet they are ſo placed as to leave a part of it naked: The body is compoſed of eight rings, including that part which terminates it: The firſt ring, or that which joins to the corcelet, is much larger than any of the reſt: The laſt ring in both ſexes, is long and ſlender; but in the female it is more remarkably long, than in the male: The body is perfectly ſmooth, there being very little hairyneſs on any part of the animal, and what little there is being placed on the corcelet, and about the reticulated eyes. Theſe are the parts which are ſeen on viewing the upper ſide of this animal; but the great curioſity is the turning the belly upwards; in this poſition there come in view the trunk, and the remarkable organization with which the female makes the holes in which it buries its eggs. In this view are alſo ſeen the organs, by means of which the creature makes that noiſe, for which it has been admired for ſo many ages. Theſe are things extremely worth a curious examination, and are as diſtinctly ſeen and underſtood in a dead *Cicada*, as in a living one.

Ariſtotle, and the other antient writers who have treated of the *Cicada*, have mentioned two ſpecies; which they have diſtinguiſhed by the names Achetæ and Tettigoniæ. Theſe have been generally underſtood to mean the two general kinds now known: The achetæ being our large *Cicada*, and the tetigoniæ our ſmall ones; but Mr. Reaumur has added to theſe two general kinds a third, which is of a middle ſize between the other two. This he ſuppoſes to have been the tettigonia of the antients, and ſeems very confident that our ſmall kind was wholly unknown to them.

Theſe three kinds do not only differ in ſize, but alſo in colour. The large kind is of a deep and blackiſh brown, with a little yellow on the breaſt, and on ſome of the rings of the body. The middle-ſiz'd kind is of a paler brown, and has much more of the yellow in it, particularly it has on the body two croſs lines of yellow, which repreſent in ſome ſort the letter X. The third kind, or ſmalleſt of all, are called Cigalons by the French; they are very different from both the others, having a reddiſh caſt on the body, and more yellow than the largeſt, and leſs than the middling kind. Theſe diſtinctions we owe to Mr. Reaumur, who very candidly acknowledges, that he had not ſo great opportunities of examining the *Cicadæ* of different countries as he could have wiſh'd; and is of opinion, that farther obſervations will give us ſeveral more kinds of them. *Reaumur*'s Hiſt. Inſ. vol. 9. p. 191.

When the large *Cicada* is examined on the under part, the belly is found to be of a dirty yellowiſh colour, ſurrounded on each ſide by a line or band of brown: This is a continuation of each extremity of every one of the upper rings of the body which are brown, and which at the two ſides of the animal fall over the under rings, or parts of the rings which form the belly. The antennæ are extremely ſhort and ſmall; they are inſerted juſt cloſe to the eyes, and when viewed by the microſcope they are found to be each compoſed of five pieces joined nicely together at the ends, and to be of a conic figure, the baſe being ſomewhat broad and the extremity terminating in a point. The anterior part of the head is covered with a ſort of conic piece which equals the diameter of the head between the eyes at its baſe, and thence terminates by degrees in a ſmaller point, the whole being bent under the head and reaching beyond the inſertion of the firſt pair of legs; to the extremity of this piece is fixed the trunk of the *Cicada*, an organ diſtinct to receive other food than what the antients allowed this creature, for their opinion was that it lived wholly upon the dew. In its firſt ſtate it has a ſtrong trunk, by means of which it feeds on the juices of the roots of plants during its abode under ground in this ſtate; and this trunk ſeems continued to it after its change into the fly-ſtate, and is made the ſame uſe of by the animal; it continually thruſting it into the ribs of the leaves of plants and trees to ſuck their juices by way of food for itſelf. Sometimes alſo the large *Cicada* will pierce the bark of a tree, in order to come at the ſap; and in this caſe, as it is difficult to get it into ſo hard a ſubſtance, ſo it is alſo hard to get it out: Perſons who have caught the *Cicada* on the branches of trees have frequently found the trunk thus engaged in the bark, and the creature has found it a matter of difficulty to get it out again. This trunk is very tender and delicate, and is well defended from injuries. When the extremity of the conic piece which covers the under part of the head of the *Cicada* is examined, there is ſeen growing from it a long and ſlender cylindric body of the length and

thickneſs of one of the ſmaller ſort of pins; this lies flat upon the breaſt and belly, reaching from the extremity of this piece to the inſertion of the third pair of legs. This, however ſmall and delicate it appears, is not the trunk of the animal, but is only the caſe or ſheath of it, deſtin'd to preſerve it from injuries. This is of a cartilaginous ſubſtance, and has a longitudinal fiſſure running all along it which the creature can ſhut or open at pleaſure for the cloſing up or exerting the trunk, which is an extremely tender and delicate long filament contained in it. The males among the *Cicadæ* only ſing; but this is a circumſtance determined but lately, and that only among the more accurate obſervers. The antients and the country people at preſent in places where the *Cicadæ* are common, declare juſt on the oppoſite ſide of the queſtion, that it is only the females that ſing; and this is an error owing to the figure of the hinder part of the body of the female, which has been uſually taken as a character of the male: The ſexes have been thus generally miſtaken one for the other; and Malpighi acknowledges that he was very near falling into it himſelf, having with the reſt of the world miſtaken the cylindric part at the extremity of the body of the female with which ſhe pierces the bodies in which ſhe lays her eggs for the penis of the male. *Reaumur*'s Hiſt. Inſ. vol. 9. p. 198.

It has been the common opinion, that the noiſe which the *Cicada* makes was occaſioned by a ſwift motion of the wings and their rubbing againſt the breaſt, and the grating of the under pair of wings in their paſſage againſt the upper ones; were this the caſe, there is no reaſon why the female *Cicada* ſhould not make this noiſe as well as the male, ſince ſhe has wings and all the other requiſites to ſinging, according to this ſyſtem; but in reality the matter is far otherwiſe, and the bare inſpection of the body of the male *Cicada* will ſhew that the noiſe is owing to other cauſes. If we are determined to call nothing a voice but the articulation of air thrown from the lungs in its paſſage through the larynx and other parts, then the *Cicada* has properly indeed no voice; but if we extend the meaning of the term farther, and take in the ſeveral ſounds made by inſects in other manners yet intelligible to other inſects, we muſt allow the *Cicada* has a voice, and a very ſtrong one, the organs of which are not in the lungs and throat, but in the belly.

On examining the belly of a large male *Cicada* there are found two large ſcaly ſpots very different from the reſt of the ſubſtance of the rings; theſe are not found in the female, and are of the ſhape of the half of an oval cut through its ſhorter axis, one ſide of them terminating in a ſtrait line, and the other part being rounded; theſe are fixed without any articulation to the lower part of the lower corcelet or breaſt, their ſtrait edge being firmly united to it; they are ſo large that they meet in the middle of the belly, covering in part one another, and are ſo long as to reach to the third ring at their rounded ends. If theſe pieces be raiſed with the point of a pin, and the part of the belly which is covered by them be nicely examined, there is found a very curious ſtructure of the parts; and there can remain no doubt but that theſe are the organizations deſtin'd to ſerve the male, in whom only they are found, to make that noiſe for which he is ſo famous. Theſe are ſo nicely formed that the ſtructure of our own throats is not more admirable than that of the parts by which the *Cicada* makes its noiſe. There is a cavity formed in a very ſingular manner in the anterior part of the belly of the creature: The firſt ring of the body is cut to form it, and the ſecond is drawn back, and the upper part of this cavity is ſurrounded by a rim or edge much ſtronger than the common matter of the rings of the body; this cavity is rounded at the ſides, and in the middle there runs up a ſmall oblong membrane toward the head. The cavity is divided into two parts by a ſcaly triangle of a convex figure, where it is in ſight; the baſe of this triangle is at the breaſt, and the apex runs to the belly, and meets the oblong membrane before-mentioned running under it. In the middle of the triangle there riſes alſo a rib which runs to the membrane, and joins with it; this raiſes the triangle to a level with the reſt of the belly. At the bottom of each of the cavities that the triangle divides the larger cavity into, there is ſeen a poliſh'd and reſplendent part looking like a ſemicircle, the one edge of it being fixed to the triangle that divides the cavity, and the other following the round of the other parts of it. Theſe reſemble two pieces of extremely thin and tranſparent glaſs, or extremely fine flakes of talc, the fineſt glaſs or pureſt talc not being more perfectly bright or tranſparent. When they are viewed ſideways we perceive all the rainbow colours upon them. It ſeems as if the *Cicada* had two windows covered with the fineſt glaſs, by means of which we are able to look into the body and ſee all that paſſes there; but theſe windows are generally cloſed with a ſort of ſhutters made by the ſcaly piece which covers the whole cavity. We may eaſily obſerve, that the ſound or noiſe made by the *Cicada* comes from this cavity, and ſhall then eaſily conceive that this fine membrane is only placed there to modify it. This ſound, tho' not agreeable to our ears, may pleaſe the female, and that is all that was intended by it, ſince it is only to her that the male deſires to ſing. The piece which covers the whole cavity is moved up and down in the making this noiſe; but nature has provided a ligament to prevent its riſing too high, and a ſupport to prevent its ſinking too low into the cavity of the belly. And finally there is a white membrane going from the anterior part of the cavity to the thorax. While many have ſuppoſed the noiſe made by the *Cicada* to be produced by the motion of its wings: Many others have been convinced that it was made by this part, becauſe none of the *Cicadæ* but thoſe which have this organization, that is, none but the males ſing.

Some have ſuppoſed that the rings of the body in bending it quickly backwards and forwards made the noiſe by their rubbing againſt the piece which covers the cavity, but it is eaſy to be aſſured that this is not the caſe, ſince in rubbing theſe ever ſo briſkly together by bending the body between the fingers there is no ſuch noiſe made: Others have judg'd that the ſound proceeded from the fine tranſparent membrane that lies extended at the bottom of each cavity, but there is no finding the pieces which they ſuppoſe to ſtrike upon this membrane: Finally, others ſuppoſe it to ariſe from the bending and again extending of the membrane, which goes from the lower edge of the cavity to the thorax; but it is eaſy to find alſo upon tryal, that the bending and unfolding of this by moving the body in different directions between the fingers makes little or no ſound. When the upper rings of the back are taken off, there are ſeen two extremely large and ſtrong muſcles running from the corcelet toward the belly, and meeting in an angle at the extremities. It is wholly by the motion which this ſtrong muſcle puts the parts contained in the cavity into, that the noiſe of the *Cicada* is produced; and even after the creature is dead and dry if this muſcle on either ſide be raiſed a little with a pin, and then ſuffer'd to fall back into its place, it makes the parts in ſome ſort perform their motions; and there is the ſame noiſe produced that the *Cicada* makes while living, only that it is more faint. The parts deſtin'd to the making this noiſe are not all contain'd in the cavity above deſcribed, but there is a triangular eminence on the firſt ring of the body, on each ſide in the male, which the females have not; this covers a part of the mechaniſm of this ſound, and this may be eaſily raiſed with the point of a knife, without hurting the part within; there is then found under this one of the principal organs of the ſound. This is a membrane of a very rigid nature, always form'd into ſeveral folds and wrinkles, and which when ſtruck upon yields a ſound like that of parchment when ſtruck upon. When we draw over this membrane a piece of paper rolled up, or any other ſoft body that is not able to hurt it, we find it immediately make a noiſe which is owing to the bending inwards of ſome parts of it which ſtood convex by means of the folds, and their immediately throwing themſelves out again in the manner of a piece of ſtiff parchment, or any the like ſubſtance. The ſound that we thus make is produced by the making ſome parts of the membrane concave which were before convex, and then ſuffering them to return to their former convexity, by means of their own elaſticity. This is eaſily performed in very quick times by the long and ſtrong muſcles before deſcribed; each of theſe is placed behind or on the concave ſide of one of theſe folded and ſonorous membranes. Its fibres are all faſtned into one or other part of this membrane, and it is very plain from hence, that the contraction of this muſcle muſt pull in the whole convex ſurface and render it concave by drawing the convexity to its ſide, and the remiſſion of the action of this muſcle muſt let the whole return into its former ſtate; this when done ſuddenly cannot be done without the noiſe that we have before deſcribed. The muſcles are capable of a very ſwift contraction and dilatation of this kind, and to that is owing the repeated noiſe of this membrane in unfolding itſelf, which makes the ſound of this creature. *Reaumur*'s Hiſt. Inſ. v. 9. p. 218.

The antients have obſerved that the tettigonia or ſmall *Cicada* did not ſing ſo well as the large, and this is plainly explain'd by the ſtructure of this membrane, which in the middle and ſmall kinds is longer than in the larger ones, and is carried up under the firſt ring of the body, and cannot be acted upon ſo ſtrongly by the muſcles which are the origin of the ſound. The tranſparent membrane at the bottom of each of the cavities is alſo much ſmaller in proportion to the ſize of the body in the little *Cicada* than in the great one; and the whole ſtructure of the parts ſhews, that tho' the membrane which cauſes the ſound be in theſe proportionably as large as in the male, yet all the other parts are leſs qualified to act upon it, and to raiſe the ſound; the muſcles are placed in theſe, juſt as in the great kind.

Tho' the female *Cicada* wants the organs of ſinging of the male, ſhe has however a part in her body which the male has not, and which deſerves a peculiar attention. The eggs of the *Cicada* muſt be lodged in the ſubſtance of wood, in order to their happily ſucceeding in the hatching, and the inſtrument of the female is intended for the purpoſe of lodging them properly. The creature makes long cavities in the wood, and in theſe places her eggs in the moſt nice order imaginable; and the inſtrument, by means of which ſhe does this, is larger and more remarkable than that of any other

inſect deſtin'd to the ſame purpoſe; it is made of a ſort of horny matter, as all theirs are, and has many obſervable peculiarities, which are ſeen even by the naked eye. This inſtrument in the larger ſpecies of *Cicadæ* is nearly half an inch long. In both the male and female of this inſect the body is terminated by a conic part, but this in the females is longer than in the males, and is larger at the baſe; this makes the body of the female appear longer than that of the male. In the female this conic part is all of one piece, not compoſed of two halves, as in the male; and this is ſlit all the way down to give paſſage to the inſtrument on occaſion. The inſtrument lodg'd in this is called by authors the piercer: It has its own peculiar ſheath over it, and this conic part of the body only ſerves to make a general covering for both. If the belly of the *Cicada* be gently preſſed between the fingers, this inſtrument ſhews itſelf in its whole length; it is alſo ſeen naked, for its peculiar caſe or ſheath does not follow it out of the body, but is fixed in part to the baſe of the conic end of the body. This inſtrument is oblong and cylindric, nearly of a bigneſs all the way, except that it is a little larger at the extremity than elſewhere, and terminates in a ſharp point which is notched with nine teeth on each ſide. A very exact account of this inſtrument is given at large in Reaumur, to whom we refer the reader. *Reaumur*'s Hiſt. Inſ. v. 9. p. 218.

Moſt other inſects which lodge their eggs in wood, do it in the young ſhoots and tender branches of ſhrubs and trees while yet living, where the eggs receive juices and nouriſhment from the ſap. See the article ROSE-*fly*.

The *Cicada*, on the contrary, knowing that her eggs only want a proper lodgment, not a nouriſhing juice, always lays them in dry or dead ſticks. The creature never regards what kind of wood ſhe meets with, but ſeizes the dead twigs of any tree, and bores a row of holes in it, putting an egg into each. The twigs which have theſe eggs in them are eaſily known by their appearing uneven and full of elevations over the places where the eggs are. The common courſe of the operation throws off the bark, but the ſmall fragments of the wood cut to pieces in making the hole uſually remain upon the place, and theſe make ſo many little hillocks which all point regularly one way, as the animal keeps one direction in making them all. In order to diſcover the mechaniſm of theſe holes, it is neceſſary to ſplit off a thin piece of the branch in which they are made, and it is common then to ſee ſeveral of them diſtinctly. The creature uſually chuſes ſuch trees as have a pith in their young branches, ſuch as the mulberry and the like; and when ſhe has pierced to the pith, ſhe never wounds the wood on the other ſide, but carries on the hole in the center to the whole length of her piercer. The length of this hole makes it a proper lodging for a number of eggs, often nine or ten; ſometimes but four or five are placed in each; theſe are oblong and pointed at both ends, and of a white colour. The number of eggs laid by every female is very great, for on opening the body of one of them there are uſually found more than an hundred and fifty in each ovary, in thoſe which are leſs filled than the common ones; and ſome authors mention the finding in the whole ſix or ſeven hundred eggs in thoſe which are full and have not begun to lay. The holes where the eggs are depoſited, are all carefully ſtopped up by the creature, to defend them from being eaten by other ſmaller inſects. Some have ſuppoſed that the female to this purpoſe covers them with a viſcous fluid ſecreted from her body; but there is no appearance of any thing of this kind to be found on examination; on the contrary, the method ſhe uſes is this, ſhe carefully places the duſt or ſmall fragments of the wood which ſhe cuts out on one ſide of the hole, and when ſhe has done, ſhe draws them into it again, making it receive as much of them as its cavity will admit; thus the orifice is well ſtopp'd, and the reſt of the duſt is piled up in a hillock over it. On opening the ſticks in which theſe eggs are placed at different ſeaſons, there are found two ſorts of inſects of different kinds, the one an oblong worm without legs and arm'd with four teeth, the other a ſhorter animal of the ſhape of a flea, and having ſix legs. Theſe laſt are the produce of the eggs of the *Cicada*, the others are the offſpring of an ichneumon fly, and are only depoſited there to feed on the proper inhabitants. The ſix-legg'd inſects have a ſmall head bending down under the body, and lengthening out into an appearance of a ſort of trunk, and the head is as it were cleft in two. Theſe creatures depoſit their firſt exuvia in the neſt, and after this they come out at the ſame hole at which the egg was let in, and they are no ſooner out than they fall to the ground, and immediately make their way into it and bury themſelves; they live ſome time under ground in the form of a hexapode worm, with a trunk, but without the fiſſure ſeen in the head of the young ones while in the neſt. After living ſome time under ground they become transformed into a ſort of nymphs, which have alſo a motive power, and have yet a part of their growth to attain to: Theſe nymphs were well known to the antients; Ariſtotle has deſcrib'd them under the name of Tettigometræ, or mothers of the *Cicadæ*. Theſe nymphs are of a dirty brown colour, and differ principally from the hexapode worms, in that the caſes of the wings of the future fly are eaſily ſeen in this ſtate, but not at all in that of the worm. The head of the nymph is of the ſame ſhape with the head of the ſucceeding fly, and has its trunk placed in the very ſame manner, and covered with the ſame ſort of ſheath or caſe. The double corcelet is divided in the ſame manner in the nymph as in the perfect *Cicada*, and the rings of the body may be as eaſily counted; but the parts which characterize the different ſexes, are not to be ſeen in theſe. The ſounding organs in the belly of the male, and the piercer at the hinder part of the female, never ſhew themſelves till the creature is in its perfect ſtate. *Reaumur*, Hiſt. Inſ. vol. 9. p. 235.

The moſt remarkable thing in the nymphs of the *Cicadæ* is their anterior pair of legs; theſe are made ſomewhat in the ſhape of a crab's claws, having a kind of foot at the ends; and theſe are armed with a ſort of hooks, which authors call claws, from their reſemblance to the claws of a bird's foot. Theſe legs ſeem admirably contrived for the creature to make its way into the ground, and travel under it at its pleaſure. The other four legs of the nymph of the *Cicada* have nothing remarkable in them, but are terminated by a ſort of claws, inſtead of the large feet which terminate the others. The ſtructure of the anterior feet of this animal is extremely neceſſary to it; for it is frequently found at two or three feet depth in the earth, in winter, having often made its way through a ſtiff clay to that depth. As the young are always hatched in the branches of trees, the old ones depoſiting their eggs in no other place, ſo theſe nymphs are uſually found in the earth, about the roots of trees, and find their nouriſhment in ſucking their roots. The creature remains in this nymph ſtate two years, and when the time of its final transformation into the fly ſtate approaches, it leaves the earth, and crawls up the body of the tree, and there faſtening itſelf to ſome of the branches, it changes into the fly, in the manner that all the other creatures paſs into that ſtate, that is, by breaking through its ſeveral coverings, by means of the repeated inflations of its body. When the fly firſt comes out of this caſe, it is green, but it becomes brown by degrees, and in a few hours loſes all its firſt agreeable colour.

Theſe inſects are extremely troubleſome, by their noiſe, in moſt of the hot countries: They are now made no uſe of any where; but we find that the antients revenged themſelves of their noiſe by eating them. They accounted them an excellent diſh in all their ſtates; but the nymph, or tettygometra, was what they were moſt of all fond of; they alſo eat them in the fly ſtate, and were ſo nice as to diſtinguiſh their ſexes and ſeaſons. They preferred the females when they were full of eggs, and the males before that time, while they were full of the ſemen. *Reaumur*, Hiſt. Inſ. vol. 9. p. 236.

HASCHE, in botany, a name by which ſome authors have called thyme. *Ger.* Emac. Ind. 2.

HASELA, in zoology, the name of a freſh water fiſh, of the malacoſtomous or leather-mouth'd kind, called, by ſome, a ſpecies of the mullet, by others, of the chubb; and in many places, the haſler. It is a ſmooth, ſoft, and ſmall fiſh, of an oblong and ſlender body, and ſeldom exceeding ſix or ſeven inches in length. It is of a blackiſh green on the back, and a ſilvery white on the belly. Its tail, and its back fin are of a bluiſh hue, the other fins are ſomewhat red. The ſcales are large, thin, and fimbriated at their edges. Its ſide lines are dotted, and are nearer the back than the belly. They are eſteemed a good fiſh, at ſome ſeaſons of the year, for the table, but at others they are ſaid to breed worms, and be very unwholeſome. They are caught in lakes and rivers; but thoſe from running waters are eſteemed the beſt; and April and May are accounted the months in which they are in higheſt ſeaſon; they are eaten alſo in June and July, but ſeldom after thoſe months. *Willughby*, Hiſt. Piſc. p. 261. *Geſner*, de Piſc.

HASINELLAS, in the glaſs-making trade, are a number of hooks faſtened to the ſides of the working furnace, by means of which the workmen are able to reſt and turn their veſſels as they ſcald them. *Neri*'s Art of Glaſs, p. 242.

HASSA *Alrhai*, in the materia medica of the Arabian phyſicians, a name given to a plant, the virtues of which they commend on many occaſions.

The meaning of the words *Haſſa Alrhai* is virga paſtoris, ſhepherd's rod; and hence many have been led to ſuppoſe, that the plant we call virga paſtoris, or dipſacus minor, the ſmaller teaſel, or ſhepherd's rod, has the virtues given to the *Haſſa Alrhai*, and was the ſame plant. But though it happens that the names of theſe two plants agree in ſignification, there is nothing elſe in which they agree, the *Haſſa Alrhai* being the ſame plant with the polygonum of the early writers, which, with the epithet of maſculum, ſtood for the common knotgraſs; and when the word fæmininum was added, ſignified the common equiſetum, or horſetail, which was called polygonum, for the ſame reaſon that the knotgraſs was; that is, becauſe its ſtalk was compoſed of a great number of joints. Theſe two plants agree in the virtues of agglutinants and aſtringents, neither of which virtues our virga paſtoris has any title to.

HASTATED *Leaf*, among botaniſts. See LEAF.

HASTATI, among the Romans, ſoldiers armed with ſpears, who were always drawn up in the firſt line of battle. *Hofm.* Lex. in voc. See BATTLE.

HASTE, or QUICKEN *your Hand*, in the manege, called, in French, *Hatez le Main*, or *Hatez*, *Hatez*, is an expreſſion frequently uſed by riding-maſters, when a ſcholar works a horſe upon volts, and the maſter has a mind he ſhould turn his hand quicker to the ſide on which the horſe works; ſo that if the horſe works to the right, he turns quicker with his ſhoulders to the right. And the contrary is obſerved, if the horſe works to the left.

HASTING *Pear*, a name given, by the gardeners, to a ſpecies of *Pear*, called alſo by ſome, the green chiſſel *Pear*. This is a moderately large *Pear*, and is longiſh toward the pedicle; its ſkin is thin, and of a whitiſh green; the pulp is melting, and of a ſugary flavour. It ripens in July.

HATCHES (*Cycl.*)—HATCHES, in mining, a term uſed, in Cornwal, to expreſs any of the openings of the earth, either into mines, or in ſearch of them. The fruitleſs openings are called eſſay *Hatches*; the real mouths of the veins, tin *Hatches*; and the places where they wind up the buckets of the ore, wind *Hatches*. See the article WIND *Hatch*, &c.

Coamings of the HATCHES, in a ſhip. When the *Hatches* are raiſed up higher than the reſt of the deck, thoſe planks, or pieces of timber, which raiſe and bear them up, are called *Coamings* of the *Hatches*.

HATCHET, (*Cycl.*) a ſmall ax, uſed by the pioneers, who go before to prepare the ways for an army, by cutting down hedges, buſhes, ſtyles, or gates. The grenadiers carry ſometimes each a *Hatchet* by his ſide; and the French dragoons, who have but one piſtol, have a *Hatchet* hanging at their ſaddle-bows, on the right ſide.

HATUMURUNGHA, in botany, a name by which ſome authors have called the tree whoſe fruit is the ben nut, the balanus myrepſica, or glans unguentaria, and whoſe wood is the lignum nephriticum of the ſhops. *Herm.* Muſ. Zeyl. p. 62.

HAVELDA, in zoology, the name of a bird of the duck kind, common in Iceland, and known, among the natives, by this name, called, by authors, *Anas caudata Iſlandica*, the long-tail'd Iceland duck. It is ſmaller than the Wigeon, and has a very ſmall flatted head; its feathers round about the eyes are white; in other parts of the head, black, with a mixture of grey; the neck is of the ſame colour; the back is of a bluiſh black, and the rump variegated with black and white; the tail is compoſed of four black feathers, two of which are nine inches long, the other two not more than three inches; the breaſt, throat, and half the belly are black; the reſt of the belly is white. *Ray*'s Ornithol. p. 290.

HAUBERGETTUM, in our old writers, the ſame with halsberga and habergeon, which all ſignify a coat of mail. *Fleta.* lib. 1. c. 24. *Blount.*

HAUNCH, or HIP, in the manege. To make a horſe bend, or lower his *hips*, you muſt frequently make him go backwards, and make uſe of the aids of the hands, and of the calves of your legs, in giving him good ſtops; and if that does not ſucceed, he muſt be tried upon a *calcade*, or ſloping ground, after the Italian faſhion.

Head in, and *Hips in*. See HEAD.

To gallop with the *Haunch in*. See GALLOPADE.

HAUSTELLUM, in natural hiſtory, a name given, by ſome authors, to a peculiar kind of ſhell-fiſh, of the purpura kind, which the French have named the *Becaſſe*, and we the woodcock ſhell. It is remarkable for its extremely long and ſlender beak. There is a very elegant echinated or ſpinoſe kind, and two or three ſmooth ones. See BECASSE.

HAUSTILIA *Succina*, in natural hiſtory, a term uſed to expreſs that kind of amber, or, more properly ſpeaking, thoſe maſſes of amber which are obtained by dragging the bottoms of the ſea near Pruſſia, or found on the ſhores, in diſtinction from thoſe pieces which are found foſſile in the ſame or other kingdoms. Hartman has evidently proved, that amber is formed of a bitumen, mixed with vitriol and other ſalts; and tho' this is allowed him in regard to the foſſile amber, many diſpute the ſea or *hauſtile* amber, as they expreſs it, being ſo produced. It is, however, very evident, that all amber is of the ſame origin, and probably all the *hauſtile* amber is firſt waſhed into the ſea out of the cliffs; tho' Hartman thinks it very poſſible, that ſome of it may be formed in the earth under the ſea, and be waſhed up thence. The *hauſtile*, or ſea amber, is uſually finer to the eye than the foſſile; but the reaſon is, that it is diveſted of that coarſe coat with which the other is covered while in the earth. *Hartman*'s Hiſt. Succini.

The foſſile amber itſelf very much differs, not only in degree of beauty and purity, but alſo in hardneſs, ſome of it being ſo poor, ſo coarſe, and ſo brittle, as not to be worthy the name of amber; and ſome, that is yet ſomewhat better than this, breaking in the taking up.

This difference in purity, hardneſs, and goodneſs, ſeems wholly owing to the different proportion in which the ſalts are mixed with the bitumen, in the compoſition of the amber; and it is no wonder that the ſea or *hauſtile* amber is never of the ſame coarſe kind with ſome of the worſt that is dug, becauſe ſuch is daſhed in pieces by the waves, and deſtroyed, and only the good preſerved. The *hauſtile* amber is uſually found in irregular maſſes, for the moſt part wholly diveſted of its rough coat, and often broken, ſo that its original ſhape cannot well be aſcertained; but the foſſile amber generally carries the marks of its origin with it, and is either found in form of large drops of a roundiſh or oval figure, or elſe in flatted cakes, formed by the narrow ſpaces it is found in, between the layers of the matrix, which is always a kind of foliated or flakey ſubſtance, by ſome miſtaken for foſſile wood, or the barks of trees preſſed together, though, in reality, it is no other than a bituminous earth coagulated by ſalts, and hardened by the gradual evaporation of its ſuperfluous moiſture by the ſun's heat. Phil. Tranſ. N°. 258. p. 18. See MATRIX.

The vulgar form to themſelves an idea of reſemblances of fruits, ſuch as almonds, peaſe, onions, pears, and the like, in the form of the natural maſſes of foſſile amber; but theſe are only the accidental form of the drops from which it was coagulated. The external ſurface of the foſſile amber is often marked with odd figures: Of the number of theſe are letters according to the alphabets of various languages. Hebrew characters are very common, and the Roman letter S has been often found marked in white, upon a brown piece; but this is all accident.

HAUTIN, in zoology, the name by which ſome call the fiſh, more uſually called *Outin*, and known, among the writers on fiſhes, by the name of *Oxyrynchus*. *Willughby*'s Hiſt. Piſc. p. 187. See OXYRYNCHUS.

HAW (*Cycl.*)—A ſmall parcel of land is ſo called in Kent; as a *Hemphaw*, or *Beanhaw*, lying near the houſe, and encloſed for thoſe uſes. Sax. Dict. But Sir Edward Coke, in an antient plea concerning Feverſham in Kent, ſays *Hawes* are houſes. Co. Litt. 5. See HAGA.

HAW, HAWGH, or HOWGH, is uſed, in the north of England, for a green plot in a valley. *Cambd.*

HAWFINCH, in zoology, an Engliſh name for the coccothrauſtes, called alſo the groſsbeak, and by the Italians, the Friſone. See COCCOTHRAUSTES.

HAWK (*Cycl.*)—The Engliſh legiſlature has thought theſe birds worthy of its protection: Taking their eggs out of any man's ground, is puniſhable by impriſonment for a year and day, and by a fine at the king's will, one half to him, and half to the owner of the ground. Stat. 11 *Hen.* 7. c. 17. See FALCON.

HAWK-*weed*, in botany, See HIERACHIUM.

HAWSE-*full*, or *to ride* HAWSE-FULL, at ſea. See RIDE.

HAY (*Cycl.*)—The herb called *ſaintfoin*, and cultivated in many parts of this kingdom, affords a kind of *Hay* preferable on all accounts to that made from the common graſs, and ſubject to fewer accidents. If the common meadow *Hay* cannot have good weather to be cut in its proper ſeaſon, it will ſerve as little elſe than dung, and yet the charge of cuting and carrying it off the ground muſt not be omitted: But if there be not weather to cut the ſaintfoin at a proper time, we may wait till it is in flower, or even till the flowers are fallen; and then if it ſtill rain on, it may ſtand for ſeed, and will turn to as good account this way as any other; ſo that a field has four chances for one that a meadow of common graſs has.

The ſecond kind, or that which is cut when the plant is in flower, is the common ſort; and this, tho' inferior to the virgin *Hay* of the ſame plant, is yet greatly ſuperior to any other kind of *Hay* propagated in Europe. About three tun to an acre is the uſual produce of this; and the larger and longer this is, the better it is eſteemed. The farmers in Oxfordſhire will go ſeveral miles to purchaſe the large ſtalked ſaintfoin *Hay* for their horſes, when they could have the low leafy ſort at the ſame price near home.

The third ſort of ſaintfoin *Hay*, is the full grown. This is cut juſt when the bloſſoms are fallen off. It is larger and longer than any of the former kinds, and yields a much greater crop as it ſhrinks very little in the drying; but this is not ſo good as the others. The ſeaſon for making this is about midſummer, and the farmer has thus three chances for the making his *Hay*. The manner of making it is this: In a day or two after it is mow'd, it will be dried on the upper ſide, and then it is to be turned, not ſingly, but two and two ſwaths together; for by thus turning them in pairs, there is a double ſpace of ground between pair and pair, which needs but once raking; whereas if the ſwaths were turned ſingly, that is, all the ſame way, the ground would require twice raking, at leaſt the greater part of it would ſo. As ſoon as both ſides of the ſwaths are dry from rain and dew, they ſhould be made up into little cocks the ſame day before the evening dews come on; for it will be much leſs expoſed to the injuries of wet when in theſe little cocks, than when ſpread all over the ground. The virtues of the plant are very ſoon carried away in the lying ſpread upon the ground. A week's lying thus expoſed to the rain and dew, will make it no better than ſo much ſtraw.

The ſaintfoin being larger in the ſtalks than common *Hay*, may be much ſooner put up in cocks, for this prevents the heating and fermenting of the *Hay*, the air having a free paſſage among and into theſe ſtalks, whereas it is excluded in

common *Hay*, whoſe ſlender ſtalks fall cloſe together. Saintfoin, on this account, gets no harm on ſunday's by remaining in the cocks; whereas the laws of this country, tho' not of others, prohibiting the working on this occaſion on that day, the Engliſh farmer often loſes his whole charges by the ruin of his *Hay*, from the cocks not being opened on a wet ſunday.

When the little cocks of ſaintfoin *Hay* have ſtood one night, let them be ſpread out the next morning, and three or four of them then made up into one larger cock; this may be done after they have been ſpread about an hour; and if the weather be unfavourable, they ſhould not be ſpread at all, but three or four cocks lightly ſhook upon one another, ſo as to leave them hollow, and the air a free paſſage between them.

Clover *Hay* will turn black, not only with every little ſhower of rain, but even with any miſt or fog that happens while it is making; but ſaintfoin having thinner leaves, is not ſo eaſily ſpoiled this way. The ricks of ſaintfoin *Hay* ought always to be thatched over as ſoon as they are made. That which is laid up when well dried, will come out of a fine green colour, but that which is ſomewhat wet or damp when put up, will not be green nor black, but browniſh.

Whatever uplands are deſigned to be mowed for *Hay*, are to be ſhut up in the beginning of February, and no cattle ſuffered to come upon them afterwards; but the meadows and marſh-lands, where the graſs grows quicker, need not be ſhut up till April, except the ſpring be bad; and many farmers feed thoſe meadows which are in danger of overflowing till the firſt of May, and then ſhut them up for mowing. *Mortimer*'s Huſbandry.

In ſpring, the ſtones, ſticks, and all other kinds of foulneſs that lie upon the land, are to be picked up, and the mole-hills all levelled and ſpread, becauſe they hinder the mowers. If the meadows lie any thing uneven, or if they have been trodden down in winter, they ſhould be rolled all over with a large wooden roller; the mowers will then be able to cut much cloſer; for this, and the quantity of the *Hay*, will very well anſwer the trouble.

The time of mowing the graſs muſt be proportioned to its ripeneſs; nothing can be more prejudicial to the crop, than the cutting it too ſoon, becauſe the ſap is not then fully come out of the root; and ſuch graſs when dry'd into *Hay*, ſhrinks up almoſt into nothing. It is very wrong alſo to let it ſtand too long, for when the ſeed has been ripened, and is ſhed, the moiſture of the ſap all dries away out of the ſtalks, and they become no better than ſo much ſtubble, as is plainly ſeen in thoſe graſſes which grow in hedges, and not being mow'd, dye away after they have perfected their ſeed, and become taſtleſs and very different from *Hay*. The middle or latter end of June is the general ſeaſon for mowing; and the red flowers of the honey-ſuckle beginning to wither, generally give the farmer notice that the time is coming on. But he may be more aſſured of this, by the tops or heads of the graſs looking full, bending downwards, and looking brown: It is then in the proper ſtate to be cut down.

If there is great plenty of the *Hay*, and it lie thick in the ſwarth, the haymakers ſhould follow the mowers, and turn the ſwarths as they cut them, unleſs there ſeems danger of wet weather; but in that caſe it is better to let them lie in the ſwarth. At night it muſt be made up into little cocks, and theſe in the morning muſt be ſpread again and turned, ſo that the other ſide may wither. After this it is to be made into ſmall cocks again, and the next day it is to be ſpread again, and drawn into long rows, which they call winrows. From theſe it is to be made up into large cocks after a little drying; and theſe large ones, if any wet comes, are to be ſpread open once again before they are carried in.

Mowing of land too often, and continuing it too long, is a very great prejudice to it, unleſs it have the advantage of being fed and renewed by land floods at times. The farmer who has not this advantage to his lands, ſhould feed them once in two or three years, inſtead of making *Hay* from them, unleſs he chuſes to lay on manure conſtantly to keep them in heart. Feeding the *Hay* lands is the ſame ſort of reſpite that fallowing is to corn lands, both very neceſſary and advantageous.

Mr. Boyle tells us, that by ſurrounding glaſſes with refuſe *Hay*, well preſſed and uniformly wetted, it would for ſeveral days afford ſuch a heat, as rendered that of horſe-dung uſeleſs. Works abr. Vol. 1. p. 72.

It is well known that *Hay* laid up wet in ſtacks, often takes fire. Hence the cuſtom of the antients to place their *Hay* ſtacks, or fœnilia, out of their villages.

HAY-*water*, a liquor prepared by the curious, and kept for the examination of the microſcope, as affording numbers of animalcules. *Hay* is not the only ſubſtance uſed to this purpoſe, but either that, or ſtraw, or graſs, oats, wheat, or barley, or indeed any other vegetable production, being infuſed in water, after a few days a whitiſh ſcum or motherineſs will appear upon it, which always contains a multitude of animalcules, and thoſe of very various ſizes, ſhapes, and kinds. Many of theſe are the ſame with ſome of the animals in pepper-water; for there are ſome which are found indifferently in all watery fluids expoſed to the air. The moſt general among theſe, is an oval one, ſomewhat reſembling an ant's egg in ſhape. Theſe are extremely nimble, and run backward and forward with great velocity; ſometimes alſo they will ſtop, and turn ſeveral times with ſurpriſing ſwiftneſs round their own axis. This is owing to a great number of legs or fins which they have, placed in a circular order; nor is this ſtrange motion peculiar to theſe, but is found in many other animalcules.

Another kind there is alſo very like the former, but that they have one end conſiderably ſharper than the other; they always move with this ſharp end foremoſt; they are moſtly tranſparent, but ribb'd longitudinally like a melon; others are only tranſparent at their ſmaller end: Theſe have no legs nor fins. Another ſort are alſo found in theſe infuſions, which are nearly as long as thoſe of the larger ſize in pepper-water; they are very nimble, and have a power of contracting themſelves as they ſwim along. Theſe have ſeveral feet viſible at the end, which ſeems their forepart, and theſe are moſt diſtinguiſhable as the water dries away, and the body of the animal ſhrinks up. Another ſort of animals are found in theſe infuſions, whoſe bodies are ſpherical, but pointed at one end ſomewhat like a pear: Theſe much reſemble bladders filled with water, and there are always ſeen a number of dark particles ſwimming in them. The motion of theſe animals is chiefly a revolving one, they will turn round an hundred times in a minute, firſt one way, and then another, and all the while will never ſtir a hair's breadth out of their place; but they are able alſo, when they pleaſe, to run backwards and forwards very nimbly. *Baker*'s Microſcope, p. 79.

Animalcules in the ſhape of eels are frequently met with alſo in theſe infuſions, and in many other liquors; their ſize is extremely different; ſome being more than a hundred times ſmaller than others.

HAY-*worms*. Beſide the ſmall worms or animalcules bred in water, in which *Hay* has been infuſed, which are only the objects of microſcopical obſervations, we find that it is a proper nidus of itſelf, ſometimes, for a much larger ſpecies of inſect called the *Hay-worm*, whoſe origin and changes have not, as yet however, been properly obſerved. An animal which can be produced from the egg, and grow to its full ſize during the ſhort time that *Hay* is left in the field in making, muſt be very quick in its growth, but yet it is found that multitudes of ſuch are produced, tho' probably few come to perfection, the removing of the *Hay* naturally deſtroying many. In the Philoſophical Tranſactions we have an account of the ſame ſort of inſect breeding among the cocks of barley while left in the field, many millions of them being diſcovered together on ſtirring or lifting up the cocks with a cane. They are alſo found in the barns where barley is laid up, and are ſo numerous that they ſtrow the way the carts go that carry the barley home, by the multitudes that are ſhook off. They are about half an inch long, as thick as a pigeon's feather, and of a whitiſh colour ſhaded with faint ſtripes of a yellowiſh brown. They have fourteen feet, and ſeem evidently by all their marks to be true caterpillars. They are of an offenſive ſmell, and their excrements are hard white pellets of pure flour, like that of barley; whence it is plain that they eat the grain.

HAZLE, *Corylus*, in botony, the name of a genus of trees, the characters of which are theſe: The flower is of the amentaceous or catkin kind, being compoſed of a number of leaves affixed in a ſquammoſe order to an axis; under each of theſe there are placed a number of apices. Theſe flowers are barren, and the embryo fruits are placed in different parts of the tree; theſe finally become a hard and roundiſh ſhell, containing a ſingle kernel, and ſurrounded by a callous fimbriated cup.

The ſpecies of *Corylus* enumerated by Mr. Tournefort, are theſe: 1. The common *Corylus* with a ſmall white fruit. 2. The *Corylus* with a very large round fruit. 3. The *Corylus* with a very long reddiſh fruit. 4. The *Corylus* with a large and long red fruit, covered with a white pellicle. 5. The cluſter fruited *Corylus*. 6. The common wild *Hazle*. And, 7. The dwarf exotic or Conſtantinople *Corylus*. *Tourn.* Inſt. p. 581.

HAZLE-*earth*, in agriculture, a moderately compact earth, much approaching to the nature of the chiſely ſoil, and indeed properly a ſpecies of it, but always containing a large quantity of a reſin-colour'd ſand. *Moreton*'s Northampt. p. 39.

HAZLE-*hen*, in zoology, the name of a bird of the gallinaceous kind, common in the woods of Germany, and ſuppoſed by many to be the *attagen* of the antients.

It is of the ſize of a very ſmall pullet; its belly is all over perfectly white; its breaſt white, variegated with black; its throat is reddiſh, and under the beak black, in the male, but in the female, of the ſame colour with the reſt; it has on each ſide of the head a white line; its head is of a greyiſh brown, and its back and rump much of the ſame colour with the partridge; its ſides are of a yellowiſh or reddiſh brown, variegated with white; its wings are variegated with black, brown, and white, as is alſo the tail, but that has an admixture of red. It is caught in thick woods, and feeds on vegetables. *Ray*'s Ornithology, p. 126.

HEAD (*Cycl*)—The diſeaſes of the *Head* are often miſtaken, even by phyſicians, for thoſe of other parts. Mr. Lieutand, of the French Academy, gives an extraordinary caſe of this kind. A man had a fever, with a violent diſorder of the *Head*; he afterwards was ſeized with a violent cough, and brought up a large quantity of matter. It was not doubted but that this was from the lungs, and no one queſtioned but that the man had an abſceſs there. On opening the body, however, the lungs were found perfectly ſound, and all his diſorder was found to be in his *Head*, where the ſphenoidal, frontal, and maxillary ſinuſes were found ſo full of matter, that they could contain no more.

Some phyſicians tell us, that perſons who are ſubject to diſorders of the *Head*, ought not to take any food at night. Dr. *Bryan Robinſon* of the Food and Diſcharges of Hum. Bod. p. 95.

M. le Dran, in his obſervations on wounds of the *Head*, ſhews how much more dangerous the caſe is, when the cranium does not break by violent blows, *&c.* than when it is fractured, becauſe of the greater commotion of the brain, *&c.* And therefore concludes it neceſſary to perform the operation of the trepan oftener than is commonly practiſed. Med. Eſſ. Edinb.

M. Winſlow has given us ſome very particular and curious remarks on the motions of the *Head* and neck, in the Memoires de l'Acad. Royale des Sciences, An. 1730.

Bleeding in the HEAD. Many phyſicians have been of opinion, that bleeding from the veins of the *Forehead* and temples is more expeditious in giving relief in diſorders of the *Head*, than the like diſcharge by veins more remote from the part affected. There ſeems, however, to be but little foundation for this, and that the bleeding by the jugular vein would much more expeditiouſly anſwer the end propoſed. If the ſurgeon, however, is called upon to perform this operation, he muſt firſt draw a handkerchief or neckcloth as tight round the neck as can be conveniently borne, that by compreſſing the jugular vein, thoſe branches of it may become more turgid and conſpicuous. The vein being opened, the patient muſt hold down his *Head*, that the blood may not trickle down into his eyes or mouth, when the ſtream does not ſpin out with ſufficient force. If the blood does not ſtop of itſelf, after a ſufficient quantity is diſcharged, you muſt compreſs the orifice with a finger, and, after wiping the forehead and face, apply a compreſs or two, with the proper bandage. *Heiſter*'s ſurgery, p. 282.

Bleeding in another part of the *Head* however, that is, by the occipital veins, which communicate with the lateral ſinuſes of the dura mater, is both by reaſon and experience approved to be ſerviceable in moſt diſorders of the brain, where that part is overcharged with blood, which may be this way diverted and evacuated. Theſe occipital veins are opened by the ſame apparatus with thoſe in the forehead.

Cartilages of the HEAD. The condyloide apophyſes of the os occipitis, the glenoide cavities, or articular foſſulæ of the oſſa temporum, the eminences next theſe cavities, and the condyloide apophyſes of the lower jaw are all cruſted over with very white and ſmooth cartilages, and there is likewiſe an interarticular or moveable cartilage in each articulation of the lower jaw with the temporal bones. The remaining cartilages of the *Head* are the cartilaginous ſeptum, and other cartilages of the noſe; the ſmall cartilaginous ring in each orbit, the cartilages of the outer ear, and thoſe which are joined to the os hyoides, which ſee in their proper places. *Winſlow*'s Anatomy, p. 150.

Ligaments of the HEAD. The ligaments of the bones of the *Head* are theſe: Thoſe between the occipital condyles and the ſuperior apophyſes of the firſt vertebra of the neck; thoſe between the os occipitis and the apophyſis dentiformis of the ſecond vertebra; thoſe of the articulation of the lower jaw with the tempoal bones; and thoſe by which the os hyoides is connected to the ſtyloide apophyſes. To theſe muſt be added the ligaments which connect the cartilages of the ear, thoſe of the noſe, the ſmall cartilaginous pulleys of the orbits, and the ciliary cartilages.

The ligaments of the occipital condyles reſemble thoſe of the vertebræ, and conſiſt of a ſtrong intertexture of ligamentary filaments, placed cloſe by each other, round the whole articulation, and fixed by one end in the occipital bone, by the other in the ſuperior apophyſes of the firſt vertebra, and ſurrounding the capſular ligaments.

The ligaments which go from the os occipitis to the apophyſis dentiformis are very thick, and diſpoſed in ſeparate faſciculi, which afterwards unite, and the ligaments of the articulation of the lower jaw are very ſtrong, and diſpoſed and inſerted in ſuch a manner as thoſe by which the clavicle is inſerted into the ſternum. They are fixed, by one extremity, round the glenoide cavity, or articular foſſula and eminence of each temporal bone, by their middle, round the interarticular cartilage, and by the other extremity round each condyle of the lower jaw. *Winſlow*'s Anatomy, p. 151.

Ulcers of the HEAD. There are ſeveral ulcers which the hairy part of the *Head* is ſubject to, and which the writers in medicine have diſtinguiſhed by the ſeveral names of *tineæ*, *favi*, and *achores*; tho' they do not all agree about the determinate ſignification of each of thoſe words. By the term *favus*, however, we now generally underſtand ſuch ulcers of the *Head* as are full of cavities, like a honeycomb; by *achores*, thoſe which are full of ſmall holes, and contain a moderately viſcid humour. Many call theſe diſorders by the common name of tinea, becauſe, from the abundance of ſmall holes in them, they make the head look like a moth-eaten garment; but this is a vague ſignification of the word, and we uſually now underſtand it, in a more determinate ſenſe, to mean a large and dry ſcab, to which the heads of children are ſubject, and which is full of thick foul ſcales, and very offenſive to the ſmell. This ſometimes alſo extends itſelf to the face, in which caſe it is called *cruſta lactea*. It is often of a mild and benign nature, but is ſometimes very ill-condition'd and dangerous. There is alſo a yet worſe kind of tinea than this, which covers the whole hairy ſcalp with an aſh-colour'd thick cruſt, attended with a violent itching and grievous ſtench. This is generally very difficult of cure, and the perſons afflicted with it have generally a pale unhealthy countenance. It much more frequently affects young perſons than adults, and is generally occaſioned either by the nurſes irregular courſe of life, or by the child's being uſed to foul feeding. Sometimes alſo ulcers of this kind, from the ſame cauſes, break out in adults, and are very difficult to cure; theſe much reſemble the leproſy: And in the pox, it is common to find the *Head* and face, particularly the forehead, ſpread with dry ſcabs and ſcabby ulcers.

When ulcers of theſe kinds are ſlight, gentle purges, with the addition of calomel, ſhould be given at proper intervals, adminiſtring between whiles, to adults, the decoctions of the woods, with the ſweetening powders. Infants at the breaſt may take diaphoretic powders; and their nurſes ought to proſecute the other methods. Externally it is proper to uſe cream, with a ſmall quantity of ceruſs mixed in it, or the oil of eggs, or of wax, with the elecampane ointment, or that of ceruſs or the diapompholygos. And if the ulcers are of a worſe kind, doſes of calomel are to be given more frequently, and a little crude quickſilver may be added to the external applications with great ſucceſs. But in worſe caſes, and where mercurials may not be employed, it will be neceſſary to take off all the hair; this may be done either by degrees, or at once, by means of a pitch plaſter ſpread upon ſtrong cloth, and applied all over the ſcalp, after the hair has been cut pretty ſhort. When a plaſter of this kind has lain on twelve, or four and twenty hours, the method is to pull it off at once, and it brings away with it both all the hair and the ſcabs. This, though a good method, is however a very harſh one, and cannot be done without great pain and effuſion of blood. When the plaiſter is taken off, the blood is to be wiped away with dry lint, and then the *Head* anointed with oil of bricks, with a ſmall admixture of oil of wax among it, and afterwards the whole ſcalp ſhould be covered with a plaſter of frogs ſpawn, with a ſmall admixture of camphor. This dreſſing ſhould be repeated every day, till the injured parts are clean, and then they may be healed with the oil of eggs and eſſence of amber. Internal medicines to ſweeten the blood, and a regularity of diet ſhould alſo be obſerved at the ſame time; a mixture of crude antimony and flower of brimſtone ſerve well for this purpoſe, and ſhould be given for ſome time before the external remedies, here directed, are employed. *Heiſter*'s Surgery, p. 268.

HEAD *of Fiſh*, *Caput Piſcium*. The *Head*, in the fiſh kind, is ſo very various in its ſhape and figure, that it makes one of the great articles of their diſtinction and characters. The *Head* is always ſingle, and placed at the anterior extremity of the body; but its proportion or ſize, as well as figure, is very various in the ſeveral kinds. Its differences in figure are five.

1. It is, in ſome fiſhes, cathetoplateous; that is, its ſides ſeem ſqueezed together, and its perpendicular meaſure, for this reaſon, is greater than its tranſverſe meaſure. We have inſtances of this in the pearch, the cyprini, and in ſeveral others.

2. In others it is plagioplateous; that is, depreſſed ſo that its top and bottom ſeem to have been ſqueezed downwards upon one another. Hence its horizontal breadth is greater than its perpendicular, and it is, in all reſpects, the contrary to the other *Head*. The conger, the ſturgeon, and the rayfiſh, give us evident inſtances of this ſort of *Head*.

3. In ſome fiſhes the *Head* is evidently rounded and cylindric, as in the petromyzæ.

4. The *Head* is, in ſome, ſmooth, as is the caſe of moſt fiſhes; but in others it is rough and aculeated, as in the ſcorpænæ, the cotti, and the legyri.

The differences with reſpect to proportion are alſo very great. The *Head*, in reſpect of the reſt of the body, is in ſome, 1. narrower than the middle of the body, as in the cyprini, ſalmons, mackrel, pearch, *&c.* 2. In ſome it is broader than the middle of the body, as in the cotti, ſiluri, *&c.* And 3. In others it is about equal to the middle of the body in breadth, as in the clarias.

The differences of the mouths of fiſhes, ſee under the article MOUTH.

The bones of the *Head*, in all animals, deſerve great attention; and in fiſh particularly, as they are more numerous in theſe than in any other creatures. They differ much alſo

in

in the various kinds of fiſh, in number, figure, and ſituation. As to number, 1. They are fewer than uſual in the cetaceous and cartilaginous kinds. 2. In the ſpinoſe fiſhes, in general, they are very numerous. The bones in the *Head* of the perca fluviatilis of Bellonius will ſerve as an inſtance of this. The number is not the ſame in the ſeveral kinds that ſeem neareſt allied. In the fiſh laſt mentioned there are no leſs than eighty. There are five in the tongue, one oblong, one in the anterior part, and four ſhorter in the hinder part. There are four in the lower jaw, two on each ſide. The oſſa hypophthalmica are ten on each ſide, four are ſmall, and of different figures from the reſt. The membrana branchioſtega contains on each ſide ſeven of them. The oſſeous laminæ, behind the eyes, are four on each ſide. The upper jaw conſiſts of four bones, two on each ſide. The noſtrils have each one bone placed below them. The bones of the palate are four; three of theſe are ſmall, and ſtand forwards; the other is long, and ſhaped like a pick-ax head, and extended all over the palate. The middle of the anterior bone is nicely articulated with this. There is, beſide theſe, a cartilaginous bone, of a very ſingular figure, extended under the bones of the palate, almoſt to the end of the ſnout; this has on each ſide an angular bone faſtened to it, and under that end which is neareſt the ſnout, there is yet another placed, which is of a very ſingular figure.

The bones that cover the *Head* above are four; the two anterior ones are ſmall, the two poſterior ones are long, and ſo broad, that they cover the greateſt part of the *Head* and cranium. The bones of the cranium are eleven in number; that which is neareſt the vertebræ is large, and has ſeveral apophyſes and cavities. In the lower part of this there are contained two oblong and flat little bones, of almoſt a ſtony hardneſs; all the reſt are ſmaller, and all of very ſingular and remarkable figures. *Artedi*, Ichthyolog.

HEAD-*Ach* (*Cycl.*)— Phyſicians commonly diſtinguiſh the *Head-ach* into two kinds, according to its degree and continuance. The gentleſt kind they call *cephalalgia*, and the more violent and obſtinate *cephalæa*; of which in order.

Cephalalgia is defined to be a pain in the *Head*, proceeding from a copious congeſtion of the blood and humours to that part, which do not find any exit or paſſage from thence.

They generally diſtinguiſh it alſo into two kinds, the idiopathic, and the ſymptomatic.

The idiopathic is that which ariſes from a plethora, and an immediate congeſtion of blood or humours in the *Head*. The ſymptomatic is that which ariſes from a fault in the primæ viæ, communicating with the *Head* by means of the par vagum of nerves, or from a tranſlation of the humours to the *Head*, in fevers, or other diſorders.

The diſtinction of the *Cephalalgia* from the *Cephalæa* is, that in the latter all the ſymptoms are more violent; the *Cephalæa* alſo is uſually chronical and habitual; the *Cephalalgia* only returns at times, and has but ſhort periods. The ſimple *Cephalalgia* is alſo diſtinguiſhed from the venereal *Head-ach* by the burning heat and ſenſation of eroſion which attends the latter, which alſo is continual, or, at leaſt, never wholly ceaſes, and is always moſt violent in the night, when the body is at reſt, and is hotter than in the day. *Junker*, Conſp. Med. p. 96.

The *Cephalalgia* ſometimes ſeizes on the whole *Head*; but more uſually the forehead is the ſeat of it; very frequently alſo it is felt about the origin of the noſe, and a weight or preſſure and burning heat are felt in the os cribroſum, and often at the ſame time there is felt a violent weight and preſſure in the bulbs of the eyes; not unfrequently a tooth-ach attends upon the *Cephalalgia*, and when this is violent, the other abates in proportion. A noiſe and ringing in the ears is often alſo an attendant on it, and the eyes are often red and inflamed; the face alſo looks red, and often turgid, but ſometimes it looks as remarkably pale, or has a redneſs irregularly ſpread over it; both theſe caſes are from ſtrictures upon the veſſels. The veſſels of the neck and temples are often turgid. Women are very ſubject to this pain about the time of their menſtrual diſcharges, either before their eruption, or at any time on their diminution; ſometimes the *Head-ach* is attended with a vertigo, which gives proof of a very violent congeſtion, and ſometimes a binding of the bowels, and a ſlight ſuppreſſion of urine attends it.

People of a plethoric habit of body are more ſubject than others to this pain, and, in general, young people more than ſuch as are older, and women more than men, and perſons who live high, and drink much wine, and uſe little exerciſe, ſuffer much more by it than thoſe who live lower, and uſe much labour and exerciſe.

Cauſes of the HEAD-ACH. Among the natural and internal cauſes, the principal are an over quantity of blood, and a derivation of great quantities of it toward the head, with an intention of nature to relieve herſelf there by a hæmorrhage from the noſe. The external or accidental means that may bring on this pain, are very numerous. The natural and habitual evacuations of blood being ſuppreſſed, and of theſe particularly a bleeding at the noſe, the neglect of accuſtom'd bleedings, ſweats prevented or repelled, and the omiſſion of purging, cuſtomary before at certain periods of the year; great commotions of the body, or paſſions of the mind; eſpecially anger, drunkenneſs with ſpirituous liquors of any kind, the attracting acrid fumes thro' the noſe, a ſudden cooling of the legs or feet, a tranſlation of the peccant matter toward the head in fevers, and a peculiar ſenſibility in the organs of ſmelling, whence perfumes give ſome perſons the *Head-ach*; and to all theſe are to be added an hereditary diſpoſition, or injuries from blows or concuſſions of the head long before. *Junker*'s Conſp. Med. p. 100.

Prognoſtics from it. The *Head-ach* is a pain rather troubleſome than dangerous in itſelf, but it too eaſily degenerates into worſe complaints, and not unfrequently preſages defects of the ſight, or hearing, or the gout; and in old age, lethargies, apoplexies, and paralytic diſorders. The *Head-ach* often is cured by nature, by plentiful hæmorrhages from the noſe, and ſometimes by inflammatory diſorders of the adjacent parts; it more eaſily leaves young people than old; and indeed where long ſettled upon a perſon, and become habitual, rarely gives way to any remedies.

Method of Cure. The congeſtions of humors are to be derived from the ſuperior to the inferior parts, and above all things the bowels are to be looſen'd by clyſters and purges, for they are uſually bound up in this diſorder. After this, medicines are to be given which will quiet the violent emotions of the blood; ſuch are powders of nitre, crabs-eyes, and ſome diaphoretic, with a little cinnabar, according to Stahl. When the blood is thick, a ſcruple of tartarum vitriolatum may be given every day with great ſucceſs. After theſe the gentle diaphoretics are to be given in ſmall doſes with the diluent decoctions of the common tea-herbs, ſuch as baum, ſage, and the like. And if the pains are exceſſive, a gentle opiate, ſuch as a ſmall doſe of the ſtorax pill may be added to theſe. External applications ſometimes alſo aſſiſt the uſe of internal medicines; of this kind are ſpirit of wine camphorated, with a ſmall admixture of ſaffron; this ſometimes almoſt inſtantaneouſly removes the pain. Coarſe bread with juniper berries, caraway-ſeeds, and ſalt, laid on as an epithem, is alſo ſometimes a preſent help; and bags of the aromatic ingredients reduced to a groſs powder are, tho' a flower, yet often a very valuable relief. All theſe are only to be uſed in the idiopathic *Head-ach*; for in the ſymptomatic, regard is to be had only to the principal diſorder; and when the cauſe is removed, the effect always ceaſes. After the fits of the *Head-ach* are over, it is proper by way of prevention for the future to bleed in the ſpring and autumn, and frequently to bathe the feet in warm water. The uſe of gentle exerciſe is to be greatly recommended. The fatty or oleaginous remedies preſcribed by ſome for rubbing on the head, are to be carefully avoided, as they ſtop up the pores, and prevent perſpiration. The ſmelling to pungent liquids is not of ſo much benefit, as uſually ſuppoſed. The urinous volatiles, ſuch as ſpirit of hartſhorn, ſal volatile, and the like, are ſometimes of a little preſent relief; but the common uſe of ſpirit of lavender and Hungary-water, on theſe occaſions, is often the cauſe of more violent pain, by cauſing a freſh derivation of humours on the parts. Cinnabar has, by many authors, been ſuppoſed a dangerous medicine in all caſes of this kind; but Stahl affirms, on repeated experience, that it has great good effects; and that in theſe and many other caſes, it ſupplys the place of opiates and anodynes. *Junker*'s Conſp. Med. p. 104.

Cephalæa is a violent and continual pain in the head, occaſioned by a rheumatic congeſtion of humours in the head. Notwithſtanding the *Cephalæa* is a continual and unintermitting pain of the head, yet it is ſubject to ſome remiſſions, and is thence diſtinguiſhed by authors into the periodic, the continual, and the vague *Cephalæa*. The continual kind is that which is always in the ſame degree, and admits not of the leaſt remiſſions. The periodical is that which has its regular periods of being leſs intenſe; theſe are called its remiſſions. And finally, the vague *Cephalæa*, is that which has times of being leſs violent; but theſe return at no regular nor ſtated periods. *Junker*'s Conſp. Med. p. 116.

Signs of it—The *Cephalæa* ſometimes ſo much reſembles the *Cephalagia*, or common *Head-ach*, that it only differs from it by its obſtinate continuance, and the violence of the pain; and in women it has all the ſame ſymptoms with the clavus hyſtericus, except that it affects indifferently all parts of the head. When this complaint ariſes from a venereal taint in the blood, it is always violent; but moſt ſo, when the perſon is warm in bed. When it ariſes from a ſcorbutic coagulation of the blood, or an inflammation of the meninges of the brain, the pain is remarkably ſharp and piercing, and is attended with a febrile heat, and an intolerable thirſt. There generally comes on a vertiginous diſorder of the head after this complaint has held the patient ſome time, and the patient can never bear any motion; and on the leaſt ſhaking, or diſturbing the head, the pain becomes violently intenſe, and reſembles the beating of an artery in pulſation. The pain is in general leſs violent while the patient lies down, but as ſoon as the *Head* is raiſed up ever ſo little, it increaſes to a great degree. The leaſt noiſe or motion is terrible to perſons in this ſtate, and the light is frequently offenſive and painful; ſo that the patient loves retirement in darkened and quiet rooms, and avoids company. Liquors of any ſtrength give

violence to the pain as ſoon as drank; and in caſes of this kind where a ſcorbutic habit is at the bottom, frequent and violent bleedings at the noſe happen, which give no laſting relief but only an abatement of the pain for the time.

Women are generally more ſubject to this terrible pain than men, theſe being rarely afflicted with it, unleſs when there is ſome violent diſorder in regard to the hæmorrhoids; or when there is a venereal taint in the blood. Among women, thoſe are moſt ſubject to it who live high, and lead ſedentary lives, and who are of a melancholy diſpoſition, or ſubject to obſtructions of the menſes.

Cauſes of it.—The general cauſe of this, as well as of all other *Head-achs* is a violent congeſtion of blood directed to the head; and the peculiar cauſes which determine the *Head-ach* to this terrible kind, are ulceroſe or exulcerated diſpoſitions of the body; theſe principally are owing to the ſcurvy, the venereal diſeaſe, or any violent cutaneous eruptions driven in, or to external injuries, as blows and wounds of the head, ill-treated. The antients ſuppoſed this owing to impoſtumes or collections of a viſcid matter in the head, and therefore always preſcribed bliſters, ſetons, and the like, and ſometimes the piercing the ſkull in the part where the pain was moſt violent. *Junker*'s Conſp. Med. p. 116.

In the moſt favourable caſes this is a diſtemper that with difficulty admits of a cure. Where there is a ſimple ulceration in the caſe, the cure becomes yet more difficult, but not quite to be deſpaired of; but where a venereal taint is at the bottom, a cure is ſcarce to be expected. For tho' the cauſe be removed, yet in this or any other kind of *Cephalæa* attended with a caries of the bones, the pain will afterwards often return, and that with little leſs violence than before.

Thoſe *Cephalæas* which ſometimes are relieved by nature, by copious diſcharges of ſerous humours, are more difficult of cure than others; and thoſe which happen to perſons of remarkably plethoric habits, threaten an approaching apoplexy.

Method of Cure.—The ſame general method is to be obſerved, as in the common *Head-ach*; which ſee above. But in this there are to be added to the medicines there preſcribed, ſuch as powerfully diſſolve mucous humours; ſuch are the roots of pimpernell, arum, and maſterwort, with the bitter herbs, ſaſſafras, gum ammoniacum, tartarum vitriolatum, and the like. After theſe, purging is proper; and in caſes where the ſcurvy or any venereal taint is joined, there muſt be always regard had to thoſe complaints in the whole method of cure. And indeed the ſcorbutic *Cephalæa* ſhould always be treated as the ſcurvy itſelf, and the venereal *Cephalæa* as the pox. And where any old ulcers have been dried up, or any other habitual diſcharge ſtopped, and the complaint is owing to that; the making iſſues or ſetons muſt be premis'd to any other attempt of a cure. Some inveterate complaints of this kind have been happily cured by mercury, whether they had or had not any thing venereal in their foundation; and in general, a ſalivation is a ſort of laſt reſource, be the origin what it will.

HEAD, in the manege, is to give a horſe *Head.* See ESCHAPER.

HEAD *in, and likewiſe the hips*, is a phraſe importing that you muſt paſſage your horſe with his *Head and Croupe in*, i. e. work him ſide-ways upon two parallel lines, at ſtep or trot, ſo that when the horſe makes a ſtep or volt, his ſhoulders mark a *piſte*, or tread, at the ſame time that his haunches give the tract of another; and the horſe plying or bending his neck, turns his head a little within the volt, and ſo looks upon the ground he is to go over.

HEAD-*Land*, in the ſea language. See LAND.

HEAD-*Lines* in a ſhip, thoſe ropes of all ſails which are next to the yards, and by which the ſails are made faſt to the yards.

HEAD-*Pence*, an exaction of a certain ſum formerly collected by the ſheriff of Northumberland from the inhabitants of that county, without any account to be made to the king. This was aboliſhed by the ſtatute 23 Hen. VI. c. 7. *Blount.*

HEADS, a term uſed by builders for that kind of tile, which they uſe to lay at the eaves of a houſe; being the full breadth of a common tile, and but half a tile in length.

HEAD-*Sails* in a ſhip, thoſe which belong to the foremaſt and boltſprit; for it is by theſe that the *Head* of the ſhip is governed, and by which it is made to fall off, and keep out of the wind. And theſe in quarter-winds are the chief drawing-ſails.

HEAD-*Stall*, among antient muſicians. See PHORBÆA.

HEAD-*Tin*, in metallurgy, is a preparation of tin ore toward the fitting it for working into metal. When the ore has been pounded and twice waſhed, that part of it which lies uppermoſt, or makes the ſurface of the maſs in the tub, is called the *Head-tin*; this is ſeparated from the reſt, and after a little more waſhing becomes fit for the blowing houſe. *Ray*'s Engliſh words, p. 122.

HEARING (*Cycl.*)—*Difficulty of* HEARING. In common caſes of difficulty of *Hearing* ſuddenly coming on, the following is an excellent remedy: Take eſſence of amber a dram, of caſtor a ſcruple, oil of chamæmile half a ſcruple, oil of amber one drop; mix theſe together, and three or four times a day put into the ear a piece of cotton wetted in them.

This is a complaint frequently happening to young women, from a ſuppreſſion of the menſes; and, in that caſe, there is no more requir'd for a cure, than barely to reſtore that diſcharge to its natural and proper courſe. It ſometimes alſo happens to men, from a ſtoppage of the hæmorrhoidal diſcharges, and is then to be cured by recalling them, and applying leeches to the part; or if the patient is averſe to that, bleeding or cupping often prove an immediate cure. When this difficulty of *Hearing* ariſes from any obſtruction in the auditory paſſage, the matter that cauſes the obſtruction is to be carefully removed by a ſurgeon. *Heiſter*'s Comp. Med. p. 174.

Old men often have a difficulty of *Hearing* from mere debility and loſs of the due ſtrength and tone of the parts. In this caſe medicines can give no aſſiſtance, but all applications uſually render the caſe worſe. And the ſame is to be obſerved in all caſes where the diſorder is very inveterate, or is hereditary; or owing to external injuries by which the tympanum has been broke, or any other of the principal parts are deſtroyed: The total loſs of *Hearing* after having held a perſon for many years, and not been at all relieved by the common methods of cure, has been ſometimes known to go off of itſelf, and the patient to hear as perfectly as ever; ſo that we are not to deſpair of relief even in the worſt caſes of this kind, and ſuch as have reſiſted all remedies. Perſons who are ſubject to returns of this complaint ſhould uſe frequent bleeding or cupping, be moderate in diet, and ſhun all exceſſes of ſtrong liquors, and uſe moderate exerciſe. Heiſter alſo affirms, on his own experience, that the drinking the mineral waters every ſpring in a proper and regular manner is of the utmoſt ſervice in preſerving the patient from returns of this diſorder during the year. *Heiſter*'s Compend. Med. p. 180.

Mr. Le Cat, in his treatiſe on the organ of ſound, propoſes an inſtrument as of his own invention, to aſſiſt dull *Hearing*. It conſiſts of a ſhell or cornet of copper, into which a ſmall funnel-like tube is fixed, ſo as its narrow end is at the center of the cornet. Dr. Parſons ſays, this inſtrument is common in England. See Philoſ. Tranſ. N°. 466. §. 9.

HEART (*Cycl.*)—The French anatomiſts have diſputed, whether or not the *Heart* is ſhortened in its ſyſtole, though all allow that it is then ſtraitned. Vid. Hiſt. de l'Acad. des Scienc. 1731.

The proportion of the weight of the *Heart* to that of the body is greater in the males than in the females of birds, both wild and tame. But this proportion differs leſs in the males and females of wild birds, than of tame birds; which may probably be owing to the exerciſe of the former being more nearly equal than that of the latter. Ibid. p. 106.

The proportion of the *Heart* to the body is much greater in birds than in fiſh; at a medium about 8 to 1. Dr. Robinſon thinks this great difference owing to the vaſtly ſuperior heat of birds. Ib. p. 108.

Dr. Bryan Robinſon has given us a table of the mean weights of the bodies, *Hearts*, and livers of ſeveral ſpecies of birds and fiſhes, as alſo of the proportions of the *Hearts* and livers to the weight of the body, and of the liver to the weight of the *Heart*. It appears from theſe tables, that the proportion of the weight of the *Heart* to the weight of the body is greater in wild birds than in tame birds. The former uſe more exerciſe, or move their muſcles more than the latter. And it is known that the motions of the *Heart* and blood are much increaſed by the motion of the muſcles. On the contrary, when the quantity of motion in the muſcular ſyſtem is greatly diminiſhed by the inactivity of bodies, the force of the *Heart* and motion of the blood will likewiſe be diminiſhed in the ſame proportion. But muſcles which are much moved, always increaſe in magnitude, weight, and ſtrength; and yet bodies which uſe much muſcular motion, are ſeldom obſerved to grow fat, or increaſe in weight; and therefore the weight of the *Heart* in proportion to the weight of the body will be greater in wild animals than in tame; and in bodies which uſe much exerciſe, than in bodies which are inactive.

The weight of the *Heart* in proportion to the weight of the body, is greater in ſmall birds than in large ones. It is likewiſe greater in a mouſe than in an ox, in a child than in a man; and probably greater in litttle men, than in large men. Now ſince ſmall animals are generally more active than great animals, we may allow the activity of the body to depend much on the proportion of the weight of the *Heart* to the weight of the body. Diſſert. on the food and diſch. of hum. bod. p. 103, 104.

The proportion of the weight of the *Heart* to the weight of the body, is leſs in fat bodies than in lean. As animals grow fat, the weight of their bodies increaſe, and their quantity of blood and weight of *Heart* leſſens; for the fat in the membranes compreſſes the blood veſſels, and leſſens the quantity of blood; and as this leſſens, the weight of the *Heart* leſſens, the weight of the *Heart* and quantity of blood always increaſing and decreaſing together. Ib. p. 105.

Various unnatural accidents happen to the *Heart*, and are the cauſes of diſorders, which never are underſtood till too late, on the diſſection of the body. Of this kind Mr. Hunauld ſhewed the Paris academy a remarkable inſtance in the *Heart* of a woman of thirty years old; in this the valves of

the left auricle were joined and cemented together, and left only a very ſmall aperture formed in the middle of the plane made by their re-union; the blood coming from the lungs into this auricle, could not without a very great and unnatural difficulty, paſs thence into the ventricle; and the auricle compelled by this to extend itſelf to contain a large quantity of blood, was become much larger than it ought to have been in its natural ſtate. In different parts of the united valves there appeared ſeveral little points where an oſſification was begun. The woman died phthiſical, nor could it be otherwiſe, ſince the lungs could not but be affected by the difficulty with which the blood entered into the left ventricle of the *Heart*. And the gentleman who gave the account obſerved, that this was no ſingle inſtance of a caſe of this kind, but that he had met with ſeveral ſuch, particularly one in the right auricle of the *Heart* of a girl of fourteen. Another inſtance of a remarkable diſtemperature of the *Heart*, is given by Mr. Du Fay of the ſame academy: A man who had lived to thirty-four in very good health, became at that age very ſubject to the vapours, but the complaint encreaſed to no particularly violent degree for the ſpace of eighteen years, but at this time he perceived a palpitation of the *Heart* to join with the other ſymptoms, and this held him to the time of his death, which was two years afterwards. Mem. Acad. Scien. Paris, 1735.

Theſe palpitations, which were ſlight at firſt, became afterwards ſo ſtrong, that they communicated their motion to the ſides, and might be ſeen through the patient's cloaths even when he was dreſſed. If the hand were applied to the region of the *Heart*, it was perceived to move very forcibly, and the arteries all partook of the diſorder, while the veins were all conſiderably ſwelled in the upper parts. In the latter part of his life he became dropſical, his legs ſwelling violently. On opening his body, the cavities of the breaſt and belly were found to be full of water, the lungs were ſound, but conſiderably waſted; the liver and ſpleen ſomewhat larger than ordinary, and the pancreas very large, and very hard and ſcirrhous. The *Heart* weighed above two pounds, and was ſo large that it threw the left lobe of the lungs toward the upper part of the breaſt. It meaſured fifteen inches round at the baſe, and the two ventricles were full of blood; the right was nearly of its natural ſize, but the left, which ought to be ſmaller than that, was ſo dilated as to be vaſtly larger, tho' its ſides had not at all loſt their thickneſs. The pericardium was ſomewhat thicker than ordinary, and was nicely applied to the *Heart*, but had on one ſide a tumor of the ſize of an egg, full of blood; the aorta was oſſified at the place where it goes out of the left ventricle. Mr. Du Fay eſteems this caſe to have been an extraordinary aneuriſm of the left ventricle of the *Heart*; a caſe ſeldom heard of.

Another ſcarce leſs memorable inſtance there is in the memoirs of the ſame academy, which proves that wounds of the *Heart* are not always ſo immediately mortal as is generally ſuppoſed. The caſe was this; a ſoldier was brought into one of the hoſpitals with a wound made by a ſword in the upper part of the left breaſt; he ſeemed very well for three days, but on the fourth he was taken with a fever and difficulty of reſpiration, and in fine died on the tenth day. On opening the body it was found that the ſword had pierced the pericardium, traverſed the right ventricle of the *Heart* in its lower part, and near the point, and pierced the pericardium on the oppoſite ſide, and gone through the diaphragm, and an inch deep into the liver; there was much blood found in the pericardium, a little clot of congealed blood in the wound in the *Heart*, and a quantity of purulent water on each ſide of the breaſt.

We have an account of a child which lived ſeveral days, yet upon diſſection its *Heart* was found without a pericardium, and turned upſide-down, ſo that its baſis, with all the veſſels, had fallen down as low as the navel, and its apex ſtill on the left ſide, lay hid between the two lungs. See Phil. Tranſ. N° 461. Sect. 7.

Mr. Boyle tells us of a kind of fiſh on the coaſt of Ireland, about the ſize of mackerel, the *Heart* of which was inverted, the baſis lying towards the tail, with the mucro pointing to the head, and adhering to the aorta. Works abridg. Vol. 1. p. 27.

Some creatures are known to live a conſiderable time after their *Hearts* are taken out: Mr. Boyle mentions frogs ſwimming in this condition, and living above an hour; and the *Heart* of an animal often gives ſigns of life after exſection. The ſame author mentions the *Heart* of a chicken unhatched, but perfectly formed, which continued to beat above an hour after the head and breaſt-bone were clipped off to diſcloſe it. And when the *Heart* was dead to appearance, it might be excited to freſh motion by puncture. The motion was alſo again excited by placing the part in the ſteam of warm water; and thus the *Heart* was kept beating for two hours and an half. See *Boyle*'s Works abridg. Vol. 1. p. 28.

HEARTS *of Fiſh*. The *Heart* in fiſhes is ſituated a little below the gills. It is uſually contained in an extremely thin membrane by way of pericardium, and placed in a large cavity. The *Heart* in the ſeveral kinds of fiſhes is of many different figures: 1. In ſome it is quadrilateral; of this we ſee inſtances in moſt of the common fiſh. 2. In ſome it is of a ſemicircular figure, but a little flatted, as in the cyprini. 3. Its ſituation is generally tranſverſe with reſpect to the head, but not always ſo. In the cetaceous fiſhes the *Heart* has two ventricles, as in land animals: but in all other fiſhes, that is, in all that have gills and not lungs, it has only one cavity. The *Heart* in all fiſh has only one auricle; this is very large, and is always placed on the left ſide of the *Heart*: At the place of the inſertion of this auricle, there are two valves, the one an upper, the other a lower one. The auricle in its lower part contains the receptacle of the veins, and this has alſo, at its inſertion into the auricle, two valves.

The aorta, or great artery in fiſhes, adheres to the upper part or baſe of the *Heart* by a ginglymus. Its firſt part, or that next the *Heart*, is ſmall, and contains two ſigmoide valves. Soon after this it is dilated into a large cavity, which is whitiſh on the outſide, and within is ſupported by ſeveral carneous fibres, forming a ſort of columns. From this part the artery is formed into a ſort of cave, and thence is carried to the gills; it gives one great branch to the hollow of each gill, that is four to each ſide; and each of theſe large branches is again, a little beyond its inſertion into the hollow part of the bow of each gill, divided into four other branches, which running along the baſe of the lamellæ, are divided finally into as many branches as there are lamellæ, each receiving one; theſe are carried to the extremity of the lamellæ, and there loſt; but the blood returns by as many veins, and is thence diſtributed throughout the whole body. In the margin of every lamina in the leaves of the branchiæ, or gills, there is a vein which diſcharges the blood it receives from the arteries of theſe parts into a trunk, which runs over the ſurface of every arch or bow of the gills; and in fine, every vein coming from all the bony circles of the gills, are by degrees, ſome higher and ſome lower, inſerted into one common trunk. This grand trunk of the vein runs along the ſpine, and performs the office of the deſcending trunk of the aorta in land animals, and diſtributes the blood to every part of the body of the fiſh. The trunks of the lower part of each bony circle take this courſe, but thoſe of the upper part are carried up to the brain and organs of ſenſation, and are returned thence by other branches, which join theſe lower trunks. Theſe veins when thus join'd, are carried to the origin of the gills, and there are diſcharged into another trunk lying upon the aorta, which is opened into the receptacle of du Verney. This receptacle is no other than a venoſe trunk formed by the meeting of ſeveral veins coming from the ſpine, from the liver, and other parts, and terminating in the auricle. Thus is the circulation in fiſh carried on in a very different manner from that in land animals; and the gills ſerve to offices little thought of by many authors. *Artedi* Ichthyolog.

HEARTS *of inſects*. It is eaſy to diſcover that many inſects have a true and regular *Heart*; nor is this any where more beautifully diſtinguiſhable than in the claſs of flies; the ſmall ones, and thoſe of tranſparent bodies, are to be choſen indeed for this examination, the larger and more opake being wholly improper for it. None is more eligible on this occaſion than the little fly produced of the puceron eater; this is a very pale yellowiſh fly of a flat body, and ſo perfectly tranſparent, that examined in a proper manner, its internal parts are ſeen as clearly as if they were in a white glaſs veſſel.

One of theſe little flies is to be taken ſoftly by the head between the fingers; the wings are to be bent backward, and held with the head, the body inverted and held up againſt a ſtrong light, and the belly then examined with the help of a magnifying glaſs. This examination will convince any one that flies have a real *Heart*; they have not a long veſſel only, in the place of one running lengthway down the back, as Malpighi thinks is the caſe in caterpillars and butterflies; but toward the middle of the ſecond ring, and ſometimes in the third, counting from the corcelet, one plainly diſcovers a part which can be taken for no other than a real *Heart*. The figure of the *Heart* in theſe animals varies however much more than in any others that we are acquainted with. Sometimes this *Heart* is of the figure of a kidney placed tranſverſely, and with its hollowed part toward the corcelet, with a long veſſel running ſtrait from this hollowed part up the corcelet. At other times the hollow of the *Heart* diſappears, it lengthens itſelf, and acquires the figure of a bottle, with the veſſel before deſcribed placed as its neck. Sometimes it is more, and ſometimes leſs inflated and diſtended; ſometimes the tranſverſe diameter ſurpaſſes the longitudinal, and at others the longitudinal diameter exceeds the other. At all times, however, one may ſee a regular alternative contraction and dilatation of the *Heart*; and to the contraction there conſtantly ſucceeds a jet of liquor thrown into the long veſſel as if by a ſyringe; but what is very ſingular is, that after four or five of theſe jets, one always ſees the liquor before thrown up deſcending into the *Heart* again out of the corcelet, by the ſame veſſel by which it was received from the *Heart*. *Reaumur*'s Hiſt. Inſ. Vol. 4, p. 261.

HEART-*burn*, a diſeaſe properly called by medical writers ſoda. See the article SODA.

HEART-*ſhells*, *Conchæ cordiformes*, in natural hiſtory, the name of a genus of ſhells, by ſome authors referred to the pectunculus or cockle kind, but by later writers juſtly diſtinguiſhed into a ſeparate genus. The characters are theſe: It is a bi-

valve ſhell-fiſh of a globoſe elated form, furrowed in deep lines, and in ſome ſpecies imbricated, in others prickly, never auriculated, and always expreſſing what we call the figure of a *Heart*. Hiſt. Nat. Eclairc. p. 332.

There are ſeveral very remarkable ſpecies of this genus. The imbricated cordiform, or *Heart-ſhell*, is a very elegant one; the French authors call this the faitage, or roof-ſhell, from its reſembling the rafters on the top of a houſe. It repreſents in one view a *Heart* opened, but its great character is the external work, which perfectly reſembles the beams and rafters on the top of a houſe. The French call another ſpecies of this the choux, or cabbage-ſhell, from its being undulated like the leaves of ſome of the garden curl'd cabbages. The Noah's-ark ſhell is alſo of this genus, which no author has been able before to reduce to any genus at all. The name *cordiformis* is as old as Matthiolus's time, but never was made a generical term before.

The ſpecies of the *Cordiformes*, or *Heart-ſhells*, may be arranged under ſeveral general heads: Some are of a very globular figure; of theſe we have the following ſpecies: 1. The yellow furrowed *Heart-ſhell*. 2. The grey ſpinoſe *Heart-ſhell*. 3. The white furrowed *Heart-ſhell*. 4. The *Cartiſſa* of Rumphius. 5. The thick *Heart-ſhell*, with the cardo ſeparated from the apex. 6. The thick *Heart-ſhell* with the cardo at the apex. 7. The *Corbula*: This is an oblong *Heart-ſhell*, very nearly approaching in ſhape to the *ſhell* called, the *Noah's-ark ſhell*.

Some of the *Cordiformes* are of a triangular ſhape; of theſe we have the following ſpecies: 1. The reticulated and ſpotted *Heart-ſhell*. 2. The ſtrawberry *Heart-ſhell*: This is elegantly variegated with ſmall red ſpots. 3. The white ſtriated *Heart-ſhell* denticulated at the edge. 4. The variegated ſtriated *Heart-ſhell*. 5. The variegated and furrowed *Heart-ſhell*. 6. The ſtriated gondola *Heart-ſhell*.

Of thoſe *Cordiformes* which are more nearly of the ſhape of the human *Heart*, there are the following ſpecies: 1. The *Heart-ſhell* variegated with roſe coloured ſpots, and denticulated at the edge. 2. The white circular *Heart-ſhell*. 3. The ſmall roſe-colour'd *Heart-ſhell*.

4. Of the imbricated *Cordiformes*, we have the following ſpecies: 1. The *Heart-ſhell* with great yellow laminæ. 2. The compreſſed *Heart-ſhell* with yellow laminæ. 3. The roſe-coloured *Heart-ſhell* with yellow laminæ. 4. The cabbage-leaf *Heart-ſhell*; this is elegantly cut and curl'd in the manner of the leaves of ſome of the curl'd cabbages, and is beautifully variegated with ſpots of red. 5. The common *Noah's-ark ſhell*. 6. The yellow and white *Noah's-ark ſhell*. 7. The elegantly variegated *Noah's-ark ſhell*. 8. The rare *Heart-ſhell* deſcribed by Fabius Columna: This is a foreign *ſhell*, and has its margin terminated in a point, and has an oblong hollow within. It is white and very tender. Hiſt. Nat. Eclairc. p. 330.

HEAT (*Cycl.*)—The changes from *Heat* to cold are ſometimes ſo great and ſudden in South Carolina, as to cauſe 30 degrees difference in Fahrenheit's thermometer, in the ſpace of a day. See Phil. Tranſ. N° 470. Sect. 4.

The *Heat* at Aſtracan, in July 1746, was ſo great as to raiſe Mr. de L'Iſle's thermometer, in the ſhade, to the 89th degree, which correſponds to 103½ of Fahrenheit's. And during the whole month of July, and for ſeveral days in Auguſt, the thermometer was higher than what it riſes to by the natural *Heat* of the blood, which in Fahrenheit's is placed at 96. Mem. de l'Acad. de Berlin, 1746.

Hence it appears, that the opinion ſome entertain of animals not being able to live in air heated beyond the heat of the human blood, or the 96th degree, is erroneous.

All bodies *heated* beyond a certain degree, and applied to our bodies, give us pain, ſtimulate, and inflame; when greatly heated they mortify whatever part they touch.

Animal HEAT. To what organs or operations the *Heat* of the human and other animal bodies is owing, is hitherto extremely doubtful. The opinions which at preſent prevail, are, 1. That the *Heat* of animal bodies is owing to the attrition betwixt the arteries and the blood. 2. That the lungs are the fountain of this *Heat*. 3. That the attrition of the parts of the ſolids on one another produce it. 4. That it is owing to the whole proceſs, by which our aliment and juices are conſtantly undergoing ſome alteration.

The arguments in favour of the firſt opinion are: That if an artery is tied or cut, the part to which it goes turns cold; on the ceaſing of the pulſation of the arteries, cold and death follow. An increaſe of *Heat* attends a briſk circulation, and a languid circulation is accompanied with a ſmall *Heat*. One who burns in a fever, or is hot with exerciſe, has a full and frequent pulſe; in cold faintings, chloroſis, &c. the pulſe is ſmall and ſlow; and laſtly, that the thermometer ſhews the arterial blood to be a little hotter than that of the veins. This is accounted for from the conical figure of the arteries, from their flexures and branchings into exquiſitely ſmall capillaries; whence the reſiſtance and conſequent attrition muſt be great; from the number, ſtrength, and elaſticity of their coats; from the propelling power of the heart, and their ſtrong reſiſtance. From all theſe the particles of the blood perpetually getting new motions, directions, and rotations, are attenuated, condenſed, have their angles ground off, and are made homogeneous: Hence the fluidity, red colour, and *Heat* of the maſs which is here perfected. But this theory is doubtful; for what is ſaid of arteries, may be ſaid of any other parts, whoſe functions are neceſſary to life. The *Heat* and pulſation of the arteries do not keep together in any regular proportion; in ſome morbid caſes there is a great ſenſible *Heat*, and a ſmall pulſe; and in others a full pulſe, and great coldneſs. Beſides, all the length this demonſtration goes, is to ſhew, that the motion of the arteries and *Heat* are generally in proportion, which however does not ſhew which is the cauſe, and which the effect; nor indeed that either is the cauſe or effect of the other, ſince both may be the effects of ſome other cauſe. As to the proof by the thermometer, it ſeems doubtful; and what adds to the doubt is, that the venal blood does not coagulate ſo ſoon as the arterial. In ſhort, this theory is not eſtabliſhed by any ſatisfactory and convincing proof.

The ſecond opinion is, that the lungs are the fountain of *Heat* in the human body. All that has been ſaid for the blood's being heated in the arteries, is advanced to prove this hypotheſis, with conſiderable addition, *viz.* that in the lungs the blood veſſels every where attend, divide, and ſubdivide along with the ramifications of the wind-pipe; and as theſe are perpetually changing their ſituation and form, becoming longer or ſhorter, making more acute or more obtuſe angles, ſo muſt the concomitant blood-veſſels every moment make new angles, and give the blood new directions; that at laſt the blood enters into an exquiſitely fine net-work, ſpread every where on the vaſtly thin air veſicles, where theſe air-bladders are perpetually changing their angles, points of contact, their form, volume, interſtices, and ſo forth. From theſe, and the elaſticity of the air, and weight of the atmoſphere, the blood is ſaid to be churned, preſſed backward and forward, broken and kneaded together, diſſolved and condenſed, made red and hot in reſpiration. This theory, however plauſible, is not ſatisfactory. For, 1. What was ſaid before of the improbability of *Heat* being generated by the ſole attrition of fluids, takes place here. 2. Tho' the lungs be regularly ſupplied with plenty of air, which has weight and elaſticity enough to carry on the alternate ſwelling and ſubſiding of the veſicles; yet life and *Heat* ſoon fail, if that air has, by paſſing through the fire, or any other way, been robbed of ſome particles or quality, different from its weight and elaſticity. 3. The argument from the additional action of the ſolids of the lungs on the blood, more than what is found in the arteries, from their greater and conſtantly varying motion, ſeems to be fully taken off by one part of Hook's experiment, exhibited before the royal ſociety, in which the lungs of a dog being kept conſtantly diſtended by a freſh blaſt of air, the dog lived, and his heart beat regularly: So that there is no need for that frequent and great variation of angles, and points of contact, upon which the additional attrition is built. 4. That the cold air ruſhing into the ſpongy lungs, on the numberleſs air-bladders, on which the blood is almoſt ſuperficially ſpread, ſhould make the blood hot, is an improbable opinion, and ſupported by no proof. And as the cauſe appears not at all promiſing à priori, ſo the effect ſeems to demonſtrate this not to be the cauſe. For, 5. That the blood is rather cooled than *heated* in the lungs, may be inferred from the benefit received by the inſpiration of cool air in many inflammatory diſeaſes, eſpecially thoſe of the lungs. In burning fevers, with a full quick pulſe, red ſkin, and a large and quick reſpiration, relief has often been given by opening a window, and admitting a ſtream of cool air to breath in: The effects of which has been obſerved to be, that tho' the body was cloſe covered, yet in one minute the reſpiration became ſlower, and very ſoon after the pulſe abated of its fullneſs; and not only the face, but the whole body, of its fiery *Heat* and colour. 6. If the blood was *heated* in the lungs, we ſhould need leſs of their function, when we are warm, or in a warm place, the *Heat* of our bodies, or of the atmoſphere, doing ſo much of the office of the lungs; and that we ſhould want more of it, when cool, or in cool air. But when we are hot, and want to be cooled, we breathe full and quick; and when we are cold, and want to be warmed, our reſpiration is ſlow and ſmall; contrary to what one would expect, if the action of the air on the blood in the lungs were to *heat* it. 7. The blood which comes from the ſmall veſſels of the lungs, is not more expanded than before, as has been aſſerted, but not proved by any experiment, which it would certainly be if it was hotter; for liquors rariſy by *Heat*, and few more than blood. 8. If the blood owes its *Heat* to the action of the lungs, we muſt look out for another ſource of *Heat* in the egg and fœtus. To the objection, that the *Heat* of the mother is ſufficient for the purpoſe, till this new function comes into action, two obſervations may be oppoſed: The firſt is, that toward the end of incubation, an egg may be left by the dam, in a cold ſeaſon, for a little longer time than would be ſafe for the chick, if all its *Heat* depended upon her; yea long enough for an egg, that contains no warm principle to become of the temperature of the ambient air; yet upon opening it, the chick has been found neither quite ſo cold, nor dead. The ſecond is, that a ripe fœtus, taken away from the mother, but continuing within the membranes, can live

ſeveral hours by its own *Heat*, without any aſſiſtance from the lungs. What is the cauſe of this *Heat* before the lungs act? How comes it to fail as ſoon as the lungs play? Med. Eſſ. Edinb. Abr. Vol. 1. p. 228. ſeq.

The third opinion is, that the cauſe of animal *Heat* is owing to the action of the ſolid parts upon one another. The heart and arteries move moſt, and it is natural to expect, that the *Heat* ſhould be owing to this motion. But even this does not ſeem very plauſible, from the following conſiderations. 1. The moving parts, however we term them ſolid, are neither hard nor dry; which two conditions are abſolutely requiſite to make them fit to generate *Heat*, by attrition. 2. None of their motions are ſwift enough to promiſe *Heat* in this way. 3. They have no great change of ſurface in their attritions. 4. The moveable fibres have fat, mucilage, or liquors every way ſurrounding them, to prevent their being deſtroyed, or *heated* by attrition. Med. Eſſ. Abr. vol. 1. p. 231.

A fourth cauſe aſſigned for the *Heat* of our bodies, is that proceſs by which our aliment and fluids are perpetually undergoing ſome alteration.

This proceſs, according to Dr. Stevenſon, may be one *ſui generis*, ſomewhat of a middle nature, betwixt fermentation and putrefaction, and he thinks it to come ſo near to the latter, that he chooſes to call it by that name. In putrefaction, which is a moſt powerful diſſolvent of bodies, the inteſtine action of their minute particles creates, collects, or ſome way or other is the cauſe or means of *Heat*. The Doctor thinks it probable, that this proceſs is conſtantly carried on in all our juices, eſpecially where there is blood, and this chiefly in the veins; ſo that the blood is both the fountain of *Heat*, and the firſt ſpring of motion. He obſerves, that it is agreeable to the laws of natural philoſophy to reaſon on the chemiſtry of the animal body, as well as on its mechanics; the minute component parts of ſolids having a ſet of laws peculiar to them; and their intimate changes and actions on one another, are not to be accounted for by the courſer mechanical laws. He obſerves laſtly, that ſince it has never been demonſtrated, that any fluid acquired *Heat* in the coarſe mechanic way, by friction with a ſolid body; or that ſo conſiderable a change was made on the ſtructure of the minute parts of bodies, as is made in this proceſs, without producing *Heat* at the ſame time; and ſince in fermentation, putrefaction, &c. the *Heat* is not pretended to be owing to the veſſels containing the changed ſubject, but to what happens to its minute parts, in undergoing the change, it ſeems, on the whole, an unphiloſophic partiality for mechanics to maintain, that our juices have all their *Heat* communicated to them from the ſolids, and acquire it by rubbing with the veſſels. See Medic. Eſſ. Edinb. vol. 5. art. 77. Abridg. Vol. 1. p. 222. ſeq.

A late author thinks the *Heat* of animals explicable from the phoſphorus and air they contain. Phoſphorus exiſts, at leaſt in a dormant ſtate, in animal fluids; and it is alſo known that they all contain air; it is therefore only neceſſary to bring the phoſphoreal and aereal particles into contact, and *Heat* muſt of conſequence be generated; and were it not for the quantity of aqueous humours in animals, fatal accenſions would frequently happen. Dr. *Mortimer* ap. Phil. Tranſ. N° 476. ſect. 20. See the article PHOSPHORUS.

HEATH, *Erica*, in botany. See the article ERICA.

HEATH-*hen*, in zoology, a common Engliſh name for the urogallus, or tetrao minor, called alſo the grouſe. See the article GROUSE.

HEATH-*moſs*, *Coralloides*, in botany, the name of a genus of the moſſes; the characters of which are theſe: They are compoſed of ſtalks often branched in the manner of corals, and compoſed of parts of a different figure and appearance, not ſimple and uniform as the byſſi and confervæ. On the ſummits of the branches there grow a ſort of fleſhy tubercles, which Micheli calls the receptacles of flowers; and the little atoms which are ſeen adhering to the different parts of the ſtalks, he calls the ſeeds. Dillenius is rather for thinking them the farina; and the tubercles, either the capſules of ſeeds, or the young plants, ready to fall off from the parent ſtem, and ſhoot for themſelves like the bulbs of the dentaria, biſtort, and the like. However this be, theſe are parts too minute to found generical diſtinctions on, theſe may be better deduced from a groſſer conſideration of the ſtalk, and the figure of the tubercles. Theſe have no rim or margin, and are uſually larger in the leſs branched kinds, and ſmaller in the more ramoſe. This being a very numerous genus of moſſes, it is divided into ſeveral orders: 1. The fungiform. 2. The cup-like. 3. The ramoſe, or corniculate ones. *Dillen.* Hiſt. Muſc. p. 76.

The fungiform *Coralloides*, are neither hollow nor branched. Of theſe there are only five known ſpecies: 1. The fleſh-coloured fungiform *Coralloides*; this has a wide cruſtaceous and granulated baſe, of a greeniſh or greyiſh colour; on this there firſt appear ſeſſile tubercles of the bigneſs of a pin's head, and of a pale fleſh-colour. Theſe afterwards riſe up, and are ſupported on ſlender pedicles, and grow to the ſize of coriander ſeeds. It has been called by moſt authors a fungus, by ſome a lichen, and by ſome a lichenoides. It is found in England and other places. 2. The brown muſhroom-like *Coralloides*. This has a duſky foliaceous baſis, from which it riſes in form of ſmall oblong ſtalks, which widen into a ſort of tubercles at the ends. This is found on Hampſtead Heath, and in other places. 3. The ſmall black pin-like tree *Coralloides*. This has very little cruſtaceous matter at the bottom, and its heads are of the ſize of muſtard-ſeeds, ſupported on ſmall black ſtalks, the whole not unaptly reſembling pins with their points ſtuck in the wood. 4. The pale ſmall ſtone pin-like *Coralloides*: This has a large cruſtaceous bottom, and its fungiform heads are very ſmall, and placed upon very ſhort ſtalks. 5. The pale fleſh-coloured ſhort-ſtemmed fungiform *Coralloides*: This has been often found on the hooſs of horſes half rotted with the weather, and has been uſually called a fungus by authors. See Tab. 2. of Botany, N° 5.

The *Coralloides* of the ſecond order, or the *Cup-moſſes*, as they are uſually called, are tubuloſe, uſually not branched, and often ſingle, often proliferous.

Of theſe there are ſome which have more regular and perfect cups, and others which have them leſs perfect. Of the more perfect kind are the following ſpecies. 1. The common *Cup Coralloides*, or *Cup-moſs*. 2. The ſcarlet-headed *Cup-moſs*. This is leſs common than the former, and is adorned with beautiful ſcarlet tubercles. 3. The *Cup-moſs*, with indented edges. This is uſually taller and ſlenderer than the common kind, and is frequent on ditch-banks, &c. 4. The *Cup-moſs*, with radiated edges. The rims of the cups in this are beautifully foliated. 5. The ſmall rattle leav'd *Cup-moſs*. The cups of this are formed like the mouth of a trumpet, and grow out of a large and beautifully divided leaf, creeping upon the ground; the cups are ſmall. 6. The ſhort-footed *Cup Coralloides*. The leaves of this ſpecies creep on the ground, and are green on the upper ſide, and white underneath; the cups which ariſe from theſe are ſmall and browniſh within. 7. The elks-horn-leav'd *Cup Coralloides*. The leaves of this are large, and ſtand ſomewhat erect, and have ſegments like an elk's horn; they are ſmooth, hard, and cartilaginous; the cups are ſmall, and riſe from every part of theſe; they are but lightly hollowed, and a little crenated at the edge. 8. The branched and indented *Cup-moſs*. This is taller and ſlenderer than the other *Cup-moſſes*, and the pedicles of the cups are ſmooth and very ſlender.

Of the *Cup-moſſes*, with leſs perfect cups, the following are the known ſpecies: 1. The ſkewer *Coralloides*. This is ſcarce at all branched, and its cups are not eaſily diſtinguiſh'd. It is commonly called *horned Moſs*; the cups have tubercles, and are ſituated near the bottom of the ſtalks; it is very common on heaths. 2. The thighbone *Cup Coralloides*. The tubercles on this are large and brown, cover the whole extremity of the ſtalk, ſo that the cup is ſcarce diſcernible. 3. The horned *Cup Coralloides*. This grows to two inches high, and is ſometimes branched; it is of a greeniſh white colour, and is hollowed into a cup at the end of each. 4. The branched cornucopiæ *Cup-moſs*. This is hoary on the ſurface, and the cups are cruſted at the edges. 5. The clumſy indented *Cup Coralloides*. This is hoary on the ſurface, and of the thickneſs of a gooſe quill, and of a greyiſh green colour. 6. The ſcarlet headed branched *Cup-moſs*. 7. The brown-headed leſs branched *Cup-moſs*. Theſe are but very lightly pixidated, and the firſt of the two ſcarce diſtinguiſhably ſo. *Dillen.* Hiſt. Muſc. p. 100.

Of the third order of the *Coralloides*, or thoſe which are branched, and appear like ſmall ſhrubs, with their tops bent, and divided into numerous fine ramifications. The following are the known ſpecies: 1. The great ſoft perforated *Coralloides*. This is very common on Heaths, and grows to three or four inches high. 2. The ſmall, ſoft, open *Coralloides*. This is whiter and more branched than the former. 3. The elegant fine cut *Coralloides*. The joints of this are hollowed like a ſaucer, and nicely foliated. It is a native of the American Iſlands. 4. The little, criſp, imperforated *Coralloides*. This is found in Virginia. 5. The prickly, diſtorted *Coralloides*. This ſpreads variouſly and irregularly on the ground. 6. The leſs branched horned *Coralloides*. This is common in woods among other *Moſſes*. 7. The more branched *Coralloides*, with ſhorter ramifications. This is frequently found about the roots of trees. 8. The ſmall, brittle, madrepora-like *Coralloides*. This ſcarce exceeds half an inch in height. 9. The common white mountain *Coralloides*, called ren-deer-*moſs*. This is every where common with us on Heaths, and is what the ren-deer feed upon in Lapland. 10. The common mountain *Coralloides*, with brown tips. This is compoſed of ſlenderer branches than the former, and the extremities of all of them are tipped with a reddiſh brown, whereas the others are white throughout. 11. The brown ſolid prickly *Coralloides*. This is a very elegant ſpecies; it rarely exceeds an inch in height, and is very much branched. 12. The black lace *Coralloides*. This alſo is a very elegant ſpecies, it rarely exceeds half an inch in height, but ſpreads very wide; it has no thick ſtalk, but is compoſed of numerous fine ones, ſo interwoven as to reſemble lace. 13. The criſp warty alpine *Coralloides*. This grows to rocks and ſtones, with a woody baſe, in the manner of the ſea fucus's, and riſes variouſly branched to an inch or two in height. 14. The alpine coralline-like *Coralloides*. This is called, by ſome, mountain

mountain *Coralline*, and would ſcarce be diſtinguiſhable from ſome of the ſmall *Corallines*, if it were articulated. 15. The cypreſs-like *Coralloides*. This has globoſe tubercles at the extremities of the branches, and when ſeen at a diſtance, has ſomewhat of the appearance of favin. 16. The cluſter branched *Coralloides*. This grows in the mountains of Ruſſia, and reſembles a ſmall ſea coral. 17. The horned wrack, or fucus-like *Coralloides*. This grows in thick tufts on the mountains in Wales. 18. The warty and pod-like *Coralloides*. This grows in ſmall cluſters, from a ſort of cretaceous baſis; the branches are furrowed, and riſe in prominences in ſeveral places, as if they were pods containing ſeeds. 19. The horned cluſter *Coralloides*, uſed in dying, and reſembling ſome of the round branched fucus's. This is commonly called argol, and canary weed, and by ſome rocella and orcella. It grows from a tophaceous or cretaceous baſis; the branches are two or three inches long, ridged, ſolid, and ſomewhat branched. This is uſed in the dyers buſineſs for making a red colour. *Dillen.* Hiſt. Muſc. p. 115.

HEATOTOTL, in zoology, the name of an American bird, deſcribed by Nieremberg, and called alſo *Avis Venti*. It is remarkable for a very large and round creſt of whitiſh feathers on its head. Its breaſt is of a browniſh grey; its belly white, and its feet yellow; its tail is round when expanded, and is variegated with black and white. Its back and wings are black. *Ray*'s Ornithol. p. 301.

HEAVING *a Peek*, in the ſea language. See the article PEEK.

HEAVY, in the manege. A horſe is ſaid to reſt *heavy* upon the hand, who, through the ſoftneſs of his neck, the weakneſs of his back, the weight of his fore-quarters, or through wearineſs, throws himſelf upon the bridle; but withal, without making any reſiſtance, or any effort to force the horſeman's hand. This fault is remedied, and the horſe made light upon the hand, by ſtopping, and making him go back frequently; if it proceeds only from lazineſs and ſtiffneſs; but if cauſed by any defect in the back, there's no remedy for it.

HEBBING-*Wears*, in our ſtatutes, is uſed for wears or engines made or laid at ebbing water, 23 Hen. 8. 5. *Blount.*

HEBDOME, Ἑβδόμη, among the Athenians, a feſtival or holy day kept always on the ſeventh day of the moon in honour of Apollo; that being ſuppoſed to have been his birth-day. *Hofm.* Lex. in voc.

HEBENSTRETIA, in botany, the name of a genus of plants, the characters of which are theſe: The Perianthium is of a tubular form; it conſiſts of one leaf lightly divided at the verge into two lips, the upper lip is ſhort, ſtrait, and narrow, the under is lanceolated, long, and bent downwards; the flower conſiſts of one irregular petal; the tube is cylindric, and ſhorter than the cup; the lip is only one, not two, as in other labeated flowers; it is broad, and divided into four ſegments at the end, and is of the length of the under lip of the cup. The ſtamina are four filaments, two ariſing from each ſide of the lower part of the lip of the flower. The germen of the piſtil is oblong, the ſtyle is ſlender, and of the length of the flower, and the ſtigma is very thin. The fruit is an oblong capſule opening into two parts. The ſeeds are two in number, and are oblong, convex and triſulcated on one ſide, and flat on the other. *Linnæi* Gen. Plant. p. 306. Hort. Amſt. 11, 109.

HEBRAICA *Concha*, in natural hiſtory, a name given by authors to a very beautiful ſea-ſhell of the voluta kind, from a number of black marks which ſeem to reſemble the Hebrew characters. See the article VOLUTA.

HEBREW *Characters*, (*Cycl.*)—It has been ſuppoſed by many very learned men, that the *Hebrew* characters or letters were often uſed hieroglyphically, and had each its ſeveral diſtinct ſenſe underſtood as an hieroglyphic. Neuman, who ſeems to have taken infinite pains to find out this ſecret meaning of theſe letters, gives the following explication: א aleph, he ſays is a character denoting motion, readineſs, and activity; ב beth, ſignifies 1°, matter, body, ſubſtance, thing. 2°, Place, ſpace, or capacity. And 3°, in, within, or contained; ג gimel, ſtands for flexion, bending, or obliquity of any kind; ד daleth, ſignifies any protruſion made from without, or any promotion of any kind; ה he, ſtands for preſence, or demonſtrative eſſence of any thing; ו vau, ſtands for copulation or growing together of things; ז dſain, expreſſes vehement protruſion and violent compreſſion, ſuch as is occaſioned by at once violently diſcharging and conſtringing a thing together; it alſo ſignifies, ſometimes, the ſtraitening of any figure into a narrow point at the end; ח cheth, expreſſes aſſociation, ſociety, or any kind of compoſition, or combination of things together; ט teth, ſtands for the withdrawing, drawing back, or receſs of any thing; י jod, ſignifies extenſion and length, whether in matter or in time; כ caph, expreſſes a turning, curvedneſs, or concavity; ל lamech, ſtands for an addition, acceſs, impulſe, or adverſation, and ſometimes for preſſure; מ mem, expreſſes amplitude, or the amplifying any thing in whatever ſenſe; in regard to continuous quantities, it ſignifies the adding length, breadth, and circumference; and in disjunct quantities it ſignifies multitude; נ nun, ſignifies the propagation of one thing from another, or of the ſame thing from one perſon to another; ס ſamech, expreſſes cincture and coarctation; ע ain, ſtands for obſervation, objection, or obviation; פ pe, ſtands for a crookedneſs or an angle of any figure; צ tſade, expreſſes contiguity and cloſe ſucceſſion; ק koph, expreſſes a circuit or ambit; ר reſh, expreſſes the egreſs of any thing, as alſo the exterior part of a thing, and the extremity or end of any thing; ש ſhin, ſignifies the number three, or the third degree, or the utmoſt perfection of any thing; ת tau, expreſſes a ſequel, continuation, or ſucceſſion of any thing.

According to this explication, as the ſeveral particular letters of the *Hebrew* alphabet ſeparately ſignify the ideas of motion, matter, ſpace, and the ſeveral modifications of matter, ſpace and motion, it follows, that a language the words of which are compoſed of ſuch expreſſive characters muſt neceſſarily be of all languages the moſt perfect and expreſſive, as the words form'd of ſuch letters according to their determinate ſeparate ſignifications muſt convey the idea of all the matters contained in the ſenſe of the ſeveral characters, and be at once a name and a definition or ſuccinct deſcription of the ſubject, and all things material as well as ſpiritual, all objects in the natural and moral world muſt be known as ſoon as their names are known, and their ſeparate letters conſidered.

The words Urim and Thummim are thus eaſily explained and found, perhaps the moſt appoſite and expreſſive words that were ever formed. See the articles URIM and THUMMIM.

HECATOMBÆON, in chronology. See the article ECATOMBÆON.

HECATONSTYLON, ἑκατονστυλον, in the antient architecture, a porch with an hundred columns. This deſignation was peculiar to the great porch of Pompey's theatre at Rome. *Pitiſc.* Lex. Ant.

HECTIC *Fever* (*Cycl.*)—The ſymptoms of this diſeaſe diſtinctively from the febris lenta, which is often confounded with it, are theſe: A perpetual dry burning in the fleſh, which is moſt ſenſible in the hands after eating; a weak, low, and quick pulſe; a thick orange-coloured urine, with a pale red ſediment, with a thin fattiſh cuticle upon it, and a ſtrong ſmell; a languid habit of body, and a particular love of all cold meats; a dryneſs of the mouth, with continual thirſt, and a frothy or glutinous ſpittle, unſettled ſleep, not at all refreſhing to the patient; a ſucceſſive and continual waſting and emaciation of the body, a loſs of ſtrength, a languor of the mind, a ſenſe of a weight and pain in one of the hypocondria, a ſenſibility of the lighteſt changes in the weather, and a continnal growing worſe at the greater changes which happen at the equinoxes, a vertiginous and dozing ſwimming in the head when the patient gets up; and in the latter ſtages of the diſeaſe colliquative ſweats; and finally the ſcene is cloſed by a diarrhæa, and the facies hippocratica, which is ſeen in no other diſeaſe ſo remarkably as in this, and a conſumption. A cough is no neceſſary conſequence of a *Hectic*, but it uſually attends it, and ariſes from ſome conjunct cauſe. *Junker*'s Conſp. Med. p. 388.

Perſons ſubject to it.—Men are much more liable to fall into *Hectics* than women; and of thoſe principally ſuch as are of a tender conſtitution and dry habit, and are violently addicted to the paſſions, and live high, eating ſeaſon'd food and drinking large quantities of wine or other ſtrong liquors; and ſuch as have exhauſted their ſtrength and ſpirits by violent exerciſes, long watching, great ſtudy, or thoughtfulneſs, want of nouriſhment, exceſſive venery, or by the taking repeated doſes of ſtrong purgative medicines. Perſons often fall into this diſeaſe alſo by omitting habitual bleedings and other evacuations, and by ſtopping cuſtomary diſcharges of blood by the hæmorrhoidal veins, or other ways, by the taking of aſtringent medicines; but more perſons are thrown into *Hectics* by injudicious treatment in fevers, than fall into them by all theſe other ways together; and eſpecially by the bad treatment of intermittents.

Prognoſtics in it.—When a *Hectic* is confirmed and of ſome ſtanding, it is in vain to attempt the cure of it; for when one of the viſcera is ulcerated, nature will always bring on this fever to endeavour to abſterge it; and as the cauſe never can be removed, the ſymptom never will ceaſe. *Junker*'s Conſp. Med. p. 387.

All that can be expected from medicine in theſe caſes, is the mitigating the ſymptoms, and putting off the fatal period longer than it would naturally have happen'd. Younger people are much more ſuddenly deſtroyed by *Hectics*, and are much more ſubject to them, than thoſe more advanced in years; hence from eighteen to five and thirty may be accounted the period of life moſt ſubject to danger from this diſeaſe; it is uſually ſudden in its deſtruction between theſe periods, afterwards if people fall into it, it becomes chronical, and they bear it a long time. The changes of the ſeaſons are dangerous times for *Hectic* people, but moſt of all the autumnal equinox, and ſo alſo the climacteric years. Young perſons firſt ſeized with *Hectics* in ſpring uſually die in the autumn following; and thoſe who are firſt ſeized with it in the ſummer ſolſtice, uſually live till the ſame ſeaſon of the following year. A diſcharge of blood by the hæmorrhoidal veins in the laſt

laſt ſtages of a *Hectic* uſually haſtens the death of the perſon; but in the beginning of the diſeaſe the ſame evacuation often proves a cure.

Method of Treatment.—The viſcous humours collected in the primæ viæ are to be attenuated by tartarum vitriolatum and the neutral ſalts, and the bowels to be kept gently open by clyſters and ſmall doſes of manna and the other gentler cathartics; next the acrimony of the ulcerous matter is to be obtunded by the abſorbents ſated with vegetable acids, as by the crabs-eyes ſated with lemon juice; by coral, oiſterſhells, and the like teſtaceous ſubſtances, ſated in the ſame manner; decoctions of pimpernel and of hartſhorn with daiſy flowers are alſo very ſerviceable; a mixture of ſpirit of hartſhorn and tincture of antimony, and powders of coral and diaphoretic antimony, are to be given twice or oftener in a day. Small doſes of the ſtorax pill will mitigate the cough, and emulſions of almonds with a ſmall mixture of lemon juice will greatly abate the febrile heat. During the whole time the diet muſt be nouriſhing; and jellies, ſtrengthening ptiſans, and milk food are to be taken. *Junker*'s Conſp. Med. p. 390.

But theſe medicines are not to be continued in an uninterrupted courſe; nature is to be ſometimes eaſed of ſuch a burthen; and in fine, the more the diſeaſe increaſes, the fewer medicines are to be given, as there grows leſs and leſs hope of benefit from them.

If a cough attends a *Hectic*, great relief is uſually found from a linctus of oil of ſweet almonds and ſyrup of poppies; or liquid laudanum may be occaſionally given in ſmall doſes. The colliquative ſweats which attend this diſeaſe are not to be cured by ſuppreſſing them violently; but the patient is to keep himſelf moderately cool, and to take powders of coral, terra lemnia and the other abſorbents, and a grain of opium may be added to the quantity of three or four doſes. Whey and the cooling emulſions alſo have their good effects. Gum arabic added in moderate quantities to theſe emulſions alſo is of great uſe in checking the diarrhæa, which often attends *Hectics*; and conſerve of red roſes with chalybeated milk are to be taken conſtantly to mitigate this ſymptom; and when it is more violent, a doſe of diaſcordium diſſolved in cinnamon water often proves a very efficacious medicine; and when the violence of the purging is once ſtopped by this, it will be kept from returning by the other methods. *Heiſter*'s Comp. Med. p. 115.

The loſs of appetite which uſually attends theſe caſes is to be remedied by bitters, ſuch as tinctures of orange-peel, and cortex eleutherii, to which may be added a ſmall quantity of the jeſuits bark; and to theſe a ſmall quantity of ſpirit of ſulphur or of vitriol may be added, the more immediately to excite the appetite.

HEDERA, *Ivy*. See the article IVY.

Lacryma HEDERÆ. See the article IVY-*Reſin*.

HEDERALIS, in botany, a name uſed by Ruellius and ſome other authors for the plant called by others Aſclepias or ſwallow-wort. *Ger.* Emac. Ind. 2. See ASCLEPIAS.

HEDERARIUS *Plexus*, a ſort of reticular plexus formed by the ſpermatic vein and artery in their progreſs to the teſticles.

HEDGE (*Cycl.*)—The hawthorn is allowed the beſt of all the Engliſh ſhrubs for quick-ſet hedges. The beſt method of raiſing this for uſe, is to put the haws into the ground as ſoon as ripe, and cover them with earth; and by the ſpring twelvemonth the young ſhoots will be of a due ſize to tranſplant from the ſeed-plot into hedge-rows. The crab-tree is a common mixture with the hawthorn in hedges; but it grows faſter than the hawthorn, and requires cutting to keep the hedge even. The young hawthorns raiſed from ſeed always thrive better than thoſe picked up wild in the fields. *Moreton*'s Northamp. p. 485.

The great conſideration in making *quickſet hedges* is to bring the plants from a worſe ſoil than that in which it is intended to ſet them. They muſt be about the thickneſs of one's thumb, well rooted and ſtrong, and muſt be planted about four or five inches out of the ground. If there be a ditch to the hedge, it ſhould be three foot wide at the top, one at the bottom, and two deep; and if wider, then deeper in proportion.

If the bank be without a ditch, the plants ſhould be ſet in two rows at a foot diſtance below one another. The turf is to be laid with the graſs-ſide downward on that ſide of the ditch on which the bank is deſigned to be made, and ſome of the beſt mould muſt be laid upon it to bed the quick; then the quick is to be laid upon it a foot aſunder, ſo that the end of it may be inclining upwards; and at equal diſtances of thirty foot plant an aſh, oak, crab, or elm, to grow with the quick. When the firſt row of quick is laid it muſt be covered with mould, and the turf laid upon it as before, and ſome more mould upon that; ſo that when the bank is a foot high, another row of ſets may be laid againſt the ſpaces of the lower quick. Theſe muſt be then covered as the former, and the bank is to be then top'd with the bottom of the ditch, and a dry or dead *hedge* laid, to ſhade the under plantation. There ſhould then be ſtakes driven into the looſe earth quite down to the firm ground, at about two foot and a half diſtance from each other; oak-ſtakes are accounted the beſt of all for this uſe, and the next to this thoſe of black-thorn or ſallow. Small buſhes are to be laid below, but not too thick, only to cover the quick from being injur'd as it ſhoots. *Miller*'s Gardeners Dict.

To line a HEDGE, in military affairs, is to plant muſketteers along it, under cover; either to fire upon an enemy that is advancing, or to ſave themſelves from the horſe, or to defend a paſs or defile.

Holly-HEDGES. See HOLLY.

HEDYOSMOS, in botany, a name given by ſome writers to mint, becauſe of its ſweet ſmell.

HEDYPNOIS, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the ſemifloſcular kind, being compoſed of ſeveral ſemifloſcules ſtanding on the embryo fruit, and incloſed in a common cup, which finally becomes a fruit of the ſhape of a melon, and containing two ſeeds; the one of which ſtands in the middle of the flower, and has a ſort of head on it, and the other is umbilicated and ſtands at the edge, and is wrapped round in the leaves of the cup. *Tournef.* Inſt. p. 478.

There is only one known ſpecies of this plant, which is the *Hierachium ſemine adunco* of authors, the hawkweed with crooked ſeeds, and is called by others the hawkweed with the bending flower.

HEDYSARUM, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the papilionaceous kind, and from its cup there ariſes a piſtil which finally becomes a jointed undulated pod, which uſually contains in each joint one kidney-ſhaped ſeed. To this it is to be added, that the flowers are collected into denſe ſpikes.

The ſpecies of *Hedyſarum* enumerated by Mr. Tournefort, are theſe: 1. The clypeate *Hedyſarum* with bright red flowers. 2. The clypeate *Hedyſarum*, with white flowers. 3. The leſſer clypeate *Hedyſarum*, with purple flowers. 4. The annual *Hedyſarum*, with rough undulated and crooked pods. 5. The alpine *Hedyſarum*, with ſmooth pods and purpliſh blue flowers. 6. The alpine *Hedyſarum*, with ſmooth pods and white flowers. 7. The trifoliate canada *Hedyſarum*. 8. The Indian *Hedyſarum*, with ſingle painted leaves. 9. The Indian *Hedyſarum*, with ſingle roundiſh leaves. 10. The little two-leaved *Hedyſarum*, with yellow flowers. 11. The ſhrubby trifoliate *Hedyſarum*, with purple flowers and variouſly diſtorted pods. 12. The leſſer ſhrubby trifoliate *Hedyſarum*. 13. The procumbent trefoil *Hedyſarum*, with purple flowers. 14. The hairy procumbent African *Hedyſarum*. 15. The great annual *Hedyſarum* of Ceylon, with leaves like the ſenſitive plant. 16. The leſſer annual *Hedyſarum* of Ceylon, with leaves like the ſenſitive plant. *Tourn.* Inſt. p. 401.

HEISTERIA, in botany, the name given by Linnæus to a genus of plants, the characters of which are theſe: The perianthium conſiſts of five leaves, which are lanceolated, erect and pointed at the ends; theſe are a little ſhorter than the petals of the flower, and do not fall with it. The flower is of the gaping kind, and conſiſts of one petal divided almoſt to its baſe into two ſegments; the upper lip, which is the vexillum, is erect and ſlightly divided into two oval ſegments which gape aſunder; the carina, which is properly the nectarium of the flower, is hollow, almoſt ſhut, and of a cordated form, and forms the lower part of the under lip. The lower lip, which makes the alæ, is placed on the ſummit of the nectarium; it is divided into two ſegments, and hangs down. The ſtamina are eight filaments which grow at the bottom into an oval membrane, and are of the diadelphous kind: The antheræ are eight in number, and are placed within the nectarium: The germen of the piſtil is oval, and is terminated by four oval points, which cloſe together; among theſe ſtands the ſtyle, which is of the length of the ſtamina, and the ſtigma which terminates this is obtuſe, compreſſed, and obliquely bifid. The fruit is a roundiſh compreſſed capſule terminated by four briſtles, which ſtand at a diſtance from one another, and is compoſed of two cells, each containing a ſeed of an oval figure. *Linnæi* Gen. Plant. p. 341.

HELCOMA, a word uſed by the old writers in ſurgery, to ſignify an ulcer.

HELCYDRION, a word uſed by the old writers in medicine and ſurgery, to expreſs a ſmall exulceration, or ulcerous puſtule in any part of the body.

HELCYSMA, a word uſed by ſome of the old writers to ſignify the ſcoriæ of ſilver, called alſo by ſome encauma. Dioſcorides ſays this has the ſame virtues with the molybdæna, and that it was in his time uſed like that in plaſters.

HELCYSTER, in ſurgery, a hook uſed to extract the fœtus in difficult parturition.

HELEGUG, in zoology, a name by which the people in ſome parts of England call the Anas Aretica Cluſii, a web-footed fowl common on our ſhores. See the article DUCK.

HELENIUM—The Greek writers do not ſeem agreed about the ſenſe of this word. That in which we take it now is plainly no older than the days of Dioſcorides, or the time between that author and Theophraſtus. It is unqueſtionable but the *Helenium* of the laſt author is not what we call by that name. He ſays it was an herb uſed in the making of garlands, and the like, and that it had ſmall and ſhort leaves.

He ranges it among the verticillate aromatic plants; and mentioning it with mint, mother of thyme, and ſuch others, it ſeems to have been a plant of that claſs. But Dioſcorides plainly ſuits his deſcription of the *Helenium* to the plant we now call by that name. He ſays, it had large and hoary leaves reſembling thoſe of the verbaſcum or mullein, and that its root was of an aromatic ſmell, but the reſt of the plant not ſo. Pliny ſeems to have diſliked the account of Dioſcorides, and to have taken his deſcription of this plant from other Greek authors. He ſays, it was a ſmall aromatic herb ſpreading upon the ground with woody ſtalks of ſix or eight inches long, and with ſmall and ſhort leaves like the ſerpyllum, or mother of thyme; and that it grew all over Greece, and was uſed in the making of garlands. This ſmall plant ſeems therefore to have been the *Helenium* of all the antients, except Dioſcorides; and it appears very ſtrange, that he who lived in Greece ſhould depart from the common opinion of his countrymen, and miſtake the name of a plant which grew commonly wild, and was in daily uſe at that time, as Dioſcorides no where ſo much as mentions this common *Helenium* of the Greeks, but treats ſolely of our *Helenium*, or elecampane; under which name we find no error, in regard to its virtues, from him. But Pliny, who tho' he has rejected Dioſcorides's account of the figure of the plant called by this name, has adopted his deſcription of its qualities and virtues, and adding theſe to the liſt of thoſe given by others of the ſmall aromatic and verticillate *Helenium*, he has made many great errors, and given occaſion to many more in others. He ſays, that the herb *Helenium* was an aromatic, and good againſt the bites of ſerpents; and that the root of it was of a ſweet taſte, very full of juice, and good in aſthmas, *&c.* Theſe and the like virtues ſhew that he had copied the qualities of different plants, known to different authors, by the ſame name of *Helenium*; and between this and his falſe tranſlations of ſome of the Greeks, his account in general is by no means to be depended upon. *Pliny* l. 23. c. 8.

The root of the *Helenium*, or *Elecampane*, has been long famous in all diſorders of the breaſt and lungs. It is alſo recommended as a ſudorific and alexipharmic, and as ſuch has a place in moſt of the compoſitions of that intention. An ointment made of the freſh roots and leaves, with lard, is alſo much recommended in the itch and other cutaneous foulneſſes.

HELFING, in our old writers, a braſs coin among the Saxons, equivalent to our halfpenny. *Blount.*

HELIANTHEMUM, *ſmall Sun-flower*, in botany, the name of a genus of plants, called alſo *Ciſtus* and *Chamæciſtus* by authors; the characters of which are theſe: The flower is of the roſaceous kind, conſiſting of ſeveral leaves, diſpoſed in a circular form. The cup is alſo compoſed of ſeveral leaves, and from this ariſes the piſtil, which afterwards becomes a ſort of globoſe fruit, which ſplits open three ways, and is full of roundiſh ſeeds, affixed to ſlender filaments, or to placentæ.

The ſpecies of *Helianthemum*, enumerated by Mr. Tournefort, are theſe: 1. The yellow-flower'd common *Helianthemum*. 2. The common *Helianthemum*, with pale yellow flowers. 3. The common *Helianthemum*, with white flowers. 4. The large-leav'd white-flowered *Helianthemum*. 5. The white-flowered German *Helianthemum*. 6. The white-flowered *Helianthemum*, with narrow hairy leaves. 7. The white-flowered ſtone *Helianthemum*, with oblong narrow leaves, and hairy ſtalks. 8. The ſerpyllum-leav'd *Helianthemum*, with large gold yellow ſweet-ſcented flowers. 9. The narrow-leav'd yellow-flower'd *Helianthemum*. 10. The *Helianthemum*, with ſmall myrtle-like leaves, hoary underneath. 11. The narrow-leav'd ſmooth, erect, yellow-flower'd *Helianthemum*. 12. The procumbent, narrow-leav'd gold yellow-flower'd *Helianthemum*. 13. The cat's-foot-leav'd alpine *Helianthemum*. 14. The hoary thyme-leav'd *Helianthemum*. 15. The ſmooth thyme-leav'd *Helianthemum*. 16. The marjoram-leav'd *Helianthemum*, with very hairy heads. 17. The moneywort-leav'd *Helianthemum*. 18. The poley-leav'd *Helianthemum*. 19. The hoary ſhrub *Helianthemum*, with marjoram-leaves. 20. The *Helianthemum*, with ſhort obtuſe leaves like thoſe of the ſea purſelain. 21. The *Helianthemum*, with broader and pointed leaves like thoſe of ſea purſelain. 22. The annual *Helianthemum*, with ſedum leaves. 23. The lavender-leav'd *Helianthemum*. 24. The ſpotted-flower'd *Helianthemum*. 25. The thyme-leav'd *Helianthemum*, with umbellated flowers. 26. The *Helianthemum* with leaves like roſemary, ſhining on the upper ſide, and hairy underneath. 27. The hoary marjoram-leav'd *Helianthemum*, with ſpotted flowers. 28. The *Helianthemum*, with ſmooth ground pine leaves. 29. The Portugal *Helianthemum*, with large and broad leaves like thoſe of poley. 30. The Portugal *Helianthemum*, with narrower poley-like leaves. 31. The procumbent Portugal *Helianthemum*, with leaves like thoſe of the ſea purſelain, and large yellow flowers. 32. The Spaniſh ſea purſelain-like *Helianthemum*, with roundiſh leaves. 33. The Spaniſh ſea purſelain-like *Helianthemum*, with narrower leaves. 34. The Spaniſh ſea purſelain-leav'd *Helianthemum*, with very ſmall leaves. 35. The Portugal *Helianthemum*, with hoary marum-like leaves, and yellow flowers. 36. The Portugal *Helianthemum*, with hoary marum-like leaves, and very hairy heads. 37. The Portugal *Helianthemum*, with marjoram leaves, and a black ſpot in every flower. 38. The Spaniſh ſea purſelain-like *Helianthemum*, with large nervous and hoary leaves. 39. The alpine *Helianthemum*, with olive-like leaves, hoary underneath. 40. The narrow-leav'd Spaniſh *Helianthemum*, with narrow leaves, and fleſh-colour'd flowers. 41. The plantain-leav'd perennial *Helianthemum*. 42. The Portugal *Helianthemum*, with hares-ear-leaves, and ſpotted flowers. 43. The daiſy-leav'd Portugal *Helianthemum*. 44. The annual Portugal plantain-leav'd *Helianthemum*, with three colour'd flowers. 45. The Spaniſh *Helianthemum*, with very ſmall roundiſh leaves. 46. The Spaniſh *Helianthemum*, with origanum leaves, hoary underneath. 47. The Spaniſh *Helianthemum*, with baſil leaves, hoary underneath. 48. The dwarf *Helianthemum*, with purſelain like leaves of a ſilvery colour. *Tourn.* Inſt. p. 249, 250.

The root of *Helianthemum*, taken internally, is eſteemed good againſt the bites of ſerpents; and the tops are effectual for the ſame purpoſe. The plant is aſtringent, and a good demulcent, in the form of a decoction, particularly in diarrhœas, hæmorrhages, and diſeaſes of the fauces. J. Bauhine ſays, it is good in all diſorders attended with a flux of any kind. Vid. *James*, Dict. Med. in voc.

HELICE, or ELICE, the name given by the antient Greeks to the willow. Theophraſtus tells us that, in his time, many called the willow not *Hele* but *Helice*. Pliny has miſunderſtood this paſſage of Theophraſtus, and has repreſented the willow as being of three kinds, and tells us, that the loweſt, or ſmalleſt of theſe kinds, was called *Helice* by the Greeks. But this is a falſe diſtinction, the word *Helice* ſignifying no more nor leſs than the itea or ſalix, and expreſſing one ſpecies of ſalix as well as another: Nor is this the only miſtake he has fallen into in this place; he has ſaid that the Aſiatics uſed the word; whereas Theophraſtus, who was the author he took the account from, mentions the Arcadians, not the Aſiatics, as uſing it; and it appears from others, that Evander the Arcadian was the firſt who uſed the word.

HELICTERES, in botany, the name given by Linnæus to a genus of plants, called *Iſoria* by Plumier, and in the *Hortus Malabaricus*. The characters are theſe: The perianthium is one leav'd, of a ſemi-oval figure, narrow at the bottom, and obliquely open at the top, like the ear of ſome beaſt, tridentated at the apex, and unidentated at the ſides, and of a coriaceous texture. The flower is compoſed of five oblong petals, equal in breadth, of the ſame length with the cup, and fixed to it. The germen is compoſed of five little petals, which ſurround the germen, and cover it. The germen of the piſtil is roundiſh, and is carried on the top of a long, ſlender, and crooked ſtyle. The ſtigma is ſimple and acute. The ſtamina are ten very ſhort filaments, placed at the baſis of the germen. The antheræ are oblong and lateral. The fruit is compoſed of five oblong capſules, ſpirally twiſted, each containing only one cell. The ſeeds are numerous, and kidney ſhaped. *Linnæi* Gen. Plant. p. 439. *Plum.* Gen. 37. Hort. Mal. vol. 6. p. 30.

HELIOCARPUS, in botany, the name of a genus of plants, deſcribed by Houſton under the name of *Monſia*; the characters of which are theſe: The perianthium is colour'd, and conſiſts of four low and ſomewhat broad ſtrait leaves, which fall with the flower. The flower conſiſts of four ſtrait petals, which are much ſmaller than the leaves of the cup. The ſtamina are ſixteen pointed filaments, of the length of the cup. The antheræ are ſtrait, double, and incumbent. The germen of the piſtil is roundiſh. The ſtyles, which are two in number, are ſtrait, erect, and of the length of the ſtamina. The ſtigmata are acute, and ſtand diſtant from one another. The fruit is a turbinated and ſomewhat oval capſule, containing two cells, and ſurrounded with ramoſe radii. It contains two cells, in each of which is lodged one ſeed, which is of a ſomewhat oval figure. *Linnæi* Gen. Plant. p. 243.

HELIOCENTROS, in natural hiſtory, a name given to an inſect of the poiſonous kind, called by Ariſtotle phalangium dectícum, and by the Latins ſolipuga. Some have erroneouſly written this word ſolifuga, and then attempted to explain that name by the creature's cuſtom of burying itſelf in the ſand, to avoid the ſun, as they ſuppoſe; but it is really only to lie under cover, that it may the more eaſily catch flies and other inſects. The Greeks have in the ſame manner called it *holocentros*, by corruption from *heliocentros*; and their commentators have not been wanting to find proper explications of that word. Solinus tells us, that this creature is common in Sardinia; he ſays indeed, that it is particular to that country; but in that he contradicts the antients, who mention many other places for it. Pliny ſays it is found in Æthiopia, and Lucan mentions it among the poiſonous creatures of Africa.

HELIOTROPE, (*Cycl.*) *Heliotropium*, among the antients, an inſtrument or machine, for ſhewing when the ſun arrived at the tropics and the æquinoctial line. *Hofm.* Lex. in voc.

HELIOSTROPHUS, in the materia medica, a name given by ſome of the Greek writers of the later ages, to the gum ammoniacum of the antients, which ſeems to have been a very

different thing from what is called gum ammoniacum at this time, it being yellow and friable, ours whitiſh and tough.

HELIOTROPIUM, *Turnſole*, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is a one leav'd tubular perianthium, remaining when the flower is fallen, and divided into five ſegments at the rim. The flower conſiſts of one petal, which is a tube of the length of the cup, the rim of which is ſlightly divided into five ſegments of different ſizes, the ſmaller being pointed and placed alternately with the larger, the opening of the flower being cloſed with five prominent ſcales, arranged into the form of a ſtar. The ſtamina are five extremely ſhort filaments, ſituated in the opening of the flower; the antheræ are ſmall and cover'd. The piſtillum has four germina. The ſtyle is ſlender, and of the length of the ſtamina; and the ſtigma is rimm'd round the edge. The cup remains unalter'd for the ripening of the ſeeds, and contains four, of an oval and pointed form. *Linnæi* Gen. Plant. p. 56. See HELIOTROPE, *Cycl.*

The characters of *Heliotropium*, according to Tournefort, are theſe: The flower conſiſts of one leaf, and is funnel ſhaped, and corrugated in the center into the ſhape of a ſtar, and divided into ten unequal ſegments at the rim. From the cup there ariſes a piſtil, which is fixed in the manner of a nail to the lower part of the flower, and is ſurrounded by four embryos, which afterwards ripen into ſo many ſeeds, angular on one ſide, and gibboſe on the other, and remaining in the cup till ripe.

The ſpecies of this plant, enumerated by Mr. Tournefort, are theſe: 1. The large white-flower'd *Heliotrope*. 2. The great Sicilian *Heliotrope*, with a large ſweet-ſcented flower. 3. The great autumnal *Heliotrope*, with the ſmell of jaſmine. 4. The middle ſized ſlender Italian *Heliotrope*. 5. The ſmaller creeping *Heliotrope*. 6. The clary-leav'd blue American *Heliotrope*. 7. The narrower-leav'd blue American *Heliotrope*. 8. The *Heliotrope* of Curaſſo, with leaves like the linum umbilicatum. 9. The woolly ſhrub ſea *Heliotrope*, with the appearance of the American cudweed. The *Heliotropium* tricoccum, uſually accounted one of this genus, is properly a ricinoides. *Tourn.* Inſt. p. 138. See RICINOIDES and TURNSOLE.

Dale ſays, that *Heliotrope* is uſed in medicine againſt cancers, gangrenous ulcers, and ſtrumous ſwellings.

HELIOTROPIUM is alſo a name given to the blood-ſtone, or *lapis hæmatitis*. See HÆMATITIS.

HELLEBORINE, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the polypetalous anomalous kind, conſiſting of ſix diſſimilar petals, five of which are placed in a ſort of orbicular figure; but the ſixth, which is the lower one, is imbricated. The cup finally becomes a ſeed-veſſel, which is pervious by three feneſtræ, to each of which adheres a valve. The ſeeds are extremely ſmall, and like duſt, and the roots are fibroſe.

The ſpecies of *Helleborine*, enumerated by Mr. Tournefort, are theſe: 1. The common broad-leav'd *Helleborine*. 2. The narrower-leav'd purple-flower'd mountain *Helleborine*. 3. The broad-leav'd white-flower'd mountain *Helleborine*. 4. The narrow-leav'd meadow or marſh *Helleborine*. 5. The narrow-leav'd meadow *Helleborine*, with green flowers. 6. The Engliſh wild marſh *Helleborine*. *Tourn.* Inſt. p. 436.

HELLEBORUS, *Black Hellebore*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, being compoſed of ſeveral petals or leaves, arranged in a circular form. From the middle of the flower there ariſes a piſtil which is compoſed of ſeveral horn-like capſules, and ſurrounded at its bottom by a vaſt number of ſtamina. The piſtil finally becomes a membranaceous fruit, compoſed of ſeveral thin capſules, collected into a head, each ending in a ſort of horn, and all, when ripe, opening lengthwiſe, and diſcovering roundiſh or oval ſeeds.

The ſpecies of black *Hellebore*, enumerated by Mr. Tournefort, are theſe: 1. The wild ſtinking black *Hellebore*. 2. The green-flower'd garden black *Hellebore*. 3. The larger garden black *Hellebore*. 4. The broader-leav'd garden black *Hellebore*. 5. The narrow-leav'd garden black *Hellebore*, or true roſe-flowered black *Hellebore*. 6. The large-flowered autumnal black *Hellebore*. 7. The ſmaller Dutch roſe-flowered black *Hellebore*. 8. The bloody-leav'd black *Hellebore*. 9. The deeply divided-leav'd black *Hellebore*, 10. The trifoliate black *Hellebore*. 11. The yellow-flower'd ranunculus-leav'd tuberoſe black *Hellebore*, commonly called the winter aconite. And 12. The crow-foot-leav'd black *Hellebore*, with ſmaller globoſe flowers. *Tourn.* Inſt. p. 271. See HELLEBORE, *Cycl.*

HELLENODICÆ, Ἑλλανοδικαι, in antiquity, the directors of the olympian games. They aſſembled in a place called Ἑλλανοδικαιον, in the Elean forum, where they were obliged to reſide ten months before the celebration of the games, to take care that ſuch as offered themſelves to contend, performed their προγυμνασματα, or preparatory exerciſes, and to be inſtructed in all the laws of the games by certain men called Νομοφυλακες, i. e. keepers of the laws. And the better to prevent all unjuſt practices, they were farther obliged to take an oath, that they would act impartially, would take no bribes, nor diſcover the reaſon, for which they diſliked, or approved of any of the contenders. At the ſolemnity they ſat naked, having before them the victorial crown, till the exerciſes were finiſhed, and then it was preſented to whomſoever they adjudged it. Nevertheleſs, there lay an appeal from the *Hellenodicæ* to the olympian ſenate. *Pott.* Archæol. Græc. l. 2. c. 22. T. 1. p. 448.

HELLENODICÆUM, Ἑλλανοδικαιον, in antiquity, the place where the *Hellenodicæ* were uſed to aſſemble. See HELLENODICÆ.

HELLENOTAMIÆ, Ἑλλανοταμιαι, in antiquity, Athenian officers appointed to receive the money due from the tributary cities. *Pott.* Archæol. Græc. l. 1. c. 14.

They were alſo called *Hellenotamiæi*, Ἑλλανοταμιαιοι.

HELLOTIA, Ἑλλωτια, in antiquity, two feſtivals, one of which was celebrated in Crete, in honour of Europa, called *Hellotia*; the other was celebrated by the Corinthians, with ſolemn games and races, wherein young men contended, running with lighted torches in their hands. See a farther account of theſe feſtivals in *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 393.

HELLOTIS, Ἑλλωτις, in antiquity, a myrtle garland, carried in proceſſion with Europa's bones at the feſtival called *Hellotia*. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 393. See HELLOTIA.

This garland was no leſs than twenty cubits in circumference.

HELM, (*Cycl.*)—*Eaſe the* HELM, at ſea. See the article EASE.

HELMET *Pigeon*, the name given to a particular ſpecies of pigeon, called by Moore the *Columba galeata*. It has its name from its having its head cover'd with a plumage of a diſtinct colour from that of the reſt of the body, and appearing ſomewhat like a helmet covering the head. It is a moderate ſiz'd pigeon, a little bigger than the ſpecies called the nun. The head, tail, and flight feathers of the wings, are always of the ſame colour, which is either black, red, or yellow, and ſometimes, tho' rarely, blue. The reſt of the body is all white. They are red eyed, and have no hood like that of the nun, otherwiſe they approach much to that ſpecies. *Moore*'s Columbarium, p. 48.

HELMINTHAGOGA, medicines contriv'd to deſtroy and expel worms.

HELMINTHES, in the medicinal writers, a word uſed to ſignify the worms in human bodies.

HELMINTHOTHECA, in botany, a name given by Vaillant to a genus of plants, ſince deſcribed by Linnæus under the name *Picris*. See the article PICRIS.

HELMONTII *Ludus*. See the article LUDUS *Helmontii*.

HELODES, in natural hiſtory, a term applied to certain plants, to ſignify their place of growth to be in fens, bogs, or marſhy places; thus a kind of St. Peter's-wort, which is diſtinguiſhed from the others by being hairy, and growing always in boggy places, is called by Ray and others, aſcyrum villoſum *Helodes*.

In medicine the ſame word is uſed as a characteriſtic epithet in certain fevers. Theſe are ſuch as are attended, in their beginning, with profuſe ſweats, which afford no relief; and all the time the tongue is dry, and the ſkin hard, and, as if it were, parched. Theſe are uſually of dangerous conſequence.

HELOPS, in ichthyology, the name of a fiſh which often occurs in the old Greek and Latin writers. Ariſtotle, Ælian, Ovid, and others, mention it. It ſeems to have been the ſame with their oniſcus and accipeſius, which was our ſturgeon. Pliny's account of the *Helops* countenances this opinion.

HELOSIS, in medicine, the name of a diſorder of the eyes, attended with an everſion, or turning up of the eyelids.

HELOTIS, a name given by ſome authors to a diſeaſe called plica polonica. See the article PLICA, *Cycl.*

HELOTS, in antiquity, a kind of ſlaves, among the Lacedæmonians, on whom lay the whole care of ſupplying the city with proviſions; the ground was tilled, and all manner of trades managed by them; whilſt their maſters, gentlemen like, ſpent all their time in dancing and feaſting, in their exerciſes, hunting matches, and the λεσχαι, or places where good company uſed to meet. Notwithſtanding the great uſefulneſs of the *Helots*, they were treated in a moſt barbarous manner, and often murdered without committing any fault, and without any ſhew of juſtice. *Potter*, Archæol. Græc. l. 1. c. 10. The *Helots* were ſo called from *Helos*, a Laconian town, conquered by the Spartans, who made all the inhabitants priſoners of war, and reduced them and their poſterity to the condition above deſcribed.

HELPESED, in natural hiſtory, a name uſed by ſome writers for coral.

HELSEBON, an affected word, uſed by ſome of the chemical writers to expreſs common ſea ſalt, well purify'd by ſolution and recryſtalization.

HELSINGEGAAS, in zoology, the name given by Hoier, in his epiſtle to Cluſius, to a ſort of Gooſe, the head and neck of which are black, the neck having a ring of white round it. The breaſt is white, the wings are grey, the back blue, and the feet red. It is of the ſize of a common duck. Mr. Ray much ſuſpects this account. *Ray*'s Ornithol. p. 306.

HELSINGIC *Character*, a character inſcribed on ſome ſtones found in Helſingland, in the north parts of Sweden. It differs from the Runic; tho' one of theſe characters may eaſily be transformed into the other. See the article RUNIC.

HELVE, the handle of a hatchet, pick-ax, mattock, *&c.* And to *helve* theſe is to put handles to them.

HELXINE, in botany, a name uſed, by ſome authors, for the parietaria, or pellitory of the wall. *Ger.* Emac. Ind. 2.

HELXINE *Ciſſampelos*, in botany, a name given by ſome authors to a ſpecies of bindweed, called by Mr. Tournefort *convolvulus major albus craſſiori & auriculato folio maritimus*. The great white-flower'd ſea bindweed, with thick auriculated leaves. See the article CONVOLVULUS.

HEM, a partition in the ovens, wherein the *lapis calaminaris*, or *calamine*, is baked. Theſe ovens have a hearth made on one ſide, divided from the oven itſelf by a partition, or *Hem*, open at the top, by which the flame paſſes over, and ſo heats and bakes the *calamine*.

HEMANDIA, in botany, the name of a genus of plants, the characters of which, as collected by Linnæus from Plumier's deſcription, are theſe: The flowers are ſome male, others female. The male flower is divided into ſix ſegments, as is alſo the female, which is ſucceeded by an oval nut of a furrowed ſurface, with one cell, containing a globoſe kernel. This nut is encloſed in the cup, which becomes very large and inflated, and of a roundiſh figure, with an undivided edge. Linnæus laments that we have yet no better account than this of ſo ſingular a fructification. *Linnæi* Gen. Pl. 517. *Plumier*. 40.

HEMATOPUS, in zoology, a name uſed by Bellonius and ſome others, for the bird commonly known in England by the name of the ſea-pie, and called by Mr. Ray and ſome authors pica marina. See the article PICA *Marina*.

HEMEROTROPHIS, in antiquity, a meaſure of capacity, the ſame with the *chœnix*. See CHOENIX. It was ſo called from its holding one days food.

The word is compounded of ἡμερα, a day, and τροφη, food.

HEMERALOPIA, a diſtemperature of the eyes, by means of which perſons can only ſee in broad day-light, and not diſtinguiſh objects at all in the duſk of the evening. It is owing to a great contraction of the pupil.

HEMEROCALLIS, in botany, the name of a genus of plants, the characters of which are theſe: There is no cup, the flower is of a funnel ſhape, and is divided at the edge into ſix ſegments; the tube is ſhort, and the limb is wide, and ſomewhat bent back; the ſtamina are ſix tubulated filaments, of the length of the flower; they droop a little, and the upper ones are ſomewhat ſhorter than the others; the antheræ are oblong and aſſurgent; the germen of the piſtil is roundiſh and ſulcated; the ſtyle is capillary, and of the length and ſituation of the ſtamina; the ſtigma is aſſurgent, and obtuſely trigonal. The fruit is a trigonal and trilobated capſule, of a ſort of oval figure. It is compoſed of three valves, and contains a great number of ſmall ſeeds, which are roundiſh. *Dillen*. Hort. Elth. p. 118. *Linnæi* Gen. Pl. p. 148.

Linnæus makes this genus comprehend the *Lilio-aſphodelus* and the *Liliaſtrum* of Tournefort; the only difference between which he obſerves is, that the germen in the *Lilio-aſphodelus* is placed within the cup, and the flower is monopetalous; whereas in the *Liliaſtrum* the germen is in the ſame manner placed in the cup, but the flower is hexapetalous. *Tournefort*'s Inſt. p. 179, 194.

HEMICRANIA, (*Cycl.*) the name of a ſpecies of *head-ach* affecting only half the head, and owing to a congeſtion of blood in the veſſels of that half.

Phyſicians divide the *Hemicrania* into four kinds: 1. The idiopathic, when it is properly a diſeaſe of itſelf. 2. The ſymptomatic, where it is properly only the ſymptom of ſome other diſeaſe. 3. The continual or fixed, where it admits of no abſolute intermiſſions. And, 4. The periodic, where the patient is regularly free from it at certain ſtated periods.

Signs of it. Among theſe are vibrative and very acute pains: The pain occupies only one part of the head, while the other part is wholly free and at eaſe. The left ſide of the head is uſually the part in pain. In that ſide of the head where the pain is, it is not fixed to any one ſpot, but wanders up and down from one part to another; and ſometimes the eye on that ſide, ſometimes the jaw and teeth are affected by it. When the lower part of the head is in pain, the upper part is ſomewhat eaſy; and in ſome caſes the pain has been known to deſcend to the arm of that ſide. To this it is to be added, that the patient is uſually coſtive, and makes very little urine. Women are much more ſubject to this diſtemper than men, and among them principally ſuch as live high, and uſe little exerciſe; ſuch as are ſubject to violent paſſions of the mind; ſuch as have had frequent ſuppreſſions of the menſes; and ſuch as live in a married ſtate without having children.

The principal cauſe of the diſeaſe is a plethora, occaſioned uſually by a ſuppreſſion of the menſes, or hæmorrhoids, or ſome other natural evacuation, or the omiſſion of habitual bleedings at ſpring and fall. To theſe cauſes are to be added a diſtemperature of the primæ viæ, a change of the courſe of life from one full of exerciſe to a ſedentary one; over-great watchings or ſtudies; too great heat of the body, or too ſudden cooling of it; violent paſſions, as of anger, or the like, ſuppreſſed; and finally, too high living, and the free uſe of ſtrong liquors. *Junker*'s Conſp. Med. p. 118.

Prognoſtics. This ſpecies of *head-ach* not unfrequently brings on ſuffuſions, and other diſorders of the eyes, and often is a forerunner of the gout, eſpecially if it be imprudently treated during the fit; if the congeſtion of blood be driven by repellents at this time to the feet, it conſtitutes that painful diſtemper; but if it fall upon the viſcera, it uſually brings on an inflammatory fever. When it extends to the arm and ſide of the affected half of the head, there is danger of a palſy coming on. In itſelf it is not difficult of cure in young people; but in women advanced in years, after the ceſſation of the menſes, it is ſcarce ever perfectly cured ſo as not to return.

Method of cure. As the primæ viæ are almoſt always obſtructed in this complaint, the regular beginning of a cure is by emptying them; and a gentle vomit, and purging medicines are to be given. Stahl adviſes, to anſwer both theſe purpoſes at once, by rhubarb and tartar emetic mixed together. After this emollient clyſters are to be given; then the violent emotion of the blood is to be quieted, by giving powders compoſed of nitre, crabs-eyes, and cinnabar; and in caſes where the pain is violent and inſufferable, a gentle opiate may be given, ſuch as a ſmall doſe of the ſtorax pill, and at other times the quantity of the cinnabar may be encreaſed from five grains to ten or twenty in a doſe; and this will ſupply the place of the opiate, and produce the ſame effect in giving eaſe. Spirit of wine camphorated may alſo be uſed externally; and frequently bathing the feet in the decoctions of the warm and emollient herbs has often a great effect. In the abſence of the fit, the methods to be uſed, by way of prevention, are bleeding in the ankle to remove the plethora; and where the ſuppreſſion of the menſtrual, or any other diſcharge, has been the cauſe, this is to be reſtored if poſſible to its wonted periods; and in all caſes a ſedentary life is to be avoided. Bleeding is never proper in the time of the fit, unleſs the plethora be very great, or the congeſtion in the head ſo great, that worſe conſequences are to be feared.

HEMIOBOLON, a weight often mentioned by the antient writers in medicine, and expreſſing the half of their obolus, or the twelfth part of a dram, that is five grains.

HEMIONITIS, *Moon-fern*, in the linnæan ſyſtem of botany, the name of a genus of *ferns*, the character of which is, that the fructifications are diſpoſed in branched lines, or ſuch as intermix with and interſect one another.

The characters of *Hemionitis*, according to Tournefort, are theſe: The flowers are not diſcovered, but the ſeeds ſtand in cluſters on the back-part of the leaves. The leaves are all furniſhed with broad auricles at their baſe, and are in ſome ſpecies ſimple, and in others branched or compound. *Tourn.* Inſt. p. 546.

The ſpecies of *Hemionitis* enumerated by Mr. Tournefort, are theſe: 1. The common *Hemionitis*. 2. The exotic *Hemionitis*. 3. The beautiful Portugal *Hemionitis*. 4. The great cinquefoil *Hemionitis*. 5. The great trifoliate *Hemionitis*. 6. The hairy golden *Hemionitis*. 7. The deeply jagged *Hemionitis*, with duſty edges. 8. The laciniated curled *Hemionitis*. 9. The various leav'd pointed *Hemionitis*. 10. The trifoliate *Hemionitis*, with fimbriæ of fine reddiſh hairs. 11. The beautiful American cinquefoil *Hemionitis*. 12. The great harts-tongue leav'd *Hemionitis*; and, 13. The dwarf cinquefoil round dented *Hemionitis*.

HEMIPAGIA, a pain that affects only one half of the head: The ſame as HEMICRANIA.

HEMIXESTON, a meaſure among the antients, containing half a xeſtes. The xeſtes contained two cotyles, and therefore the *Hemixeſton* was a cotyle. *Caſtel.* & *Gorr.* in voc.

HEMLOCK, *Cicuta* (*Cycl.*) — Many poiſonous plants have had this word uſed in ſome manner as a part of their name; ſuch are the *Hemlock* dropwort, and the water *Hemlock*, both well known to be fatal in their effects. But the learned world ſeem'd divided about the effects of the common *Hemlock*, or *cicuta vulgaris*, for a long time; the true knowledge of which has been diſcovered by a very fatal late inſtance. This is a plant much more common than either of the before mentioned, growing every where in our hedges, and diſtinguiſhed by its painted ſtalks. Cardan mentions a man who was killed by eating a cake in which *Hemlock* was an ingredient; and Braſſavola affirms, that it is fatal not only to men, but to geeſe and ſwine; and Matthiolus, Scaliger, Kircher, Boccone, and others, all agree with the common opinion of its poiſonous qualities: Yet it has been much doubted whether this plant, growing in England, had this poiſonous quality or not: And ſo faithful a writer as Mr. Ray mentions, that his friend Mr. Petiver eat half an ounce of the root of it; and that Mr. Henly, a friend of Mr. Petiver's, eat in his preſence three or four ounces of it, without any hurt or inconvenience from it. From hence it has been generally believed with us, either that the root had different virtues from the ſtalks and leaves, or that the plant had very different effects in different countries, and was without that poiſonous quality in England which it had in hotter climates.

The

The German Ephemerides mention an inſtance alſo of its being eaten without injury; and the judicious Linnæus doubted of its malignity, and thence gave it the old name of coccium, reſerving that of *cicuta* for the water *Hemlock*, known to be a poiſon. Philoſ. Tranſ. N° 473. p. 18.

Whatever may be the effects of the roots, we have lately had a very fatal proof that the leaves are poiſonous. Four perſons having ignorantly boiled a large quantity of them with bacon, and after eating the broth with bread, eat the leaves with their bacon; of theſe, two of them grew convulſed, and died in a few hours, and the other two became comatoſe, and would probably have ſhar'd the ſame fate, had they not had large quantities of oil given them, and by that means voided by vomit what they had taken. The effects of this poiſon on them all, were obſerved in every particular to be the ſame with over large doſes of opium. Philoſ. Tranſ. N° 473. p. 20.

Water HEMLOCK. See the article PHELLANDRIUM.

HEMP, *Cannabis* (*Cycl.*)—This valuable plant delights in a ſtrong and rich mould, but it muſt be warm and dry. Lands where hay and woodſtacks have ſtood, are often found to yield very great crops of *Hemp*. A land that is gravelly, if rich and deep, will do very well; but if it be ſtiff or moiſt, it will by no means ſucceed. *Hemp* is a very good thing for deſtroying weeds, but it is what the farmers call a *peeler* of land, that is, it robs and exhauſts it very quick; therefore it is beſt to be ſown on very rank lands, and not repeated too often on the ſame piece.

The beſt *Hemp-ſeed* for ſowing, is that which looks brighteſt, and which will retain its brightneſs, and not break when rubbed. Three buſhels of ſeed is the general allowance for an acre; but the richer the land is, the thicker it ſhould be ſown; and the poorer, on the contrary, the thinner ſown. Some people only give the land one plowing for *Hemp*, which is juſt before they ſow it; but others prepare it as finely as the gardeners do their mould. The time for ſowing *Hemp* is from the beginning of April till the end. The ſeed muſt not be buried, but only juſt covered in the ground. If it be ſown in a dry time, it muſt be at firſt carefully preſerved from the birds, which are great devourers of the ſeed before it ſhoots.

The male *Hemp*, or ſummer *Hemp*, which bears no ſeeds, and is called by the farmers *Fimble-hemp*, will have its ſtalks turn white in July, and it is then to be gathered. The remaining plants, which are the female *Hemp*, called by the farmer *Karle-hemp*, are to be left till Michaelmas. When this is gathered, it is to be left as the other to dry a little, and then houſed. After this the *Karle-hemp* is to be threſhed for the ſeed. *Mortimer*'s Huſbandry, p. 153.

An acre of *Hemp* in the beſt land yields from two to three quarters of ſeed; and this ſeed, with the *Hemp* unwrought, is worth from five to eight pounds; and if the *Hemp* be wrought, from ten to twelve pounds, or more; but the male, or *Fimble-hemp*, is not worth more than half as much as the other. The growing of *Hemp* on proper lands, would not only be a great advantage to the farmers, but alſo to the poor, as it would give them a ſecond harveſt-work after the corn harveſt was over, and which would employ them even in wet ſeaſons; yet it is a piece of huſbandry too much neglected among us.

HEMP-*ſeeds* are uſed in medicine on many occaſions, but they are ſuſpected of being bad for the head. An emulſion made from them, is of great uſe in jaundices. They are ſaid alſo to abate the quantity of ſemen, if taken for a long time together.

HEN, *Gallina*, in zoology. See the article GALLINA.

HENBANE, in botany. See the article HYOSCIAMUS.

This plant has been always eſteemed poiſonous, and we have a late account of the manner of its affecting thoſe who have taken it, from Touey in France, which appears very ſingular. A working man of that place digging in his garden in ſpring, met with ſome roots of this plant, which being long and large he took for parſneps; he carried them as ſuch to his wife, who dreſſed them, and herſelf and eight children eat of them, the man accidentally not dining at home. The conſequence was that they were all ſeized with convulſions in a terrible manner; they were in general ſpeechleſs, but when they ſpoke they uttered abſolute madneſs; they had many of them the riſus ſardonicus, and all had their eyes ſtarting as it were out of their heads. The madneſs of all of them continued ſo compleat, that there could be no uſe in ſpeaking to them; and the convulſions ſo ſtrong, that five or ſix perſons were neceſſary to hold them while they had the medicines poured down their throats. One of the boys eſcaping while they were giving the medicines to the reſt, ran into a pond, where he would inevitably have been drowned, if he had not been followed and taken out. The medicines given theſe people, were tartarum ſtibiatum to the ſtrongeſt, in doſes of forty-five grains; and to the others theriaca with ſalt of rue. They all recovered, but with great difficulty, and with very odd ſymptoms at the going off of the heavier effects of the poiſon. The next day they had all recovered the uſe of their reaſon, but had not the leaſt remembrance of any thing that had happened; and all this day every object that they viewed appeared double to them. On the day following this ſymptom was removed, but in the place of this there came on another in the ſame organ, every thing they ſaw now appearing red as ſcarlet. This ſymptom gradually went off afterwards, and they found themſelves perfectly well. Phil. Tranſ. N° 450. p. 449.

HENBANE *Louſe*, in natural hiſtory, a name given by ſome to a peculiar inſect found very frequently on that plant in the ſummer months. It is one of the cimices of authors, and is very well deſcribed by Liſter in the Philoſophical Tranſactions. It is a very large cimex, of a fine red, ſpotted with black. It feeds on the juices of the *Henbane*, whoſe leaves and ſtalks it pierces with its trunk. It is very remarkable that the juices of this ſtinking plant become of a very agreeable and aromatic flavour in the body of this inſect, and on trial it may perhaps be found, that the miſchievous narcotic quality of the plant may be rendered wholeſome, and a good medicine, in the body of this inſect. Phil. Tranſ. N° 71.

In June and July it is common to ſee ſeveral ſeries of oblong orange-coloured bodies adhering to the upper ſides of the leaves of this plant; theſe are the eggs of this cimex. Theſe eggs are white in the belly of the inſect, and whitiſh when laid firſt, but they grow more deep coloured when the young ones come near the time of hatching. They are hatched into perfect cimices, not in that of worms. Theſe eggs yield a colour which is ſo fine, that it may be worth introducing into uſe in ſome manner; it is a fine lively carnation. There needs no more to obtain it, but the rubbing or cruſhing the eggs, while freſh, upon white paper. The inſects themſelves are ſo common, that from May to the end of June it is ſcarce poſſible to find a plant without them; and the eggs are not leſs frequent in their ſeaſon, in hot weather. They are ſometimes laid in May, but never later than June; their colour is apt to fade of itſelf; but this might probably be much aſſiſted as to holding, by alum or other additions.

HENBANE-*ſeed*. This is a ſeed uſed by many people in the tooth-ach, and in ſeveral other maladies, and is an ingredient in ſome of the officinal compoſitions, particularly in the philonium romanum; but it has been found, when taken alone, to be poiſonous. Sir Hans Sloane gives an account in the Philoſophical Tranſactions, of ſome children who, eating the ſeeds of the common *Henbane*, were affected with intenſe thirſt, ravings, dimneſs of ſight, and a profound ſleep, which in one of them laſted two days.

Theſe were all recovered by bleeding, bliſtering, purging, and vomiting. What Sir Hans obſerves particularly of the caſe is, that the delirium which was occaſioned by theſe ſeeds, was not of the common kind, but was of the nature of that produced by the dutroa, a ſpecies of ſtramonium, and by the baugue of the Eaſt-Indies, which is a plant with leaves like hemp. Philoſ. Tranſ. N° 430.

The virtues of this ſeed may compenſate for the miſchief it may do when taken in an improper manner; in the tooth-ach nothing is perhaps equal to it. Sir Hans Sloane mentions an account of a quack who cured this pain immediately by burning theſe ſeeds, and cauſing the vapour to be received into the tooth through a funnel. The empiric ſlily contrived to have ſome ſmall maggots conveyed at the ſame time into a pail of water placed under the perſon's head, which he pretended to have fallen out of the tooth, by the virtues of the medicine; but theſe being bred up to their change, became ſmall beetles, and were doubtleſs of the common kind.

HENED *Penny*, in our old writers, a cuſtomary payment of money inſtead of *Hens* at Chriſtmas. It is mentioned in a charter of king Edward III. Mon. Angl. Tom. 2. p. 327. Du Cange is of opinion it may be *Hen-penny*, *Gallinagium*, or a compoſition for eggs: But Cowel thinks it is miſprinted *Hened-penny* for *Heved-penny*, or *Head-penny*.

HEN-HARRIER, in zoology, the Engliſh name for the male ſubbuteo, the female of which is ſo very different, that it is called by another name, the ring-tail. See the article RING-TAIL.

The male ſubbuteo, or *Hen-harrier*, is ſmaller than the ring-tail; its head, neck, and back, are of a dove colour; its ſhoulder feathers, however, are ſomewhat browniſh; its rump is ſomewhat whitiſh, and its breaſt of a fine clean white, variegated with tranſverſe brown ſpots; its wings and tail are grey or dove-coloured, variegated with black, and its legs ſmaller and ſlenderer than is uſual in the hawk kind. *Ray*'s Ornithol. p. 40.

HENIECOE, in botany, a name given by the people of Guinea to a ſpecies of plant which we are unacquainted with, but which they give with very great ſucceſs in all kinds of the colic, boiled in water. Philoſ. Tranſ. N° 232.

HENIOCHAS, in aſtronomy, a northern conſtellation. See the article AURIGA.

HEN-MOULD *Soil*, in agriculture, a term uſed by the huſbandmen in Northamptonſhire, and other counties, to expreſs a black, hollow, ſpungy, and mouldering earth, uſually found at the bottoms of hills.

It is an earth much fitter for grazing than for corn, becauſe it will never ſettle cloſe enough to the grain to keep it ſufficiently ſteady while it is growing up, without which, the farmers obſerve, it either does not grow well; or if it ſeem to thrive,

thrive, as it will in ſome years, the growth is rank, and yields much ſtraw, but little ear.

It is over-moiſt, and to that is principally to be attributed this rankneſs of the crop in ſome years; and the occaſion of its retaining ſo much moiſture is, that it uſually has a bed of a ſtiff clay, which will not let the water run off into the under ſtrata.

In ſome places they alſo give this name to a black, rich, and denſe earth, with ſtreaks of a whitiſh mould in many parts. This ſort of *Hen-mould* is uſually found very rich and fertile. *Moreton*'s Northamp. p. 37.

HENNA, in botany, a name given by Ludwig to a genus of plants, called *alhen* by Dr. Shaw and others, and ſince named by Linnæus lawſonia. See the article LAWSONIA.

HENOTHRIX, in natural hiſtory, the name of a fly of the ſeticauda or hair-tail'd kind. This is diſtinguiſhed from the others by having only one hair, and is called alſo by ſome uniſeta. The whole body of this ſpecies is black, except the middle of the back and belly, which are red; the wings are ſilvery, and the antennæ very ſmall and black. It is very common in the warm climates, and is uſually found ſitting on the ammi, or biſhop's-weed; whence it is called by ſome the ammi-fly.

HENRICUS *rubens*, in the affected language of ſome chemiſts, a name given to vitriol when calcined to a redneſs.

HENTINGS, in agriculture, a term uſed by the farmers for a particular method of ſowing before the plough; the corn being caſt in a ſtrait line juſt where the plough is to come, is by this means preſently ploughed in. By this way of ſowing they think they ſave a great deal of ſeed and other charge, a dexterous boy being as capable of ſowing this way out of his hat, as the moſt dexterous ſeeds-man. *Plot*'s Oxfordſhire, p. 251.

HENTING is alſo a term uſed by the plowmen, and others, to ſignify the two furrows that are turned from one another at the bottom, in the plowing a ridge; the word ſeems to be a corruption of *ending*, becauſe thoſe furrows make an end of plowing the ridges. The tops of the ridges they call veerings.

HEORDPENNY, in our old writers, the ſame with what at firſt was called *Romeſcot*, and afterwards *Peter-pence*. See ROMESCOT, and PETER-PENCE, *Cycl.*

The word is Saxon, from *Heorth*, *focus*, a hearth, and *penning*, *denarius*, a penny.

HEPAR (*Cycl.*)—HEPAR *ſulphuris*, brimſtone melted with half the quantity of a fixed alkali. A like ſubſtance may alſo be produced by tartarum vitriolatum, ſandiver, or other of the neutral ſalts containing the vitriolic acid, if when they are red-hot in the fire there be added to them powder of charcoal, or any other more fixed phlogiſtic; but the *Hepar ſulphuris* is not ſo ſtrong, as otherwiſe, when it is made with nitre fixed with coals, or with the alkali compoſed of tartar and nitre, or with neutral ſalts with an addition of ſulphur already containing the vitriolic acid. The *Hepar ſulphuris* runs earths and ſtones into fuſion over the fire; and when melted with the metals it makes them eaſily fuſe, but renders them brittle, and in ſome degree ſoluble in water. *Hoffman*'s Obſerv. Phyſ. Chem.

HEPATICA, in botany, a name given by Micheli to certain ſpecies of the marchantia, a kind of lichen. Theſe have the male cup of a conic figure, and divided into five ſegments which wrap round the flowers; whereas thoſe which he calls marchantia have eight or ten ſegments in the cup, and thoſe plain, not curled or bent downwards *Micheli* Nov. Gen. Plant. 55. See the article MARCHANTIA.

HEPATIC *Flux*, *Fluxus Hepaticus*, a flux of the belly of a very ſingular kind, and ſo rarely met with, that many authors have confounded the accounts of it with thoſe of dyſenteries and hæmorrhoidal fluxes. The ſigns by which it is known, are theſe: The patient voids by the anus a liquid matter, reſembling water in which raw fleſh had been waſhed; this is attended with pains and a ſenſe of weight and tenſion in the abdomen, and ſpaſtic motions about the loins, which ſometimes extend themſelves to the right ſide toward the region of the liver. In ſome patients there is no ſenſation of any pain, or any particular ſymptom, and in ſome a teneſmus is joined continually with this voiding of a bloody fluid.

The perſons principally ſubject to this diſeaſe are men, and thoſe between the age of eighteen and forty for the moſt part, as alſo ſuch as are of a ſanguineo-phlegmatic habit, and of a ſedentary life. This diſeaſe is obviouſly diſtinguiſhed from a dyſentery, in that there is always in that diſeaſe blood mixed with a mucous matter voided, which is not at all the caſe in this. And in that there always is more or leſs of a fever attending, whereas in this there is none.

Cauſes of it. The antients ſuppoſed this to be owing to a debility of the liver, which was not able in this caſe properly to attract or retain the blood. But it ſeems rather to belong to the hæmorrhoidal diſcharges; and as in the menſes, when the pure and proper blood is not diſcharged, a bloody water is; ſo in theſe caſes when true blood is not voided, this fluid comes in its place. This flux is never dangerous at the time, but when it is long continued it will at length wear down the ſtrength, and bring on bad habits. *Junker*'s Conſp. Med. p. 50.

Method of Cure.—This is to be treated in the ſame manner as a hæmorrhoidal diſcharge when obſtructed, and attemperating and abſtergent medicines are to be given, with gentle purges. Rhubarb, in doſes from a ſcruple to two or more, is to be given every day for a long time; after this nitre, tartarum vitriolatum, the alkaline ſalts of plants, as of wormwood, with the abſorbent powders, ſuch as crabs-eyes; and to theſe may be added decoctions of ſmall centaury, and the like herbs. Id. ibid.

HEPATIS *Infarctus*, in medicine, the name of a diſeaſe conſiſting in a ſtagnatory congeſtion of the blood in the liver. This is of two kinds, the one owing to an inordinate contraction of the liver, which is uſually the caſe when this happens to adults; the other is owing to a too great expanſion of this viſcus, which is the caſe more frequently in youths. Either of theſe diſtemperatures of this organ prevent the free paſſage of the blood through it, and by that means lay the baſis of this infarction. *Junker*'s Conſp. Med. p. 204.

Signs of it.—Theſe are a ſtraitneſs of the precordia, eſpecially about the right hypocondrium, and a difficulty of breathing, a heavy and obtuſe pain in the ſame part, which ſometimes becomes pulſatile, an uncertain and irregular heat of the whole body, and frequent fluſhings of the face, a violent thirſt at times but not continual, a dryneſs of the mouth and often a bitter taſte in it, a glutinous texture of the ſpittle, a dry cough, a loſs of appetite, and laſſitude of the limbs; uneaſy and not ſound ſleep, frequent toſſing about while in bed, a flaccid habit of body; and to all theſe it is to be added, that the urine is thin and limpid at firſt, but as the hectic that always attends, increaſes, it becomes of a deep orange colour, and finally depoſits a deep red ſediment; and in caſe of an expanſion of the liver being the cauſe, the right hypochondrium is ſenſibly ſwelled.

Perſons ſubject to this diſorder are principally ſuch as are of a ſtudious and ſedentary, or idle life; ſuch as have omitted uſual bleedings, or have had ſuppreſſions of the natural diſcharges by the hæmorrhoids or menſes, and ſuch as uſe too thick a diet. *Junker*'s Conſp. Med. p. 204.

Cauſes of it.—Theſe are a plethora joined with a too great thickneſs of the blood, and this occaſionally increaſed by improper treatment in different diſeaſes, as in intermittents with too powerful aſtringents; and in acute fevers with too cooling a regimen, or the abuſe of the volatile ſalts in large doſes. To theſe may be added violent paſſions of the mind; and the ſudden chilling the body when very hot.

Prognoſtics.—This is a diſeaſe that when recent admits of a cure under the proper methods of treatment; but when neglected, it very eaſily degenerates into a ſchirrus, and finally into a hectic and a dropſy.

Method of Cure.—This differs greatly in regard to the different cauſes of the diſeaſe, which as before obſerved are exact contraries: It ſometimes ariſing from an over contraction, ſometimes from an over expanſion of the liver. In caſes ariſing from the expanſion, the ſame method is to be uſed as in infarctions of the ſpleen. See SPLEEN. But on the contrary, when it ariſes from a contraction of this viſcus, the method muſt be this: The primæ viæ muſt be firſt cleanſed and evacuated by gentle purges; after this bleeding in the foot is to be ordered, and then the matter impacted in the liver is to be incided and attenuated by decoctions of dandelion and pimpernel roots, with maiden hair, ſorrel, dodder, and daiſy flowers; after this the gums, as ammoniacum, and the reſt, are to be taken; and after theſe the digeſtive ſalts, as tartarum vitriolatum, nitre, and the like: And during the taking theſe, all the external medicines of the emollient kind are to be applied to the right hypocondrium; but this not continually, but at different intervals, leſt they ſhould bring on a ſuppuration in the liver. Id. ibid.

HEPATITIS, in medicine, the name of an acute continuous and inflammatory fever, in which nature frequently and forcibly propels the humours through the liver, ſeemingly with intent to reſolve and abſterge congeſtions and ſtaſes of the blood in that viſcus.

The *Hepatitis* is diſtinguiſhed from all other fevers by the ſeat of it in the liver, and by its being of all other fevers the moſt fatal. It differs however in degree, ſome caſes depending on a more ſuperficial, ſome on a deeper and more internal inflammation of the liver. *Junker*'s Conſp. Med. p. 283.

Signs of it.—This dangerous fever uſually ſeizes the patient with a chillneſs, which laſts a conſiderable time; this is at length ſucceeded by a violent heat, which is much more intenſe at ſome times than at others, and is attended with an inſupportable thirſt. The patient perceives a ſevere and heavy pain in the right ſide about the ſeventh or eighth rib, and is afflicted with a violent ſtraitneſs of the breaſt and difficulty of breathing, and the extremities are very apt to become cold. After drinking any thing they uſually belch, and the narrowneſs of the breaſt and difficulty of breathing always increaſe upon this, tho' not the pain. Often alſo there are nauſeas and reachings to vomit, and a bilious matter is thrown up, and ſometimes ſpaſtic motions of the throat are very

very frequent and painful. The one or the other of theſe ſymptoms occur as the gibbous ſide or the other part of the liver are affected. The cough attending this diſeaſe is dry, and not violent, and the ſweats are continual but moderate and eaſily ſtruck back, or often cold and clammy. The urine for the firſt days is reddiſh and thick, and about the fourth day it uſually begins to depoſit a ſediment, the remaining part of it being however ſtill turbid; the ſediment is mucous and of a pale fleſh colour; it has ſo much the appearance of putrid matter that many have ſuppoſed it to be ſuch, but the diſtinction between theſe ſediments and true pus is eaſily made, as the pus always ſubſides immediately on the making the water; but the other ſediment not till it has ſtood to be cold, and this ſediment becomes diſſolved and mixed again with the urine, if the veſſel containing it be ſet in hot water. This is one great proof of inflammation. Another very peculiar ſymptom in this diſeaſe is, that the patient frequently changes colour, being at times pale, and at times browniſh or yellowiſh; the yellowneſs principally affecting the eyes and face. In caſes where the matter in the liver comes to a ſuppuration all the ſymptoms become more ſevere, the heat is greater, the reſpiration more difficult, and the anxieties and ſenſe of pain in the part, and the coldneſs of the extremities all become greater. Finally the breaking of the tumor is known by a ſudden remiſſion of the pain, with a terrible faintneſs and lowneſs of ſpirits, and a hectic; and when the matter is diſcharged into the cavity of the abdomen, it is known by the ſwelling of that part.

Cauſes of it.—The general cauſes of the *Hepatites* are a plethora, and a derivation of blood into the liver, which there forms congeſtions and ſtaſes. This is brought on by violent motions of the body, ſuch as running, dancing, leaping, and the like, and by endeavouring to lift great weights, by ſuddenly cooling the body at times, when the blood is in a great heat; by taking aſtringent medicines in inflammatory fevers, and by driving back the matter of cutaneous eruptions, ſuch as the St. Anthony's fire, and the like, into the blood; and finally, by applying cold external medicines to the region of the liver, or by cupping upon the part.

Prognoſtics.—The *Hepatites* is one of the moſt dangerous kinds of inflammation, and the deeper it lies the more obſtinate it is, and the more difficult to be diſcuſſed, and the more liable to corruption, which muſt occaſion immediate death, or elſe to maturating and breaking, which would be attended with no leſs danger, though not ſo ſudden. A vehement and unaccuſtomed commotion of the humours immediately at the beginning of the diſeaſe, is a bad omen. The more violently inflammatory fevers attack perſons in the morning, and that without any particular cauſe, the greater always is the danger. The cure of this diſeaſe is very difficult, and its manner of going off very variable and uncertain. In ſome caſes it goes off by regular diſcuſſion in a longer time, ſometimes by copious hæmorrhages of the noſe, or by profuſe ſweats which come on on the regular critical days. Black matter reſembling the rob of elder, whether diſcharged by vomit or ſtool, is a very bad omen, in this and all other inflammatory diſeaſes of this kind; but when voided by vomit, the danger is greater than when by ſtool.

Method of treatment. Bleeding is very proper in the beginning of the diſeaſe, and after this the bowels are to be kept gently open, not by ſtimulating purges, but by emollient glyſters, and the mildeſt and gentleſt cathartics. The mixtura ſimplex is a very valuable medicine given ſeveral times a day; and in the intermediate hours the following powder is to be given: Take purified nitre, and tartarum vitriolatum, each two drams; crabs eyes, and the jaw of a pike, reduced to powder, and ſated with lemon juice, of each four ſcruples; diaphoretic antimony a dram. The doſe of this mixed powder is a ſcruple. While theſe things are given internally, the region of the liver ſhould be bathed externally with ſpirit of wine camphorated, impregnated with ſaffron. If the diſeaſe is very violent, a gentle anodyne may be mixed with one of the powders, to be taken at night; but this muſt only be done while the diſeaſe is in its encreaſe. And above all things, reſt, moderate warmth, and a placid regimen, are to be obſerved. With all theſe the diſeaſe is oftener fatal than curable. *Junker*'s Conſp. Med. p. 287.

HEPATITIS *Lapis*, in natural hiſtory, a name given by ſome of the antients to a ferrugineous ſtone of a yellowiſh red colour; others called a coarſe jaſper, and ſome a dirty kind of hyacinth, by this name: In ſhort, they ſeem to have called any thing *Hepatitis* that was of a liver colour. The ſtone moſt univerſally ſo called, however, ſeems to have been of the nature of ſome of our poor iron ores.

HEPATOSCOPIA, Ἡπατοσκοπια, in antiquity, a ſpecies of divination, wherein predictions were made by inſpecting the livers of animals.

HEPATOSCOPIA is alſo uſed as a general name for divination by intrails. See an account of the ſymptoms of the liver, whence good or evil were foretold, in *Potter*'s Archæol. Græc. l. 2. c. 14. T. 1. p. 316.

HEPATUS, in zoology, the name of a ſea fiſh caught in the Mediterranean, and remarkable for its colour, which is that of a liver, from whence it has its name. It is of a broad flat ſhape, and has very prominent eyes, and a remarkably broad tail, in which near the baſis there is a large black ſpot; its teeth are round and large, and ſomewhat pointed; and it has only one back fin, the anterior rays of which are prickly, the hinder ones ſoft to the touch. *Rondelet* de Piſc. l. 5. c. 21.

This name is given by Bellonius, Geſner, and others, to the fiſh more uſually called *Sachettas*, and by ſome *Channadella*. All theſe however are arbitrary and unexpreſſive names. Artedi has referr'd the fiſh to its proper genus, which is the labrus, and calls it the labrus with the lower jaw longer than the upper, with a forked tail, and with black tranſverſe lines on the ſides. See the article LABRUS.

HEPHÆSTIA, Ἡφαιστεια, in antiquity, an Athenian feſtival in honour of Ἡφαιστος, i. e. Vulcan. For an account of the ceremonies and games, on this occaſion, ſee *Potter*'s Archæol. Græc. l. 2. c. 20. T. 1. p. 399. See alſo the article LAMPADEPHORUS.

HEPHÆSTIAS, in the writings of the antients, a name of a plaſter uſed among the ſurgeons to induce a cicatrix: It was principally compoſed of burnt earth, or of the tiles that had been long burnt in the kilns, reduced to powder.

HEP, in the materia medica. See the article HIP.

HEPSETUS, in ichthyology, the name of a ſmall ſea-fiſh called alſo *anguella*, and by ſome *atherina*. It is long, ſlender, and almoſt pellucid; its tail is forked, and its back variegated with black ſpots. When the ſcales are taken off, theſe ſpots appear much plainer than before, and are placed in ſuch order, that four of them uſually make a ſort of rhombic figure. The ſcales are alſo divided into a ſort of rhombic figures by black lines. The ſides of this fiſh are of a ſilvery white; the mouth is large, and the teeth very ſmalll; its eyes are large, and it has two fins on the back. It is caught on the ſhores of the Mediterranean, and ſome other ſeas, and is of a delicate taſte, but very full of bones, whence it is not much valued. *Willughby*'s Hiſt. Piſc. p. 209.

HEPTAMERIS, in muſic, is uſed by Mr. Sauveur for the ſeventh part of the meris or $\frac{1}{42}$ of an octave.

Hence the *Heptameris* is $\frac{1}{301}$ of an octave.

HEPTANDRIA, in botany, a claſs of plants with hermaphrodite flowers, and ſeven male parts or ſtamina in each.

The word is formed of the Greek ἑπτὰ, ſeven; and ἀνὴρ, male. Of this claſs are the horſe-cheſnut, finitelis, &c.

HEPTANGULAR *figure*, in geometry, a figure with ſeven angles, or ſeven ſides.

HEPTAPHARMACUM, a relaxing, ſuppurating, and incarnating medicine, compoſed of ſeven ingredients. This is much talked of among the antient writers in medicine. The ingredients were, ceruſs, wax, pitch, litharge, colophony, bull's fat, and frankincenſe. It is deſcribed by Aetius in his Tetrab. Serm. 3. c. 27.

HEPTAPLEURON, *ſeptinervia*, having ſeven ribs; a word uſed in botany to expreſs a ſort of common plantain, every leaf of which has ſeven ribs belonging to it.

HERACANTHA, in botany, a term uſed by ſome authors to expreſs the common wild carline thiſtle. See the article CARLINA.

HERACLEON, in botany, a name given by ſome of the Greek writers to the lithoſpermum, or gromwell. It was originally called heracleon ſporon, ηρακλεον σπορον, the Herculean ſeed, from the remarkable hardneſs of the ſeed; but the latter word was drop'd, and the *Heracleon* only preſerved. There is great reaſon againſt uſing the word dioſpyros as a ſynonym for the gromwell, becauſe it is a name given by ſome of the Greeks to a very different kind of vegetable, a ſort of cherry. *Pliny*, l. 26. c. 11.

HERACLEUS *Lapis*, in the natural hiſtory of the antients, a name by which many have called the loadſtone. This was the name given to it by the antient Greeks from Heraclea, a city of Lydia, near which it uſed to be found; but after writers ſo far err'd from the origin and orthography of the word, as to call it *Herculeus lapis*, as if it had been named from Hercules.

The after ages of the Greeks called it alſo *magnetis lapis*, but this was a name by no means applied to it in the earlier times, but then was uſed to expreſs a very different ſubſtance, a white ſilvery-looking ſtone, which had no power of attraction, but was turned into beautiful veſſels for the uſe of the table: And the not attending to the ages in which the authors lived who uſe the word *magnetis*, has been the occaſion of great errors in their commentators, who did not conſider that in the ſucceſſion of a few ages, the ſame word became the name of two very different things. *Hill*'s Theoph. p. 79. See the article BASALTES.

HERACLIA, Ηρακλεια, in antiquity, an Athenian feſtival celebrated every fifth year in honour of Hercules.

The Thiſbians and Thebans in Bœotia obſerved a ſolemn feſtival in honour of Hercules, ſurnamed Μηλων, becauſe apples were offered to him. Beſides theſe there were other feſtivals kept in honour of Hercules; for a deſcription of all which, ſee *Potter*'s Archæol. Græc. l. 2. c. 20. T. 1. p. 398, ſeq.

HERÆA, Ἡραια, in antiquity, a feſtival celebrated at Argos in honour of Juno, called in Greek Ἡρη. See a deſcription of the ceremonies attending this ſolemnity, in *Potter*'s Archæol. Græc. l. 2. c. 20. T. 1. p. 397.

There

There was another feſtival of this name, celebrated every fifth year in Elis, where ſixteen matrons were appointed to weave a garment for the goddeſs. There were games alſo which are ſaid to have been inſtituted by Hippodamia, in honour of Juno, by whoſe aſſiſtance ſhe was married to Pelops. The preſidents were ſixteen matrons, every one of which was attended by a maid. The contenders were virgins, who being diſtinguiſhed into ſeveral claſſes, according to their ages, ran races in their order, beginning from the youngeſt. The habit of all was the ſame; their hair was diſhevelled, their right ſhoulders bare to their breaſts, and their garments reached no lower than their knees. They had a ſecond race in the olympic ſtadium, which was at that time ſhortened about a ſixth part. Such as obtained a victory, were rewarded with crowns of olive, and a ſhare of the ox that was offered in ſacrifice, and were permitted to dedicate their own picture to the goddeſs. There were other ſolemnities of this name. See *Potter*, loc. cit. ſeq.

HERBA *Lucis*, in botany, a name by which ſome authors have called the chelidonium majus, or great celandine. *Ger.* Emac. Ind. 2.

HERBA *Paris*, *Herb Truelove*, in botany, the name of a genus of plants, of which there is only one known ſpecies; the characters of which are theſe: The flower conſiſts of four leaves, and is of the cruciform kind, and contains four ſtamina; the piſtil ariſes from the cup, and finally becomes a round ſoft fruit or berry, divided into four cells, containing oblong ſeeds. *Tourn.* Inſt. p. 233.

HERBA *Roſſa*, in botany, a name given by Latin writers, to a plant uſed by the dyers in making their yellow colours, and by the women in tinging their hair yellow, which was the favourite colour of antient times. It is alſo by ſome called *Robia Herba*. It was from this ſimilitude with the word rubia, which ſignifies madder, a vegetable uſed alſo in the dying trade, ſuppoſed to be the ſame plant: But all the accounts we have of the robia or *Roſſa Herba*, ſhew it to be different in all reſpects from the madder. Paulus Ægineta, who calls it *Robia Herba*, takes pains to diſtinguiſh it from the rubia, and ſhews that it was the plant called œcomenium and cymene by the Greeks, and lutum, lutea *Herba*, and corniola by the Latins. It is the geniſta tinctoria, or dyers weed, at this time common both in England and Greece, and uſed in both places in dying yellow. Pliny tells us, that the lutum had the leaves of flax, and the flowers of broom: this ſufficiently ſhews, that it was the plant we have mentioned.

HERBA *Scythica*, in botany, a name by which ſome authors have called the common liquorice, the root and inſpiſſated juice of which are uſed in the ſhops. *Ger.* Emac. Ind. 2.

HERBA *Vulcani*, in botany, a name uſed by ſome writers for the ranunculus. *Ger.* Emac. Ind. 2.

HERBER, in the manege, is uſed by farriers to denote an application for ſome diſeaſes in horſes, particularly of the head and the anticor. It conſiſts only of a piece of Hellebore root, which, being put into the middle of a horſe's counter, makes it ſwell and ſuppurate. *Guill.* Gent. Dict. p. 1. in voc.

HERBIDÆ *Veſtes*, green habits. See the article EARINÆ *Veſtes*.

HERBIVOROUS, an epithet given to thoſe creatures which feed only on vegetables, to diſtinguiſh them from the carnivorous, or ſuch as feed on fleſh.

HERBOSUM *Marmor*, the name of a ſpecies of marble, much eſteemed and uſed by the antient architects and ſtatuaries. It was of a beautiful green colour, but had always with it ſome caſt of yellow. It was dug in the quarries of Taigetum, but was eſteemed by the workmen the ſame in all reſpects, except colour, with the black marble dug at Tænarus in Lacedæmonia, and thence called the Tænarian marble.

HERCULANIA, in botany, a name by which ſome authors have called the verbena or vervain. *Ger.* Emac. Ind. 2.

HERDS, among zoologiſts. See the article JUMENTA.

HERDING, among ſportſmen, is the reverſe of breaking herd. See the article BREAKING *Herd*.

HEREGELD, in our old writers, a tribute or tax levied for the maintenance of an army. See the article SUBSIDY, *Cycl.*

HERESY (*Cycl.*)—It ſeems difficult, in the law of England, preciſely to determine, what errors amount to *Hereſy*, and what not. The 1 Eliz. which erected the high commiſſion-court, having reſtrained it to ſuch as are either determined by ſcripture, or by one of the four firſt general councils, or by ſome other council, by expreſs words of ſcripture, or by parliament, with the aſſent of the convocation, theſe rules are, at preſent, generally thought the beſt directions concerning this matter. It is agreed that the convocation may and always might declare what opinions are *heretical*, and that a conviction before them was antiently a good foundation for the writ *De Heretico comburendo*; but 'tis doubted whether they can, at this day, convene and convict an *Heretic*. A biſhop, but no other ſpiritual judge, may puniſh an *Heretic* by church cenſures; and a conviction before him was, as ſome ſay, antiently a good foundation for the writ *De Heretico comburendo*. By the 24 H. 8. if the biſhop neglects to proceed againſt an *Heretic*, the archbiſhop may do it. But the temporal courts cannot puniſh an *Heretic*, as ſuch, but only as a diſturber of the public peace; yet ſuch courts may incidently take knowledge, whether a tenet be *heretical*, or not; as antiently, where biſhops grounded their commitment of a man, as an heretic, on 2 Hen. 4. which impowered them to impriſon for *Hereſy*; or even at this day, where a biſhop pleads to a *quare impedit*, that he refuſed the clerk for *Hereſy*; in both which caſes the temporal courts will relieve the party, unleſs the particular point, charged againſt him, be ſet forth, and ſuch point appear to be heretical. But regularly, the temporal courts cannot determine what is *Hereſy*; and therefore if a man thinks himſelf aggrieved by a ſuit in the ſpiritual court, *pro ſalute animæ*, for *Hereſy*, his moſt proper remedy is by appeal, not prohibition. Antiently an heretic convict, refuſing to abjure, or relapſing after abjuration, might be burnt by force of the writ *De Heretico comburendo*; but he forfeited neither lands nor goods. And by the common law, ſtill in force, an obſtinate heretic may be impriſoned by force of the writ *De Excommunicato Capiendo*. V. *Hawk.* P. C. B. 1.

HERMÆA, Ἑρμαια, in antiquity, a feſtival obſerved in honour of Mercury. There were ſeveral ſolemnities of this kind, ſome celebrated in Peloponneſus, others in Bæotia, Crete, &c. See *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 896.

In Crete, during the celebration of the *Hermæa*, the maſters ſerved their ſlaves at table. This cuſtom obtained likewiſe among the Athenians and Babylonians, as alſo among the Romans, witneſs the Saturnalia. *Hofm.* Lex. in voc. See SATURNALIA, *Cycl.*

HERMANNIA, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, being compoſed of ſeveral tubular and corniculate leaves, arranged in a circular form. The cup is compoſed of only one leaf, and is ſwoln like a bladder; and from it there ariſes a piſtil, which finally becomes a roundiſh fruit, which, when ripe, burſts into five parts at the top, and is found to be compoſed of five capſules, which contain very ſmall ſeeds, *Tourn.* Inſt. p. 656.

There is only one known ſpecies of this plant, which is the *Hermannia*, with oblong ſerrated leaves.

HERMAPHRODITE (*Cycl.*) It is diſputed, whether there be any *Hermaphrodites* among the human ſpecies, altho' many laws have been made in different parts of the world concerning them. Dr. Parſons has given us a treatiſe on this ſubject, where he endeavours to ſhew the notion of *Hermaphrodites* to be a vulgar error. And, in particular, that the Angola negro, ſhewn about this town ſome years ago, was a woman, whoſe clitoris was overgrown. See his Mechanical and Critical Enquiry into the nature of *Hermaphrodites*. Lond. 1741. 8°.

In vegetables, the male and female parts, or the apices and piſtillum, are uſually contained in the ſame flower; ſometimes in different flowers on the ſame plant, and ſometimes, though more rarely, on different plants of the ſame ſpecies. In this laſt caſe the ſexes are diſtinct, though the ſpecies is the ſame; and theſe moſt approach to the nature of the larger animals: But though theſe have the individuals of diſtinct ſexes, yet the ſmaller creatures of the animal kingdom, have often the two ſexes in the ſame individual, and are therefore what we call *Hermaphrodites*. Of this kind are the common earth-worms, the round worms found in the bowels of men, and other animals, and all the ſpecies of ſnails and leeches. And as all theſe are of the ſofter kinds of inſects, and have no bones, it is not improbable but that all the other inſects of the ſame kind may be alſo *Hermaphrodites*, as nature is uſually very ſimilar in all her works. Among the inſects of the ſoft or boneleſs kind, there are great numbers, indeed, which are ſo far from being *Hermaphrodites*, that they are of no ſex at all. Of this kind are all the caterpillars, maggots, and worms, produced of the eggs of flies of all kinds; but the reaſon of this is plain; theſe are not animals in a perfect ſtate, but diſguiſes under which animals lurk. They have no buſineſs with the propagating of their ſpecies, but are to be transformed into animals of another kind, by the putting off their ſeveral coverings, and then only they are in their perfect ſtate, and therefore then only ſhew the differences of ſex, which are always in the diſtinct animals, each being only male, or only female. Theſe copulate, and their eggs produce theſe creatures, which ſhew no ſex till they arrive at that perfect ſtate again. Mem. Acad. Par. 1707.

The common earth-worms eaſily ſhew their *Hermaphrodite* nature, and manner of copulation, if they are attended to in the ſpring ſeaſon, in the mornings. Theſe creatures meet one another, and, applying their bodies together, the head of one going toward the tail of the other, and their bodies being joined in right lines; and in this ſtate a little button or protuberant part of the one, formed in the ſhape of a ſmall line, is received into a little aperture in the body of the other; and this, at a little diſtance, has ſuch a protuberant part alſo, which is reciprocally received into an aperture in the body of the firſt. This is eaſily ſeen, if two worms in this ſtate are taken up, and examin'd in a good light, by pulling them aſunder. As theſe animals are males in one part of their body, and females in the other; and, being formed without bone, are capable of moving themſelves eaſily, and turning every way about, it is very probable that the ſame individual may be able to couple with itſelf, and be the father and mother of its progeny. This may ſeem a ſtrange ſort of generation; but we are to conſider that it only appears ſtrange to us, from our limited

limited knowledge of the general works of nature. Mem. Acad. Paris, 1707.

HERMESIA, a name given, by ſome authors, to hermetic chemiſtry. See CHEMISTRY.

HERMODACTYLS (*Cycl.*)—Theſe have been too generally ſuppoſed a fruit, but they are unqueſtionably a root, and ſeem to be the roots of that ſpecies of meadow-ſaffron, called by authors *Colchicum Chinenſe floribus frittillariæ inſtar variegatis, foliis undulatis*, or the Chineſe meadow-ſaffron, with undulated leaves, and with flowers chequer'd like thoſe of the fritillary. They were in great uſe among the antients as a purge; but their operation is very ſlow, tedious, and fatiguing. They are beſt corrected by being joined with aromatics, and are now ſometimes uſed, mixed with jalap, in rheumatiſms. The women of Egypt eat the freſh roots roaſted, to make them grow fat. *Pomet*'s Hiſt of Drugs.

HERNIA (*Cycl.*)—Old age is an advantage in performing the operations for *Herniæ*, becauſe old people's guts are not ſo liable to inflame or gangrene, as thoſe of young perſons. Medic. Eſſ. Edinb. from *Garengeot*.

Herniæ, where the omentum falls down with the inteſtines, are more dangerous than where the gut is alone, becauſe the omentum hinders the reduction of the gut, grows to the rings of the muſcles, ſwells, and forms a thick ring, which ſtrangulates the gut. See Phil. Tranſ. N°. 450. §. 2.

HERNIARIA, *Rupturewort*, in botany, the name of a genus of plants, the characters of which are theſe: The flower has no petals, but conſiſts of ſeveral ſtamina, ariſing from a cup. The piſtil finally becomes a ſeed, which is inveloped in a long ſtriated capſule, which was the cup of the flower.

The ſpecies of *Herniaria*, enumerated by Mr. Tournefort, are theſe: 1. The ſmooth *Herniaria*. 2. The hairy *Herniaria*. 3. The ſhrubby *Herniaria*, with woody twigs. And 4. The chickweed-leav'd *Herniaria*. *Tourn.* Inſt. p. 507.

This plant has been long celebrated for the virtues its name expreſſes in the curing of ruptures; but though the modern practice does not ſeem to allow all thoſe virtues to it, yet there is another caſe in which a German phyſician ſtrongly recommends it. It is in the diſorder of the eyes, which is brought on by reading or writing by candlelight, or by examining nice objects, or very fine work. This diſtemperature ſeems to be properly a diminution of ſight, without any apparent cauſe, or viſible alteration in the eye, and is probably owing to a viſcid matter obſtructing the optic nerves, and preventing a ſupply of their proper fluid. The *Herniaria*, being a gentle and mild attenuant, comes in admirably for the relief of this diſorder. *Gruhlman.* de novo Caliginis remedio.

The author gives many inſtances of the ſucceſs of this remedy, and mentions two methods of giving it; the one in powder, and the other in tincture: The former way is preferr'd, and the method is to gather the herb in its prime, and powder it after it has been dried in the ſhade; then to ſprinkle the quantity of a ſcruple of this powder on the bread and butter uſed for breakfaſt. If this is not liked, the tincture is to be made with ſpirit of wine, as ſtrong as the plant will make it, and forty drops are to be taken every morning and evening in any liquor. The diſtemperature this is propoſed to cure, is very common, yet this is almoſt the only thing that has been preſcribed by way of remedy, and deſerves to be fairly try'd.

HERODIUS *Avis*, in natural hiſtory, a name given by Aldrovand, and ſome others, to the chryſaëtos, or golden eagle. See the article AQUILA.

HERON, *Ardea*, in zoology, the name of a large genus of birds, the diſtinguiſhing character of which is, by Mr. Ray, fixed in their inteſtines, they having only one inteſtinum cæcum, or blind gut, as is the cuſtom of nature in quadrupeds, moſt other birds having two.

Of this bird there are many ſpecies. 1. The common *Heron*, well known to every one. 2. The *Ardea cinerea tertium genus* of Aldrovand, which has not been allotted any diſtinguiſhing name, either in Latin or Engliſh. This is diſtinguiſhed by having every one of its feathers, which are greyiſh and blackiſh, variegated with a ſpot of reddiſh brown at the extremity, and its leggs being of a greeniſh colour. 3. The *Ardea cinerea minor*, or ſmaller grey *Heron*, called the nycticorax, or night raven. See NYCTICORAX. 4. The great white *Heron*, called by the Venetians and others, gazza. See GAZZA. 5. The ſmall white *Heron*, called the *Gaza Giovane*. See GAZA *Giovane*. 6. The ſmall white *Heron*, called the *Ardea tertia minor* of Aldrovand. This is a ſmall, but a very fleſhy bird, its beak very ſhort, in compariſon of the other *Herons*, and all over yellow; its head and neck alſo are of a ſaffron colour, and its breaſt of a pale yellow. 7. The *Ardea hæmatopus*, or *cirris* of the antients. See CIRRIS. 8. The *Heron* called *Sguacco*. See SGUACCO. 9. The *Heron* called *Squaiotta*. See SQUAIOTTA. 10. The hooked-beak'd ſmall *Heron* of Aldrovand, which is a ſmall kind, with a beak more hooked at the end than any other ſpecies, and is white, variegated with ſtreaks of black on the belly, and grey on the back. 11. The *Ardea congener*, called the baſtard *Heron*, of the ſame author, which has ſo ſhort a beak, as not to be properly reducible to this genus. Its neck, legs, and toes, are all very long, and it is all over black, except that it has a white ring about the neck. 12. The *Ardea Stellaris*, or *Bittern*. See BITTERN. 13. The *Ardea Stellaris tertium genus* of Aldrovand, to which neither the Latins nor Engliſh have given any diſtinguiſhing name. This is all over of a reddiſh brown colour. Its beak is a hand's breadth long, ſtrait, pointed, and of a horn colour; the upper chap a little longer than the under one, and ſlightly hooked at the extremity. 14. The great red *Bittern* of Aldrovand, which ſeems a ſort of baſtard kind between the common *Heron* and the bittern, but comes neareſt the grey *Heron* kind, and has a grey back, and reddiſh breaſt and ſides. 15. The *American Heron*, called *Soco*. See SOCO. 16. The Braſilian *Heron*, called *Cocoi*. 17. The Braſilian *Heron*, with the ſerrated beak, which is the ſame ſize with our common tame duck, and reſembles the bittern in colour. 18. The *Heron* called *Guiratinga* by the Braſilians. See GUIRATINGA. And laſtly, the *Ardeola*, or ſmall *Heron*, a Braſilian kind, ſcarce ſo large as a pigeon. See ARDEOLA. *Ray*'s Ornithology, p. 203 to 210.

This bird is a very great devourer of fiſh, and is of more miſchief to a pond than even an otter. Some ſay that a *Heron* will deſtroy more fiſh in a week, than an otter will in three months; but that ſeems carrying it too far. People who have kept *Herons*, have had the curioſity to number out the fiſh they fed them with into a tub of water, and counting them again afterwards, it has been found that they will eat fifty moderate ſiz'd dace and roaches in a day. It has been found that in carp ponds, viſited by this bird, one *Heron* will eat up a thouſand ſtore carp in a year, and will hunt them ſo cloſe as to let very few eſcape. The readieſt method of deſtroying this miſchievous bird, is by fiſhing for him in the manner of pike, with a baited hook. When the haunt of the *Heron* is found out, three or four ſmall roach or dace are to be procured, and each of them is to be baited on a wire, with a ſtrong hook at the end, entering the wire juſt under the gills, and letting it run juſt under the ſkin to the tail, the fiſh will live in this manner five or ſix days, which is a very eſſential thing, for if it be dead, the *Heron* will not touch it. A ſtrong line is then to be prepared of ſilk and wire twiſted together, and is to be about two yards long; tie this to the wire that holds the hook, and to the other end of it there is to be tied a ſtone of about a pound weight; let three or four of theſe baits be ſunk in different ſhallow parts of the pond, and in a night or two's time, the *Heron* will not fail of being taken by one or other of them.

When hawking was more in uſe, the *Heron* afforded a great deal of ſport to the people who loved that diverſion. There is but very little art in this flight of the hawk; but as both the birds are large and courageous, the ſight is finer than in the flight of ſmaller birds that make no reſiſtance. At the beginning of March the *Herons* begin to make their paſſage: If therefore you will adapt your hawks to the *Heron*, they muſt be at this time uſed to fly at the rivers, and about waters; and they muſt be fed with light meats. Then the hawk is to be entered at the game by getting a living *Heron*, and cutting its wings, or diſabling it in ſuch a manner that it cannot fly. Then it is to be ſet on the ground, and the hawk unhooded and let go at her. If the hawk ſeize the *Heron*, the falconer muſt run in to her aſſiſtance, and kill the *Heron*, giving the hawk her reward, the heart, and letting her ſtand over the opened breaſt, and feed on other parts of the entrails. Then let her be hooded; and afterwards the bird is to be ſwung about the head, and the hawk taught to come and feed on it out of the falconer's hand.

When the hawk is thus fairly entered, another live *Heron* is to be procured, and let off in an open field undiſabled: As ſoon as ſhe is riſen to a conſiderable height in the air, the hawk is to be let out after her; if the hawk cloſe with her, and bring her down, the falconer is to run up to her aſſiſtance, and ſticking the *Heron*'s bill in the ground, and breaking her wings and legs, the hawk is to be left to feed and plume upon her. When ſhe is thus well managed, ſhe may be taken to the waters, and let at a wild *Heron*, in the following manner.

When a *Heron* is found, the falconer is to get as nigh her as he can, going under the wind with his hawk, which muſt be a gerfalcon, or jerkin, with a haggared falcon for the driver. Thus having the hoods looſe, as ſoon as ever the *Heron* is up, let off the driver, which makes up to her, and cauſes her to work in the wind; then let go the hawks that are to fly at her; but when they have worked above the *Heron* that they come through her, they will make her come to ſiege. When they have got her down, the falconer muſt make up to them as quick as poſſible, and aſſiſt them by breaking her legs and wings, and thruſting her bill into the ground. For this flight of the hawk there ſhould always be a dog trained up to the ſport, whoſe buſineſs it is to come up and kill the *Heron* the moment that he ſees her fall.

If the hawk cannot bring her down, or gives over the flight, then give her a train *Heron* or two, in a proper place, before ſhe is truſted at a wild *Heron* again, otherwiſe ſhe will be diſheartened and ſpoiled.

HEROS *Coagulationis*, the *Hero of Coagulations*, an affected name given by Paracelſus to the ſpirit of ſea ſalt; a menſtruum

um he was particularly fond of, and which ſeems to have been one great ingredient in his alcaheſt.

HERRING, in ichthyology. See the article HARENGUS.

HERRING *Gull*, in zoology, the name of a bird of the larus kind, called by authors *larus cinereus maximus*, or the great grey gull. It is of the ſize of our common duck, its beak is yellow, and is narrow, and two fingers breadth long, a little hooked at the end, and has on the lower chap a fine red ſpot. The eyes are encircled with yellow or red, perhaps in the different ſexes; its hinder toe is very ſmall; its head, neck, rump, and tail, and its whole upper ſurface is white, except that the back and ſhort feathers of the wings have a little greyiſhneſs; the long wing feathers are black and white; its wings, when folded, reach to the end of the tail. It feeds on herrings and other fiſh, and is a very voracious bird. *Ray*'s Onitholog. p. 262.

HERTHAMAN, in the materia medica, a name given by Aviſenna and Serapion to the grain called zea, uſed much in medicine in their time, and ſuppoſed to be of a middle nature between wheat and barley.

HESPERIS, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of four leaves, and is of the cruciform kind; the piſtil ariſes from the cup, and ripens into a long pod of a cylindric form, divided by an intermediate membrane into two cells, and containing roundiſh or oblong, and cylindric ſeeds, which are lodged in the depreſſions of the intermediate membrane.

The ſpecies of *Heſperis* enumerated by Mr. Tournefort, are theſe: 1. The purple-flowered garden *Heſperis*. 2. The white-flowered garden *Heſperis*. 3. The green-flowered garden *Heſperis*. 4. The double purple garden *Heſperis*. 5. The double white garden *Heſperis*. 6. The double garden *Heſperis*, with variegated flowers. 7. The ſweet-ſcented pale-flowered mountain *Heſperis*. 8. The wild ſcentleſs *Heſperis*. 9. The Syrian *Heſperis*, with articulated pods. 10. The wild *Heſperis*, ſmelling like garlic, commonly called alliaria, jack by the hedge, or ſauce alone. 11. The yellow flowered *Heſperis*, with very narrow pods. 12. The ſquare-podded *Heſperis*, with leaves like thoſe of leucoium. 13. The ſquare-podded *Heſperis*, with ſerrated leucoium leaves. 14. The duſky-flowered *Heſperis*, with horned pods. 15. The little procumbent ſea *Heſperis*. 16. The ſmall-flowered wild *Heſperis*. 17. The narrow-leaved hoary ſea *Heſperis*. 18. The blue-flowered hairy African *Heſperis*. 19. The cut-leaved *Heſperis*, with variegated flowers. 20. The narrow-leaved Portugal *Heſperis*, with dentated leaves and purple flowers. 21. The Spaniſh *Heſperis*, with divided leaves, and lunated pods. 22. The broad-leaved ſea *Heſperis*, with a three-pointed pod. 23. The ſhrub Sicilian *Heſperis*, with three-pointed pods. 24. The Sicilian *Heſperis*, with coronopus leaves, and with three-pointed pods. 25. The great African *Heſperis*, with coronopus leaves, and blue flowers. 26. The ſmaller African *Heſperis*, with coronopus leaves and blue flowers. The great diſtinction of the *Heſperis* from the leucoium, is that its pods are cylindric, not flatted; and its ſeeds tumid, and not marginated, and are received in certain hollows in the ſeptum of the pod. *Tourn.* Inſt. p. 322.

The *Heſperis* of Caſpar Bauhine, Ray, &c. is the *viola matronalis*, or dames violet. Vid. *Dale*'s Pharm. p. 200, 201.

HESYCIUS, in natural hiſtory, the name of a fly of the carnivorous kind, often found preying on the bodies of other flies, beetles, &c. and of ſerpents; whence it has been called alſo ophioboros. Its wings are of a ſhining pale yellow, or the colour of poliſhed braſs; whence it has alſo been called by ſome chalcomuia.

HETERODOX, *heterodoxi*, in botany, that ſet of ſyſtematical writers on this ſcience, who formed their diſtributions and claſſes of the plants on wrong foundations, not on the diviſions made by nature in the different ſtructure of the parts of fructification in the different claſſes, but on the ſhape of their leaves, or roots; or who rang'd them by their common names, according to the letters of the alphabet. *Linnæi* Fund. Bot. p. 2.

HETEROPHAGI, in natural hiſtory, a term uſed by ſome authors to expreſs a peculiar claſs of inſects diſtinguiſhed by their eating many different things, but not feeding on one another, as thoſe do which are of the claſs of the allelophagi, of which there are a great number of ſpecies.

HETEROSTROPHE, an epithet applied to certain ſhells, the wreaths of which turn a contrary way from thoſe of other ſhells of the ſame genera. We have in the Philoſophical Tranſactions an account of two very remarkable ſpecies of ſnail-ſhells of this kind, eaſily diſtinguiſhable from one another, and more eaſily from all other ſhells, becauſe the turn of the wreathes is from the right hand to the left, contrary to what is to be ſeen in other ſnails. Theſe are ſmall, and therefore eſcaped the obſervation of naturaliſts a long time; neither of them much exceeds an oat corn in thickneſs, and they are of the figure of the *turbines læves* of Aldrovand and other authors. The ſmaller of theſe is very thin and tender, the opening of the ſhell is pretty round, and the ſecond turn or wreathe is very large in proportion to the ſize of the creature; the other wreathes, which are about ſix in number, are ſtill leſſened to a point. The turben, or conical figure, is nearly a quarter of an inch, and the colour of the ſhell appears duſkiſh; but when the animal ſhrinks into it, and the ſhell is held up to the light, it appears of a pale yellowiſh hue. The larger ſort are twice as long as theſe, and are conſiderably thick-ſhelled: Theſe are very much of the figure of an oat corn, being pointed at the ends, and ſomewhat ſwelled in the middle. The opening of this ſpecies is not round, as in the other, but has a ſinus in the lower part; there are about ten ſpires, which all turn from the right hand to the left; the colour of this ſhell is a dark and reddiſh brown. When theſe ſmall ſnails creep, they lift up their ſhells ſo as to turn the point towards a perpendicular, and throw out two pair of horns, as moſt of the other ſnails do. Ariſtotle affirms all theſe creatures to be of ſpontaneous birth, not at all contributing to the generation of one another, and having no ſex; but later obſervation proves the error of this abundantly; and the author of the account of theſe two remarkable kind of ſnails obſerves, that they are always found in pairs in the month of March, and that about that time it is common to ſee them in the very act of venery. Philoſ. Tranſ. N° 56.

HEWHOLE, or, as it is pronounced in ſome places, the *high-hoo*, a name given by many to the common green woodpecker, from its making holes in trees.

HEXACHORD, (*Cycl.*) in muſic, is by ſome uſed for the ſixth. Hence we meet with *Hexachordum majus & minus*. In the table inſerted under the head INTERVAL, we have reſtrained the term *Hexachord* to ſignify the ſixth of the Greek ſcale, which is not a true ſixth major, but a comma more, being a tone major above the fifth. See the article INTERVAL.

HEXACONTALITHUS, in natural hiſtory, the name of a ſtone deſcribed by Pliny, and other of the antient writers, as being very ſmall, yet ſhewing an almoſt infinite variety of colours. It ſeems only another name for the opal.

HEXAEDROSTYLA, in natural hiſtory, the name of a genus of ſpars. The word is derived of the Greek ἕξ, ſix, ἕδρα, ſide, and στύλος, a column. The bodies of this genus are ſpars of a columnar form, adhering to ſome ſolid body at the baſe, and terminated at the point by a pyramid. The pyramid and column being both hexahedral, or compoſed each of ſix ſides. Of this genus there are three known ſpecies: 1. A ſlender one with a long pyramid; this is compoſed of ſo pure and clear a ſpar, that it reſembles cryſtal, and is found in Ookey Hole, on Mendip Hills, and in ſome other parts of England. 2. A ſomewhat thick one, with a long irregular pyramid, found in the mines of Cornwall and Devonſhire, and common alſo in thoſe of Germany. 3. One with a very ſhort pyramid; this is found in the Derbyſhire lead-mines, and in great plenty in thoſe of the Harts Foreſt in Germany. *Hill*'s Hiſt. of Foſſ. p. 218.

HEXANDRIA, in botany, a claſs of plants with hermaphrodite flowers, and ſix ſtamina or male parts in each, which are in ſome plants all of the ſame length, and in others are alternately one ſhorter and another longer.

The word is derived from the Greek ἕξ, ſix, and ἀνὴρ, male. The plants of this claſs are garlic, hyacinth, meadow-ſaffron, &c. See Tab. 1. of Botany, Claſs 1.

HEXAPYRAMIDES, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek ἕξ, ſix, and πύραμις, a pyramid. The bodies of this genus are ſpars formed into pyramids, compoſed of ſix ſides or planes, and affixed to no column, but adhering to ſome ſolid body by their baſes. Of this genus there are only two known ſpecies. 1. A ſhort one with a broad baſe; this is a very rare ſpecies, and found only, ſo far as is yet known, in the great mine at Goſſelar in Saxony. And, 2. A long-pointed one, with a narrow baſe; this is found in the fiſſures of the alabaſter quarries of the Harts Foreſt. *Hill*'s Hiſt. of Foſſ. p. 225.

HEXIS, in the writings of the Greek phyſicians, a word uſed to expreſs a firm and permanent habitude, in oppoſition to ſcheſis and diatheſis, importing a tranſient or eaſily removed diſpoſition.

HIÆNA, in zoology. See the article HYÆNA.

HIASTAOTOMTEHOM, a Chineſe name, expreſſing a plant, the root of which is ſaid to change, at a certain time, into a worm. Mr. Reaumur has given it the name of *plante-ver* in the French, but he has diſcovered the error of ſuppoſing ſuch a transformation; the whole truth of the caſe being, that a certain caterpillar, when about to change into the chryſalis ſtate, ſo nicely joins itſelf to the root of this plant, as to appear a part of it, See the article PLANTE-VER.

HIATICULA, in zoology, a name which many uſe for the bird called in Engliſh the *ſea-lark*, and by ſome authors *charadrius*. This laſt name being however given by different authors to other birds, it ſhould ſeem beſt to retain the word *hiaticula*, as the diſtinctive name of the ſea-lark. This bird is ſomewhat larger than the common lark; it has a black ſtreak above the beak, and a white one running from one eye to the other; its neck is variegated with two rings, the upper white, and reaching up to the beak, and the lower black, and covering part of the breaſt. Its back is grey, and its breaſt and belly white; its beak is ſhort, and part yellow, part black, and its legs of a pale yellow. It builds among the rocks on the ſea-ſhores, and lays greeniſh eggs ſpotted with brown, and altogether brown at the larger end. It is very

very common on the ſea-ſhores, and makes but ſhort flights, making a ſhrill noiſe all the while it is on the wing; it runs ſwiftly. *Ray*'s Ornitholog. p. 231.

This ſeems in all reſpects the ſame with the Braſilian bird deſcribed by Marggrave under the name *matuitui*; ſo that ſome birds are common to both theſe regions, however different the greater number of them are. See the articles MATUITUI and CHARADRIUS.

HIATULA, in ichthyology, a name given by ſome to the fiſh more uſually called the *channa*. It has this name from its opening its mouth to a great width, eſpecially when dying, which is owing to its under jaw, being much longer than the upper. *Willughby*'s Hiſt. Piſc. p. 327. See the article CHANNA.

HIATULA, is alſo a name by which Gaza, and ſome other authors, have called the ſhell-fiſh more uſually named *Chama*; a genus diſtinguiſhed from other kinds by its always keeping its ſhells in ſome degree open, and in many ſpecies having no power to ſhut them entirely; for this reaſon they defend their naked bodies by burying themſelves in the mud, or in other ſubſtances. See the article CHAMA.

HICCOUGH, (*Cycl.*) in medicine, a ſemiconvulſive motion of the diaphragm and meſentery with the inteſtines, by means of which nature attempts to eliminate and throw off ſomewhat that offends her in thoſe parts. This motion, when it happens in acute diſeaſes, is to be diſtinguiſhed from that which happens at other times; and there is yet another kind of it different from either of theſe, which is familiar to children in dying.

The chronic *Hiccough* is of two kinds; in its common ſtate it remains on a perſon but a very ſhort time, and in the other it remains long, and is attended with a febrile heat, and a difficulty of breathing, with a remarkable noiſe in exſpiration.

Signs of it. It is uſually preceded by a ſenſe of a heavy pain in the breaſt and abdomen, and this is followed by a more or leſs difficult breathing, with a ſound or noiſe in the exſpiration; and the *Hiccough* itſelf, which in chronic caſes is attended with a ſenſation of internal ulceration. *Junker*'s Conſp. Med. p. 638.

Perſons ſubject to it. Theſe are principally men who eat large meals, and load the ſtomach by drinking largely after them, and who eat large quantities of the ſummer fruits, eſpecially when unripe. In acute fevers a *Hiccough* is very familiar to thoſe perſons who have any internal inflammation; and it is very common in the fevers that attend women in their lying-in. The cauſes of the common *Hiccough* are an overloading the ſtomach with food, chiefly with ſuch as is hard of digeſtion; eſpecially if ſwallowed voraciouſly, and large draughts taken after it: Large draughts of cold liquors, or cooling internal medicines, alſo ſometimes bring it on; and it frequently happens when the periſtaltic motion of the bowels is diſturbed by violent purges or vomits. In acute diſeaſes it is principally owing to an inflammation either in the pylorus, the meſentery, or the ſinuous part of the liver; and in dyſenteries it ſometimes comes on from an inflammation of the ileum. Slow poiſons alſo ſometimes ſhew their firſt effects in a violent and unmitigable *Hiccough*.

Prognoſtics. The common *Hiccough* is uſually a diſtemper of little trouble, and attended with no danger; yet there have been inſtances of perſons dying of it without any other diſorder; but theſe fatal *Hiccoughs* will be found, when all circumſtances are conſidered, to have been very different in their nature and origin from the common kind, and uſually to have ariſen from ſome violent motion of the body. When the *Hiccough* comes on in acute fevers about the day of the criſis, it is always dangerous; for this, though in itſelf but a ſemiconvulſive motion, yet very eaſily degenerates into an univerſal convulſion of the whole body, under which the patient uſually ſoon expires. *Hiccoughs* attending colics in perſons who have not before been ſubject to them, are always a bad omen. See FEVER and COLIC.

Method of cure. The common *Hiccough* ſeldom requires any thing of medicine for its cure; it uſually goes off in a little time of itſelf, or if not, is eaſily thrown off by warm liquors, as tea, coffee, or the like. But when it remains on the perſon a long time, as it ſometimes will for ſeveral weeks, then the following method is proper for its cure. The crudities of the primæ viæ are to be carried off by gentle purges, as ſmall doſes of rhubarb, and the like; and by the aſſiſtance of the abſtergent and emollient clyſters. After this the ſtomach is to be ſtrengthened by bitters and mild chalybeats, and by wearing externally bags with camphor, and the aromatic roots and carminative ſeeds. Sometimes alſo it will be neceſſary to give abſorbents mixed with the calx of antimony, to correct the acrimony of the humours. When the fit has by theſe means been carried off, the return of it is to be prevented by taking now and then a doſe of ſome gentle purge, and after every meal ſwallowing two or three corns of pepper in a glaſs of hot wine. When the *Hiccough* comes on as a ſymptom in acute diſeaſes, reſpect is always to be had to the primary diſeaſe, and then the common alexipharmics are to be given, with ſpirit of nitre dulcified, and a gentle doſe of the nitrous and abſorbent medicines, ſuch as a powder prepared of purified nitre and crabs-eyes, or the like; and bags with aromatics may be worn externally. Caſtor, and the other nervous medicines externally have their uſe in this caſe, but internally taken they have no effect, either in this or any the like complaints in the lower belly. Caſſia fiſtula, ſena, and the other purges, which are apt to create flatulencies, are not to be given in theſe caſes. People who are ſubject to habitual *Hiccoughs*, will find relief by uſually wearing a belt round the abdomen, and ſuch ſhould always uſe moderate exerciſe, and avoid large draughts of cold liquors. *Junker*'s Conſp. Med. p. 639.

Dr. Hoyer informs us, that a moſt violent *Hiccough*, which had reſiſted a great number of medicines, was at laſt cured by ſucking womens milk. Act. Acad. Nat. Curioſ. vol. 4. Obſ. 3.

HICKWALL, in zoology, the name of a ſmall ſpecies of woodpecker, called by authors picus varius minor; a ſmall bird of not above an ounce weight, very beautifully variegated with black, white, and brown. The head in the female of this ſpecies has a white ſpot on the crown, and in the males a red one. It climbs trees like the common large woodpecker, and like it feeds on worms and other inſects which it finds there. *Ray*'s Ornithology, p. 93.

HIDE *and* GAIN, in our old writers, ſignified arable land; to gain the land being as much as to till it. Co. Litt. 85. *Blount*, *Cowel*.

HIDES—*Tanned Hides* are commonly carried along with the artillery of an army. They are uſed in the fire-workers ſtores, for covering powder, or charged bombs, from the rain, or from ſparks of fire. They are alſo uſed on batteries, or in a laboratory.

HIDROA, in the medicinal writings of the antients, a kind of puſtules ariſing from bilious, viſcid, and irritating humours, very troubleſome to the ſkin, and moſt ſo in ſummer time, when they make their eruption with the ſweat. They are reckoned by Hippocrates among the diſeaſes peculiar to the ſummer.

The word is Greek, ἱδρωα, from ἱδρως. *Sudor*.

HIDROCRITICA, a term uſed to expreſs the judgments paſſed by phyſicians on their patients, on obſerving the ſweats that have attended the diſeaſe.

HIDRONOSOS, a name given, by ſome authors, to that terrible diſeaſe the ſudor Anglicus. See SUDOR, *Cycl.*

HYDROPYRETOS, the ſweating fever, a name given by ſome to the ſudor Anglicus.

HIDROTICS, in medicine, ſuch things as ſerve to promote ſweating.

HIERACHIOIDES, in botany, a name given by Vaillant to a genus of plants, ſince called by Linnæus, crepis. See the article CREPIS.

HIEMALIA, in antiquity, the ſame with *Brumalia*. See the article BRUMALIA.

HIERACHIUM, *Hawkweed*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the ſemifloſculous kind, being compoſed of a number of ſmall ſemifloſcules, ſtanding each on its embryo ſeed, and all contained in one common cup. The embryo finally becomes a ſeed wing'd with down, and of which there are a large number collected in a head. To this it is to be added, that the ſtalks are branched, and that there is a general family face and appearance among all the *Hawkweeds*, by which they are eaſily diſtinguiſhed at ſight from the ſcorzoneras, &c. *Tourn.* Inſt. p. 469.

The ſpecies of *Hawkweed*, enumerated by Mr. Tournefort, are theſe: 1. The great upright narrow-leav'd *Hawkweed*, with ſmooth ſtalks. 2. The bright red-flower'd *Hawkweed*, with dandelion leaves. 3. The *Hawkweed*, ſmelling like bitter almonds, or like the red Apulian kind. 4. The yellow hairy *Hawkweed*. 5. The hairy rocket-leav'd *Hawkweed*. 6. The greateſt rocket-leav'd *Hawkweed*. 7. The great flowered rough *Hawkweed*, growing in the borders of corn fields. 8. The great obtuſe dandelion-leav'd *Hawkweed*. 9. The great bulboſe-rooted dandelion-leav'd *Hawkweed*. 10. The ſweet hairy dandelion-leav'd *Hawkweed*. 11. The ſmall ſmooth *Hawkweed*, with beautifully green leaves. 12. The dandelion-leav'd *Hawkweed*, with ſmall flowers. 13. The little *Hawkweed*, with rough dandelion-like leaves. 14. The ſmall *Hawkweed*, with long ſmooth dandelion-like leaves. 15. The ſmall *Hawkweed*, with reddiſh white flowers. 16. The great ſuccory-leav'd rough *Hawkweed*. 17. The hairy ſuccory-leav'd *Hawkweed*. 18. The ſmooth ſuccory-leav'd *Hawkweed*, with bitter roots, called by many the yellow devils-bit. 19. The common ſmooth ſuccory-leav'd *Hawkweed*. 20. The coronopus-leav'd *Hawkweed*. 21. The rough echioide *Hawkweed*, with carduus benedictus heads, commonly called *Langue de Bœuf*, or ox-tongue. 22. The great Arabian carduus benedictus-headed *Hawkweed*, with rough ſinuated leaves. 23. The common great ſuccory *Hawkweed*. 24. The great woolly *Hawkweed*, called by many, the woolly great ſow-thiſtle. 25. The hairy *Hawkweed*, called, by Dalechamp, the true ſuccory of Dioſcorides. 26. The endive-like *Hawkweed*, with large white flowers. 27. The wall *Hawkweed*, with leaves covered with very long hairs, called by ſome, lungwort. 28. The wall *Hawkweed*, with jagged and leſs hairy leaves. 29. The wall *Hawkweed*, with narrower jagged and leſs hairy leaves. 30. The wall *Hawkweed*, with leſs hairy and not ſpotted leaves. 31. The nar-

row-leav'd and wall *Hawkweed*, with leaves not ſinuated. 32. The ſmooth narrow-leav'd *Hawkweed*, or great ſmooth piloſella. 33. The *Hawkweed*, with deeply ſinuated hoary leaves. 34. The mountain woolly *Hawkweed*. 35. The great upright mouſe-ear-leav'd *Hawkweed*. 36. The woolly American *Hawkweed*, with the appearance of the French lungwort. 37. The ſmall upright mouſe-ear-leav'd *Hawkweed*. 38. The narrow-leav'd mountain *Hawkweed*, with umbellated flowers. 39. The garden *Hawkweed*, with blackiſh purple flowers. 40. The great flower'd branched *Hawkweed*. 41. The ſtatice-leav'd *Hawkweed*, with a leafy ſtalk. 42. The ſtatice-leav'd *Hawkweed*, with a naked ſtalk. 43. The bladder ſuccory *Hawkweed*. 44. The Sicilian *Hawkweed*, with ſhepherds-purſe leaves. 45. The common yellow-flower'd ſmooth, or but lightly hairy *Hawkweed*. 46. The ſmooth broad-leav'd mountain *Hawkweed*. 47. The leſſer ſmooth broad-leav'd mountain *Hawkweed*. 48. The turnep-leav'd mountain *Hawkweed*. 49. The rough alpine *Hierachium*, with the look of the conyza. 50. The great flower'd alpine *Hawkweed*, with broad hairy leaves. 51. The great flower'd alpine *Hawkeed*, with broad, hairy, and ſpotted leaves. 52. The great flower'd alpine *Hawkweed*, with broad very hairy leaves. 53. The dwarf ſuccory-leav'd alpine *Hawkweed*. 54. The ſmooth ſhrubby *Hawkweed*, with broad dentated leaves. 55. The common broad-leav'd hairy ſhrubby *Hawkweed*. 56. The hairy ſhrubby *Hawkweed*, with leaves much narrower and longer, a little dentated, and very hairy. 57. The ſhrubby *Hawkweed*, with roundiſh leaves. 58. The great narrow-leav'd ſhrubby *Hawkweed*. 59. The leſſer ſhrubby *Hawkweed*. 60. The ſhrubby *Hawkweed*, with very narrow and hairy leaves. 61. The Pyrenean ſhrubby *Hawkweed*, with woolly mullein-like leaves. 62. The tall Pyrenean *Hawkweed*, with the leaves and whole appearance of the doronicum. 63. The nipplewort-leav'd Pyrenean *Hawkweed*. 64. The hairy Pyrenean *Hawkweed*, with moth mullein leaves. 65. The moth mullein-leav'd leſs hairy Pyrenean *Hawkweed*. 66. The Pyrenean *Hawkweed*, with broad honeywort-like leaves. 67. The Pyrenean *Hawkweed*, with narrower honeywort leaves. 68. The round-leav'd Pyrenean *Hawkweed*, with leaves embracing the ſtalks. 69. The broad dandelion-leav'd Pyrenean *Hawkweed*. 70. The low Doronicum-leav'd alpine *Hawkweed*. 71. The alpine *Hawkweed*, with ſcorzonera-leaves. And 72. The dwarf woolly Portugal *Hawkweed*. *Tourn.* Inſt. p. 472.

HIEROBULBUM, in botany, a name given by the antients to the colchicum.

Some have wonder'd that the medical writers of thoſe times ſhould give this name, which ſignifies the ſacred root, to a thing that was generally allowed to be a poiſon; but Wedelius has proved that it may be given, under proper regulations, with ſafety and great ſucceſs in malignant and petechial fevers, and in the worſt kinds of the ſmall pox and meaſles. The manner he gave it was in a mixture with bezoar and plantain root, and this he called his *Arcanum Duplicatum Catholicum*, or peſtilential alexipharmic. The antients had a cuſtom of wearing this root about their necks, by way of an amulet, to prevent infection; and it was probably from this that it obtained the name of the ſacred bulb. Act. Eruditor. Ann. 1719.

HIEROMANTIA, Ἱερομαντεια, in antiquity, a general name for all the kinds of divination, made from the various things offered in ſacrifice to the gods. They firſt made conjectures from the external parts, and motions of the victim; then from its entrails; from the flame in which it was conſumed; from the cakes and flour; from the wine and water, &c. Vid. *Pott.* Archæol. Græc. l. 2. c. 14. T. 1. p. 314.

HIEROMENIA, Ἱερομηνια, in antient chronology, a name given to the month in which the Nemean games were celebrated. It was the ſame with the Athenian month Bœdromion, and likewiſe called *Panemos*. See PANEMOS.

HIEROMNEMON, Ἱερομνημων, among the antient Greeks, ſignified a delegate choſen by lot, and ſent to the great council of the amphyctyons, where he was to take care of what concerned religion. The *Hieromnemones* were reckoned more honourable than the other members of that aſſembly, the general meetings of which were always ſummoned by them; and their names were prefixed to the decrees made by that council. See Mem. Acad. Inſcript. vol. 4. p. 289. ſeq. and 306.

HIEROMNENON, in the writings of the antients, the name of a ſtone ſaid to have been uſed in divination, and called by others erotylos and amphicome. There is no deſcription left us of it by the antients, from which we might gueſs what ſtone it was, or from whence it was brought.

HIJABILA, in botany, a name given by ſome authors to the tamarind tree. *Herm.* Muſ. Zeyl. p. 27.

HILUM, a word uſed by botaniſts to expreſs the blackiſh ſpot in beans, commonly called by us the eye of the bean.

HIMANTOPUS, in zoology, the name of a water bird, very remarkable for the length and ſlenderneſs of its legs; it is all over white on the breaſt, belly, and throat, and blackiſh on the back and wings. Its beak is black, about a hand's breadth long, and very weak and ſlender, fit for nothing but to deſtroy the ſofter ſmall inſects. Its tail is of a whitiſh grey; its neck has ſeveral oblong black ſpots drawn downwards, and its wings are very long. Its feet are red, and have no hinder toe. *Aldrovand.* de Avib. L. 20. c. 30.

HIMAS. The proper ſignification of the word is a thong of leather. But in medicine it is uſed to ſignify a laxneſs of the uvula, when it becomes long and ſlender, and hangs pendulous. It differs from the cionis, in that under this latter diſorder the uvula is not extenuated, but ſeems to acquire a greater thickneſs, as well as length, than what it naturally has.

HINGWANG, in natural hiſtory, a name given, by the people of the Eaſt Indies, to a ſpecies of red arſenic, which they uſe in painting and in medicine. They find it in and about the copper mines. It is calcin'd ſeveral times in order to fit it for internal uſe. In painting it makes a very fine orange colour, but when mixed with ceruſs, it makes a lemon colour, and any other ſhade of yellow. It ſeems to contain ſome portion of ſilver, and ſome cinnabar.

HIOENA, in natural hiſtory. See the article HYÆNA.

HIP, in the manege. See the article HAUNCH.

HIP, in the materia medica, the fruit of the cynoſbatus ſhrub. *Hips* are eſteemed attenuant and diuretic, but little uſed in the ſhops, except in the conſerve, which is a very pleaſant one.

HIPPAGOGA, in antiquity, a veſſel uſed in tranſporting horſes. It was otherwiſe called *Hippago*. *Pitiſc.* Lex. Ant. in voc.

HIPPIA, in botany, a name uſed by ſome authors for the common chickweed. *Ger.* Emac. Ind. 2.

HIPPION, or HIPPIUM, in botany, a name by which John Bauhine, and ſome other authors, have called the larger ſpecies of the autumnal dwarf gentian. See the article GENTIANA.

HIPPIUM, in antiquity, that part or tract of the hippodrome which was beaten with the horſes feet. See the article HIPPODROME, *Cycl.*

HIPPOBOSCOS, in natural hiſtory, the name given by authors to the horſe fly. This is of the bigneſs of the common fly, and has a broad flat body, which is hard and ſmooth, and of ſo firm a ſtructure, that it can ſcarce be cruſh'd or broken by the fingers. It is remarkable for its flying ſideways.

HIPPOCAMPUS, the *Sea Horſe*, in zoology, the name of a ſmall ſea animal caught in the Mediterranean, and eſteemed uſeful in medicine among the antients, but at preſent not uſed.

It has its name from the Greek ἱππος, a horſe, and κάμπη, a caterpillar, from its reſembling a horſe in its head, and a caterpillar in the reſt of its body. It ſeldom exceeds the length of three inches, and is about as thick as a finger, or a little more; its ſnout is long and hollow like a pipe, and is not ſplit, as in other animals, in general; but it has an operculum from below, which opens or ſhuts up its aperture at the creature's pleaſure; its whole ſnout is perfectly like that of the acus or needle-fiſh; its eyes are round and prominent, and between the eyes there are two more prominent tubercles. The body, down to the anus, is heptaedral, or ſeven-ſided, and terminated at the angles with a ſort of thorny protuberances; from the anus to the tail the ſhape is only three or four ſided, and ends in a point, and is twiſted into a ſort of ſpiral line. In the place where the gills of other fiſhes are ſituated, this has two fins in the ſhape of ears, and above theſe there are two apertures opening upwards, but no gills are any way diſcoverable. It has two apertures on the belly, out of one of which the excrements are voided, and by the other the female depoſits her eggs. Its whole body is compoſed of a ſort of annular cartilages, from diſtinct parts of which are propagated a ſort of prickles; it is while freſh of a duſky green colour, and blackiſh toward the tail, and is ſpotted principally on the belly with bluiſh white ſpecks; it has a ſingle fin in the middle of its back of an equal height all the way. Into whatever poſture you turn the tail, while the creature is yet living, it will retain it when dead. Some of this ſpecies have a mane like that of a horſe, but moſt want this character; and naturaliſts are not yet determined whether it be the character of a diſtinct ſpecies of the animal, or be owing to the different age or ſex. It is hairy in many parts of the body, but principally about the head; but the hairs often fall off in drying the creature. *Willugh.* Hiſt. Piſc. p. 157.

HIPPOCASTANUM, *Horſe-cheſnut*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, being compoſed of ſeveral leaves diſpoſed in a circular form; the piſtil ariſes from the cup of the flower, and finally becomes a large fruit, which when ripe burſts open in many places, and is unicapſular, containing ſeeds of the ſhape of cheſnuts.

There is only one known ſpecies of *Hippocaſtanum*, which is the common one. *Tourn.* Inſt. p. 611.

Jo. Jac. Zannichelli [a] affirms, that after a great many trials, he has found the bark of the *Hippocaſtanum* to have the ſame effect as the Peruvian bark. [[a] Hippocaſtani facultatibus ap. Med. Eſſ. Edinb.]

HIPPOCEPHALOIDES, the *Horſe-head ſtone*. The word is derived from the Greek ἱππος, a horſe, and κεφαλη, the head, and is a name given by Dr. Plot to a ſtone found in Oxfordſhire and many other places, and ſuppoſed to reſemble the head of a

horſe in figure, though the truth is it requires a very warm imagination to make out the reſemblance.

The ſtone is compoſed of the matter of the common coarſer quarry-ſtone, and owes its figure to a ſhell of the cockle-kind, into which having been received at a time when it was moiſt and ſoft, it has taken the exact figure and lineaments of its inner parts. It is about the ſize of the larger bucarditæ, from an inch and half, to two inches and a half in length, and indeed very much reſembles that ſtone, having been formed wholly in the ſame manner, and that in a ſhell of the ſame genus. *Hill*'s Hiſt. of Foſſ. p. 646.

HIPPOCRATEA, in botany, the name of a genus of plants firſt deſcribed by Plumier under the name of *coa*. The characters are theſe: The cup is a one-leaved perianthium lightly divided into five ſegments, which are obtuſe, expanded, and larger than the flowers. The flower conſiſts of one leaf, and is of an oval form, with a truncated undivided edge. The fruit is a capſule of a flatted figure, expanded and divided into three parts, and each of theſe again divided into three ſegments. It contains three cells, each of them compoſed of two valves of a compreſſed and carniated figure. The ſeeds are oblong and edged with a membranaceous rim. Linnæus is very ſuſpicious that the author from whom he takes theſe characters, has deſcribed the plant too careleſsly, as the whole ſeems a very extraordinary fructification. *Linnæi* Gen. Pl. p. 518. *Plumier*. p. 35.

HIPPOCREPIS, in botany, the name given by Linnæus to the plant uſually called by authors *ferrum equinum*, or the horſe-ſhoe vetch. *Linnæi* Gen. Pl. p. 364. See the article FERRUM *Equinum*.

HIPPODROMUS, in chronology, the Bœotian name for the Athenian month Hecatombæon, which was the firſt of their year, and anſwered to the latter part of our June, and beginning of July. Vid. *Potter*'s Arch. Græc. l. 3. c. 26. See the article ECATOMBÆON.

HIPPOGLOSSUS, in zoology, the name of the holibut; a large flat fiſh caught in the Britiſh ſeas and elſewhere. It is the biggeſt of all the fiſh of this kind, and is ſomewhat of the ſhape of a turbot, but larger and longer bodied, and conſequently leſs ſquare; its back is of a duſky browniſh green, its ſcales extremely ſmall, and the whole ſurface of the fiſh very ſmooth, having no crooked prickles on the ſides. The eyes are on the right ſide, and the belly has ſix ſmall fins beſide the larger ſtrait ones. It is caught in the German and Britiſh ſeas, and its fleſh is very delicate. *Rondelet* de Piſc. p. 351. *Geſner*. p. 787.

HIPPOGLOSSUM, *Horſe-tongue*, in botany, the name of a plant of the *ruſcus*, or butcher's broom kind, called by others the Alexandrian bay, or *laurus Alexandrina*. See the article RUSCUS.

HIPPOLITHOS, a name given by ſome authors to the ſtones found in the ſtomachs and inteſtines of horſes: there are often a great number of theſe in one horſe, and they are frequently found in the colon, of a very large ſize.

HIPPOMANE, in botany, the name of a genus of plants firſt deſcribed by Plumier under the name of *mancanilla*. The characters are theſe: It produces ſeparate male and female flowers on different parts of the ſame plant; theſe are both very imperfectly deſcribed by Plumier, who only obſerves, that the male flower has no petals. The fruit ſucceeding the female flower is an extremely large round berry, lightly umbilicated, and containing only one cell, in which is encloſed a woody nut. *Plumier*. p. 30. *Linnæi* Gen. Plan. p. 517.

HIPPOMYRMEX, the *Horſe-ant*, the name of a ſpecies of ant much larger and nimbler than the common kind. This builds in woods, and makes its neſt of ſticks and ſtraws, and fragments of various parts of trees. The common ant builds only with earth.

HIPPOPHAE, in botany, the name given by Linnæus to a genus of plants called *Rhamnoides* by Tournefort and others. The characters of which are theſe: It produces ſeparate male and female flowers. In the male flowers the perianthium is whole at the baſe, but divided into two roundiſh, obtuſe, and hollow ſegments; theſe ſtand erect, and bend towards one another at the top, but ſeparate at the ſides. There are no petals; the ſtamina are four filaments, very ſhort, and bearing oblong and angular apices of the length of the cup. In the female flower the cup is compoſed of one leaf of an oval, oblong, and tubulated figure, and is ſlightly bifid at the mouth. There are no petals. The piſtil has a ſmall roundiſh germen; the ſtyle is ſingle, and very ſhort; the ſtigma is thick, oblong, and erect, and is twice as long as the cup; the fruit is a globoſe berry, having only one cell, and containing only one roundiſh ſeed. *Linnæi* Gen. Pl. p. 473. *Tournefort*, p. 481.

HIPPOPHEOS. This was a name given not only to the larger ſpecies of the pheos or ſteebe, but to a very different plant, a kind of dodder, more vulgarly called epipheos, from its growing upon the pheos, as the dodder of thyme is called epithymum from its growing upon that plant. It is poſſible indeed that it might be called originally *Hippopheos*, from its riding, as it were, on the pheos. But however this be, there is great reaſon to ſuſpect that Dioſcorides confounds this dodder with the plant itſelf, and gives its virtues as thoſe of the proper *Hippopheos*; which, according Theophraſtus, and all the other writers of credit in antiquity, is only a larger ſpecies of the pheos, a prickly ſhrub, not a plant, growing on it. See the article EPIPHEOS.

HIPPOPHTHALMIC *muſcles*, a name given by the ichthyologiſts to a pair of large muſcles found in the heads of fiſhes, one placed immediately under each eye; theſe ſerve to move the eyes; and with the two maxillary muſcles placed under the jaws, are the principal muſcular parts of the head of fiſhes.

HIPPOPOTAMUS, in zoology, the name of a very ſingular quadruped, called in Engliſh the river horſe, and by ſome, though leſs properly, the ſea horſe. It approaches in figure partly to the buffalo, and partly to the bear. It is larger than the buffalo, and its legs are very like the bear's. The full grown animal is thirteen foot long from its head to its tail, and four foot and a half in the diameter of its body, and its belly is rather flat than ridged; the circumference of its body is uſually equal to its whole length, and its legs three foot and a half long; its legs three foot round, and its feet a foot broad; its head is very large in proportion to its body, and its mouth is capable of opening a foot wide; its eyes are ſmall, its ears alſo ſmall and thin; its teeth are as hard as flint, and will readily give fire with ſteel; it is uſually very fat; its hoofs are black, much like thoſe of the common cloven-footed beaſts, but divided into four claws inſtead of two; its upper jaw is moveable in the manner of the crocodile's. Its tail is more like that of a bear or a tortoiſe, than a hog's, to which it has uſually been compared; it is very thick at its inſertion, and tapers away to the end; it is not above ſix inches long, and ſo thick that it cannot twiſt about. Its ſkin is extremely hard and tough, and in colour black; and its noſe is furniſhed with ſtiff hairs or whiſkers, in the manner of a cat's, ſeveral ſtiff hairs growing from the ſame hole; and theſe are the only hairs the creature has, its whole body being naked. It has two large teeth in the lower jaw, ſomewhat reſembling the tuſks of the boar, and a little crooked, but not ſtanding out of the mouth like the boar's tuſks; theſe are much larger than the other teeth, and ſometimes grow to a foot in length.

It is found in the Nile and Niger, and many other great rivers; it comes out of the water to bring forth its young, and feeds upon rice, herbs, and the roots of the colocaſia. Its feet being not web'd, ſhew that it is not intended for ſwimming, and probably it ſpends its time in walking about at the bottom of the rivers. It is very plainly proved by Bochart, that this is the creature mentioned under the name of the behemoth in the book of Job. *Ray*'s Syn. Quad. p. 124.

In the Linnæan ſyſtem of zoology, the *Hippopotamus* makes a diſtinct genus of animals of the jumenta kind, the characters of which are, that it has two paps ſituated in the groin; its dentes inciſores, or cutting teeth, are four on each ſide, the upper ones placed at diſtances by pairs, the lower ones prominent, with the middle two the largeſt; the dog-teeth are ſingle, and ſeem as if cut off obliquely. *Linnæi* Syſt. Naturæ, p. 48.

HIPPOSIS, in the writings of the antient phyſicians, ſignifies a reducing any part of the body into its natural ſituation, by means of compreſſion.

HIPPOSORCHIS, in ſome diſpenſatories, a name given to a powder of the teſticles of horſes.

HIPPOTAURUS, in natural hiſtory, the name given by authors to a creature generated between a bull and a mare. It ſeems a very unnatural copulation; but Wagner in his hiſtory of Swiſſerland aſſures us, that the creature produced by it is ſometimes found wild in the mountainous parts of that country.

HIPPURIS, in the Linnæan ſyſtem of botany, a genus of plants called by others *limnopeuce*. The characters of this genus are, an extremely ſmall calyx, made up of two very ſmall rims placed oppoſite to one another, and ſurrounding the germen. It has no viſible flower, and only one ſtamen fixed upon the calix, and furniſhed with a ſemibifid anthera; the piſtillum is compoſed of an oblong germen under the receptacle of ſeeds, and a ſingle, pointed, and erect ſtyle, contained in the ſtamen, but larger than it, and an angular ſtigma. The ſeed is ſingle, roundiſh, and naked, or ſurrounded with no ſort of pericarpium. *Linnæi* Gen. Pl. p. 1.

HIPPURIS, in ichthyography, the name of a large ſea fiſh, very much reſembling the dorado, or gold fiſh, and by many ſuſpected to be the ſame ſpecies. It is a very remarkable fiſh, having a ſort of creſt riſing immediately behind its head, which is continued in a long fin to the tail; and there is another in ſome meaſure anſwering this, and reaching from the anus to the tail; its gill-fins are ſhort and broad, and in ſome ſort reſemble ears; its belly-fins are longer, of a blackiſh colour, and reach nearly to the anus, which is ſituated in the middle of the belly; its mouth is of a moderate ſize, its teeth ſmall, but ſharp, and placed not only in the jaws, but on the palate and the tongue; its eyes are large, and its ſcales very ſmall. It is the quickeſt of all fiſh in its growth, which is an obſervation as old as the time of Ariſtotle, but is found true to this day. It is caught upon the coaſts of Spain, but that only at one time of the year in the month of Auguſt. It is a very delicate and well-taſted fiſh, and is much eſteemed at table.

table. *Willughby*'s Hiſt. Piſc. p. 273. *Geſn.* de Piſc. p. 501.

HIPPURITES, in natural hiſtory, a name given by ſome writers to a ſtone which they fancy to repreſent a ſaddle. It is deſcribed to be a ſoft argillaceous ſtone, owing its figure of a ſaddle to certain depreſſions. This is only a luſus naturæ, and is of the nature of the hand-ſtones and foot-ſtones, with ſeveral others, which fancy has aſſiſted in their reſemblances, but which have been very improperly called by particular names.

HIRA, a word uſed by the writers in medicine either for the inteſtinum jejunum, or for all the inteſtines, or in a yet larger ſenſe, for all the contents of the abdomen. *Caſtel.* Lex. in voc.

HIRNGRILL, a name given by ſome authors to the *Serinus*.

HIRQUUS, a name given by ſome authors to the great canthus of the eye.

HIRUDO, in zoology. See the article LEECH.

HIRUDELLA *Marina*, in natural hiſtory, the name of a very remarkable little animal of the leech kind. The body of this creature is roundiſh and oblong, and adorned with many longitudinal lines or furrows; it is about an inch in length, and is of a greyiſh colour, and ſomewhat tranſparent; the bowels are ſeen through the ſkin, and appear at firſt ſight like ſtreaks on its ſurface; in the middle of the belly there is a remarkable protuberance, which, when cloſely examined, is found to be a muſcular body in form of a ſpherical bladder; this, when moſt diſtended, has the appearance of a ſpherical air-pump, and has all the properties of that machine, to be employed for the ſervice of the animal, and at its pleaſure. It reſembles, in its common figure, the cup of an acorn, with the mouth a little contracted. The head of the animal is of the ſame figure with that of the common leech, and ſerves to ſuck the juices of other animals, in the ſame manner as in that inſect. That part of the body which reaches from the head to the middle protuberance is of a very irregular form, frequently in motion, and continually changing its figure; but the other part moves more ſlowly, and leſs frequently, and preſerves its ſhape unaltered. The protuberance has two motions, expanſion, and undulation.

When the creature has a mind to fix itſelf any where, it does it by means of this protuberance, which it applies cloſely down to the ſubſtance, and void of air. Hence the external air ſo firmly preſſes its ſides againſt the ſubſtance, that it is not eaſy to remove it. When the creature changes its place, it draws the head round to the protuberance, and looſens it ſo as to be able to change its place as it has occaſion.

When this creature is kept out of water, it dies in a few hours; and when after being thus kept out a few minutes, it is put into ſea water, it immediately darts out a fine green thread from its mouth; this it uſually makes of the length of its body, or thereabout, though it varies it occaſionally; and by means of this it ſuſpends its body at any length that it pleaſes in the water. It ſeems to be calculated only for living in the body of fiſhes, for the ſea water ſoon kills it; and it is obſerved to diminiſh in bulk very ſenſibly all the time that it is kept in it. Philoſ. Tranſ. N° 410.

HIRUNDO, the *Swallow*, in the Linnæan ſyſtem of zoology, makes a diſtinct genus of birds of the order of the *Paſſeres*. The characters of this are, that the beak is extremely ſmall, pointed, and depreſſed at the baſe, and the opening of the mouth larger than the very head of the bird. *Linnæi* Syſt. Nat. p. 49.

The characters of this genus, according to Ray, are theſe: They have very large heads, and very ſhort beaks, but very wide mouths, adapted to the ſwallowing large inſects, which are their food. Their tails are long and forked, their eggs are white, they are birds of paſſage, and with us are the foretellers of ſummer.

We have in England four ſpecies of ſwallows: 1. The *Hirundo domeſtica*, or houſe *Swallow*. 2. The *Hirundo agreſtis*, or martin. 3. The *Hirundo riparia*, called the ſand martin, or ſhoar bird. 4. The *Hirundo apus*, called the black martin, or ſwift. Beſide theſe, there are three other known ſpecies: 1. The *Hirundo marina*, or ſea *Swallow*. 2. The *Hirundo Americana*, called *tapera*. And 3. The Chineſe *Swallow*, whoſe neſt is eaten in ſoops, *&c.* *Ray*'s Ornithology, p. 154. See TAPERA.

The common houſe *Swallow* is well known every where with us, and is ſometimes ſeen all over of a fine white.

The martin, or martlett, has a very broad and flat head, and a very broad beak pointed at the end; its legs are very ſhort, and its claws white; its toes are all cover'd, to the very claws, with a white downy plumage, by which it is diſtinguiſhed from all the other ſwallows. *Ray*'s Ornithology, p. 155.

The ſand martin, or ſhore bird, is the ſmalleſt of all the *Swallow* kind. Its head, neck, and back, are of a mouſe colour; its breaſt and belly white; and it has a ring of brown round the lower part of its throat. It builds in the banks of rivers, and makes its neſt of ſtraw, the ſtalks of plants, *&c.* and covers it with feathers. It is not uncommon with us; but is extremely plentiful in Spain, in the ſummer months, where it is eaten, and is called by the common people, *papilion di montana*. *Ray*'s Ornithology, p. 156.

The black martin, or ſwift, by ſome called the diveling, is the largeſt of all the *Swallow* kind: Its head is remarkably broad and flat; its beak is very ſmall, ſhort, and weak; but its mouth opens to an immenſe width, like that of the goat-ſucker, or churn owl. It is all over of a brown colour, with a ſlight admixture of green, and has no other variegation, but a greyiſh white ſpot at the top of its throat. Its legs are extremely ſhort, and its feet remarkably ſmall. It feeds on beetles, and other inſects, and ſeldom alights on the ground, the ſhortneſs of its legs making it not eaſy for it to riſe again. *Ray*'s Ornithology, p. 156.

HIRUNDO *Aquatica*, the *Water Swallow*, a name very improperly given by Beſler, and ſome others, to the northern colymbus, commonly known by the name of the *Lumme*.

HIRUNDO *Marina*, the *Sea Swallow*, the name of a large bird of the *Swallow* kind. Its belly is all white; its head and back of a duſky brown; its wings and tail are very long and blackiſh, but ſomewhat brown underneath; its tail is forked; its beak very ſtrong, and its mouth very wide and red within. It has on each ſide a long line, reaching from the beak to the breaſt, and making a ſort of ring near the breaſt. Its legs are black, and longer than in the other *Swallows*. *Aldrovand.* de Avibus.

HIRUNDO *Piſcis*, the *Swallow Fiſh*, or, as it is called in Cornwall, the *Tub Fiſh*, a ſea fiſh of the cuculus kind, remarkable for the ſize of its gill-fins. Its head is very large and bony, of an angular figure, and armed with ſeveral prickles. It gradually diminiſhes in thickneſs from the head to the tail, and near that is very ſlender. Its ſcales are very ſmall; its back is of a greeniſh brown; its ſides of a pale red, and its belly whitiſh. Its lower pair of belly-fins, as alſo the ſingle fin behind the anus, and the tail, are of a reddiſh hue. The ſide lines run ſtrait and ſingly to the tail. The bony covering of the head runs out behind into two horns. Over the inſertion of the gill-fins, there is alſo a remarkable ſtrong ſcale, with a thorn or prickle at the end of it. The teeth are very ſmall. The back has two ridges of bony points, and the gill-fins are extremely large, and variouſly colour'd. Their outer edge is of a ſhining blue; and there are, near the baſe of the ſeventh or eighth nerve, fine black ſpots in a pale blue area. Under theſe fins there are, on each ſide, three filaments, called fingers, in theſe fiſhes, and theſe are gradually one longer than another. Its tail is a little forked. It is caught in the Mediterranean, and other ſeas, and feeds on ſmall fiſh. *Ray*'s Ichthyogr. p. 280.

HISPANICUM *Viride*, *Spaniſh green*, a name given by ſome to verdegreaſe.

HISPID *Leaf*, among botaniſts. See the article LEAF.

HISPID *Stalk*. See the article STALK.

HISTORICAL *Muſic*, *muſica hiſtorica*, is that branch of muſic which treats of the origin and invention of muſic, of modes, of notes, inſtruments, *&c.* as alſo the lives and writings of celebrated authors on that ſubject.

HISTORY (*Cycl.*) — *Natural* HISTORY. See NATURAL *Hiſtory*.

HISTRIX, the *Porcupine*, an animal well known in many parts of the world, and ſo common in the mountainous parts of Italy, that it is brought to market at Rome, and ſells but at a very low price, the fleſh not being greatly eſteemed. *Ray*'s Syn. Quad. p. 206.

It reſembles the badger in ſhape, but in its nature more reſembles the hare, and is properly of the leporine kind. It uſually weighs between twenty and thirty pounds. Its body is often two foot long, and is all over cover'd with a very ſingular and remarkable kind of briſtles. Its ſhoulders, legs, ſides, and belly, are wholly black; and its back variegated with black and white. Its briſtles more reſembles thoſe of the hog than of any other animal; its neck is ſhort and thick; its head alſo ſhort, and its noſe obtuſe; its noſtrils very large, opening tranſverſely, and its upper lip ſplit, as in the hare. All about and over its noſtrils, it has a number of black hairs, by way of whiſkers, as the rat and mouſe have; and it has, in each jaw, two large and long fore teeth, like thoſe of the hare. The eyes are ſmall and blue, and the ears of a very ſingular ſhape, repreſenting thoſe of the human ſpecies; and about theſe there is a grey down, very different from the covering of the reſt of the creature. It has the like down upon the lower jaw; and all along the head and neck, quite to the ſhoulders, it has a ſort of creſt of very long briſtles, ſometimes eight inches long; this looks like an erect mane, and the briſtles it is compoſed of are ſome white, ſome black, and others variegated with both theſe colours. Its legs are ſhort, and the fore feet have each five toes, the hinder ones only four, of which the outer one is the largeſt, as in the bear. The briſtles of the whole body are very thick, flatted at the bottom, and pointed at the extremity, and ſtanding each on a ſhort pedicle. Its briſtles are of two very different kinds; ſome of them are very ſharp, rigid, and ſhort; others longer, flexible, and flatted at the end; thoſe of the firſt ſort are white at the bottom, and cheſnut-colour'd at the top; the longer ones are white at both ends, and variegated with black and white in the middle.

The tail is a little more than a hand's breadth long, and is beſet with ſpines, in ſeveral annular ranges; and at the extremity, inſtead of ſpines, it has ten or twelve tubular bodies,

of

of the thickneſs of the ſpines, but of not more than half their length, very thin and tranſparent, open at the end, and placed on ſhort pedicles. *Ray*, Syn. Quad. p. 208.

HISTRIX, in ichthyography, the name of a fiſh of the orbis, or globe-fiſh kind, uſually called in Engliſh, the porcupine fiſh. Its uſual ſize is between twelve and twenty inches in length. It is very thick, and is covered, inſtead of ſcales, with a whitiſh coriaceous ſkin, every way beſet with ſtrong and ſharp thorns, the baſis of each of which has two other ſmaller ones buried under the ſkin. The opening of the mouth is very large, not leſs than three inches in the largeſt ſpecies. It has rough and rugged lips, and two broad bones in the place of teeth, one placed above, and the other below, and both arched, and a little prominent, as is alſo the whole mouth. The Eyes are large, the eye-lids elevated, and armed with four thorns. The thorns are from one to three inches in length; the ſides always have the longeſt, and they gradually ſhorten toward the back and belly. Its belly is white, and its back brown, ſpotted with black, as are alſo the ſides. *Cluſ.* Exot. L. 6. C. 21.

HITCH, on ſhip-board; a word uſed for catching hold of any thing with a hook or a rope, and to hold it faſt. Thus, when the boat is to be hoiſed in, they ſay, *hitch* the tackles into the rings of the boat: And when about to weigh anchor, *hitch* the fiſh-hook to the fluke of the anchor.

HIVE. *Bee-hives* in different places, and on different occaſions, are of very different materials. In ſome places the hollow trunk of a tree ſerves the purpoſe; in others they are made of four boards nailed together in the ſhape of a long box, and placed with one end upon the ground, or upon a frame of woodwork erected for that purpoſe. The moſt uſual form of them, however, is conic and bell-faſhion'd; and the common materials of which they are made are twiſted oſier, or ſtraw, nicely matted together, and made into a ſort of thick cords, bound round with oſier bark. The laſt is the moſt common kind, and ſerves perfectly well to all the purpoſes of the bees, and of the people who make their profits of the honey. The lodgment is ſufficiently warm and cloſe for the bees; and a thin frame of boards defends it from being injured by the wet. *Reaumur*, Hiſt. Inſect. vol. 9. p. 279.

People of ſpeculative diſpoſitions have at all times been deſirous of ſeeing what paſſed in the *Hive*, and of obſerving theſe induſtrious creatures at their work; for this purpoſe the antients contrived a way of placing certain ſquares or panes of a tranſparent matter, ſuch as horn, or the lapis ſpecularis, or iſinglaſs, in ſome parts of the ſides of the *Hive*, through which they might ſee all that paſſed within. This is mentioned by Ariſtotle, Pliny, and others; but it ſoon grew into diſuſe, and the later ages have ſuppoſed it an idle attempt. Mouffet, in particular, laughs at it, and ſays, that the bees within would immediately ſpoil the tranſparence of the materials, be they what they would.

Of late, however, this method of making a tranſparent ſort of *Bee-hive*, or leaving a tranſparent part in one, has been reviv'd, to the great amuſement and pleaſure of thoſe who have attempted it. The beſt method of doing this, is to leave certain ſquares in the common *Hive* empty, and afterwards putting clear glaſs to them; this is to be neatly faſtened in, and then a frame of wood to cover the whole, ſo that the light is not always let in upon the bees, but only the panes of glaſs opened by removing the covering, at the times when the obſerver is to look at them. By this means it is found that the ſquares of glaſs, when properly placed, will keep clean and tranſparent, and all that paſſes within may be ſeen, whenever the caſe that covers them is removed. The numbers of little animals, thus diſcover'd, all laborioufly employed in the ſame manner, is a wonderful and highly pleaſing ſight.

The revival of this invention of the antients is ſo late, that it is evident from the writings of Swammerdam, that in the year 1680 there was no ſuch thing known; and it is to this that we are to impute the great imperfections of that author's accounts of the bee; becauſe, though a moſt accurate and faithful writer, he had no opportunities of ſeeing what we have diſcovered by means of this advantage.

The ſquares of glaſs in the ſides of *Hives* will continue clear and unſullied for years together; and when they are fouled, there are eaſy means of cleaning them, by taking them out, and replacing them again when wiped.

When the obſerver places himſelf behind the *Hive*, and has one of theſe ſquares of glaſs before his eye, he ſees exactly all that paſſes within, and that without at all incommoding or interrupting the creatures at their work. The whole number of bees in the *Hive* are ſeen employed in different places, in their ſeveral works, and all with the moſt ſurprizing activity.

The honeycombs, or waxen receptacles for the honey, are begun as near the top as the form of the *Hive* will permit, and thence are carried down to the bottom, each being placed parallel to the former, but not touching it, ſuch a ſpace being left between, that the bees have room to walk about in it. Theſe are the public ſtreets, or places of reſort of the whole people; and it is by means of this ſpace between, that they are able to make uſe of every cell. Moreover, as the bees have frequent occaſions to paſs between one pair of combs, to the ſpace between another pair, there are a ſort of alleys cut between theſe larger ſtreets. Theſe are certain holes made through the ſubſtances of the ſeveral combs; and theſe without doing any conſiderable harm to the whole, give the bees a much ſhorter paſſage from place to place than they otherwiſe could have. Though the parallel diſpoſition of the ſeveral combs is the moſt frequent, it is not the only one in which they are found, for theſe creatures vary this according to the nature of the place they are lodged in. Frequently part of the combs which fill the *Hive* are thus placed, and part are arranged perpendicularly to them; and very often part of the combs are perpendicular, and the reſt oblique. There are alſo ſeveral other directions, in which they are found to be placed; but all theſe may be eaſily accounted for from the nature of the place, and will be always found to be the very beſt that could be uſed on that occaſion. *Reaumur*, Hiſt. Inſ. vol. 9. p. 282.

It has generally been ſuppoſed, that every bee of the ſwarm had its particular cell in ſome comb which was its own, and contained honey for its peculiar food; but this is by no means the caſe. The uſe of the glaſs *Hives* has ſhewn us, that all the cells are uſed in common; that ſome of them contain only honey, and are covered over with a lid of wax; others open at the top, and that the bees often viſit theſe laſt.

Common obſervation ſhewing, that a bee was often ſo lodged in one of theſe cells, that its hinder part only appeared, gave riſe to the opinion of each having, in this manner, its peculiar cell, the honey of which he eat in this manner; but, on viewing the whole through theſe glaſſes, we ſee the matter to be far otherwiſe. The covered cells, which contain only honey, are never touched at theſe times by any bee; and each of theſe open ones containing, at its bottom, the worm of a bee, which is the proper offſpring of the family. There are certain bees that are deputed to viſit theſe, and to ſee how the young ones thrive; and theſe are ſeen in this manner plunging their heads into the ſeveral cells, one after another, and not continuing thus immerſed in any one, as had been ſuppoſed.

Though all this is ſeen, it is not, however, ſeen ſo perfectly or diſtinctly as might be wiſhed; for in *Hives* well filled with inhabitants, every thing, though really done in the greateſt regularity and order in the world, yet ſeems done in tumult and confuſion; and on whatever bee the eye is fixed, in order to obſerve its operations, the ſight is hinder'd by numbers of others, which continually hide him, by coming over his head, or before him. The general ſquare figure of the glaſs *Hives* gives leſs opportunity of ſeeing what paſſes within than many other figures might, becauſe very little ſpace is under the eye at once. Reaumur, therefore having a great deſire to go through the whole operations of theſe little animals, and ſee every part of their work performed under his eye, had a great number of *Hives* made in different forms, in one or other of which he could ſee the whole work. Some he made ſo very narrow, that by having a glaſs on each ſide, he could ſee all that paſſed within from each ſide; but the principal of his diſcoveries were owing to ſome *Hives* of a pyramidal figure, which were compoſed of three parts, eaſily ſeparable from one another, and each armed with its glaſſes. The ſtructure of theſe ſeveral kinds is deſcribed at large in his work, to which we refer the reader.

By means of a glaſs *Hive*, it will be obſerved that, at moſt times, and thro' moſt ſeaſons of the year, we ſee only one kind of bees at work in the ſeveral parts of the *Hive*, or at leaſt ſuch as have very little difference from one another in ſize and colour. At other times there are ſeen among them a very different race; theſe were called by the Latins, *fuci*, in Engliſh, *drones*. The French confound theſe with the common humble bee, under the name of *bourdons*. Mr. Reaumur, however, has ſet this right, and called them *faux bourdons*, baſtard humble bees, by reaſon they make a humming noiſe with their wings, in the manner of the humble bee, but are very different from them in ſhape and ſtructure. *Reaumur*, Hiſt. Inſ. vol. 9. p. 293.

Theſe, indeed, are no other than the male bees, and are never found in the *Hives* but in the months of May, June, and July. There appear but a very few of them at firſt, but their number encreaſes every day afterwards. Their proportion to the other bees is but ſmall; and though they are differently numerous in different *Hives*, yet if they make ſo large a proportion as one to ſix, they are to be accounted very numerous.

This number, however, will appear very conſiderable, in proportion to the reſt, when we know that they are of no uſe in the work of the *Hive*; that they never go out like the reſt, or bring home wax or honey; but that their whole buſineſs is the doing the office of their ſex, and peopling the *Hive*.

The other bees, which we obſerve ſo very numerous, are by the French called, *les ouvriers*, or the working bees. Theſe, which are of no ſex at all, neither male nor female, perform all the drudgery of the work; they go out in ſearch of wax and honey, and afterwards build and fill the combs. They have, after this, the care of the whole *Hive*, and are deſtin'd for the looking after the young progeny, and taking care of

the little white worms which are depoſited in the bottoms of the cells, and are hereafter to be bees like themſelves.

It has been long ſince obſerved, that in every *Hive* there is always one bee, much larger than the reſt, to which they all pay obedience as their ſovereign. It was a very natural thought to call this the king of the bees; and the creature enjoyed that title in ſucceſſion for many centuries, till Butler, an Engliſh writer, publiſhed a book entitled *Monarchia feminina*, the female monarchy. In this he proved inconteſtibly, that this great bee was always a female, and that if any title was to be given to it, it was to be that of queen. He calls the whole a nation of amazons, and ſuppoſes all the common bees females. Swammerdam finally proved this queen of the bees to be properly the mother bee, and has clearly ſhewn that this creature is ſo prodigiouſly prolific, that ſhe is able to people a whole *Hive*, and that every one of theſe is the mother of the whole ſwarm, the common bees never either begetting or bringing forth any young ones, tho' both Butler, and all the writers before his time, had ſuppoſed it.

The great fecundity of this female is the leſs to be wondered at, when we conſider the number of males that ſhe has at her ſervice; the males, or drones, in any *Hive* being, at the proper ſeaſons, always ſeveral hundreds, and ſometimes even two or three thouſand. Theſe ſpend all their lives in the ſervice of one female, and are the joint fathers of this numerous offſpring. If they live with two or three, as it ſometimes happens, this is at the utmoſt only for a few days. At moſt ſeaſons of the year there is only one female in each *Hive*, which is eaſily diſtinguiſhed from the common bees by her ſize, and from the males, or drones, by the length of her body; her wings are alſo much ſhorter than thoſe of any of the other bees; thoſe both of the common bees, and of the drones, always are ſo long as to cover the whole body, but thoſe of the female cover but a part of hers. They reach only to the third ring of the body, all beyond that being left naked. Tho' there is one of theſe bees in every *Hive*, and tho' ſhe is thus eaſily diſtinguiſhed at ſight from the reſt, yet few have ever ſeen her. She is always cloſe cover'd in the *Hive*, and many people who make a trade of honey-making, tho' they annually open numbers of *Hives*, never ſaw a female in their lives.

The ſeveral accounts given by authors, of the deference and homage paid by the other bees to this queen and mother, appearing ſuſpicious, as to its truth, Mr. Reaumur was determined to try the experiment that might determine the truth of them. He cauſed a parcel of bees from among a large cluſter, which had gone out in manner of a colony from an old *Hive* to find a new habitation, to be ſwept down into a glaſs *Hive*; among theſe there happened to be a female bee. While they were all together in the *Hive*, it was eaſy to diſtinguiſh her from the reſt by her ſhape, and the ſhortneſs of her wings. In the firſt moments after this impriſonment, the female walked by herſelf in a ſolitary manner at the bottom of the *Hive*, the reſt being all in the utmoſt confuſion, and ſeeming to take no thought but for their own ſafety. The female, after going up the ſides of the *Hive* twice or thrice in vain to the top of it, where they were hung, at laſt going in among the cluſter, brought a dozen, or thereabouts down with her: Theſe attended her in the manner of a guard, as ſhe walked along ſlowly at the bottom of the *Hive*; but the reſt continuing at the top, ſhe went up among them again and again, till at length they all came down, and formed a circle about her, leaving a free paſſage wherever ſhe turned herſelf to walk, and feeding her with the honey they had collected for their own nouriſhment. It was a common ſight to ſee a bee that was near her put out its trunk to her, to ſuck the honey out of it; and often, as ſhe paſſed along, ſhe would put out her own trunk to any that ſhe paſſed by. And the bees always ſeemed pleaſed with an opportunity of thus ſupplying her.

The bees were kept ſome time in this *Hive*, which was a ſmall one, but large enough for more than their number; the female bee, however, ſeemed to find that it would not be large enough for the family ſhe was to raiſe; and conſequently after getting all the reſt about her, ſhe went out and flew to a tree in the neighbourhood, where ſhe ſettled; all the bees of the *Hive* followed her, and form'd a cluſter on the branch in the common way.

In this manner the bees will always follow their queen whereever ſhe goes; and Swammerdam obſerves, that if the female, or queen, as ſhe is called, be tied by one of the legs to a ſtick, all the bees of the ſwarm will gather in a cluſter about her, hanging by the legs one to another, and may be carried any where by removing the ſtick.

Nature ſeems to have informed the common bees, that it is their proper care to bring up and feed the offſpring of this female, and therefore it is no wonder that they always flock about her. Father Labbat, who has decorated his accounts of his voyages with many odd ſtories, has been ſuſpected of falſity in an inſtance, in which the knowledge of this ſecret in the nature of bees, would have wholly cleared his credit. *Reaumer*'s Hiſt. Inſ. v. 9. p. 323.

He ſays that he, ſomewhere in his travels met with a man who called himſelf the bee-maſter, for that wherever he went the bees always followed him in ſwarms, and that he was covered over with cluſters of them, in the ſame manner as they ſwarm upon a tree, his hat, head, and ſhoulders, nay, his whole body being covered with them, and whole troops of others following him in the air. It was ſuppoſed by thoſe who ſaw this man, that he had the ſecret of knowing certain plants which the bees loved, and of rubbing himſelf over with their juices; but it is plain that any man here might do the ſame thing, without any farther trouble than the getting a female bee tied by one leg to his hat, or ſome other part of his cloaths.

If the female of a ſwarm by any means be dirtied, the whole ſet of bees that are round her, try which ſhall be moſt ſerviceable in the cleaning of her; and in the cold weather they gather in cluſters about her to keep her warm. The reſpect thus paid to the queen, as ſhe is called, is not however peculiar to her, but the ſame is ſhewn to all other bees of that ſex, any female that happens to come into the *Hive* being received with as great reſpect as the peculiar one which belongs to it; and this even to a third or fourth. It is probably very ſeldom that theſe occaſions of courteſy happen; but Mr. Reaumur took ſeveral females, and put them at ſeveral times into the ſame ſwarm of bees, which he kept in a glaſs *Hive*, to ſee how they would be received. He took care to mark theſe ſo that they might be known from the proper female of the *Hive*, and painted the breaſt of one red, that of the others blue or yellow. Theſe he found were all as well received in the *Hive* as the proper female, which was the mother of the ſwarm.

HIVING, the placing a ſwarm of bees in a *Hive*, in order to have the profit of their labours. When the ſwarm of bees has left an old hive, and is placed in form of a cluſter hanging down from the branch of ſome ſhrub or low buſh, the *hiving* is extremely eaſy, and may be done in half an hour after the time of their being ſtill, and calm in the cluſter; or it may be let alone till an hour or two before ſunſet, provided that the ſun do not ſhine too vehemently upon the place where they are, for that would diſquiet them, and force them to riſe; and in that caſe they uſually take a long flight before they ſettle again, and are very often loſt; this however may at any time be prevented, by placing an artificial ſcreen before them, compoſed either of a coarſe cloth, or of a few branches of trees well covered with leaves.

Thoſe authors who ſpeak largely of the œconomy of bees, give the new queen a ſet of officers, whoſe buſineſs it is to ſettle the proper places of reſort; and they pretend that theſe bees go out of the hive a day or two before the ſwarm iſſues out, in order to fix upon a proper place. This however appears but a romantic conjecture, and we uſually find the bees buſied in ſearch of a place, while the whole ſwarm is in the air; nor is it much to their credit, that they chuſe ſuch places as they do, for they uſually fix in ſuch as they can by no means ſubſiſt in. *Reaumur*'s Hiſt. Inſ. v. 10. p. 299.

It is commonly the branch of ſome ſhrub or tree that they ſettle upon, and we always find that they mean this as their ſettled habitation; for however ſoon they are *hived*, the rudiments and beginnings of combs are found on it. It is true, they always leave theſe places, if left to themſelves, in five or ſix days; but this is not till they find them ſo inconvenient that they cannot keep them, either from their being too much ſcorched by the ſun, or expoſed to winds and rain. The quantity of wax and honey left in theſe places, when they have quitted them, abundantly proves however that they had meant them for their fixed abode.

When they are placed in a hive, they very ſoon find themſelves much better lodged than in the place they had provided for themſelves, and they uſually ſtay in it, and begin to work the next morning.

It might appear a very difficult taſk to get ſo large a number of bees into a hive, but it is much leſs ſo than it appears to be. They will often take poſſeſſion of the hive of their own accord when it is hung over them; but the ſhorteſt way is to hold the hive under the branch where they are, and then ſweep them down into it. This may be done with a branch of a tree with its leaves on it, or with the hand armed with a ſtrong glove, and the face covered. But there are country fellows who will go without any ſort of defence, and with their naked hand ſweep them carefully off the bough into the hive, which they hold in the other hand underneath.

It is not to be expected that the whole ſwarm will be thus ſwept peaceably into the hive, many will fly away, and many cluſters will fall beſide the hive to the ground. All this however creates no difficulty, for the hive being turned bottom upwards, and ſet on the ground near the tree, with its edges a little raiſed above the ſurface. Thoſe bees which fell in cluſters to the ground, will ſoon crawl to their companions in the hive; and ſoon after thoſe which flew off, will deſcend and follow their example. If it happen however that ſome bees will obſtinately keep to the place where they at firſt fix'd themſelves, the branch is to be rubb'd over with the juice of ſuch plants as theſe creatures hate the ſmell of, ſuch are elder, rue, and ſome others. And if this does not ſucceed, there muſt be linnen rags burnt under them, the ſmoak of which will ſoon drive them off, and make them join their companions, who find themſelves more at eaſe in the hive.

As it is neceſſary to render the places diſagreeable to the bees from which they are to be taken into the hive, ſo many people think it very proper to prepare the hive for their reception, by ſcenting it with ſuch things as they love the ſmell of. To this purpoſe they rub the inſide of it with baum and bean flowers, and daub a little honey in ſome parts of it. This however does not ſeem neceſſary, thoſe hives having been found to ſucceed full as well where it was not done, as thoſe where it was. *Reaumur*'s Hiſt. Inſ. vol. 10. p. 305.

If it be about noon that the ſwarm is taken into the hive, it muſt not be removed from the place before evening; and in the mean time it muſt be ſheltered from the too violent heat of the ſun, by the ſhade of the trees; or if that be not ſufficient, a ſort of ſkreen muſt be made for it, either of a coarſe cloth properly ſupported, or of branches of trees with their leaves on. In this manner it muſt remain till ſunſet, and then the hive muſt be gently lifted up, and carried to the place where it is to remain, and the next morning the bees will be ſeen as buſy in their work in it, as the old ſwarm in their hive. See HIVE.

It ſometimes happens that the ſwarm is not placed ſo favourably as in the inſtance before mentioned; they often hang themſelves in a long cluſter from the young ſhoots, or ſmall branches of high trees; and in this caſe many different expedients are to be uſed to hive them, according to the circumſtances of their poſition. The common method is for one man to climb the tree with a long ſtaff in his hand, and another to mount a ladder placed againſt the tree, and hold the hive under the ſwarm, while the other ſweeps them into it with the ſtaff; and when the bough on which they hang is ſo far from the body of the tree, that this is impracticable by the ladder, the hive is to be fixed to the end of a long pole, and by that means ſuſpended under the ſwarm while they are ſwept into it. When all this is impracticable, by reaſon of the great height of the branch on which the ſwarm hangs, a large cloth is to be ſpread on ſome of the lower branches, and the whole ſwarm ſwept down in a cluſter upon it; this is then to be thrown carefully to the ground, and another perſon is to be ready there to whelm the hive over the greater part of the cluſter, and the reſt will uſually ſoon creep into it, and join them. If they are ſlow in doing this, they are to be driven in by burning linnen rags about the places where they fly, the diſagreeable ſmell of which will ſend them towards the hive, where finding their companions not incommoded with it, they will naturally remain.

Another method of getting a ſwarm from a branch of a high tree, is to cut off the branch with a ſaw, as gently and with as little diſturbance to the bees as poſſible. In this caſe, when the branch is off, a man may carefully deſcend with it, and the bees will not quit their hold, but will be all carried where he pleaſes with it, and may by that means be very eaſily put into the hive.

Sometimes the bees which go out in a ſwarm, fix upon a hole in a wall, or a hollow in the trunk of a tree for the aſſembling themſelves in. This is a much better choice for them than the branch of a tree, but it is much worſe for the perſon who is to hive them, for they are very difficult to be got out of theſe places. The common way of the country people is to attack theſe ſwarms in the middle of a cold night, and they then enlarge the opening from without, and placing the hive under it, ſcoop the bees out of their neſt with a ladle, and put them into the hive.

It uſually happens that there are more than one young female in the hive at the time when the ſwarm goes out; and it is not uncommon for two of them go out with the ſwarm. In this caſe the ſwarm conſtantly divides into two bodies, and on whatever branch it fixes, there are ſeen two cluſters of bees, one placed near the other. Each of theſe is a compleat ſwarm, and has its female, but one of them is often much more numerous than the other; and as the bees always love to live in large communities, the bees of the ſmaller cluſter become tired of their condition, and by degrees join the larger; ſo that this is ſeen to encreaſe, and the other to decreaſe in ſize every moment, till at length there remains no more of the ſmaller ſwarm than a few faithful creatures, forming a ſort of guard about the female. In this caſe it is in vain for them to think of forming a community by themſelves; and they finally, with the female, join the other ſwarm; ſo that the new ſwarm has two females. *Reaumur*'s Hiſt. Inſ. v. 10. p. 309.

It ſeems to have been only accident that occaſioned one of theſe females, which came out of the hive with the ſwarm, to be more followed than the other; and it is very certain that which ever is moſt followed, will in the end have the whole ſwarm. All this ſeems mere accident at firſt, but thoſe authors who treat of bees as the model of government, and in other the like extravagancies, declare that only one of theſe is the true and proper queen, and that the other is an uſurper, and merits death. Ariſtotle has talked at this rate, and from him Virgil has been led into the diſtinction he makes between the two royal perſonages; the one of which he deſcribes as very beautiful, the other as very ugly, the true ſovereign being, according to his deſcription, covered with red ſcales ſpotted with gold colour, and the uſurper duſty, ill-favoured, and big-bellied. The general conſent of the writers on this ſubject devotes this unhappy creature to death; they call her an uſurper; and Butler ſays, that no ſooner is the right queen ſettled on her throne, than this uſurper is doomed to death, with her adherents; and the next morning her carcaſs, with theirs, is found under the hive. And not unfrequently, when each of the females has many adherents, the ſwarm is divided into parties, and there are bloody conflicts in the hive till one is the ſuperior.

All theſe, however, are imaginary notions, which have for their foundation real facts. It is very certain that the ſwarm which leaves an old hive, has not only two, but often three, and ſometimes more females: Theſe have their ſeveral followers; and were they in ſufficient number, each with her followers would form a diſtinct ſwarm. But as it is not ſo, they are in fine all received into the ſame hive, where it really happens that all the females except one are deſtroyed; and till this butchery is over, and the hive ſettled with only one female, the bees never go out to work. The reaſon of this ſeems, that the working bees of a hive have enough to do to prepare cells for the lodgment of the eggs of one female, and that it would be impoſſible for them to prepare twice or three times that number; in conſequence of which the ſupernumerary females, who muſt at a proper time depoſit their eggs ſomewhere, would lay them in cells already occupied by thoſe of another parent, and an endleſs confuſion and diſorder would enſue. *Reaumur*'s Hiſt. Inſ. v. 10. p. 315.

It is ſometimes found that in two parts of a ſwarm there are more than two mothers, or female bees, and in this caſe the event is the ſame; for as ſoon as they are lodged in the hive, all are killed but one. Nature ſeems plainly to have deſtined only one female to each ſwarm or hive; but as many accidents may deſtroy the egg or worm of this ſingle female, it is neceſſary that proviſion ſhould be made for accidents, and more than one egg laid by each female for the production of the female of a future ſwarm. Thus there are often twenty females which live to maturity with the bees of one ſwarm; but as the other bees are ſenſible that they can only provide for one of theſe in each hive, all the reſt are devoted to inevitable deſtruction. If only one or two of theſe go out with the ſwarm, the whole number that remain within fare no better with the old bees, than the ſupernumeraries among the young ones.

As ſoon as the ſwarm is gone out, the hive is reſtored to tranquillity; and the firſt ſtep taken by the bees to maintain this, is the deſtruction of the young females which are left of the new brood; theſe are all immediately killed, and carried out of the hive; and it is common on the morning after the going out of a ſwarm, to ſee ſix or eight, or more female bees, thrown out of the hive, and lying dead in a heap, at a ſmall diſtance from the mouth of it.

Alexander Montfort, who is for giving all the moral virtues in a very high degree to theſe little animals, will have it that thoſe females which are killed are uſurpers, and only the true queen is left alive; but this ſeems altogether the figment of imagination; and if there is any thing beyond mere chance in the preſervation of any one particular bee, it is that the ſwarm are careful to preſerve alive that particular female which is beſt furniſhed with eggs.

It is very probable however, that the birth-right takes place in this caſe, though by accident: For as the bees naturally follow that female which is moſt active, and is the firſt to place herſelf at their head and go out, it is probably the firſt-born female which arrives firſt at this neceſſary degree of vigour; and very often the departure of the ſwarm ſeems a work of mere accident as to the time of it, and the female that leads it.

A female who finds herſelf ill at eaſe from the number of eggs ſhe contains, and wants to find a place to lay them in, uſually keeps at or about the edge of the hive. In this caſe, if a warm hour calls out a ſcore or two of the bees at once, this female joins company with them; and then it is no ſooner perceived that a female is gone forth, but a vaſt number of the young brood follow, and a ſwarm is by degrees found in the air, which ſeeks a place to ſettle upon, and is from thence received into a hive in the method before deſcribed.

As ſoon as this ſwarm is gone, the old inhabitants of the hive finding a number of ſiſter females of that brood remaining among them, and well knowing they will be of no uſe to them, deſtroy them.

This is a caſe eaſily decided; but it appears ſomewhat more difficult for the bees to determine how to act when ſeveral females go out with them in the ſwarm. In this caſe there muſt be a choice made, and what is to influence and direct that choice? If there were all the gold about the proper queen that the poet deſcribes, and if bees were as fond of gold as men are, it would be then very eaſy to determine the motive of their chuſing her; but as it is in fact, there is a reaſon of this kind that has given foundation to the pleaſant fiction of the poet.

The eldeſt of the females of the young brood, is always the moſt proper to be choſen for the queen of the new ſwarm, as ſhe is in the propereſt ſtate to depoſit eggs for the hatching of a new progeny; and this female is eaſily diſtinguiſhed

from the others; for as her eggs are in a more advanced ſtate than theirs, her belly muſt be more diſtended; and as all the bees become of a brighter colour afterwards than they are at the firſt hatching from the nymph ſtate, this eldeſt will be eaſily diſtinguiſhed from the others by her colour.

Ariſtotle ſays, that the proper ſovereign is red, and the uſurpers black; but theſe expreſſions are to be underſtood with their proper reſtrictions, and then it will be only underſtood, that the younger females are yet of the duſky brown colour, of which they all are when firſt hatched, and that the eldeſt has begun to aſſume the reddiſh yellow colour, which they are all to have when of a certain age. Experience proves that the having the eggs in a ſtate almoſt ready to be hatched, is the great circumſtance that determines the bees in favour of one particular female, when they are brought to a choice; for if the bodies of the rejected females, which are murdered and thrown out of the hive, be opened and examined with glaſſes, there will be found in them either no eggs at all, or at the utmoſt ſuch extremely minute ones, that it muſt have been a long time before they could have been in a condition to lay them; whereas if the ſelected female, who is become their queen, be opened, ſhe is always found quite full of eggs, very near the time of their being laid.

It is a very miſchievous practice to murder a female in this circumſtance, and indeed the proof may be had without it, ſince if the works of the new ſwarm be examined, ſhe will be found the very next day to have laid eggs in ſeveral, if not all of the cells they have formed, and at the utmoſt in two or three days will be found to have laid a great number.

It is not however ſo ſtrictly limited by nature, that there can be only one happy female in every hive: There are often three or four, which ſucceed alike, and lead out, and become the ſovereigns of as many little colonies. It is only miſerable for thoſe females which are hatched all nearly at the ſame time, for of theſe all are doomed to periſh but one; but others which appear at more diſtant periods have a better fate, as there are produced alſo at theſe different times numerous ſwarms of the common bees. Thus it often happens that one hive ſends out three, four, or more ſwarms in one ſummer, at the diſtance of a fortnight or leſs from one another, each headed and led out by a queen produced at the ſame time with themſelves. *Reaumur*'s Hiſt. Inſ. v. 10. p. 321.

It is not at all times however that the bees are thus cruel to the ſupernumerary females, and neceſſity ſeems to compel them to it when they are ſo. It would be wrong in them to receive a plurality of females among them, at a time when they were newly eſtabliſhed in their habitation, and as yet in want of all things, ſo that they could be in no condition to bring up an additional family; but at other times they are as kind to ſtrange females brought into their hive as ſupernumeraries, as to their own: For Mr. Reaumur tried the experiment of giving a ſtrange female to a hive, the combs of which were perfect and well filled with honey, and the bees received her with all poſſible reſpect, and treated her as they did their proper ſovereign.

Some are of opinion that the females which are found killed and thrown out of the hives, are all murdered by the reigning female herſelf, and not by the other bees; and this is ſuppoſed to be the only uſe for which nature has given her a ſting, as ſhe never goes abroad, and has not the occaſion the common bees have for it as a defenſive weapon. But allowing this to be the caſe, there ſeems nothing ſtrange in the female of another hive being well received by the ſovereign in her own dominions, at a time when ſhe finds all the combs of a hive in a flouriſhing ſtate at her diſpoſal, and perceives that there is room for herſelf and another in the hive. Id. ibid.

HOACHE, in natural hiſtory, a name given by the Chineſe to a peculiar kind of earth, which they have found lately, very uſeful in the manufacture of their China ware.

It is called *Hoache* from the word *hoa*, which ſignifies ſoft and glutinous, and is deſcribed to us as being an earth approaching to the nature of chalk, but harder, and feeling like ſoap to the touch. There is great reaſon to believe that this is either the ſame earth with our ſoap-rock of Cornwall, or ſomething very like it. Ours has very much the appearance of the French chalk with which they take out ſpots of cloaths, and which marks white in the ſame manner as chalk.

The word chalk is ſo little determinate in its general ſenſe, and the white ſubſtance we commonly call by that name, is ſo little likely ever to be uſed in earthen-ware of any kind, that there is great reaſon to believe French chalk is the ſubſtance to which the *Hoache* is compared; and if ſo, all the characters agree ſo well, that it is probably the very ſame thing with our ſteatites. We have often attempted to make a porcelain ware with this, and that with good proſpects of ſucceſs. But we are to learn in regard to the Chineſe way of uſing it, that it is only one of the ingredients of their fine ware, not the whole matter of which it is made.

The Chineſe phyſicians had long uſed this earth as a medicine, giving it in diſorders of the lungs; but it is only of late times that the workmen in porcelane attempted to uſe it inſtead of kaolin. It ſucceeds, however, ſo well, that the porcelane made of it ſells dearer in the Indies than any other kind. The grain of this porcelane is remarkably fine and even, ſo that it is fitter for receiving the fineſt pencilling than any other, and it may be made ſurpriſingly light. But there is this diſadvantage, that the whole is more brittle than ordinary china, and the juſt degree of baking it is very difficult to hit; without which it is never ſtrong. The Chineſe ſometimes make the body of their veſſels of the common China ware, and dip them when dry into a thick liquor like cream, in which the *Hoache* is diſſolved. This gives a new and beautiful coat to the veſſel. They give the common varniſhing over this, and it ſucceeds to a very great perfection. Obſerv. ſur les Coutumes de l'Aſie, p. 300.

Suppoſing we could not, for want of the petunſe, or ſomething analogous to it, ever arrive at making the true porcelane in England, there is yet room to hope for great advantage in the making the varniſh or coating of other veſſels with this ſteatites or ſoap-rock. The manner in which the Chineſe uſe it is this: They firſt waſh it clean with river water to ſeparate a yellow ſort of earth, which lies near it in the mine where they dig it, and is often brought up with it. When it is thus cleaned, they beat it to powder, and mix it in large quantities of water; they ſtir the mixture well, and then letting the coarſer part ſettle, they pour off the thick liquor, and let it ſtand till a ſubſtance like cream ſubſides, which they keep moiſt and uſe, as before mentioned, to dip the veſſels in, or elſe they dry it, and uſe it with the petunſe inſtead of the kaolin in the common manufactures.

It is ſaid that a very good porcelane ware may be made with this earth alone, without any other mixture; but the workmen themſelves are unwilling to do this, and always chuſe, if they do not work in the common way, to add at leaſt two parts of the petunſe to eight of the *Hoache*, and with this mixture they make a very good ware, working it in the ſame manner as they do the petunſe and kaolin. Id. ibid.

The *Hoache*, though ever ſo proper to ſupply the place of the kaolin, could not be uſed in the common works, becauſe it coſts three times the price, it being much ſcarcer, and brought much farther.

There is another very elegant ſort of China ware which depends entirely on the *Hoache* for its beauty. It is all white; but though the ſurface is perfectly ſmooth and poliſhed, there are ſeen flowers and other ornaments on it in a very delicate manner. The method of making this is as follows: They make the veſſels of the common matter of the porcelane ware; they then diſſolve in a ſufficient quantity of clear water, as much of the refined *Hoache* as will give it the conſiſtence of a ſyrup. With this they pencil out the figures they intend on the ſurface of the veſſel while yet not quite dry. This penetrates the ſurface, and the lines and ſtrokes all appear very determinate. They let this dry thoroughly, and then cover the whole veſſel with the common varniſh of the porcelane. When it has been baked, the whole appears white, but the figures are very diſtinctly ſeen, and appear extremely beautiful. They are of a brighter white than any of the reſt, and ſeem formed of a thin white vapour, running with regularity juſt under the ſurface of the veſſel. They have a way of doing this with another ſort of earth, which they call *chekao*; but this requires more trouble, as it muſt be roaſted and powdered before it is fit for uſe. The white of this alſo is not ſo fine when done as the other.

HOACTLI, in zoology, the name of an American bird deſcribed by Nieremberg: It is of the ſize of a common hen, the legs and neck are long, its head is black, and is ornamented with a beautiful creſt of the ſame colour; its whole body is of a fine white, but its tail is grey, as are alſo the upper ſides of its wings. The wings have a greeniſh caſt, and the back ſometimes has many black feathers. Its feet are not web'd, its legs are of a pale whitiſh colour; it has a circle of white, beginning at the eyes, and going round the head. It is common on the lakes of Mexico, and builds among reeds and ſedge. It bites very deſperately. *Ray*'s Ornithol. p. 300.

HOACTON, in zoology, the name of a Mexican bird, deſcribed by Nieremberg, and ſeeming of the heron or bittern kind. Its neck and belly are white, ſlightly variegated with brown; the reſt of the body is brown variegated with white; its eyes are large, and have a pale iris. *Ray*'s Ornithol. p. 302.

HOACTZIN, in zoology, a name under which Nieremberg has deſcribed a ſpecies of American bird, which is of the ſize of an hen, and has a crooked beak; the breaſt is of a yellowiſh white, and its wings and tail are variegated with large ſpots of a pale grey and white colour; its neck and back are of a browniſh yellow, and it has on its head a creſt made of white feathers, which are black on their inſides. Its voice is very loud, and it feeds on ſnakes. It is ſeen in the autumn about Mexico, and generally frequents high trees near waters; its bones, feathers, and ſome other parts, are eſteemed by the natives ſpecific in the jaundice and other diſeaſes. *Ray*'s Append. p. 300.

HOANGICOYA, in natural hiſtory, an amphibious animal which in ſummer is a bird, and in winter a fiſh. See the article CROCEUS.

HOARHOUND, *Marubium*, in medicine. See the article MARUBIUM.

HOARSENESS, (*Cycl.*) in medicine. See the article RAUCEDO.

HOASTMEN, an antient fraternity of dealers in ſea coal, at Newcaſtle upon Tine. Vid. 21 Jac. 1. c. 3. *Blount.*

HOBBY, (*Cycl.*) in zoology, the Engliſh name of a hawk, of the long-winged kind, called, by many authors, by the name *ſubbuteo*, the name by which others expreſs the ringtail and hen-harrier. The *Hobby* has a prominent and crooked beak, covered at the baſe with a yellow ſkin, the beak is white near this membrane; elſewhere it is blue. Its tongue is a little bifid, and the iris of its eyes hazel-colour'd. It has a reddiſh brown line, mixed with white over the eyes, and its head feathers are black and brown; its neck feathers are of a whitiſh brown; its back and wings are of a blackiſh grey; its chin, and the upper part of its throat, are of a yellowiſh white, with a black ſpot on each ſide; its belly is brown; its tail is long, and pointed and variegated with brown and white. The legs and feet are yellow. It builds with us in high trees, but does not ſtay the winter with us; it feeds principally upon larks. See Tab. of Birds, N°. 3. and *Ray*'s Ornithology, p. 49.

HOCIAMSANUM, in botany, a name given by ſome writers to agrimony. See the article AGRIMONY.

HOCUB, in botany, a name given by Vaillant to a genus of plants, called by Tournefort, and other authors, gundelia. See the article GUNDELIA.

HODENSTEIN, in natural hiſtory, a name given by the Germans to the ſtone uſually called by authors *enorchis*. It is a kind of ætites, or eagle-ſtone; but the internal nucleus is not looſe, but fixed to one ſide.

HODOMETRICAL *Method of finding the Longitude at ſea*, is that of the computation of the meaſure of the way of a ſhip between place and place, *i. e.* of obſerving the ſeveral rhumbs or lines in which the ſhip ſails, and what way ſhe has made, or how many leagues, and parts of a league, ſhe has run. This method is liable to great errors.

HOG, in zoology. See the article SUS.

The dung of *Hogs* is one of the richeſt manures we are acquainted with; it ſeems to come next in value after ſheep's dung, and is found to be equal in virtue to twice the quantity of any other dung except this. The antients ſeem to have been diſpleaſed with it, on account of its breeding weeds, as they expreſs it; but this is only accuſing it of being too rich, for any dung will do this, when laid too thick. It is an excellent manure for paſture grounds, and excels all other kinds of dung for trees. The farmers who uſe the dung for their lands, generally take care to ſave it, by well paving the ſtyes, and encreaſe the quantity by throwing in bean-ſtalks, ſtubble, and many other things of a like kind; and, by good management of this kind, many farmers have procured fifty or ſixty load of excellent manure a year, out of a ſmall ſtye. The very beſt way of uſing this dung, is to mix it with horſe-dung, and, for this reaſon, it is beſt to have the ſtye near the ſtable, that the two cleanſings may be mixed in one heap, and uſed together.

They have, in many parts of Staffordſhire, a poor light ſhallow land, on which they ſow a kind of white pea. The land is neither able to bear this, nor any thing elſe to advantage, for their reaping. But when the peaſe are ripe, they turn in as many *Hogs* as the quantity of peaſe will fatten, ſuffering them to live at large and remain there day and night; and, in conſequence of this, the land will produce good crops of hay for ſeveral years afterwards, or, if too poor for that, it will, at worſt, raiſe graſs enough to make it a good paſture ground.

HOGI, in the eaſtern churches, as at Cairo, is an under-attendant on the moſque, who is the reader under the ſheik. *Pocock*'s Egypt. p. 171.

HOEING, according to Tull, is the breaking or dividing the ſoil by tillage, while the corn, or other plants, are growing thereon. It differs from common tillage, which is always performed before the corn or plants are ſown or planted, in the time of performing it; and it is much more beneficial to the crops than any other tillage. This ſort of tillage is performed various ways, and by means of different inſtruments.

Land which, before the tilling, would have yielded little, tho' the more it is tilled before ſowing, the more plenty of crop it yields, yet, if tilled only before the ſowing, will always have ſome weeds, and they will partake of the advantage of the tillage as well as the corn. This is one reaſon for an after tillage, ſuch as that by *Hoeing*. But there is another conſideration that yet more requires it; this is, that as ſoon as the ploughman has done his buſineſs, by plowing and harrowing the land, after ſowing, the ſoil, of its own accord, begins to undo it all again, by tending towards its original texture and ſpecific gravity again; the altering of which was the only buſineſs of all the former tillage. The breaking the particles of the earth, and making in it new pores, and new particles or new ſuperficies, is the great buſineſs of the plow and harrow; but as ſoon as their uſe is over, the earth begins to coaleſce again into its own form, the particles unite together, and the artificial pores in a great meaſure cloſe up. The ſeed is nouriſhed in a worſe ground than it was firſt put into, and the more the plant grows up, and requires a larger ſupply of food, the worſe the paſture becomes. While nouriſhment is thus denied the growing plants, they are at the ſame time choaked with weeds, which being of a hardier nature than they, will grow with leſs ſupplies, and therefore thrive more vigorouſly, and rob them of a great part of the little food the land before allowed them. *Tull*'s Horſehoeing Husbandry, p. 27.

Farmers in all ages have been acquainted, in ſome degree, with the uſe of tillage and dung to crops of uſeful plants, but they have ſo ill managed the time of giving theſe aſſiſtances to nature, that there is no doubt but one third part of the nouriſhment raiſed by dung and tillage, if it were given to plants and corn at many proper ſeaſons, and proportioned to the different times of their exigencies, would be of more benefit to the crop, than the whole is, when applied all together at the time of ſowing.

Nature, by what ſhe does in the animal œconomy, ſeems to point out to us ſomething like the remedying this by *Hoeing*; for when the teeth, as the plough, have tilled that ſoil or maſs which is earth altered; and when the ſaliva and the juices of the ſtomach have ſerved to divide and attenuate it, as the ſalts of dung and other manure do land; after all this, the bile and pancreatic juices are ordain'd to farther attenuate it, at the very time when it is ready to be exhauſted by the numerous mouths of the lacteals, ſituate in the inteſtines. This laſt operation of theſe juices ſeems analogous to the meliorating the ſoil by *Hoeing*, after the plants are grown, and are becoming fit for uſe.

Tranſplanting is nearly allied in its nature to *Hoeing*, but it is much inferior. The nature of this will not admit of its being a general thing; and even if it would, *Hoeing* is better: For, by tranſplanting, the plants can only be kept up to a certain period, after which they will not bear it; but *Hoeing* may be uſed to them with advantage, to their utmoſt ſtanding, and makes them vigorous all the while.

The roots of a plant are all neceſſarily broken off in tranſplanting, and it requires ſome time for it to ſtrike a whole ſet of new ones; and if the earth about it is not kept thoroughly moiſtened all this time, the new formed roots will not be able to ſhoot, and the plant will ſtarve in the midſt of plenty. But, on the contrary, in *Hoeing*, the ſame advantage of a new paſture for the plant is obtained, by the breaking the particles of the earth, and at the ſame time no more of the roots are broken off than can eaſily be ſupplied, and the reſt remaining in their places, the plant continues growing without that ſtop and decay, which muſt happen on tranſplanting, and which it recovers only by degrees. It is obſerved, that ſome plants are the worſe for tranſplanting: Lucerne and ſaintfoin are never ſo good after tranſplanting, as when they are left in their native places, at the ſame diſtances; and ſinochia removed, is never ſo good and tender as when it is not. This laſt plant receives ſuch a check from tranſplanting in its infancy, that it has afterwards a diſeaſe like the rickets, which cauſes knots and ſwellings in it, that ſpoil it as a delicacy. All the top-rooted plants ſuffer by tranſplanting, for it is neceſſary in this to cut off the main long root, which afterwards, however good the ſoil may be, never arrives at the length it otherwiſe would have had, and which was neceſſary for the ſucceſs of the plant.

One great benefit of *Hoeing* is, that it keeps plants moiſt in dry weather, the advantage of which to their growth is eaſily ſeen. This good office it performs on a double account. Firſt, as they are better nouriſhed by *Hoeing*, they require leſs moiſture, and conſequently carry off leſs; for thoſe plants which receive the greateſt encreaſe, having moſt terreſtrial nouriſhment, carry of the leaſt water, in proportion to their augment, as is proved by Woodward's experiments. Thus barley or oats being ſown on a piece of ground, well divided by tillage and dung, will come up and grow well without rains, when the ſame grains ſown on another part of the ſame land, not thus dunged or tilled, will ſcarce come up at all without rains, or if they do, will wait wholly for the rains for their growth and increaſe. *Tull*'s Huſbandry, p. 29.

The *Hoe* alſo, particularly the horſe-*Hoe*, for the other does not go deep enough, procures moiſture for the roots from the dews which fall moſt in dry weather; and theſe dews ſeem to be the moſt enriching of all moiſture, as it contains in it a fine black earth, which will ſubſide from it in ſtanding, and which ſeems fine enough to be the proper pabulum, or food for plants.

A demonſtration that the tilled earth receives an advantage from theſe dews, which the untilled does not, is this: Dig a hole in any piece of land, of ſuch a depth as the plough uſually goes to; fill this with powdered earth, and after a day or two, examine the place, and the bottom part of this earth, and bottom of the hole, will be found moiſt, while all the reſt of the ground, at the ſame depth, is dry. Or if a field be tilled in lands, and one land be made fine by frequent deep ploughings, while another is left rough by inſufficient tillage, and the whole field be then ploughed acroſs in the drieſt weather, which has continued long, every fine land will be turned up moiſt, and every rough land as dry as powder from top to bottom.

Altho' hard ground, when thoroughly ſoaked with rain, will continue wet longer than fine tilled land adjoining to it, yet this water ſerves rather to chill than to nouriſh the plants ſtanding in it, and to keep out the other benefits of the atmoſphere; it leaves the ground much harder alſo than before,

when

when it is finally exhaled out of it; and when, at length, the earth is thus hardened, it can receive no benefit from any thing leſs than a deluge of rain, which ſeldom falls till the ſeaſon of vegetation is over.

As fine *hoe'd* ground is not ſo long ſoaked with rain, ſo the dews never ſuffer it to become perfectly dry. This appears from the flouriſhing ſtate of plants in *hoe'd* ground, while others near them, but in ground not *hoe'd*, are ſtarved for want of nouriſhment. The common opinion is againſt this, but obſervation proves it to be true againſt the common opinion. The vulgar are guided by this, however, and will not *hoe* their ground in dry weather for fear of letting in the drought, as they call it; whereas *hoeing* this is the only method of keeping away the drought, and without either this, or watering, they muſt periſh in theſe ſeaſons. *Tull*'s Horſe-hoeing Huſbandry.

There is alſo another advantage given to plants by *Hoeing*, which animals are not capable of. Meat and drink, in a proper degree, is all they require, or can diſpenſe with, and unleſs new mouths could be made to them, they can uſe no more; but in plants, the *Hoeing* at once gives encreaſe of nouriſhment in abundant quantities, and encreaſe of mouths to receive it; for every time the *Hoe* is ſtruck into the ground, new particles of earth are made by breaking the old ones; the new pores made by theſe, afford a new ſupply of food to the plant, and every ſtroke of the *Hoe* at the ſame time cutting off ſome of the fibrous roots of the plant, great numbers are propagated in the places of every one that is cut, and the plant has at once more food, and more mouths to feed with.

HOISE, in the ſea language. See the article HOYSE, *Cycl.*

HOITLALLOTL, in zoology, the name of an America. bird, deſcribed by Nieremberg, and called by him *Avis longa*. It is very remarkable for the ſwiftneſs of its running, and is of a very long ſhape, having alſo a long tail. Its beak is alſo very long, black above, and grey underneath. Its tail is green, and has all the ſplendor and beauty of the peacock's. Its whole body is of a whitiſh yellow, and near the tail of a blackiſh yellow. But the ſhoulders are black, with white ſpots. It does not fly high, nor very well, but runs ſo ſwiftly as is ſcarce to be conceived. It is but an ill taſted bird. *Ray*'s Ornithol. p. 304.

HOITZILOTXITL, in botany, a name by which ſome authors have called the tree which affords the balſam of Peru. *Jonſ.* Dendr. p. 309.

HOITZITZIL, in zoology, the name by which ſome authors have called the guainumbi, or humming bird, the ſmalleſt of all birds. *Hernandez*, Nov. Hiſpan. L. 9. C. 11. See the article GUAINUMBI.

HOITZITZILLIN, in zoology, the name of a beautiful American bird, deſcribed by Nieremberg. The Indians prodigiouſly eſteem this bird, and uſe its feathers in ornamenting their images. It is not lawful to kill it, only to ſtrip it of its feathers, and then turn it looſe; and this no one may do but the principal perſon of the place. The method of getting their feathers, according to Hernandez, is the inviting them to ſome boiled Indian wheat, and placing lime twigs in their way. They fly in large flocks, and ſit together on trees, making a confuſed hiſſing noiſe. They breed in the holes of trees. *Ray*'s Ornithol. p. 303.

HOKE *Tide*, a ſolemn feſtival celebrated for many ages in England, in memory of the great ſlaughter of the Danes in the time of king Ethelred, they having been, in that reign, almoſt all deſtroyed in one day, in the different parts of the kingdom, and that principally by women. This is ſtill kept up in ſome counties, and the women bear the principal ſway in it, ſtopping all paſſengers with ropes and chains, and exacting ſome ſmall matter from them to make merry with. *Plot*'s Oxfordſhire, p. 206.

HOLCE, ὁλκη, a word uſed, by ſome of the Greek authors, as the name of a dram weight; and by others, as Dioſcorides, *&c.* to ſignify a weight in general.

HOLCUS, the name by which the antients called the common gramen ſecalinum, or rye graſs, commonly called by us barley graſs, or wild baſtard barley; a low graſs, with a large bearded ear, growing under old walls.

HOLD, in the manege. See the article RETAIN.

HOLD *Off*, on board a ſhip, a term uſed in heaving in the cable at the capſtan; for if it be very ſtiff and great, or have lain long in a ſlimy or oozy ground, unleſs that part which is heaved in be haled away hard from the capſtan, the cable will ſurge or ſlip back; therefore it muſt be haled away as faſt as it comes in, that the cable may keep cloſe about the whelps: And this work is called *Holding off*, and may be done by hand with a ſmall cable; but in all great ſhips they either *hold off* with nippers, or elſe bring the cable alſo to the jeer capſtan.

Predy the HOLD, in the ſea language. See the article PREDY.

To Rummage the HOLD, at ſea, is to remove and clear the goods and things therein.

HOLDS *its own*, at ſea. A ſhip is ſaid to *hold* its own, that keeps its courſe right forward.

Stowing the HOLD, a ſea phraſe for taking goods into the *Hold*.

HOLLOW *Toothed Horſe*, in the manege. See the article SHELL *Toothed*.

HOLLOWNESS *of Trees*. This is one of the moſt miſchievous diſtemperatures to which trees are ſubject. It is generally occaſioned by the lopping of them in an improper manner, and leaving the wet to fall in upon them, eſpecially on their heads. When this miſchief is found out in its beginning, the only method is to cut the trunk off to the quick, ſacrificing the whole *hollow* part; it is, in this caſe, to be cut off ſloping, that the wet may run off from it. All ſoft woods are liable to this miſchief, after the lopping, particularly the elm; and when it takes hold of any tree, it grows upon it daily, till the whole ſubſtance of the tree is at length eaten away, and only a coat of bark is left. The beſt way of preventing it in the elm, is never to cut off the head or top of the tree at all, but only to lop the ſide branches; theſe will yield a very large quantity, and the body of the tree will thrive the better for their being often cut off, and will be good timber at laſt. *Mortimer*'s Huſbandry, vol. 2. p. 79.

Theſe tall elms ſometimes grow *hollow* from another cauſe, that is, from the decay of ſome of the large roots; but the ſtarving condition of its branches will ſhew this, tho' there be no external mark of it. This ſort of *Hollowneſs* always begins at the bottom of the tree. Blaſted parts of trees are to be cut away to the quick, in the ſame manner as the hollow ones, and the wounds will heal in the ſame manner.

HOLLY, in botany. See the article AQUIFOLIUM.

The manner of propagating the fine ſtriped and variegated *Hollies*, is by budding or grafting them on plain *Holly* ſtocks. And the common *Holly* is very eaſily raiſed by ſowing the berries, as ſoon as they are ripe. They lie two years in the ground before they appear, therefore a good way is to mix them with dry ſand, and putting them into a large garden-pot, bury them in the ground till the next Auguſt or September; then take them out, and ſow them in a bed of common earth, covering the ſeeds a quarter of an inch thick with light mould, and the ſpring following the plants will appear above the ground. Theſe young trees make but a very ſlow progreſs for the three or four firſt years.

The beſt time for tranſplanting the *Holly* is in April, in moiſt weather, and, if the ſeaſon is good, there will be little danger of their growing. They may alſo be tranſplanted in Auguſt; and the roots, in this caſe, muſt be ſurrounded with mulch, to keep them from the injuries of the froſts. And if the ſeaſons prove dry, the new planted trees muſt be at times ſupplied with water for two years. *Miller*'s Gardener's Dict.

HOLLY *Hedges*, are a very beautiful ever-green and ſtrong fence, but liable to periſh in hard winters. It has been ſuppoſed, that the ſeverity of the cold in theſe ſeaſons, was the occaſion of this; but a cloſer obſervation has ſhewn, that the miſchief is owing to the field mice, which, in very ſevere ſeaſons, when they can get at nothing elſe, diſbark the roots of theſe ſhrubs. The method of preſerving theſe hedges, in ſuch ſeaſons, is found to be by clearing away the weeds which are a harbour to theſe little animals, and placing traps and boxes in proper places, with a paſte made of butter and ratſbane, daubed over their inſides, and holes made in their ſides no bigger than what the mice or rats, if there be any there, can creep into; and thus the vermin are deſtroyed, and the miſchief which might attend ratſbane being expoſed, are prevented. *Moreton*'s Northampt. p. 486.

HOLLYHOCK, or HOLY-OAK, in botany. See MALVA.

We have many ſpecies of this plant cultivated in our gardens, for the beauty of their flowers. They are all propagated from ſeeds, which are to be ſown in March, upon a bed of light rich earth. When the plants are come up pretty ſtrong, they ſhould be tranſplanted out into nurſery beds at about eight inches diſtance from one another. They muſt be watered till they have taken root, and will then require no farther care for the ſummer, but being kept clear of weeds. At the latter end of the September following, they ſhould be tranſplanted into the places where they are to remain, and ſet in rows of two foot diſtance, and at a foot from each other in the rows where they may flower: And when it is obſerved which roots produce the fineſt flowers, thoſe ſhould, the Michaelmas after, be tranſplanted into garden beds, where they will live four or five years; after which they grow weak, and ſhould be replaced by new ones. When the ſtalks of the plants begin to decay, they ſhould be cut down cloſe to the ground, otherwiſe they are apt to rot and deſtroy the roots.

HOLM *Oak*. See the article ILEX.

HOLOCAUTOMA, ὁλοκαύτωμα, among the antients, the ſame with *Holocauſt*. See the article HOLOCAUST, *Cycl.*

HOLOSCHÆNOS, in the materia medica, the name of the great bulruſh, or *Juncus lævis maximus*, common in rivers. *Dale*, Pharm. p. 258.

HOLOSERICA *Veſtis*, a garment entirely of ſilk, which were not uſed at Rome till the time of Heliogabalus. *Hofm.* Lex. in voc.

HOLOSTEUM, in zoology, a name by which Bellonius, and ſome others, call the oſtracion, a fiſh of the river Nile, covered with a hard ſhelly ſkin, and approaching, in its body, to a pentangular form. *Willughby*, Hiſt. Piſc. p. 148.

HOLOTONICOS, a word uſed by ſome authors to ſignify an univerſal convulſion or rigor over the whole body.

HOLQUAHVILT, in botany, a name by which ſome authors have called the tree which produces the jeſuits bark. *Hernand.* p. 50.

HOLT-*Waters*. Theſe have been found by experience to be of admirable efficacy in all ſcorbutic and ſcrophulous caſes: An account of ſome very remarkable cures performed by them in theſe caſes, was printed ſeveral years ago, and tho' known to be fact in the place, was diſbelieved by almoſt every body beſide.

Mr. Lewis, the late miniſter of the place, confirms their efficacy from his own obſervation, and obſerves, that they are of an attenuating, aſtringent, and drying nature. The firſt of theſe properties they poſſeſs in common with all waters, which dilute, attenuate, and fit the juices for paſſing the proper veſſels; their aſtringency they owe to the alum and iron which they contain, and their drying, abſorbing, and healing qualities, are probably owing to a quantity of ſulphur, and a fine light ochre, which they are impregnated with. Philoſ. Tranſ. N° 408.

HOMER, a Jewiſh meaſure. See the article CORUS.

HOMINE *eligendo ad cuſtodiendam peciam ſigilli pro mercatoribus editi*, in law, a writ directed to a corporation for the choice of a new perſon to keep one part of the ſeal appointed for *ſtatutes-merchant*, when a former is dead, according to the ſtatute of Acton Burnel. Reg. Orig. 178. *Blount*, *Cowel*.

HOMOCHROA, in natural hiſtory, the name of a genus of pebbles. See the article PEBBLE.

The word is derived from the Greek ὁμὸς, ſimilar, and χρῶα, colour, and expreſſes ſuch pebbles as are not veined, but all of one ſimple and ſimilar colour. Theſe are bodies compoſed of cryſtalline matter, conſiderably debaſed by earth, and this of various kinds in the different ſpecies, but only of one kind in the ſame ſpecies, which is thence always of one colour, and not ſubject to veins. Of this genus there are only five known ſpecies: 1. A whitiſh one, common in many parts of England, particularly in Northamptonſhire, and not unfrequently found in the ballaſt hill at Deptford. 2. A red one, very frequent in all our gravel-pits. 3. A yellow one, a very pure and bright ſtone, but leſs common than the two former, though ſometimes found on Hampſtead-heath. 4. A bluiſh one; this is uſually ſtreaked with ſmall irregular lines of white on the ſurface, and is very common among the gravel in St. James's Park. And, 5. A greeniſh one, a very foul and opake ſpecies, but remarkable for the ſingularity of its colour. This is a ſcarce ſpecies, and has not been found in the neighbourhood of London. All theſe are covered with external coats or cruſts, like thoſe of the common pebbles. *Hill*'s Hiſt. of Foſſ. p. 510.

HOMODROMUS *Vectis*, in mechanics, a leaver, in which the weight is in the middle between the power and fulcrum, or the power in the middle between the weight and fulcrum.

HOMOGRAMMI, Ὁμογραμμοι, among the antients, an appellation given to the Athletæ who drew the ſame letter, and on that account were to engage together: for when any number of Athletæ were to enter the liſts, in order to determine with whom every one ſhould contend, they threw into an urn a number of letters equal to that of the Athletæ, but ſo that there were always two letters of a ſort, as two a's, or two b's. After theſe had been ſhaken together, the Athletæ drew them out, and thoſe who got the ſame letter were to fight each other. *Hoffm.* Lex. in voc.

HOMOIOCATALECTON, Ὁμοιοκαταληκτον, in rhetoric, a figure wherein the different parts of a ſentence have the ſame termination.

Homoiocatalecton is uſed as the genus to denote ſimilar terminations of words; and *Homoioptoton* and *Homoioteleuton* are made its ſpecies. See *Voſſ.* Rhet. l. 5. p. 327.

HOMOLINON, a word uſed by ſome authors to expreſs crude flax, and by others for a coarſe ſort of flaxen linnen made of the rough threads unwhitened, which was uſed by the antients for towels to rub people after bathing.

HOMONOPAGIA, a word uſed by ſome medicinal authors for a head-ach. See the article HEAD-ACH.

HOMONYMIA, *Homonymy*, or equivocation, that is, the calling two or more things by the ſame name; a thing which has occaſioned great confuſion in the accounts of the materia medica of the antients; and to explain which, the learned Salmaſius has publiſhed a treatiſe expreſs, De homonymiis materiæ medicæ, vel Hyles Iatricæ.

HOMOPHONOUS, in muſic, is ſaid of two or more chords, ſtrings, or voices, that are of the ſame pitch of tune, or at uniſon. Vid. *Broſſ.* Muſ. Dict. in voc.

HOMOTONOS, in medicine, an epithet made the characteriſtic of a certain kind of fevers which continue from the beginning to the end in one equable and uniform tenor, without exacerbation, or relaxation.

HOMUNCIONALES, an appellation given by the Arians to the orthodox, who ſaid there were two natures and ſubſtances in Chriſt. *Hoffm.* Lex. in voc.

HONEY (*Cycl.*)—It is evidently from the flowers of plants that the bees collect their great ſtore of *Honey*, as well as their wax. The earlier writers knew this, but they had no diſtinct knowledge of the ſeveral parts of the flowers which furniſhed this induſtrious inſect with theſe two ſo different ſubſtances.

The wax we find is furniſhed by the farina contained in the apices of flowers, or the buttons that terminate their ſtamina; and the *Honey* is furniſhed by a part of the flowers which ſeem not to have been known to exiſt in them, till the diſcoveries of that great botaniſt Linnæus. This author has given the name of *nectaria* to theſe parts of flowers. They are certain veſicles or glands ſituated near the baſis of every petal, and continually ſecreting a nectareous or melleous juice. Theſe are ſo different in figure and ſituation in different flowers, that this author has made them a part of his generical diſtinctions. As it has been before obſerved, that the bees underſtood the ſtructure of the ſtamina of flowers better than we did till of very late times, ſo it muſt be acknowledged, that they alſo have always known the exiſtence, and the proper place and nature of theſe nectaria, though we were ignorant of them till within a few years paſt. The bee always ſeizes upon this part of the flower, and ſucks from thence either *Honey*, or a juice of that nature, which will become *Honey* under her management. She receives this into her body, and carries it then home to the hive, where ſhe unloads herſelf of it, and empties it into the cells ſhe had before prepared to receive it. *Reaumur*'s Hiſt. Inſ. v. 9. p. 386.

The manner in which bees procure this juice, will be beſt known by obſerving the ſtructure of their trunks. This inſtrument is of a very different ſtructure from that of the gnat, and ſuch other inſects as live on our blood, but it is of the ſame figure and make with that of the ſeveral humble-bees, and ſome other creatures of that kind. This trunk appears at different times more or leſs long. When the creature is in a ſtate of reſt, the trunk is ſhort; and, if examined at that time by holding the head of the bee between the fingers, it will be found to be a flattiſh, bright, and ſhining ſubſtance, of the conſiſtence of horn, and of a cheſnut colour. This ariſes from the under part of the head, and is carried in an equal breadth to the end of the teeth, and there bends and returns towards the breaſt, diminiſhing in ſize all the way, till it terminates in a point. When the creature pleaſes, it unbends this a little, and forms a ſort of hook with it under the head, and frequently it fully extends it, and it then ſtands out in a ſtrait line from the head; it very much reſembles the beak of a bird when in this ſituation, and the more ſo as it is pointed, hard, and gloſſy. The origin of this trunk is on the hinder part of the head, near the place where the neck is joined on, and it has a ſort of joint at the part where it reaches to the extremity of the teeth, and bends back again in its ſtate of reſt. Naturaliſts diſtinguiſh this trunk into two portions by means of this joint; they call that which reaches to the extremity the anterior; and that which has the inſertion with the head, the poſterior portion. *Reaumur*'s Hiſt. Inſ. v. 9. p. 391.

When the trunk is in a ſtate of reſt, we ſee no part of its real ſurface, but only a ſort of caſe or ſheath in which it is preſerved. This caſe, when nicely examined, is found to be compoſed of two parts, which may be called two ſeparate ſheaths, the one only covering a part of its length, and the other only a part of its ſuperficies. Each of theſe caſes is made of two hollow pieces which may be called half ſheaths, and theſe may always be ſeen on preſſing the trunk. The ſingle flat filament, which is the real organ of ſuction, or, in other words, the real trunk, will be ſeen extending itſelf along theſe pieces, which will ſtart from it on each ſide. The anterior portion of the trunk itſelf, when in a ſtate of inaction, is ſomewhat flatted, being three or four times as broad as thick, and having rounded edges; this grows all the way ſmaller from its origin to its extremity, where it is terminated by a little button or knob, which is ſeen to be pierced through its middle. The edges of this button are covered with hairs, and the whole anterior part of the trunk is alſo hairy. The upper ſurface of this part ſeems wholly cartilaginous, but the under ſurface appears to be only in part ſo, the reſt of it ſeeming compoſed of a folded membrane, which is capable of opening, upon occaſion, to a greater extent. This membrane runs all along the middle of the under part of the trunk, and is of the nature of the membrane which connects together the ſeveral rings of the body.

When the creature is ſucking the juices of any flower, this anterior part of the trunk ſwells and loſes its flatneſs. This is an obſervation of ſome difficulty, but may be made in this manner: Place the head of a bee before a candle, and while it is in the focus of a good glaſs, let the poſterior portion of the trunk be preſſed; this will force a drop of liquor into the anterior portion, which will by degrees make its way up to the button at the extremity. All the way that this paſſes, the trunk will be ſeen to ſwell and become rounder in ſhape. The ſwelling of the anterior or upper ſurface, which is complete horn or cartilage, will not be ſo eaſily ſeen, but the membrane which runs along the under part, and makes a ſort of white rib or ſtreak in the center, will be ſeen to extend, and become greatly wider than before; and by this means alone the cavity of the trunk will be made much greater than otherwiſe, even though the horny part did not ſwell out at all. The poſterior part of the trunk is much thicker, and appears to be much ſtronger than the other. Mr. Reaumur

has given excellent figures and deſcriptions at large of the ſeveral parts of this curious organ, to which we refer the reader. *Reaumur*'s Hiſt. Inſ. v. 9. p. 398.

Beſides this trunk, the bee has a very large mouth. This, however, is ſo frequently covered with the other parts, that it is not eaſy to ſee it. When the trunk is extended to its length, the mouth is to be ſought for immediately under the teeth, or grinders, and, in this caſe, it is often ſo perfectly covered with the tongue, that unleſs that be removed, it is not to be ſeen. This mouth, with this large and viſible kind of tongue, is not to be ſuppoſed peculiar to the bee; ſeveral other flies have it, and the large humble bees all have it very perfect. As their ſeveral parts are alſo larger than thoſe of the bee, it is better to examine the mouth and its tongue, in thoſe inſects, than in the bee itſelf. The tongue puts on many appearances at different times; ſometimes it is of the ſhape of the tongues of other animals, and at others it is more or leſs thin or narrow; ſometimes its point is ſingle, and ſometimes divided into three parts, which, on ſome occaſions, are diſpoſed in the manner of a flower de luce.

The mouth, though a part of great importance to the bee, is in general over-looked by authors; but its uſe is plainly to give paſſage to certain ſubſtances into the body. Thus if a bee, which has been collecting *Honey*, be held between the fingers, and ſqueezed a little, the *Honey* will be forced in drops out of the end of the trunk, and theſe will fall upon and be received into the aperture of the mouth.

When a bee enters into a flower which has the nectaria, or melleous glands, or veſicles at the baſe of the petals, it generally meets with ſome of this juice, which has been thrown out by theſe glands, and lies in form of a ſaccharine matter, in the bottom of the flower. The juices of vegetables are ſaccharine and melleous in other parts beſide the flowers, and there are certain times of the year in which we find the leaves of the maple, and ſome other trees, covered over with this juice, extravaſated from their leaves, and lying on their ſurface, in a form very much reſembling *Honey*, rendering them gloſſy to the eye, very ſticky when touched, and ſweet as honey or manna to the taſte. This only happens at ſome times to the leaves, but it is continually the caſe in the flowers of plants; we may always taſte honey in their bottoms, and theſe nectaria continually diſcharging it from their ſeveral veſſels, the bee needs only thruſt his trunk into the bottom of the flower to find it. If the creature be obſerved in this work, it will be wonderful to ſee how quickly ſhe executes it. The trunk, which is the only inſtrument that receives it, is thrown into a thouſand different motions, and is ſhortened or lengthened, ſhrunk up or diſtended, and bent a number of ways, in order to bring it to touch ſeverally every part of the bottom of the flower, and thus take up all the matter depoſited there.

The general opinion of the writers on inſects has been, that the trunk of the bee is a ſort of pump, and that the *Honey*-juices of flowers are received into it by ſuction. This ſhould ſeem not to render ſo many motions as theſe neceſſary for the purpoſe, ſince if the trunk acted as a pump, it would be only neceſſary to plunge it once into the liquor, and its common action muſt ſuck the whole up; but Mr. Reaumur, by repeated experiments, proves that this part of the bee is not a pump, but merely a tongue, proper to lap with, placed at the end of a proper conveyance, by which the matter lapped up is thrown into the body. If the inſide of a glaſs tube, of about half an inch diameter, be daubed over in certain places with *Honey*, the *Honey* being left in ſome places in drops, and in others ſpread thin upon the ſurface, the bees will be eaſily ſeen to perform their ſeveral actions in the taking it in.

If this tube be placed any where near the places of reſort of bees, two or three will ſoon enter into it, and the ends may be cloſed up to keep them there. They will then immediately forget that they are priſoners, and begin to devour the *Honey*; and in their doing this, the ſeveral motions of the trunk will be eaſily ſeen through the ſides of the tube. In places where the *Honey* is ſpread thin upon the ſurface, they will turn the end of the trunk every way about, and apply it ſeveral ways to the glaſs, as a dog would do to lap up the remains of any thing ſticking to the ſides of a diſh; and in the places where it lies in drops, the bee introduces its trunk into it; but then it does not let it quietly remain there, as if at work in pumping up the matter, but takes it out at times, and when it is in, gives it many contortions from ſide to ſide, and the whole appears ſtill like the motions of the head and tongue of a dog, not like any operation of ſucking. The whole intent of the bee ſeems to be the covering its tongue thoroughly with the liquor, and then drawing it back into the caſe or ſheath which makes the reſt of the trunk. The matter it had collected is there wiped off; and then, by the repeated diſtentions and contractions of the trunk, it is carried up to the head, and thence carried into the body. The nice art of the bee, in taking up into her body only ſuch ſubſtances as are proper for her purpoſe, was very finely ſeen accidentally by means of an experiment made by Mr. Reaumur, with a very different intent. He was deſirous of ſeeing the paſſage marked out, by which the bee conveyed the melleous juices into her body. With this intent he mixed ſome very fine powder blue with a quantity of *Honey*, and ſet it before the bee; expecting that the coloured liquor would mark the way by which it paſſed; but, on the contrary, he found that this little creature was able to ſeparate ſo extremely fine a powder as this from the *Honey*, and, in fine, eat up all the *Honey* pure, and left the blue behind. *Reaumur*, Hiſt. Inſ. vol. 9. p. 403.

It is very certain, that the *Honey* or melleous juice is received into the body of the bee by this kind of lapping, not by the method of ſucking, ſince the aperture at the end of the trunk, if there really be one, which is much to be doubted, is ſo very ſmall, that the liquor could be but very ſlowly received; whereas it is plain, that a drop of *Honey*, though conſiderably large, laid upon a plate of glaſs, or otherwiſe, is taken in almoſt momentarily by the bee. This is eaſily underſtood, by ſuppoſing the bee to lap it up, as we have before mentioned.

Honey has been ſuppoſed by many to be the only food of the bees who collect it; but this is evidently erroneous. The common food of the bee is the farina of flowers of different kinds, which, when it has ſerved their little bodies as nouriſhment, is again thrown out, in great part, at their mouths, in form of wax. With this wax they form combs, compoſed of cells, in which they rear their young offſpring, and in which they depoſit *Honey* to ſerve them in ſeaſons when they cannot go abroad in ſearch of their other food. There are many ſeaſons of this kind, in which they cannot go out; and in ſome of which there is no food for them if they could. In theſe hard times they remain within the hives, and feed on the *Honey* they had before hoarded up; and if this proves inſufficient in quantity, they are reduced to great diſtreſs, and whole ſwarms of them often periſh through famine. *Reaumur*, Hiſt. Inſ. vol. 10. p. 85.

The bee does not receive the *Honey*, in the firſt collecting it from the flowers, into the body by means of her trunk, as many have ſuppoſed; this trunk only ſerves to collect the ſweet juice, in ſmall drops, from the nectaria of flowers. When this trunk is loaded with this juice, or *Honey*, it depoſits it on the tongue, which is exerted for that purpoſe; and when that organ has received it, it immediately draws back into the mouth, and the *Honey* is ſwallowed into the œſophagus.

The œſophagus of the bee is a long and ſlender canal, paſſing from the mouth of the animal into the thorax. Towards its termination in that part, it is diſtended into a ſort of bag, which forms the firſt ſtomach of the bee.

The children in country places are well acquainted with this receptacle of the *Honey*, and frequently kill the great humble bees in order to get at this part, and ſuck the honey. But tho' theſe children are acquainted with the part, very great men have been much miſtaken as to its uſe. Maraldi took it to be a bag, cloſed at the lower end, and only deſtined to receive the *Honey*, and diſgorge it again upon occaſion; but Swammerdam, on more careful diſſections of the creature, found it to be a real ſtomach, opening into another or ſecond ventricle.

The firſt ſtomach, when empty, is no more than a white filament, which, being hollow, is capable of receiving the *Honey*; and when received, it becomes ſwelled and diſtended in proportion to the quantity it contains, and grows very narrow at its lower part, where it is joined to the ſecond ſtomach. This is a ſort of bladder, very white, but tranſparent, and is uſually much diſtended, and ſo covered with large and broad circular muſcles, that it reſembles, upon the whole, a tub with many hoops. This ſtomach becomes again very ſlender and narrow at its lower end, where it is joined to the inteſtines. The ſecond ſtomach, and the inteſtines of the bee, are often found to contain a great quantity of the rough wax; but the firſt ſtomach contains only *Honey*. *Reaumur*, Hiſt. Inſ. vol. 10. p. 89.

The quantity of *Honey* that each flower is able to afford the bee, is but very ſmall; and the creature is uſually forced to go to a great number before it can take in enough to fill this firſt ſtomach; but as ſoon as this is done, the creature immediately flies home and diſgorges the treaſure into a ſafe place, where it may ſerve for food at ſome other time, when there is leſs opportunity of feeding abroad. Ariſtotle, and ſome other of the antients, have obſerved, that the bee, in collecting one parcel of *Honey*, will only have recourſe to one ſpecies of flower: Thus if ſhe takes in the firſt parcel from a violet, ſhe will go only to violets for the remainder. But this is an error; ſince it is common to ſee a bee on a flower-bed in a garden, ſupplying herſelf from all the variety that are ſet there.

Swammerdam, who had no idea of the bees having any mouth, ſuppoſed that this creature diſcharged the *Honey* into the cell of the comb, by the ſmall orifice which he thought there was in the end of the trunk; but this muſt have been a very tedious operation, ſince the *Honey* is not diſgorged into the comb in the ſame ſtate in which it was received into the ſtomach, but is much thicker, having paſſed a ſort of concoction. The truth is, that the *Honey* is diſgorged through the ſame part through which it was taken in, and this is the mouth, which is ſufficiently large for the purpoſe. The manner in which bees fill the combs is very regular; they always begin with the very fartheſt cells of the uppermoſt comb, and,

filling theſe firſt, the reſt are filled as they follow in order of place.

The firſt ſtomach of the bee has all the neceſſary motions of contraction and diſtention, for the throwing out its contents. This is eaſily ſeen in the diſſecting a bee whoſe ſtomach is filled with *Honey*; and it is eaſy to conceive, that the conſequence of the contractions muſt be the forcing the *Honey* out. Id. ibid.

The method of the bee's diſgorging itſelf in the common cells cannot be ſeen, becauſe of the opakeneſs of their ſides; but there are cells in the glaſs hives, in which the whole operation is eaſily ſeen. It is no uncommon thing to have the extreme cells of a comb reach to the glaſs, and many of them, in this caſe, joining the glaſs, have only four ſides of wax, the glaſs ſupplying the other two; in theſe cells it is very pleaſant to ſee the whole operation. The bee, who comes loaded to the cell, thruſts its head very deep into it, and diſgorges the *Honey* from its ſtomach in a very little time, and ſeemingly with very little trouble, by the mouth. But as the quantity of *Honey*, collected by one bee, is very ſmall in proportion to the ſize of the cell, this cannot be filled but by a great number of repeated operations of the ſame kind. As theſe cannot be performed by the ſame bee, in any convenient time, and as all the labour of theſe creatures is carried on in common, the firſt bee is no ſooner gone, than another comes, and ſo on till the whole cell is filled. In the proceſs of this work, it is very eaſy to obſerve, that what appears to be the laſt quantity of *Honey* diſgorged into the cell, is always of a different appearance from the reſt. The whole quantity beſides is of one colour and conſiſtence; and this is of the nature of a cream, which is always much thicker than the reſt of the honey, and ſeems very uſeful in the œconomy of the work, ſerving at once to keep the *Honey* moiſt, and to prevent its running out by any accident. *Reaumur*, Hiſt. Inſ. vol. 10. p. 89.

Tho' this cream or cruſt appears to be the laſt voided quantity, it is not ſo in reality; for it ſeems to have been gathering together from the firſt; and every freſh quantity of *Honey* is added under, not upon its ſurface. To this purpoſe it is always obſerved, that the bee which comes loaded to the cell, does not at once diſcharge its *Honey* into it, but, entering into the cell as deep as may be, it puts forward the anterior pair of legs, and with them pierces a hole through the cruſt or cream. While this hole is kept open by the feet, the bee diſgorges the *Honey* in large drops from the mouth; theſe falling into the hole made by the feet, mix with the maſs below; and the bee, before it flies off, new models the cruſt, and cloſes up the hole it had before made; and this is regularly done by every bee that contributes to the general ſtore of the cell. Id. ibid.

Every bee that returns to the hive loaded with *Honey* does not, however, go to a cell to depoſit it, but they often ſtop and get rid of it by the way. The labour of the hive being carried on in common, the bee, who has been abroad in ſearch of *Honey*, inſtead of going to any cell, often makes her way to the places where others are at work, in erecting the combs, or upon any other neceſſary ſervice; there ſhe puts forth her head, and, forcing the *Honey* to her mouth, calls them about her to feed upon it, that they may not be obliged to leave their work on account of hunger. They feed on her ſtore by putting their trunk into her mouth, exactly as they do into the bottoms of the flowers; and often the loaded bee in this manner feeds ſingle and ſtraggling ones which ſhe meets with in her way, tired with the labour of their laſt employment.

The ſeveral cells of the combs in every hive are differently filled with *Honey*, and to different purpoſes; ſome is laid up for their immediate conſumption, on occaſions of bad weather, and the like accidents; and ſome is more carefully preſerved, and is deſtined for the ſupport of the ſwarm in the winter.

It often happens that, in the *Honey* ſeaſon, there are very rainy or very ſtormy and cold days, in which the bees cannot go out in ſearch of food; the whole ſwarm, on theſe occaſions, feed on the *Honey* in the cells, deſtined for immediate uſe; and even in good weather, thoſe bees which ſtay at home to work, and are not ſupplied by thoſe which have been abroad, have recourſe to theſe cells for their food.

The cells of *Honey*, deſtined for this neceſſary uſe, are eaſily diſtinguiſhed from thoſe which are to be the ſupply when the ſeaſon of gathering *Honey* is over, and when the whole ſwarm muſt neceſſarily ſubſiſt on the hoards of their former excurſions. The cells meant for immediate uſe are always open at the top, whereas thoſe intended for the winter's proviſion are all covered and cloſed down at the top with a thick and ſtrong lid, and may be compared to ſo many glaſſes of ſweetmeats, hermetically ſealed, the faſtening being of the ſame matter with the ſubſtance of the pot. *Reaumur*, Hiſt. Inſt. v. 10. p. 94.

In a bad ſeaſon for the collecting of *Honey*, the combs in all hives are found very abundant in the occaſional cells, moſt of which are emptied by the bees; but in the plentiful ſeaſons, when there has been great ſtore of food to be had abroad, it is common to find the whole combs compoſed of full cells, cloſed up at the top, for winter's ſtores.

The manner in which the bees make the lid or cover of the cells, is this: They form a circle, or ring of wax, juſt within the verge of the cell; to this they add another ſuch ring, and then another within that; by this means the aperture is rendered ſmaller and ſmaller, and, by a continuance of the ſame workmanſhip, is finally cloſed, the lid or cover being finiſhed, and being thus compoſed of a vaſt number of concentric circles.

The uſe of this covering is not to preſerve the *Honey* from running out of the cell, for its own thickneſs, and adherence to the ſides of the cell, together with the cruſt or cream with which it is covered at top, would prevent that; but it is by this means preſerved from a ſet of idle and gluttonous bees, which eat up more than thoſe which work, but are too lazy to work through the cover, to come at what is contained in theſe cells.

It has alſo another uſe, which is the preſerving the encloſed *Honey* in its proper conſiſtence; for it would, if left open, ſoon loſe its natural thickneſs; and it has been often obſerved, that the bees will not eat their honey, when any way altered in this reſpect.

The product of the labours of the bee, as well in *Honey* as in wax, is of very great ſervice to the world in general, and of the greateſt advantage to the places where bees ſucceed beſt. The value of *Honey* is indeed ſomewhat leſs at preſent than it was in former ages, when the world was not acquainted with ſugar; but though the uſe of that commodity has much taken off from the neceſſity of *Honey*, yet the other article, wax, has grown in value all the while; and as it has been found of uſe on many occaſions, at that time unknown, and as there has been no other ſubſtance found that will ſupply its place, it is become much more valuable than it was before.

It is very evident that the whole produce of the labours of theſe inſects, both wax and *Honey*, are matters collected from the flowers of plants; and as it is alſo evident that there are ten thouſand flowers that die untouch'd in the fields and woods, for one that grows near the places where bees are kept, and is in the way of being uſed to this purpoſe. It is an undeniable truth, that there are a thouſand times as many pounds of theſe ſubſtances annually let go to waſte, as there are worked up, and brought to market. This is ſo conſiderable an article in the riches of a kingdom, that Mr. Reaumur thought it worthy of a ſtrong recommendation to the court of France, to encourage the raiſing ſwarms of bees in all places, that greater quantities of ſuch uſeful commodities might be had in their own kingdom, than they have at preſent. And, indeed, as bees are a ſort of huſbandry ſo eaſily raiſed, and kept at ſo ſmall a ſhare of trouble and expence, it is a wonder that they are not more largely propagated with us, as well as with that nation.

The method propoſed, by Mr. Reaumur, of encouraging this branch of huſbandry, is a very good one; namely, that there ſhould be ſomething taken off from the taxes to be paid by every farmer, in proportion to every hive of bees he kept above a certain number.

The great article to be attempted, in order to the increaſe of theſe little inſects, muſt be the avoiding to kill or injure any of them ourſelves, and the preventing their mortality at certain times, when there naturally die great numbers of them. Theſe ſeaſons of mortality are the autumn and winter. One great means of preſerving and multiplying the bees, would be the aboliſhing that barbarous as well as prejudicial cuſtom, in many nations, of deſtroying the whole hive of bees, in order to get at the *Honey*.

The common method in France and England is this: When the farmer finds, by the weight, that a hive is full of combs and honey, he digs a hole in the ground, capable of receiving the baſe of the hive. Then putting into this hole a quantity of linnen rags dipped in melted ſulphur; he ſes them on fire, and immediately placing the hive upon them, covers the ſides up with earth, that neither the fume nor any of the bees can eſcape; in this manner the bees are all ſuffocated. Others uſe turff inſtead of ſulphur, and others other things; and they pretend that in England, and other cold countries, there is no way but this of getting any advantage from the hives; and that it is only in Greece and Italy, and ſuch other places as are ſtored with vaſt quantities of flowers all the year round, that they can make any profit of ſharing their produce with them, and leaving them alive.

In juſtification of this procedure, they ſay that they only deſtroy, by this means, a ſort of old bees which are incapable of either producing more *Honey*, or being the parents of a new ſwarm, and which would eat up in the ſucceeding winter the greateſt part of what they had ſtored up in the ſummer. *Reaumur*'s Hiſt. Inſ. v. 10. p. 358.

This laſt is indeed the true reaſon of the procedure, and they in reality, for the ſake of having a few pounds the more of wax and *Honey*, deſtroy a ſwarm of bees capable of collecting ſuch another parcel, and of producing other bees that ſhould ſupply their places when they periſhed naturally.

The

The deſtruction of theſe creatures has yet leſs to be ſaid for it in reality, than appears at firſt to be the caſe, for the wax would have ſuffered no diminution during the winter, and it would only have been the price of a few pounds of *Honey* that would have been loſt, for the preſerving a ſwarm much more uſeful than ſeems generally ſuppoſed. It may happen ſometimes indeed, that a ſwarm may periſh at the end of four or five years, but it much more frequently happens that they live eight or ten; nay, there are inſtances of ſome having lived more than thirty years. In this caſe, how vaſt a deſtruction is occaſioned by the killing that ſwarm at four years old, which would have lived ſix and twenty years longer, and ſent out three or four young ſwarms every year? It will be eaſily ſeen from this, how great the increaſe of bees would be in a few years, compared to what it is, if this one barbarous cuſtom only could be ſet aſide among us, which not only deſtroys, in this caſe, three times twenty-ſix ſwarms, but all thoſe ſwarms which, in the common courſe of things, would have been produced by each of theſe, a number much greater than can be at firſt imagined.

If inſtead of deſtroying the bees every time we take their *Honey*, we would try a little to preſerve their lives, the thing would not be found ſo difficult as many may think; it would be no great difficulty to get them all into another hive; and in ſome caſes they might be the means of preſerving another ſwarm. There are many weak ſwarms, as they are called, which all periſh during the winter. The true cauſe of the death of theſe, is their being ſo few in the ſwarm; and, if inſtead of deſtroying all the bees of a well-peopled hive, they ſhould be added to one of theſe weak ſwarms, both would in this caſe be preſerved, and their works, in the ſucceeding ſummer, would amply repay the ſmall quantity of *Honey* neceſſary to feed them with in the winter.

Montfort, in his treatiſe of bees, mentions a law made by the great duke of Tuſcany, inflicting a puniſhment on any perſon who was known to deſtroy a ſwarm of bees; and if the ſame law were in force among us, the conſequence would be, that we ſhould ſoon have a much larger quantity of wax and *Honey* annually produced from the vaſt encreaſe of thoſe bees, which an ill-placed avarice devotes every year to deſtruction. Beſide the great number of bees annually deſtroyed in this manner, there are a very great number that periſh every winter between the months of November and April; ſo that of large ſwarms that went into the hives in the beginning of winter, there are but ſmall remains in the beginning of the ſucceeding ſummer.

The authors who have written of bees, have ſaid much about the diſeaſes of bees, and their proper remedies; but Mr. Reaumur has reduced the whole to a much ſmaller compaſs, and affirms, that the two great deſtroyers of bees are hunger and cold, and that whoever will take care to guard them from theſe during the winter, will always find as many alive in the hives in ſpring as went into them in autumn. *Reaumur's* Hiſt. Inſ. v. 10. p. 357.

There is great nicety to be obſerved, however, in the management in order to the preſerving them; for it often happens that the carefully defending them from the cold, is the very occaſion of their dying of hunger. The wiſe author of nature has ſo provided for theſe animals, that at ſuch ſeaſons as the fields ceaſe to afford them a plentiful ſtore of food, they ceaſe to want ſo large a quantity of it; the ſame cold that nips the plants, and keeps them from flowering, nips alſo the bees, and puts them into a ſtate in which they perſpire very little, and therefore require very little nouriſhment. Nay, in the coldeſt time of the year they perſpire ſo very little, that their life is in no danger, even if they take in nothing at all to replace their loſs.

If the hives are examined in the time of ſevere froſts, which they may be without any danger, for the bees are in ſo torpid a ſtate, that the hive may be turned upſide-down, and moved any way, without putting any of them in motion; they are there always found in large cluſters near the center of the hive, between the combs. When a thaw comes on, and the ſun ſhines upon the hive, the warmth wakens the bees out of their lethargy, they begin to move about, and uſe their wings; but as the neceſſity of eating comes on with their livelineſs and motion, and the fields at that time afford them no food, they are obliged to have recourſe to the combs, and eat out of their cells the *Honey* and rough wax which they had ſtored up for that occaſion.

They always, on this occaſion, begin with the lower combs, and, as they have occaſion, they gradually advance to the upper. This might ſeem an odd procedure, as the *Honey* of the lower combs was laſt of all collected; but that is the very reaſon why it is the propereſt to be firſt eaten, for it is that *Honey* which was collected in the autumn, and which is always found to be leſs proper for keeping, than ſuch as is collected in the ſpring and ſummer months.

It ſhould ſeem, that as the winter is the ſeaſon that kills the bees, the more ſevere the winter proves, the more it ſhould deſtroy them. But this is found not to be the caſe; but on the contrary, the warmeſt winters are the moſt deſtructive of them, as they keep them in an eating ſtate, and do not ſupply them with any food abroad. It is always found alſo that thoſe ſwarms which were hived late, that is, ſuch as have had but a little time to collect their ſtores, during the time they have been together before the winter overtakes them, are moſt liable to periſh before the return of the ſpring, if they are not ſupplied with *Honey* to prevent it.

A certain degree of cold is therefore neceſſary in the winter for the preſerving theſe creatures; but on the other hand a too great degree of cold deſtroys them. The moderate winters therefore are the beſt for them, ſince in the extreme ſevere ones they die of cold, and in the extremely mild ones of hunger. It is certain that the bee is more able to bear the cold than others of our inſects, in a ſingle ſtate; but as theſe creatures are preſerved among the combs, in great cluſters together, and under the covert of a warm hive, the degree of cold is much ſmaller there than abroad, where any ſingle bee would inevitably periſh. This is eaſily underſtood by the familiar compariſon between one man's ſleeping on the open ground in a field, in a very ſevere night, and a number of men ſleeping together in the ſame night under a cloſe tent erected in the ſame field; in all probability the ſingle expoſed perſon would periſh, while the others received no injury. *Reaumur's* Hiſt. Inſ. v. 10. p. 360.

As the number of bees in the hive occaſion a warmth that preſerves them all, the obſervation of their periſhing in the winter, when they are but few in number in the hive, is very eaſily explained. It may ſeem ſtrange that an inſect, which is cold to the touch, ſhould be able to diffuſe a warmth of this kind; but it is proved by experiment to be ſo in the hives; and this warmth is obſerved to be much leſs during the time that they are ſtill and quiet, than at thoſe times when they flutter their wings about.

Varro and Columella are of the number of the old writers on huſbandry, who give that eaſy method of bringing the bees to life when they ſeem dead with the cold, which is now practiſed in many places. This is the laying hot aſhes about the hive, or ſprinkling them on cluſters of bees which lie ſeemingly dead at the bottom.

The bees, while they remain alive and in a good condition in the cold weather, are found in cluſters, which are compoſed of great numbers of them hanging to one another by the legs: When the cold becomes ſo intenſe as to prevent their motions, and deſtroy the uſe of their limbs, their legs loſe the hold, and they fall down in great numbers to the bottom of the hive, where they ſeem to be abſolutely dead. In this condition they may be taken into the hand without any danger of hurt from their ſtings; and yet in this ſtate they may be recovered to life by ſprinkling them over with warm aſhes. This, however, is but a ſlovenly method; and as the warmth is the only thing wanting, it may be much more conveniently given by bringing the hive into a warm room, and on this the bees will all be ſeen to revive. In ſeaſons of leſs ſevere cold, it will be ſufficient to take up the bees that lie as dead, and warm them on a diſh by the fire till they come to themſelves, and crawl about, and then put them under the hive again. But if the weather continue ſevere, the mouths of the hive muſt be ſtopped up, and it muſt be placed in a ſufficiently warm place, till ſome warmer weather come on.

This warming the motionleſs bees found at the bottoms of hives in winter, never fails to bring them to life if done in time; but if it be deferred till they have lain in this ſtate ſeveral days, it ſeldom ſucceeds. It is a very great number of bees that may be preſerved during the courſe of a winter, by watching the hives in this manner, and bringing all that are found at the bottom to the fire to recover them; and this is a much better method than the removing the hives into a warmer place; which though ſometimes abſolutely neceſſary, yet is never to be done when it can any way be avoided, as it always is attended with many ill conſequences; ſo that the beſt method ſeems to be, in very ſevere winters, the taking in only thoſe hives which have but few inhabitants, and the leaving out thoſe which are well peopled, where the number of the creatures will preſerve one another, and the few that fall down from the cluſters may be recovered by warmth from time to time. *Reaumur's* Hiſt. Inſ. v. 10. p. 382.

As it is much to be wiſhed, however, that a method could be found of preſerving all the hives from miſchief, and yet leaving them in their places where they ſtand in ſummer, Mr. Reaumur tried many things on this head: The firſt and moſt familiar method he attempted, was the covering them over with ſtraw, in order to keep out as much of the cold air as poſſible. This he did by ſetting up ſticks in the ground, at ſeven or eight inches every way from the baſe of the hive, and ſo tall that their points reached as many inches above the top of the hive; then putting ſtraw ſo as to fill up all the vacant ſpace between the ſticks and the ſides of the hive. Among ſeveral hives which he defended in this manner, the bees of ſeveral were all found dead in the ſpring, but on examining the hives it appeared that they had died of hunger, not of cold; for there was never any *Honey* found in the combs of theſe hives.

The antients mention a very extraordinary method of preſerving the bees in their hives, which was the filling up a conſiderable part of the vacancy of every hive with the bodies of

ſmall birds, which had been killed, gutted, and dried for that purpoſe; this was certainly a way of keeping out ſome of the cold air, but it is ſo odd a one, that probably no body ſince their time has tried it.

Another method of Reaumur's ſucceded better; which was the preſerving the hives in large tubs, with earth or hay. To this purpoſe he choſe ſome of the weakeſt and pooreſt hives he could get, and in the beginning of winter put each of theſe into a large tub, whoſe top was taken out for that purpoſe; they were not placed, however, immediately on the bottom of the tub, but a bed of earth or of hay, ſix inches deep, was placed at the bottom, and covered with the lid taken off from the top of the tub. When the hives were thus placed, all the remaining ſpace between the ſides of the hive and thoſe of the veſſel, were filled either with earth, or with hay chopped ſmall, and both the hay and the earth were put in till they reached the top of the tub, and ſtood in a heap over the verge.

Several of the country people have the contrivance to cover their hives with ſheaves of corn, or other things, during the winter; but in this caſe they often die in winter, as they do when taken into a chamber, by too much heat, or too confined a ſtate. To prevent this, the author contrived to give them a means of communication with the open air even in this ſtate, when it ſhould be neceſſary. In order to this he cauſed a hole to be cut in the ſide of each tub, capable of admitting a ſquare tube made of four thin pieces of board; this tube was of two inches in width, and about half an inch in depth; and it went in and lodged itſelf on the falſe bottom of the tub on which the hive was to ſtand, ſo as to reach the mouth of the hive, and was of ſuch a length as to reach out three or four inches from the ſides of the tub. The tube being introduced, and a pan full of *Honey* placed on the bottom, with a paper pricked full of holes lying over the ſurface of the *Honey*, ſo that the bees might eat it without daubing themſelves, the apparatus was ready for receiving the hive; which was then placed over the pan of *Honey*, with its mouth anſwering to that of the tube. When the hive was thus placed, the earth or hay was put in, and the tub filled up. *Reaumur*'s Hiſt. Inſ. vol. 10. p. 384.

The bees remained quiet in theſe habitations during the months of November, December, and January, and in the months of February and March, great numbers of them were ſeen coming out of the veſſels at the little tubes, and returning to the ſame place loaded in the manner of the common bees in ſummer. Though the hives appeared very well preſerved at this time, yet a ſevere ſeaſon coming on in the latter end of March, and continuing till April, the bees of two hives came out no more, and on examination were found to be all dead within; theſe had died however of mere hunger, for there was not the leaſt remains of *Honey* in the pots. The other hives had had ſome *Honey* in their combs at the time they were put into the tubs; and they had ſubſiſted on that, and the reſt that was given them in the pots, ſo that they lived during the whole time, and made a flouriſhing ſwarm for the ſucceeding ſummer.

This ſeems therefore an admirable method of preſerving all the hives of bees during the winter, and is to be done with very little trouble and expence. The earth ſeems to do better than the hay as a covering, but it muſt be perfectly dry when put in, and preſerved from rain afterwards, by a covering of ſtraw placed over the top of the tub. The hay ſeemed however not to be found fault with as a covering; for though it was the two hives covered with earth that ſucceded in this experiment, yet as the others had paſſed the whole winter in ſafety, and only became a ſacrifice to famine during ſome bad weather in the ſpring, there is no room to doubt of their doing as well as the others, if more *Honey* had been given them. *Reaumur*, ib.

There are many circumſtances neceſſary to the forming of good *Honey*, ſuch as a warm and clear air, a good ſtate of health in the bees, and a quantity of aromatic and ſweet flowers in the neighbourhood of their hives. The *Honey* taken out of the hives in the beginning of the ſummer, is alſo preferable greatly to that gathered in autumn, ſince the firſt is the ſeaſon in which the bees are in their beſt vigour, and the plants in their flowering ſtate.

Mr. Lemery, in his analyſis of *Honey*, obſerves, that two pound of fine *Honey* diſtilled in balneo mariæ, afford ſix ounces of clear water of an inſipid taſte, and of the ſmell of *Honey*. This is commonly called the dew of *Honey*. A larger quantity of phlegm may be procured by continuing the diſtillation, but it becomes foul. This liquor, though inſipid to the taſte, yet contains a latent acid, for it reddens the turnſole; but it neither ferments with the volatile nor fixed alkalies. The cucurbit being now placed in a ſand-heat, there comes over four ounces of a yellowiſh pellucid water, of an acrid taſte, of a ſtrong ſmell of *Honey*, and ſomewhat empyreumatic. This liquor reddens the turneſole colour more than the former. The fire being encreaſed, there ariſe white clouds, which fill the head of the cucurbit and the receiver, and theſe finally condenſe into a third liquor, which is called the ſpirit of *Honey*. This will be about three ounces in quantity, and of a red colour and empyreumatic ſmell, yet with an agreeable flavour, and of an acrid and burning taſte. This is a ſtronger acid than either of the former, and ferments with an alkali.

The fire being again encreaſed, more clouds ariſe, and in fine there is a fourth liquor produced; this is in quantity about two ounces, of an orange colour, and of an acid taſte, but leſs acrid than the third liquor, as it contains more oil, which ſoftens and ſweetens it. Like the former it ferments with alkalies, and reddens the colour of turnſole. When the diſtillation is thus finiſhed, there will remain in the cucurbit fifteen ounces and an half of a light ſpungy black coal. Mem. Acad. Par. 1706.

This is to be then put into a retort for a freſh diſtillation; and a ſtrong fire under this veſſel will raiſe from it ſeven ounces of a reddiſh brown liquor, which ſtains the fingers to an orange colour, of a burnt ſmell, yet with ſomething agreeable in it, and of an acid and very acrid pungent taſte. Beſides this, there comes over two drams of a thick black oil, looking like tar; this alſo was of an acrid taſte, which was owing to ſome of the ſalts of the *Honey* being blended with it. There is much more oil contained in the *Honey*, but it does not come over ſeparate, but blended with the other liquors; and after they have ſtood ſome days, precipitates itſelf from them, and is found ſticking to the ſides and bottom of the veſſel. The matter remaining in the retort is about ſeven ounces of a black coal, of a light ſpungy texture, and of a taſte almoſt inſipid, and only ſeeming to contain a little ſalt. We ſee by this proceſs, that thirty-two ounces of *Honey* yield twenty-four ounces and two drams of liquor, that being the difference in weight between the *Honey* when put in, and the laſt caput mortuum. Twenty-two ounces and ſix drams are the quantity here preſerved of the ſeveral liquors, the reſt having eſcaped through the junctures of the veſſels, as will always be the caſe in ſuch diſtillations. Id. ibid.

The caput mortuum of this and of ſeveral other diſtillations of *Honey*, the whole making three pound and a half, were put into an unglazed earthen pot, and calcined over the fire for ten hours; this readily took fire like common charcoal, and burnt till it loſt ten ounces in weight, but without falling into aſhes. The remaining coal had then a more ſaline taſte than before. Any acid liquor poured upon this, fermented as with the common alkalies; and when thrown into water to make a lixivium, it bubbled in the manner of quicklime thrown into water; and in the common way of making the lixivial ſalts, this yielded a dram and a half of an acrid alkaline one. It is remarkable that the calcined caput mortuum of *Honey* contains, like other vegetable aſhes, true particles of iron, which adhere to a knife touched with a magnet.

HONEY *Buzzard*, the Engliſh name of the buteo apivorus. See the article APIVORUS.

HONEY *of roſes*. See the article MEL *roſarum*.

HONEY-*Comb* (*Cycl.*)—The conſtruction of the *Honeycomb* ſeems one of the moſt ſurpriſing parts of the works of inſects, and the materials of which it is compoſed, which though evidently collected from flowers of plants, yet do not, that we know of, exiſt in them in that form, has given great cauſe of ſpeculation to the curious. The regular ſtructure of the comb is alſo equally wonderful. When the ſeveral cells in it are examined, it ſhould ſeem that the niceſt rules of geometry had been conſulted for its compoſition, and all the advantages that could be wiſhed or deſired in a thing of that kind, are evidently found in it. *Reaumur*'s Hiſt. Inſ. vol. 9. p. 410.

The bees in the ſtructure of this receptacle of their honey, ſeem to have reſolved a geometrical problem far from an eaſy one, and indeed clog'd with ſo many conditions, that it might have puzzled able proficients in that ſcience. This may be expreſſed in theſe words: A quantity of wax being given, to form it into a number of angular and equal cells, of a determinate capacity, but the greateſt that can be made with that quantity of wax, and at the ſame time, that theſe cells ſhall be ſo diſpoſed as to take up as little room as poſſible in the hive. In order to this laſt condition, it is neceſſary that the cells touch one another, in ſuch a manner, that there be no angular ſpace, nor cavity between them. The bees have effected all this by making the cells all hexangular, or tubes of ſix equal ſides: Triangular, quadrangular, and ſome other figures for the cells might have been indeed ſo diſpoſed between one another, as to leave no ſpace; but then an equal number of them could not be made with the ſame quantity of wax. The body of the bee being rounded, it will alſo be received into a hexangular cell, without leaving ſuch large ſpaces as it muſt if received into a triangular or ſquare one.

The method of making two ſets of cells in each comb, is alſo admirably contrived to ſave the expence of wax; ſince had they been made ſingle, every comb muſt have had its peculiar baſe, and every ſet of cells their bottom of wax; whereas one bottom now ſerves to two cells, and there is but one plate of wax in the center of a double comb. There is however this farther difficulty attending it, that the ſeveral cells are not ſo many hexagonal tubes with flat and broad baſes, or tubes of an equal breadth all the way; but they are truly pointed at the bottom,

bottom, being every one of them an hexangular cell, with a pyramidal baſe. Each of theſe baſes is compoſed of three equal rhombus's, and each baſe, in this manner, becomes the baſe of three other cells on the oppoſite ſide of the comb.

This is eaſily demonſtrated to thoſe who underſtand geometry, by means of the ſeveral figures and poſitions of the oppoſite baſes of the cells of the two ſides of the comb; but the moſt familiar explication of it to a common obſerver, is to ſtick three ſmall pins through the baſe of any one cell, each in the center of the rhomb that makes one ſide of that baſe: If after this the comb be turned, the three pins will be found in the centers of three different cells of the oppoſite ſide. This occaſions a very great ſparing of the wax or matter of the comb; but beſides this there is another great advantage, which is, that the angles reſulting from this combination of the baſes, greatly ſtrengthen the whole work.

The matter of which the comb is made, coſts the bees ſo great pains and labour in collecting, that it is no wonder they are careful and ſparing of it in the work. The ſides of the cells are all much thinner than the fineſt paper, and yet they are ſo ſtrengthened by their diſpoſition, that they are able to reſiſt all the motions of the bee when within them, as they are very frequently obliged to be. The effect of their thruſting their bodies into the cells, would be the burſting of thoſe cells at the top, were not this well guarded againſt. But to prevent this, the creatures extend a cord or roll of wax round the verge of every cell in ſuch a manner, that it is ſcarce poſſible they ſhould ſplit in that particular part. This cord or roll is at leaſt three times as thick as the ſides of the cell, and is even much thicker and ſtronger at the angles of the cells than elſewhere; ſo that the aperture of each cell is not regularly hexagonal, though its inner cavity be perfectly ſo. *Reaumer*'s Hiſt. Inſ. vol. 10. p. 21.

The baſes of the cells are not always perfectly trilateral; ſometimes inſtead of the three rhombs they ſhould be compoſed of, they conſiſt of four pieces, the bee having begun her work wrong; but then it is admirable to obſerve how nicely the two ſmaller pieces are afterwards joined, that the angle they make may be as nearly as poſſible equal to that of one of the rhombs, ſo that the baſe of the cell ſtill remains very nearly trilateral.

It would be a moſt deſirable thing to ſee the bees at work in their making theſe elegant and regular fabricks; but it is ſcarce poſſible to ſee any thing of this kind diſtinctly, even with the advantage of glaſs hives; for no bee ever works ſingly on this occaſion, but wherever the fabrick is erecting, there are numbers together all trying to aſſiſt one another; and their motions are ſo ſwift, and ſo hid by their ſtanding before one another, that very little is to be ſeen of them. New bees are every moment coming to the place, and old ones going away; and very frequently thoſe which arrive late are diſpatched away immediately after they arrive. There are only ſome very ſhort moments in which the glaſſes of the hives can give a view of the creatures regularly employed in their work, for the moment that one ſees a bee at work in building, that moment we ſee one either fly off, or ſome other bee get before her, ſo as to hinder the view.

Theſe momentary ſights, however, are ſufficient to make it plain, that the bee uſes her teeth in modelling and faſhioning the wax. The ſide of a cell is always received between the two teeth on this occaſion, and by means of repeated blows on each ſide from each tooth, the ſide is brought to a proper thinneſs, and the wax is by the ſame means wrought up to a proper conſiſtence and firmneſs.

It has been ſuppoſed by ſome, that all this talk of a geometrical exactneſs in the ſtructure of the combs is fancy; that the bee has leſs merit in it than is uſually ſuppoſed; and that the mere juxtapoſition of a number of round pieces or globules of wax, would produce a number of regular hexagonal figures when they were preſſed together. The bee, however, is indebted to no ſuch eaſy method in her ſtructures; ſhe regularly begins every cell by its baſe, which is not hexagonal but triangular; ſhe firſt erects one of the three rhombs which is to be the baſe of two of the ſides of the hexagon; on this they erect the two ſides of the cell of which it is to be the baſe. They then form the ſecond rhomb, and its ſides of the cell; and finally they make the third, which cloſes with the other two; and the two angular ſides erected upon that, cloſing in the ſame manner with the others, the whole cell is finiſhed.

While one ſet of bees are employed in thus erecting one cell, others are equally buſy in making the farther uſes of its parts in the ſtructure of other cells; and ſome finiſh the adjoining cells, of which its ſides make a part: Others again are at work at the baſe, laying the foundation for the other cells, the baſes of which are to be formed in part upon the ſeveral rhombs of theſe; for they always work upon both ſides of the comb at once. *Reaumur*'s Hiſt. Inſ. vol. 10, p. 30.

There are ſome occaſions on which the bees are much preſſed for time in the erecting their edifices; in this caſe they frequently only lay the foundations of the cells, and leave them to be finiſhed and carried to a proper height afterwards. In ſuch caſes a comb is frequently finiſhed on both ſides, as to the rhombic or triangular baſes of the cells, and only a ſmall height of their hexangular ſides added, which is all finiſhed at more leiſure afterwards. As in the ſeveral works of art there are many hands employed to the finiſhing any piece of workmanſhip, juſt ſo it is in the labour of the bees; no one of them ever brings a cell to perfection, but the firſt labourer only caſts the rough work, and leaves it to others to refine and finiſh.

In our works it is well known that the rough work is much the eaſieſt, and ſooneſt performed; and as one caſter of metals can furniſh employment for a great number of filers and poliſhers, ſo one bee will form the rough work of ſeveral cells in a very ſhort time, when a great number of others muſt be employed afterwards in the finiſhing of each. This is the more neceſſary, becauſe if the firſt former of the cell ſhould make its ſides of their deſtined thinneſs, they would break under the weight of the workers in the formation; they are therefore left thick and clumſy, and the bees that come after, faſhion it better with their teeth, and getting into it, may be ſeen to work it fine by degrees, till they come out and leave it perfect. This finiſhing is done by extremely quick repeated blows of the teeth againſt the ſides, and by frequent bringing them together, ſo as to make them cut. Theſe means ſeverally ſerve to flat the walls of wax that forms the ſides, and to cut off the inequalities in places where they are too thick.

The wax is a very precious commodity among theſe little workers, it coſts them too dear to be waſted, and accordingly the bee that has cut off a large quantity, does not leave it in the cell, but takes it carefully out, gathers it into a little globule as big as the head of a pin, and carries it to the places where others are at work in erecting new cells. The moment that the bee is flown out with its load, another takes its place, and getting into the cell, finiſhes the work it was about; while the former worker either gets into another cell, or helps thoſe which are employed in the erecting new ones. Thus the labour is jointly carried on by all, and each has its ſhare in the whole work, not in any particular part of it.

In the ſwarm of bees there are many males, or large bees, which are commonly called drones; theſe have their peculiar cells, as thoſe fitted for the ordinary or working bees, which are of no ſex, would not be ſufficient to hold them in the worm ſtate. As among the cells of the ſame comb ſome are deſtined to receive the honey, others to be the lodging of the worm, or young bee, ſo among theſe laſt there are a great number larger than the others fitted for theſe males. The uſual ſize of the cells is ſuch, that in a hive of fifteen inches high, and ten inches wide, there are commonly contained about nine thouſand of them. The larger cells deſtined for the male bees, are found not to be regular hexagons, two of their ſides placed oppoſite to each other being ſmaller than the others. The difference, however, is very trifling; and when the other cells are very ſtrictly examined, there will be found alſo the ſame difference in their ſides in proportion to their bigneſs, two of the ſides of the hexagon being always ſomething ſmaller than the other four. *Reaum.* Hiſt. Inſ. v. 10. p. 34.

The cells which have ſerved, or are to ſerve for the habitation of the worms of the common, and of the male bees, are often made alſo at other times the receptacles of honey; but though theſe are indifferently made to ſerve either uſe, there are others deſtined only to receive honey.

The celerity with which a ſwarm of bees received into a hive, where they find themſelves lodged to their minds, bring their works of the combs to perfection, is amazing. There are vaſt numbers at work all at once, and that they may not incommode one another, they do not work upon the firſt comb till it is finiſhed; but when the foundation of that is laid, they go to work upon another; ſo that there are often the beginnings of three or four ſtories made at once, and ſo many ſwarms alotted to the carrying on the work of each.

The ſeveral combs are all placed parallel one to another, and there is ſuch a ſpace left between them, that the bees can eaſily paſs between; and often they place a part of the combs in a contrary direction to the reſt; ſo that while the others are placed horizontally, theſe ſtand perpendicular.

Though the ſides of all the cells are extremely thin, yet the combs are very heavy when full of honey. This might endanger their breaking their hold, if only ſuſtained from the top; and for this reaſon the bees give them ſeveral additional ſupports in whatever places they can, often faſtening them in many places one to another, and often fixing them to the ſides of the edifice by large and ſolid lumps of wax.

HONEYCOMB-*Stone*, in natural hiſtory, the name given by many authors to a ſpecies of foſſile coral, which is uſually found in large maſſes, and thoſe full of large hexagonal cells, reſembling thoſe of a *Honeycomb*. Theſe are but lightly ſtriated, and uſually run deep into the ſtone.

HONEY-*Suckle*, *Caprifolium*, in botany, the name of a genus of plants, the characters of which are theſe: The flowers are generally placed many on the ſame ſtalk, and diſpoſed in a circular form. The ſingle flowers are compoſed of one leaf each, of a tubulated form, and divided at the end into two lips, the upper of which is divided into many ſegments, the lower whole, and of the ſhape of a tongue. The cup finally becomes a ſoft fruit or berry, containing a flatted and round ſhaped ſeed.

The ſpecies of *Caprifolium*, enumerated by Mr. Tournefort, are theſe: 1. The common German *Honeyſuckle*, or not perfoliate *Honeyſuckle*. 2. The common perfoliate, or Italian *Honeyſuckle*. 3. The late flowering German *Honeyſuckle*, with a very red flower. 4. The early flowering perfoliate Italian *Honeyſuckle*. 5. The perfoliate *Honeyſuckle*, with variegated and ſinuous leaves. And 6. The ſinuated-leav'd, not perfoliate *Honeyſuckle*. *Tonrn.* Inſt. p. 608.

The Virginian ſcarlet *Honeyſuckle*, called the trumpet *Honeyſuckle*, is a very beautiful flowering kind, and in great eſteem. It is propagated by laying down the tender branches in ſpring, obſerving, in dry weather, to refreſh them with water, and the ſpring following they will be ready to tranſplant, when they are to be cut off from the old plants, and carefully removed without diſturbing their roots. The beſt time to remove them is in March, juſt before they ſhoot out; but if the ſeaſon ſhould prove dry, they muſt be watered, and have a little mulch laid at their roots, to prevent the earth about them from drying too faſt. They ſhould be planted in a ſtrong ſoil, and expoſed to the ſouth eaſt ſun; but they muſt have a wall or pale behind them to ſupport the branches, otherwiſe they will trail upon the ground. It is a native of Virginia, but will thrive very well with us, bearing all the cold of our winters, but does not ſucceed well near London, where the ſmoak commonly deſtroys it. *Miller*'s Gardener's Dict.

The propagation of all the ſeveral ſorts of *Honeyſuckles* is by laying down their branches in the ſpring, which, if they are ſupplied with water, will by the Michaelmas following have taken root ſo well, as to be fit to remove. They ſhould at this time be tranſplanted into nurſery beds for a year or two, the better to train them up, either for headed plants, or for creepers, to plant againſt trees, walls, *&c.*

They may alſo be propagated by planting cuttings in September, or in ſpring; but they ſometimes fail this way, and always require much care and trouble. Their ſweetneſs, and long continuance in flower, make them of great value in ſmall quarters. Among flowering ſhrubs they are alſo very beautiful, when planted againſt the ſtems of old trees, where, if they are not too much ſhaded, they will flouriſh exceedingly.

The proper ſeaſon for cutting them, to keep them in a regular form, is about Michaelmas, ſoon after they have done flowering. This is to be done with a knife, obſerving always to cut behind a leaf bud; for how much ſoever the ſhoot is left longer, it will always die down to that part. They are moſt of them very hardy. *Miller*, Gard. Dict.

HONEY-*Wort*, *Cerinthe*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf only, tubular, and in the ſhape of a bell, with its edge divided into ſeveral ſegments; the mouth, in ſeveral ſpecies, being cloſed or ſhut, and in ſeveral others, open. From the cup of the flower there riſes a piſtil, which is fixed into the back part of the flower, in the manner of a nail. This is ſquare, and finally ripens into a fruit, conſiſting of two ſhells, and divided into two cells, filled uſually with long ſhaped ſeeds. *Tourn.* Inſt. p. 79.

The ſpecies of this plant are, 1. The large kind, with the changeable flower. 2. The large purpliſh red-flower'd one. 3. The prickly-leav'd yellow-flower'd one. 4. The ſmall yellow-flower'd one. 5. The ſmall white-flower'd one. 6. The plain green-leav'd one. 7. The perennial alpine kind, with ſtriated flowers. The ſpecies of *Cerinthe* may be known in general by their bluiſh green leaves, ſpotted with white, at ſuch times as they are not either in flower or ſeed. *Tourn.* Inſt. p. 80.

HONOUR, (*Cycl.*) among the antients, was worſhipped as a divinity, and had a temple erected to it; which had no entry but through the temple of virtue. See Hiſt. Acad. Inſcript. vol. 1. p. 144. ſeq.

HOOF (*Cycl.*)—*Brittle* HOOF, a name of an infirmity to which horſes are ſubject. It comes ſometimes naturally, and ſometimes artificially. When it comes naturally, it is generally hereditary, the ſire or dam having had the ſame complaint. When it comes on accidentally, it is ſometimes owing to a diſtemper falling down into the feet; ſometimes to the creature's being much founder'd.

The *Hoof*, in this diſtemper, is ſo friable and rotten, as it were, that it cracks and flakes off on every ſlight occaſion. The cure is to be attempted in this manner: Take wax, turpentine, ſuet, and hog's lard, of each four ounces; ſallad oil a quarter of a pint by meaſure, and of dog's greaſe half a pound; let the whole be melted together, and ſtrained thro' a piece of canvas into a gallypot. The *Hoof* is to be thoroughly anointed with this every day, morning and evening, eſpecially at the root; and if there are any large cracks, they muſt be filled up at every dreſſing with a mixture of equal parts of cow-dung and hog's lard.

HOOK (*Cycl.*)—HOOKS *of a Ship*, are all thoſe forked timbers which are placed directly upon the keel, as well in her run, as in her rake.

Boat-HOOK, in a ſhip, a hook uſed to fend off the boat from bruiſing.

Can-HOOKS, thoſe which being made faſt to the end of a rope, with a nooſe (like that which brewers uſe to ſling or carry their barrels on) are made uſe of for ſlings.

Foot-HOOKS, in a ſhip, the ſame with ſuttocks. See the article FUTTOCKS.

Loof-HOOKS, in a ſhip, a tackle with two hooks; one to hitch into a cringle of the main or fore ſail, in the bolt rope at the leetch of the ſail by the clew; and the other is to hitch into a ſtrap, which is ſpliced to the cheſs-tree. Their uſe is to pull down the ſail, and ſuccour the tackles in a large ſail, and ſtiff gale, that all the ſtreſs may not bear upon the tack. It is alſo uſed when the tack is to be ſeized more ſecure; and to take off or put on a bonnet or drabler.

Sheer-HOOKS, in a ſhip, thoſe *Hooks* like ſickles fixed in the ends of the yard-arms, that if a ſhip under ſail come to board her, thoſe *ſheers* may cut her ſhrowds, and ſo ſpoil her tackling. But as thoſe *Sheer-Hooks* are ſubject to break their own yards, and cut the ropes that come from the top ſails, they are now very ſeldom uſed.

Trill-HOOKS. See the article TRILL-*Hooks*.

Draught-HOOKS. See the article DRAUGHT-*Hooks*.

HOOP-*Wheel*. See the article DETENT-*Wheel*.

HOOPER, in zoology, a name by which ſeveral have called the cygnus ferus, or wild ſwan. See the article CYGNUS.

HOP. See the article HOPS.

HOPLITES *Lapis*, in natural hiſtory, a name given, by ſome of the writers among the antients, to a ſtone of a ſhining braſs-like appearance, looking like the ſurface of the poliſhed braſs armour worn in thoſe times. It is eaſy to conclude, from this account, that the *Hoplites* was one of our mundics.

HOPLITODROMOS, in the antient gymnaſtic ſports, a term applied to ſuch perſons as went through thoſe toilſome and robuſt exerciſes, in compleat armour; by which the exerciſe became much more violent, and the wearing of armour, in the time of battle, much more eaſy.

HOPLOCHRISMA, a term uſed, by the antient writers in medicine, for the anointing a ſword, or other weapon, with which a perſon had been wounded, in order to the curing of the wound. So early was the idle notion of curing by ſympathetic remedies received in the world. Some late authors have alſo uſed the word in a very different ſenſe, namely, for the anointing the points of darts or ſwords with poiſonous ingredients, in order to render the leaſt wound given with them fatal. A practice moſt known, as it is ſaid, among the ſavage inhabitants of America.

HOPS, in botany. See the article LUPULUS.

There are four kinds of *Hops*. 1. The wild or garlic *Hop*. 2. The long ſquare garlic *Hop*. 3. The long white; and 4. The oval *Hop*. The firſt of theſe is not worth cultivating. The ſecond is a good *Hop*, but generally looking red toward the ſtalk, it will not fetch ſo good a price at the market. The long white *Hop* is the moſt beautiful of all, and produces the greateſt quantity. This kind, and the oval, will grow very well together. They all delight in a deep rich garden mould; this may have ſand among it, but ſhould never have any clay. Moory black land is what they are generally planted in, in Eſſex, but any light land will do. The *Hop* ſends its roots four or five yards perpendicularly deep; and, for this reaſon, they thrive beſt of all in lands where there is a good bottom, below what is uſually ſtirred or manured in agriculture. If the *Hop* land be wet, it muſt be laid up in high ridges, and drained in winter, that the roots be not rotted or chilled. *Mortimer*'s Huſbandry, p. 70.

New land is found to ſucceed better with *Hops* than old, and on this principle they are very cautious in their plantations in Kent, and look forward for the after produce. When they make a new *Hop*-ground, they plant it with apple-trees, at a large diſtance aſunder, and with cherry-trees between; by this means, when the *Hops* have grown ten years, which they judge to be as much as they will do well for, they place their account in the cherry trees which bear large crops. Theſe they gather for about thirty years, and then they cut them up, and depend upon their apple trees only, which they find very large and ſtrong by that time.

The dry ſtalks of the *Hops* ſhould be burnt on the ground in winter, covering them with a little freſh earth as they burn. This makes together an excellent compoſt to make the hills of. And if a piece of land can be obtained that lies low, and warm, expoſed to the ſouth, and defended by hills or trees, and where there is depth of ground, and ſufficient water, there is no doubt of a *Hop*-ground ſucceeding well in it.

The land muſt be dug, or ploughed well, and laid very even, and then the places for the hills marked out by a line, and a ſtick put in every place where one is to be. A thouſand hills may be made in an acre of ground, and ſix or ſeven plants ſet on every hill. The young plants are ſold at about ninepence a hundred. From ſix to nine foot diſtance ſhould be allowed between hill and hill, and the ground in the hills ſhould be better and richer than the common earth, and laid in a foot deep under the ſurface.

If the ground is too thick planted, it is beſt to uſe fewer poles than the number of plants may ſeem to require; and if it is under planted, it will be proper to enlarge the hills, and make them

them contain plants enough for twenty poles to each. Too great a number of poles, and too high ones, are equally injurious to the growth of the *Hops*. It is much better to err in having them too ſhort, or too few in number. *Mortimer*'s Huſbandry, p. 173.

Some plant *Hops* in March and April; but the moſt experienced people prefer the month of October, becauſe they will then ſtrike firm roots, and be very ſtrong and vigorous againſt ſpring. The largeſt plants are to be choſen, and it is beſt to procure them from ſome rich ground, where the hills have been laid high; they ſhould be about eight or ten inches long, and have three or four joints or buds a-piece. The holes for planting them are to be dug eight or ten inches deep, and about a foot over; and in each of theſe holes four plants are to be ſet, one in each corner. They may be covered an inch deep over the top, if planted in October; but if in ſpring, when they have ſhot from the joints, then they muſt not be buried. After this the ground muſt be kept carefully clear of weeds.

If the *Hop*-ground be poor and exhauſted, it ſhould be dreſſed in winter, and the earth about the hills dug away, and freſh and well manured ſoil put in its place; but if the ground be in good heart, it is better to dreſs it in ſpring; and if this be done as late as in April, it is ſtill the better, as it kills the weeds beſt of all, and prevents the too early ſhooting of the *Hops*, which often proves a very great miſchief to them.

Dreſſing of HOPS. This is preparing the ground in winter and ſpring, for the making a good ſummer crop. In doing this, the hills upon which the plants ſtand, muſt be all pulled down, and undermined on every ſide, till the ſpade comes near the principal root; then ſhake off, or remove with the hand, the looſe mould from the upper or younger roots, that you may ſee where the new roots grow out of the old ſets. The old ſets are to be carefully preſerved, but the other roots may be cut away. Whatever time the hills are pulled down, the roots muſt not be cut till March.

When the young *Hops* are dreſſed for the firſt time, all the roots are to be cut away that grew the year before; and the ſets are to be cut off within one inch of the ſame, and every year after they muſt be cut as cloſe as can be to the old roots: but to a weak *Hop*, ſome of the ſhoots are to be left at the dreſſing. The not obſerving this ſingle article has been the ruin of many a *Hop*-garden, that might elſe have flouriſhed. Thoſe roots of the plants which grow downward are never to to be injured, but only thoſe which run horizontally are to be cut. The old roots and the young ones may be eaſily diſtinguiſhed, in that the old ones are always red, and the young white. If there are, by accident, any wild *Hops* got among the reſt, the places where they grow are to be marked with ſticks, or otherwiſe, at the time of their being gathered, and after this, at the time of dreſſing the ground, that whole hill is to be deſtroyed, and a new one made with new plants, in the room of the old ones. When the roots are cut and dreſſed, the rich compoſt is to be put to them, and the hills muſt not be made too high at firſt, leſt they hinder the young ſhoots. If the *Hops* are ſpringing out of the hills, it is always proper to cut them off in the dreſſing; and one very neceſſary caution to the owner, is, that all poultry, but eſpecially geeſe, are to be kept off the ground.

In a dry ſpring, where there is water near the ground, the hills ſhould be well watered ſeveral times; and if the ſummer prove very dry and ſcorching, it may be proper to water them once or twice, at diſtant times, and to lay parings of the earth on the hills, and dead weeds over that, to keep the roots of the plants moiſt. The *Hops* blow in the latter end of July, and in the beginning of Auguſt they bell, and they are ſometimes ripe at the beginning of September, ſometimes later. When they begin to change colour, and are eaſily pulled to pieces, and their ſeeds look brown within them, they are ripe, and they are then to be gathered as quick as poſſible, for the leaſt blaſt of wind will hurt them at this time, and one ſtormy day may do vaſt miſchief. *Mortimer*'s Huſbandry, p. 179.

The manner of gathering *Hops*, is to take down four hills ſtanding together in the midſt of the garden, and to cut the roots even with the ground; then lay the ground level, and when it is ſwept clean, it makes a kind of floors, on which the *Hops* may be laid and picked. The *Hop* plants are firſt unwound from the poles, and then the people ſit round the clear place, and pick off the *Hops* into baſkets. Another way yet more expeditious, is to make a frame with four ſhort poles, or ſticks, laid on four forks driven into the ground, of ſuch a bigneſs as to be covered with a hair cloth of the kiln, or a blanket tacked about the edges. On theſe the poles are laid, with the plants on them, and the people pick the *Hops* into the blanket. This blanket is removed when full, and the whole frame is eaſily removed from one part of the ground to another, as they clear away the plants. When the ground is large, it is proper to erect a little ſhed to ſhelter the people employed in picking, and to keep the cut *Hops* in, for them to work upon in a morning before the dew is off from the others. The *Hops* ſhould never be gathered wet; but if any dew hangs upon them, the poles are to be ſhaken to throw it, in part, off; but if the *Hops* are ever ſo little too ripe, there is danger of their ſhedding their ſeeds by this ſhaking, and it is very well known, that their principal ſtrength is in their ſeeds. They will alſo loſe their green colour, and look browniſh, which will take off from their value in the market. Some of the people who raiſe them, bear with this inconvenience, however, to prevent a greater; and as *Hops* waſte much more in the drying, when gathered green, than when more fully ripe, they let them hang on the plants till brown; in this caſe four pound of *Hops* yield one pound dry, whereas, when gathered green, five pound make only one when dried; and they get more by the advantage in weight, than they loſe by the colour. Some leave pieces of the ſtalks, and fragments of the leaves, among them, in the picking; but this is very bad policy, for much more is loſt by this, in the price, than is gained in the quantity. Care ſhould be taken to dry the *Hops* as faſt as they are picked, for in lying undried they are apt to heat and change colour very quickly. If the quantity picked be ſo large, that the kiln in which they are to be dried is over ſtocked, they muſt be ſpread thin upon a floor, and they will keep two or three days in that manner without any harm. Indeed, where the quantity is but ſmall, there is no need to have recourſe to the kiln at all, for they will dry much better than any other way, by being ſpread thin upon a floor, and often turned. The drying of *Hops* is the moſt material part of their manufacture, for if they be ill dried, they loſe all their agreeable flavour; and great caution muſt be uſed, that they be all equally dried, for one pound of ill dried *Hops*, mixed among a large parcel of thoſe which are ever ſo well dried, will ſpoil all the reſt.

Bagging of HOPS, a term uſed by our farmers, who cultivate *Hops*, for the laſt thing they have to do with them, in order to bring them to market; that is, the putting them up in large bags of coarſe cloth for carriage. When the *Hops* have been picked, and dried in the ooſt or tin floor, they are ſo brittle that they would break to pieces, and be ſpoiled, if they were immediately put up; they are therefore to lie together three weeks, or thereabouts, that they may become tough. If they are covered from the air with blankets, in the heap, they may be bagg'd much ſooner than if left open.

The manner of bagging them is this: A hole is made in an upper floor, ſo large that a man may eaſily go up and down it, then a hoop is fitted to the mouth of the bag, and ſo firmly ſewed on, that it cannot be torn off. The bag is then let down thro' the hole, and the hoop remaining above, ſtops it from being pulled quite through, being larger than the hole. A few *Hops* are to be thrown firſt into the bag, and a perſon below is to take up a parcel of theſe in each corner of the bag, tying it up with packthread. This makes a ſort of toſſel, by which the bags are afterwards the eaſier managed, and turned about. When this is done, one man muſt go down into the bag, and while another caſts in the *Hops*, he muſt tread them down equally every way with his feet. When the bag is in this manner filled, the top is to be unripped from the hoop, and ſown up, leaving two toſſels at the corners, as at the bottom. A bag of *Hops*, thus prepared, may be kept ſeveral years, in a dry place, only taking care that the mice do not get into it. Theſe creatures will not eat the *Hops*, but they make their neſts in them, and ſpoil them. Many a fair bag has been deſtroyed this way.

The harder the *Hops* are trodden in the bag, the better they will keep. The bags in which they are packed are made of a coarſe linnen cloth; four ells and a half of that which is ell wide, makes a bag to contain about two hundred and a half of *Hops*, or ſomething more.

HOP *Poles*. See the article POLES.

HORÆA, Ὡραια, in antiquity, ſolemn ſacrifices, conſiſting of fruits, *&c.* offered in ſpring, ſummer, autumn, and winter, that heaven might grant mild and temperate weather. Theſe, according to Meurſius, were offered to the goddeſſes, called Ὧραι, *i. e.* hours, who were three in number, attended upon the ſun, preſided over the four ſeaſons of the year, and had divine worſhip paid them at Athens. *Potter.* Archæol. Græc. l. 2. c. 20. T. 1. p. 439.

HORCUS *Lapis*, the name of a ſtone, mentioned by the writers of the middle ages as uſeful in ſoldering ſilver and other metals. All the deſcription they give of it, is, that it was black, and was eaſily reduced to powder. It was called alſo catemia.

HORDEUM, *Barley*. In the Linnæan ſyſtem of botany, this is ſhewn to be a diſtinct genus of plants, the characters of which are theſe: The calix, or cup, is a partial covering, made up of ſix leaves, and containing three flowers. The leaves are ſtrait, pointed, and erect, and are two of them placed under every flower. There is, in this genus, no glume. The flower is compoſed of two valves; the under one is bellied, angular, and ovally pointed; this is longer than the cup, and is terminated by a very long beard or awn; the other is ſmaller, and is flat and pointed. The ſtamina are three capillary filaments, ſhorter than the flower; the antheræ are oblong; the germen of the piſtil is oval, and ſomewhat turbinated;

tubrinated; the ſtyles are two in number, hairy, and bent back. The ſtigmata are alſo hairy. The flower cloſely ſurrounds the ſeed, and falls with it. The ſeed is oblong, bellied, and angular, pointed at both ends, and marked with a longitudinal furrow. *Linnæi* Gen. Plant. p. 16.

HOREHOUND. See the article MARUBIUM.

HORIZONTAL (*Cycl.*)—HORIZONTAL *Line*, or baſe of a hill, in ſurveying, a line drawn on the *horizontal* plane of the hill, or that on which it ſtands.

HORIZONTAL *Roots*. See the article FIBROSE *Roots*.

HORMEZION, or HORMESION, in natural hiſtory, the name of a gem deſcribed by Pliny, and ſeeming to have been a ſpecies of hyacinth; he ſays it was very bright, and of a yellowiſh red or flame colour, with a whitiſh caſt at the edges.

HORMINODES, in natural hiſtory, the name of a gem deſcribed by Pliny, and others of the antient writers. The ſtone itſelf, they tell us, was either black or white, but had in it a green ſpeck, ſurrounded by a circle of a bright yellow. It ſeems to have been no other than one of the oculus beli's of our jewellers.

HORMINUM, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of the labiated kind. The upper lip is ſmall and galeated, the under one is large, and divided into three ſegments, the middle one being hollowed like a ſpoon. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower; this is ſurrounded by four embryo's, which afterwards become four ſeeds, and ripen in the cup of the flower.

The ſpecies of *Horminum*, enumerated by Mr. Tournefort, are theſe: 1. The garden *Horminum*, with purple ſpikes. 2. The red ſpiked *Horminum*. 3. The green ſpiked *Horminum*. 4. The broad-leav'd wild verticillate *Horminum*. 5. The napus-leav'd *Horminum*. 6. The leſſer *Horminum*, with ſinuated leaves, and a ſmall blue flower. 7. The meadow *Horminum*, with very ſmall flowers. 8. The lavender-flower'd wild *Horminum*. 9. The lavender-flower'd wild *Horminum*, ſmelling alſo like lavender.

The Engliſh name of this genus of plants is *Clary*, but it is an indeterminate one, becauſe it is alſo uſed as the name for the *ſclareæ*, a different genus of plants, though by many authors confounded with the other under the name *Horminum*. *Tourn.* Inſt. p. 178.

Horminum has been much celebrated as a cardiac, but is now leſs uſed than formerly. The dried herb, given in infuſion or decoction, is good in the fluor albus, but ſhould be given with other medicines. It is alſo commended in colics, flatulencies, and hyſteric complaints; alſo as an antiſpaſmodic, and in epilepſies.

HORN (*Cycl.*)—The *Horns* of many animals, particularly of the deer kind, are caſt every year, and new ones grow up in their places. With us the deer drop them in March, and the new *Horns* are full grown by the July following. Voſſius very juſtly ranks this among the moſt wonderful phænomena of nature; he ſays, that we have nothing analogous to the growth of ſuch hard and ſolid bodies of ſo great a bulk, in ſo ſhort a time.

Many idle opinions have been formed of the cauſe of the falling of theſe parts of the animal; and worms in the head, and many other things, have been ſuppoſed inſtrumental to it, which have no ſhare in it. The true reaſon ſeems, that theſe are a ſort of vegetables growing on the animal, as our nails and hair have by many been ſaid alſo to be; and there appears a great analogy between them and the ſprouting of the leaves and branches in trees and plants. Trees commonly caſt their ripe fruit in ſummer, and drop their leaves in autumn, becauſe the ſap, or nouriſhing juice flows into them no longer; and in the ſame manner, at certain ſtated periods, the blood and juices ceaſe to flow into theſe parts of the animal, and they drop off. The cavernous part, at the root of the *Horns*, probably grows hard, and the pores through which the veſſels paſs, grow up at this time, and then, as no juices can be carried through them to the *Horn*, it is not at all wonderful that it decays, and falls off, for want of nouriſhment.

It is probable that this ſtoppage of the pores, and denying of the paſſage of any juices, happen in the *Horns* as ſoon as they are arrived at their full growth in July; but they are ſo firmly fixed to the head, that it takes a long time for them to looſen and fall, whereas in the leaves of plants the pedicles are ſo tender, that they wither and fall immediately on the juices ceaſing to flow into them. This analogy between the operations of nature, in the caſting the *Horns* of deer, and the falling off of ripe fruit and leaves from vegetables, will gather great ſtrength from obſervation of the orange and other trees. If the ſtalk, from which a ripe orange has fallen, be compared with that part of the forehead of a deer from which a *Horn* is juſt fallen, there will be ſeen ſuch a ſimilarity between the one and the other, that it will appear very obvious, that nature has operated by the ſame laws in both. Philoſ. Tranſ. N°. 227. p. 494.

The growth, and caſting of the *Horns* of deer, is a very ſingular circumſtance in the animal world. The ſtag puts out its firſt *Horns* in the ſecond year of it age, and after this they caſt them every year in March. The luſty and well fed ones caſt their *Horns* firſt; the ſickly or weak ones ſometimes keep the old ones till the end of April. Theſe *Horns* are faſtened to the bones of the ſkull, not to the ſkin of the head only, as ſome people would have it thought, who are for making the caſting of them the leſs wonderful. About ten days after the *Horns* are caſt, the new or young *Horns* begin to appear; they are ſoft and hairy at firſt, but they grow hard in about three months, and the ſtag then rubs off their hairy ſkin.

The number of branches in the *Horns* is proportioned to the age of the animal, the young ones always having but few, the old ones moſt. Six or ſeven branches are the common number, and in Tuſcany they have ſometimes eight or nine. But in Saxony, where theſe creatures are very long lived, they are ſometimes ſeen with fourteen or fifteen branches, and ſometimes more. The young *Horns*, while yet ſoft, are full of blood-veſſels, and if cut off, eſpecially if near the head, they are found to bleed very violently, and the creature will ſometimes even bleed to death at the wound. This blood was found by Redi to coagulate alſo like the other blood of the ſtag, let out of the other parts of the body; though this is contrary to the accounts of Ariſtotle and Galen. Blood-veſſels are ſent in large numbers into all *Horns*, while young, to furniſh them with nouriſhment for their increaſe and growth; but when they are arrived at their full growth, theſe veſſels dry up, there being no farther occaſion for them; and hence it is that no ill ſymptoms attend the falling off of theſe parts, when full grown. If a ſtag be caſtrated while he is ſo young as not to have *Horns*, he will never have any at all, and if caſtrated afterwards, while his *Horns* are on, he will never caſt them, but always retain the ſame pair which he had at the time of the operation. *Redi*, Exper. See the articles CASTRATION, STAG, *&c.*

HORN, in the manege: To give a ſtroke with the *Horn*, is to blood a horſe in the roof of the mouth, with the *Horn* of a ſtag or roebuck, the tip or end of which is ſo ſharp and pointed, as to produce the ſame effect as a lancet. We ſtrike with the *Horn* in the middle of the fourth notch or ridge of the upper jaw.

HORN *Coot*, a name given by fowlers to the great *Horn* owl. A ſportſman who has got one of theſe birds, has a conſtant lure to draw together almoſt what numbers of others he pleaſes. The method of taking other birds by it, is thus: The ſportſman fixes upon ſome ſingle tree which ſtands in the middle of an open field, and cutting the boughs of this into a regularity, he ſpreads nets all about it, and then places his owl within them, with a ſtring faſtened to its leg, by means of which the bird may be put in motion by the ſportſman as he ſtands at a diſtance under covert. There are to be two perches placed near one another, ſo that the owl can eaſily go from the one to the other. It is the nature of this bird to fly only by night, and therefore whenever it is ſeen by daylight, all the other birds quarrel with it, and abuſe it; even the hawks will make at it wherever it comes in their way. The ſportſman depends upon this, and as ſoon as he ſees any bird approach, or as ſoon as the owl, who ſees farther than he can, gives him the ſignal that ſome bird is in ſight, he pulls the ſtring, on which the owl, being diſturbed, flys from one perch to the other. This draws the ſtrange bird to her, and flying violently at her, it is entangled in the net placed with that intent, and the ſportſman muſt immediately run up and take it out, and replace the net for the next.

HORN-*Fiſh*, an Engliſh name for the fiſh which we alſo call the garfiſh. It is by ſome accounted a ſpecies of the acus or tobacco-pipe fiſh; but the only reaſon for this opinion, ſeems to have been, that it is as long and ſlender as that fiſh. It is properly a ſpecies of pike or eſox. See the articles ACUS and ESOX.

HORN-*Fiſh*, in zoology. See the article CORNUTUS *Piſcis*.

HORN-*Owl*, in zoology, the name of a ſort of owl diſtinguiſhed by two cluſters of feathers ſtanding up over its ears, and reſembling horns. There are two kinds of this bird, a larger and a ſmaller; the firſt diſtinguiſhed by the name of the bubo, the great *Horn-owl*, or eagle-owl; and the other called the *otus*, or *noctua aurita*. *Ray*'s Ornithol. p. 63. See the articles BUBO and OTUS.

HORNET, *Crabro*, in zoology; this inſect is very bold and venomous; and wholly reſembles the waſp, only it is twice as large, and that the head is of a longer and ſlenderer ſhape, and the eyes formed ſomewhat like a half moon. They build under ground, and in winter hide themſelves in hollow trees. They feed on fleſh, and, when very hungry, will ſeize upon a ſmall bird. Mouffett relates, that they have been ſeen ſingly to purſue and kill a ſparrow, and afterwards feed on its fleſh. See the article WASP.

HORNET *Fly*, in natural hiſtory, a very large two-winged fly, which has the ſhape and colours of the *Hornet*, and is, at firſt ſight, ſcarce to be diſtinguiſhed from it. The principal colour of the body of this fly is yellow; but it has two long and large black lines placed tranſverſely on it, and has a black corcelet, and a yellow head. *Reaumur*, Hiſt. Inſ. vol. 4. p. 481.

These lay, at a proper season, a large number of oblong white eggs, which hatch into large and long worms, whose chief food is the worms and nymphs of the humble bees. The worm of this fly is continually found in the nests of these bees, where it never meddles either with the wax or honey, but preys only on the young offspring of the creature. Ibid. p. 482.

These worms grow to a very considerable size; they have no legs, their body is pointed at the anterior part, but grows larger all the way toward the posterior. This part of its body is of the radiated figure of this whole class of fly worms; on it there are placed six fleshy bodies, in form of rays, disposed in a semi-circular form, the upper part of the body marking its diameter. Near the center of this semi-circle are placed two pipes or tubes, placed close to one another, which are shorter than the rays, and their use much more important to the animal, at least their importance is much better known to us: These are the two posterior stigmata. Ibid. p. 483.

The anterior stigmata, in the worm of this fly, are not so very plain to the eye as these, but may be distinguished when carefully looked for; they are placed one on each side of the second ring of the body, near its junction with the third. The body seems composed of a vast number of rings, or full of almost innumerable fine small furrows; the upper part of the body, where it joins the under part, is all the way round adorned with a series of fine small prickles; and when it moves, it shews two very short horns. The head is of the variable kind, and is furnished like the rest of that class, with two hooks; but these in this species may properly enough be called teeth; each is also split at the end, and supplies the place of two strong teeth. Ibid. p. 484.

HOROMETRY, the art of measuring, or dividing the hours, and keeping an account of time.

HOROPTER, (*Cycl.*) in optics, an imaginary line drawn through the intersection of the optic axes, parallel to a line drawn through the center of both eyes; so that the space comprehended between these two lines forms a plane, in which the two optic axes are always found. All the objects seen in this plane have a relation to the *Horopter*, or to the line which terminates it. The *Horopter* has several properties in optics, which are described at large in *Aguillonius*, Opt. lib. 2. Diff. 10.

HORSE, in zoology. See the article EQUUS.

Mettled HORSE, a term used by our dealers in *Horses* to express a creature of that species, which has a great deal of vigour and heart, as they call it otherwise. There is great difference between a *mettled Horse*, a *Horse* of vigour, and a fiery *Horse*; but as this is not sufficiently attended to by gentlemen in their purchases of this animal, some general rules for the distinguishing real vigour in a *Horse*, may be acceptable in a work of this general kind.

When a *Horse* is standing still, the rider who has a mind to try whether he has vigour in him, should keep him fast with the bridle-hand, and apply the spurs to the hair of his sides; this is called by horsemen pinching. If the *Horse* is impatient under this, gathering himself up, and endeavouring to go forwards, and champs upon the bit, without thrusting out his nose, it is a sign of vigour and right mettle in him. Some caution is to be used, however, in judging by this, to distinguish between a *Horse* that has vigour really in him, and one that has only a fine skin, and is rather tickliſh than mettled. This is the case with a great many *Horses*, and is found by their being very sensible of the touch of the spur, and shewing the appearance of a great deal of mettle and vigour when touched, but immediately losing the apprehension of it. These are of a dull disposition, but only have a tender skin.

The *mettled Horse* is to be highly valued, but the fiery one is good for nothing; a *Horse* that is truly vigorous, should be calm and cool, he should in general move on patiently, and only shew his mettle when it is required of him.

The surest method is to chuse such *Horses* as are extremely apprehensive of strokes, and are afraid at the least appearance of their coming. These, at the only closing of the legs and thighs, seem to be seized with fear, and alarmed, but that without fretting or fierceness. A *Horse* that walks deliberately and securely, and that without requiring the whip too often will go on briskly and without fretting, will go from the walk to the gallop, and as easily from the gallop to the walk again, and continually champs upon the bit, and trots with glibness, upon the shoulders easily, and snorting a little thro' his nostrils. This is generally a creature of true mettle and vigour, though it does not rise to such a fierceness as is troublesome or dangerous. If to these good qualities a *Horse* be well upon his haunches, and have a light and easy stop, his head well placed and firm, and the feeling of his bit equal and just, the gentleman who loves riding will seldom need to complain of the price. All the good qualities of a *Horse* should, however, never recommend him, unless he has a good mouth, and a sensible obedience to the spur.

Backing of HORSES. The first backing of a *Horse* is a thing of great consequence, as his value afterwards very much depends on it. After a colt has been exercised some time morning and evening, and becomes somewhat obedient, he is to be taken to some ploughed lands, the lighter the better; he must be made to trot over these in the hand, by that means to tire him and abate his wantonness. When this is done, care must be taken that all the tackling be good and firm, and every thing in its due and proper place; then a person is to hold his head, and another to mount him; but this must not be done suddenly, or at a jerk, but very gradually and slowly, by several half risings and heavings. If he bears this patiently, the person is to seat himself firmly on his back; but if he be troublesome, and not tamed enough, the person is to forbear the attempt to mount, and he is to be trotted hard in the hand over the same ploughed lands again, till he is willing to receive the rider quietly on his back. When this is done, the person who is on his back must cherish him, and the man who has his head must lead him a few paces forward; then he is to be cherished again. The feet are to be fitted well in the stirrups, and the toes turned out; afterwards the rider is to shrink and move himself in the saddle, and the person who holds his head, is to withdraw his hand a little farther from the mouth. As the rider moves his toes forward, the holder must move him forward with the rein, till he is made to apprehend the rider's motion of body and foot, which must always go together, and with spirit, and will go forward without the other's assistance, and stay upon the restraint of the rider's hands.

When this is accomplished, let him be cherished, and have grass and bread to eat; and then let the rider mount and alight several times, cherishing him between each time; and thus he is to be managed till he will go on, or stand still at pleasure. This being done, the long rein may be laid aside, and the band about the neck, which are always used on this occasion, and nothing will be necessary but the trenches and caveson, with the martingal. A groom must lead the way before; or another *Horse* going only strait forwards, and making him stand still when desired. In this manner, by sometimes following, and sometimes going before another *Horse* on the trot, the creature will by degrees be brought to know that it is his business to be quiet and governable.

Breeding of HORSES. In order to have a good and beautiful race of *Horses*, it is necessary to chuse for a stallion a fine barb, free from hereditary infirmities, such as weak eyes, bad feet, spavins, pursiness, or the like: Disorders that arise from accidents are of no consequence, nor is the *Horse* to be at all the less valued for them as a stallion. Three months before this *Horse* is to cover a mare, he should be fed with sound oats, pease, or beans, or with coarse bread, and a little hay, but a good quantity of wheat straw; he should be led out twice a day to water all this time, and after every watering walked about an hour, but not over-heated. If he be not prepared and put in heart in this manner, the colts will be weakly, and the *Horse* himself will be spoiled, growing pursy and broken-winded.

If he is put to too many mares, he will not last long, his main and tail will begin to fall off through weakness, and it will be difficult to get up his flesh again by the next year. The number of mares should be proportioned to his strength, and twelve, fifteen, or at the most twenty, are as many as a *Horse* will well serve for in a season. Mares go with foal eleven months, and as many days over as they are years old. This being certainly known, it is easy to contrive so that all the foals may be brought forth at a time when there is plenty of grass. About the end of May the mares are to be put into an enclosure capable of feeding them as long as the stallion is to be with them, or that they are in season. In this enclosure all the mares are to be put together, as well those which are barren as others. The stallion's hind-shoes are to be taken off, but the fore-shoes should be left on to preserve his feet; then lead him forth, and let him cover a mare twice in hand, to render him more tame and gentle. After this take off the bridle, and turn him loose among the rest, where he will become familiar with them, and not one of them will be horsed but when they are in season. There should be a little lodge built up in some part of the enclosure, and pease, beans, oats, bread, and other good food, put into the manger in it, that the *Horse* may retire into it in the scorching heats, and eat what he likes best. He must be thus entertained during the whole time he is with the mares, which is to be about six or seven weeks.

Mares that are very fat and gross do not hold well, but those which are moderately fat conceive with the greatest success and ease. To bring a mare in season, it is a common thing to give her a quart of hempseed, or twice that quantity, night and morning, for eight days before she is brought to the *Horse*. If she refuse it alone, it may be mixed with beans or oats, and will go down; and if the stallion eat of it also, it will make him the better.

The stallion should not cover before he is six years old, nor after he is fifteen. A mare should never be covered before she is three years old; they should be always sound and healthful, and of a good breed; such as these will bring forth better and finer foals than any others. The colts produced from these, are not to be used for stallions, for they will degenerate, and the race will soon become exactly our own country breed. If a barb is not to be had, a Spanish *Horse* is to be chosen.

Gelding of HORSES. See the article GELDING.

Fattening

Fattening of HORSES. See the article FATTENING.

Watering of HORSES. See the article WATERING.

HORSES *of draught*. See the article DRAUGHT *Horſes*.

River-HORSE, in zoology. See the article HIPPOPOTAMUS.

Sea-HORSE. See the article HIPPOCAMPUS.

War-HORSE. See the article WAR.

HORSE, in a ſhip, that rope which is made faſt to the ſhrowds to preſerve him that heaves the lead there, from falling into the ſea.

HORSES is alſo an appellation ſometimes given to the waps, as alſo to thoſe ſhort waps that are ſeized to the middle of the top-maſt and top-gallant maſt ſtays, wherein are reeved the top-ſail, and top-gallant ſail bow-lines.

HORSE-*Bean*. The *Horſe-bean* is the only kind propagated by the plough; it delights chiefly in a ſtiff and moiſt clay; three buſhels will ſow an acre, and this is to be done in February. The common produce is about twenty buſhels from an acre. They muſt lie ſome time upon the ground after they are cut, before they are carried in. Some farmers ſow tares and *Horſe-beans* together, which is a very good way, for the ſeeds are eaſily ſeparated by a riddle. *Mortimer*'s Huſbandry, p. 139.

HORSE-*Block*, in the manege. See the article MONTOIR.

HORSE-*Bread*. Bread of a proper kind is often given *Horſes* to hearten and ſtrengthen them when they have gone through great fatigues, or are to prepare for ſuch. Common houſe-hold-bread will anſwer the purpoſe, but the more common way is to prepare a kind of bread on purpoſe. There are two different receipts for making this ſort of bread, each of which has its admirers. The firſt method is this: Take wheat-meal, oat-meal, and beans ground fine, of each half a peck, aniſeed two ounces, gentian and fenugreek-ſeed, of each an ounce, liquorice two ounces; let all theſe be made into a a fine powder, and ſifted together, that they may be perfectly mixed. Then add the whites of twenty new-laid eggs, and as much fine-ale as will knead the whole into dough. This is to be made into loaves, and well baked, but not burnt; and the *Horſe* is to have a good quantity of it every morning for five or ſix days, without any other provender.

The other method is much nicer, but perhaps does not any way better anſwer the intended purpoſe of heartening up the creature. It is this: Take wheat-meal, rye-meal, bean-meal, and oat-meal, of each half a peck; aniſeed and liquorice, of each an ounce; white ſugar-candy, four ounces: Beat all theſe to powder, and ſift them together; then add the whites and yolks of twenty new-laid eggs, and as much white-wine as will make the whole into a dough. Let this be made into great loaves, and well baked; it muſt not be given the *Horſe* too new, but when it has ſtood about three days, it may begin to be uſed; the outſide is always to be chipp'd off when any of it is given. Theſe are the two ſorts of bread uſually given to prepare *Horſes* for long journies. But there are three other receipts for making bread for race *Horſes*, which are as much eſteemed, and are given by our expert jockies for the ſecond, third, and fourth fortnight's feed. The firſt kind is made in this manner:

Take three pecks of clean beans, and one peck of fine wheat; let theſe be ground together, and kneaded into dough, with a large quantity of freſh barm or yeaſt, but with as little water as may be. When this has heaved and worked up a little, let it be kneaded again, and then made into large loaves and carefully baked; when three days old, it may be given to the *Horſe*, but not ſooner.

The ſecond ſort is to be made as the other, only with equal quantities of beans and wheat, and the cruſt of this is to be cut quite away before it is eat. This is to be given to the *Horſe* at his uſual meals, either alone, or mixed with oats and ſplit beans.

The third ſort of bread is ſtronger than either of the others, and is to be made thus: Take three pecks of wheat, and one of beans; let them be ground together, and made into very fine flour; knead this up into dough with a good quantity of yeaſt diſſolved in as much ſtrong ale as is neceſſary; add the whites of twenty eggs, and make the whole into large loaves. Theſe muſt be thoroughly baked, and when they have ſtood three days, the cruſt muſt be cut off, and the crumb only given, either alone, or mixed with oats or ſplit beans. This is to be the food for the laſt fortnight.

Animated HORSE-*Hairs*, a term uſed to expreſs a ſort of long and ſlender water-worm, of a blackiſh colour, and ſo much reſembling a *Horſe-hair*, that it is generally, by the vulgar, ſuppoſed to be the hair fallen from a *Horſe*'s mane into the water as he drinks, and there animated by ſome ſtrange power. Dr. Lifter has at large confuted this abſurd opinion, in the Philoſophical Tranſactions. See the article SETACEOUS *Worms*.

HORSE-*Hair Worms*. See the article AMPHISBÆNA.

HORSE-*Mackrel*, in ichthyology, a name given by us to a pecular ſpecies of mackrel, called alſo in Cornwall a *ſcad*. It is the trachurus of authors in general. Bellonius calls it the *lacertus*, and the old Greek writers, as Ariſtotle and the reſt, the *ſaurus*. Artedi diſtinguiſhes it by the name of the *ſcomber*, or mackrel, with the lateral lines aculeated, and with thirty rays in the pinna ani. See the article SCOMBER.

HORSE-*man*, the name given to a particular ſpecies of pigeon, called by Moore the *columba tabellaria minor*. It very much reſembles in ſhape the carrier-pigeon, but it is ſmaller, and ſhorter necked; the protuberant fleſh on the beak, and round the eye, is alſo leſs in quantity; it is more barrel-headed alſo, and the eye is ſomewhat pinched. It is matter of diſpute whether this be an original ſpecies of pigeon, or a baſtard between the carrier and tumbler pigeons. *Moore*'s Columbarium, p. 31.

There are of this ſpecies of all ſorts of feathers, but the blue and blue-pieds are the moſt valued. Theſe are one of the ſorts of pigeons made uſe of in England for carrying letters, and flying for wagers; for the true original carriers are now very ſcarce, and not riſk'd on every trifling occaſion.

HORSE-*Muſcle*, a common Engliſh name for the freſh-water muſcle, a large ſpecies of ſhell-fiſh, very common in our fiſh-ponds. Mr. Mery, of the Paris academy, has been at the pains of making a number of curious obſervations on this animal. He obſerves, that they are all hermaphrodites, and that, by a ſtrange and before unheard-of method of generation, each individual is in itſelf capable of propagating its ſpecies, and annually does it without the intercourſe of any other. This is extremely ſingular, becauſe tho' we know many animals which are hermaphrodites, or in which each individual contains the parts of both ſexes, yet in ſnails, earth-worms, and all the reſt of theſe kinds, there is always a congreſs of two animals for the propagation of the ſpecies.

The ſhell of the freſh-water muſcle is compoſed of ſeveral laminæ or beds of matter, in the manner of many of the ſea-ſhells, and is lined within with an extremely delicate and thin membrane, which is not eaſily diſtinguiſhed while the ſhell is recent, but when it becomes dry it uſually ſeparates from it, and peels wholly off. This fiſh opens and ſhuts its ſhell by a very ſtrong hinge, aſſiſted by two ſtrong muſcles; the contraction of theſe ſhuts the ſhells firmly together, and a powerful ſpring or force in the animal opens them at pleaſure. The part which performs this office, is diſtinctly ſeen on the back of the fiſh, and is an inch and half long, and about a ſixth of an inch broad. Mem. Acad. Par. 1710.

The muſcles act ſo ſtrongly, as to keep the ſhells always firmly cloſed in their natural ſtate; and this power ſubſiſts in them even after the death of the animal, till it begins to rot, and at that time the ſhells naturally open. This creature is capable of a progreſſive motion of two kinds; it can either creep along the bottom, or crawl up the ſides of a pond at the banks, or at pleaſure raiſe itſelf up to the ſurface of the water and ſwim. This laſt is a motion it performs but rarely; but whatever movement it is employed in, all that is ſeen to aſſiſt in it, is, the belly of the fiſh hanging an inch or two out beyond the edges of the ſhells. The belly of this fiſh repreſents very well the hulk of a ſhip, and is larger toward the head, and ſmaller toward the anus. This large part of the body, however, is the lighteſt, and in ſwimming is always carried uppermoſt, for in this part the lungs are ſituated, by means of which it is capable of a great dilatation of its bulk, in proportion to its weight, a thing of the firſt conſequence in ſwimming. When it is to move along upon the mud, which is its common buſineſs, it does this by means of five muſcles which the belly is furniſhed with, which by their contractions and relaxations eaſily give a force able to pull along the whole fiſh. The mouth of this fiſh is ſo placed within the body, that it cannot extend or exert it in the common way of animals in ſearch of food; it muſt neceſſarily be that the water brings always nouriſhment with it to the mouth; which may well be ſuppoſed, when we conſider what numbers of minute animals inhabit every drop of it. As the ſhells of this fiſh are, however, uſually kept ſhut, it might be ſuppoſed that the animal would want food; but it has a power of retaining a quantity of water a long time in the ſhell, and ſeems to ſlowly collect from that all the nouriſhment it contains, before it diſcharges it to take in more. This water is kept in four large reſervoirs, and thence paſſes by the parts of generation to a large glandular ſubſtance, which this gentleman takes to be properly the head of the fiſh, though it wants the characters of the more perfect animals; and the mouth being placed in this part, the nouriſhment is received from the water here. It is ſoon conveyed from the mouth into the inteſtine, whoſe courſe in this fiſh is very extraordinary; it begins directly behind the creature's mouth, it thence paſſes through the ſubſtance of the brain, enters the liver, and makes ſeveral convolutions there; hence it paſſes in a ſtrait line to the heart, which it alſo enters and paſſes through, and thence makes its way immediately to the anus, the orifice of which has its rim beſet with ſeveral pyramidal points, and its inner part with ſeveral glands, of which two are particularly diſtinguiſhable; they are of the ſhape of an almond, and ſtand one on each ſide; theſe diſcharge a glutinous liquor. The ovaries of this creature are always found empty in ſummer, and full in winter, the eggs being always laid in the ſpring for the production of the young progeny, and the internal copulation of the parts of both ſexes not furniſhing others till toward autumn. Mem. Acad. Par. 1710.

HORSE-*Tail*, in botany. See the article EQUISETUM.

HORSE-*Worm*, in natural hiſtory, a ſpecies of fly-worm produced of eggs depoſited by a two-winged fly of the ſhape and ſize of the humble-bee, in the inteſtines of *Horſes*.

It is indeed a very ſtrange place this little creature chuſes for the depoſiting its eggs; but as noble a creature as the *Horſe* ſeems, and as much as we may ſuppoſe him created for our uſe, we are to conſider, that the ſame great hand made both him and this little fly, and that he ſeems indeed more created for the fly than for us; he is uſeful to us, but to the fly he is abſolutely neceſſary, ſince without him ſhe could not propagate her ſpecies.

The worms of the human bowels have not been longer known to the world than thoſe of the *Horſe*; and the farriers in all ages, who have undertaken the care of theſe valuable animals, have had their remedies for the long worms bred in their inteſtines, and alſo for the ſhort ones. The ſhort ones are the creatures here to be deſcribed. But though the world has ſo long been acquainted with their exiſtence, it never knew their origin till Mr. Valliſnieri diſcovered of late that they were produced from one of the humble-bee flies. *Reaumur*'s Hiſt. Inſ. vol. 4. p. 542.

Theſe flies always live in the open fields, and are never found about towns and houſes, and this is the reaſon that thoſe *Horſes* which are kept up in the ſtable in the ſummer and autumn, are never found to be ſubject to theſe worms.

In the latter end of ſummer, and toward autumn, theſe flies are found continually buzing about the backs of *Horſes* in the open fields, and their whole buſineſs there is to depoſit their eggs, where nature has inſtructed them to do it.

Horſes at this ſeaſon are ſenſible of the buſineſs of this little annoyer, and have been ſeen from the moſt quiet ſtate to jump, run about, and kick, only at the ſound of the wings of one of theſe flies, which has been at that time ſearching for an opportunity to depoſit its eggs in them.

A fly has been ſeen, when it has not ſucceeded in its attempt in this manner, to fly with leſs noiſe toward a ſingle *Horſe* in another part of the field, ſlily to creep under his tail, to uſe ſome gentle titillation in order to make the creature open his fundament, and, when a little open, has ventured to crawl in, and without doubt then only found herſelf in a proper place for the depoſiting her eggs for a few moments. After this the *Horſe* has jump'd, kick'd, and caper'd as if mad, and continued ſo for a quarter of an hour.

The worms hatched from theſe eggs, or perhaps living worms there depoſited, if the fly be of the viviparous kind, ſoon find their way farther up the inteſtines, and often penetrate even into the ſtomach.

After a ſufficient time for theſe worms to acquire their deſtin'd growth, they naturally quit their old place of abode; in order to this they all get toward the lower part of the inteſtines, and are either voided by the creature with its dung, or of themſelves crawl out.

There is nothing ſingular in the figure of theſe worms, they are larger than thoſe of the common fleſh fly, and ſmaller than thoſe of the ox-fly; they are ſomewhat of a conic figure, their head being pointed, and their poſterior part much larger; they are of different colours, ſome greeniſh, and others yellowiſh, and ſome brown; they are provided with each two cruſtaceous hooks, by which they lay hold of things, and pull themſelves along by that means.

The great danger of theſe worms would be, that they might be forced out of their habitation by the fæces of the *Horſes*, and with them carried out of its body, but theſe hooks prevent that, for by means of theſe the creature is able to lay ſo faſt hold of the fleſh of one's hand, as not to be eaſily removed. But beſides theſe, nature has given to theſe worms, a multitude of ſmall triangular points, like ſo many prickles, placed all over its body, and by means of theſe it is able to hold itſelf faſt againſt the ſides of the guts.

The body of this ſpecies of worm is compoſed of eleven rings; the mouth is placed below the two hooks, and juſt above them the worm, when it pleaſes, thruſts out two ſhort fleſhy horns. The hinder part of the worm, however, is much more obſervable; this is drawn up and wrinkled like a purſe, but is continually opening from time to time, and when open, one diſcovers in it a deep cavity, at the bottom of which are placed ſix double furrows; theſe are the poſterior ſtigmata of the worm, and the fleſhy purſe, drawn over them, is evidently intended to defend them from being ſtopped up by liquid ſubſtances running over them.

It is ſuppoſed that clyſters of oil are a remedy for this diſorder in *Horſes*; but it probably is of no effect, ſince the oiling over the whole body of the worm, nay, the introducing drops of oil into the cavity where the great ſtigmata are, has not been found to kill the animal.

When theſe worms are only in ſmall numbers in a *Horſe*, they are of no harm to the animal; but there are ſeaſons in which they increaſe to ſuch vaſt numbers, that they are a very fatal malady; and, in ſome years, when *Horſes* have died of a ſort of epidemic malady, after they have been opened, prodigious numbers of theſe worms have been found living in their ſtomachs, each having eat itſelf a ſort of cell in the membrane of the ſtomach, and all being lodged there as cloſe together as the ſeeds in a pomegranate.

We are not to wonder at all how ſuch immenſe numbers of worms come into one *Horſe*, ſince one female is able to depoſit more than ſeven hundred, as Mr. Valliſnieri has obſerved.

When theſe worms are fallen from the inteſtines of the *Horſe*, they crawl about till they find ſome place of ſafety, where they make a ſhell of their ſkin, and paſs all their changes, and from whence they finally come out in form of the parent fly.

The males of theſe flies have ſhorter bodies, and have, for that reaſon, more of the appearance of the humble-bees than the females. They are all very hairy; they are two-winged flies, and of the ſecond claſs of thoſe, having a mouth without either teeth or trunk. Their antennæ are ſhort and ſhining, and each has a ſingle long hair growing from it.

There is no ſpecies of fly which varies ſo much in the colours and marks of the individuals as this; the colours are black, yellow, white, and brown; but in the different flies they are differently placed, and mixed with one another.

The wings of theſe are alſo leſs tranſparent than thoſe of moſt other flies, and uſually appear irregularly ſmoaked as it were in different places. The male is alſo eaſily known from the female, by his having two ſtrong brown hooks on his hinder parts, turned one towards the other, and laid cloſely againſt his belly. Theſe ſerve him in the time of his congreſſes with the female, to lay faſt hold of her. See *Reaumur*, Hiſt. Inſ. vol. 4. p. 540. ſeq. See alſo *Valliſnieri*.

HORTATOR, in the Roman navigation, an officer whoſe buſineſs it was to give the word of command to the rowers, and to direct them when to ſtop, and when to ply their oars.

The Greeks gave the name of *celeuſtes* to this officer.

HORTULANUS, in zoology, the name of a genus of birds, of the ſmaller kind, the general character of which is, that they have a tubercle, or hard eminence, on the upper chap of the beak. Of this genus are the bunting, the yellow-hammer, the cirlus, the reed ſparrow, the berluccio, and the cirlus ſtultus. See Tab. of Botany, N° 32.

HORTUS, a name uſed by ſome authors for the female genital parts of animals.

HOSPITAL (*Cycl.*) — *Foundling* HOSPITAL. See the article FOUNDLING.

HOSTILERS, in our old writers, is uſed for inn-keepers; and in ſome old books the word *Hoſters* is taken in the ſame ſenſe, 31 Ed. 3. c. 2. *Blount*.

The word is French, *Hoſteliers*, of the ſame import.

HOT (*Cycl.*) — HOT-*Beds*, in gardening, are of general uſe in the northern parts of Europe, without which we could not enjoy ſo many of the products of the warmer climes as we now do, nor have our tables furniſhed with the various products of the ſummer ſo early in the ſpring.

The common *Hot-beds*, uſed in kitchen gardens, are made with horſe-dung in the following manner: A large quantity of new dung from the ſtable, with the litter among it, ſhould be mixed with ſome ſea coal-aſhes, and when it has ſtood a week, it will have acquired a conſiderable heat. This dung is then to be placed in a ſhallow trench, made in a ſhelter'd part of the garden, and if it be intended for the planting out of melons or cucumbers, there muſt be made, at proper diſtances, where the middle of the light of the glaſs they are to be covered with will come, holes of ten inches over, and ſix deep, which muſt be filled with freſh earth, thruſting a ſtick in the middle, to ſhew the place where the hole is. The whole bed is then to be covered about four inches thick, with the earth taken out of the trench. When this is done, the beds are to be covered with frames of wood, fitted with lights of glaſs, and after about two days the earth will be of a proper degree of warmth to receive the plants to be ſet in it. *Miller*'s Gardener's Dict.

In the making theſe beds, great care muſt be taken to lay the dung cloſe and even; and if it be full of long litter, it ſhould be trod down, otherwiſe it will heat too violently, and the warmth be ſoon diſſipated. For the firſt ten days the glaſſes muſt be but ſlightly covered in the night, and in the day-time carefully raiſed to let out the ſteam, which is ſubject to riſe very copiouſly while the dung is freſh. Afterwards the covering muſt be encreaſed, and if the bed cools too faſt, new dung muſt be laid about its ſides, which will give it a great warmth throughout, and by that time this is diſſipated, the ſun's rays will have power enough to ſupply the place of artificial heat. Only, at this time, if the nights happen to be cold, as is indeed often the caſe, it will be neceſſary to lay ſome mowings of graſs about the ſides of the bed.

This is the ſort of *Hot-bed* moſt in uſe in kitchen gardens; but thoſe made with tanners bark are much properer for the tender exotic plants and fruits, which require a ſteady and equal degree of warmth to be kept up for ſeveral months. In order to the making of theſe, a trench muſt be dug in the earth, about three feet deep, if the ſoil be dry; but if it be wet, it muſt be only dug one foot, and the bed raiſed two foot above ground. The length muſt be proportioned to the number of frames it is intended to be covered with, but it ſhould never be leſs than eleven or twelve feet, nor its breadth leſs than ſix, this being abſolutely neceſſary to their being a body

body of bark enough to keep up the heat. This trench is to be bricked up to the height above-mentioned, and in the ſpring ſhould be filled with freſh tanners bark, that is, ſuch as the tanners have lately drawn out of their vats, after having tanned leather with it. This ſhould be laid in a round heap for two or three days before it is put into the trench, that the moiſture may run off. It is then to be put into the trench, and gently beat down with a dung-fork. It muſt then be covered with a wooden frame and glaſſes, and in about ten days it will begin to heat, and is then fit to have the pots of plants and ſeeds plunged into it. *Miller*'s Gardener's Dict.

A bed of this kind will continue in a good temper for warmth, ſix months; and when the heat declines, if it be ſtirred up thoroughly from the bottom, with a fork, and a load or two of freſh bark added to it, will recover its heat, and keep it for two or three months longer.

The frames that cover theſe beds ſhould be proportioned to the plants they are to contain; if for the pine-apple, the back ſhould be three foot high, and the lower part fifteen inches. If the bed be intended for taller plants, the frame muſt be higher in proportion; but if meant only for ſowing of ſeeds, it need not be more than fourteen inches high at the back, and about ſeven inches deep at the front.

HOT-*Houſe*, in the ſalt works, the place where they dry the ſalt after it is taken out of the boiling pan. In the Cheſhire ſalt-works, this is ſituated between the furnace, and the funnels of the chimney which convey up the ſmoak. Along the floor of this room there run two funnels, nearly in an horizontal direction. From the furnace, after this courſe along the floor, they riſe perpendicularly. In theſe the flame and ſmoak running along, heat the room by the way. *Ray*'s Engliſh Words, p. 176.

HOTAMBÆIA, in zoology, the name of a ſpecies of ſerpent found in the Eaſt Indies, of a greyiſh yellow colour, and very rank ſmell.

HOTTONIA, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is a perianthium, compoſed of one leaf, divided at the extremity into ſtrait, erect, and open ſegments. The flower is a ſingle petal, of the length of the cup, formed into a tube, and divided into five oval rimmed ſegments. The ſtamina are five tapering, ſhort, erect filaments, placed oppoſite to the ſegments of the flower. The antheræ are oblong. The germen of the piſtillum is globoſe and pointed. The ſtyle is ſhort and ſlender. The ſtigma is globoſe. The fruit is a rounded capſule, but pointed at one end, containing only one cell, and ſtanding on the cup. The ſeeds are numerous, and of a globoſe figure. The receptacle is round and looſe. *Linnæi* Genera Plantarum. p. 64.

HOTTS, or HUTS, among cock-fighters, are the pounces, or round balls of ſtuffed leather, which are tied on the ſharp end of fighting-cocks ſpurs, to keep them from hurting one another in ſparring or breathing. Ruſt. Dict. in voc. See the article SPARRING.

HOUGHING, or HOEING, in gardening, the cutting up with a ſmall iron inſtrument, called a *Hough*, all the weeds from among the plants of more value. This is done by digging up the ſurface of the earth about the beds, and has this double advantage, that, beſide deſtroying the weeds, it breaks the hardened ſurface of the ground, and makes it much more fitted to imbibe the night dews, which are extremely beneficial to plants. *Miller*'s Gardener's Dict. See the article HOEING.

HOUND (*Cycl.*)—*Grey*-HOUND. See the article GREY-*Hound*.

Entrance of HOUNDS. See the article ENTRANCE.

HOUND-*Fiſh*, in ichthyology, an Engliſh name given to two different fiſh of the ſqualus kind, the one called the ſmooth, and the other the prickly *Hound*. The firſt is the ſpecies deſcribed by Artedi under the name of the ſqualus, with obtuſe or granulous teeth. This is the galeus lævis and muſtelus lævis of authors. The other is diſtinguiſhed by the name of the ſqualus, with a rounded body, and with no anus fin. This is the galeus acanthias and muſtelus ſpinax of authors. We find in Willughby, and almoſt all the other writers on fiſhes, the name of another ſpecies of *Hound*-fiſh beſide theſe, call the ſtarry *Hound*, or galeus aſterias, and muſtelus aſterias, or ſtellaris; but this has been found by Artedi to be no other than a variety of the firſt ſpecies, or ſmooth *Hound*-fiſh. See the articles SQUALUS, GALEUS, and MUSTELUS.

There is alſo another fiſh of the ſqualus kind, ſometimes called by this name, with the addition of the epithet rough. This is the morgay, or rough *Hound*-fiſh. It is the peſce gotto of the Italians, andthe catulus minor of authors; and the muſtelus ſtellaris tertius, or the third ſpecies of ſtarry *Hound*-fiſh of Bellonius. Artedi diſtinguiſhes it from the others, and from all the other ſquali, by the name of the ſqualus, with a variegated back, and with the belly-fins concreted together. See the articles SQUALUS and CATULUS.

HOUND's *Tongue*, *Cynogloſſum*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf, is funnel ſhaped, and divided into ſegments at the edges. From the cup of the flower there riſes a piſtil, which is fixed in manner of a nail to the hinder part of the flower, and is ſurrounded by four capſules, which are rough in moſt ſpecies, and contain a flat ſeed, fixed to a pyramidal quadrilateral placenta.

The ſpecies of *Hounds-tongue*, enumerated by Mr. Tournefort, are theſe: 1. The common great *Hounds-tongue*. 2. The great white-flowered *Hounds-tongue*. 3. The largeſt Dutch *Hounds-tongue*. 4. The large-flowered green-leav'd mountain *Hounds-tongue*. 5. The ſmaller-flower'd green-leav'd mountain *Hounds-tongue*. 6. The hoary mountain *Hounds-tongue*, with globular flowers. 7. The *Hounds-tongue*, with umbilicated fruit. 8. The broad-leav'd cretic ſtinking *Hounds-tongue*. 9. The cretic *Hounds-tongue*, with a narrow ſilvery leaf. 10. The Spaniſh gromwel-leav'd *Hounds-tongue*.

The plants called by Caſpar Bauhine, and others, the middle and the leſſer *Hounds-tongue*, are to be excluded from this genus, being properly ſpecies of bugloſs. *Tourn.* Inſt. p. 139.

The characters of *Hounds-tongue*, according to Linnæus, are theſe: The cup is an oblong acute perianthium, divided into five ſegments, and remaining when the flower is fallen. The flower conſiſts of a ſingle petal, of the length of the cup; this has a ſhort cylindric tube, and its end or edge is divided into five ſegments, and obtuſe. The opening of the flower is covered with five ſmall ſcales, which are convex, prominent, and converging one toward the other. The ſtamina are five very ſhort filaments, placed in the mouth of the flower. The antheræ are roundiſh and naked. The piſtillum has four germina. The ſtyle is tapering, of the length of the ſtamina, and remains when the flower is fallen. The ſtigma is rimmed round the edge. The fruit is compoſed of four capſules, of a flatted and roundiſh form, more obtuſe externally than within, and very rough, and not ſplitting open. The ſeeds are ſingle, or one in each capſule, and are ſmooth, of an oval figure, but gibboſe and pointed. The eſſential character of this genus is, that there are four capſules, each containing one ſeed, affixed to the ſtyle. *Linnæi* Gen. Plant. p. 58.

The common *Hounds-tongue* is eaſily known by the whitiſh colour, and ſoftneſs of its leaves, the beautiful purple of its flowers, and its diſagreeable ſmell. It is an excellent remedy in catarrhs, and will alone often cure a gonorrhœa ſimplex. The root is the part in which its virtues principally reſide. Externally it is uſed as a vulnerary, and is ſaid to cure even in ſcrophulous caſes.

HOUNDS, in a ſhip, are holes in the cheeks at the top of the maſts, through which the ties run to hoiſe the yards. A top-maſt hath but one *Hound*.

HOUR (*Cycl.*)—HOUR *Scale*, a divided line on the edge of Collins's quadrant, being only of tangents of forty-five degrees each, ſet together in the middle. Its uſe, together with the lines of latitudes, is to draw the *Hour*-lines of dials that have centers, by means of an equilateral triangle, drawn on the dial planes.

HOUSE (*Cycl.*)—HOUSE *of Lords*. Towards the latter end of the reign of king Charles the firſt, the *Houſe of Lords* aſſerted their juriſdiction of hearing appeals from the chancery, which they do, upon a paper petition, without any writ directed from the king; and for this their foundation is, that they are the great court of the king, and that therefore the chancery is derived out of it, and by conſequence, that a petition will bring the cauſe and the record before them. This was much controverted by the commons, in the reign of Charles the ſecond, but is now pretty well ſubmitted to, becauſe it has been thought too much, that the chancellor ſhould bind the whole property of the kingdom without appeal. New Abr. of Law, vol. 1. p. 584.

HOUSE *of Commons*. See the article COMMONS.

Hot-HOUSE. See the article HOT.

Green-HOUSE. See the article GREEN.

HOUSE-*Leek*. See the article SEDUM.

HOUSE *Painter*. See the article PAINTER.

HOUSED-*In*, in ſhip-building. The ſeamen ſay of a ſhip, which, after the breadth of her bearing is brought in too narrow to her upper works, that ſhe is *Houſed-in*, or pinched in too much.

HOUSSÉE, in the manege. See the article HOUSING, *Cycl.*

HOUSTONIA, in the Linnæan ſyſtem of botany, the name of a plant called *paronychiæ affinis* by Moriſon and ſome others. This makes alſo a diſtinct genus of plants, the characters of which are, that the calyx is an extremely ſmall erect perianthium, divided into four ſegments, and remaining after the flower is fallen. The flower conſiſts of one petal, in the ſhape of a funnel, with a long cylindric tube, and an open mouth, divided into four ſegments, which are roundiſh at their ends. The ſtamina are four extremely ſmall filaments, ſituated in the neck of the flower. The antheræ are ſimple. The germen of the piſtillum is roundiſh, and flatted. The ſtyle is ſingle, and ſhorter than the ſtamina; and the ſtigma bifid and acute. The fruit is a roundiſh double capſule, containing two cells, with two valves. The ſeeds are ſingle; and the valves placed oppoſite to the partition of the cells. *Linnæi* Gen. Plant. p. 26.

HOWLE, in ſhip-building. When the foot-hooks of a ſhip are ſcarfed into the ground timbers, and bolted, and then the plank laid on them up to the orlop, the carpenters ſay, they begin to make the ſhip *Howle*.

HOYACHU, in botany, the name given by the Chineſe to the acacia tree. They make great uſe of this tree in arts and medicine. They have a way of ſtriking a fine yellow upon paper with its flowers. And they give the ſeeds in ſeveral diſeaſes, in ſome of which, as in the dyſentery and hæmorrhages, they are of great ſervice. But, beſide theſe, they make an odd medicine of them, which they take with great readineſs for purpoſes it can never anſwer. They pick out the ſeeds carefully from the pods, as ſoon as ripe; they put theſe into a flat veſſel, and cover them with ox's gall; this is to be ſet for a hundred days to dry, in a place where the ſun does not come. After this, one of theſe ſeeds is to be ſwallowed every day before the firſt meal; and, by continuing this a proper time, they ſay the eye-ſight, if loſt, is reſtored, and their grey hairs become black. Obſerv. ſur les Coutumes de l'Aſie. p. 240.

HUBARI, in natural hiſtory, the name of a bird very often mentioned in the Arabian authors. It is deſcribed to be a bird ſomewhat larger than a gooſe, having very ſhort wings in proportion to its bulk, ſo that it cannot fly well, and therefore affording great ſport to the Syrian hunters. It is ſaid to be common about Damaſcus. By this place of its frequenting, and by the deſcription, it appears to be the buſtard, that bird being very plentifully found about Damaſcus, and being hunted with ſwift dogs on the ſandy plains thereabout.

HUCK, in ichthyography, a name uſed by ſome authors for the German river trout. It much reſembles the common river trout in ſhape, but is covered all over the back with innumerable black ſpots. The ſides are red, and have alſo ſome black ſpots, tho' they are not very numerous, on them. The under jaw has alſo ſome ſpots; but there are none on any other part of the head. The fins are red, and it differs from the common trout in having no teeth on the middle of its palate. It alſo grows to a much larger ſize than our trout, and has none of the red ſpots which are ſo plentiful on that fiſh. *Aldrovand.* de Piſc. L. 5. c. 14.

HUDSON'*s-Bay Porcupine*. See Tab. of Quadrupeds, N°. 15. and the articles HYSTRIX and PORCUPINE.

HUGONIA, in botany, the name of a genus of plants, the characters of which are theſe: The perianthium is ſmall, narrow, acute, and divided into five ſegments. The flower is compoſed of five large, round, and expanded petals. The ſtamina are ten ſubulated filaments, ſhorter than the flower. The antheræ are ſimple. The germen of the piſtil is roundiſh. The ſtyles are five in number, and are very ſlender. The ſtigmata are capitated. The fruit is a globoſe berry, affixed upon the cup. The ſeed is ſingle, ſtriated, and hard. *Linnæi* Gent. Plant. p. 203. Hort. Mal. vol. 2. p. 19.

HUITINGO *Pollachius*, in zoology, the fiſh we commonly call in Engliſh, the whiting pollack. It is a fiſh very like the common whiting in ſhape, but much larger, and is ſomething broader, and leſs thick. The back is either black, or of a very deep and duſky green; and its ſides, below the lines that run longitudinally through them, are variegated with ſhort lines of a duſky yellow. It is covered with extremely ſmall ſcales; and the longitudinal lines, on the ſides, riſe into an arch under the firſt back fin. The mouth is large, and the lower jaw projects a little beyond the upper. The teeth are ſmall, and very numerous in both jaws. The eyes are large, and its back prominent or arched up. It is common in the northern ſeas, and is a good fiſh for the table. Its food is other ſmaller fiſh, and particularly the ammodytæ or ſand eels, numbers of which are uſually found in its ſtomach. It is diſtinguiſhed from the cod by its head, being ſmaller, and its body broader and thinner; by its having no beard; and its loweſt pair of fins is much ſmaller than in that fiſh. *Willughby*, Hiſt. Piſc. p. 167.

HULLOCK *of a Sail*, at ſea, is when, in a great ſtorm, ſome ſmall part of a ſail is cut and left looſe: It is chiefly uſed in the mizzen-ſail, to keep the ſhip's head to the ſea; then all the reſt of the ſail is made up, except a little at the mizzen-yard-arm: Alſo when a ſhip will not *weather coyle*, to lay her head the other way, they looſe a *Hullock* of her fore-ſails; and then changing the helm to the weather ſide, ſhe is made to fall off, and to lay her head where her ſtern lay.

HUMATION, *Humatio*. The moſt antient way of diſpoſing of the dead was by *Humation*, or interrment. *Pitiſc.* See the articles BURYING and BURIAL.

HUMBLE-*Bee*, in the hiſtory of inſects. See the article BOMBYLIUS.

Baſtard HUMBLE-*Bee*. See the article FAUX *Bourdon*.

HUMBLE-*Bee Flies*, in natural hiſtory, the name of a claſs of flies of different ſizes, but all agreeing in the great reſemblance they bear to the *Humble* bees, of the ſmaller or middle-ſized ſpecies. Theſe might, at firſt ſight, very naturally paſs for real *Humble* bees; but a cloſer examination will ſhew them not to be ſuch, as they have not the trunk of the *Humble* bee, and have only two wings. The ſpecies of the *Humble* bee fly are many of them of abſolutely different genera one from another, ſome of them having trunks, and others having a diſtinguiſhable mouth. *Reaumur*, Hiſt. Inſ. vol. 4. p. 497.

If the figure of theſe flies, in their winged ſtate, attracts our curioſity and attention, their prior ſtate, that of the fly worm of moſt of them, ought ſurely much more to do ſo. The place nature has aſſigned the worms of theſe flies for their habitation, is indeed a moſt ſtrange one; there is no other place for them to live in under this form, to begin their deſtin'd growth, and be fitted for their transformations, but in the inteſtines of horſes, or under the thick and firm ſkin of oxen. In the latter caſe, the worm hatched from the egg of its parent fly, depoſited there, makes a tumour in the place, which alone furniſhes it with food and habitation, and in the middle of which it has a place to breathe. Ibid. p. 498. See the article HORSE-*Worm*.

It is not an invariable law of nature, however, that all the worms of the *Humble*-bee flies are to feed on animal ſubſtances, for we find ſome delighted with vegetable food, and particularly one which loves none but the bulbous roots of flowers. Ibid.

HUMERUS (*Cycl.*)—HUMERI *Octavus*, in anatomy, a name given by Fallopius, and others, to a muſcle called by Cowper, and ſince by Albinus and others, *teres minor*, and by the French anatomiſts, *la petit ronde*. Se the article TERES.

HUMERI *Os*. See the article Os *Humeri*.

HUMERUM *attollens*, in anatomy, a name given by Spigelius, and others, to a muſcle now generally known by the name of the *deltoides*.

HUMERI *primus*, in anatomy, a name given by ſome anatomical writers, to a muſcle generally known under the name of the *pectoralis*. See the article PECTORALIS.

Luxated HUMERUS. The *Humerus*, from the length and laxity of its ligaments, the largeneſs of its motion, and the ſhallowneſs of its cavity in the ſcapula, into which it is articulated, is rendered, of all the bones, the moſt ſubject and eaſy to be luxated. The head of this bone may often be diſlocated, under the arm-pit; ſometimes forward, ſometimes backward, and even below the ſcapula; but ſeldom perpendicularly downwards, and never directly upwards, unleſs the acromion and coracoide proceſſes of the ſcapula ſhould chance to be fractured at the ſame time; beſide, as long as the ſtrong deltoide and bicipital muſcle of the *Humerus* remain entire, they greatly reſiſt and keep down the *Humerus* from being luxated upwards. As ſoon as a luxation is diſcovered in the *Humerus*, the ſafeſt way to attempt the reduction of it, is to place the patient on the floor, or on a low ſtool; two ſtrong aſſiſtants are then to be placed on each ſide of him, one to keep firmly hold of his body, that it may not give way to the extenſion, while the other lays hold of the luxated arm with both his hands, a little above the cubitus, gradually and ſtrongly extending it. But before that extenſion be made, the ſurgeon himſelf ſhould have a large and ſtrong napkin, of a ſufficient length, tied at the ends, and hung about his neck, ſo that the knot may hang behind, but the other part of the napkin over his breaſt. The patient's arm muſt then be put through this napkin, up to the ſhoulder, and the ſurgeon muſt lay hold of the head of the *Humerus* with both his hands. This done, the aſſiſtant, who has hold of the arm, is to extend it ſufficiently, and the ſurgeon is to elevate the head of the *Humerus*, by means of the napkin through which the arm is put, directing it with his hands, till it ſlips into its former cavity in the ſcapula.

This ſeems the moſt ſafe, ready, and commodious of all methods, for reducing luxations of the *Humerus*; but it is to be acknowledged, that the extenſion cannot, by this means, be made ſufficiently ſtrong, in ſome caſes, particularly when the patient is very robuſt, or when the caſe has been delayed a conſiderable time without aſſiſtance. When one or two aſſiſtants therefore are not ſufficient to make a proper extenſion, it is eaſy to employ more, by means of napkins tied about the limb, and a proper number of aſſiſtants to hold the patient's body ſteady againſt that force. And when all this is not ſufficient, the ſurgeon is forced to have recourſe to machines with ropes and pullies; which, though the patient is uſually terrified a little at them, yet make an eaſier, and a more equal and regular extenſion, than can be done by the hands of ever ſo many aſſiſtants. *Heiſter*, p. 160.

HUMILIS *Muſculus*, (*Cycl.*) in anatomy, a name mentioned by Caſſerius, as given by ſome people of his time to one of the muſcles of the eye, the rectus inferior of Fabricius, and deprimens of Riolan: It is the depreſſor oculi of Albinus, being one of the quatuor recti muſculi oculorum of that author.

HUMILIATI, a congregation of religious in the church of Rome, which was aboliſhed by pope Pius the fifth, for their luxury and cruelty. *Hofm.* Lex. in voc.

HUMISUGA, the *Ground-Sucker*, in natural hiſtory, the name of a fly, ſo called, becauſe it is ſuppoſed to live by ſucking the juices of the earth, without taking in any ſolid food. It has a browniſh or dun body; a white ſpot at the inſertion of the wings, and another at the head; the legs are black; the back is grey, with four ſullied white lines running longitudinally. The wings are ſilvery, and, if put into water, they ſhine with a bright light like that of the glow-worm. This creature is common with us about path-ways, and on mole-hills, and other places where the ground is newly turned up. We call it the *path-fly*.

HUMMING *Bird*, the name of a very beautiful genus of American birds, the ſmalleſt of all birds; which make a *humming* like a bee as they fly. See Tab. of Birds, N°. 34. and the article GUAINUMBI.

HUMOR (*Cycl.*) — *Chryſtalline* HUMOR. See the article CHRYSTALLINE.

HUMP-*back*. See the article GIBBOUS.

HUNDRED (*Cycl.*)—*Docimaſtic* HUNDRED, or *Centner*, in metallurgy and aſſaying, is a weight diviſible, firſt into an *hundred*, and thence into a great number of other ſmaller parts; but though the word is the ſame, both with the aſſayers and metallurgiſts, yet is to be underſtood as expreſſing a very different quantity in their different acceptation of it. The weights of the metallurgiſts are eaſily underſtood, as being of the common proportion, but thoſe of the aſſayers are a thouſand times ſmaller than theſe, as the portions of metals or ores examined by the aſſayers are uſually very ſmall.

The metallurgiſts, who extract metals out of their ores, uſe a weight divided into an *hundred* equal parts, each part a pound; the whole they call a *centner* or *hundred* weight; the pound is divided into thirty-two parts, or half ounces; and the half ounce into two quarters of ounces, and theſe each into two drams.

Theſe diviſions and denominations of the metallurgiſts are eaſily underſtood; but the ſame words, though they are are equally uſed by aſſayers, with them expreſs very different quantities; for as the *centner* of the metallurgiſts contains an *hundred* pounds, the *centner* of the aſſayers is really no more than one dram, to which the other parts are proportioned.

As the aſſayers weights are divided into ſuch an extreme degree of minuteneſs, and are ſo very different from all the common weights, the aſſayers uſually make them themſelves in the following manner, out of ſmall ſilver, or fine ſolder plates, of ſuch a ſize, that the mark of their weight, according to the diviſion of the dram, which is the *docimaſtic*, or aſſaying *centner*, may be put upon them. They firſt take for a baſis one weight, being about two-thirds of a common dram: This they mark (64 lb.) Then having at hand ſome granulated lead, waſhed clean, well dried, and ſifted very fine, they put as much of it in one of the ſmall diſhes of a fine ballance, as will equipoiſe the (64 lb.) as it is called, juſt mentioned: Then dividing this granulated lead into very nice halves, in the two ſcales, after taking out the firſt ſilver weight, they obtain a perfect equilibrium between the two ſcales; they then pour the granulated lead out of one diſh of the ſcales, and inſtead of it put in another ſilver weight, which they make exactly equiponderant with the lead in the other ſcale, and mark it (32 lb.). If this ſecond weight, when firſt put into the ſcale, exceed by much the weight of the lead, they take a little from it by a very fine file, but when it comes very near, they uſe only a whetſtone to wear off an extremely ſmall portion at a time. When it is brought to be perfectly even and equal to the lead, they change the ſcales to ſee that no error has been committed, and then go on in the ſame manner till they have made all the diviſions, and all the ſmall weights. Then to have an entire *centner*, or *hundred* weight, they add to the (64 lb.) as they call it a 32 lb. and a 4 lb. and weighing againſt them one ſmall weight, they make it equal to them, and mark it (100 lb.). This is the docimaſtical or aſſaying *centner*, and is really one dram. *Cramer*, Art. Aſſ. p. 108.

HUNEN, in the materia medica, a name given by ſome writers to the jujube. *Ger.* Emac. Ind. 2.

HUNGARICA *Bolus*, in the materia medica, a medicinal earth, commonly known by the name of *bolus toccavienſis*. *Hill*'s Hiſt. of Foſſ. p. 7. See the article TOCCAVIENSIS.

HUNGER (*Cycl.*)—See the articles BULIMY and OREXIS.

HUNGRY *Evil*, a term uſed among the farriers for the ſame diſtemperature in horſes, which in men we call a canine appetite. It manifeſts itſelf ſufficiently in an inordinate deſire to eat, and is ſometimes the effect of long ſtarving, ſometimes of cold, or ſome other internal or external cauſe. In the latter caſe the horſe not only eats a large quantity, but he devours it in a very remarkable manner, chopping it up as if he would eat the very manger. The method of cure is to give him large toaſts of bread ſteeped in ſack, or ſome other ſweet wine; or give him a quantity of wheat flower in wine, or in milk, a quart or more at a time. Theſe are very good remedies in caſe of extremity, but otherwiſe he may be cured by feeding him moderately with bean bread ſeveral times a day, allowing no other food.

HUNTER, a name given to a horſe qualified to carry a perſon in the chaſe. The ſhape of the horſe deſigned for this ſervice, ſhould be ſtrong and well knit together, as the jockies expreſs it. Irregular or unequal ſhapes in theſe creatures, are always a token of weakneſs. The inequalities in ſhape which ſhew a horſe improper for the chace, are the having a large head and a ſmall neck, a large leg and a ſmall foot, and the like. The head of the *Hunter* ſhould indeed always be large, but the neck ſhould alſo be thick and ſtrong to ſupport it. The head ſhould be lean, the noſtrils wide, and the wind pipe ſtrait.

The *Hunter* in order to his behaving well in the field, ought to have great care and indulgence in the ſtable, he ought to have as much reſt and quiet as may be, to be kept well ſupplied with good meat, clean litter, and freſh water by him; he ſhould be often dreſſed, and ſuffered to ſleep as much as he pleaſes. He ſhould be ſo fed that his dung may be rather ſoft than hard, and it muſt be of a bright and clean colour. All this may be eaſily managed by the continual obſervance and change of his food, as occaſion requires. After his uſual ſcowerings he ſhould have exerciſes and maſhes of ſweet malt, or bread and beans, or wheat and beans mixed together, are to be his beſt food, and beans and oats his worſt.

Some very great ſportſmen are for keeping their horſes out at graſs all the buck-hunting ſeaſon, never taking them up into the ſtable at all, but allowing them in the field as much oats with their graſs as they will eat. The horſe may be thus rid three days in the week for the whole ſeaſon, and never damaged by it, nor ever ſhewing any marks of harm afterwards.

The whole ſhape of a horſe intended for a *Hunter*, ſhould be this: The ears ſhould be ſmall, open, and pricked; or tho' they be ſomewhat long, yet if they ſtand up erect, and bold like thoſe of a fox, it is a ſign of toughneſs or hardineſs. The forehead ſhould be long and broad, not flat; or, as it is uſually termed, mare-faced, but riſing in the middle like that of an hare; the feather ſhould be placed above the eye, the contrary being thought by ſome to threaten blindneſs. The eyes ſhould be full, large, and bright; the noſtrils not only large, but looking red and freſh within, for an open and freſh noſtril is always eſteemed a ſign of a good wind. The mouth ſhould be large, deep in the wicks and hairy. The wind-pipe ſhould be large, and appear ſtrait when he bridles his head; for if, on the contrary, it bends like a bow on his bridling, it is not formed for a free paſſage of the breath. This defect in a horſe is expreſſed among the dealers by the phraſe cock-throppled. The head ſhould be ſo ſet on to the neck, that a ſpace may be felt between the neck and the chine; when there is no ſuch ſpace, the horſe is ſaid to be bull-necked, and this is not only a blemiſh in the beauty of the horſe, but it alſo occaſions his wind not to be ſo good. The creſt ſhould be ſtrong, firm, and well riſen; the neck ſhould be ſtrait and firm, not looſe and pliant; the breaſt ſhould be ſtrong and broad, the ribs round like a barrel, the fillets large, the buttocks rather oval than broad, the legs clean, flat, and ſtrait; and, finally, the mane and tail ought to be long and thin, not ſhort and buſhy, the laſt being counted a mark of dullneſs.

When a *Hunter* is thus choſen, and has been taught ſuch obedience, that he will readily anſwer to the rider's ſignals both of the bridle and hand, the voice, the calf of the leg, and the ſpurs; that he knows how to make his way forward, and has gained a true temper of mouth, and a right placing of his head, and has learned to ſtop and to turn readily, if his age be ſufficiently advanced he is ready for the field. It is a rule with all ſtaunch ſportſmen, that no horſe ſhould be uſed in hunting till he is full five years old; ſome will hunt them at four, but the horſe at this time is not come up to his true ſtrength and courage, and will not only fail at very tough trials, but will be ſubject to ſtrains and accidents of that kind, much more than if he were to be kept another year firſt, when his ſtrength would be more confirmed.

When the *Hunter* is five years old, he may be put to graſs from the middle of May till Bartholomew-tide; for the weather between theſe is ſo hot, that it will be very proper to ſpare him from work. At Bartholomew-tide the ſtrength of the graſs beginning to be nipp'd by froſts and cold dews, ſo that it is apt to engender crudities in the horſe, he ſhould be taken up, while his coat is yet ſmooth and ſleek, and put into the ſtable. When he is firſt brought home, he ſhould be put in ſome ſecure and ſpacious place, where he may evacuate his body by degrees, and be brought not all at once to the warm keeping; the next night he may be ſtabled up. It is a general rule with many not to cloath and ſtable up their horſes till two or three days after they are taken from graſs, and others who put them in the ſtable after the firſt night, yet will not dreſs and cloath them till three or four days afterward; but all this, except the keeping the horſe one day in a large and cool place, is needleſs caution.

There is a general practice among the grooms, in many places, of giving their *Hunters* wheat ſtraw as ſoon as they take them up from graſs. They ſay they do this to take up his belly; but there ſeems much reaſon to diſapprove of this. The change is very violent, and the nature of the ſtraw ſo heating and drying, that there ſeems great reaſon to fear that the aſtringent nature of it would be prejudicial, more than is at firſt perceived. It is always found that the dung is hard after this food, and is voided with pain and difficulty, which is in general very wrong for this ſort of horſe. It is better therefore to avoid this ſtraw-feeding, and to depend upon moderate airing, warm cloathing, and good old hay, and old corn, than to have recourſe to any thing of this kind.

When the horſe has evacuated all his graſs, and has been properly ſhod, and the ſhoes have had time to ſettle to his feet, he may be ridden abroad, and treated in this manner: The groom ought to viſit him early in the morning, at five o'clock in the long days, and at ſix in the ſhort ones; he muſt then clean out the ſtable, and feel the horſe's neck, flank, and belly, to find the ſtate of his health. If the flank feels ſoft and flabby, there is neceſſity of good diet to harden it, otherwiſe any great exerciſe will occaſion ſwellings and goutineſs in the heels. After this examination, a handful or

two of good old oats well ſifted ſhould be given him; this will make him have more inclination to water, and will alſo make the water ſit better on his ſtomach, than if he drank faſting. After this he is to be tied up and dreſſed. If in the doing of this he opens his mouth, as if he would bite, or attempts to kick at the perſon, it is a proof that the teeth of the currycomb are too ſharp, and muſt be filed blunter. If after this he continues the ſame tricks, it is through wantonneſs, and he ſhould be corrected for it with the whip. The intent of currying being only to raiſe the duſt, this is to be bruſhed off afterwards with a horſe-tail nailed to a handle, or any other light bruſh. Then he is to be rubbed down with the bruſh, and duſted a ſecond time; he ſhould then be rubbed over with a wet hand, and all the looſe hairs, and whatever foulneſs there is, ſhould be picked off. When this is done, and he is wiped dry as at firſt, a large ſaddle-cloth is to be put on, reaching down to the ſpurring place; then the ſaddle is to be put on, and a cloth thrown over it that he may not take cold: Then rub down his legs, and pick his feet with an iron picker, and let the mane and tail be combed with a wet mane-comb. Laſtly, it is a cuſtom to ſpurt ſome beer in his mouth juſt before the leading him out of the ſtable. He ſhould then be mounted, and walked a mile at leaſt to ſome running water, and there watered; but he muſt only be ſuffered to take about half his water at one drinking.

It is the cuſtom of many to gallop the horſe at a violent rate as ſoon as he comes out of the water, but this is extremely wrong for many reaſons. It endangers the breaking a horſe's wind more than any other practice, and often has been the occaſion of burſting very good horſes. It uſes them alſo to the diſagreeable trick we find in many horſes, of running away as ſoon as ever they come out of the water; and with ſome it makes them averſe to drinking, ſo that they will rather endure thirſt, and hurt themſelves greatly by it, than bring on the violent exerciſe which they remember always follows it. The better way is to walk him a little after he is out of the water, then put him to a gentle gallop for a little while, and after this to bring him to the water again. This ſhould be done three or four times, till he will not drink any more. If there is a hilly place near the watering place, it is always well to ride up to it; if otherwiſe, any place is to be choſen where there is free air and ſun. That the creature may enjoy the benefit of this, he is not to be galloped, but walked about in this place an hour, and then taken home to the ſtable. The pleaſure the horſe himſelf takes in theſe airings when well managed, is very evident, for he will gape, yawn, and ſhrug up his body; and in theſe, whenever he would ſtand ſtill to ſtale, dung, or liſten to any noiſe, he is not to be hindered from it, but encouraged in every thing of this kind.

The advantages of theſe airings are very evident, they purify the blood, teach the creature how to make his breathing agree with the reſt of the motions of his body, and give him an appetite to his food, which *Hunters* and racers, that are kept ſtalled up, are otherwiſe very apt to loſe. On returning from airing the litter in the ſtable ſhould be freſh, and by ſtirring this, and whiſtling, he will be brought to ſtale. Then he is to be led to his ſtall, and tied up, and again carefully rubbed down; then he ſhould be covered with a linnen cloth next his body, and a canvas one over that, made to fit him, and reaching down to his legs. This, as the duke of Newcaſtle obſerves, is a cuſtom which we learnt of the Turks, who are of all people the moſt nice and careful of their horſes. Over this covering there ſhould be put a body-cloth of ſix or eight ſtraps; this keeps his belly in ſhape, and does not hurt him. This cloathing will be ſufficient while the weather is not very ſharp, but in ſevere ſeaſons, when the hair begins to riſe and ſtart in the uncovered parts, a woollen cloth is to be added, and this will always prove fully ſufficient.

Different horſes, and different ſeaſons, make variety of the degree of cloathing neceſſary; but there always is an obvious rule to point out the neceſſary changes, the roughneſs of the coat being a mark of the want of cloathing, and the ſmoothneſs of it a proof that the cloathing is ſufficient. Therefore if at any time the hair is found to ſtart, it is a notice that ſome farther cloathing is to be added.

If the horſe ſweat much in the night, it is a ſign that he is over fed, and wants exerciſe, this therefore is eaſily remedied. An hour or more after the horſe is come in from his airing, the groom ſhould give him a wiſp of clean hay, making him eat it out of his hand; after this let the manger be well cleaned out, and a quartern of oats clean ſifted be given him. If he eats up this with an appetite, he ſhould have more given him; but if he is ſlow and indifferent about it, he muſt have no more. The buſineſs is to give him enough, but not to cloy him with food.

If the horſe gets fleſh too faſt on this home feeding, he is not to be ſtinted to prevent it, but only his exerciſe encreaſed; this will take down his fleſh, and at the ſame time give him ſtrength and wind. After the feeding in the morning is over, the ſtable is to be ſhut up, only leaving him a little hay on his litter. He need be no more looked at till one o'clock, and then only rubbed down, and left again to the time of his evening watering, which is four o'clock in the ſummer, and three in the winter. When he has been watered, he muſt be kept out an hour or two, or more if neceſſary, and then taken home and rubbed as after the morning watering. Then he is to have a feed of corn at ſix o'clock, and another at nine at night; and being then cleaned, and his litter put in order, and hay enough left for the night, he is to be left till morning. This is the direction for one day, and in this manner he is to be treated every day for a fortnight, at the end of which time his fleſh will be ſo hardened, his wind ſo improved, and his mouth ſo quickened, and his gallop brought to ſo good a ſtroke, that he will be fit to be put to moderate hunting. During the time that he is uſed in hunting, he muſt be ordered on his days of reſt exactly as is directed for the fortnight when he is in preparation; but as his exerciſe is now greatly increaſed, he muſt be allowed a more ſtrengthning food, mixing ſome old ſplit beans at every feeding with his oats.

And if this is not found to be ſufficient, the following bread muſt be given: Let two pecks of old beans, and one peck of wheat be ground together, and made into an indifferently fine meal; then knead it into dough with ſome warm water, and a good quantity of yeaſt; let it lie a time that it may riſe and ſwell, which will make the bread the lighter; then make it into loaves of a peck each, and let it be baked in a ſlow oven that it may be thoroughly done without being burnt; when it is taken out of the oven, it muſt be ſet bottom upwards to cool; when it is one day old the cruſt is to be chipp'd off, and the crumb given him as food. When this is ready, he ſhould have ſome of it at leaſt once in the day; but it is not to be made the only food, but ſome feeds are to be of oats alone, ſome of oats and this bread, and ſome of oats and beans mixed together. The making a variety in this manner, being the beſt of all methods of keeping up the appetite, which is often apt to fail.

The day before the horſe is to hunt, he muſt have no beans, becauſe they are hard of digeſtion, but only ſome oats with this bread; or if he will be brought to eat the bread alone, that will be beſt of all. His evening feed ſhould, on this day, be ſomewhat earlier than uſual; and after this he is only to have a wiſp of hay out of the groom's hand till he return from hunting. See the article HUNTING, *Cycl.*

HUNTING *Saddle.* See the article SADDLE.

HURRERS, in our old writers. The cappers and hat-makers of London, formerly one company of the haberdaſhers were called by this name. *Stow*'s Survey of London, p. 312.

HURRICANES (*Cycl.*)—Great miſchiefs are done to our veſſels about the Caribbee Iſlands and elſewhere by means of the *Hurricanes*, and at the time of year when they are moſt frequent, which is in the midſt of ſummer. It has been uſual with our captains to ſend to the negroes to know whether there would be any within a week or ten days, in which they were very rarely diſappointed, the natives having, by long obſervation, acquired a way of prognoſticating them, which ſeldoms fails. The method of thus foretelling them, as communicated by one of the natives to captain Langford, depended on theſe obſervations: All *Hurricanes* come on either on the day of full moon, or at the change, or on ſome of the quarters. If the *Hurricane* is to come on at the full moon, the ſigns are to be obſerved at the change, and they are theſe: The ſky will appear very turbulent, and the ſun will look more red than at other times; a great calm alſo, with no clouds or fogs about the hills, is another ſign; for the highlands ſeldom are ſeen to be ſo, unleſs by this accident of an enſuing *Hurricane* at ſuch a time. Alſo there will be heard a great murmuring noiſe in wells, or other hollows of the earth; and at night the ſtars will look very bright, but they will have barrs about them. The north-weſt ſky will look very black and foul; the ſea ſwelling ſtronger than at other times; and ſometimes that day the winds will blow very ſtrong weſterly for about two hours. At the full moon there happen the ſame ſigns, if the *Hurricane* is to be about the quarters, and there is ſeen a hazy circle about the moon, and ſometimes the ſame day about the ſun. The like ſigns muſt be taken notice of on the quarter days of the moon, in the months of July, Auguſt, and September.

All the *Hurricanes* about Jamaica begin with a north wind, and on the wind's coming about eaſt they ceaſe. It is obſervable, that the air is much colder during theſe *Hurricanes* than at other times; but Ligon, and ſome others, fond of relating ſtrange ſtories, make it much more ſo than it really is, the ſailors who have been in theſe ſtorms, declaring that they have felt no ſuch chilline's as thoſe authors relate. The wind during the *Hurricane* is ſo ſtrong, and varies ſo faſt between the north and north-eaſt point, that it is impoſſible for any ſhip to anſwer the veerings of it; it is hence that all the art of the ſailors often cannot prevent the backs of the veſſels from being broken, and the maſts carried by the board. The main-maſt of a ſhip of four hundred tun, will be in an inſtant wreathed like a wyth, and borne by the board before they can hand a ſail. Phil. Tranſ. N° 36.

Swiſſerland is ſubject to very violent *Hurricanes*, which do great miſchief, and that in a very ſingular manner. Thunder and lightening are frequent with them in winter as well as in ſummer; and the more violent ſtorms of theſe, are ſometimes attended

attended with whirlwinds and *Hurricanes*, which will raiſe up the water of ſome lakes in form of a thick pillar up to the cloud, and carrying on before the wind this vaſt body of water, will ſometimes fall in other places on dry land, and drown the houſes and gardens where it chances to fall.

HURST, or HYRST, in our old writers, denotes a wood or grove of trees. Hence ſuch places as have this word for part of their names, have been ſituate near a wood. In Kent, Suſſex, and Hampſhire, there are many ſuch, becauſe formerly the great wood called *Andreſwald*, extended itſelf thro' theſe counties.

HUSBAND (*Cycl.*)—HUSBAND-*land*, a term uſed in Scotland for a portion of land containing ſix acres of ſock and ſcythe land; that is, of land that may be tilled with a plough, and mowen with a ſcythe. Tr. Pract. Geom. p. 86.

HUSBANDRY. The new method of *Huſbandry*, called by Tull the horſehoeing *Huſbandry*, has many evident advantages over the other, or old way; but the difference between them in regard to the former, is beſt explained by a fair compariſon. In order to do this juſtly, there are four things to be carefully conſidered: 1. The expence of a crop. 2. The goodneſs of the crop. 3. The certainty of it. And, 4. The condition in which the land is left after the crop.

The profit or loſs ariſing from land, is not to be computed only from the value of the crop it produces, but from its value after all expences of ſeed, tillage, &c. are deducted. Thus when an acre of land produces a crop worth four pounds, and the expences of it amount to five pounds, the loſs of the farmer is one pound upon it; whereas, when as much land produces a crop only of the value of thirty ſhillings, and the expences are only ten ſhillings, the owner receives one pound advantage. The common expence of an acre of ſowed wheat, in the uſual way, is four pounds ten ſhillings, and the common expence of an acre of wheat, in the horſe-hoeing *Huſbandry*, is only ten ſhillings, including all the expences that can attend it. Thus this method of *Huſbandry* is but a ninth part of the charge of the common way; and as no ſheep are required, as there are in the other way, the leſs ſtock will do to begin with.

The goodneſs of a crop conſiſts in the quality of it as well as in the quantity, and wheat being the moſt uſeful of all grain, a crop of this is more valuable than a crop of any other corn. Add to this, that a crop of hoed wheat has always larger ears, and a fuller body, than a crop when ſown in the common way. More wheat may alſo be obtained this way than any other, becauſe the ſame land will thus produce crops every year; and even the land which has been exhauſted by the common *Huſbandry*, will produce wheat in plenty this way, without fallowing or dunging, both which would otherwiſe be neceſſary. So that, in many places, this *Huſbandry* can raiſe ten acres of wheat for one that the old way could produce, becauſe where land is poor, they ſow but a tenth part of it in wheat. *Tull*'s Horſe-hoeing Huſbandry, p. 124.

The largeſt produce of an acre of wheat land, ſo far as has yet been experienced, ſeems to be ten quarters, or eighty buſhels to an acre. This is leſs indeed than the produce of an acre in the common way, according to *Houghton*'s computation; but to compare the different profits to the farmer, we proceed thus: The rent and expences of a drilled acre being one pound, and that of a ſowed acre in the common way being five pounds, one quarter of corn produced by the drilled, bears an equal proportion to one pound in profit, as five quarters produced in the common way do to five pounds. As ſuppoſe it to be of wheat at two ſhillings and ſix-pence a buſhel, there is neither gain nor loſs in the one nor the other acre, tho' the drilled produce only one quarter, and the other five quarters.

But if the drilled acre yield two quarters, and the ſown acre yield only four quarters at the ſame price, the drilled acre brings the farmer one pound profit, while the other has one pound loſs. Likewiſe ſuppoſe the drilling farmer to have his five pounds laid out in five acres of wheat, and the other to have his five pounds laid out in one dunged acre, then let the price be what it will for the wheat, if the five acres have an equal crop to the one acre, the gain and loſs muſt be equal. But if the price of wheat be at two ſhillings and ſix-pence, the farmer in the common way, if he have five quarters on his acre, muſt ſell it all to pay his rent; whereas if he who drills the land have five quarters on each acre, the produce of one acre will pay for all five. Or ſuppoſe a drilled acre to produce no more than one third of the ſown acre, which is rating it very low indeed, the expence of the ſown acre being five times as much as that of the drilled one, it is much more profitable to the owner to have the drilled acre; becauſe a third part of five pound is one pound thirteen and four-pence, and a fifth of the rent and expence, which is all his charge, being only one pound, ſuch a drilled acre brings the owner thirteen and four-pence profit more than the ſown acre, tho' that brings three times as great a crop. Id. ibid. p. 130.

The certainty of a crop is greater this way than in the old way of ſowing; for moſt of the accidents attending wheat crops, are owing to their being late ſown, which is neceſſary to the farmer in the old way; but in the horſe-hoeing method the farmer may plough two furrows whereon the next crop is to ſtand, immediately after the firſt crop is off. In this manner of *Huſbandry* the land may be ploughed dry and drilled wet, without any inconvenience; and the ſeed is never planted under the furrow, but placed juſt at the depth which is moſt proper, that is at about two inches, in which caſe it is eaſy to preſerve it, and there is no danger of burying it. Thus the ſeed has all the advantage of early ſowing, and none of the diſadvantages that may attend it in the other way, and the crop is much more certain than by any other means that can be uſed.

The condition in which the land is left after the crop, is no leſs in favour of the horſe-hoeing *Huſbandry*, than all the other articles. The number of plants is the great principle of the exhauſting of land. In the common *Huſbandry*, the number is vaſtly greater than in the drilling way, and three plants in four often come to nothing, after having exhauſted the ground as much as profitable plants; and the weeds which live to the time of harveſt in the common way, exhauſt the land no leſs than ſo many plants of corn, often much more. The horſe-hoeing method deſtroys all the weeds in the far greater part of the land, and leaves that part unexhauſted and perfectly freſh for another crop. The wheat plants being alſo but a third part of the number at the utmoſt of thoſe in the ſowing way, the land is ſo much the leſs exhauſted by them; and it is very evident from the whole, that it muſt be, as experience proves that it is, left in a much better condition after this than after the common *Huſbandry*.

The farmers who are againſt this method, object that it makes the plants too ſtrong, and that they are more liable to the blacks, or blights of inſects for that reaſon; but as this allows that the hoeing can, without the uſe of dung, give too much nouriſhment, it is very plain that it can give enough; and it is the farmer's fault if he do not proportion his pains ſo as to have the advantage of the nouriſhment without the diſadvantages. It is alſo objected, that as hoeing can make poor land rich enough to bear good crops of wheat, it may make good land too rich for it. But if this ſhould happen, the ſowing of wheat on it may be let alone a while, and in the place of it the farmer may have a crop of turneps, carrots, cabbages, and the like, which are excellent food for cattle, and cannot be over-nouriſhed: Or if this is not choſen, the land, when thus made too rich, may ſoon be ſufficiently impoveriſhed by ſowing corn upon it in the common old way. See HOEING.

Virgilian HUSBANDRY, a term uſed by authors to expreſs that ſort of *Huſbandry*, the precepts of which are ſo beautifully delivered in Virgil's georgics. The *Huſbandry* in England is *virgilian* in general, as is ſeen by the method of paring and burning the ſurface, of raftering or croſs-plowing, and of the care in deſtroying weeds upon the ſame principle, and by much the ſame means. In thoſe parts of England along the ſouthern coaſt, where the Romans principally inhabited, not only the practice, but the expreſſions are in many reſpects the ſame with thoſe of the antient Romans, many of the terms uſed by the plowmen being of Latin origin, and the ſame with thoſe uſed by thoſe people on the like occaſions. And on a ſtrict obſervation, more of Virgil's *Huſbandry* is at this time practiſed in England than in Italy itſelf. This change in the Italian *Huſbandry*, is, however, much more to the credit of that people, than the retaining the *virgilian* ſcheme is to ours.

Tull, who has eſtabliſhed a new method of *Huſbandry*, obſerves, that it is upon the whole ſo contradictory to this old plan, that it may be called the *antivirgilian Huſbandry*; and adds, that no practice can be worſe than the *virgilian*.

Antivirgilian HUSBANDRY, a term uſed by Mr. Tull to expreſs a new ſyſtem of *Huſbandry* which he has introduced, founded upon principles ſo different from the common *Huſbandry* of England, which in general is the ſame with that delivered in Virgil, that it deſerves this contrary title. See the articles HOEING and HUSBANDRY, ſupra.

HUSBRECE, in our old writers, an offence now called *Burglary*. See BURGLARY, *Cycl.*

The word is Saxon from *hus*, a houſe; and *brice*, a breaking. *Blount*, in voc.

HUSCANS, in our old writers, a ſort of boot or buſkin made of coarſe cloth, and worn over the ſtockings: We find them mentioned in the Stat. 4 Edw. 4. c. 7. *Blount*.

HUSGABLE, *Huſgablum*, in our old writers, denotes houſe-rents, or ſome tax or tribute laid upon houſes. *Blount*.

HUSKS (*Cycl.*)—The *Huſks* or cup of the flowers of plants are not ſo much regarded with a view to their medicinal virtues as they deſerve. Petiver, in the Philoſophical Tranſactions, ſpeaking of the virtues of the verticellate claſs of plants, among which are included the ſage, roſemary, and the like, obſerves that it is an erroneous, though general opinion, that the flowers of theſe plants contain their principal virtues, for that the *Huſks* are the part in which this is lodged. For inſtance in the roſemary, the fine ſcent of the Hungary-water is not in the flowers, but *Huſks*; and the flowers alone, when clean pick'd from them, yield very little odour. The cups in this and other plants of the ſame claſs, is the only part in which their viſcous and ſulphureous qualities are lodged, and that ſomething of this kind is depoſited particularly there, may be perceived by the touch and ſmell; for they appear moiſt, and feel

feel clammy; and this clammy matter, when received upon the fingers, is of a very ſtrong and agreeable ſmell, much more ſo than the reſt of the plant.

HUSO *Germanorum*, in zoology, the name of a large fiſh of the ſturgeon kind, caught in the Danube, Boriſthenes, and other large rivers, and paſſing at times into the ſea. It has a very long ſnout, and under it either four or eight beards. It has one back-fin, which is placed near the tail, and two pair under the belly; its general ſhape ſomewhat reſembles that of the pike, and its back is black, and its belly yellow; it has no ſcales, and has cartilages in the ſtead of bones. It is caught in October and November, and in ſome places till January; and great numbers of them are uſually brought to market together in thoſe months in the countries where they are caught. They always ſwim in ſhoals. It grows to twenty four feet long, and weighs one, two, three, or even four hundred pounds. The drug called iſinglaſs is prepared from this fiſh. *Ray*'s Ichthyograp. p. 243. See Tab. of Fiſhes, N° 42. and the article ISINGLASS.

HUTZOCHITL, in botany, a name by which ſome authors have called the tree which affords the black balſam of Peru. *De Laet.* Ind. Occ. p. 224.

HYACINTH, ὑάκινθος, (*Cycl.*) in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the liliaceous kind, but conſiſts only of one petal divided into ſix ſegments at the end, and is of the tubular ſhape of many of the bell-faſhioned flowers. The piſtil ariſes from the bottom of the flower, and finally becomes a roundiſh ſeed veſſel, lightly ridged into a ſort of three-cornered ſhape, and divided into three cells, each of which contains a number of roundiſh or flatted ſeeds.

The ſpecies of *Hyacinth* enumerated by Mr. Tournefort are theſe: 1. The great blue *Hyacinth* with oblong flowers. 2. The great amethyſtine *Hyacinth* with oblong flowers. 3. The fleſh-coloured Engliſh *Hyacinth*. 4. The grey Engliſh *Hyacinth*. 5. The white *Hyacinth* of Dodonæus. 6. The *Hyacinth* with oblong flowers of blue and white. 7. The *Hyacinth* with oblong brown flowers. 8. The duſky-flowered *Hyacinth*. 9. The duſky greeniſh-flowered *Hyacinth*. 10. The late flowering duſky *Hyacinth*. 11. The late flowering white *Hyacinth*. 12. The *Hyacinth* with greeniſh yellow flowers. 13. The *Hyacinth* with ſmall oblong blue flowers. 14. The *Hyacinth* with ſmall oblong white flowers. 15. The ſmall Spaniſh *Hyacinth* with mixed flowers, and with the appearance of the oriental kinds. 16. The *Hyacinth* with oblong bright red flowers. 17. The *Hyacinth* with bell-faſhioned flowers, ſtanding all on one ſide of the ſtalk. 18. The bell-flowered *Hyacinth* with flowers on both ſides the ſtalk. 19. The oriental, or Conſtantinople *Hyacinth*, with ſpotted ſtalks. 20. The ſpotted-ſtalked oriental *Hyacinth*, with violet-coloured flowers. 21. The purple oriental *Hyacinth*. 22. The many flowered oriental *Hyacinth*, with blue flowers and very ſhort cups. 23. The purpliſh-white oriental *Hyacinth*. 24. The duſky-white oriental *Hyacinth*. 25. The ſnow-white oriental winter *Hyacinth*. 26. The ſilver-coloured oriental *Hyacinth*. 27. The winter oriental *Hyacinth*, with blue flowers, and with leaves ſtained toward their bottoms, with purple ſpots. 28. The large white oriental winter *Hyacinth*. 29. The largeſt oriental *Hyacinth*. 30. The largeſt oriental *Hyacinth*, with white flowers. 31. The largeſt oriental *Hyacinth*, with bright red flower cups. 32. The many flowered oriental *Hyacinth*, with blue flowers. 33. The many flowered oriental *Hyacinth*, with white flowers. 34. The many flowered oriental *Hyacinth*, with grey flowers. 35. The oriental *Hyacinth*, with very ſweet-ſcented blue flowers. 36. The great oriental *Hyacinth*, with fleſh-coloured flowers. 37. The amethyſtine *Hyacinth*, with large double bell-faſhioned flowers. 38. The early white *Hyacinth*. 39. The broad-leaved oriental *Hyacinth*. 40. The red cup variegated flowered oriental *Hyacinth*. 41. The great many flowered white *Hyacinth*. 42. The great many-flowered oriental *Hyacinth*, with beautiful blue flowers. 43. The branched oriental *Hyacinth*. 44. The oriental *Hyacinth*, with variegated reflex petals. 45. The violet-flowered oriental *Hyacinth*, with ſtreaks of white. 46. The oriental *Hyacinth*, with leafy ſtalks. 47. The late flowering oriental *Hyacinth*. 48. The late flowering oriental *Hyacinth*, with erect white flowers. 49. The late flowering oriental *Hyacinth*, with erect blue flowers. 50. The late flowering oriental *Hyacinth*, with ſtriated flowers. 51. The double flowered white oriental *Hyacinth*. 52. The double flowered blue oriental *Hyacinth*. 53. The double flowered blue Roman *Hyacinth*. 54. The double pale-blue oriental *Hyacinth*. 55. The double purple oriental *Hyacinth*. 56. The great whitiſh blue, double oriental *Hyacinth*. 57. The oriental *Hyacinth*, with violet purple flowers, and turgid cups. 58. The ſnow-white double oriental *Hyacinth*. 59. The double pale fleſh-coloured oriental *Hyacinth*. 60. The great double-flowered white oriental *Hyacinth*, with roſe-like flowers, called by ſome the Italian *Hyacinth*. 61. The double oriental *Hyacinth*, called the Capucine *Hyacinth*. 62. The more elegant flowered Capucine *Hyacinth*. 63. The tuberoſe Indian *Hyacinth*, with the oriental *Hyacinth* flowers. *Tournefort*'s Inſt. p. 346.

All the kinds of this beautiful flower may be propagated either by ſowing their ſeeds, or by parting their bulbous roots. The latter has been the method moſt practiſed among us, tho' the former is evidently the way to procure the fineſt varieties of the flowers, and has been always practiſed in Holland. The diſcouragement in this, is the long time the plants take from the ſowing, which is uſually four years before they flower; but then if they are ſowed every year, after the firſt four years there is always a yearly ſucceſſion of flowers from ſeed.

The ſeed ſhould be carefully ſaved either from ſemi-double, or the fineſt ſingle flowers, and ſown on a freſh, light, and ſomewhat ſandy ſoil, in ſhallow pots or boxes, covering them with half an inch of the ſame earth. This ſhould be done in the beginning of Auguſt, and the pots ſhould be placed where they may have the morning ſun till the middle of September; they ſhould then be removed to a ſomewhat warmer ſituation, and toward the end of October, be put under a common hot-bed frame.

In February the young plants will appear above ground, and muſt be carefully ſcreened from froſts; but they muſt not be cloſe covered, except at nights. In March they muſt be taken out of the frames, and ſet in a warm place, and when the weather is dry, they muſt be gently watered at times, and always kept carefully clear from weeds.

Toward the latter end of April, or beginning of May, they muſt be removed into a cooler ſituation, as the heat of the ſun would then be too much for them. After their blades are decayed, they muſt have no more watering; but toward the latter end of auguſt, about half an inch of freſh earth ſhould be ſifted over the pots; after this they muſt be preſerved and managed as the former ſeaſon, and in the auguſt following, a bed of a light, rich, ſandy ſoil, ſhould be prepared. Then the earth is to be taken out of the pots and boxes, and the roots, which will at this time be about the bigneſs of a quill, muſt be ſeparated, and carefully placed upon the bed, at two or three inches aſunder. They are to be ſet with the bottom part downwards, and covered two inches thick, with the ſame fine earth ſifted over them. Theſe beds muſt be arched over, and in froſty weather covered with mats. In ſpring, if the weather prove dry, they muſt be watered ſparingly. In ſummer they muſt be carefully kept clear of weeds, and in autumn have an inch more of light earth ſtrewed over them. This management muſt be continued till they flower, which is uſually not till four or five years after they were ſown.

When they are in flower, the finer ſorts ſhould be marked with a ſtick, that they may be taken up and planted ſeparate.

When the green leaves of theſe plants begin to decay, their roots muſt be taken up, and the earth of the bed being raiſed into a ridge to ſhoot off the moiſture, they ſhould be laid into the earth again in an horizontal poſition, leaving the green leaves hanging down from the roots, to prevent their moiſture from running into the roots, which often rots them. When the leaves are quite dried off, the roots are to be taken up and cleared of filth, and laid up in boxes till September, which is the time of planting them again. The proper ſoil for planting theſe in is this: Take one half freſh earth from a common, or paſture, which is of a ſandy loam; this ſhould not be got beyond nine inches deep; to this add a fourth part of ſea ſand, and a fourth part of rotten cow-dung.

This ſhould be mixed a long while before it is uſed, and often turned; and ſhould be ſpread ten inches deep on the beds, with a little rotten cow-dung, or old tanners bark, at the bottom. Theſe beds ſhould be raiſed from three to ſix inches above the ſurface of the earth, and be a little riſing or rounded in the middle. When the flowers are about to blow, the ſtalks ſhould be faſtened by a loop of wire to a ſmall ſtick, to prevent their bending down, and they muſt be ſheltered from the great heat of the ſun in the middle of the day, by which means they will continue in flower a month or longer. *Miller*'s Gardener's Dict.

HYACINTH, is alſo a name given by the moderns to a gem, the diſtinguiſhing character of which is, that it is red, with an admixture of yellow. This is a very different gem from that known by the antients under the name of the *Hyacinth*, which was a variety of the amethyſt, with a larger admixture of a deep blue, a ſtone ſeldom ſeen among us. The antients knew this gem, called the *Hyacinth* by us, under the name of *lapis lyncurius*.

The common opinions of authors have been, that the *lapis lyncurius* of the antients was either amber, or the ſtone we now call belemnites. Theophraſtus's account of it is this; that it was of a very ſolid texture; that it was uſed to engrave ſeals upon, and that it had the attractive power of amber, and was in colour of a yellowiſh red, or flame colour. It need not be obſerved, that of all the antients, this is the author moſt to be depended upon for his accounts of foſſils; and it is plain, from his accounts, that the *lapis lyncurius* could not be the belemnites, becauſe that foſſil is neither hard, nor fit to cut ſeals on, but very ſoft, and of a ſtriated texture; nor could it be amber, ſince no author would have compared a body to itſelf.

It is hence evident, therefore, that a new foſſil is to be looked

for to anſwer the name of the *lincurius* of the antients; and it is alſo equally plain, that the gem we now call the *Hyacinth* was known to them by no other name, though we cannot but believe that a gem, always ſo common, muſt have been known to them: And it is equally plain, that our *Hyacinth*, and no other known gem, anſwers to all the characters they have given of the *lapis lyncurius*; and it appears hence reaſonable to conclude, that this is the gem known to them by that name.

Pliny's account wholly confirms this opinion, and the deſcription of the *lyncurius* given by Theophraſtus; though Pliny ſeems evidently to have taken it from ſome other author. He ſays it was a gem reſembling the carbuncle, that is, reſembling the generality of red gems; for at his time they called all thoſe by the common name carbuncle; and differing from them, in that it was of a flame colour; words which could never have been ſpoken of the belemnites, but which very happily expreſs our *Hyacinth*.

It is a leſs gaudy looking gem than any other of the red ones; but is not without its beauty, which in the fineſt ſpecimens is great, though not glaring; and is as ſeldom found blemiſhed or faulty as almoſt any other gem. It is of various ſizes, but is ſeldom found ſmaller than a hempſeed, or larger than a nutmeg. We have had accounts, indeed, of ſome of a much larger ſize; but they ſeem not much to be depended upon. It is not leſs irregular in ſhape than ſize, being found ſometimes in the figure of a regularly hexangular column, terminated by an hexangular pyramid, and in all reſpects, except colour and hardneſs, reſembling ſprig cryſtal; and at other times it is found in form of a ſmall roundiſh or oblong pebble, generally flatted on one ſide. It makes much the beſt external appearance in its cryſtalliform ſtate; but the pebble-ſhap'd maſſes are much the harder, and of the finer luſtre. It is leſs hard than the ruby or ſapphire, but greatly more ſo than cryſtal. *Hill's* Hiſt. of Foſſils, p. 592.

It is found of various degrees of deepneſs or paleneſs, but its colour is always a deadiſh red, with a conſiderable admixture of yellow, ſometimes indeed ſo much, that the laſt ſeems the predominant colour. It is ſometimes ſo deep as to ſeem almoſt black, till held up againſt a ſtrong light, and at others is almoſt colourleſs; and probably, not unfrequently is wholly ſo, though in that caſe, wanting its true character, which is taken from its colour, it is not to be diſtinguiſhed from pebble cryſtal on the one hand, nor from the white ſapphire on the other, without the aſſiſtance of the wheel to aſcertain its hardneſs. Its moſt uſual ſtate, however, is its having that colour mixed of red and yellow, which we uſually call flame colour.

Theſe are the characters by which the *lyncurius* of the antients, or *Hyacinth* of our times, is to be diſtinguiſhed from all other gems; and our jewellers and lapidaries, according to its different degrees of colour, diſtinguiſh it into three kinds, which they call by its own name, with different epithets, and a fourth, which uſually, but improperly, is accounted by authors a ruby.

The firſt kind is the *la bella Hyacintha*. This is the name given to the *Hyacinth*, in its moſt perfect and beautiful ſtate, when it is of a pure and bright flame colour, ſeemingly made of a mixture of cinnabarine red, and a moderate proportion of a fine amber yellow.

The ſecond is the ſaffron *Hyacinth*. This is the name they give this gem, when it has more of the red, and that of a deeper and duſkier colour, and is tinged with an admixture of a dead and browniſh yellow.

The third is the amber *Hyacinth*. This is the name they give thoſe *Hyacinths* which are tinged with a fainter red, in a ſmall proportion, and a dead whitiſh yellow.

The fourth is the *Rubacelle*, a name given to the *Hyacinth* when of a very deep and ſtrong red, blended with a very deep but duſky yellow. The ſtrong colour of the red, in this ſtone, has generally made it have a place among the rubies, in the accounts of authors; but a compariſon of it with the two gems will evidently ſhew, that it belongs not to the ruby, but to the *Hyacinth* kind.

The firſt of theſe are the finer *Hyacinths*, and are of conſiderable value. They are brought to us both from the Eaſt and Weſt Indies. The *Rubacelle* is only found in the Eaſt Indies, but is of very little value; and the other two varieties are common both to the Eaſt and Weſt Indies, and to Sileſia and Bohemia, and ſeveral other parts of Europe. Theſe are, indeed, ſometimes brought over to us from the Eaſt Indies, among the finer kind; as is alſo the *la bella Hyacintha*, ſometimes found in Bohemia, though poor in compariſon of the oriental. It is no wonder, indeed, that they ſhould be all found equally in both places, being all, in reality, only varieties of the ſame gem; but the oriental are in general greatly the finer and better colour'd.

HYÆNA, or HIÆNA, in natural hiſtory. The animal which is known to us by this name is a quadruped almoſt as large as a wolf, excepting that its legs are not ſo long. The hair of it is rough, and its ſkin ſpotted with divers colours. *Hiæna's* were formerly produced at Rome in the public games, and they have been repreſented on ſome medals, on account of their rarity. It is an uncommon creature, ſcarce to be ſeen any where but in Egypt. Spanheim, who had copies of it engraved from medals, deſcribes it with the head of a maſtiff, with ſhort triangular ears, a lion's tail and feet, and hair ſpotted all over like a tyger's.

Bochart and Ludolphus [a], in his hiſtory of Ethiopia, maintain, that the *Hyæna* is in the Hebrew called *Tzeboa*. Jeremiah ſpeaks of it in chap. xii. 9. Pliny [b] ſpeaks of the *Hyæna*, and deſcribes it in a manner which ſeems fabulous. He ſays, that it changes its ſex every year, being one year male, and the next female; and that from its eyes are taken precious ſtones, from the name of this creature called *Hyæna*. Ariſtotle and Ælian ſay, that it makes dogs dumb with its ſhadow; that it imitates the ſpeech of mankind, and deceives them, in order to draw them out of their houſes, and devour them. They add, that it has feet like a man's, and no vertebræ in the neck. — [a See *Bochart's* Hierozoicon, P. 1. l. 3. c. 11. and *Ludolph.* Comment. in Hiſt. Ethiop. l. 1. n. 81. b Plin. l. 8. c. 30. & l. 28. c. 8.]

Buſbequius, in his travels to Amaſia, relates ſeveral particulars of this animal. He ſays it is almoſt of the ſhape of a wolf, but not ſo tall. That its hair is like that of a wolf, except its being more briſtly, and marked at certain diſtances with great black ſpots. It has no neck, but its head is faſtened to the vertebræ of the back, ſo that it is forced to turn itſelf quite round, whenever it would look behind. It is very cruel and voracious; it drags dead bodies out of graves, and carries them to its den. Inſtead of teeth, it has one continued bone in the jaw. It is ſaid to imitate the voice of a man, and that by this means it often deceives travellers.

The daughter of the *Hyæna* is a bird, the uſe whereof is forbidden by Moſes. *Calm.* Dict. *Buſbeq.* Iter. Amaſian. p. 76.

HYALINÆ, in natural hiſtory, the name of a genus of foſſils, of the claſs of the talcs, the characters of which are, that they are compoſed of ſeparate plates of conſiderable thickneſs, and thoſe not fiſſile into any thinner.

The word is derived from the Greek ὕαλη, glaſs. The ſeveral plates which compoſe theſe bodies being very much of the appearance of the finer glaſs, and uſually about the thickneſs of that uſed for faſh windows. See Tab. of Foſſils, Claſs 1. and *Hill's* Hiſt. of Foſſils, p. 75.

There is but one ſpecies known of this genus, which is found lodged in the clay, in the ſteep banks of the river Aube in Champaigne, near the town of Bar, and in ſome other places along that river; but ſo far as is yet known, in no other part of the world.

HYALOIDES, in the natural hiſtory of the antients, the name of a tranſparent ſtone fit to engrave ſeals on, which was the great uſe they made of the gems, and very bright and readily reflecting the images of things. Different authors have had different gueſſes about this ſtone; but it ſeems to be the ſame gem which Pliny calls *aſtrios*, which, he ſays, was of the nature of cryſtal, and was brought from the Indies. We have this ſtone to this day in many parts of America, particularly about the river of the amazons, from whence many fair ſtones of it have at times been brought, and have been by ſome miſtaken for diamonds; they are a ſort of pebble cryſtal, approaching to what the jewellers call the white ſapphire. *Hill's* Theophraſt. p. 80.

HYALOIDES, in anatomy, is ſometimes applied to the vitreous humour of the eye, contained betwixt the tunica-retina and the uvea.

HYANCHE, a word uſed by the old medicinal writers to ſignify a quinſy, attended with a ſwelling on each ſide of the throat.

HYARITH, a word uſed, by ſome of the affected chemical writers, for ſilver.

HYBERNAL *Occident.* See the article OCCIDENT.

HYBERNAL *Orient.* See the article ORIENT.

HYBERNICUS *Lapis.* See the article LAPIS *Hybernicus.*

HYBOMA, a word uſed by the old medicinal writers for a gibboſity of the ſpine.

HYDARTHROS, a word uſed by the antient writers in medicine to expreſs a clear water running from the joints when wounded or ulcerated; it is a very common ſymptom in horſes, and our farriers call it *joint-water.*

HYDATIDES, in natural hiſtory, a name given, by ſome writers, to a ſpecies of aſtroites, the lineations of which reſemble waves. It is by others uſed as a name of the enhydros. See the articles ASTROITES and ENHYDROS.

HYDATIDES, in medicine (*Cycl.*)— Theſe tumours are ſometimes voided by the vagina. Of this Mr. Watſon has given a remarkable inſtance in a gentlewoman of about forty-eight years of age, the mother of ſeveral children, and who, after a reſpite of ſix years, had again the ſigns of conception for three months, after which time they left her, and from that time ſhe diſcharged every night, for a month together, large quantities of blood by the vagina, and not perceiving any increaſe in her belly, nor in the ſize of her breaſts, ſhe concluded that the menſes were leaving her at their uſual period. But ſome weeks after this, ſhe was taken with pains like thoſe of labour, and there came away a vaſt number of *Hydatides*, of all the ſizes between a nutmeg and a pin's head, ſome filled with clear water, ſome with a bloody lymph, all of them growing in the manner of a cluſter of grapes, from a ſpungy ſubſtance, ſerving as

a placenta. After the diſcharge of theſe, ſhe in a few days recovered her accuſtomed health. Upon boiling theſe *Hydatides*, they appeared like the boiled ovary of a hen, only with this difference, that as the eggs in the ovary of the hen concrete and grow hard, theſe continued to contain a fluid matter only. It was leſs tranſparent, and appeared of a faint yellowiſh colour. Philoſ. Tranſ. N°. 461. p. 770.

HYDATINON, in the medical writings of the antients, the name of a collyrium made principally of rain water.

HYDATISM, a word uſed, by ſome writers in ſurgery, to expreſs the noiſe or ſound made by the fluctuating humours contained in abſceſſes.

HYDATOCHOLOS, an epithet uſed by the old writers on medicine, for ſtools more than ordinary liquid or bilious.

HYDNOPHYLLUM, or HYDNOPHYLLON, in botany, a name given by the antient Greeks to a plant which they tell us grew on thoſe places where the tubera or truffles lay underneath.

They have left us no deſcription of this plant, ſo that it is not eaſy to gueſs what it was; and the whole account ſeems ſo contrary both to their own opinions delivered in other places, and to truth, that there is reaſon to ſuſpect ſome error in the caſe. They tell us, that they were led by this plant to look for the truffles, and knew by it where they were. But we obſerve, that in places where truffles are, there grows no plant at all upon the ſurface: They alſo tell us the ſame thing in other places.

It is probable that ſome of the writers of that age confounded the truffle and the bulbocaſtanum, or earth-nut. In this caſe, the leaves of the latter would, indeed, ſerve as a certain indication; and the udnophyllon would then be only another name for the bulbocaſtanum. See the article UDNON.

HYDNUM, in botany, the name of a genus of funguſes, called by Dillenius and Micheli, *Erinacei*. Theſe are a ſort of horizontal fungus's, which always grow by the ſide to trees, *&c.* having no pedicle. There are three of this kind; the agaric, which is lamellated underneath; the boletus, which is porous underneath; and the *Hydnum*, which is echinated, or beſet with pointed fibres on its under part. See the articles AGARICUS, BOLETUS, and FUNGUS.

HYDRANGEA, in botany, the name of a genus of plants, the characters of which are theſe: The perianthium is ſmall and permanent, and is compoſed of one leaf, divided into five ſegments at the edge. The flower is compoſed of five roundiſh petals, equal in ſize, and larger than the ſegments of the cup. The ſtamina are ten filaments, five of which are ſhorter than the other five, but all longer than the flower. The antheræ are roundiſh and double. The germen of the piſtil is roundiſh, and ſtands under the cup. The ſtyles are two; they ſtand diſtant from one another, and are ſhort. The ſtigmata are obtuſe and permanent. The fruit is a roundiſh double capſule; it has two beaks, which are owing to the double ſtyle, and is rendered angular by ſeveral ridges; it is crowned at the extremity with the cup, and is divided into two cells by a tranſverſe membrane, and opens at a foramen between the two horns. The ſeeds are very numerous, and very ſmall, and are of an angular figure, and pointed at the end. *Linnæi* Gen. Pl. p. 193.

HYDRARGYROSIS, a term uſed by the chirurgical writers to expreſs the anointing the body with a mercurial unction, in order to the raiſing a ſalivation.

HYDRINUS, a name given by ſome authors to the ophites, or ſerpent ſtone.

HYDRIAPHORÆ, ὑδριαφοραι, among the Athenians, a deſignation given to wives of ſtrangers, reſiding at Athens.

They were thus called, as being obliged, during the proceſſion of the feſtival *Panathenæa*, to carry veſſels of water. *Potter*, T. 1. p. 56, and 421.

The word is Greek, compounded of ὑδωρ, water, and φερω, I carry.

HYDROCARDIA, a term invented by Hildanus to expreſs a ſerous, ſanious, or purulent tumour of the pericardium.

HYDROCEPHALUS, (*Cycl.*)—We owe to Mr. Hunauld, of the royal academy of Paris, ſome very ſingular and valuable obſervations on this remarkable ſubject. This gentleman, examining the head of a child which had died at ſeven months old of a *Hydrocephalus*, found it larger, in all parts, except before, than that of an adult. Toward the face the ſkull was no larger than is natural at that age; but ſideways and behind it had ſwelled to this monſtrous bulk. The water was encloſed in the ventricles, and was in quantity a pint.

On conſidering what could be the time when this unhappy diſorder began, it appeared to that gentleman, that it did not happen till after the bones of the ſkull began to be joined to one another by the ſutures; for otherwiſe the head muſt have been in the ſame ſtate with thoſe in which the *Hydrocephalus* has begun earlier; in which caſe, the bones of the ſkull ſeparate themſelves to a great diſtance one from another, and the membrane which unites them to one another is extremely extended. The beginning of this *Hydrocephalus* muſt have been at a time when the bones of the ſkull, united by their ſutures, had already had time conſiderably to extend themſelves; and the action of the water on the ſides of the ventricles, and on the brain, forced the bones of the ſkull to take this unnatural growth. And from the whole, it is eaſy to conclude that thoſe children in whom a *Hydrocephalus* begins, before the bones of the ſkull are ſtrongly united, may live a conſiderable time. Memoirs Acad. Scienc. Par. 1740.

The effect which the water, contained in the head, had had on the brain, in the caſe under conſideration, deſerves to be remarked. The ſides of the ventricles are, in a natural ſtate, applied cloſely on one another, and ſcarce leave any ſenſible cavity; whereas in this head, theſe ſides were ſo far ſeparated from one another, as to contain a pint of water. It muſt therefore have happened, that the ſubſtance of the brain, which compoſes theſe ſides, muſt have been conſiderably elongated, and the cortical ſubſtance muſt alſo have been greatly extended beyond its natural dimenſions. And, in order to be capable of this extenſion, it was found without any circumvolutions, and made only a flat even ſurface, regularly of that extent and ſize that would reſult from the expanding all its circumvolutions. The medullary ſubſtance formed a ſecond even ſurface like the former. This was very thin, and lay under the former. The reaſon of this diſpoſition of the parts of the brain, in this caſe, is obvious; for the pia mater not having, in this caſe, the circumvolutions of the brain to follow, as in a natural ſtate, formed of itſelf a flat ſubſtance upon the cortical part.

It is evident, from theſe obſervations, and from others in Veſalius and other authors, that the brain may, from accidental cauſes, become of a growth and figure very different from what it naturally would have had; and that the very bones of the ſkull are in like manner capable of aſſuming a different figure and growth, and that even after they have acquired a great deal of their natural thickneſs and hardneſs, and are capable of reſiſting, with conſiderable force, the accidents which tend to determine this unnatural growth in them: And applying this to the caſe of a tender fœtus, in which the parts have yet ſcarce any degree of ſolidity or hardneſs, we ſhall ſee an eaſy account for all the unnatural configurations which anatomiſts ſometimes meet with in the ſkull of adults. Memoirs de l'Acad. de Scien. Par. 1740.

In the internal *Hydrocephalus*, when the water is collected in the inſide of the cranium, there is little hope of relief, for if a paracenteſis be made to diſcharge the lymph, the infant dies as ſoon as the operation is over. But in the external *Hydrocephalus*, where the water is retained between the common integuments and the cranium, there is ſome hopes of a cure, eſpecially if it be not of very long ſtanding. Internal medicines muſt be given. Theſe muſt be cathartics, diuretics, and diaphoretics; and at the ſame time externally large compreſſes, covering the whole head, muſt be applied, dipped in lime-water and ſpirit of lavender, or Hungary water. Bags of the dried herbs of lavender, marjoram, penny-royal, and the like herbs, may be wetted in the ſame liquors, and applied; and the frequent uſe of an errhine made of marjoram, lilly of the valley, marum, and the like, ſhould be recommended, as alſo the chewing of tobacco, to diſcharge the ſeroſities in form of ſaliva. If theſe do not ſucceed, a bliſter muſt be tried behind the ears, on the occiput and neck, and cupping on the parts. Iſſues and ſetons alſo are of great uſe. And, in the cupping, the ſcarification may be made very deep, and afterwards dreſſed with digeſtive ointments and precipitate, to keep up the diſcharge. *Heiſter's* Surgery, p. 355.

HYDROCERATOPHYLLON, in botany, the name given by Vaillant, and many others, to a genus of plants called by Dillenius, dichotophyllum; and by Linnæus in his genera plantarum, ceratophyllum. *Vaillant*, Act. Germ. 1719. See the article CERATOPHYLLUM.

HYDROCHARIS, in botany, the name of a genus of plants in Linnæus's ſyſtem, which comprehends the *ſtratiotes*, the *morſus ranæ*, and the *microleuco-nymphæa* of other authors. The characters of the genus are theſe: The flowers are ſome male, others female. In the male the cup is a two-leav'd oblong ſpatha, containing two flowers. The peculiar perianthium of each flower is compoſed of three leaves, of an oblong oval figure, hollow, and with membranaceous edges. The flower conſiſts of three large petals, flat, and of a roundiſh figure. The ſtamina are nine erect pointed filaments, diſpoſed in three orders. The antheræ are ſimple. The piſtil is a ſort of rudiment of a germen in the center of the flower. In the female flowers there is no ſpatha, but the flowers grow each by itſelf. The perianthium and petals are the ſame as in the male. The piſtil has a roundiſh germen placed under the cup, and from this ariſe ſix ſtyles of the length of the cup; theſe are compreſſed and furrowed. The ſtigmata are bifid and pointed. The fruit is a coriaceous capſule of a roundiſh figure, containing ſix cells. The ſeeds are very numerous, and are ſmall and roundiſh. *Linnæi* Gen. Plant. p. 482.

HYDROCOTYLE, *Marſh Pennywort*, in botany, the name of a genus of plants, the characters of which are theſe: The flowers are diſpoſed into ſmall umbels, and are of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular order upon a cup, which afterwards becomes a fruit compoſed of two plain and ſemi-orbicular ſeeds.

The ſpecies of *Hydrocotyle*, enumerated by Mr. Tournefort, are theſe: 1. The common marſh *Hydrocotyle*. 2. The *Hydrocotyle* of Ceylon, with aſarabacca leaves. 3. The Ameri-

can *Hydrocotyle*, with leaves like the little water lily. 4. The great American *Hydrocotyle*, with umbilicated leaves, and flowers growing in radiated umbels. *Tourn.* Inſt. p. 328.

HYDRODES *Febris*, a fever, in which the patient is from the beginning afflicted with very copious and weakening ſweats, and great weakneſs.

HYDROGARON, a word uſed by ſome of the old authors for garum, or brine diluted with water, and uſed as a purge, taken in large quantities.

HYDROMELON, a name given by the antients to a liquor prepared with one part of honey, impregnated with the juice of quinces, and two parts of boiled water ſet in the ſun during the dog days.

HYDROPHANÆ, in natural hiſtory, the name of a genus of the ſemi-pellucid gems. The word is derived from ὕδωρ, water, and φάινεσκω, to ſhine; the diſtinguiſhing character of theſe ſtones being, that they become lucid on being plunged into water. They are ſemi-tranſparent ſtones, compoſed of cryſtal and earth, the latter ingredient being in large proportion, and mixed but imperfectly, as in the chalcedony, and giving a general miſty or cloudy look to the maſs, but conſiderably opake, and not capable of a fine poliſh; but appearing of a duſky and foul ſurface, till thrown into water, in which they become lucid, and in ſome degree tranſparent, and either in part or wholly change their colour, which returns to them again when taken out and dried. Of this genus we know only two ſpecies, one a whitiſh grey, without veins, called *lapis mutabilis*, and *oculus mundi*; and the other a whitiſh-grey one, variegated with yellow, and with a black central nucleus, called by authors the *oculus beli*. *Hill*'s Hiſt. of Foſſ. See the article OCULUS.

HYDROPHTHALMIA, a name by which ſome have called the *prolapſus oculi*, when owing to a quantity of aqueous humours. *Heiſter*'s Surgery, p. 437. See the article PROLAPSUS *Oculi*.

HYDROPHYLACIA, a word uſed by Kircher, and ſome others who have written in the ſame ſyſtem, to expreſs thoſe great reſervoirs of water which he places in the Alps, and other mountains, for the ſupply of the rivers which run through the ſeveral lower countries. This he makes to be one of the great uſes of mountains in the œconomy of the univerſe.

HYDROPHYLLUM, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf, and is ſhaped like a bell, and divided into ſeveral ſegments at the edges. From the baſe of the cup of the flower there riſes a piſtil, which perforates the bottom of the flower, and is fixed in its hinder part like a nail. This ripens into a roundiſh bivalve fruit, full of roundiſh ſeeds.

Of this genus of plants there is only one known ſpecies, which, before it had this generical name, uſed to be diſtinguiſhed by authors by the name *Dentariæ affinis echii flore*, a plant reſembling the toothwort, with flowers like viper's bugloſs. *Tourn.* Inſt. p. 81.

HYDROPHYLLUM, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is a perianthium, divided into five ſegments, and almoſt as long as the flower. The ſegments are tapering in ſhape, and the cup remains after the flower is fallen. The flower conſiſts of a ſingle petal, in form of a bell, ſlightly divided into five obtuſe emarginated ſegments. The flower has alſo five nectaria; theſe are in each ſegment of the flower, or cavity, or cleft, with two longitudinal lamellæ, which converge and ſhut over it. The nectaria are in the lower half of the petals. The ſtamina are five tapering filaments, longer than the flower. The antheræ are oblong, and lean on theſe. The germen of the piſtillum is oval and pointed. The ſtyle is tapering, and of the length of the ſtamina: And the ſtigma is bifid and open. The fruit is a globoſe capſule, containing one cell, with two valves. The ſeed is ſingle, round, and large. *Linnæi* Gen. Plant. p. 65.

HYDROPHYSOCELE, a term uſed by ſome authors for a ſort of hernia, or rupture, occaſioned by a mixture of water and flatulencies.

HYDROPNEUMOSARCA, a word uſed, by ſome writers in ſurgery, to expreſs a tumour filled partly with water, partly with flatulencies, and partly with fleſh.

HYDROPS (*Cycl.*)—HYDROPS *Pulmonum*, a *dropſy of the lungs*. This is a very uncommon diſtemper; but it has been ſometimes obſerved by the phyſicians of our own nation. The moſt perfect account, however, any where given of this diſeaſe, is that of Mr. Maloet, of the Paris academy, in the caſe of a poor invalide ſoldier, whom he had attended through all the ſtages of it. He had a very great difficulty of reſpiration, accompanied with a flow fever. When in bed he could neither lie with eaſe on either ſide, nor on his back; but was forced to lie upon his belly, and conſequently, as that was a very troubleſome poſture, he uſually took his reſt in a chair. His hands and arms were much ſwelled, as were alſo his legs and feet, and his urine was of a brick colour. Mr. Maloet, from all theſe circumſtances, ſuſpected water in the breaſt, but was never able to perceive any fluctuation, into whatever change of poſture he made the patient go, nor could he find that the man himſelf ever perceived any ſuch ſenſation within him. The unhappy creature died, after two years illneſs; and his body being opened, there was no water found looſe in the breaſt, but on each ſide of the lungs there was obſerved an oval tumour of ſix inches long, and four inches broad; they were both of the ſame ſize, and on touching them with the hand, there was a very ſenſible fluctuation obſerved. On opening theſe, water run out in a large quantity, and on examining their ſtructure, they were found encyſted tumours, with conſiderably thick membranes, compoſed of ſeveral beds, or coats of matter, but with no blood veſſels diſtinguiſhable in them. Examining the liver, there was found another encyſted tumour there, the contents of which were a lymph, tinged to a yellowiſh green by gall. Mem. Acad. Par. 1732.

HYDROPYRETOS, a word uſed by ſome authors to expreſs a malignant fever, attended with very copious ſweats. Some make it the ſame with the ſudor anglicus.

HYDRORHODINON, a name given by the antients to a mixture of water and oil of roſes; this, as it was at once cooling and emetic, was very much uſed by the antients, to provoke vomiting after the taking of poiſons.

HYDROROSATON, in the writings of the antient phyſicians, a name given to a drink made of water, honey, and the juice of roſes. The proportions were four pound of roſes, five pints of water, and two pints of honey.

HYDROSARCA, in the writers of ſurgery, a word uſed to expreſs a tumour, compoſed partly of water, and partly of fleſh.

HYDROSELINUM, in botany, a name given by ſome authors to ſmallage. *Ger.* Emac. Ind. 2.

HYEMAL *Solſtice*. The ſame with *winter-ſolſtice*. See the article SOLSTICE, *Cycl.*

HYEMANTES, in the primitive church, offenders who had been guilty of ſuch enormities, that they were not allowed to enter the porch of the churches with the other penitents, but were obliged to ſtand without, expoſed to all the inclemency of the weather. *Hofm.* Lex. in voc.

HYÆNIUS *Lapis*, in natural hiſtory, the name of a ſtone ſaid to be found in the eyes of the *Hyæna*. Pliny tells us, that thoſe creatures were, in old times, hunted and deſtroyed for the ſake of theſe ſtones, and that it was ſuppoſed that they gave a man the gift of propheſy, on being put under his tongue.

HYGRA, a name given by the antients to what they called liquid plaſters, in oppoſition to thoſe called xeria, or dry ones. Theſe firſt were a ſort of liniments.

HYGROMETER. See the article HYGROSCOPE.

HYGROSCOPE (*Cycl.*)—The following *Hygroſcope* is recommended in the philoſophical tranſactions, N°. 479. where a figure of it given.

It conſiſts of a thin piece of ſponge, ſo cut as to contain as large a ſuperficies as poſſible. This hangs by a fine thread of ſilk, upon the beam of a ballance, and is exactly ballanced on the other ſide by another thread of ſilk, ſtrung with the ſmalleſt lead ſhot, at equal diſtances, and ſo adjuſted as to cauſe an index to point at the middle of a graduated arch, when the air is in a middle ſtate, between the greateſt moiſture and the greateſt dryneſs. Under this ſilk ſo ſtrung with ſhot, is placed a little table or ſhelf, for that part of the ſilk and ſhot, which is not ſuſpended, to reſt upon. When the moiſture imbibed by the ſponge increaſes its weight, it will raiſe the index, and alſo part of the ſhot, from the table; and *vice verſa* when the air is dry. N°. cit. p. 76.

In the philoſophical tranſactions, N°. 480. we have the deſcription of an *Hygroſcope*, or *Hygrometer*, made of deal rods, ſaid to be very ſerviceable.

HYLARCHIUS, a word by which ſome authors expreſs what they call a ruling and preſiding ſpirit, which governs and actuates all matter.

HYMENÆA, in botany, the name of a genus of plants, firſt deſcribed by Plumier under the name of *courbaril*. The characters are theſe: The cup is a one leaved perianthium divided into five unequal ſegments; the flower is of the papilionaceous kind, the vexillum is large and reflex, the wings ſmall, and lanceolated, and the carina pointed; longer than the wings, and pointing upwards, the germen of the piſtil is oblong. The fruit is a very large pod of an oval oblong figure, obtuſe, and containing only one cell; the ſeeds are very numerous, and of an oval figure, and are ſurrounded in the pod with duſt and fibres. *Linnæi* Gen. Plan. p. 521. *Plumier*, p. 36.

HYMENODES, an epithet applied by the old authors to ſuch urine as is found to be full of little films and pellicles. Hippocrates alſo applies it to the menſtrual diſcharges when they are mixed with a tough viſcid phlegm.

HYMETTIUM *Marmor*, a name given by many of the old writers to a ſort of white marble, ſometimes variegated with other colours, but remarkable for its great gloſs, and the high poliſh it was capable of; this was greatly uſed among the Romans for the columns of their public buildings.

HYOSCIAMUS, *Henbane*, in botany, the name of a large genus of plants, the characters of which are theſe: The flower is of the infundibuliform kind, conſiſting of one leaf, and divided into ſeveral ſegments at the end. From the cup there ariſes a piſtil, which is fixed in the manner of a nail to the hinder part of the flower. This afterwards becomes a fruit, which is encloſed within the cup, and is like a pot or other veſſel with its cover, and is divided by an intermediate ſeptum into two cells, which contain ſmall ſeeds.

The ſpecies of *Henbane* enumerated by Tournefort, are theſe: 1. The

1. The common black *Henbane*. 2. The common white *Henbane*. 3. The ſmaller white *Henbane*. 4. The ſmall yellow *Henbane* of Crete. 5. The red flowered *Henbane*. 6. The white flowered Egyptian *Henbane*. 7. The little golden *Henbane* of America, with ſmooth narrow leaves. 8. The ſmall yellow flowered annual exotic *Henbane*. *Tournef.* Inſt. p. 117.

There are two kinds of *Henbane* ſeed uſed in medicine, which poſſeſs the ſame narcotic virtues, but in a different degree; the white is the milder of the two, and therefore generally preſcribed; many, however, look upon them as poiſonous, while others recommend them in many caſes, particularly in ſpitting of blood.

HYOSCIAMUS *Peruvianus*, *Henbane of Peru*, a name by which Dodonæus and many other authors have called the tobacco plants, more uſually known by the name *nicotiana*. See the article NICOTIANA.

HYOSYRIS, in botany, a name given by Pliny and ſome other authors to the common knapweed, or *jacea nigra*.

HYPACTIC *medicines*, a term uſed by ſome authors for cathartic medicines.

HYPATE, in the antient muſic, an appellation given to the loweſt chord or ſound of a tetrachord.

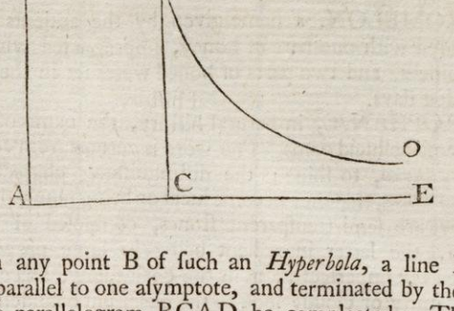
The word is Greek, ὑπατη, which ſome Latin interpreters tranſlate by *ſuprema*; as they tranſlate νητη by *ultima* or *ima* [a]. Dr. Wallis [b] ſays, that the firſt contrivers of theſe names, took, contrary to our cuſtom, the grave for the higheſt place, and the acute for the loweſt of their ſchemes. This was the practice of Bœthius; and Nichomachus, in the heptachord lyre, aſcribes the *Hypate* to Saturn, and the *neate*, or *nete*, to the Moon. Some however interpret ὑπατος as if it were ὑποατος, but erroneouſly, according to the learned doctor juſt quoted, who obſerves, that Homer calls Jove ὑπατον κρειοντων, as if ὑπατον were derived from ὑπερτατον. Afterwards it is ſaid, the grave was taken for the loweſt, and the acute for the higheſt place, agreeably to our notions. Some think that the *Hypate* might obtain its name from being placed higheſt in the lyre [c]. Martianus Capella and Bœthius tranſlate *Hypate*, *principalis*; and *parypate*, *ſubprincipalis*. Alſo Ariſtides Quintilianus chuſes to call the *Hypate* firſt, rather than ſupreme or higheſt, and calls the *nete*, laſt, inſtead of loweſt [d]. Perhaps the truth of the matter is, that the *Hypate* was called higheſt or loweſt, according as muſicians conſidered the deſcending or the aſcending ſcale [e]. The moveable chord next the *Hypate*, was called *parypate*; and that next the *nete* was called *paranete* [f]. [[a] *Hen. Steph.* Theſ. in voc. νητη, ap. *Wallis*, append. ad Ptolem. Harm. p. 159. [b] *Wallis*, ibid. [c] *Malcolm's* Treat. of Muſic, p. 519. [d] *Wallis*, ubi ſupra. [e] Vid. Phil. Tranſ. N° 481. p. 269. [f] *Wallis*, ibid.] See the articles TETRACHORD and INTERVAL.

HYPATE *Hypaton*, in the antient Greek ſcale, was the note next to the proſlambanomenos, and anſwers to the loweſt *mi* of Guido's ſcale. *Wallis*, Append. ad Ptolem. Harmon. p. 157. See the articles DIAGRAM and INTERVAL.

HYPATE *Meſon*, in the Greek ſcale of muſic, was the firſt note of the meſon, and the laſt of the hypaton tetrachord. It anſwers to *Elami* of the Guidonian Scale. Id. ibid. See the articles DIAGRAM and INTERVAL.

HYPECOUM, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is a ſmall perianthium compoſed of two leaves, placed oppoſite to one another, of an oval figure, pointed, and ſtanding erect, and falling with the flower. The flower is compoſed of four petals, the two outer of which are placed oppoſite to one another, and are broad, divided into three lobes, and obtuſe. The two interior petals are placed alternately with the outer, and are ſlightly trifid, the middle ſegment being flatted, but ſomewhat hollow, and placed erect. The ſtamina are four erect tapering filaments, ariſing from the jaggs or ſegments of the inner petals; the antheræ are erect and oblong; the germen of the piſtillum is oblong, and of a cylindric form; the ſtyles are two in number, and are very ſhort; the ſtigmata are acute. The fruit is a long, crooked, flatted, and jointed pod; the ſeeds are of a roundiſh compreſſed form, and placed ſingly one in each joint of the pod. *Linnæi* Gen. Plan. p. 54.

The characters of *Hypecoum*, according to Tournefort, are theſe: The flower conſiſts of four leaves, diſpoſed in form of a croſs, and each of them is uſually trifid at the edge; the piſtil ariſes from the cup, and finally becomes a flatted and jointed pod, containing in every joint or knot one reniform ſeed.



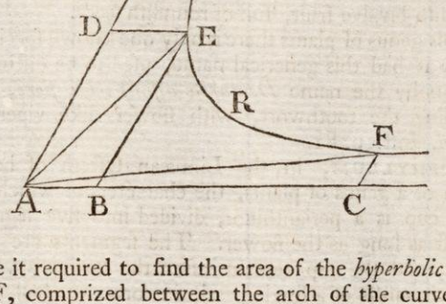
The ſpecies of *Hypecoum* enumerated by Mr. Tournefort, are two: 1. The broader leaved *Hypecoum*. And, 2. The narrower leaved kind.

Theſe have been uſed to be called *cuminum ſiliquoſum*, or podded cummin, by the old writers in botany. *Tournefort's* Inſt. p. 230.

HYPENEMIUS, an epithet applied by authors to barren eggs, or ſuch as a hen lays before ſhe has been trod by the cock. They are alſo called *zephyria ova*, and had both theſe names from the winds being ſuppoſed to generate them.

HYPERBIBASMUS, Ὑπερβιβασμος, in rhetoric, a figure which inverts the order of conſtruction. Cornelius Nepos gives an inſtance of it in his life of Chabrias: *Athenienſes diem certam Chabriæ præſtituerunt, quam ante domum niſi rediſſet*, &c. for *ante quam*. *Voſſ.* Rhet. l. 4. p. 36.

HYPERBOLA (*Cycl.*)—*Hyperbolas* of all degrees may be expreſſed by the equalion $x^m y^n = a^{m+n}$ where a is a given quantity, x an abſciſſa taken on the aſymptote, and y an ordinate to the aſymptote.



If from any point B of ſuch an *Hyperbola*, a line BC be drawn parallel to one aſymptote, and terminated by the other, and the parallelogram BCAD be compleated: Then will this parallelogram be to the *hyperbolic* ſpace BCEO infinitely produced, as m—n to n. *L'Hopital.* Sect. Coniq. Art. 240. Hence, 1°. When m—n is poſitive; that is, when m is greater than n, we may always find the quadrature of ſuch *hyperbolic* ſpaces.

2°. When $m = n$, then $m - n = o$, and the ratio of the parallelogram is to the *hyperbolic* area as o to n. In which caſe this area becomes infinite.

3°. When m is leſs than n, $m - n$ is negative; and in this caſe the parallelogram is to the *hyperbolic* ſpace as a negative number is to a poſitive; which led Dr. Wallis and others to ſay, that theſe *hyperbolic* areas were more than infinite. See *L'Hopital.* Sect. Coniq. Art. 242.

But the truth is, this ratio of a negative number to a poſitive only ſhews, that the ſpace bounded by DB (the other ſide of the parallelogram) by the curve and aſymptote infinitely produced, is to CBDA as m to $n - m$. *L'Hopital*, ibid. See alſo *Maclaurin's* Fluxions, Art. 294.

Although the area comprehended between the Apollonian *Hyperbola* and its aſymptote, be infinite, yet any ſegment, or ſector of this curve, may be ſquared by means of logarithms. For inſtance:

Suppoſe it required to find the area of the *hyperbolic* ſegment EBCF, comprized between the arch of the curve ERF, the lines EB, FC parallel to the aſymptote AD, and BC, the portion of the other aſymptote intercepted between them. Then if ABED, the parallelogram of the *Hyperbola*, be taken as unity, the ſpace EBCF will be Napier's logarithm of the ratio of AC to AB, or of BE to FC. Hence if we had tables of ſuch logarithms, we might find the area of EBCF by ſubducting the logarithm of FC from that of BE, and the difference would expreſs the ratio of the ſegment to the parallelogram ABED or 1. But as ſuch tables are not extant, ſome farther trouble is requiſite to convert the common or Briggs's logarithm into Napier's. Take therefore from the common tables the logarithm of the ratio of BE to FC, that is, the difference of their logarithms, and multiply this difference by 2.3025851, the *hyperbolic* logarithm of 10, the product will give the ratio of the ſegment to the parallelogram ABED or 1. Thus ſuppoſing BE = 36, and CF = 5, and the parallelogram ABED = 1.

From 1.5563025 = log. of 36.
Subduct 0.6989700 = log. of 5.
Difference 0.8573325 = log. of $\frac{36}{5}$.

Then 0.8573325 × 2.3025851 = 1.9740810 for the area of the ſegment BEFC. This multiplication may be performed in Oughtred's contracted way.

Huygens, to avoid the multiplication by 2.302, &c. finds its logarithm = 0.3622156887, and always adds this to the logarithm of the difference before found, and then finds the number correſponding to this ſum. See *Horol.* Oſcillat. and *Grandi*, Dem. Theor. *Huygen.* in fine.

If it were propoſed to find the area of the ſector AERF; as this is equal to the ſegment EBCF, the ſame method may ſerve. But it may alſo be done by ſeveral other analogies; for which ſee *Cotes*, Harm. Menſur. p. 12, 13. See alſo p. 25, 26, of the ſame book.

HYPERBOLIC (*Cycl.*)—HYPERBOLIC *Logarithm*. See the article LOGARITHM.

HYPERBOLIC *Space*, in the higher geometry, the area or ſpace contained between the curve of the hyperbola, the aſymptote, and the ordinate.

HYPERBOLICUM *Acutum*, a ſolid made by the revolution of the infinite area of the ſpace contained between the curve of the hyperbola and its aſymptote. This produces a ſolid infinitely long, and yet is demonſtrated to be equal to a finite ſolid or body. For the true ſenſe of ſuch expreſſions ſee the article LOGARITHMIC.

HYPERICUM, *St. John's Wort*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, conſiſting of ſeveral leaves diſpoſed in a circular form; the cup conſiſts alſo of ſeveral leaves, and from this there ariſes a piſtil, which finally becomes a trigonal, three pointed, and tricapſular ſeed veſſel, filled with ſmall ſeeds. To theſe marks it may alſo be added, that the leaves of the *Hypericum* grow two at every joint. The ſpecies of *Hypericum*, enumerated by Mr. Tournefort, are theſe:

1. The common yellow-flowered *Hypericum*. 2. The common *Hypericum*, with blood-coloured ſpots. 3. The moneywort leaved *Hypericum*. 4. The ſhort leaved *Hypericum*, called the Syrian and Alexandrian St. John's wort. 5. The curled *Hypericum*, with triangular pointed leaves. 6. The ſmaller upright *Hypericum*. 7. The ſmall procumbent ſmooth *Hypericum*. 8. The larger woolly procumbent Spaniſh *Hypericum*. 9. The ſmaller woolly procumhent French *Hypericum*. 10. The woolly procumbent marſh *Hypericum*, commonly called the marſh *aſcyron*, or *St. Peter's wort*, with hoary leaves. 11. The round ſtalked upright hairy *Hypericum*. 12. The *Hypericum* of mount Olympus, with leaves hairy about the edges. 13. The beautiful, not branched, broad-leaved *Hypericum*. 14. The large leaved perfoliate *Hypericum*. 15. The ſquare-ſtalked *Hypericum*, commonly called *aſcyron*, and *St. Peter's wort*. 16. The ſtone *Hypericum*, with very fine bluiſh-green leaves. 17. The ſtinking ſhrubby *Hypericum*. 18. The perfoliated and perforated leaved *Hypericum*. 19. The great flowered low Alpine *Hypericum*, with ſpotted flowers. 20. The broad leaved Portugal *Hypericum*, with myrtle-like leaves. 21. The toad-flax leaved Portugal *Hypericum*. And, 22. The ſmalleſt woolly Portugal *Hypericum*. *Tourn.* Inſt. p. 254.

Hypericum is a good vulnerary, detergent, and nervous medicine: it is given with ſucceſs in ſpitting of blood, or voiding it by urine; it reſolves coagulated blood, promotes the menſes and urine, deſtroys worms, and ſtands recommended in all nervous caſes.

HYPERINESIS, a word uſed by Hippocrates for any exceſſive evacuation, but moſt frequently in the ſame ſenſe as hypercatharſis, an over-purging.

HYPEROA, a word applied by authors to the upper part, or palate of the mouth, and the baſis cerebri. It properly ſignifies any upper place.

HYPEROCHE, in muſic, is the difference between the enharmonic and chromatic dieſes. It is expreſſed by the proportion of 3125 to 3072: For, $\frac{3125}{3072} = \frac{25}{24} : \frac{128}{125}$. Mr. Henſling has made uſe of this term. Miſc. Berol. v. 1. p. 279, 280.

HYPNOTICUS *Serpens*, the *ſleep-ſnake*, in zoology, the name of an Eaſt Indian ſpecies of ſerpent, called by the Ceyloneſe *nintipolong*, a word importing the ſame ſenſe. It is of a deep blackiſh brown, variegated with ſpots of white, and is a very fatal kind in its poiſon, its bite always bringing on a ſleep which ends in death. *Ray*'s Syn. Anim. p. 332.

HYPNUM, in botany, the name of a genus of moſſes, the characters of which are theſe: The capſules or heads are uniform, and covered with a calyptra and operculum; they are uſually of an oval or oblong figure, and commonly ſtand on long pedicles which ariſe from the alæ of the leaves, and are ſurrounded at the bottom with a foliaceous or lanuginous bed different from the leaves. This covering of the bottom of the ſtalk, is called by authors perichætium, and is itſelf a ſufficient diſtinction of the *Hypna* from all other moſſes, the brya, mnia, ſphagna, &c. having none of them any ſuch thing. To this it is to be added, that the branches of the *Hypnums* are uſually ſpread about upon the ground, and are perennial; and that there is what Botaniſts call a *facies propria*, or peculiar look of the plant, which at firſt ſight diſtinguiſhes the genus to an obſerver uſed to ſuch things. *Dillen.* Hiſt. Muſc. p. 270.

As the family of the *Hypna* is very numerous, they are uſually divided into ſeveral orders. Of the firſt order are thoſe *Hypna* which have erect heads, or at leaſt ſuch as are but a little bent; and of this order the firſt ſeries comprehends ſuch as are pennated, or whoſe pinnæ are placed in two, ſometimes in three rows on each ſtalk, or in the ſame plane. The firſt diviſion of this ſeries comprehends thoſe which have flat and ſmooth pinnæ: Of theſe the following are all the known ſpecies: 1. The ſmalleſt yew-leaved *Hypnum*; this produces its capſules always toward the ſummits of the ſtalks. 2. The ſmall procumbent yew-leaved *Hypnum*; this produces capſules at the baſis of the ſtalk. 3. The great branched, upright, and yew-leaved bog *Hypnum*; this grows in wet places, and is much larger than the two former, and branched, they being only ſingle leaves of half an inch or a little more in height. 4. The Acacia leaved *Hypnum*, with ſhort pedicles; the branches of this are ſhort, ſometimes ſimple, ſometimes branched. 5. The double-rowed *Hypnum*, with crooked fins; this is compoſed of numerous branches of about an inch long, ſpread every way about upon the ground. 6. The ſingle rowed *Hypnum*, with ſtraiter fins; the pinnulæ on this ſtand looſely together, and the ſtalks are branched. 7. The glittering feather-leaved *Hypnum*, with oval heads; this grows to two or three inches long, and uſually fixes itſelf on the branches of trees. 8. The trichomanes-like gliſtering feathered *Hypnum*; this alſo grows on the barks of trees, but it adheres leſs firmly to them than the former. 9. The tranſparent bird's-foot leaved *Hypnum*; this is found in Patagonia. 10. The large ſhining membranaceous water *Hypnum*; this grows in watery places, and is uſually two or three inches long, and the heads grow uſually from the lower part of the ſtalk, though ſometimes higher. Id. ibid. p. 271.

The ſecond diviſion of this ſeries of the *Hypnums*, contains thoſe which have undulated and curled leaves; of theſe the following are all the known genera: 1. The trailing *Hypnum* with waved fins; this is remarkably diſtinguiſhed from the other *Hypna*, by its ſpreading on the ground in the manner of the lycopodium. 2. The wavey feathered *Hypnum* with ſhort ſhanks; this grows from two inches to ſix or ſeven in length, and is a very beautiful kind; it is found on the chalk-hills about Graveſend. Id. ibid. p. 274.

The ſecond ſeries of the *Hypnums* is that of the fern-like kinds, called by many fern-moſſes; theſe have their ſtalks every way ſurrounded with leaves, and their ramifications all placed in the ſame plane, ſo that they reſemble the ferns. Of theſe the following are all the known ſpecies: 1. The large ſhining fern *Hypnum* with tamariſk leaves; this is a very beautiful moſs, it grows erect, and is ſix inches high; it is common in our woods. 2. The leſſer fern *Hypnum* with tamariſk leaves; the branches of this are as long as thoſe of the former, but they are more flexuous, and bent in ſeveral parts. 3. The fine dented trailing fern *Hypnum*; it grows ſometimes on the ground, and ſometimes on the trunks of old trees, and is diſtinguiſhed by the remarkable ſmallneſs of its leaves. 4. The ſhining plume fern *Hypnum*; this is a fine ſilky kind, found not unfrequently on walls and old trees. 5. The tough thready hill *Hypnum*; this is of a yellowiſh colour, and its branches are remarkably pointed. 6. The yellow thready *Hypnum*; this is a very ſmall ſpecies, but uſually grows in large tufts, and is found on old trees in Virginia. 7. The curled fern *Hypnum*; this grows to three or four inches in length, and is common in wet places in Suſſex and ſome other counties. 8. The plume creſted *Hypnum*; this is a very elegant plant, and varies much in its ſize in different ſoils, being very ſhort, and in thick tufts in dry places; and longer, and growing more looſely, in wet ones. 9. The fine leaved bog *Hypnum*; the leaves of this kind are of a very beautiful yellowiſh green, and are in moſt parts of the plant reflected at their points; this is frequent in boggy places about London, as on Hampſtead-heath, &c. 10. The ſoft and pale glittering fern-like *Hypnum*; this is common about the ſtumps of trees, but very rarely produces its capſules. Id. ibid. p. 293.

The third ſeries comprehends the ſquammoſe *Hypnums*; that is, ſuch as have their leaves every way ſurrounding the ſtalks in the manner of ſcales. Of theſe the firſt diviſion contains ſuch as have their leaves and the ends of the branches bent downwards. The following are all the known ſpecies of theſe: 1. The curled cypreſs-like *Hypnum*; this has crooked leaves, and does not creep, but grows in large tufts, in which the ſeveral branches lie over one another; it is very common in woods about the roots of trees. 2. The yellow, wolf's-claw *Hypnum*; this ſeldom grows to more than three inches in length, yet has very much of the appearance of the lycopodium. 3. The great ſcorpioide creeping bog *Hypnum*; this alſo ſpreads itſelf in the manner of the lycopodium, and is found in watery places in Shropſhire and elſewhere. 4. The leſſer upright ſcorpioide bog *Hypnum*; this is a very elegant moſs, and is very frequent in boggy places in moſt parts of England. 5. The creeping many-headed water *Hypnum*; the branches of this ſpecies are long and trailing, and uſually deſtitute of leaves, but from their ſides and extremities there iſſue young ſhoots covered with thick-ſet and deep green ones; it is common on the Thames ſhore, but ſeldom produces any capſules. Id. ibid. p. 292.

The ſecond diviſion of this ſeries of the *Hypnums*, takes in thoſe which are ſquammoſe and dentated; a firſt ſubdiviſion of theſe alſo is eſtabliſhed, to comprehend ſuch as have their leaves ſtanding out, whether broad or narrow. Of this ſubdiviſion are the following ſpecies: 1. The great triangular pale-green *Hypnum*; this grows to ſix or ſeven inches long, and is not unfrequent in woods and under hedges. 2. The moſt common dented ground *Hypnum* with obtuſe heads; this is very frequent at the roots of old trees, and in dry paſtures, and produces a great number of heads. 3. The common dented ground *Hypnum* with ſharp beaked heads; this alſo is very common about the ſtumps of trees in woods and hedges. 4. The knee-holly leaved *Hypnum*; this is ſmaller and ſhorter than the former, and grows in wet places upon ſtones,

ſtones. 5. The long water *Hypnum* with oval ſhining leaves; the ſtalks of this are eight inches or more in length, and the leaves ſmall and arranged cloſely together. 6. The long-leaved floating *Hypnum*; this is very common in watery places in Ireland. 7. The ſpear-pointed bog *Hypnum*; this is an elegant moſs, very common on Hampſtead-heath; the leaves are ſo convoluted at the ends of all the branches, that they form points which appear prickly. 8. The yellow ſtarry bog *Hypnum*; this is ſmaller than the former, and the leaves, inſtead of being convoluted into points at the ends of the branches, are expanded ſo as to form a ſort of radicated ſtar at the end of each. 9. The yellow woolly bog *Hypnum*; this is a beautiful erect bog moſs, with a yellow tufted head, and a black baſis, the bottom part of every ſtalk being black and deſtitute of leaves. 10. The larger *Hypnum*, with reflex or drooping leaves; this is a very elegant moſs, every leaf appearing in ſhape of a hook from the ſtalk. 11. The leſſer drooping leaved *Hypnum*; this is of a paler colour than the former, and the leaves are more bent and ſhorter; both theſe are very common in our woods. 12. The rambling round-headed mountain *Hypnum*; the heads of this ſpecies are remarkably round in ſhape; it is common in Ireland, but leſs frequent with us. 13. The fox-tail *Hypnum*; the name carries a ſufficient deſcription of this remarkable ſpecies, which is not found with us, and no where, ſo far as is yet known, except in the Canary Iſlands. 14. The rambling ſlender-headed ſtone *Hypnum*; this is a native of Germany, and is common there about the rocks, whence ſprings iſſue. 15. The upright ſlender *Hypnum*, with cylindrical heads; this is moſt frequently found on the ſtumps of trees, but ſometimes on the ground in dry hilly places. Id. ibid. p. 302.

The ſecond ſubdiviſion of theſe *Hypnums*, comprehends thoſe whoſe leaves being cloſely applied to the ſtalks, give them a cylindric figure; of this kind are the following ſpecies: 1. The water *Hypnum*, with round and feathered branches; that part of this plant which grows out of the water, has cylindric branches; but that which is under water, has the leaves ſtanding out in the manner of the *Hypna* of the former ſubdiviſion; it is common in the Thames and other rivers. 2. The blunt cypreſs-like *Hypnum*; this is ſometimes ſingle, ſometimes branched, and is common in woods and on large ſtones. 3. The round cypreſs or ſtone crop-like *Hypnum*; the ſtalks and branches in this are more erect than in the former, and more rounded; it grows on the ground in dry places. 4. The finer cypreſs-like *Hypnum*; this has the ſtalks of the young ſhoots covered with ſmaller and more pointed leaves; the branches are long and trailing, it grows on the ground in dry places, but rarely produces its capſules. 5. The long-ſhanked ſhining ſhrub *Hypnum* with upright heads; this is a very elegant moſs, it grows to three inches in height, the ſtalks are hard and woody, and naked from the ground to two-thirds of the height, it grows in woods. 6. The larger mouſe-tail *Hypnum* with upright heads; this is of a pale green, and is common on rocks, and at the roots of old trees. 7. The ſhort ſhanked dark-green ſhrub *Hypnum* with bowing heads; this is taller than the common ſhrub *Hypnum*, and more branched; it grows in thick woods. 8. The ſlender mouſe-tail *Hypnum* with ſtooping heads; this is of a very beautiful green, and is common under hedges at the ſtumps of trees. 9. The leſſer thick mouſe-tail *Hypnum* with ſtooping heads; the ſtalks of this are about an inch long, and the young ſhoots very ſhort and ſmall, the leaves are oval and obtuſe; it is of a yellowiſh-green, and is frequently found on old walls. 10. The fine ſhining mouſe-tail *Hypnum* with upright heads; this is leſs branched than the former, and of a darker green, it grows on old walls. 11. The ſquirrel-tail tree *Hypnum*; the ſtalks of this are long and variouſly interwoven, and the leaves are of a deep green; it grows on the trunks of trees. 12. The ſlender crooked *Hypnum*, reſembling the pods of the ſmooth-podded bird's-foot; this is a very elegant ſpecies; it is of a ſilky yellowiſh-green, and the branches are ſhort and crooked, bending into the ſhape of the pods of that plant; it grows on the ſtumps of trees, and on rocks. 13. The catkin *Hypnum* with long hoſes; the leaves are oval and obtuſe, and the young ſhoots much reſemble the juli or catkins of the hazel; the perichætia, or coats ſurrounding the baſes of the pedicles of the capſules, are remarkably long. 14. The creeping catkin *Hypnum* with ſoft ſhining branches and ſlender heads; it is ſmall, and of a yellowiſh green, and grows on the ground; and is common in Virginia and Penſylvania. 15. The catkin *Hypnum* reſembling the ſilver bryum; this grows in thick tufts unmixed with other moſſes, and is common on the ſtumps of trees in Maryland and Virginia. Ibid. p. 307.

The third diviſion of this order of *Hypna*, comprehends thoſe called the trichoide and ſilky ones; theſe have extremely fine and ſmall leaves, placed in the manner of ſcales one over another. The following are the known ſpecies of this kind: 1. The common bending ſilk *Hypnum* with ſtrait-pointed heads; this is ſmall and very ſilky; it grows on the ground, and on walls and trees, in great plenty, in moſt places. 2. The trailing ſilk *Hypnum* with bending heads; the branches of this are longer and more erect than thoſe of the former; it grows uſually upon the ground in dry places. 3. The velvet *Hypnum* with ſtooping oval heads; this grows in thick tufts about the roots of trees, and is of a yellowiſh-green. 4. The ſlender ſilk *Hypnum* with pointed heads; this is very much branched, and its ſtalks are uſually entangled one within another; this is very frequent on old trees, ſtones, bones, and other things, and is what is generally found on the human ſkull, after being long expoſed to the weather. 5. The ſlender ſilk *Hypnum* with roundiſh heads; this is a ſmall moſs, and grows tolerably erect, and ſeldom in thick tufts; it is of a mixed colour of green and yellow, and grows in heaths where there is little graſs. 6. The long red-ſhanked capillary trailing *Hypnum* with long heads; the branches of this are long, the young ſhoots very ſmall and ſhort; it grows on the earth, and ſpreads itſelf over ſtones, ſticks, or whatever lies in its way. 7. The ſhort-ſhanked capillary *Hypnum* with long heads; the leaves of this are broader and ſhorter than thoſe of the precedent, and it produces a great number of heads; it is common in the woods of Germany, and in North America. 8. The branched hairy tree *Hypnum*; this is a large moſs, and the ſtalks are very much branched; it is common in the woods of Germany. *Dillen.* Hiſt. Muſc. p. 331.

The ſecond order of the *Hypnums* contains thoſe with pendulous heads; of theſe there are only three known ſpecies: 1. The ſmall dented black *Hypnum* with ſtooping heads; the ſtalks are very ſhort and ſlender, the leaves of an oval figure, and ſet looſely one by another; they are of a deep dead green, and become black in drying; it is a remarkably ſmall moſs, and grows in Patagonia on the ſtumps of trees. 2. The herring-bone *Hypnum*; this is an upright moſs not branched, and its leaves are very long and ſlender, and ſo diſpoſed as to reſemble the ſpine of a ſmall fiſh; it was found by Sir Hans Sloane on the mountains of Jamaica. 3. The ſtiff-branched ſhort-ſhanked *Hypnum* with pendulous heads; this is a procumbent moſs, and has its branches uſually interwoven variouſly together; it is of a deep green, and grows on the ſtumps of old trees. Ibid. p. 333.

The third order of the *Hypna* contains a number of ſpecies leſs known than the others, and about which there is ſome doubt among authors, whether they are truly *Hypna*, and regularly diſtinct from the others. Theſe are, 1. The black water *Hypnum* with hooked leaves; this is deſcribed by Pontedera, Micheli, and other writers, and is wholly different from all the other *Hypna*, and indeed from all other moſſes; but it ſomewhat approaches to the character of the bryums. 2. The elegant ſcaly *Water-moſs* deſcribed by Feuillée; the branches of this are long, the leaves are of a pleaſant green, and placed like ſcales over one another; it grows in the rivers of Peru. 3. The ſquare-branched *Hypnum* of Jamaica; this is a ſmall moſs, and its leaves are very numerous, and very little, but are ſo diſpoſed in four ſeries, as to make the ſtalks appear ſquare. Sir Hans Sloane found this in the woods on the mountains of Jamaica. 4. The great creeping *Ground-moſs*, with branches conglobated at the extremities, and with ſmall leaves every way ſurrounding and hiding the ſtalk. This alſo was found by Sir Hans Sloane in Jamaica. 5. The ſmaller creeping *Earth-moſs*, with ſtalks conglomerated at their extremities, and with capillaceous leaves. 6. The ſubterranean *Water-moſs*, found in Pruſſia at a great depth under ground, in a watery place, digging for a well. 7. The black ſcaly middle-ſized *Water-moſs*. 8. The greater black-branched *Water-moſs*. 9. The ſcaly *Earth-moſs* with ſmall leaves and a little red head. 10. The creeping ſcaly *Earth-moſs*, with ſmall deep green leaves ſet very cloſely together, 11. The white leaved ſcaly *Earth-moſs*. 12. The ſcaly *Earth-moſs*, with long pale-green ſhoots. 13. The *Earth-moſs*, with conglobated heads, and very few leaves upon the ſtalks. 14. The common ſmall creeping *Earth-moſs*. 15. The little ſcaly *Moſs*, with heads growing on long pedicles at the ends of the branches. All theſe laſt are deſcribed by Pontedera, but imperfectly; and both they, and many of Micheli's, probably belong to ſome of the before-mentioned ſpecies; but as they want in the deſcriptions and figures the diſtinguiſhing characters of the ſpecies, Dillenius has prudently avoided determining any thing about them. Ibid. p. 342.

HYPOCAUSTUM (*Cycl.*)—The remains of a Roman *Hypocauſtum*, or ſweating-room, were diſcovered under ground at Lincoln, in 1739. We have an account of theſe remains in the Phil. Tranſ. N°. 461. Sect. 29.

HYPOCHÆRIS, in botany, the name of a genus of plants, the characters of which are theſe: The common cup is of an imbricated figure, and is ſwelled at the baſe, and compoſed of ſharp-pointed ſcales. The flower is of the compound kind; it is imbricated and uniform. The ſeparate flowers of which this is compoſed are numerous, and equal in ſize; each is compoſed of one leaf, and is narrow, of a ligulated ſhape, truncated, and divided into five ſegments at the edge. The ſtamina are five very ſhort and capillary filaments. The antheræ are cylindric and tubular. The germen of the piſtil ſtands under the flower. The ſtyle is capillary, and of the length of the ſtamina. The ſtigmata are two in number, and are reflex. The cup, after the flower is fallen, ſerves as a ſeed veſſel; it ſcales cloſe at the top, and it becomes of a roundiſh but pointed figure. The ſeeds are ſingle and oblong,

long, and terminate in a ſubulated and pappoſe ſtalk. The receptacle is beſet all over with little chaffy ſubſtances. Theſe are of the length of the ſeeds, and are placed between them. Linnæus makes this genus comprehend the *Hypochæris* and the achyrophorus of Vaillant. The only difference between which is, that the *Hypochæris* has a roundiſh cup all over imbricated, and a plumoſe down upon the ſeeds, whereas the achyrophorus has an oblong cup, which is imbricated only at the baſe, and a ſimple down on the ſeed. *Linnæi* Gen. Pl. p. 377.

HYPOCHONDRIAC *Malady* (*Cycl.*)—It is obſervable that perſons, ſubject to this diſorder, very rarely fall into continued, epidemic, or contagious fevers, and even eſcape the plague, and remain free from many other diſorders. *Hofm.* Oper. T. 3. p. 65.

This diſorder is confounded by Sydenham and others, with *hyſterics*; but Hofman inſiſts that the difference is conſiderable, and deſerves to be attended to in practice. See Oper. T. 3. p. 50. ſeq. See the article HYSTERICS.

HYPOCRATERIFORMIS, *faucer-ſhaped*, in botany, the name given by Mr. Tournefort to a peculiar ſort of flowers of plants, of the general order of the infundibuliform, but not ſo deep and narrow at the mouth as thoſe ſimply ſo called, but expanded into the figure of a ſaucer. *Tourn.* Inſt. p. 116. See the article INFUNDIBULIFORMIS.

HYPODIACONORUM *Feſtum.* See the article CALENDARIUM *Feſtum.*

HYPODORIAN, in antient muſic, a name for the ſeventh ſpecies of the diapaſon, otherwiſe called *locrian*, and *common*. See the article DIAPASON.

HYPOLYDIAN, in antient muſic, the fifth ſpecies of the diapaſon. See DIAPASON.

HYPOMNEMATOGRAPHUS, ὑπομνηματογραφος, in the primitive church, an officer who attended on the biſhop, and kept a regiſter of his conſecrations. *Hofm.* Lex. in voc.

HYPONITIS, in botany, a name given by Dillenius to a genus of plants, called by Tournefort, *orobanchoides*. See the article OROBANCHOIDES.

HYPOPHORA, Ὑποφορά, in rhetoric, the firſt part of the *prolepſis*: Thus, in the inſtance mentioned in the cyclopædia, *but ſome men will ſay, How are the dead raiſed, or with what body do they come?* is the *Hypophora*. And, *thou fool, that which thou ſoweſt*, &c. is the *Anthypophora*, or ſolution of the objection. *Voſſ.* Rhet. l. 5. p. 393. See the article PROLEPSIS, *Cycl.*

HYPOPHRYGIAN, in antient muſic, the ſixth ſpecies of the diapaſon. See the article DIAPASON.

HYPOPHTHALMUM, in botany, a name uſed by ſome authors for the aſter atticus. *Ger.* Emac. Ind. 2.

HYPOPODIUM, in antiquity, a piece of furniture belonging to the baths; its uſe was to ſet or reſt the feet on. *Pitiſc.* Lex. in voc.

HYPOPROSLAMBANOMENOS, in muſic, the name of the chord added by Guido Aretine, below the *Proſlambanomenos* of the Grecian ſcale, anſwering to our 6. See DIAGRAM.

HYPOPYON (*Cycl.*)—The cure of this diſtemperature of the eyes is ſometimes effected by violently ſhaking the head. The antients uſed this practice as an approved remedy; and accident has ſhewn it to be often ſucceſsful ſtill. The jolting of a chariot, in a long journey, having been known to remove the diſorder, by making the purulent matter ſubſide behind the uvea. This method of ſhaking ought, therefore, always to be made the firſt attempt, to give relief in this caſe, diſpoſing the patient's head in a ſupine poſture, and preſſing the eye before-hand with the fingers, in order to remove, or at leaſt looſen the matter. *Heiſter*'s Surgery, p. 425.

But if this attempt proves unſucceſsful, the neceſſary operation muſt be performed. The patient muſt be ſeated againſt the light, with his head and hands firmly ſecured by an aſſiſtant. The ſurgeon is then to depreſs the lower eyelid, while the aſſiſtant elevates the upper; and the ſurgeon is then with a lancet to incide cautiouſly through the cornea, below the pupil, making the opening large enough to diſcharge the matter, with the aqueous humour; but taking great care not to wound the uvea behind the matter. About three or four hours afterward the eye muſt be dreſſed with a compreſs, dipped in a collyrium of roſe-water, white of eggs, mucilage of quince ſeeds, and a little camphor; and by this means the wound in the cornea will be healed, the aqueous humour will be reſtored, and if none of the interval parts are injured, the patient will recover his ſight.

HYPOSCENIUM, Ὑποσκηνιον, in antiquity, a partition under the pulpit or logeum of the Greek theatre, appointed for the muſic. *Potter*, Archæol. Græc. l. 1. c. 8. p. 42. See the article LOGEUM.

HYPOSCHESIS, Ὑποσχεσις, in rhetoric, the ſame with *diviſion*. See the article DIVISION.

HYSSOP, *Hyſſopus*, (*Cycl.*) in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf, and is of the labiated kind; the upper lip is erect, roundiſh, and bifid; the lower is divided into three ſegments, the middle one being hollowed in the manner of a ſpoon, and double pointed, and as it were elated. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and ſurrounded by four embryo's, which afterwards become ſo many ſeeds, ripening in the cup of the flower.

The ſpecies of *Hyſſop*, enumerated by Mr. Tournefort, are theſe: 1. The common blue flower'd *Hyſſop*. 2. The *Hyſſop*, with flowers all round the ſtalks. 3. The ſweet ſmelling or muſk *Hyſſop*. 4. The curl'd-leav'd *Hyſſop*. 5. The *Hyſſop* with deeply divided leaves. 6. The ſhort round ſpiked *Hyſſop*. 7. The variegated or golden *Hyſſop*. 8. The common *Hyſſop*, with white flowers. 9. The common *Hyſſop*, with purple flowers. 10. The hairy *Hyſſop*. 11. The white-flower'd hairy *Hyſſop*. And, 12. The low myrtle-leav'd *Hyſſop*. *Tourn.* Inſt. p. 200.

The ſeveral ſpecies of *Hyſſop*, when not in flower, may be known by their long narrow leaves, and their peculiar agreeable ſmell.

All the ſorts of this plant, the common, as well as the more ſcarce, are propagated by ſowing or by cuttings. The ſeeds muſt be ſown in March, on beds of a light ſandy ſoil, and when the plants are come up, they muſt be cleared to a foot aſunder every way; or if they are intended to remain many years, they ſhould be left at two foot diſtance, for they grow quick, and ſpread very much. They thrive beſt on a poor dry ſoil, and will bear the ſeverities of winter much better on ſuch a ſoil, than on a richer. When they are to be propagated from cuttings, it is to be done in April or May, in a border where they may be defended from the violent heat of the ſun, and, being frequently watered, they will take root in two months, after which they may be tranſplanted to the places where they are to remain, managing them as the ſeedling plants. *Miller*'s Gardener's Dict.

Hyſſop is greatly commended is caſes of bruiſes from falls, blows, &c. uſed externally by way of cataplaſm, or only a little bundle of the plant ſewed up in a linnen rag, and applied to the part. Ray gives an account from Mr. Boyle, of a violent contuſion of the thigh, from a kick of a horſe; which was happily cured by this herb, boiled and applied as a cataplaſm. He tells us, the violent pain was almoſt inſtantly removed, and the very mark and blackneſs taken off in a few hours.

HYSSOP, among the antient Jews. A bunch of *Hyſſop* could only be uſed to ſprinkle the door-poſts and threſholds of their houſes with the blood of the paſſover-lamb. See the article PASSOVER, *Cycl.*

Hedge HYSSOP. See the article GRATIOLA.

HYSTERA, a term uſed by ſome of the old writers in medicine to expreſs the ſecundines.

HYSTERICS, (*Cycl.*) *Hyſterica Paſſio*, in medicine, the name of a diſtemper attending women, which is, in many reſpects, of the ſame nature with the hypochondriac paſſion in men: But as they are uſually of more tender conſtitutions than men, it afflicts them more violently, and often brings on a terrible ſenſation of ſtricture of the breaſt, and a ſort of ſuffocation, whence it is called by ſome *ſuffocatio uterina*, together with convulſions and ſpaſms of violent kinds. Hence ſome have alſo called it an uterine epilepſy; violent anxieties, with nauſeas, reaching to vomit, and other painful and often dangerous complaints uſually alſo attend it, which are unknown to men in their hypochondriac diſorders.

This diſtemper ſeems to ariſe from congeſtions of blood in the abdomen, and in the viſcera, ſituated there, which ſhould find paſſage by the uterus, or the hæmorrhoidal veins, but is impeded. And as this is alſo the cauſe of the hypocondriac affections in men, it is no wonder that the generality of ſymptoms are the ſame in both, and that the method of cure muſt be nearly the ſame. It is to be obſerved, however, that tho' obſtructions are the common cauſe of theſe diſeaſes in both ſexes, yet women are ſometimes found afflicted with this while the menſes flow properly, in due quantity, and at their regular periods. In this caſe, the diſorder ſeems owing to acrid humours in the primæ viæ, exciting ſpaſms wherever they come. *Heiſter*'s Comp. Med. p. 184.

In the time of the fit, when the ſenſation of ſtrangulation is violent, or there are convulſive motions, or faintings, the fœtid and volatile medicines ſerve to recover the patient; ſuch are ſpirit of hartſhorn, oil of amber, tincture of caſtor, and the volatile ſalts held to the noſe, or taken internally, as alſo the burning of feathers, horn, or leather, or any other ſubſtance, which has a very diſagreeable ſmell while in the fire; rubbing the hands and feet alſo are of great ſervice, and ſome recommend the pulling off of the hairs ſingly, and other methods which give pain, to bring the patients to themſelves.

Theſe are the methods to be uſed in the time of the fit; but when the patient is reſtored from that, the ſame method is to be uſed as in the hypochondriac paſſion; only that, in this caſe, a little caſtor is to be added to the ſaline and cinnabarine medicines. After this, care is to be taken to reſtore the menſes to their proper order, if the patient be at a time of life when they ought to flow; but if that period is paſt, the evacuation muſt be, in ſome meaſure, ſupplied by bleeding in the foot, and repeating this every year at the ſpring and fall, and with this ſome doſes of a gentle purge, with a proper regimen.

Vomits are always found very hurtful in theſe caſes, and when violent,

violent, are dangerous in the higheſt degree. Strong purges are alſo liable to the ſame objections, and are never to be meddled with. All hot medicines are alſo prejudicial, and the common uterine elixirs, with the diſtilled oils, and volatile ſalts, are liable to the ſame objections. Some give the common terreſtrial alkalies and abſorbents, but they give no relief in theſe caſes; becauſe an acid either is no cauſe, or, at the utmoſt, is not the eſſential cauſe of theſe diſorders.

Steel medicines are alſo given by many; but they are to be uſed with great caution; and, in general, they ſeldom do any good, but very often a great deal of harm. As there are, however, ſome caſes of this kind in which they excel all other medicines, it is always proper to give them a fair trial, under the proper regulations.

The common chalybeate waters often prove of more ſervice in this diſeaſe than all the medicines in the world; but they are to be taken with the proper cautions, and a due regimen. It is neceſſary to bleed in the foot before entering on a courſe of them, and then they are to be drank in moderate quantities, and always a little warmed, uſing a moderate exerciſe during the time of drinking them. See the article MINERAL *Waters*.

HYSTERICUS *Lapis*, in natural hiſtory, a name given to an American ſtone, called alſo *lapis uterinus*, famous for it virtues againſt diſorders of the womb, externally applied. It is black, and capable of a fine poliſh.

HYSTERICUS *Clavus*. See the article CLAVUS.

HYSTEROPHORUS, in botany, the name of a genus of plants, deſcribed by Vaillant in the Acta Germanica, the characters of which are the ſame with thoſe of the common parthenium. *Vaillant*, A. G. 1720. See the article PARTHENIUM.

HYSTEROPOTMI, ὑστεροπότμοι, in antiquity, perſons who had returned ſafe to their own homes, after having ſtaid ſo long in foreign countries that they were believed to be dead. Theſe were not allowed to be preſent at the celebration of any religious rites, till they had been purified by being let thro' the lap of a woman's gown, that ſo they might ſeem to be new born. *Potter*, Archæol. Græc. l. 2. c. 4. T. 1. p. 223.

HYSTRIX, the *Porcupine*. In the Linnæan ſyſtem of zoology, this makes a diſtinct genus of animals; the characters of which are, that the creatures of it have ears reſembling thoſe of the human ſpecies, and their body armed with thorns. *Linnæi* Syſtem. Natur. p. 38.

J.

JABIRU, in zoology, the name of a large water bird approaching to the crane kind, and called by ſome the *Negro*. It is larger than our ſwan, its neck is as thick as a man's arm, and its head very large; its beak is ſtrait, eleven fingers breadth long, pointed and a little hooked at the end: Its legs are two feet long, and thick and as it were ſcaly. It is all over on the body white, as the ſwan or gooſe. Its neck is naked, and for a long way below the head, is covered, as is alſo the head with a tough black ſkin: It is poſſible however, that there naturally may be feathers on this part; but that only dead birds having been ſeen of this ſpecies the feathers may have fallen off. Its tail is broad and ſhort. *Margrave*'s Hiſt. Braſil.

JABIRUGUACU, in zoology, the name of a Braſilian bird, called by others nanduapoa, and by the Dutch ſcurvogel. See the article SCURVOGEL.

JABOTAPITA, in botany, the name given by Plumier to a genus of plants; ſince characteriſed by Linnæus under the name of ochna. See the article OCHNA.

JABOTI, in zoology, the name of a remarkable ſpecies of tortoiſe found in America. The ſhell of this ſpecies is black, and has many hexangular figures marked upon it: The head and legs are brown variegated with ſpots of a duſky greeniſh hue. The liver of this ſpecies is accounted a very delicate food. *Ray*'s Syn. Quad. p. 254.

JACA, in natural hiſtory, the name of a kind of nut, very common in China, which is reckoned the largeſt of all yet known. It is produced from the trunk of the tree, as if the branches however large and ſtrong were not able to bear it. Its ſhell is ſo ſtrong, that there is occaſion for an ax or hatchet to open it; and within are innumerable cells or veſicles containing a pulp of a yellow colour, which ſurrounds a kernel like the cheſnut, that is exceeding ſweet when ripe. *Hoffm.* Lex. in voc.

JACAMACIRI, in zoology, the name of a very remarkable Braſilian bird, approaching to the nature of the woodpecker, and having feet of the ſame ſort with the birds of that genus, the toes ſtanding two before and two behind. It is of the ſize of a lark. Its feet are yellow, its head, back and wings, are all of a very lively green, variegated with yellow and red; and its breaſt and belly of a duſky yellow. It is a very ſplendid and beautiful bird, its colours glowing very brightly in the ſun. *Margrave*'s Hiſt. Braſil.

JACANA, in zoology, the name of a Braſilian bird, a ſpecies of moor-hen. It is a very elegant and beautiful kind, it is of the ſize of a pigeon, but its legs are much longer, and are of a greeniſh yellow, and all its toes eſpecially the hinder one, are of a very remarkable length. Its tail is ſhort, its colour on the back, belly and wings, is a mixt green and black: Its neck and breaſt are of the changeable colours they are in the peacock, and in ſome pigeons: Its head is ſmall, and is covered with a membrane of the colour of the oriental turquoiſe ſtone: The beak is ſhaped like that of the gallinaceous kind, and is about a finger's breadth long, and is partly of a greeniſh yellow, partly of a very elegant red. It is very common in watery places in Braſil, and is eaten, but not eſteemed a fine fowl. *Margrave*'s Hiſt. Braſil.

JACAPU, in zoology, the name of a bird of the merula or blackbird kind, and of the ſize and ſhape of the common blackbird. Its upper part is all of a deep black, except that the tips of the feathers on the rump are ſlightly greyiſh. Its breaſt is of a very fine red, and its tail long and like that of the common blackbird; as are alſo its beak and feet. *Ray*'s Ornitholog. p. 143.

JACARANDA, in botany, a name given by ſome authors to the tree the wood of which is the logwood, uſed in dying and in medicine. *Piſo*, p. 11.

JACARE, in zoology, the name of an animal found in the Braſils, and very little differing from the crocodile of the other parts of the world, if at all ſpecifically, which Mr. Ray doubts. It has no tongue, but only a ſort of membrane which reſembles the ſhape of one, and which it cannot lift up or move: Its eyes are large, round, clear, and very bright, the iris blue, and the pupil of a fine black: The forelegs are very ſlender and weak; the hinder ones longer, and more robuſt. The forefeet have each five toes; three in the middle, which are long, and armed with very ſharp claws; and two at the ſides, which have none. The hinder feet have only four toes each; one of which only on each foot wants a claw, and is the outer one. The farther half of the tail has a ſtrong erect fin upon it, which is of great uſe to the creature when in the water, ſerving as the fins of fiſhes to aſſiſt it in ſwimming. *Ray*'s Syn. Quad. p. 262.

JACARECATINGA, in the materia medica, the name by which ſome authors have called the Acorus Aſiaticus, or Aſiatic ſweet flag. *Piſo*, p. 24.

JACARINI, in zoology, the name of a Braſilian bird of the goldfinch kind, and of the ſize of our common goldfinch. Its beak is thick and grey, as are alſo its legs and feet; it is all over of a fine ſhining black, like poliſhed ſteel; its wings are white underneath. *Margrave*'s Hiſtor. Braſil.

JACCHAGOGI, Ἰακχαγωγοι, in antiquity, thoſe who carried the ſtatue of the hero Jacchus in proceſſion at the celebration of the Athenian feſtival, called *Eleuſinia*. They had their heads crowned with myrtle. See ELEUSINIA, *Cycl.*

JACEA, *Knapweed*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the floſculous kind, or compoſed of numbers of ſmall floſcules, each divided into ſeveral ſegments at the end, and ſtanding upon an embryo ſeed: Theſe are all contained in one general cup, which is of a ſcaly ſtructure, but not prickly. The embryos finally become each a ſeed winged with down.

The ſpecies of *Jacea* enumerated by Mr. Tournefort, are theſe: 1. The common broad-leav'd field *Knapweed*. 2. The common broad-leav'd field *Jacea*, with white flowers. 3. The black *Jacea*, with jagged leaves. 4. The narrow-leav'd black *Jacea*, with wild gromwel leaves, and a rough ſtalk. 5. The narrow-leav'd black *Jacea*, with wild gromwel leaves and a ſmooth ſtalk. 6. The low *Jacea*, with undivided leaves. 7. The *Jacea*, with hairy ſcales of the cup. 8. The *Jacea*, with pennated ſcales and a hairy head. 9. The great black *Jacea*, with a ſcaly head. 10. The leſſer black *Jacea*, with a ſcaly head. 11. The narrow-leav'd *Jacea*, with hairy heads. 12. The white flower'd hairy headed *Jacea*. 13. The common *Jacea*, with jagged leaves and purple flowers. 14. The common *Jacea*, with jagged leaves and white flowers. 15. The jagged-leav'd *Jacea*, with ſcaly heads. 16. The broad-leav'd *Jacea*, with jagged leaves. 17. The ſoft hoary mountain *Jacea*, with rough heads. 18. The white mountain *Jacea*, with heads like the ſteebe. 19. The purple flowered grey-leav'd jagged *Jacea*. 20. The degenerate grey-leav'd *Jacea*. 21. The tall purple-flowered *Jacea*, with hairy ſuccory-like leaves. 22. The tall white-flowered *Jacea*, with hairy ſuccory-like leaves. 23. The *Jacea*, with woolly rocket-like leaves. 24. The *Jacea*, with white jagged leaves, and not ſhining huſks. 25. The great jagged-leav'd *Jacea*, with ſilvery cups. 26. The greater *Jacea*, with ſilvery huſks. 27. The leſſer *Jacea*, with ſilvery huſks. 28. The jagged and ſerrated-leav'd annual *Jacea*, with purple flowers. 29. The wood *Jacea*, commonly called ſerratula, or ſawwort. 30. The white-flower'd wood *Jacea*, or ſawwort. 31. The tall peach-leav'd wood *Jacea*, or ſawwort. 32. The tall centaury-like wood *Jacea*, or ſawwort. 33. The Virginian wood *Jacea*, or ſawwort with rigid leaves. 34. The blue-flower'd alpine *Jacea*, with calcitrapa leaves. 35. The white-flowered alpine *Jacea*, with calcitrapa leaves. 36. The evergreen Portugal *Jacea*. 37. The Portugal marſh elecampane-like *Jacea*. 38. The dwarf Portugal *Jacea*, with ſawwort leaves and large flowers. 39. The alpine *Jacea*, with the leaves of devils-bit. 40. The honeywort-leav'd *Jacea*. 41. The broad-leav'd Spaniſh *Jacea*, with the nerves of the leaves hoary. 42. The ſilvery white woolly *Jacea*. 43. The ſtorax-leav'd tree *Jacea*. 44. The hoary and prickly cretic *Jacea*. 45. The woolly *Jacea*, with undulated leaves. 46. The dwarf Spaniſh *Jacea*, with toadflax-leaves. 47. The roſemary-leav'd headed *Jacea*. 48. The ſtone *Jacea*, with long narrow hoary leaves. *Tourn.* Inſt. p. 444.

The *Jaceas* are diſtinguiſhed from the thiſtles by their flower cups not being prickly, and from the cirſiums by their leaves not being ſo.

JACENT, in medicine, a term uſed to expreſs the ſtate of the body in a perſon who is lying down, and has a ceſſation of the actions and motions proper to the muſcles and tendons. The ears are called *jacent* alſo in ſome newly brought forth animals, as the hind, *&c.* when they lie flat to the head, and have never yet been erected; and finally Helmont has apply'd the term to nature, which, he ſays, is *jacent* when a diſeaſe is riſen to a head, and the morbific cauſe ſtrives to ſuppreſs the vital flame.

JACK (*Cycl.*)—JACK *Wambaſium*, in our old writers, a kind of defenſive coat-armour, worn by horſemen in war, not made of ſolid iron, but of many plates faſtened together; which ſome perſons by tenure were bound to find upon any invaſion. *Walſingham*, *Blount*.

JACK, in zoology. See the article LUCIUS.

JACK-*Daw*, the Engliſh name of a ſpecies of the corvus. See the article CORVUS.

This bird is very miſchievous to the farmer and gardener, and

and is of ſuch a thieviſh diſpoſition, that he will carry away much more than he can make any uſe of. There is a method of deſtroying this bird by a particular ſort of ſpringe, which is much practiſed in ſome parts of England, and is ſo uſeful, that it ought to be made univerſal. The method is this: A ſtake of about five foot long is to be driven firmly into the ground, and made ſo faſt that it cannot move, and ſo ſharp pointed at the top that the *Jack-daw* cannot reſt upon it: Within a foot of the top there muſt be a hole bored through it, of three quarters of an inch in diameter; through this hole is to be put a ſtick of about eight inches long, then a horſe-hair ſpringe or nooſe is to be faſtned to a thin hazel wand, and this brought up to the place where the ſhort ſtick is placed and carried with it thro' the hole: The remainder being left open under that ſtick. The other end of the hazel rod is to be put through a hole in the ſtake near the ground, and faſtned there. The ſtake is to be planted among the *Jack-daws* food, and he will naturally be led to ſettle on it; but finding the point too ſharp he will deſcend to the little croſs ſtick; this will ſink with his weight, and the ſpringe will receive his leg and hold him faſt.

JACKALL, in zoology, the name of a creature of the dog-kind, called by authors *lupus aureus*, the gold-coloured wolf, and by the modern Greeks *Squilachi*. It is ſmaller than the wolf, and of a very beautiful yellow colour. Theſe animals are always ſeen in large flocks together, not unfrequently to the number of two hundred in a flock. It is a very thieviſh animal, and will ſteal people's things away while they ſleep, even in the day-time, not ſparing ſuch as can be of no uſe to it, as their hats, ſhoes, or the like. It is a very common creature in Cilicia, and is heard barking all night long. *Ray*'s Syn. Quad. p. 174. *Bellon.* Obſ. l. 2. c. 108.

JACOBÆA, *Ragwort*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is radiated, and its diſk is wholly made up of floſcules, its outer circle of ſemi-floſcules. Theſe all ſtand upon the embryo ſeeds, and are contained in a tubular cup, divided into many ſegments at the edge. The embryos finally ripen into ſeeds, which are winged with down, and remain affixed to the thalamus of the flower. *Tourn.* Inſt. p. 485.

The ſpecies of *Ragwort* enumerated by Mr. Tournefort, are theſe: 1. The common jagged-leav'd *Ragwort*. 2. The common *Ragwort*, with leaves divided like thoſe of the rocket. 3. The common *Ragwort*, with leaves like thoſe of the raddiſh. 4. The tall Portugal *Ragwort*, with finely divided leaves. 5. The broad-leav'd marſh or water *Ragwort*. 6. The alpine *Jacobæa*, with roundiſh ſerrated leaves. 7. The mountain *Ragwort*, with roundiſh undivided leaves. 8. The mountain *Jacobæa*, with longiſh undivided leaves. 9. The betony-leav'd mountain *Jacobæa*. 10. The mountain *Jacobæa*, with oblong ſerrated leaves. 11. The tall marſh *Jacobæa*, with ſerrated leaves. 12. The tall marſh *Jacobæa*, with leaves like the limonium. 13. The tall limonium-leav'd marſh *Jacobæa*, with thick-ſet flowers. 14. The woad-leav'd Sicilian *Jacobæa*. 15. The *Jacobæa*, with bluiſh green leaves like the cretic corn-marygold. 16. The ox-eye flower'd *Ragwort*, with deeply divided leaves. 17. The roſemary-leav'd Spaniſh *Jacobæa*. 18. The umbellated annual *Jacobæa*, with deeply divided leaves. 19. The perennial *Ragwort*, with hoary groundſel like leaves. 20. The common groundſel-leav'd *Jacobæa*. 21. The ſea *Ragwort*, with thick ſhining groundſel like leaves. 22. The Spaniſh *Jacobæa*, with ſlightly divided leaves and very ſhort petals. 23. The Pannonian *Jacobæa*, called the hoary ſtinking and viſcid groundſel. 24. The mountain lanuginous *Jacobæa*, with narrow and not divided leaves. 25. The woolly ſea *Jacobæa*, with broad undivided leaves. 26. The *Jacobæa*, with very large woolly leaves. 27. The common ſea *Jacobæa*. 28. The hoary grey-leav'd ſea *Jacobæa*. 29. The degenerate ſea *Jacobæa*. 30. The dwarf wormwood-leav'd alpine *Jacobæa*. 31. The broad leav'd hoary ſtone Pyrenæan *Jacobæa*. 32. The *Jacobæa*, with thick undivided hawkweed leaves. 33. The peach-leav'd Pyrenæan *Jacobæa*. 34. The large flowered fennel-leav'd *Jacobæa*. 35. The ſmall flowered fennel-leav'd *Jacobæa*. 36. The ſouthern-wood-leav'd ſhrubby African *Jacobæa*. 37. The clary-leav'd ſhrub African *Jacobæa*. 38. The ſonchus-leav'd African *Jacobæa*. 39. The dandelion-leav'd African *Jacobæa*. 40. The wormwood-leav'd African *Jacobæa*. 41. The African *Jacobæa*, with undivided undulated and curled leaves. 42. The purple-flowered, broad-leav'd, jagged African *Jacobæa*. 43. The purple-flowered, narrow-leav'd, jagged African *Jacobæa*. 44. The tuberoſe-rooted African *Jacobæa*. 45. The American-tree *Jacobæa*, with large ſhining leaves like the elecampane. 46. The willow-leav'd *Jacobæa*, with hairy edges. 47. The hypericum-leav'd procumbent American *Jacobæa*. *Tourn.* Inſt. p. 486. See RAGWORT.

JACOBINE, the name of a particular ſpecies of pigeon, called by Moore the *Columba Cypria cucullata*. It is generally called the jack, for ſhortneſs. It is, when genuine and of the true breed, the ſmalleſt of all pigeons. It has a range of feathers inverted quite over the hinder part of its head, and reaching down on each ſide of the neck to the ſhoulders of the wings, which forms a kind of friars-hood, from whence the bird has its name. The upper part of theſe feathers is called the hood, and the more compact theſe feathers are and the cloſer to the head, ſo much the more the bird is eſteemed. The lower part of this range of feathers we call the chain, the Dutch call it the cravat: This ſpecies has alſo a ſhort bill, and a pearly eye. The colour is various in the feathers; there are reds, yellows, blues, blacks, and mottles; but whatever is the general colour, th head, tail, and flight are white. Some pigeons of this ſpecies are feather-legg'd, others are not. *Moore*'s Columbarium, p. 46.

JACULUM, in zoology, the name of a ſpecies of ſerpent found in Rhodes, and ſome other places, and more uſually called acontias. See the article ACONTIAS.

JACUPEMA, in zoology, the name of a Braſilian bird of the pheaſant kind, nearly as large as the common European hen. Its tail is very broad, and uſually a foot long. Its legs are long, and it is all over covered with browniſh black feathers. It can raiſe its head feathers into a ſort of creſt, which is bordered with white; the tips of the feathers which compoſe it, being of that colour. Its throat near the head is naked, and has a red appendage like the wattles of a cock; and its belly is lightly variegated with white ſpots. Its feet are of a fine red. It is a very well taſted fowl, and is eaſily kept tame. It has its name from the noiſe it makes, which is *Jacu*, *Jacu*, *Jacu*. *Marggrave*'s Hiſt. Braſil.

JACUT, in the natural hiſtory of the Arabians, is generally ſuppoſed to be the name of the ruby only; and it is owing to this, that among the gems uſed by the Arabian phyſicians in medicine, the ruby is ſuppoſed to have been moſt of all in eſteem, as the name *Jacut* oftener occurs in their writings than that of any other of the gems. The precious ſtones owe their colours to tinges from metalline particles; and it has been found, that as the emerald owes its colour to copper, and the amethyſt to iron, ſo the ruby owes its colour to gold; nay there are ſome places in the Eaſt-Indies, where rubies are found in conſiderable plenty, too ſmall for uſe as gems, and theſe being wrought for the gold they contain, yield a very conſiderable quantity of it. The chemical writers on this account extol the ſagacity of the Arabians, who could find out the virtues of gold in this gem, and therefore uſed it as a cordial, *&c.* preferably to all the other gems; but the merit of all this diſcernment is cancelled by obſerving, that tho' the word *Jacut* among the Indians, is the name of this peculiar gem only, yet the Arabians did not uſe it in this determinate ſenſe; but, according to the obſervations of the beſt critics and commentators, they uſed it as a general name for the ruby, the ſapphire, and the hyacinth. It ſhould ſeem that if the knowledge of the peculiar metals from which the gems received their colours influenced theſe writers in the direction of them in medicines, the copper from which the ſapphire is coloured, ſhould have as much deterred them from its uſe, as the gold in the ruby could have invited them to preſcribe that gem. All this ſcheme of preference ſeems therefore to be merely imaginary, and the Arabians as well as other of the antient writers in medicine, ſeem to have preſcribed all the gems in common, partly as pompous names in their preſcriptions, and partly from idle rumours of their virtues founded on no principles at all. *Garcias ab Orto.*

JAGRA, a name given to a peculiar ſpecies of ſugar, prepared from the cocoa nut.

JAGUACATI-*Guacu*, in zoology, the name of a Braſilian bird of the kingfiſher kind, called by the Portugueſe *Papa pẽẽxe*. It is of the ſize of a thruſh, and in ſhape much reſembles the European kingfiſher. Its beak is black, long, and ſharp; its legs very ſhort, and the toes placed one behind, not ſo as in the woodpecker kind, to which this bird otherwiſe has ſome affinity. Its back, head, tail, and wings, are of a duſky ferrugineous hue; its neck has a tranſverſe circular ſtreak of perfectly white feathers; and its throat, breaſt, and belly, are perfectly white. It has a white ſpot over each eye, and its tail and wings have a few white variegations; but theſe are not eaſily diſtinguiſhed, except when it is flying. *Marggrave*'s Hiſt. Braſil.

JAGUARA, in natural hiſtory, the name of a Braſilian animal, accounted by Marggrave a ſpecies of tyger; but differing from that creature, and approaching to the leopard in the ſhape of its variegations, which are ſo many round ſpots. The Portugueſe call this creature *Onça*, the ounce; whence it ſhould ſeem ally'd at leaſt to the lynx or ounce, properly ſo called. Its head, ears, feet, and all its other parts agree with the cat kind; as do thoſe of the lynx: Its claws are hooked like a half moon, and are very ſharp; its eyes are blue, and ſhine in the dark; and its tail is long like that of a cat, in which particular it varies from the common lynx. It is all over of a yellowiſh colour, beautifully variegated with black ſpots differently diſpos'd. It is a very fierce animal, and as ravenous of human fleſh as of that of beaſts. *Ray*'s Syn. Quad. p. 163.

JAGUARACA, in zoology, the name of a Braſilian fiſh in many things reſembling the ſcorpius of the Mediterranean.

It is of the ſize of the freſh-water perch, and its mouth is very large, but without teeth. It has only one back fin, which has eleven rigid and prickly rays. The tail is forked. Its gills are armed with ſeveral prickles, with which it wounds thoſe who take it. Its ſcales are ſmall, elegantly arranged, and ſerrated at their edges. It is of a ſilvery brightneſs all over, except on the belly, where it is of a dead white; the head is red, and covered with a ſort of hairy cruſt; the fins alſo are all of a pale red. It is caught among the rocks, and is a very well taſted fiſh. *Marggrave*'s Hiſt. Braſil.

JAGUARETE, in natural hiſtory, the name of a Braſilian beaſt of prey, accounted by Marggrave a ſpecies of tyger, but improperly; its roundiſh ſpots arguing it of the lynx or leopard kind. It is of the ſize of a young heifer, of a yelloviſh colour, variegated with black and brown ſpots, and is a very fierce and deſtructive animal. It much reſembles the creature called Jaguara, but is larger; and the ſpots which in that are all round, are in this ſome round, and ſome of other figures. The Portugueſe call both by the ſame name onça. *Ray*'s Syn. Quad. p. 169. See the article JAGUARA.

JALAP, *Jalapa*, in botany, the name of a genus of plants: The characters of which are theſe: The flower conſiſts only of one leaf which is of the ſhape of a funnel, with a broad opening, and uſually lightly crenated round the edge. The flower has a double calyx, or cup; on one of theſe it ſtands, and is incloſed at its bottom in the other. The lower of theſe finally becomes a fruit of a roundiſh figure, and containing roundiſh ſeeds.

The ſpecies of *Jalap*, enumerated by Mr. Tournefort, are theſe: 1. The purple-flowered *Jalap*. 2. The yellow-flowered *Jalap*. 3. The deep red-flowered *Jalap*. 4. The whitiſh-flowered *Jalap*. 5. The variegated *Jalap*, with flowers of a mixt purple and yellow. 6. The variegated *Jalap*, with flowers mixed of red, yellow, and white. 7. The variegated *Jalap*, with flowers half white half purple. 8. The variegated *Jalap*, with a white flower ſpotted, and ſtreaked with a deep purple. 9. The variegated *Jalap*, with flowers ſtreaked with yellow. 10. The ſmall flowered *Jalap*. 11. The rough-fruited *Jalap*. The root of the laſt is the drug called *Jalap*, in the ſhops. *Tourn.* Inſt. p. 129.

After all the preparations the chemiſts have invented for this root, the beſt way of giving it is in ſubſtance. Mr. Bolduc in his analyſis of it found, that when he ſeparated its ſaline and its reſinous parts, by making extracts of it firſt with ſpirits of wine, and then with water, that the ſaline or watery extract was much larger in quantity than the other, but that it purged weakly; and that the reſinous extract, tho' it operated in a ſmall doſe, was yet a very rough medicine; ſo that the beſt way of uſing them was together, and that nature gave us the medicine ready prepared. Mem. Acad. Par. 1701.

JALEMUS, Ἰαλεμος, in antiquity, a kind of mournful ſong, uſed upon occaſion of death, or any other afflicting accident. Hence the Greek proverbs had their original, Ἰαλεμω οικροτερος, or ψυχροτερος, *i. e.* more ſad or colder than a *Jalemus*, εις της Ἰαλεμως εγγραπτος, worthy to be ranked among *Jalemus*'s. Mem. Acad. Inſcrip. T. 13. p. 554.

JAM, or JAMB, in the language of our lead-miners in Mendip, a thick bed of ſtone, which hinders their work when they are purſuing the veins of oar.

JAMACAII, in zoology, the name of a Braſilian bird, of the ſize of a lark; its head is ſmall, its beak a little bent downwards. Its head is black, its throat alſo black; but the upper part of its neck yellow. Its back, breaſt and belly, are alſo yellow. Its wings are black, but have each one white ſpot. Its tail alſo is black, and its legs and feet brown. It is an extremely beautiful bird, and has ſo long a tail that it ſeems to belong to the wagtail or motacilla kind. *Marggrave*'s Hiſt. Braſil.

JAMAICA *Pepper-tree*. See the article PIMIENTA.

JAMAICA-*Wood*. See the article BRAZIL, *Cycl.*

JAMBEAUX, in our old writers, armour for the legs. The word is French, from *Jambe*, *tibia*, the leg. *Blount.*

JAMBLICI *Sal*, in medicine, a kind of ſalt prepared with ſal ammoniac, and ſeveral aromatic ingredients, ſuch as pepper, ginger, thyme, origanum, and the like; it has its name from its reputed author Jamblichus, and is ſuppoſed by many old writers to be an excellent medicine for concocting the crude humours, and gently producing ſtools. It was taken faſting in the quantity of half a ſpoonful, either alone or in a poach'd egg, or mix'd with any liquor. *Gorræi* Med. Defin. in voc.

JAMBON, in natural hiſtory, a name given by authors to a kind of ſea-ſhell, reſembling a ham of bacon. It is a ſpecies of pinna marina. See the article MYTULUS.

JAMBU, in zoology, the name of a Braſilian ſpecies of partridge, of which there are two ſpecies. They are of a duſky yellow colour, and are equal to the European partridges in the delicacy of their taſte. *Marggrave*'s Hiſt. Braſil.

JAMPNUM, in our old writers, furze or gorſe, and gorſy ground. This word is uſed in fines of lands, &c. and ſeems to come from the French *Jaune*, i. e. yellow; becauſe the bloſſoms of furze or gorſe are of that colour. 1 *Croke* 179. *Blount.*

JANA, among the Romans, a name given to the moon. *Hoffm.* Lex. in voc. See the article LUNA.

JANITOR, an affected name given by ſome writers to the Pylorus.

JANITORES, door-keepers, among the Romans, the meaneſt of their ſlaves, who were commonly chained to their poſts. *Hoffm.* Lex. in voc.

JANITRIX, an affected name given by ſome writers to the vena portæ.

JANSENISTS, in the church of Rome, the followers of Janſenius biſhop of Ipres, in Flanders. See the article JANSENISM, *Cycl.*

JANUA-*Plaſter*, a name given by ſome to the emplaſtrum de betonia, or betony plaſter, preſcribed in Lemery's pharmacopœia, and by other authors.

JAPACANI, in zoology, the name of a Braſilian bird of the ſmaller ſort; its beak is black, long, and pointed, and a little bent downward; its head is black, and its back, neck, and wings, are of a greeniſh brown mixed with black; the tail is black above, and is ſpotted with white underneath. Its breaſt is of a mixture of white and yellow, as are alſo its belly and thighs; and theſe are variegated with tranſverſe black ſtreaks. *Marggrave*'s Hiſt. Brail.

JAPANNING (*Cycl.*)—The varniſh made and uſed in China and Japan, is compoſed of turpentine and a curious ſort of oil they have. This they mix and boil up to a proper conſiſtence, and this never cauſes any ſwelling in the hands or face of the people who uſe it. The ſwellings in theſe parts which often happen to thoſe who work the lacquer'd ware, and ſometimes to thoſe who only paſs by the ſhops of theſe people, is from the lack and not the varniſh. This lack is the ſap or juice of a tree, which runs ſlowly out on cutting the lower part of the trunk of the tree, and is received in pots ſet on purpoſe under the inciſions. This juice as it flows from the tree is of the colour and conſiſtence of cream, and as it comes in contact with the external air its ſurface becomes black. As they only uſe it when black, their method of preparing it is to ſet it out in the open air, in large flat bowls, in which it looks all ſurface; but that the whole may be of the ſame uniform colour, they continually ſtir it for twenty-four hours together, with a ſmooth piece of iron: By this means the whole becomes thicker than it was before, and of a fine deep black. When it is in this ſtate they powder ſome burnt boughs of trees, and mix them throughly with it, and then ſpreading it thin over any board which they intend to japan, it is ſoon dried in the ſun, and is then abſolutely harder than the board it is laid on. When this is throughly dry they poliſh it over with a ſmooth ſtone and water, till it is as ſmooth as glaſs; and then wiping it very dry, they lay on the varniſh made of oil and turpentine, and boil'd to a proper conſiſtence for this kind of work.

If the work is to be of any other colour than black, that colour is to be mixed with the varniſh, and then the whole ſpread on very thinly and evenly; for in this laying it on depends the principal art of varniſhing. When there are to be figures in gold or ſilver, theſe muſt be trac'd out with a pencil in the varniſh over the reſt of the work, and when this varniſh is almoſt dry the leaf-gold or leaf-ſilver is to be laid on, and poliſh'd afterwards with any ſmooth ſubſtance.

JAPU, in zoology, the name of a Braſilian bird, of the woodpecker kind, called alſo *Jupujuba*. It is all over of a fine ſhining black colour, but that it has a large yellow ſpot on the middle of each wing, and a broad yellow ſtreak near the rump. This bird hangs its neſt very nicely from the extreme boughs of trees; and from the ſeeing theſe neſts, and not knowing to what bird they belonged, has ariſen the error of ſuppoſing that the parrots hang their neſts in this manner. *Ray*'s Ornitholog. p. 98.

JARARA-*Coaypitinga*, in zoology, the name of a ſpecies of ſerpent found in America, not much unlike the common viper, and equally venomous. Its tail is of a paler colour than the reſt of the body, and thence it has its name; which in the language of the natives expreſſes this property.

JARARA-*Epeba*, in zoology, the name of a ſpecies of American ſerpent, of a brown colour, but variegated by a very beautiful undulated red line, running all along the back like a chain. *Ray*'s Syn. An. p. 330.

JARARACA, in zoology, the name of a ſpecies of ſerpent, common in America. It is a very ſhort ſerpent, ſeldom exceeding a foot and a half in length. It has ſome prominent veins on its head, and is of a duſky browniſh colour, variegated with red and black ſpots. It is a very poiſonous ſpecies. The natives uſe for a remedy the root of a plant called Caatia, and by the Portugueſe Herva de Cobros. *Ray*, ibid. De Laët has deſcribed four different ſpecies of this ſerpent.

JARARACUCU, in zoology, the name of an American ſpecies of ſerpent. It is of the viviparous kind, and produces a great number of young; thirteen having been found perfectly formed in the body of a female of this kind. It grows to between two and three foot long, and has like the other poiſonous ſerpents very large and long teeth, which are hid in the gums, and contain a yellow poiſonous liquor. Theſe

it only exerts at the time of biting, and its poiſon is ſo fatal that it will deſtroy a man within four and twenty hours. *Ray*'s Syn. An. p. 330.

JARDES, or JARDONS, in the manege, are callous and hard ſwellings in the hinder legs of a horſe, ſeated on the outſide of the hough, as the ſpavin is on the inſide. *Jardons* lame a horſe, unleſs you give the fire dextrouſly and betimes. *Guillet.* See the article FIRE.

JARIBOLUS, Ιαριβωλος, in antiquity, one of the Palmyrenian gods. This deity in all appearance had the ſame attributes with the god Lunus; for *Jari* ſignifies the month over which the moon preſides. Mem. Acad. Inſcrip. T. 3. p. 177. See the article LUNUS.

JARRETIER, in the manege, an obſolete French word, ſignifying a horſe, whoſe houghs are too cloſe together; which is now expreſſed in French by *Crochu*, i. e. crooked or hooked.

JARUS, in botany, a name by which ſome authors have called the arum, or wake-robin. *Ger.* Emac. Ind. 2.

JASINE, in botany, a name uſed by the antients to expreſs a ſmall kind of climbing plant, much reſembling that from which they obtained the drug called ſcammony. They therefore called this ſometimes the ſmall ſcammony, or *ſcammonia parva*. It climb'd upon trees, and had ſmall ivy-like leaves. Pliny has deſcribed ſuch a plant as this under the name of *Langini*; and it ſeems very probable that this was only a corruption of the word *Jaſine*, that author having taken moſt of his accounts from the Greeks, and having frequently miſtaken their names.

JASIONE, in botany, a name given by Linnæus to a genus of plants; the characters of which are theſe: The common perianthium of the flowers is compoſed of ten leaves, which ſtand alternately one below another: This contains a great number of flowers which are affixed to ſhort pedicles. The peculiar perianthium of each flower is indented in five places, and is placed upon the germen of the piſtil. The ſeparate flowers are each compoſed of five leaves, which are joined at the baſe: The ſtamina are five very ſhort filaments; the apices are oblong, of the ſame number, and are joined alſo at the baſe. The piſtil has a roundiſh germen placed under the cup of the flower. The ſtyle is very ſlender, and of the length of the flower, and the ſtigma is bifid. The fruit is a roundiſh capſule crowned with its proper cup, and contains numerous ſmall ſeeds lodged in two cells. *Linnæi* Gen. Plant. p. 427.

JASMELÆUM, a medicinal oil, called alſo by the Perſians *Jaſme:* It is made by putting two ounces of the white flowers of violets into a pint of oil of ſeſamum. It is uſed to anoint the body after bathing, and is in great eſteem among the Perſians for its fragrancy, tho' it is a ſort of ſmell which many would rather think offenſive.

JASMINE, *Jaſminum*, in the Linnæan ſyſtem of botany, a ſhrub which makes a peculiar genus of plants; the characters of which are, that the perianthium or cup of the flower is oblong, tabular, and compoſed of one leaf, with an erect extremity divided into five ſegments. The flower is compoſed of one petal which makes a long cylindraceous tube; the extremity or mouth of the flower is flat and parted into five ſegments; the ſtamina are two ſhort filaments; the antheræ are ſmall and hid in the tube of the flower; the piſtillum is compoſed of a roundiſh germen; the ſtyle which is ſingle, and like a thread of the ſame length with the ſtamina, and a bifid ſtigma. The fruit is a ſmooth oval berry, with one cell within it, which contains two large oval but ſomewhat long ſeeds covered with a membrane, and convex on one ſide and plain on the other. *Linnæi* Gen. Plant. p. 3.

The characters of this genus, according to Tournefort, are theſe: The flower conſiſts of one leaf, and is of a funnel-like ſhape, and divided into ſeveral ſegments at the edges. The piſtil ariſes from the cup, and is fixed in the manner of a nail into the hinder part of the flower. This finally becomes a ſoft fruit or berry, which contains one or two ſeeds. *Tournef.* Inſt. p. 597.

The ſpecies of *Jaſmine* enumerated by Mr. Tournefort, are theſe: 1. The common white-flowered *Jaſmine*, or *Jeſſamy*. 2. The great Spaniſh *Jaſmine*, with the flowers red on the outſide. 3. The Spaniſh *Jaſmine*, with proliferous flowers. 4. The white-flowered ſweet-ſcented trifoliate *Jaſmine*. 5. The trifoliate *Jaſmine*, with yellow flowers. 6. The common berry-bearing trifoliate yellow *Jaſmine*. 7. The broad-leav'd double-fruited Indian *Jaſmine*. 8. The narrow-leav'd double-fruited Indian *Jaſmine*. 9. The broad-leav'd Indian *Jaſmine*, with double-belly'd fruit. 10. The broad-leav'd ſingle-ſeeded Indian *Jaſmine*. 11. The white-flowered tree *Jaſmine*, with ſweet-ſcented bay-like leaves. 12. The white-flowered tobacco-leav'd tree *Jaſmine*. 13. The nightſhade-leav'd tree *Jaſmine*, with bluiſh-black berries. 14. The violet-leav'd ſcentleſs creeping *Jaſmine*.

JASPACHATES, in the natural hiſtory of the antients, a name given to a ſpecies of agate, variegated with the matter of the jaſper, and therefore being properly diſtinguiſhed by this name. It is found at this time very plentifully both in the Eaſt and Weſt-Indies, and in many parts of Italy, Germany, and other parts of Europe; and is a very elegant ſtone. Its colouring is always compoſed of a brown and green, but it is very irregular in the admixture of theſe. Sometimes it is one equally coloured maſs, and is only diſtinguiſhable from the green jaſpers by its ſuperior hardneſs and brightneſs; but it is much more frequently found of a browniſh green ground, variegated with irregular concentric circles of a fairer green; and often with ſome of a beautiful red, or with a browniſh green ground, irregularly clouded and ſpotted with thoſe colours; it often has alſo an admixture of white and yellow.

Our lapidaries eſteem the oriental pieces of this ſtone very valuable, and work them into many ſorts of toys. The German are ſofter, and of little value. *Hill*'s Hiſt. of Foſſils, p. 489.

JASPER (*Cycl.*)—The curious Beccher having a mind to melt a *Jaſper*, powdered it, and putting it into a crucible, luted down the lid on it, and giving it an intenſe fire melted it, and found this very remarkable truth, that the colour of this ſtone tho' no more permanent in the fire than that of other gems, yet may be ſaved after its being raiſed in vapour as other ſublimed ſubſtances are; accident, and not any plan of operation, afforded this; but the fact is worth farther conſideration. *Beccher*'s Phyſ. Subter.

On unluting the crucible and opening it, the *Jaſper* was found melted into one lump, nearly as hard as before; but milk-white and ſemiopake, reſembling in all reſpects a natural white agate. The cover and the upper parts of the crucible which were unfilled, and which could not be touched by the *Jaſper* in ſubſtance, were tinged with the colours that the *Jaſper* had loſt. Theſe had the appearance of the fineſt *Jaſpers*, but the colours were ſuperficial only, not penetrating into the ſubſtance of the matter. The ground was green, as in the natural *Jaſper*, and the variegations red and yellow, and as beautifully diſpos'd as in the ſtone itſelf; the colours were ſo evenly laid alſo that they had a fine poliſh, and might have paſſed for wrought *Jaſpers* of the ſame ſpecies with the melted one, if cunningly ſet, and not ſuffered to be handled. Id. ibid.

Dr. Brown, in his travels thro' Germany, gives an account of a maſs of *Jaſper* dug out of a quarry at Saltſburg, and now making a part of the pavement of one of the emperor's courts at his palace at Vienna, which is of nine foot diameter.

JASPICAMEO, in natural hiſtory, the name of one of the ſemipellucid gems of the camea kind, very well known among the Italian lapidaries, but very ſeldom ſeen among us. It is ſeldom found of any conſiderable ſize, and is compoſed of broad zones of a pure and elegant white, and a very delicate green, much reſembling the matter of ſome of the green jaſpers. It is found in the Eaſt-Indies, and in ſome parts of America. The Italians are very fond of it, and uſe it as the common camea for cutting heads and other figures on, either in relief or creux. *Hill*'s Hiſt. of Foſſ. p. 501.

JASPONYX, in natural hiſtory, the name of a ſpecies of onyx, called by Dr. Hill *Onyx puriſſima cornea zonis læte virentibus*, or the pureſt horn-coloured onyx with green zones. It is an extremely beautiful ſtone. It is uſually found in the ſhape of a ſmall pebble, compoſed of a nucleus of a ſhattered or flaw'd cryſtal of an irregularly angular figure, round which are alternately diſpoſed zones of a fine pure cryſtalline matter lightly tinged to a horn-colour, and green ones little inferior to the emerald in beauty, being truly compoſed of the matter of the fineſt oriental Jaſper; and ſometimes between and among theſe there are fine ſlender zones of a pure white, which add greatly to the beauty of the ſtone. It is found in the Eaſt-Indies, and in New Spain; but in neither of thoſe places very frequently. It is greatly eſteemed among all the European nations, and cut into toys; but its ſcarcity has given occaſion to our jewellers very frequently to put off a green-vein'd German agate under its name. *Hill*'s Hiſt. of Foſſ. p. 492.

JASSENSE-*Marmor*, a name given by the antients to a very beautiful ſpecies of marble. It was remarkably hard, capable of a very fine poliſh, and was of a beautiful red approaching to what we call blood-colour, elegantly variegated with veins and clouds of a bluiſh white.

JATRALIPTES, Ιατραλειπτης, in antiquity, in its original ſignification was uſed for an officer in the Gymnaſia, whoſe employment was to anoint the Athletæ. The *Jatraliptes* was alſo called *Aliptes*; both which terms were ſometimes alſo uſed to denote the maſters of the exerciſe, ſuch as the *Gymnaſtes* and *Pædotriba*.

JATRALIPTES is alſo a term uſed by the antient writers in medicine, to denote ſuch phyſicians as pretended to cure all diſeaſes by external unctions. This method of cure was called *Jatroliptice*, and was firſt introduced into practice among the antients by Prodicus, a native of Selymbria, and diſciple of Æſculapius.

JATROCHEMIA, a term uſed by ſome writers, to expreſs the method of curing diſeaſes by chemical remedies.

JATROPHA, in botany, the name given by Linnæus to a genus of plants, firſt called by Houſton *Juſſievia*. The characters are theſe: It produces male and female flowers on the ſame plant. In the male flowers, the cup is ſo ſmall

as to be ſcarce viſible; the flower conſiſts of one leaf, and is of the ſaucer-ſhaped kind; the tube is extremely ſhort, and the mouth is divided into five ſegments; theſe are of a roundiſh figure; they ſtand expanded, and are convex above, and concave underneath. The ſtamina are ten pointed filaments, they ſtand cloſe to one another in the middle, five of them are ſhorter than the others, and they all ſtand erect, and are of the length of the cup: The antheræ are roundiſh, and turn about upon the ſtamina, There is a faint rudiment of a piſtil in the bottom of theſe flowers. The female flowers ſtand in the ſame umbel with the male ones; in theſe the cup is wholly wanting. The flower conſiſts of five petals diſpoſed in a roſaceous form: The germen of the piſtil is roundiſh and triſulcated. There are three ſtyles, each divided into two at the end, and the ſtigmata are ſimple. The fruit is a round capſule, compoſed of three cells, each compoſed of two valves; the ſeeds are ſolitary and roundiſh. *Linnæi* Gen. Plant. p. 457. *Tournefort*, 438. *Dill.* Elth. 173.

JAUNDICE (*Cycl.*)—Medical writers diſtinguiſh the *Jaundice* into idiopathic and ſymptomatic. The idiopathic *Jaundice* is that which ariſes of itſelf, and has no dependance on any other diſeaſe; the ſymptomatic is that which ariſes in the courſe of fevers and other diſtempers, in which the gall is affected.

The yellowneſs of the ſkin in ſome infants as ſoon as born, is by no means to be ſuppoſed a *Jaundice*, as it is a thing of no conſequence, and uſually goes off of itſelf after the voiding of the firſt ſtools.

Signs of the JAUNDICE. This diſeaſe always attacks people with a remarkable laſſitude, which laſts for ſome time; and this is more particularly the caſe, where violent paſſions of the mind have given riſe to the diſeaſe: This ſymptom is ſucceeded by a ſenſe of a ſtricture and compreſſion at the pit of the ſtomach; hence ariſe anxieties and ſtraitneſs of the præcordia, with difficulty of breathing, which is often ſo violent as to threaten ſuffocation; and uſually there is a ſenſe of weight and uneaſineſs in the right hypochondrium. The patient is always eaſier while ſitting, than while lying, or walking. There is a ſlight fever joined with the other ſymptoms, the patient being hotter than at other times, and uſually feeling a ſlight chilneſs or ſhivering before this. The bowels are ſometimes coſtive, but ſometimes more lax than uſual, and the ſtools are always whitiſh. Theſe ſymptoms are very ſoon ſucceeded by a yellowneſs beginning in and about the eyes, and by degrees ſpreading itſelf over the whole ſurface of the body. The urine is of a fine yellow colour, tinging the veſſels in which it ſtands; and if only a few drops of it are poured over a linnen cloth, they immediately tinge it like ſaffron. The appetite is always bad; and when any thing is eaten, the uneaſy ſenſation always returns with more violence at the pit of the ſtomach. The ſleep is uſually troubled, and there is ever a great languor of the mind attending the diſeaſe through all its periods. Theſe are the ſymptoms of the yellow *Jaundice*.

The black *Jaundice* is diſtinguiſhed by a more violent and uneaſy dejection and languor of the mind, and the colour brought on by the diſeaſe is blackiſh; and this is not only in the eyes and ſkin of the whole body, but alſo in the urine and ſpittle, or at leaſt the laſt is of a duſky and deep yellow. To theſe ſymptoms there is joined in this caſe a hectic heat, with great reſtleſſneſs, waſting of the fleſh, and a ſingular and terrible dejection of the ſtrength; and as there is uſually a ſenſation of a preſſure and weight in the right ſide in the yellow *Jaundice*, the ſame ſenſation is felt in this on the left. Perſons of all ages, and of both ſexes, are ſubject to this diſeaſe, but particularly ſuch as are of a choleric habit; and the extremes of life, youth and old age, are more frequently ſubject to it than the middle ſtage. *Junker*'s Conſp. Med. p. 440.

Cauſes of it. Theſe are a coarſe and thick diet, and an immoderate ſtomach for food, a ſudden obſtruction or repreſſion of hæmorrhages, particularly of the diſcharges of the menſes and hæmorrhoidal veins. In theſe caſes this diſeaſe is alſo too often either the forerunner, or the attendant of an hepatitis. It is alſo ſometimes brought on by a ſuppreſſion of intermittent fevers, particularly of quartans by aſtringents, and by violent paſſions of the mind, eſpecially when they are ſuppreſſed. Violent emetics will ſometimes alſo bring on this diſeaſe, as will alſo a ſudden draught of cold water when the body is very hot. A ſchirrus in the liver, or a ſtone in the gall bladder, are alſo known too often to occaſion it. Theſe are the cauſes of the yellow *Jaundice*; but the black uſually takes its riſe from obſtinate and habitual obſtructions of the ſpleen, which is properly the ſeat of this diſorder.

Prognoſtics. Young people are ſeldom ſo violently attacked with the *Jaundice* as thoſe advanced in years, and are always more eaſily cured of it. When this diſeaſe comes on with more than ordinary violence, there is reaſon to ſuſpect a hectic or ſlow fever at the bottom, or ſometimes an acute one. And when a *Jaundice* attacks perſons on the fourth day of an acute fever, or before that time, and comes on with great violence, there is always danger of the death of the patient. The greater the obſtructions of the viſcera are from the ſuppreſſion of intermittent fevers, the greater is the danger that attends the *Jaundice* ariſing from ſuch obſtructions. People who have had the *Jaundice* two or three times fall into a ſort of habitual tendency to it on different occaſions, and are uſually ſubject afterwards to frequent returns of it. When the *Jaundice* is attended with great difficulty of reſpiration, anxiety, and oppreſſion about the præcordia, and with a ſort of aſthmatic oppletion of the breaſt, a hectic or aſcites, and an atrophy, too frequently follow. If at any time the yellow colour of the ſkin in this diſeaſe changes ſuddenly to white, it is a very fatal preſage; ſhewing that there is a ſchirrous conſtitution in the liver. A diſcharge of blood by the hæmorrhoidal veins happening in the time of this diſeaſe, is a preſage of a ſpeedy cure, and copious yellow ſweats which ſtain the linnen, are alſo a very favourable ſymptom. A *Jaundice* which happens to perſons advanced in years, from the too free uſe of ſpirituous liquors, is a much more difficult one to cure than the common kind, as there is always in this caſe a remarkable dryneſs of the liver. A *Jaundice* not unfrequently ariſes from a ſuppreſſion of a quartan by the bark alone, or given in an injudicious manner; and when this proves obſtinate and difficult of cure, it gives a very bad preſage of a hectic, and obſtruction of the liver. On the whole, a ſimple *Jaundice* of the common ſlighter kind is eaſily cured, and is of no danger; but when this diſeaſe is complicated with others, and is obſtinate of cure, it uſually proves fatal either in itſelf, or in its conſequences.

The black *Jaundice* is always more difficult of cure than the yellow; and where it attacks old people, and is of long ſtanding, it generally proves fatal either in itſelf, or by bringing on hectics and other incurable diſorders. *Junker's* Conſp. Med. p. 442.

Method of Cure. When the diſeaſe is recent, the patient ſhould take three or four times a day powders of nitre and tartar vitriolated; and in caſes where violent paſſions have been in the cauſe of it, the abſorbent powders are to be added, as crabs-eyes, and the like. At times there muſt be given with theſe, ſmall doſes of rhubarb or other gentle purgatives, and decoctions of turmeric, celandine, and a little ſaffron. By theſe means a recent *Jaundice* is often happily taken off in a very little time, or as it were nipped in the very bud. A few grains of diaphoretic antimony may be added to that powder, which is to be taken going to reſt; and this will be very efficacious in carrying off the yellowneſs of the ſkin. When the diſeaſe is going off by theſe gentle means, ſome gentle chalybeate is to be given twice a day, and after this the purging by rhubarb is to be repeated. *Junker*'s Conſp. Med. p. 445.

When the diſeaſe is more ſtubborn, a gentle ſweat is to be kept up continually, and powder of turmeric to be given at a ſcruple for a doſe, and powders of diaphoretic antimony and the digeſtive ſalts, ſuch as tartar vitriolated, are to be given frequently. In young people, there needs little more to cure the *Jaundice*, than the keeping up a gentle perſpiration, and a few doſes of rhubarb. And in general, as the *Jaundice* is a diſeaſe very ſubject to return upon perſons who have once had it, gentle evacuations ſhould be uſed at times to keep it off, and a medicated drink with rhubarb, ſenna, and the like, ſhould be taken for ſome days once in a quarter of a year. The *Jaundice* is a diſeaſe which will not bear any rough methods; vomits and ſtrong purges always do harm, and ſweats forced by the hot medicines make the diſeaſe worſe, inſtead of giving the relief in it which is always had from perſpiration brought on by gentler means.

Horſes are ſubject to this diſtemper, as well as men. The farriers commonly call it the yellows, and divide it as we do the *Jaundice* into two kinds, the yellow and the black. The yellow kind is known by the creature's white of his eyes turning to a yellowiſh colour, and his tongue and lips alſo partaking of the ſame tinge, but in a ſmaller degree. In the black kind all theſe parts are tinged with a duſkiſh or blackiſh colour. The common cure among the farriers is by means of an ounce of mithridate diſſolved in two quarts of ſtrong beer, and given to the horſe warm; and repeating this doſe once in twelve hours, as long as the diſtemper continues.

JAUNDICE-*Bird.* See the article ICTERUS.

JAU-RAIA, in botany, a name given by Plumier to a genus of plants; another ſpecies of which he afterwards deſcribes under the name of Bryoniæ ſpecies. Theſe are included by Linnæus under one genus: The characters of which are delivered in his Genera Plantarum, p. 479. under the name *Raiania*. *Plum.* Gen. p. 29. Species rar. See the article RAIANIA.

JAW (*Cycl.*)—*Diſlocated* JAW. The lower *Jaw* is ſeldom luxated, becauſe it is held very firmly by ſtrong ligaments and muſcles in two ſinus's in the baſis of the cranium; but when it is by accident forced from thence, whether it be on one ſide only, or on both; it is in this caſe thruſt directly forward. This accident is ſometimes brought on by a blow, or fall, but moſt frequently it happens from the opening the mouth too wide in yawning. If it be luxated on both ſides, the chin will incline downward, and the *Jaw* will be thruſt very forward; but if only on one ſide, the chin will be inclined

clined towards the oppoſite ſide; the elapſed little head of the *Jaw* not being capable of diſlocation otherwiſe than forward, and inward. When the *Jaw* is out only on one ſide, the cure is uſually not very difficult; but when both heads are diſlocated, and not preſently reſtored to their place, it always occaſions the worſt of ſymptoms, as pains, inflammations, convulſions, fevers, vomitings, and even death at length; and theſe ſymptoms are the more violent, as the adjacent nerves, tendons, and ligaments ſuffer a greater extenſion; but if an expert ſurgeon is applied to in time, all theſe are prevented by the ends being reduced.

The patient is to be ſeated on a low ſtool, ſo that an aſſiſtant may hold his head firm back againſt his breaſt; then the ſurgeon is to thruſt his two thumbs as far back into the patient's mouth as he well can, but they are to be firſt wrap'd round in an handkerchief, to prevent them either from ſlipping, or from being hurt; his other fingers are at the ſame time to be applied to the *Jaw*, externally. When he has thus got firmly hold of the *Jaw*, it is to be ſtrongly preſſed firſt downwards, and then backwards, and laſtly upwards. Theſe different directions of the force are however to be given all in one inſtant; and by theſe means the elapſed heads of the *Jaw*, are at once reſtored into their former cavities; but the ſurgeon muſt alſo be very careful always to ſnatch his thumbs very ſwiftly out of the patient's mouth, leſt they ſhould be compreſſed, bruiſed, or bit by reducing the *Jaw*.

If the *Jaw* be out on one ſide only, the method of reducing it muſt be exactly the ſame, only that the luxated ſide muſt be forced more ſtrongly downward and backward, than the ſound one. As to bandages, there is no occaſion for them in this caſe, unleſs the luxation has remained ſome time before it was reduc'd; for in that caſe, it may not be improper to apply for ſeveral days, the four-headed bandage, with ſome ſtrengthning ſpirit; which may be taken off, when the patient intends to eat. *Heiſter*'s Surg. p. 152.

We have a method by Mr. Monro, of reducing the *Jaw*-bone when luxated. Who ſays, he has more than once found Mr. Petit's method of reducing the luxated *Jaw*-bone ineffectual, after the muſcles have been ſwelled by unartful attempts of reduction, but that he ſucceeded by a ſmall improvement; for the particulars of which we refer to the Medic. Eſſ. Edinb. Vol. I. Art. 11.

This learned profeſſor thinks the common opinion, that the *Jaw* is brought down by the force of the digaſtric muſcles ſolely, not ſufficiently founded.

Fractures of the JAW. The lower *Jaw* is not ſo liable to fractures as the reſt of the bones; but when it is broke, whether it be on one ſide or both, the divided parts do not recede to any diſtance from one another. For the reſtoring the bones in a fractur'd *Jaw* to their proper ſituation, the patient muſt be commodiouſly ſeated over-againſt the light, and his head held firm by an aſſiſtant. The ſurgeon is then to introduce the thumb or fore-finger of one hand into the mouth, applying the other externally; and by this means he is to preſs the fragments of the *Jaw* on each ſide, till they have regained their former ſituation; which may be always known by the regular diſpoſition of the teeth. And if any of the teeth be found looſe or ſlip'd out, it may not be improper, if nothing hinders, to reſtore them afterwards to their proper places; faſtening them by a ſilver wire to ſuch as are next them. After the bones are thus properly reduced, they muſt be covered firſt with a plaſter, and then a compreſs dipt in ſpirit of wine, and applied internally; and another compreſs ſewed to a piece of paſteboard of the form of a half *Jaw*, is to be laid on externally; theſe are to be kept on by a four-headed bandage, perforated in the middle to let in the chin. But when the *Jaw* is found to be fractured on both ſides, it is uſual to introduce and apply internally, after the compreſs dipt in ſpirit of wine, another made of thin paſteboard; perforated in its middle, and accommodated to the figure of the chin in this manner. Its middle that is perforated is to be applied to the chin, and its two extremities towards the ears. But fractures of this part may often be well enough cured without plaſters and ſplints, where we can conveniently apply a proper bandage; for theſe bones are not eaſily diſplaced again, when they are once reduced. The patient muſt for ſome days live upon liquids, avoiding chewing and talking; and the fracture generally is well in twenty or thirty days. *Heiſter*'s Surg. p. 119.

IBERAPITANGA, in botany, a name by which ſome authors have called arbor braſilia, or lignum braſilianum. *Piſo*, p. 164. See the article BRAZIL, *Cycl.* and *Suppl.*

IBERIS, in botany, is with ſome authors the name of the common cardamine, the lady's ſmock or cuckow flower. *J. Bauhin*, V. II. p. 887.

IBEX, in natural hiſtory, the name of an animal of the goat kind. It is found in the mountains, and is extremely ſwift; but carries on its head a pair of horns, which one would think were ſufficient to weigh it down. Bellonius obſerves, that he ſaw ſome whoſe horns were four cubits long: They are bent down upon the back, and are wreathed and knotty, one knot growing every year. The head is ſmall, and the legs very ſlender; ſo that this creature, tho' properly of the goat kind, much reſembles a ſtag; the male has a very long black beard. It is not uncommon in ſome parts of Germany. *Ray*'s Syn. Quadr. p. 77. *Grew*, Muſ. p. 24.

Bochart, from ſome Arabian authors, ſays that this animal bends its horns back as far as its buttocks, and thereby leaps from the higheſt precipices, and falls upon its back without hurting itſelf; becauſe its horns receive and break the blow. *Calmet*, Dict. Bibl.

IBIBOBOCA, in zoology, the name of a ſpecies of ſerpent called by the Portugueſe *Cobra de Coral*. It is about two foot in length, and of the thickneſs of a man's thumb; and tapers off at the tail to a thinneſs, till at laſt it ends in a ſharp point. Its belly is all over white, and very bright and gloſſy; and its head is covered with white ſcales of a cubic figure, and with ſome black ones towards the edges. Its body is variegated with black, white and red. It is a very ſlow mover; but is of a very terrible and poiſonous kind. *Ray*'s Syn. Anim. p. 327.

IBIGA, in botany, a name uſed by ſome authors for the chamæpitys, or ground pine. *Ger.* Emac. Ind. p. 2.

IBIJARA, in zoology, the name of an American ſpecies of ſperent, called alſo *Bodty*, and by the Portugueſe, *Cega*, *Cobre Vega*, and *Cobra de las Cabeças*. It is of the amphiſbena kind, and is generally ſaid to have two heads, one at each end; but that is wholly erroneous. The head and tail are of the ſame ſhape, and of equal thickneſs, and the creature will ſtrike equally with either; and as it is ſaid its poiſon is equally contained at both. It is a ſnake of the ſmaller kind, being of about a foot long, and as thick as one's finger. It is white in colour, and as ſhining and gloſſy as glaſs; and is very elegantly marked with rings and ſtreaks of a brown or copper colour. Its eyes are ſmall, and ſcarce conſpicuous, looking only like dots made by the point of a needle; it lives under ground, and feeds on ants and other ſmall inſects. It is often thrown up in digging; and the Portugueſe ſay, it is a creature whoſe poiſon is beyond the reach of all the known remedies. *Ray*'s Syn. Anim. p. 289.

IBIJAU, in zoology, the name of a Braſilian bird, of the capri mulgus, or goat-ſucker kind. It is a very beautiful little owl, not larger than a ſwallow. Its head is large, broad and flat, and its eyes black and very lively; its beak is extremely ſmall, not exceeding the ſize of the large phang of a ſpider; but at the top of this, the noſtrils are very diſtinguiſhable. Its mouth is monſtrouſly large; when ſhut this is not perceived, but when it is open, it reaches each way to the eyes. Its legs are very ſhort, and its tail broad. It is all over of a blackiſh colour, ſpotted and variegated with white and yellow. *Marggrave*'s Hiſt. Braſ.

IBIRA, in botany, a name given by ſome authors to the tree which produces the cubebæ, or cubebs of the Shops. *Piſo*, p. 144. See the article CUBEBS, *Cycl.* and *Suppl.*

IBIRACOA, in zoology, the name of a ſpecies of ſerpent, found in the Weſt Indies; whoſe bite is poiſonous, and always attended with very terrible effects. It is of a variegated colour, mottled with black, white, and red.

IBIS, in zoology, the name of an Egyptian bird, approaching to the ſtork kind; and by ſome confounded very erroneouſly with the hæmatopus, or red-legged heron. It is all over of a fine ſhining black; its beak is long, ſomewhat hooked, and all over of a fine red, as are alſo its legs, which are as long as thoſe of the bittern. Its neck is as long as that of the common heron. It is ſaid to be peculiar to Egypt, and incapable of living in any other region; and is there very ſerviceable in deſtroying the ſerpents, locuſts, and other devouring inſects; and hence it was, that in early ages they had divine honours paid them. *Bellonius* de Avib.

It is remarkable in this bird, that altho' it lives principally about the *Nile*, yet it never enters the water, nor can it ſwim. The uſe of glyſters is ſaid to have been learned from the *Ibis*, and not from the ſtork. It generally builds its neſt upon palm-trees, to avoid the cats. The antients aſſerted in their writings, that it conceived at its beak, and even laid its eggs that way; but theſe are miſtakes. Aldrovandus relates, that the fleſh of the *Ibis* is red, like a ſalmon's; that it is ſweet; that its ſkin is very hard, and ſmells like wild-fowl. *Calm.* Dict. Bibl. *Salmaſ.* in Solin. p. 418. *Solin.* c. 34.

IBUM. The Rabbins give this name to the ceremony of a brother's marrying his ſiſter-in-law, the widow of his brother deceaſed without children, by virtue of the *Moſaic* law mentioned in Deut. xxv. *Calmet*, Dict. Bibl.

ICAN *Setany*, in zoology, a name by which Bontius has called the piſcis triangularis. *Willughby*'s Hiſt. Piſc. p. 156. See the article TRIANGULARIS *Piſcis*.

ICE *(Cycl.)*—*Ice* may be preſerved in a dry place under ground, by covering it well with chaff, ſtraw, or reeds. Phil. Tranſ. N°. 8. p. 140. See the article SNOW.

The ſpecific gravity of *Ice* to water, is as eight to nine: hence being lighter than water, it floats upon it. This rarefaction of *Ice* is owing to the air-bubbles produced in *Ice* while freezing; theſe being conſiderably large in proportion to the water frozen, render the *Ice* ſo much ſpecifically lighter. It is well known, that a conſiderable quantity of air is lodged in the interſtices of water, tho' it has not there any elaſtic property,

on account of the diſunion of its particles; but theſe particles coming cloſer together, and uniting as the water freezes, light, expanſive, and elaſtic air-bubbles are thus generated, and increaſe in bulk as the cold grows ſtronger; whence of courſe the *Ice* grows lighter, and theſe air-bubbles acquiring an elaſtic force burſt to pieces any veſſel in which the water is cloſely contained. But ſnow-water, or any water long boiled over the fire, affords an *Ice* more ſolid than ordinary, and with fewer bubbles. This alſo freezes much ſlower than common water; whereas, on the contrary, pure water long kept in vacuo and frozen afterwards there, freezes much ſooner, on being expoſed to the ſame degree of cold, than water unpurged of its air and ſet in the open atmoſphere. And the *Ice* made of water thus diveſted of its air, is much harder, more ſolid and tranſparent, and more ponderous than common *Ice*. *Boerh.* Chem. P. I. p. 376.

To make the moſt perfect *Ice* we ſhould take the pureſt water, and perfectly purge it of its air by the air-pump; then freeze it in the ſevereſt froſt, by means of Mr. Farenheit's contrivance. Thus we obtain an *Ice* of the greateſt hardneſs, denſity, purity, tranſparence, and gravity.

In the mountains of Swiſſerland there are immenſe maſſes of *Ice*, which by the tradition and hiſtories of the country muſt have lain there for many centuries. At certain times there happen cracks in theſe, and by theſe cracks the vaſt thickneſs of the maſſes may in ſome meaſure be gueſſed at; ſome of them being three or four hundred ells deep, and yet none of them ever having gone through the whole thickneſs. *Wagner*'s Hiſt. Nat. Helv.

The vaſt bodies of *Ice* met with in the northern ſeas near Hudſon's-Bay, are ſurpriſing; ſome of them being immerſed an hundred fathoms or more under the the ſurface of the ocean, and a fifth or ſixth part above, and three or four miles in circumference. See Phil. Tranſ. N° 465. Sect. 2.

Theſe floating mountains of *Ice* owe their vaſt bigneſs and durable nature to a cauſe not conſidered by many; that is, to their not being common *Ice*, but the *Ice* of ſea-water; many experiments proving, that in acid and ſpirituous liquors, when the froſt has power over them, the watery parts only are affected, and the *Ice* is taſteleſs, while the liquor remains concentrated, and much ſtronger than before at the bottom, or in the center. It was generally ſuppoſed that the ſaline liquors, and conſequently ſea-water, were affected by freezing in the ſame manner; that is, its watery part alone was frozen, and the ſalt ſeparated from the part ſo congealed; but Dr. Liſter has proved, that the *Ice* formed of ſea-water is really ſalt, and does contain ſea-ſalt, and finally that it is, by means of this ſalt contained in it, rendered more durable than common *Ice*. If a vial of ſalt-water be expoſed to the air in froſty weather till flakes of *Ice* are found in it, and then brought into a warm room, thoſe flakes will remain even in that place a long time undiſſolved; and if they are taken out and expoſed at a ſmall diſtance to the fire, they will not run into water as common *Ice* would, but they will by degrees evaporate, and there will be left only a little white ſalt.

Since ſea-water when frozen thus forms a very durable *Ice*, it appears eaſy to conceive, that the immenſe maſſes of ſuch *Ice* found in the northern ſeas ſhould continue undiſſolved through the whole year, and at the return of the freezing ſeaſon remaining of the ſame bigneſs as at firſt, they muſt of conſequence then become much bigger by the freezing of more *Ice* about them; and thus continuing to loſe very little, and that only by accidents, and annually to increaſe a great deal, it is not wonderful that they become ſo large. Philoſ. Tranſ. N° 167. p. 836.

ICE-*Plant*, a very ſingular and beautiful plant of the *Ficoides* kind, called by Mr. Tournefort, *Ficoides africana folio plantagenis undulato micis argenteis adſperſo*, or the African Ficoides with a wav'd plantain-like leaf, and covered with ſilver drops. It is alſo commonly called with us the diamond-plant, and the froſt-plant, from its leaves and ſtalks being all over beſet with tranſparent cryſtal-like drops, as if covered over with ſmall icicles. The ſeeds of this plant are to be ſown very early in the ſpring upon a good hot bed; when the plants are come up they are to be tranſplanted into ſmall pots filled with freſh light ſandy earth, and plunged into another hot bed; as that hot bed declines in heat they ſhould be moved into a third, and this will bring them forward toward flowering. In July theſe plants may be expoſed by degrees to the open air, and ſoon after this their flowers will appear. If it is deſired to have theſe plants very large, they ſhould be ſhook out of their pots into an old hot bed of tanners bark, in which their roots will extend every way, and the branches in proportion; ſo that a ſingle plant will ſometimes ſpread to a yard ſquare, and its leaves and branches grow to a very ſurpriſing ſize. The flowers of this ſpecies are of no great beauty, but its *Ice-like* appearance in the midſt of ſummer is ſo ſingular, as to make it very univerſally admired.

ICHNEUMON, in zoology, the name of an animal, of which there have been a multitude of idle and fabulous things aſſerted. It is a creature of the weaſel kind, with a longer and narrower body than a cat, and ſomething approaching both in ſhape and colour to the badger. Its noſe is black and ſharp, like that of a ferret. It has no beard, or whiſkers: Its noſe is prominent, and its ears ſhort and round. Its colour is a yellowiſh grey, much like that of ſome of the monkey claſs. This is its appearance when in a good humour; but when frighted or provoked, it raiſes its hairs upright, and ſhews them variegated at intervals with grey and yellow in diſtinct portions. Its legs are ſhort, and its feet have all five toes. Its tail is very long, and thick at the inſertion; its teeth, and its tongue, like thoſe of the cat. And what is very ſingular, is, that in both ſexes it has a large aperture ſituated below the anus, which it dilates and contracts at pleaſure. Hence came the old opinion, that both male and female conceived, and brought forth young in this animal. It is naturally a very cleanly animal, and is very briſk and nimble, and of great courage. It will engage a large dog, and if it have a quarrel with a cat, will deſtroy that creature by three bites on the throat. Its noſe is ſo ſharp and narrow, that it can very hardly lay hold of any thing large with its teeth, and ſcarce can bite a man's clenched fiſt. It is very expert in ſeizing its prey; it ſtands erect on its hinder legs to deſcry where it is, then throwing itſelf flat on its belly, crawls very ſlyly towards it, and when within reach, darts violently upon it. It feeds indifferently on all animals that it can get at. Its common food are the ſnail, the lizard, the chameleon, ſuch ſerpents as it can manage, and frogs and mice; it is alſo very fond of birds, and of none ſo much as the hen and chicken. *Ray*'s Syn. Quad. p. 201.

It is much valued in Ægypt for deſtroying ſerpents, and is kept tame in the houſes, as the cat with us. The people call it Pharaoh's rat, and the peaſants frequently bring its young to market. *Bellonius* de Animal.

ICHNEUMON-*Waſp*, the name given by the old writers on inſects to the ſmall ſlender-bodied waſp, which is frequently found about mud-walls and dry banks of earth. It is very different from the fly ſimply called the *Ichneumon*; of which there are numerous ſpecies. This is a true waſp, and is mottled with black and yellow in the manner of the common waſp.

ICHNEUMON-*Fly*. Theſe flies ſometimes are at great pains to deſtroy and carry the caterpillars, in whoſe bodies they intend to lay their eggs, to places where it is proper thoſe eggs ſhould be hatched. There is one ſpecies whoſe worm produced from the egg can never ſucceed, unleſs it be both bred in the body of a caterpillar, and alſo have that habitation bury'd under ground. To this purpoſe the parent-fly, when the time of her laying her eggs is come, forms a hole in the ground, which ſhe covers with a little clod of earth, that no duſt may fall in to fill it up; when this is prepared ſhe goes out in ſearch of a caterpillar, proper for her purpoſe. Dr. Liſter aſſures us, that he has often ſeen one of theſe flies ſeize a caterpillar much larger than herſelf for this intent, and tho' this has been at a conſiderable diſtance from her hole, ſhe has with great labour dragged the creature to it; as ſoon as ſhe arrives with this load ſhe takes off the little pellet of earth from the mouth of the hole, and going down into it to ſee that all is right and ready for the reception of the new gueſt, ſhe returns out of it and draws in the caterpillar, which ſhe leaves there, after giving it ſuch wounds as tho' they will not cauſe immediate death, yet will diſable the creature ſo far as to make an eſcape impracticable. When the creature is thus lodged, ſhe depoſits her eggs in its fleſh. And this great buſineſs being done, ſhe ſtops up the orifice of the hole very firmly with ſeveral pellets of dirt, and with duſt carefully rammed in between, and will even fly up into gummy and reſinous trees to get a cement to hold all firmly together. When the hole is thus filled up, even to the ſurface of the reſt of the ground, ſhe draws a leaf or two to the place, and laying them over the mouth, flies away. There is after this no more care taken, but the young worms are hatched from the eggs, and feed on the fleſh of the caterpillar till they are full grown. They then change into the nymph ſtate, and come out of that in form of their parent flies, in which ſtate they eaſily make their way out of the ground. Some of theſe *Ichneumons* make the bodies of other ſmaller flies the places of hatching their eggs. They may be often met with flying with one of theſe ſmall flies in their legs, the head of it being held cloſe to their bellies. If they be watched on this occaſion, they will be found uſually to carry theſe flies to certain holes in the ground reſembling worm-holes. The firſt that they carry ſerves as the nidus for their eggs, the reſt are for food for their young while in the ſtate of worms; theſe being too voracious to be long ſubſiſted on the body of one fly, and therefore their parents carry them more every day. The old ones on this occaſion crawl backwards into the hole, dragging in the flies after them. When their young worms have fed ſufficiently they are converted into nymphæ; the caſes of which are made up of the wings, legs, and other hard parts of the flies they had been feeding on. Phil. Tranſ. N° 76.

ICHTHYOCOLLA (*Cycl.*)—*Iſing-glaſs*, a very valuable glue is to be made of this drug. See the article GLUE.

It is valuable, in that it will keep alſo, and is a very proper form to keep iſing-glaſs in, for readineſs for the wine-cooper's uſe; beſides this it ſerves alſo very elegantly for the taking off the impreſſions of medals, coins, &c. *Shaw*'s Lectures, p. 430. See the article MEDAL.

ICHTHYOCOLLA *Piſcis*, in zoology, the name of a large fiſh of the ſturgeon kind; from which, as alſo from the *Huſo Germanorum*, the drug called iſinglaſs or *Ichthyocolla* is made. It is a fiſh of very great ſize, and is cartilaginous, having no bones nor ſcales. Its head is large and thick, and its mouth ſtands very forward. The upper jaw has four fleſhy apophyſes hanging from it. Its eyes are ſmall: Its fleſh is very well taſted, but glutinous. It is of a yellowiſh colour, and its tail is large and forked. *Willughby*'s Hiſt. Piſc. p, 244.

ICHTHYOLOGY, the ſcience which treats of fiſhes. The proper objects of this ſtudy are aquatic animals, which have fins, and have no feet. The buſineſs of *Ichthyology* is, firſt to diſtinguiſh all the parts of fiſhes, by their ſeveral proper names; then to adapt to each fiſh its proper generical and ſpecific names; and finally, to commemorate ſome of its peculiar qualities. The naturaliſt who ſtudies fiſhes, is firſt to examine the ſeveral parts, as well internal as external of the animal under conſideration, and be able to treat of each under its proper denomination; then to refer whatever ſtrange and unknown fiſh is brought before him, to its proper family; and on examining its near characters to bring it to the genus of that family to which it is found to belong; and by conſidering its parts, with the deſcriptions authors have given of the ſeveral ſpecies of that genus, to find by compariſon which it moſt ſuits, and therefore of which ſpecies it is. This done, the fiſh is known. After this, by ſubſequent obſervations, he is to find out its place of habitation, whether in ſalt or freſh, in running or ſtanding waters. Its food whether animal or vegetable, and of what kinds; and its time and manner of propagating its ſpecies, and bringing forth its young. Theſe laſt particulars are to be added to the deſcription of the parts of the fiſh, in few words, for long and diffuſe narrations of this kind ſerve rather as a load than an inſtruction to the judicious reader; and the true and natural method in the genera and ſpecies of created things, is the true intent and end of natural hiſtory. *Artedi* Ichthyol. p. 3. See GENERICAL *Name*.

The general diviſion of fiſhes is into three claſſes; the cetaceous, the cartilaginous, and the ſpinoſe. The cetaceous fiſhes are thoſe whoſe tail is ſo placed that when the fiſh is in its natural poſture, it ſtands parallel to the horizon. The cartilaginous fiſhes are thoſe whoſe fins ſerving for ſwimming are ſuſtained by cartilages in the place of the bony rays which ſupport them in the other, and which have alſo cartilages in the whole body, inſtead of bones. Theſe are the characters of the two firſt claſſes; and all thoſe fiſh which have their fins ſupported by bony rays, which have their tails placed perpendicularly, not horizontally, and which have bones not cartilages in their bodies, are called the ſpinoſe fiſhes.

Theſe are the diviſions of the fiſh in general among authors. The cetaceous fiſhes are arranged together, by the later writers on natural hiſtory, under the name of Plagiuri. Theſe agree in many things with the land animals, and are diſtinguiſhed from one another by the ſame characters which ſerve for the diſtinction of the quadrupeds, particularly by the teeth. The general ſtructure of theſe fiſhes is alike in all; and their only differences are in the teeth, and the number of fins. From the teeth and fins alone therefore, are to be properly taken the generical characters of the Plagiuri. *Artedi* Ichthyolog.

The cartilaginous fiſhes differ from each other only in the form of their body, and in the number of the foramina of the bronchia. For the number of the fins, and figure and poſition of the teeth, which in the former claſs make the only characters of generical diſtinctions, in theſe are ſo variable, that they frequently differ in the different ſpecies of the ſame genus. The characters for the diſtinction of the cartilaginous fiſhes into genera, can therefore only be taken from the ſhape and foramina. Thus all the rays have flat or depreſſed bodies, and five foramina at the bronchia. All the petromyzæ have, on the contrary, rounded bodies, and ſeven foramina at the bronchia. The chonepterus and mola have roundiſh bodies, and only one foramen or hole for the bronchia; and ſo of the reſt. The ſeveral ſpecies of the rays, tho' all properly belonging to the ſame natural genus, yet differ greatly in their number of fins, and in the ſhape and diſpoſition of their teeth.

The true characters of theſe two great claſſes of fiſhes, the cetaceous and cartilaginous, are thus eaſily found; but the characters of the ſpinoſe kinds are to be ſought for deeper, and do not offer themſelves ſo readily. The multitude of theſe, and the great likeneſs between ſeveral of the different genera, render it no eaſy taſk to diſtinguiſh them one from another. Though it be a general rule that the generical characters of fiſhes are to be taken from their external parts; yet in caſes where theſe external parts differ in themſelves in number, figure, and proportion, it is neceſſary that the primary character of the genus ſhould be taken from thoſe parts which are the leaſt variable of all others; and which are the moſt peculiar to the fiſh under conſideration, and the leaſt common to other genera. The utmoſt care and ſkill of the *Ichthyologiſt* is neceſſary to the diſtinguiſhing theſe characters; and on a ſtrict enquiry he will find, that thoſe parts which ſeem at firſt moſt proper to found diſtinctions on, are in reality leaſt of all ſo. The figure of the fins and tail in fiſh might ſeem one of the moſt eſſential characters for a generical diſtinction, yet a farther ſearch into their nature will ſhew that they can be of no uſe at all in this ſenſe. Almoſt all the ſpecies of the cyprini, a genus conſtituted on eſſential and invariable characters, and a truly natural one, have fins acute at the end, and have forked tails; yet had theſe been made characters of the genus, they would have excluded fiſh that are properly of it. Thus the tench and the caraſſius have both obtuſe fins, and tails ſtrait or plain, not forked at the end. There are indeed many natural genera of fiſhes in which the fins and tail are alike in all, as the pearch, the mackrel, the conger. Theſe allow the fins and tail as very good collateral circumſtances of the diſtinction; but even theſe could not well be diſtinguiſhed by ſuch marks alone, as they are common to many other genera beſides.

The figure of the breaſt, the belly, and the back, and the whole figure of the body in regard to length and breadth, are all very obvious characters; but they are not eſſential enough to be of any uſe in the diſtinctions of the genera. The back in ſome of the cyprini is ſubacute, as in the common bream; whereas in almoſt all the others, it is only moderately convex. This ſets aſide the uſe of the figure of the back as a generical character, ſince the bream, notwithſtanding this difference from the reſt of the cyprini, is truly of that genus. The belly, in the far greater number of the cyprini, alſo is plane in the anterior part, and between the pinnæ ventrales and the anus is raiſed into a ridge; but in the tench, the whole belly from the head to the tail is flat. And to this it may be added, that the general figure of the body, as to length or breadth, is extremely different in the cyprini of various ſpecies, as witneſs the bream, the alburnus, the rutilus, &c. ſome of which are properly flat, and others almoſt round.

The figure of the head, the mouth, the eyes, the noſtrils, and other parts belonging to the head, are very different from theſe variable parts; they are in general fixed and permanent, and are of the utmoſt conſequence in the diſtinctions; but as this figure is too common, and belongs to too many ſpecies equally, they are rather of uſe in the diſtinguiſhing the orders, claſſes, and families of fiſhes, than their genera. Thus the clupeæ, the cotti, the coregones, and ſcorpænæ of authors have a plain general reſemblance in the form of their heads, and yet they are of very different genera.

The figure of the ſcales is generally always the ſame in the ſame genus, and therefore may be made a good collateral circumſtance in the diſtinctions; but as the ſame form is common to the ſcales of many genera, it is impoſſible to bring them to any great uſe in the conſtituting the characters of the genera. As to the ſituation of the external parts, as that of the eyes, noſtrils, mouth and anus, they are generally regular and alike in all the ſpecies of the ſame genus, regard being had to the proportion; but as their ſituation tho' alike in theſe genera is not peculiar to each, the marks are too common to be uſed as diſtinctive characters for genera. The ſituation of the fins alſo is uſually very regularly the ſame in all the ſpecies of the ſame genus; but the ſame objection lies againſt this as againſt the others, in regard to making generical characters from it. The clupeæ, the coregones, the ſalmons, and cobitides, every body muſt allow to be very different genera of fiſhes; yet in all theſe the fins are placed in the ſame ſituation. The pectoral fins in all theſe ſtand neareſt the head, the neareſt next to theſe is the back-fin; after this come the ventral fins, and behind all the reſt the pinna ani. The ſame obſervation will alſo hold good in ſeveral other genera, which have theſe and other marks in common. The ſituation of the ſcales of fiſhes, in regard to their denſity or rarity, always holds the ſame in the ſeveral ſpecies of the ſame genus; but this alſo is a mark common to many genera. The ſituation of the teeth agrees in the ſame manner in all of the ſame genus, and in many genera. All the cyprini have their teeth placed in the ſame order and manner; they all ſtand in the fauces at the orifice of the ſtomach. The ſalmons and pike have their teeth in four places, the jaws, palate, tongue, and fauces. The pearch, the cotti, and clariæ have them in three places, the jaws, palate, and fauces; but not on the tongue. But among the coregones, one ſpecies, the albula nobilis of Schonfield, has the teeth in three places, in the upper jaw, the palate, and the fauces. Another ſpecies, called by the Swedes the ſilk-joia, has them only in one place, which is on the tongue; and another ſpecies of the ſame genus, the thymallus of authors, has them in both jaws, in the palate, and on the tongue. Therefore it is evident, that no generical character can be eſtabliſhed on them. The number of the teeth can be of no uſe in the making characters of genera; for this very often varies in the ſame ſpecies in different individuals, as in the pikes, ſalmons, &c. The

number of the fins is no more proper than that of the teeth for this purpoſe; for this is the ſame in many genera, and is ſometimes different in the ſeveral ſpecies of the ſame genus. The aſellus longus of authors is evidently of the ſame genus with the reſt of the aſelli, yet they have all three fins on the back, and this has only two; and on the belly it has only one, whereas they have two there. The ſcomber has ſeventeen fins, and the thynnus or tunny has twenty-five, or thereabouts; yet no one can call theſe two genera of fiſhes, when they agree in all other particulars. The perca, the lucioperca, and the cernua fluviatilis, are all of the ſame genus, and have all the ſame internal and external characters; but that the two firſt have two fins each on the back, and the laſt has only one. The number of the rays in the fins of fiſh, particularly in thoſe of the back and anus, are very different even in the ſeveral ſpecies of the ſame genus: Hence they are very uſeful in diſtinguiſhing the ſpecies, but not at all in the genera. We have very evident examples of this, in the ſeveral ſpecies of pearch, cyprini, and many other fiſh.

In regard to the other external parts of fiſhes, there are none which are found in all the ſpinoſe fiſhes, and differ in all the ſeveral genera, except thoſe little bones which are found on each ſide in the membrane of the head, which covers the gills. Theſe bones are found in almoſt all the fiſhes that have any bones, tho' in ſome kinds the thickneſs of this membrane makes them leſs conſpicuous than in others. The number of theſe bones is much more regularly and conſtantly the ſame in the ſame genera, than that of the fins, as we may find by many obſervations. The four genera of the ſcombri, gadi, percæ, and ſyngnathi, have the number of the fins very various in the ſeveral ſpecies of each genus; but in all theſe genera the number of the bones in the membrane that covers the gills, is regularly the ſame in every ſpecies. All the gadi have regularly ſeven bones on each ſide, and ſo on of the reſt. All the cyprini have three of theſe bones on each ſide: All the cotti have ſix on each ſide: All the clariæ ſeven: All the clupeæ eight: All the eſoces fourteen; and ſo of the reſt. There are only two known genera of fiſh, that do not agree in all the ſpecies in the number of theſe bones; theſe are the ſalmons and the coregoni. In the firſt of theſe the number of the bones is in the ſeveral ſpecies ten, eleven, or twelve; and in the ſeveral ſpecies of the other, there are eight, nine, or ten, and ſometimes but ſeven. It is an obſervation, however, worthy the naturaliſt's conſideration, that nature has given this difference in the number of theſe bones in the ſeveral ſpecies only to thoſe genera in which all the ſpecies have ſuch a ſtrong external reſemblance in all parts, that ſcarce any thing more than the facies externa, was neceſſary for the knowing that they belonged to one another; for beſide that all the ſalmons and coregoni have a membranous appendage reſembling a fin on the hinder part of the back, the ſeveral ſpecies of each genus are ſo very remarkably like one another, that it is not eaſy to diſtinguiſh them in many caſes.

As to the number of the fins on fiſh, there are a vaſt number of genera which have all the ſame general number, as the cyprini, clupeæ, coregoni, oſmeri, ſalmons, cobitides, eſoces, pleuronecti, ſpari, labri, gobii, and gaſteroſtei; all have ſeven fins radiated with bony ribs: The ſame number of ſeven fins, and thoſe of the ſame kind, is common alſo to the ſeveral other genera; but on the contrary, tho' all the ſpecies of the ſame genus have conſtantly the ſame number of bones in the membrane that covers the gills, yet it is very rare that the different genera have the ſame number. The pearch, the gadi, the ammodytes, and the ſcombri, have indeed all ſeven on each ſide. The cyprini and the gaſteroſtei have each of them three on each ſide. The cotti, the pleuronecti, and the mugil, have ſix each: Theſe however are genera ſo very different in their other characters, and in their facies externa, that there is not the leaſt danger of their being confounded one with another.

From this it appears very evidently, that the number of theſe bones in the membrana branchioſtega, affords the firſt and moſt eſſential of all characters for the diſtinction of the genera of the catheturous and oſteopterygious, or bony-fin'd fiſhes. This however is not ſufficient alone, tho' it is a great aſſiſtant in determining the genera; but in order to bring fiſh to their proper genera, it is neceſſary firſt, that all of the ſame genus ſhould have the ſame number of bones in the gills; then, that they ſhould have in the genera the ſame external form and figure; after this, that they muſt have the ſame ſituation of the fins, provided that the number does not differ, which ſometimes will be found to vary in ſpecies truly of the ſame genus; but in general it is, and ought to be the ſame in all.

The ſituation of the teeth alſo ſhould be the ſame, and this generally holds right in the different genera of fiſhes, all the ſpecies having in each natural genus the ſame orders of teeth. After this, the ſcales are to be examined, and theſe ought to be of the ſame ſort, and to have the ſame ſituation. Theſe are the circumſtances neceſſary to be enquired into, in regard to the eſtabliſhing juſt and natural genera. If all theſe agree in all the ſpecies; and added to this agreement there be an analogy in the ſituation and form of the other internal and external parts, particularly in the ſtomach, and its appendices, in the inteſtines, and in the air-bladder, there will remain no doubt of the genus eſtabliſhed on ſuch foundations being perfectly juſt and natural.

It is not to be expected however, that every one of theſe characters ſhould be found regularly in every ſpecies of the ſame genus in the ſame perfection; ſome will ſhew them more, others leſs, and others will want ſomething of them: But the three grand things that are eſſential to the ſameneſs of the genus, are the ſame number of bones in the branchioſtege membrane, and the ſame general external face or figure, and the ſame ſituation of the fins. The other circumſtances are additional and confirmative.

Upon the whole it appears, the number of certain parts is the firſt great foundation of generical diſtinctions in fiſhes; and that no one note or generical character can be ſo extenſive as to take in the whole at once, but that other characters leſs eſſential but more numerous muſt be in ſome caſes taken in for the eſtabliſhing the whole ſeries of *Ichthyological* diſtinctions. *Artedi* Ichthyolog.

ICHTHYOLOGISTS, authors, who have written concerning fiſhes. The authors who have left us treatiſes on this ſubject, are very numerous; and are ranged by Artedi into their ſeveral proper claſſes, with great care and candor.

The ſyſtematical *Ichthyologiſts* are Ariſtotle, Pliny, Iſidore, Albertus Magnus, Gaza the interpreter of Ariſtotle, Marſchall, Wootton, Bellonius, Rondeletius, Salvian, Geſner, Aldrovand, Johnſton, Charlton, Willughby, Ray.

The *Ichthyologiſts* who have written of the fiſhes only of ſome particular places, are theſe: Ovid, of the fiſhes of the Euxine; Oppian, of thoſe of the Adriatic; Auſonius, of thoſe of the Moſelle; Mangolt, of thoſe of the Podamic lake; Paulus Jovius, of thoſe of the Tyrrhene ſea; Bened. Jovius, of thoſe of the lake Larius; Petrus Gillius, of thoſe of the Maſſilian ſea; Figulus, of thoſe of the Moſelle; Salvian, of thoſe of the Tyrrhene ſea; Schwenkfeldt, of thoſe of Sileſia; Schonfeldt, of thoſe of Hamburgh; Marggrave, of the Braſilian fiſhes; Ruyſel, of thoſe of Amboina; and Francis Valentine, of thoſe of the ſame place. Of theſe authors, Ovid, Auſonius, Oppian, and Bened. Jovius wrote in verſe, the reſt in proſe.

The *Ichthyologiſts* who have copied all they have written from the works of other writers, and therefore leaſt deſerve the name, are the following: Pliny, Ælian, Athæneus, Iſidore, the author of the Libri de natura rerum, Albertus Magnus, Joannes Cuba, Marſchall, Geſner in great part, Aldrovand in great part, Johnſton, Charlton, and perhaps ſome others.

In regard to method, ſome have written of fiſhes without any method at all; ſome have treated of them in the alphabetical order of their names, and ſome have followed a method more or leſs perfect throughout their works.

Thoſe *Ichthyologiſts* who have attended to no method at all, are Ovid, Ælian, Athenæus, Auſonius, Hildegarde de Pinguia, Paulus, and Bened. Jovius, Figulus, Salvian in his hiſtory of the Roman fiſhes, and Ruyſch.

Thoſe who have written alphabetically, are Cuba, Marſchall, Salvian in his Tabula Piſcatoria, Geſner, Schonfeldt, Johnſton.

Among the authors who have uſed ſome ſort of method, thoſe come firſt who have treated of fiſhes, according to the places where they are uſually caught. Of theſe are Oppian, Rondeletius, Aldrovand, Johnſton, and Charlton.

Thoſe who have treated of fiſhes, according to the general diviſion of them into cetaceous, ſpinoſe, and cartilaginous, are Ariſtotle who was author of the method, Wootton, Willughby, Ray; the laſt two authors have added to this the numbering the rays of the fins on the back, which is one ſtep toward the Artedian method.

The principal and beſt authors in this ſtudy, and who have reformed and amended it, are Ariſtotle, Bellonius, Rondeletius, Salvian, Geſner, Willughby and Ray. To theſe are to be added ſuch as have deſcribed only new or particular fiſhes, who have merited greatly of the world by the new lights they have thrown in upon this part of natural hiſtory. Theſe are Paul Jovius, Petrus Gillius, Schonfeldt, Sibbald, Marſigli, Hebenſtreit, and our countryman Mark Cateſby: All the reſt, except Pliny, Athenæus, Aldrovand, and Johnſton, are of no uſe or value. Willughby is allowed by Artedi to be by far the beſt author on the ſubject; but the world will now give that character to Artedi himſelf. *Artedi* de Script. Ichthyol.

ICHTHYOMANTIA, Ιχθυομαντεια, in antiquity, a ſpecies of divination by means of the entrails of fiſhes. *Potter*, Archæol. Græc. l. 2. c. 14. T. 1. p. 319.

ICHTHYPERIA, in natural hiſtory, the name given by Dr. Hill to the bony palates of fiſhes, which are frequently found foſſile at great depths in the earth, and uſually immerſed in the ſtrata of ſtone; and in this ſtate had been named by Mr. Lhuyd, from their reſemblance in ſhape to the pods of lupines, and ſome of the other leguminous plants, *ſiliquaſtra*. Many from this name, and this caſual reſemblance to the pods of plants, have been miſ-led into the believing them

foſſils of vegetable origin. But they have plainly all of them been the bony coverings of different parts of the mouths of certain fiſh of the cartilagineous, and perhaps other kinds, whoſe principal food being ſhell-fiſh, theſe bony palates were neceſſary to the eating them. Many of the *Ichthyperia* are found indeed plainly worn and rounded by uſe.

They are ſometimes found in their foſſile ſtate in congeries joined one to another, as they originally ſtood in the mouth of the fiſh, but this is more rare; the great quantities that are found being either in ſingle pieces or joints as they may be called, or in fragments of ſuch. They are all of the ſame ſubſtance with the bufonitæ, and are of very various figures according to the different ſpecies of fiſh, or different part of the mouth they have belonged to, the ſame fiſh very probably having furniſhed from the middle and the ſides of its mouth very differently ſhaped *Ichthyperia*.

The moſt uſual figure of theſe bodies is that of half the ſhell of the pod of a lupine, or other leguminous plant, according to the ſeveral ſpecies, and this has uſually its inner part filled up with the matter of the ſtratum, in which it is depoſited. The principal differences of their figure are theſe: The moſt common are thoſe reſembling the half lupine pod; next to theſe, are thoſe which more reſemble that of the field pea; and there are ſome found, which reſemble that of a kidney-bean, or a part of ſuch a pod. Some of them are very broad and ſhort, others as remarkably long and ſlender; ſome are very gibboſe on the back, others are plainly arched; and the ſeveral kinds are at times found more or leſs flat. Some of them are crooked at one end; others are wreathed or twiſted, as it were; ſome approach to a triangular, and others to a rhomboidal form; ſome are roundiſh and flatted, and others are remarkably prominent in the middle; and many of them reſemble in ſome degree the bufonitæ.

They are found of various ſizes from the tenth of an inch to two inches in length, and an inch in breadth; and are ſometimes of a perfectly ſmooth even and poliſhed ſurface; but more frequently they are finely ſtriated or ſinuated, and ſometimes they are wholly covered with tubercles. Their colour is not leſs various, than their ſhape. They are moſt frequently either black, or of dark and blackiſh cheſnut colour; but they are ſometimes found greeniſh, bluiſh, yellowiſh, or whitiſh; and ſometimes, tho' rarely, they are ſpotted with different colours. *Hill*'s Hiſt. of Foſſ. p. 645.

They are found lodged and bedded in the ſtrata of ſtone, in Germany, Italy, and France, and in the iſlands of the Archipelago, and in Syria among the ſpines of the echini; but they are no where ſo frequent as in England, there being with us very few quarries of ſtone which do not afford more or leſs of them. See Tab. of Foſſils, Claſs 8.

ICHTHYS, Ιχθυς, a famous acroſtic of the Erythræan ſibyl, mentioned by Euſebius and St. Auſtin; the firſt words of every verſe of which make up Ιησους χριστος θεου υιος σωτηρ, *Jeſus Chriſtus, Dei filius, ſervator*. The initial letters of which compoſe the word *Ichthys*, Ιχθυς. See *Hoffm.* Lex. in voc.

ICICA, in the materia medica, a name given by ſome to the gum elemi. *Piſo*, p. 59.

ICICARIBA, in botany, a name uſed by ſome authors for the tree which affords us the gum elemi, uſed in medicine. *Piſo*, p. 59.

ICOCA, in botany, the name of a genus of plants, deſcribed by Plumier; ſince called by Linnæus, Chryſobalanus. *Plumier* Gen. 3. See the article CHRYSOBALANUS.

ICON, Εικων, in rhetoric, the ſame with image. See the article IMAGE, *Cycl.*

ICOSANDRIA, in botany, a claſs of plants with hermaphrodite flowers, and a large number of ſtamina or male parts in each. The word is derived from the Greek εικοσι, twenty, and ανηρ, male. See Tab. 1. of Botany, Claſs 1.

It ſhould therefore ſtrictly ſignify a flower with twenty ſtamina, but it is only underſtood in an indefinite ſenſe, and made to expreſs ſuch plants as have any large number, or more than twelve ſtamina in each flower, and thoſe growing to the inner ſide of the cup of the flower, not to the receptacle of the future ſeeds. Of this claſs are the torch thiſtle, the myrtle, the ſtorax, the almond, &c.

ICTERIAS *Lapis*, in natural hiſtory, a name given by the antients to a ſtone, famous for the cure of the jaundice. Pliny deſcribes four ſpecies of this ſtone. The firſt of a greyiſh yellow; the ſecond of a paler colour, and more pellucid; the third uſually found in flat pieces, of a greeniſh colour with duſky veins; and the fourth with black veins in the ſame greeniſh colours. The third was alſo diſtinguiſhed from all the others, by its remarkable lightneſs. Theſe deſcriptions are ſo ſhort, that we cannot determine from them which of the ſtones of thoſe known at preſent, were intended by them.

ICTERUS, the *jaundice-bird*, in zoology, a name by which ſeveral of the old authors have called the Galbula, a bird of the turdus kind, very beautifully coloured all over with a gold yellow, but with black wings. *Aldrovand.* de Avib. See the article GALBULA.

ICTIAR, in the Eaſtern military orders, an officer who has gone through all the degrees of poſts in his reſpective body; and has a right to be a member of the divan. *Poſock*'s Egypt. p. 166.

ICTIS, in zoology, a name originally Greek, by which ſome authors call the ferret. See the article VIVERRA.

IDÆÆ *Radix*, in botany, a name uſed by Columna and ſome other authors for the large narrow-leav'd kind of ruſcus, or butcher's broom; called by others *Biſlingua*. See the article RUSCUS.

IDEA (*Cycl.*)—The term *Idea* has, by Mr. Locke, been extended to every thing we know or have any notion of, any thing about which the mind is employed in thinking. But this extenſive uſe of the term *Idea* is thought improper by a very ingenious and acute writer [a], who obſerves that we may be ſaid to have ſome knowledge or notion of our own minds, of ſpirits and active beings, whereof in a ſtrict ſenſe we have not *Ideas*. In like manner, we know and have a notion of relations between things or *Ideas*, which relations are diſtinct from the *Ideas* or things related, inaſmuch as the latter may be perceived by us, without our perceiving the former. The ſame author elſewhere obſerves [b], that by *mind*, *ſpirit*, *ſoul*, or *ſelf*, he does not denote any one of his *Ideas*, but a thing entirely diſtinct from them; wherein they exiſt, or which is the ſame thing, whereby they are perceived; for the exiſtence of an *Idea* conſiſts, as he ſays, in being perceived. He alſo obſerves [c] the word *thing* or *being*, is the moſt general name of all, and comprehends under it two kinds entirely diſtinct and heterogeneous; having nothing common but the name, to wit, *ſpirits* and *Ideas*. And in another part of his treatiſe, he expreſsly affirms [d], there can be no *Idea* formed of a ſoul or ſpirit.—[[a] *Berkley* Princip. of Human Knowledge, 2d edit. ſect. 89. p. 112. [b] Ibid. ſect. 2. p. 36. [c] Ibid. ſect. 89. p. 111. [d] Ibid. ſect. 27. p. 57. See alſo ſect. 142. p. 160.]

Another author, has alſo blamed Mr. Locke, for confounding *Ideas* and notions. He obſerves, that by *Idea*, according to the common and moſt uſual ſignification of the word is meant, the image, picture, or repreſentation in the mind of a ſenſible appearance, or of an object which hath before been perceived by ſenſe. To which ſenſible appearance therefore the *Idea* neceſſarily refers, for whatever is in it, or upon any account can be aſcribed to it: And it ſerves, or is made uſe of in its ſtead, for the mind to contemplate or employ itſelf about in thinking, at ſuch time when the object it repreſents is not immediately perceived, as in the act of ſenſe.—*Vid.* pag. 105, & 106. of a book intitled Two Diſſertations concerning Senſe and the Imagination, with an Eſſay on Conſciouſneſs, Lond. 1728. 8°.

This author farther aſſerts in oppoſition to Mr. Locke, that the perception of an *Idea* is not an act of underſtanding. He urges, that an *Idea* by Mr. Locke's own account of it, is an object or ſomething perceived, and about which the mind is employed in thinking. Wherefore if perception (ſuppoſe) which is an operation or act of the mind, ſhould itſelf be conſidered as an *Idea*, (and under this very title Mr. Locke treats of perception) then one *Idea* would be the object of another *Idea*, and ſo there would be an *Idea* of an *Idea*, or an object of an object; and one *Idea* would perceive another *Idea*, which there is no making any tolerable ſenſe of. And indeed in explaining or declaring the operation of any faculty, to give it the ſame name and appellation, with the object itſelf about which it is employed, and which there is a neceſſity of conſidering in order to ſet forth the particular quality and nature of the operation, and the preciſe manner of its concerning and having to do with the object, ſeems very inconſiſtent with ſuch a purpoſe or deſign.

This author has been very elaborate in proving and inforcing the diſtinction between notions and *Ideas*. In another treatiſe, he obſerves that Mr. Locke in his eſſay on Human Underſtanding, takes no notice of rational notions, and thereby has not only given a partial and imperfect account of his ſubject, but made an unjuſt and unfair repreſentation of it. —*Vid.* an eſſay concerning rational notions, printed at London, 1723.

That ſome confuſion may have ariſen from giving the ſame name to theſe heterogeneous things, cannot be queſtioned. However Mr. Locke is in this reſpect no more guilty than Malebranche and the Carteſians, who uſe the term *Idea* in the ſame extenſive ſenſe with him, and from whom indeed he ſeems to have taken it. But then the Carteſians ſeem to have been more ſollicitous to diſtinguiſh between the *Ideas* of the imagination, and thoſe of the intellect, underſtanding, or *de l'eſprit pur*, as they ſometimes expreſs themſelves, and have thereby guarded againſt the inconveniencies ariſing from the too general ſignification of the term *Idea*. See the article NOTION.

The origin of our *Ideas* and notions is a perplexed queſtion, and not at all cleared up by the labours of metaphyſicians. As to *Ideas* of ſenſe, ſome philoſophers have pretended that bodies acting or preſſing upon our nerves, or putting the animal ſpirits in motion produce ſenſations: But as the motion communicated to the nerves or ſpirits has nothing in common either with the thing or body moving, or with the *Idea* excited in the mind, and that we do not conceive the leaſt relation between the motion of the nerve or ſpirits and the production of an *Idea*, to ſay that the motion of, or impreſſion upon the nerves or animal ſpirits, is the cauſe of *Ideas*, is explaining nothing at all. The

The ſpecies emitted by objects, and the formation of *Ideas* by the ſoul itſelf, mentioned in the Cyclopœdia, are not more clear. As to innate *Ideas*, it is true indeed, that the arguments of thoſe who maintain them, have been refuted by Locke; but when he goes farther, and denies innate *Ideas*, his arguments are not concluſive. An opinion may be true, tho' ill defended.

Upon the whole, the queſtion about innate *Ideas*, is as much undecided as ever. Nor has any one difficulty or obſcurity attending this ſubject, been cleared up.

The opinion of Leibnitz concerning the origin of *Ideas*, ſeems to have ſome affinity with innate *Ideas*. He aſſerts the ſoul to be ſimple, and without parts or compoſition; hence he concludes, that no created thing can act internally upon it, but that all the changes it undergoes, depend upon ſome internal principle.

God has formed every ſoul, ſo as to have different perceptions; ſome diſtinct, many confuſed; and a great number ſo obſcure, as hardly to be perceived. All theſe *Ideas* together, repreſent the univerſe; underſtanding by this term, every thing that has been, is, or ſhall be. According to the different relations that each particular ſoul has with the univerſe, ſome of its *Ideas* are diſtinct, and diſtinctly repreſent a certain part of the univerſe. The foundation of this opinion is, that as each part of the univerſe diſtinctly repreſented, has a neceſſary relation with every thing that exiſts, with every thing that has been, or ſhall be, all things being connected, ſo that the one is the conſequence of another; in like manner, the repreſentation of a certain part of the univerſe, has a neceſſary and inſeparable relation to the repreſentation of the whole.

From whence it follows, that all diſtinct perceptions of the ſoul being connected with the *Ideas* of all other things, theſe muſt likewiſe be in the ſoul, tho' obſcurely. In this ſenſe Mr. Leibnitz aſſerted, that the ſoul is the mirror of the univerſe.

Now all things that happen in the univerſe, ſucceed each other according to certain laws: In like manner in the ſoul, *Ideas* become ſucceſſively diſtinct according to other laws; which, though they have a relation to the former, are yet conſiſtent with the nature of intelligence.

All human ſouls have the ſame *Ideas*, taking the *Ideas* of each individual collectively. But diſtinct *Ideas* are not the ſame in each; theſe depending upon the relation which each ſoul has to the univerſe; and this relation is different, according to the ſtation which God has pleaſed to aſſign to each.

This ſeems a fair repreſentation of Mr. Leibnitz's ſyſtem, relating to the origin of *Ideas*; upon which we may remark, that the foundation of this ſyſtem, is, that all the parts of the univerſe, have a neceſſary connexion: But to make juſt concluſions from this propoſition, the connexion muſt be ſuch, that things being conſidered in themſelves, no one thing can be ſuppoſed, without all others being ſo neceſſary a conſequence thereof, that the *Idea* of another univerſe, in which there ſhould be any thing belonging to our actual univerſe, muſt be contradictory.

If ſuch a connexion took place, what is ſuppoſed concerning obſcure *Ideas*, would be true in a certain ſenſe; to wit, that it might be ſaid, that a man who has a diſtinct *Idea* of a triangle, has thereby obſcure *Ideas* of all the properties of this figure, becauſe of the neceſſary connexion between theſe laſt *Ideas* and the former.

But no ſuch connexion between *Ideas* ſucceeding each other in the ſoul is perceivable. For if paſſing from a dark place to one that is enlightened, I thereby ſuddenly acquire the *Ideas* of ſeveral objects, never before ſeen, it does not appear that the previous perception of darkneſs muſt neceſſarily lead me to theſe new *Ideas*.

Theſe and other difficulties may be urged againſt Mr. Leibnitz's ſyſtem; nor is Mallebranche's more fortunate. This philoſopher ſuppoſes there can be no cauſe of an *Idea*, but this *Idea* itſelf in another intelligent being; and from hence he concludes, that we acquire our *Ideas* while our ſoul perceives them in God.

To prove his opinion, he enumerates all the ways in which the origin of *Ideas* is explicable; and concludes after having refuted all others, that his own is the only true one. But his reaſoning labours under two defects. Firſt, who can pretend, in a ſubject ſo obſcure, to enumerate all the poſſible ways of the ſoul's acquiring its *Ideas*. He did not know Leibnitz's opinion, very different from that of the Carteſians; and other ſolutions might perhaps be found out. Secondly, the falſity of other opinions is not ſufficiently demonſtrated. So that upon the whole, nothing is yet clear about the origin of *Ideas*.

The conſideration of the memory does not a little encreaſe the difficulties concerning our *Ideas*. Many *Ideas* not preſent may be recalled to mind. Theſe *Ideas* are certainly ſome how differently related to the ſoul, than thoſe it never did perceive, or thoſe which it cannot recollect. But what is an *Idea* in the ſoul, which the ſoul does not perceive? Yet ſuch there are. If to explain this we recur to the conſtitution of the brain, new difficulties ariſe. What memory can ſpirits ſeparated from bodies have? if no memory, what intelligence? See *s'Graveſande* Introduct. à la Philoſophie, p. 134.

As to Mallebranche's notion, ſee alſo *Locke*'s poſthumous works, where this opinion is particularly examined; and *Berkeley*'s Dialogues, 2d. Edit. p. 257, 258, &c.

IDEOT. See the article LUNATIC.

IDOL *(Cycl.)* in antiquity, the *Idol* or image, whatever materials it conſiſted of, was by certain ceremonies, called conſecration, converted into a god. While under the artificer's hands, it was only a mere ſtatue.

Three things were neceſſary in order to turn it into a god; proper ornaments, conſecration, and oration. The ornaments were various, and wholly deſigned to blind the eyes of the ignorant and ſtupid multitude, who are chiefly taken with ſhow and pageantry. Then followed the conſecration and oration, which were performed with great ſolemnity among the Romans. *Pitiſc.* Lex. Ant. in voc.

IDOLOPŒIA, Εἰδωλοποιΐα, in rhetoric, a ſpecies of Proſopopœia, where dead perſons are ſuppoſed to ſpeak. *Voſſ.* Rhet. l. 5. p. 358. See the article PROSOPOPOEIA, *Cycl.*

IDOLOTHYTA, Εἰδωλοθυτα, things offered in ſacrifice to idols; concerning the uſe of which, the apoſtle Paul lays down rules in 1 Corinth. c. viii. v. 4, 7 and 10. *Hofm.* Lex. in voc.

IDULIA, in antiquity, certain eggs offered to Jupiter on the ides of every month. They were ſo called, from their being offered on the ides.

IDYLLION *(Cycl.)*—According to Mr. Fraguier, the uncertain and indeterminate meaning of *Idyllion*, as well as of eclogue, is owing to this, that neither of theſe words, originally and of themſelves, ſignify what they are uſed for. The word *Idyllion*, tho' generally uſed for a paſtoral poem, is notwithſtanding leſs appropriated to ſuch a compoſition, than the word *Eclogue*; for, as the ſame author obſerves, Pindar's odes had the title of Εἶδος, of which Εἰδυλλιον, *Idyllion*, is only a diminutive; and properly ſignifies a work of moderate extent, without conſidering the ſubject. However, Theocritus's paſtoral poems, to which he gave originally the title of *Bucolics*, being afterwards collected into one body with his other poems, which were called Εἰδυλλια, *Idyllia*, the antient grammarians, who are noted for having made great changes in the titles of books, gave the common titles of *Idyllia* to the whole collection. And as the bucolics or paſtoral poems were by far the fineſt pieces of the collection, and as the whole works of that poet are now only known by the name of *Idyllia*; common uſe ſeems to have appropriated this word to bucolics or paſtoral poems, tho' in a leſs degree than eclogue, which is entirely reſtrained to this acceptation: Thus, only the ten bucolics of Theocritus can be called eclogues; tho' the term *Idyllia* may with equal propriety be given to his other pieces. Mem. Acad. Inſcrip. T. 2. p. 159. ſeq. See the article ECLOGUE, *Cycl.*

The modern *Idyllions* differ from thoſe of the antients, by introducing none but allegorical ſhepherds or courtiers diſguiſed in their dreſs; whereas thoſe of the antients repreſent true ſhepherds. Mr. Hardion obſerves, that the taſte of the preſent age is ſo very different from that of the antients in this reſpect, that he would not take upon him to give a literal tranſlation of Theocritus's *Idyllions*; not that he reckons them bad in themſelves, nor that he condemns the rules followed in their compoſition; but becauſe the rules that were good at the time thoſe poems were written, would, in the preſent age, be reliſhed but by very few.

There is a great variety of characters obſervable among the ſhepherds, in the antient *Idyllions*; the reaſon of which is, that there were four kinds of ſhepherds, differing from one another, in manners, opinions, and in language. The firſt and chief of theſe was the *Bucoli*, Βουκολοι, herdſmen; whoſe buſineſs it was to feed and bring up cattle. We muſt not ſuppoſe that theſe were ſtupid and groſs clowns, void of all politeneſs and underſtanding. On the contrary, they were all rich and well educated, and were the principal perſons in the villages and countries where they lived. The ſecond kind of ſhepherds, who came very near the former, were called *Poimenes*, Ποιμενες, ſhepherds properly ſo called, or feeders of ſheep. Theſe are, by Theocritus, no-wiſe diſtinguiſhed from the *Bucoli*, as to politeneſs; but both are introduced diverting themſelves with paſtoral ſongs, much of the ſame taſte. The third kind was the Αιπολοι, who were employed in feeding goats; theſe were in all reſpects much inferior to the former two. The fourth and laſt kind was the mercenary ſhepherds, who had no herds or flocks of their own, but were hired by others. The actors in the fourth *Idyllion* of Theocritus are of this laſt kind. And it muſt be obſerved to the honour of that poet, that he never fails, in every *Idyllion*, to inform his readers of the quality and condition of the ſhepherds he introduces on the ſcene. A rule, the importance of which in dramatic poetry no body can be ignorant of. Mem. Acad. Inſcrip. T. 6. p. 251. ſeq. See the articles BUCOLI, POIMENES, &c.

The ſubject of *Idyllions*, as being low of itſelf, requires the greateſt elegance of diction to ſet it off. Mr. Hardion is of opinion, that Theocritus has the advantage of Virgil in this reſpect; obſerving always the ſtructure peculiar to paſtoral poems, which conſtitutes one of its chief beauties. This ſtructure requires that the fourth foot of every verſe ſhould

be a dactylus, and ſometimes alſo the firſt, when it can be done without affectation. Beſides 'tis alſo neceſſary theſe dactyli ſhould be made without any cæſura following; and if poſſible there ſhould be a reſt in the ſenſe after each dactyle, which would add greatly to the regularity and perfection of the verſe. Such are the following verſes of Theocritus and Virgil:

Ειπέ μοι, ὦ Κορυδῶν, τινος αἱ βοες; ἢ ῥα Φιλωνδα; *Theoc.* Idyl. 4. v. 1.
Dic mihi, Damœta, cujum pecus? An Melibœi? Virg. Ecl. 3. v. 1.

This ſtructure in paſtoral poems gives a vivacity, which is wonderfully pleaſing in the mouth of a ſhepherd. Theſe rules are obſerved by Theocritus, with all the exactneſs poſſible; but by Virgil ſeldom; which is rather to be imputed to the genius of the Latin tongue, than his want of ability; it being leſs copious, bold and pliant, than the Greek. Mem. Acad. Inſcrip. T. 6. p. 255, 256.

The invention of the *Idyllion* is aſcribed to Daphnis, who by his extraordinary genius, ſays Diodorus Siculus, "invented "the bucolic poem and ſong, in the form it continues to ap- "pear in at preſent, in Sicily [a]". This paſſage is conſiderable, as it fully aſcertains the origin of the *Idyllion*, ſuch as it appears in Theocritus, and thoſe that have imitated him. A fate that paſtoral poetry in general cannot pretend to; for tho' much pains has been taken to diſcover its origin, and ſeveral nations diſpute that honour one with another; yet the reſult of the whole ſerves only to convince us, that ſhepherds have for many ages amuſed themſelves in their leiſure hours with ſinging, without our being able to determine exactly when, or in what country they began to do ſo. After Daphnis, another Sicilian ſhepherd, called *Diomus*, made himſelf famous for his paſtoral poems. Next came Steſichorus, who, according to Ælian, was the firſt that made the misfortunes of Daphnis the ſubject of his ſongs. He lived, as ſome chronologers will have it, in the time of *Phalaris*, about 550 years before the vulgar æra. And laſtly, ſome ages after this Theocritus appeared, who forming himſelf on theſe firſt models, ſo far excelled as to give paſtoral poetry all the perfection it was capable of receiving [b].—[a L. 4. c. 16. b Mem. Acad. Inſcrip. T. 9. p. 101. ſeq.]

JECARINUS *Piſcis*, in ichthyology, a name given by Gaza, and many other writers, to the fiſh more commonly called *Hepatus piſcis*, by ſome *Jecur marinum*. See the article HEPATUS.

JECUR *Marinum*, in ichthyology, is uſed by Hermolaus and ſome other writers in the ſame ſenſe for hepatus. See the article HEPATUS.

JEER (*Cycl.*)—JEER, or JEER-*Rope*, in a ſhip, a piece of a hawſer faſtened to the main-yard and fore-yard (in great ſhips only) cloſe to the ties; it is then reeved through a block, which is ſeized cloſe to the top, and ſo comes down again, and is reeved through another block at the bottom of the maſt cloſe by the deck. There are uſually two of theſe, one on each ſide the ties. Its uſe is to help to hoiſe up the yard, but more eſpecially to ſuccour the ties, and to keep the yards from falling, if they ſhould break.

JEERS, in a ſhip. They ſay a man is brought to the *Jeers*, when going to be puniſhed at the *Jeer-capſtan*. This is done in the following manner: A capſtan bar being thruſt through the hole of the barrel, the offender's arms are extended at full length croſs-wiſe, and ſo tied to the bar; having ſometimes a baſket of bullets, or ſome other like weight, hanging by his neck. In this poſture he continues till he be either brought to confeſs ſome plot or crime, whereof he is ſuſpected; or that he has ſuffered what he is cenſured to undergo, at the diſcretion of the captain.

JENDAYA, in zoology, the name of a Braſilian ſpecies of peroquette. It is of the ſize of a black-bird; its beak and legs are black, and its back, wings, and tail, are of a bluiſh green; the tips of its wings are blackiſh, and its head, neck, and breaſt are of a pale yellow, with an admixture of a deeper yellow in ſome places. *Marggrave*'s Hiſt. Braſil.

JENNY-*Wren*, a name given by the writers on ſong-birds to the wren.

This bird tho' very ſmall is of a very chearful diſpoſition, and has a very agreeable voice, which he throws out with great chearfulneſs and ſprightlineſs, uſually cocking up his tail all the time he is ſinging. The female breeds twice in the year, firſt in the latter end of April, and afterwards in the middle of June. The neſt is uſually placed among cluſters of moſs and ivy, in ſuch a manner, that it is very hard to diſcover it. It is made of dry moſs and leaves put together in a very artificial manner, being cloſed all round except for a ſmall hole left to go in and out at; they lay a great number of eggs, not leſs than eighteen; and it has been often found that they all hatch, except one or two; and thus ſixteen young ones have been found together in one neſt. Theſe are brought up ſo well as to ſhift for themſelves by the end of May; and then another brood is provided for by the middle of the month following. The young ones may be eaſily raiſed: They ſhould for this purpoſe be taken out of the neſt at about fourteen days old, and fed with ſheep's, calf's, or ox's heart cut ſmall, with eggs minced among it. When they are able to peck this meat for themſelves, they may be put into cages; but they muſt ſtill be fed for ſome days, leſt they ſhould neglect themſelves and die of hunger after the greateſt part of the trouble is thus over.

When they are grown up they may be fed with paſte, and will need no more heart. Afterwards it will be a great feaſt to them to give each a ſpider or two once in two or three days; and after they are grown up, they may either be left to ſing their own wild notes which are very agreeable, or if it be deſired that they ſhould whiſtle tunes, they will eaſily be taught it.

JENTLING, in zoology, the name of a river-fiſh caught in the Danube, and moſt of the great rivers in Germany, and called by the Germans *Schead*, *Scheat*, *Jent*, and *Koppen*; and by Geſner *Capito cæruleus*, the blue chub. *Willughby* Hiſt. Piſc. p. 256.

Its figure is broader than the chub, and narrower than the rudd or finſeal; its head is broad and flat, from the noſe to occiput; but from thence to the back it riſes conſiderably. Its mouth is conſiderably large, its tail forked, and its back of a duſky bluiſh black, and its belly and ſides white and ſilvery. Its belly-fins are ſomewhat reddiſh, and the belly itſelf in the larger fiſh becomes yellowiſh. It has no teeth in the jaws, but near the orifice of the ſtomach has two dentated bones. It lives on worms and other ſmall animals, and ſpawns in April. When very fat it will be yellow on the ſides, and is then better taſted, but leſs wholeſome food.

JERFALCON, the Engliſh name of the Gyrfalco, a very fierce bold and large bird, the largeſt of all the falcon kind. *Ray*'s Ornithol. p. 44. See the article GYRFALCO.

JERKIN, a name given by ſome to the male of the Jerfalcon. See the article GYRFALCO.

JERTH, in the materia medica, a name given to a certain kind of moſs, according to Scheffer, growing very plentifully in Lapland, and other cold countries. The root of this is the part uſed in medicine, and the method of giving it is in decoction. They boil a large quantity of it in the whey made of raindeer's milk, and give the patient large draughts of it warm every hour or two; by that means keeping up a good perſpiration, which they increaſe or diminiſh according to the nature of the caſe. The principal diſeaſes to which they are ſubject, are plurifies, and the ſmall-pox; and it is wonderful to find how well they get thro' theſe two dangerous complaints by this regimen alone. And upon the whole, the virtues of ſo much warm and diluting liquor ſeem the principal thing to be depended upon by them; for if they cannot readily get the *Jerth*-root, they ſcruple not to ſupply its place with the ſtalks of angelica, and the medicine ſeems to ſucceed as well this way as the other, both in the ſmall-pox and other caſes. *Scheffer*'s Lapland.

JERUSALEM-*Artichoke*. See the article ARTICHOKE.

JESEN, in zoology, a name given by ſome to the fiſh more uſually called the jentliny; a fiſh common in the Danube, and moſt of the larger rivers of Germany, and called the blue chubb, capito cæruleus, by Aldrovand, Geſner, &c. *Ray*'s Ichthyogr. p. 256. See the article JENTLINY.

JESSE, a large braſs candleſtick, with many ſconces hanging down in the middle of a church or choir. This invention was firſt called *Jeſſe*, from the ſimilitude of the branches to thoſe of the *arbor Jeſſæ*. This uſeful ornament of churches was firſt brought over into this kingdom by Hugh de Flory, abbot of St. Auſtin's in Canterbury, about the year 1100. Chron. Will. Thorn. ap. *Blount*.

JESUITISSÆ, in the Romiſh church, an order of nuns which was ſuppreſſed by pope Urban VIII. See *Hoffm.* Lex. in voc.

JESUS, in ichthyology, a name given by the people of Dantzick to the fiſh called by Geſner the blue chubb, or capito cæruleus. It is called alſo *Jeſe*, *Jeſen*, and *Jeſitz*.

JET, *Gagates*, in natural hiſtory. See the article GAGATES.

JET-*Rings*, annular pieces of jet of large dimenſions, found in many parts of England, and eſteemed Roman antiquities. They are of different kinds; ſome being plain, others wrought, but all of them are greatly too large for rings. The ſmalleſt of them are three inches in diameter; yet the bore is not above an inch and half, which makes them as much too ſmall for the wriſt, as they are too large for the fingers. *Hook*'s Philoſ. Col. p. 90.

IGASUR, in the materia medica, a name given by ſome authors to the *faba ſancti Ignatii*, or ſaint Ignatius's bean. *Ray*'s Dendr. p. 118.

IGNATIUS'*s-Bean*, *faba ſancti Ignatii*, in the materia medica, the fruit of a plant deſcribed by father Camilli, in the Philoſophical Tranſactions, under the name of *Catalongay*, and *Cantara*; and by Pluknet, under that of *Cucurbitifera malabathri foliis ſcandens, cujus nuclei faba ſancti Ignatii nuncupati*. The Spaniards call it *Cathalogon*.

It is a dry and hard fruit, or kernel of a fruit, of the ſize of a large hazel nut; and is much celebrated for its medicinal virtues, being recommended in vertigoes, lethargies, epilepſies, aſthma's, quartan agues, and worms. It is alſo given againſt

againſt diſtemperatures of the ſtomach, and as an alexipharmic. See a farther account of it in *Hill*'s Hiſt. Mat. Med. p. 506, ſeq.

IGNAVUS, in natural hiſtory, a name given to the animal called in Engliſh the *Sloath*, from his ſlow motion. *Grew* Muſ. p. 11. See the article SLOATH.

IGNIARIUS *Lapis*, in natural hiſtory, a name given by ſome to the pyrites, or fire-ſtone, from its yielding a great quantity of ſparks when ſtruck againſt a ſteel. *Boet.* de Boot. de Lap. See the article PYRITES.

IGNIS *Aqua*, *Fire-water*, a name by which Helmont in ſome of his writings calls the alkaheſt, or univerſal diſſolvent, ſo much talked of by him and Paracelſus.

IGNIS *Gehennæ*, in chemiſtry, a name given by Paracelſus to a certain menſtruum, capable of diſſolving all bodies, and remaining itſelf unaltered by them.

Van Helmont ſeems to make this the ſame with the alkaheſt, ſo celebrated in his writings, and ſo ardently ſought after by all the chemiſts ſince his time.

IGNIS *Judicii*. See the articles JUDICIUM *Dei*, and ORDEAL, *Cycl.*

IGNISPICIUM, among the Romans, a ſpecies of divination taken from the fire uſed in ſacrifices. *Pitiſc.* See the article PYROMANCY, *Cycl.*

IGUANA, in zoology, the name of a ſpecies of lizard, very frequent in the Weſt-Indies. It is an amphibious animal, of the lizard ſhape, and in colour partly brown and partly grey, in ſome of the animals; and in others of a beautiful green, variegated with black and white ſpots. From its neck to the extremity of its tail, it has a continued ſeries of flat-pointed and ſerrated ſcales, of a fine green colour. Theſe are largeſt at the neck.

JIYA, in zoology, the name of an American animal of the otter kind, called alſo *Carigueibeiu*. It is an amphibious creature, of the ſize of a middle-ſiz'd dog. Its head is round, and like a cat's; but its noſe is ſomewhat pointed. Its eyes are black; its ears roundiſh, and placed very low as in the otter; and it has a ſort of beard or whiſkers compoſed of a few ſtiff hairs. The feet have all five toes, the inner one being ſmaller than any of the others. The hair is ſoft, not long, and all black, except thoſe on the head, which are brown, and ſome which compoſe a yelloviſh ſpot under the throat. Its note is much like that of a young puppy. It feeds on fiſh, and other animals. *Ray*'s Syn. Quad. p. 189.

ILEX, the *holm-oak*, in the Linnæan ſyſtem of botany, the name of a genus of trees, the characters of which are theſe: The calyx is a ſmall perianthium, divided into four ſegments, and remaining after the flower is fallen. The flower is compoſed of one petal, divided into four roundiſh hollow open ſegments, cohering only at their bottoms. The ſtamina are four tapering filaments, ſhorter than the flower; the antheræ are ſmall; the germen of the piſtillum is roundiſh; there is no ſtyle, but only four obtuſe ſtigmata. The fruit is a roundiſh berry, containing four cells; the ſeeds are placed one in each cell, and are very hard, oblong and obtuſe, and gibbous on one ſide and angular on the other. See Tab. 1. of Botany, Claſſ. 19. and *Linnæi* Gen. Plant. p. 54.

The characters of this genus, according to Mr. Tournefort, are theſe: The flower is of the amentaceous kind, and is compoſed of a great number of ſtamina, ariſing from a hollow or funnel-faſhioned cup affixed by a ſlender capillament. The embryo fruit appear in other parts of the tree, and finally become acorns ſurrounded by their proper cups, and containing a kernel which eaſily ſeparates into two parts. To this it is to be added, that the leaves are uſually denticulated, but not ſinuated in the manner of the common oak. *Tourn.* Inſt. p. 583.

The ſpecies of *Ilex*, enumerated by Mr. Tournefort, are theſe.

1. The *Ilex*, with oblong ſerrated leaves. 2. The *Ilex*, with long and narrow, not ſerrated leaves. 3. The *Ilex*, with roundiſh ſoft and moderately ſinuated leaves, called the *ſmilax* by many of the old authors. 4. The holly-leav'd *Ilex*. 5. The Montpelier *Ilex*, with leaves woolly on both ſides. 6. The prickly *Ilex*, on which the kermes are found, called *Ilex cocciglandifera*.

There are ſeveral ſpecies of this tree propagated for gardens. They are to be raiſed by ſowing the acorns in March; in order to which they ſhould be gathered in Auguſt as ſoon as ripe, and kept in dry earth or ſand till ſpring. The ground on which they are to be ſown muſt be well dug, and cleans'd from all noxious weeds; then levelled even, and the great clods broken; after this ſeveral rills are to be drawn along it with a hoe of about two inches deep, and from one foot to two diſtant. In theſe the acorns are to be laid two or three inches aſunder, and the ground then drawn over them with a rake. In the middle of April the young plants will appear; but for the firſt year they will make but very little progreſs in ſize, and are to be kept clear of weeds; the year following they will grow very quick, and in the March after their ſowing, the ground between the rows muſt be carefully and lightly dug up, which will greatly facilitate their taking root. In the April after their ſowing, the plants which ſtand too cloſe muſt be taken up, and tranſplanted to the places where they are to ſtand. There is much care to be taken in the tranſplanting them, for having a long top-root they are not ſo quick in taking root in a new ground, as thoſe which have more ſtringy ones. They uſually ſucceed better when of four or five years growth, than while ſmaller; but they require a great deal of watering, and when firſt planted ſhould have the earth all about them made ſoft as pap. They do beſt in a loamy ſoil, and are much in eſteem for hedges in wilderneſs quarters. *Miller*'s Gardeners Dict.

ILIVILIHU, in natural hiſtory, a name given by the inhabitants of the Philippine iſlands to a very remarkable ſpecies of bird, common in that country. It is called by ſome writers *Coturnix parvula montana*, the ſmall mountain quail, and it is indeed a quail in all the characters; but it is very beautifully variegated in its colours, and is ſmaller than a ſparrow. It lives in hilly places, and is a very well taſted bird. See the articles COTURNIX, and QUAIL.

ILIUM *Os* (*Cycl.*)—This bone was ſo called by the antients, becauſe it ſupports the parts they called the *Ilia*. It is the largeſt of the three bones of the pelvis. It is flat, very broad, unequally convex, and concave; partly round, and partly of an irregular ſquare figure. It is divided commodiouſly enough into the criſta, baſis, anterior and poſterior edge; and two ſides, one external, the other internal. The criſta is the upper part, and is a pretty thick arched border, the circumference of it is a little more than a quadrant of a circle; the anterior and middle part is convex outward, the poſterior part a little convex inward. Anatomiſts, for the ſake of regularity in their deſcriptions, diſtinguiſh in it two labia and a middle ſpace or interſtice between them. It is originally an epiphyſis, of which we ſometimes ſee plain marks in a very advanced age. The poſterior portion of the criſta, which is convex inward, is much thicker than the anterior; and, for that reaſon, may be called the tuberculum of the criſta. The whole criſta appears to be covered over with a cartilage; but this in reality is no more than the dried tendinous expanſion of the muſcles. The anterior edge of this bone has two eminences or tubercles, called the anterior ſpines, one ſuperior, the other inferior; and likewiſe two notches, one between the ſpines, the other below the inferior ſpine. The poſterior edge is ſhorter and thicker than the anterior; it terminates likewiſe in two eminences or ſpines, between which there is a conſiderable notch. The baſis or inferior part of the bone, is the thickeſt and narroweſt of all; it forms anteriorly a portion of the acetabulum, and poſteriorly almoſt all the iſchiatic ſinus. The outſide is convex on the fore-part, and concave on the back-part; we obſerve on it the remains of a long ſemicircular line, which reaches from the upper anterior ſpine to the great iſchiatic ſinus, being a muſcular mark; and above, and behind this impreſſion, there are ſeveral other muſcular marks. A little above the edge of the acetabulum, we ſee likewiſe many inequalities, which ſurround part of the edge in a ſemicircular form, being a collection of muſcular and ligamentary marks. The inſide of this bone is unequally concave, and has ſeveral inequalities toward the back part. The chief of theſe is that large cartilaginous ſurface of the figure of a great S, or of a bird's head; which anſwers to the lateral ſurface of the os ſacrum, with which it is connected by a cartilaginous ſymphyſis. The other inequalities are much of the ſame kind with thoſe in the lateral part of the os ſacrum, with which they form ſeveral rough and irregular cavities. From the upper part of the cartilaginous ſurface or ſymphyſis, all the way to the oblique eminence runs a prominent line, which bounds the concavity of the inſide of this bone, and diſtinguiſhes the margin of the pelvis from the bottom. *Winſlow*'s Anat. p. 69.

IMAGINARY (*Cycl.*)—IMAGINARY *Quantity*, in algebra See the article ROOT.

IMAGINIFER, among the Romans, an enſign-bearer, who carried the ſtandard on which was repreſented the image of the reigning emperor. *Danet* in voc. See the article SIGNA.

IMAMIA, a name given to that ſect of the Mahometans, to which the Perſians adhere. *Hoſm.* Lex. in voc. See the article IMAM, *Cycl.*

IMBANKING. See the article BANKING.

IMBLOCATION, in middle age writers, a particular method of diſpoſing of the dead bodies of excommunicated perſons, by raiſing over them a heap of ſtones, or earth. This was done in the fields, or near high-ways; it being unlawful to bury them in holy ground, or even inter them at all. See the article BURIAL.

The word is derived from *bloc*, tumulus. Vid. *Du Cange*, Gloſſ. Lat. T. 3. p. 22. voc. *imblocatus*.

IMBRICATED-*Leaves*, *imbricata folia*, among botaniſts. See the article LEAF.

IMBRICATED *Shell*, *imbricata concha*, in natural hiſtory, a term uſed in general to expreſs any ſpecies of ſhell-fiſh, whoſe ſhells are elevated into tranſverſe ridges, lying over one another

ther at the base, in the manner of the tiles on a house-top. It has also been used as the name of a peculiar species of shell: This is a *cordiformis* or heart-shell, whose sides are remarkably ridg'd in this transverse manner, and at the same time so divided longitudinally by seven high ribs running from the apex to the edge, that the whole represents a roof of a house with the beams and rastors, before covered by the tiling. Hence the French call it *Faitiere*.

IMBRICATED-*Cup*, *Imbricatus calyx*, in botany, a term used by authors to express the cups of some of the plants which have compound flowers; in which the common perianthium, surrounding the whole cluster of flowers, is composed of several series of squammæ, the exterior of which are short, and the interior longer, but in great part hid under these upper ones.

IMITATION *of antient Gems*. See the article GEM.

IMMERSUS *Scapulæ*, in anatomy, a name given by Riolanus and some other authors, to a muscle since called the *subscapularis*. See the article SUBSCAPULARIS.

IMMOBILITY *of infants*. See the article INFANT.

IMPARSONEE, in law, is applied to a parson that is inducted, and in possession of a benefice. *Blount*.

IMPECCABILES, in church history, a name given to those heretics, who boasted that they were *impeccable*, and that there was no need of repentance: Such were the Gnostics, Priscillianists, &c. *Hofm.* Lex. in voc.

IMPERATOR, among the Romans, a title of honour given to generals after a victory; first by the acclamations of the soldiers, and afterwards confirmed by the senate. *Hofm.* Lex. in voc. See the article ACCLAMATION.

IMPERATORIA, in botany, the name of a genus of plants, the characters of which are these. The flowers stand in umbels, and are of the rosaceous kind, being composed of several petals, in some bifid at the ends, and in others whole. These petals are disposed in a circular order on a cup, which afterwards becomes a fruit, composed of two flattish and oval seeds, lightly striated and marginated, and usually casting off their coats. To this it may be added, that the leaves are large and alated.

The species of *Imperatoria* enumerated by Mr. Tournefort, are these: 1. The common large *Imperatoria*. 2. The greatest alpine *Imperatoria*. 3. The common cultivated *Imperatoria*, called garden angelica. 4. The great *Imperatoria*, called arch-angelica. 5. The greater marsh *Imperatoria*, commonly called the great wild angelica. 6. The Canada *Imperatoria*, with shining leaves, called the shining Canada angelica. And 7. The fine leav'd Pyrenean *Imperatoria*. *Tourn.* Inst. p. 316.

IMPERATORIÆ *radix*, in the materia medica, the root of the common masterwort, or *Imperatoria major*; a plant kept in gardens with us, but very commonly wild in France, Italy, and Germany. The leaves are large, indented, and of a fine green; and the flowers small and white, and disposed in umbels, which are succeeded by seeds, much resembling those of angelica. The root should be chosen very fair and clean, fresh dried, hard to break; of a brown colour without, and a somewhat greenish one within; and of a strong smell, and aromatic taste. It is usually long, and of the thickness of one's thumb, wrinkled on the surface, and entangled with fibres. It is esteemed cordiac, sudorific and alexipharmic, good against pestilential and malignant diseases, and against poisons. A decoction of it in wine, used as a gargle, is said to cure the tooch-ach; and externally it is much commended for the itch, and other scabs and ulcers. It is also an ingredient in some of the officinal compositions. *Pomet*'s Hist. of Drugs, p. 44.

This root is likewise good in flatulences; and if *Hoffman*'s authority may be depended on, it is one of the greatest medicines in the world in colics arising from windy causes. The seeds are reckoned by many among the provocatives, and are said by some, to be of the very first class of those medicines. The roots dried, and given in powder, are a powerful remedy in obstructions of the menses; and are of great service in asthmatic cases, tooth-ach, and in many disorders in the head. Simon Pauli tells us, that an ointment made of the fresh roots of this plant boiled in lard, is one of the best remedies known for ring-worms.

IMPERATRIX, in botany, a name given by some authors to the meum or spignel. *Ger.* Emac. Ind. See the article MEUM.

IMPERFECT *(Cycl.)*—IMPERFECT *concord*, in music. See the article CONCORD.

IMPERFORATE *Anus*. See the articles ANUS and INFANT.

IMPERIAL *(Cycl.)*—IMPERIAL *table*, in surveying, an instrument made of brass, with a box and needle, staff, &c. used in measuring land.

IMPERIAL *Salt*, *imperiale sal*, a term used by some of the old writers to express the common sal gemmæ; and used by others for the *sal ammoniacum*.

IMPOSSIBLE *(Cycl.)*—IMPOSSIBLE *quantity*, in algebra. See the article ROOT.

IMPOSTHUME, or ABSCESS. See the article ABSCESS.

In opening of *Abscesses*, and discharging their matter, the first great caution is, that it be not done too soon, that is, before the matter is arrived at a perfect maturity. *Abscesses* are known to be mature and ripe, when the swelling that was before hard and firm, feels soft and pliant, turns pale, or of a yellowish colour, and upon applying the finger, a fluid may be perceived to be lodged within; and when the pain, redness, heat, and pulsation of the swelling are gone off, either wholly or in part, and the sensation of a weight or heaviness siezes the part, instead of the former symptoms.

When these signs appear, the *Abscess* is to be opened in the most prominent, or the most depending part, without delay. For the opening a tumor too soon, is of bad consequence, yet delaying to open it when really ripe, is always of much worse; for when the matter is detained longer than it should be, especially in a large suppuration, and on a nervous part, the corrupted matter may corrode the adjacent parts, and produce fistulæ, or a caries of the bones; or by insinuating itself into the small vessels, and corrupting such parts of the blood as it mixes with, it may excite ill-conditioned fevers; or lastly, by disturbing the functions of the brains, lungs, liver, or kidneys, it may bring on inflammations and suppurations in those parts, and lastly death itself. Sometimes it happens in *Abscesses*, that the more fine and subtile part of the matter perspires, and only the grosser particles are left behind; and this gives rise to hard tumors, especially in the glandular parts. Since these therefore are the consequences if *Abscesses* are not timely opened, the great care is to make use of the first proper opportunity of opening the maturated tumor, either by the knife or caustic. If by incision, the surgeon is to grasp the basis of the tumor with one hand, pressing the contained matter outward towards the skin, that he may avoid hurting any vessels or nerves in the subjacent parts; he is then to make the incision by the sharp scalpel, in the softest and most depending part of the tumor, that the matter may have the freer exit. When the *Abscess* is large, the scalpel is not to be taken out as soon as the opening is made, but the incision in the skin is to be farther enlarged with it, but with great caution, to avoid the nerves and larger vessels, with the muscles of the subjacent parts.

The *Abscess* being thus opened, the putrid matter is to be let out; and when it is glutinous and thick, must be gently press'd forth with the hands. If the quantity of matter contained however be very large, and the patient tremble at the thoughts of the knife, or faints away, which is sometimes the case, the best way is then to discharge the matter only in part, and fill up the cavity with lint; and after the patient has been recovered by some cordial, to compleat the dressing with a plaster, compress, and bandage, leaving the perfect discharge and cleansing of it to the next dressing. When the whole of the matter is discharg'd, the wound is to be cleansed, and afterwards sarcotic medicines applied till it is incarned, and then it will cicatrize and close externally. Hard tents are on these occasions very carefully to be avoided, as they often produce very troublesome ulcers; soft dossils of lint are much better for use; the cavity should be lightly filled with these, and they may be taken out once or twice a day, as the discharge shall require. If the patient be of a tender frame, and cannot bear the knife, the *Abscess* may be opened by a caustic: Among these the most valuable are those made of pot-ashes and lime, or of soap-boilers lees. This is to be applied to the *Abscess*, either whole or in powder; but a defensative plaster must first be applied to the *Abscess*, perforated with an oblong narrow hole, that the caustic may not spread itself upon the skin, but only make an opening of a proper size, and in a proper place. Over the caustic is to be applied a compress of lint or linnen, and over that a plaster with a still larger compress of linnen over it; and the whole must be kept firm by a proper bandage.

Things being thus managed, the patient is to be advised to rest; and the caustic must be suffered to lie on three, four, five, or sometimes six hours, in proportion to the thickness of the skin on the part, and the strength of the medicine. When this is taken off, if the opening be not large enough, it may be easily enlarged a little with the scalpel, or even with a probe, without pain to the patient, and all the matter may have a free passage. As soon as the eschar is formed by the caustic, it must be softened by applying fresh butter, or the common digestive ointment or basilicon, retaining these on by a plaster and proper bandage; and when this is loose or separated, the cure of the wound is to be carried on exactly as in the *Abscesses* opened by the knife. The knife however is always greatly preferable to the caustic, as it is neater, more safe, and more expeditious; and the aperture made by it heals much more evenly, and with a smaller cicatrix than that made by a caustic. *Heister*'s Surgery, p. 183.

Bartholine, in his observations, gives us a very remarkable account of the termination of a pleurisy by an *Abscess* situated in the thigh, which when the matter was perfectly formed, discharged itself by urine.

In *Abscesses in ano*, Mr. Faget advises to slit open the intestinum rectum, whenever it is laid bare by an *Abscess*; and gives an example of a cure he made, by cutting away the extremity of this gut, which had been laid bare all round by *Abscesses*. See Mem. de L'Acad. de Chirurg. Tom. I.

Mr,

Mr. Queſnay encourages ſurgeons to open *Abſceſſes*, when they form in the brain; and even to puſh a lancet into the brain, when the ſymptoms indicate a ſuppuration, tho' the pus be neither felt nor ſeen. Mem. de L'Acad. de Chirurg. Tom. I.

IMPOTENCE, or IMPOTENCY *(Cycl.)*—We have inſtances of unfitneſs for generation in men, by an impediment to the ejection of the ſemen in coition from a wrong direction, which the orifices at the verumontanum got, whereby the ſeed was thrown up into the bladder. Mr. Petit cured one patient under ſuch a difficulty of emiſſion, by making an inciſion like to that commonly made in the great operation for the ſtone. See Mem. de L'Acad. de Chirurg. Tom. I.

Impotence may be cauſed by various accidents, but moſt frequently takes its riſe from early and immoderate venery; and often from the venereal diſeaſe. See the article VENEREAL *Diſeaſe*.

IMPRACTICABLE *Caſe*, in algebra. See the article IRREDUCIBLE.

IMPREST, in the ſea language. See the article MANNING *the fleet*.

IMPURE, in the *Moſaic* law. There were ſeveral ſorts of *Impurity* contracted under the law of *Moſes*. Some were voluntary, as the touching of a dead body [a], or of any animal that died of itſelf, or of any creeping things, or unlean creature [b]; or the touching things holy by one who was not clean, or was not a prieſt; or the touching one who had a leproſy, one who had a gonorrhœa, or was polluted by a dead carcaſs; a woman who had lately lain in [c], or was in the condition which her ſex is every month liable to [d], or was incommoded with an extraordinary iſſue of blood. Other kinds of *Impurity* there were, of an involuntary nature; for which we muſt refer the reader to Calmet, who ſhews what kind of purification was preſcribed for each ſpecies of pollution [e]. —[Vid. [a] Numb. xix. 11, 14. [b] Levit. xi. 24, 43. [c] Levit. xii. 23, 45. [d] Id. xv. 25. [e] *Calm.* Dict. Bibl. in voc.]

IN, in the manege,—*To put a horſe* IN, is an expreſſion that ſignifies to breed and dreſs him, by putting him right upon the hand and the heels.

IN-*Penny and Out-penny*, in our old writers, money paid by the cuſtom of ſome manors on the alienation of tenants, &c.— In-penny and out-penny *conſuetudo talis eſt in villa de* Eaſt Radham, *de omnibus terris quæ infra Burgagium tenentur, viz. quod ipſe, qui vendiderit vel dederit dictam tenuram alicui, dabit pro exitu ſuo de eadem tenura unum denarium, & ſimile de ingreſſu alterius; et ſi prædicti denarij a retro fuerint, Ballivus domini diſtringet pro eiſdem denariis in eadem tenura.* Regiſt. Prior. de Cokesford, p. 25. *Blount.*

INACHIA, Ἰναχία, in antiquity, a feſtival in Crete, celebrated in honour of Leucothea, or Ino.

The word is compounded of Ino, and ἄχος, *i. e.* Grief; being perhaps a commemoration of Ino's misfortunes. *Pott.* Archæol. Græc. l. 2. c. 20.

INAJA *Guacuiba*, in botany, a name by which ſome authors have called the cocoa-nut tree, or *palma indica nucifera* of other writers. *Marggrave*, p. 138.

INAMBLUCIA, in natural hiſtory, the name of a genus of foſſils of the claſs of the ſelenitæ; but of the number of the columnar, not the rhomboidal kinds, and compoſed merely of parallel fibres. See the article SELENITES.

The word is derived from the Greek ἶς, a filament, ἀμβλύς, blunt, and κίων, a column; and expreſſes a body in form of a blunt column, and compoſed of ſeveral filaments.

The ſelenitæ of this genus conſiſt of ſix equal ſides or planes, and have much of the appearance of ſprigs of rock-cryſtal in their external form, but are not compoſed of flat tables or flakes, but of a number of long parallel filaments, extended thro' the whole length of the body, and as aptly reſemble the fibraria, commonly called fibroſe tubes, as the common ſelenitæ do the foliaceous. *Hill*'s Hiſt. of Foſſ. p. 122.

Of this genus there are only two known ſpecies. The firſt compoſed of very fine thin and ſlender filaments; this is found in the clay-pits of Northamptonſhire, but is not common there. The other is compoſed of thick coarſe and whitiſh filaments; and is found in the ſtrata of clay, in the cliffs of Sheppey iſland. Id. ibid. p. 142, 143.

INANITY, the ſchool-term for emptineſs or abſolute vacuity, and implies the abſence of all body and matter whatſoever, ſo that nothing remains but bare ſpace.

INARCHING, in gardening, a particular ſort of grafting, called alſo by ſome grafting by approach. It is uſed when the ſtock intended to be grafted on, and the tree from which the graft is to be taken, ſtand ſo near one another, that they may be brought to touch. The branch to be *inarched* is to be fitted to that part of the ſtock where it is to be joined, the rind and wood are to be pared away on one ſide for the length of three inches, and the ſtock or branch where the graft is to be united is to be ſerved in the ſame manner, ſo that the two may join equally together, and the ſap meet; a little tongue is then to be cut upwards in the graft, and a notch made in the ſtock to admit it, ſo that when they are joined, the tongue will prevent their ſlipping, and the graft will more cloſely unite to the ſtock. Having thus brought them exactly together, they muſt be tied with ſome boſs or worſted, or other ſoft tying, and then the place muſt be covered with ſome grafting clay, to prevent the air from drying the wound, and the wet from rotting the ſtock; a ſtake muſt be fixed in the ground, to which both the ſtock and the graft muſt be tied, to prevent the winds diſplacing them. When they have remained in this ſtate four months, they will be ſufficiently united, and the graft may then be cut off from the mother tree, obſerving to ſlope it cloſe to the ſtock, and at this time there ſhould be freſh clay laid all round the part. This operation ſhould be performed in April or May, that the graft may be perfectly united to the ſtock, before the enſuing winter. It is principally practiſed upon oranges, myrtles, jeſamines, walnuts, and firs, and ſome other trees, which do not ſucceed well in the common way of grafting. But it is a wrong practice when orange-trees are deſigned to grow large, for theſe are ſeldom long liv'd after the operation. *Miller*'s Gardeners Dict. See the article GRAFTING.

INCALESCENT *Mercury*, a name given by Mr. Boyle to ſome mercuries of an uncommon preparation; which, by being mingled with a due proportion of gold leaves, or ſmall filings, would amalgamate and grow hot with the gold.

INCERATION, among apothecaries, the mixing of liquids with ſomething that is dry, by a gentle ſoaking, till the compoſition be brought to a ſubſtance of the conſiſtence of ſoft wax. *Caſt.* Lex. Med. in voc.

INCIDENT *(Cycl.)*—*Incident*, in law, is a thing appertaining to, or following another, that is more worthy or principal. A court-baron is inſeparably *incident* to a manor; and a court of pie-powders to a fair. Kitch. 36. 1 Inſt. 151.

INCIDENTS, or ATTENUANTS, in the materia medica. Theſe medicines are of the utmoſt importance in the practice of phyſic, as a little reflection upon their natures, qualities, and manners of operation, will eaſily convince us. To this claſs belong the roots of arum, aſarabacca, acorus, elecampane, and florentine orris; the leaves of brook-lime, ſcurvy-graſs, water-creſs, Indian creſſes, dittander, fumitory, marſh-trefoil, ſmall centaury; all the ſpecies of garlick, onion, and leek, and the wood and bark of guaiacum; among the ſpices, pepper, and ginger; among the ſeeds, thoſe of muſtard, ſcurvy-graſs, and creſſes; among the gums, galbanum, ammoniacum, myrrh, and benjamin. Among the chemical preparations, the moſt powerful *Attenuants* are calomel, æthiops, flower of brimſtone, the fix'd alcaline ſalts, the ſalts of the purging waters, vitriolated tartar, regenerated tartar, and a ſolution of crabs eyes, nitre, and ſal armoniac; the volatile ſalt and urinous ſpirit of ſal armoniac alſo; to which may be added oxymel of ſquills, and the acrid tincture of antimony. Medicated ſprings alſo belong to this claſs of medicines, becauſe they, beſide their diluting and aperient natures, are alſo highly *attenuating*. Infuſions in form of tea, from the quantity of warm water they conſiſt of, are alſo very efficacious *Attenuants*, and are very powerful in the diſuniting coaleſcent molecules. Of this claſs alſo are ſweet whey, and a multitude of other leſs us'd and leſs powerful medicines.

Of theſe, ſome act upon the fluid, and others upon the ſolid parts of the human body. Thoſe which act upon the fluids, by mere contact, are very few in number, being only the watery diluents, which are of ſingular efficacy in colliquating the viſcid and glutinous humours. The alcaline, fix'd, volatile, and nitrous ſalts, if mixed with the inſpiſſated blood and humours, eſpecially if in a liquid form, colliquate and *attenuate* them in ſo powerful a manner, as to be perceptible even to the naked eye. All the other medicines mentioned as *Attenuants* act only on the ſolids, by encreaſing their tone, augmenting their ſtrength, heightening their contractile force, and adding to the elaſticity and ſyſtolic motion of the veſſels; by which means they preſs and impel more vigorouſly their contain'd fluids, and by that means divide and break them, by driving them forcibly thro' ſmall paſſages. *Hoffman.* Oper. Vol. I. ſect. 2. c. 4.

Among the *attenuating* medicines which act upon the ſolids, ſome produce their effects by means of a conſiderable fix'd and acrid ſalt; ſuch are the roots of arum, aſarabacca, as alſo lepidium, pepper, and ginger; all which, tho' of a pungent taſte, yet neither yield an acrid volatil oil, nor a water of an acrid taſte, when diſtilled with water, which ſufficiently proves their fix'd nature. Others, which act upon the ſolids, produce their effects by means of an acrid volatile ſalt, ſuch are the creſſes, ſcurvy-graſs, muſtard, and the like. Some alſo act by means of a neutral ſalt, which is very ſtimulating. Of which kind are thoſe neutral ſalts whoſe acrimony and irritating quality are not only diſcovered by the taſte, but alſo by their proving purging, or diuretic, when given in large doſes. Others operate by means of an acrid ſalt impregnated with a large quantity of ſulphureous particles, which is evidently the caſe with gum ammoniacum and the reſt; as alſo guaiacum and its reſin, which beſide their acrid ſalt, contain alſo an oil which they yield in great plenty by diſtillation with water. And finally, ſome *Attenuants* act by means of a ſubtle penetrating metallic ſalt; ſuch is mercury in its ſeveral forms.

Attenuating and *inciding* medicines are of very extenſive uſe in phyſic, and come under different denominations, according to the different effects they produce. Thus, when tenacious and viſcid juices not only ſtagnate on the cavities of

the veſſels, but obſtruct the minute ducts of the viſcera and emunctories, theſe medicines by their *inciding* and *attenuating* quality diſcharge the humors, and remove the obſtructions; for which reaſon they are not improperly called *aperients*; and they deſerve alſo, in theſe caſes, the names of antiſcorbutics, and ſweetners of the blood: For ſince the purity and proper temperament of the vital juices depend upon the due ſecretion and excretion of every thing ſuperfluous and recrementitious in the conſtitution; and ſince the neceſſary degrees of ſecretion and excretion are intercepted, by the minute glands of the emunctories being blocked up by thick and viſcid juices, 'tis therefore obvious that ſuch medicines as *attenuate* the inſpiſſated humors, and remove the obſtructions, muſt be ſweetners of the blood, and excellent remedies againſt the ſcurvy; in which the humors have evidently loſt their due temperament, and are become impregnated with heterogeneous, viſcid, ſaline, ſulphureous, and acrid particles. *Hoffman.* Oper. Vol. 1. Sect. 2. c. 4.

Attenuants produce ſo great a variety of effects, that 'tis proper we ſhould be well acquainted with their ſeveral kinds as appropriated to the ſeveral diſorders, and know which will prove moſt ſerviceable in each. The diſſolving and attenuating viſcid crudities in the ſtomach and primæ viæ, is well anſwered by the roots of arum, acorus, pepper, ginger, and the like; as alſo by ſal armoniac, vitriolated tartar, the fixed alcaline ſalts, and the ſimple or dulcifyed ſpirit of ſalt. When crude and unconcocted humours are to be evacuated by ſtool, this intention is very well anſwered by the neutral ſalts, as the ſalts of the purging waters, and the ſal polycreſtum, with a ſufficient quantity of a watery vehicle.

When viſcid humors occaſioning diſorders of the breaſt, are to be *attenuated* and expectorated; the intention is moſt effectually anſwered by elecampane and orrice roots; and by gum ammoniacum, myrrh, or benjamin, and balſam of Peru, or by regenerated tartar, oxymel of ſquills, a ſolution of crabs-eyes in diſtilled vinegar, and the ſyrups of tobacco, and the like.

When the maſs of blood is tainted by thick and tenacious ſordes, and the emunctories are by that means obſtructed and the humors contaminated by a ſaline ſulphurous and ſcorbutic dyſcracy, the moſt efficacious of the *Attenuants* are the horſe-radiſh, ſcurvy-graſs, water and garden-creſſes, muſtard, gum-ammoniacum, benjamin, myrrh, the oil of fixed nitre, oil of tartar per deliquium, ſolutions of nitre, ſpirit of ſal armoniac, ſalt of wormwood with lemon-juice, and the ſalts of the medicinal waters.

When grumous or coagulated blood, occaſioned by contuſions or blows, is to be *attenuated*, and again diſſolved, the intention is admirably anſwered by the roots of Solomon's-ſeal, vinegar, and crabs-eyes, the regenerated tartar, and nitre prepared with antimony.

And in caſes where the lymph has acquired a preternatural thickneſs and viſcidity, eſpecially if from a venereal taint, the curative intention is moſt effectually anſwered by guaiacum, the acrid tincture of antimony, calomel, æthiops mineral, and the like; which, when ſkilfully uſed, are of ſingular efficacy in diſſolving and attenuating the viſcid juices impacted on the glands of the liver. *Hoffman.* Oper. Vol. 1. ſect. 2. c. 4.

INCISIVE (*Cycl.*)—Incisivus *lateralis*, in anatomy, a name given by authors to a muſcle of the face, called by Albinus *Levator labii ſuperioris alæque naſi.*

INCISORIUS *Muſculus*, in anatomy, a name given by Santorini to the muſcle called by Albinus *Levator labii ſuperioris*; and *Elevator labii ſuperioris*, by Cowper.

INCLAVE, a term uſed by Morgan, to expreſs an irregular line in heraldry, differing from the indented, invected, and all the others. It is called by ſome patee, and by others the dovetail line, from its reſemblance to that joint, known among our joiners by this name. It is alſo called by ſome, the labelled line. It has theſe names from the figure of the points, as they proceed from the ordinary, ſuch as a chef or feſs reſembling the ends of labels. *Morgan*'s Sphere of Gentry.

INCLINATION (*Cycl.*)—Inclination *of Meridians*, in dialling, the angle that the hour-line on the globe, which is perpendicular to the dial-plane, makes with the meridian.

INCLOSING *of Land.* The *incloſing* land into fields and paſtures, lays the foundation for all the induſtry and good huſbandry of the farmer, as it ſecures him of the advantages of his labour. Many have pleaded indeed for the leaving land in open fields, but experience ſhews the profit to be on the other ſide; ſince vaſt quantities of land have been of late years *incloſed*, which before lay open; and rent every where increaſes, as lands are more and more *incloſed.* The advantage of *incloſing* land is more neglected in the north of England, than in any other part of it. It is a very unlucky miſtake in the farmers in that part; becauſe one ſignal advantage of *incloſures* is, that the lands are kept warmer by them than they otherwiſe would be; and this warmth is wanted much more in thoſe northern cold parts, than in the more ſouthern parts of the iſland, which are much warmer. Land is *incloſed* in different parts of England by fences of different kinds, according to the nature of the country, and its produce. The moſt common *Incloſure* is by a ditch and a bank raiſed by its ſide, ſet with quick: This takes place in almoſt any ground; but as this is expenſive, and ſtone or water are more plentiful in particular places, they are uſed in its ſtead. In marſhy lands they only cut ditches, by way of fence between ground and ground; and theſe when wide and deep enough, are a very good fence in all places where there is water to keep them full. *Mortimer*'s Huſbandry.

In Cornwal, and Devonſhire, and ſome other of the weſtern counties, they uſe a ſtone-fence; which is the beſt kind both for the lands and for the cattle. Flat ſtones are very plentiful in theſe counties, and to be had at little or no expence. They build round the land that is to be *incloſed*, two walls of theſe ſtones near one another, laying the ſtones one upon another, firſt two and then one all the way up, and as it riſes they fill up the ſpace with earth, which brings it together; and ſo they continue the ſtone-work filling it to what height and breadth they pleaſe, beating the ſtones in flat to the ſides, which makes the whole very firm. On the top of theſe walls they plant quick and even timber-trees, which thrive extremely well.

In the northern counties of England, and ſome others where there is plenty of ſtone of a large and rough kind, they make their fences with the rough and unhewn ſtones, piling them up into a wall with no ſort of cement or mortar, only laying on large ones at the top in a bed of clay, which keep all the reſt together. They make theſe walls about five foot high; and in the north they dig the ſtones for eighteen-pence a rood, and make the walls for the ſame price, reckoning twenty-one foot to the rood or pole. To dig the ſtones for fences-building, or lime, in Suſſex, they reckon three ſhillings the cart load. See the article Fences.

INCLOSURE, a word uſed ſometimes to expreſs an *incloſed* piece of ground, and ſometimes for the fence or hedge made to incloſe it. Theſe hedges are uſually made of white-thorn, ſometimes of black-thorn, of crab, or of holly. See the article Fence.

A very good *Incloſure* for gardens may be made of the common elder. Where the ground is good, this ſucceeds extremely well. Elder ſticks or truncheons ten or twelve foot long are to be cut and ſtuck in the bank ſlope-wiſe each way, ſo as to make a chequer-work. This makes the ſpeedieſt ſhelter of any. When the trees grow old, they are alſo ſtill of value, their wood is a very fine one for turning, and is at leaſt equal to box, if not ſurpaſſing it. *Mortimer's* Huſbandry.

The elder-tree makes an extremely good fence in watery places, and when planted on the banks of rivers is of great uſe in preventing them from being undermined by the current; the roots being very numerous, ſtrong, and compact. It is always ſending ſuckers alſo from its loweſt roots, which makes it very uſeful where ſtreams wear away their banks, and are widening their courſe.

The furze-buſh, tho' an irregular grower, makes an excellent fence on dry banks, where nothing elſe will grow. It may be raiſed either by ſeeds, or by ſets; but the ſeeds are the beſt, eſpecially thoſe of the French furze, which grows to the height of fifteen or ſixteen foot, and is not ſubject to ſpread with its roots and get into the good ground, as our common heath furze will always do. This has the advantage of being a very ſpeedy grower. It will make a very good hedge in three years, if taken care of. It muſt be kept well weeded while young; and the ſheep muſt be kept away from it, for they are very fond of its young ſhoots. But it only requires this care for a little while, for when grown up to any conſiderable height, nothing can hurt it. If a furze hedge be clipped, it will grow large and thick; but if left to itſelf, it will run up to a conſiderable height, and afford good ſhelter, and yield an excellent fuel. They ſow much of the poor land in Devonſhire with furze, and make very conſiderable advantage of it.

INCOMBUSTIBLE (*Cycl.*)—Incombustible *Cloth*, a kind of cloth made of the aſbeſtus, and therefore not to be conſumed by fire. The manufacture of this cloth is loſt in Europe; but in ſome parts of Tartary they have a very long and fine kind of aſbeſtus, and have the way of manufacturing it, ſo as to make a ſort of handkerchiefs, and ſome larger things of it. They tell the people there, that it is made of the root of a tree; but this is only a pretence invented to keep the Chineſe in the dark about it; for they are very fond in ſome places of the cloth, and purchaſe it of the few Tartars who have the ſecret, at a very great price. See the article Asbestus.

All the antient authors talk of this cloth, but many among the moderns have doubted whether any ſuch was ever actually made. Dalechamp ſeems to think it impoſſible, becauſe of the ſhortneſs of the fibres of the aſbeſtus. And Schildius, in his commentaries on Suetonius, abſolutely denies it. Boxhornius ſeems to think, that the Indians might have ſuch a cloth in the time of the Romans, becauſe the materials of it were found among them; but he is of opinion, that no ſuch cloth was ever made by the Romans themſelves. Cauſabon is of the ſame opinion; and indeed there ſeems great probability in it, as we ſtill find

the beſt materials are of the produce of that part of the world, and the ſecret of weaving and working them is only among that people. Philoſ. Tranſ. N° 172. p. 1050.

Thoſe who ſuppoſe that no ſuch cloth was ever made at all, found their opinion, like Daleſchamp, on the ſhortneſs of the fibres of the aſbeſtus; but tho' what they may have ſeen was ſhort, there is enough that is ſufficiently long, and that very fine alſo, and fit for working, even in Europe. Mr. Monteſquieu having collected very lately, and ſent into England, ſome aſbeſtus from the rocks near Barege, which any common hand might work into cloth.

The Eaſt-Indies ſeems to have been always the principal place of its manufacture. Cælius Rhodoginus ſays, it was only made there, and that the beſt materials of it were not found elſewhere. And Paulus Venetus ſays, that Tartary was the place where it was made for many ages, and in no other place: He mentions alſo a fine piece of it ſent to pope Alexander, by the then emperor of that country. Agricola tells us of a mantle of this linnen, at Vereburg in Saxony. And Simon Majolus ſays, he ſaw one at Lovain expoſed to the fire: And Mr. Ray ſaw a purſe of it at Heidelberg, which bore being made red hot, without any hurt. By theſe accounts it is plain, that in all ages, and in many places, this cloth has been preſerved; and all experiments made on it agree in confirming the truth of the accounts given of its bearing fire unhurt. Paper is more eaſily made of it than cloth, and has the ſame qualities.

INCOMBUSTIBLE *Lint*, a name given by authors to a peculiar kind of aſbeſtus or earth flax, which never is formed into compact maſſes as the other ſpecies are, but is always found in looſe filaments, and thoſe of a very flexible nature, and extremely fit to work.

This is a kind of aſbeſtus, wholly different from the ſpecies known to the antients, and is found, ſo far as is yet known, only in the county of Aberdeen in Scotland, in the neighbourhood of Achintore near the Highlands. In this place there are found many very elegant pieces of foſſile wood petrified in a beautiful manner. On the ſide of a hill near this place in a heathy and ſomewhat boggy ſoil, and about the edges of a ſmall brook that runs down there, there is a ſpace of about ten or twelve yards ſquare, in which pieces of this foſſile wood lie very thick. Near this place, if the ground be only dug into with a knife, there is found a ſort of fibrous matter lying near the ſurface among the roots of the graſs; the knife will not cut this, and on examining it, it proves to be a ſubſtance of the aſbeſtus kind, tho' not in lumps. It is very ſoft and flexile, and is not injured by the fire.

Tho' this matter generally lies in theſe looſe filaments, yet it is ſometimes collected into parcels, and ſeems to form a tolerably compact body. When this, however, is more nearly examined, it is found not to be a real lump, but a congeries reſembling a ſurgeon's pledgit of preſſed lint, and on being put into water it ſeparates into its natural looſe threads, which no other ſpecies of aſbeſtus will do. All the aſbeſtus of this kind lies within an inch of the ſurface, parallel to it, and ſo interwoven among the roots of the graſs and ſmall plants, that it is not eaſily ſeparated from them.

The petrified wood found in the ſame place very much reſembles the texture of this aſbeſtus, and probably, whether this be really not petrified wood, but only an aſbeſtus with the appearance of the veins of trees, or whether foſſile wood in ſome places gives origin to aſbeſtus, theſe maſſes and the looſe lint are very nearly allied to one another. The ſtones or pieces of petrified wood are of different kinds; ſome are white of the colour of lint, and of ſo ſoft a ſubſtance, that a knife eaſily cuts through them without being blunted by it; others are mixt with a kind of greyiſh talc, and are very hard.

The looſe lint is always abrupt at both ends, as if cut off with a knife; and the ground in which it lies is a grey ſoil, of about two inches deep, covering a ſtratum of vegetable mould of two foot. In ſome places in the neighbourhood, there are found large quantities of a glittering talcky ſand; and near this there always is more or leſs of the lint. Sometimes alſo in theſe places there are pieces of the petrified wood, which degenerate more than the reſt from the nature of wood, and appear very white, bright, and talcky. It appears hence, that talc may have ſome ſhare in its origin, and this is the more probable, as talc as well as aſbeſtus is not to be injured by the fire. The antient Romans ſpun pieces of their aſbeſtus's into cloths, and uſed them in the funeral rites of the dead, preſerving the aſhes ſafe from thoſe of the wood, by firſt wrapping up the body in a winding ſheet of this cloth. What they had for this purpoſe, ſeem by the accounts of Pliny and others to have been all very ſhort; but this here mentioned would be much more eaſily wrought, as it is ſeven or eight inches long in ſome pieces. The fabricating a cloth of this ſubſtance, has not yet been attempted; but Mr. Wilſon, who firſt diſcovered it, had ſome of it ſpun into yarn, which gives proof that the other is practicable. Phil. Tranſ. N° 276. p. 1005.

INCREMENT, *Incrementum*, in rhetoric, a ſpecies of climax, which riſes from the loweſt to the higheſt: Such is that of Seneca, *turpiſſima tamen eſt jactura, quæ per negligentiam venit: et, ſi volueris attendere*, magna *vitæ pars elabitur male agentibus*, maxima *nihil agentibus*, tota *aliud agentibus*. *Voſſ.* Rhet. l. 5. p. 374. ſeq. See the article CLIMAX, *Cycl.*

INCUBUS, (*Cycl.*) in medicine, the name of a diſeaſe, which conſiſts in a ſpaſmodic contraction of the muſcles of the breaſt uſually happening in the night-time, and attended with a very painful difficulty of reſpiration, and great anxiety.

Signs of it. The moſt obvious ſymptom of this diſeaſe, is a ſenſation like that of ſome great weight laid upon the breaſt; this is attended with ſo violent a cohibition of reſpiration, that the perſon becomes unable to move any part of his body, or to utter any diſtinct or articulate ſound. This whole complaint goes off as ſoon as any one limb is moved, but there is often an univerſal laſſitude of the whole body left behind it, which remains for ſome ſpace of time. This diſeaſe generally attacks people in the night-time, in a ſort of middle ſtate between ſleep and waking.

Perſons ſubject to it. Thoſe of plethoric habits are moſt ſubject to fall into this diſeaſe, and among them ſuch particularly as have a great thickneſs of the blood. Perſons who are ſubject to hypocondriac complaints, and to diſorders of the ſpleen, are alſo much affected with it; and it is uſually brought on by eating large ſuppers, and afterwards ſleeping upon the back.

Cauſes of it. Theſe are a ſtagnation of the blood in plethoric habits, where it is thick about the vena portæ, which nature is endeavouring to throw off by means of thoſe ſpaſmodic motions, which conſtitute this diſeaſe; and very often crudities in the primæ viæ become additional cauſes, and exaſperate the complaint.

Prognoſtics in it. This is uſually eſteemed a trifling complaint, and at the utmoſt if it does not go off of itſelf, to be cured by bleeding. Phyſicians eſteem it a diſeaſe of no danger; but it is much to be ſuſpected, that many of thoſe people who are found dead in their beds periſh by it.

Method of Cure. When this diſtemper returns ſo often as to occaſion the patient to call in the aſſiſtance of a phyſician, the method is to give gentle purges three or four times, with the digeſtive medicines, ſuch as gum ammoniacum or the tartarum vitriolatum on the intermediate days; after this, bleeding in the foot is proper; and when this has been done, powders of nitre and cinnabar uſually compleat the cure: If they fail, the common method in hypocondriac caſes is to be uſed. When there are crudities in the primæ viæ which exaſperate this diſeaſe, then after the purges, gentle bitters and other medicines which will reſtore the tone of the ſtomach, are to be given. Gentian and orange-peel in infuſion, are very good for this purpoſe. When it happens almoſt wholly from a load on the ſtomach, a gentle vomit alone will perform a cure; but in this caſe great care is to be taken, that there is not a miſtake in the nature of the diſeaſe, for ſome hypocondriac caſes much reſemble this; and in all theſe, vomits are extremely hurtful. To prevent returns, the patients muſt accuſtom themſelves to lie on one or the other ſide, never on the back. *Junker*'s Conſp. Med. p. 631.

INCUS (*Cycl.*)—The *Incus* or anvil contained in the barrel of the ear, reſembles in ſome meaſure one of the anterior grinders, with its roots at a great diſtance from each other; at leaſt it comes nearer to this than to the ſhape of an anvil. Anatomiſts divide it into the body, and the branches: The body is a ſomewhat large ſubſtance; the branches or legs are two, one long and one ſhort. The body is turned forward, the ſhort leg backward, and the long leg downward. The body of the *Incus* is broader than it is thick; it has two eminences, and two cavities between them, much as we ſee in the crown of the firſt grinders. The ſhort leg is thick at its origin, and from thence decreaſing gradually it ends in a point. It is ſituated horizontally, its point being turned backward, and joined to the edge of the maſtoide opening of the tympanum. The long leg viewed through the external auditory paſſage appears to be ſituated vertically, but if we look upon it either on the fore or back-ſide we ſee it is inclined, the extremity of it being turned much more inward than the root or origin. The point of the extremity is a little flatted, and bent back like a hook, and ſometimes a little hollow'd like a kind of ear-picker. By this the *Incus* of one ear may be diſtinguiſhed from that of the other, when out of their places; for turning the ſhort leg backward and the long leg downward, if the curvature of this long leg be toward the left hand, the bone belongs to the right ear, if toward the right it belongs to the left ear. *Winſlow*'s Anat. p. 48.

INDECIMABLE, *Indecimabilis*, in law, is applied to things not tythable, or which by law ought not to pay tythe. 2 Inſt. 490. *Blount.*

INDENTED (*Cycl.*)—INDENTED *Line*, in fortification, a line running out and in, like the teeth of a ſaw, forming ſeveral angles, ſo that one ſide defends another. They are uſed on the banks of rivers, where they enter a town; likewiſe the parapet of the covert way is often indented. This is by the French engineers called *Redents*. Small places are ſometimes fortified with ſuch a line. But the fault of ſuch fortifications is, that the beſiegers from one battery may ruin both the ſides of the tenaille or front of a place, and make an aſ-

fault, without fear of being enfiladed, ſince the defences are ruined.

INDEX (*Cycl.*)—INDEX { *of the variation* / *of the inequability* } *of Curvature.*

INDICATOR, (*Cycl.*) in anatomy, a name given by Albinus, and ſome other authors, to a muſcle called by the generality of writers *Indicis abductor*, and *Extenſor Indicis*.

INDICAVIT, in law, a writ or prohibition that lies for a patron of a church, whoſe clerk is ſued in the ſpiritual court by another clerk for tythes, which do amount to a fourth part of the profits of the advowſon; then the ſuit belongs to the king's court, by the ſtat. Weſtm. 2. c. 5. And the patron of the defendant being like to be prejudiced in his church and advowſon, if the plaintiff recovers in the ſpiritual court, hath this means to remove it to the king's court. Reg. Orig. 35. Old Nat. Br. 31. Terms of Law, *Blount*, *Cowel*.

INDICTOR, in law, he that indicteth another for an offence; and *Indictee* is the party who is indicted. 1 Ed. 3. c. 11. 21 Jac. 1. c. 8. *Blount*.

INDICUM. In the writings of the antients we find this word very frequently uſed, as the name of a blue colour, or pigment uſed in dying, and imported to Rome, Greece, and other parts of the world from the Eaſt-Indies. The greater number of writers make this the ſame with our indigo, or anil fæculæ; and ſome ſay it was the ſame with our woad; but the former opinion ſeems moſt probable. The antient Greeks ſometimes wrote this ſimply ἰνδικον, *Indicum*, and ſometimes ἰνδικον μελαν, *nigrum Indicum*, or Indian black. We are not to be ſurpriſed at this name for a blue colour, ſince it is plain that the Greeks and Romans often uſed the words generally underſtood to expreſs black, for a blue colour. Thus Theophraſtus calls the fine deep blue ſapphires, μελανες; and Virgil talks of the nigra viola, which is our fine deep blue violet.

Pliny however did not diſtinguiſh this; but finding his Greek authors, from whom he borrowed the greater part of his natural hiſtory, ſometimes ſpeaking of *Indicum*, and ſometimes of *Indicum nigrum*, he ſuppoſed the uſe of this epithet to denote a different ſubſtance; miſtaking it for a ſubſtantive, and taking it to mean *atramentum*, or ink. Hence he deſcribes in two places the *Indicum*, and the *Indicum atramentum*. And hence, ſome have not only ſuppoſed two ſubſtances to have been known to the antients under this name, but that the *Indian-ink*, uſed at this time by our limners and deſigners, was known to Pliny. This author, according to the tradition of the times, ſuppoſed that the *Indicum* or blue colour, which came over to them in large cakes, in the manner of what our dealers in that commodity call rock blue at this time, was the mud gathered from about the roots of a kind of Indian reeds. The greater part of the authors of antiquity give us the ſame account of it; but this was only owing to their ignorance of its true nature. For, by their own accounts of its nature and effects, it appears plainly to have been the ſame kind of thing with our indigo, that is, the fæculæ or ſubſidence of a vegetable juice. The antients were in this manner ignorant of the true hiſtory of many things which they had in common uſe among them, ſuch as ſilk, &c. and our rock blue, which is the indigo in the firſt ſtate before it is formed into regular cakes, looks ſo like dry'd mud that any one who examines it in that condition will readily pardon the antients for ſuppoſing it to be ſuch. Pliny gives this account of the *Indicum*; but he ſays, that as to the *Indicum atramentum*, he could no were find any account of the making it, which is not very wonderful; ſince himſelf was the firſt who ſuppoſed that the antients from whom he expected to have taken ſuch an account ever thought of any ſuch ſubſtance ſeparate from the common blue indigo.

This ſubſtance, which the Greeks called *Indicum*, the Arabian writers, Aviſenna, Serapion, and others have called *Nil*. Tho' the ſame word is alſo ſometimes uſed by them for the pigment made from woad. The author of the Periplus maris Erythræi mentions the common *Indicum* under the name of *Indicum nigrum*, and ſays that it was one of thoſe merchandiſes in his time bought up at ſome of the markets of the ſavage Indians. Leo Africanus tells us, that the *Indicum* plant grows frequently about Dara in Africa; and that the colour is there made from it, in the ſame manner that the woad is prepared from that plant with us. Linſcot and Paludanus deſcribe the herb as being like roſemary; and this, tho' no exact deſcription, yet conveys an idea of their having known the plant, and of what they deſcribe being the ſame with our anil of America, of which we prepare indigo; that being a low ſhrubby plant, and being uſually cut when three or four foot high, which is the common height of roſemary. It is called in ſome places *Gali*; and Garcias, among others, gives us this name for it; but Cluſius has much perplexed this account, by telling us, that the gali is like the ocimum or baſil, which has not the leaſt reſemblance either to the plant anil or to roſemary, the other ſhrub to which it was compared. Advardus Barboſa, when he enumerates all the merchandiſes of the Indies, and gives their price, mentions the anil and the *Indicum*, as two different things; but he allots them both exactly the ſame price, and it appears therefore an error to have ſeparated them. The Arabians call it *nil*, but they alſo call the ſeed of a blue-flowered campanula by the ſame name, which has occaſioned ſome errors in the tranſlating thoſe parts of their works, when this word occurs.

INDICUS *Color*, a term uſed by ſeveral of the antient writers to expreſs black. The generality of the Greek and Roman phyſicians of old times have called the black lignum aloes, *Agollochum Indicum*; and the only black kind of myrobalan they were acquainted with was in the ſame manner called the *Indicum*; not that theſe were ſuppoſed peculiarly the product of the Indies, in diſtinction from the paler lignum aloes, or the other myrobalan; but that they were of that colour which they called *Indicus Color*.

INDIGNATORIUS (*Cycl.*)—This muſcle is called by others the *rectus exterior*, and *abducens*; and by Albinus, the *abductor*. It is one of his quatuor *recti oculi*.

INDIVISUM *Folium* among botaniſts. See the article LEAF.

INFALISTATIO, an antient puniſhment of felons, by throwing them among the rocks and ſands, cuſtomarily uſed in port-towns. It is the opinion of ſome writers, that *Infaliſtatus* did imply ſome capital puniſhment, by expoſing the malefactor upon the ſands till the next tide carried him away; of which cuſtom, 'tis ſaid, there is an old tradition. However the penalty ſeems to take its name from the Norman *Faleſe*, or *Faleſia*, which ſignified not the ſands, but the rocks and cliffs adjoining, or impending on the ſea ſhore. Mon. Angl. T. 2. p. 165.— *Commiſit feloniam ob quam fuit ſuſpenſus, utlagatus vel alio modo morti damnatus*, &c. *vel apud Dover* Infaliſtatus, *apud Southampton ſubmerſus*, &c. *Blount*.

INFANT (*Cycl.*)—*Diſtemperatures of* INFANTS. It is to be obſerved in general, that all *Infants* are not equally expoſed to diſtemperatures of many kinds, but that the children of perſons of tender conſtitutions and idle lives are moſt ſubject to them. The children of poorer people, which are uſually hardly brought up from the firſt, are alſo leſs troubled with diſorders, in general, than thoſe which are taken more care of; and all their lives afterwards are much abler to bear external injuries, and are much leſs affected by them.

The ſeveral diſtempers of *Infants* are theſe: *Immobility at the birth*, called by authors *Anaiſtheſia*. In this caſe the *Infant* as ſoon as born remains immoveable in its poſition, as if dead. It is to be brought to life and motion in this caſe, by breathing into its mouth, and burning ſaffron under its noſtrils, letting it receive the fume of it, and ſprinkling cold water or wine upon it. When the caſe is leſs violent, the *Infant* is often brought to itſelf by applying it immediately to the breaſt and letting it ſuck: And in the other caſes, this is very proper after the before-mentioned means have been uſed. *Junker's* Conſp. Med. p. 739.

A yellow colour of the ſkin is another very common complaint in new-born *Infants*, ſo that they look as if they had the jaundice. This is an accident of no ill conſequence. It often goes off of itſelf, after voiding the firſt ſtools; and if it does not, is eaſily removed by giving the *Infant* a ſmall quantity of ſyrup of rhubarb, and of the common abſorbent powders, with antimonium diaphoreticum. In this caſe the child is to be kept warm, ſo that it may ſweat moderately while it takes theſe medicines.

Difficulty of ſwallowing is alſo a common complaint in *Infants*. If this happens from that fault of the frenulum of the tongue, which renders the child tongue-tied, as the good women expreſs it; this is to be removed by cutting it. If it be cauſed by aphthæ, or little ulcers in the mouth; theſe are to be treated as below. If it proceed from a tumor of the tongue, the diſcutient waters are to be put in ſmall quantities into the mouth every two or three hours; and if there be ulcerations upon the tongue, the beſt of all applications is the oil of eggs. But before any thing is done for the child, it is neceſſary to ſee, whether the fault be not in the mother from her having no milk, or from the nipples being ſo depreſſed that the child cannot uſe them.

Imperforations of the neceſſary parts. Theſe ſometimes happen in *Infants*, ſo that there is either no paſſage for the ſtools, or for the urine; ſometimes for neither. This caſe is rare; but when it happens, ſpeedy help muſt be had, or the *Infant* periſhes. In caſes where the paſſage is regularly formed, but is only ſtopt up by mucous matter, which ſometimes happens; the gentle abſtergents are to be given, as the crabs-eyes or ſome other abſorbent half fated with an acid, and the uſe of a ſmall catheter or glyſter-pipe muſt be called in.

But

But when there is a preternatural membrane formed, which ſtops the paſſages, this muſt be cut through by a ſurgeon. *Junker*'s Conſp. Med. p. 742.

Retention of the firſt ſtools, or meconium, which is in the bowels at the time of the birth. This diſtemperature in the body occaſions the *Infant* many ſevere pains, and throws it into great danger; difficulty of breathing, pains in the abdomen, inquietude and convulſions, are the conſequences of it. Nature often cures theſe by a diſcharge of bilious acrid ſtools, which are ſometimes green, ſometimes yellow like the yolk of an egg. When nature is not able to do this in time, ſhe is to be aſſiſted by giving ſyrup of rhubarb, or a very ſmall quantity of oxymel of ſquills; ſyrup of roſes may alſo be given, and oil of ſweet almonds with fine ſugar. When this goes off in a diarrhœa with acrid ſtools, the common abſorbents and attemperating medicines are to be given. Powder of calcined cryſtal is much recommended for this purpoſe; to which ſome propoſe the adding half a grain of aurum fulminans; and the mucilaginous ſubſtances, ſuch as gum-arabic, and tragacanth diſſolved in barley-water, are of great ſervice.

Stuffings of the breaſt attend ſome *Infants* in ſuch a degree, that they ſeem aſthmatic. In theſe caſes the ſolutive ſyrups of rhubarb and roſes are to be given; and afterwards the pectorals, as the ſyrup of eryſimum and maidenhair, or ſyrup of liquorice. An emetic may alſo be given of the ſyrup or conſerve of peach-bloſſoms, and a ſingle grain of calomel or two at the utmoſt may be given, and often have great ſucceſs. If theſe fail, ſmall doſes may be given of powders prepared of diaphoretic antimony with twice its weight of detonated nitre; and the common reſolvents, ſuch as the orrice-root and ſperma-ceti, may be added; and ſometimes it is neceſſary to add a ſmall doſe of tartarum vitriolatum, with ſome of the common abſorbent powders.

Coughs ſometimes attend *Infants*, but they are ſeldom obſtinate, uſually giving way to the common pectoral ſyrups, or a little ſpermaceti, after the bowels have been unloaded by the laxative ſyrups, or other gentle cathartics.

Coryza's and Gravedo's happen alſo ſometimes to *Infants*; in theſe caſes the common ſyrups before preſcribed are to be given; and if they fail of effect, the nurſe muſt take the medicines proper in theſe caſes; which, ſee under their proper heads.

Running of the eyes and ears. This is a very common complaint, and is to be cured by ſmall doſes of decoctions of pimpernel root, ſaſſafras, and the other ſweetning woods, and by gentle laxatives on the intermediate days, in which calomel in ſmall doſes of a grain or two ought always to have its part; and the more acrid the matter diſcharged is, the more neceſſary is it to add to theſe things the mucilaginous medicines, ſuch as ſolutions of gum-arabic and tragacanth in water, and mucilage of the ſeeds of quinces made by gently boiling them.

Chaffings of the fleſh are very common in *Infants*, and uſually ariſe from the ſweats, urine, or acrid ſtools diſcharged upon the parts, eſpecially when their nurſes are ſo careleſs as to keep them dirty, and ſuffer theſe things to remain long on the parts. In this caſe common flour, or powder, will often prove a cure; or, when that fails, a little camphor and ceruſs mixed among it, uſually proves effectual. But if internal cauſes concur, ſuch as a ſharpneſs of the blood, and humors in the child, then the common abſorbent and ſweetning powders are to be given internally, at the ſame time that the others are applied externally to the parts.

Vomitings, in *Infants*, are rather ſalutary than hurtful, provided they are moderate; but when they are violent, they are to be remedied by giving gentle glyſters, to give a derivation to the mucous matter downward, and at the ſame time applying externally the common ſtrengthening and ſtomachic plaiſters, as oil of mace, and the like, and repeating theſe applications as often as found neceſſary.

Diarrhœas in *Infants* are uſually attended with pain, and the ſtools are either green or of the colour of the yolk of an egg; it is not ſafe to uſe aſtringents to them, but they may generally be cured by abſorbents, ſuch as powder of cryſtal, or crabs-eyes. *Junker*'s Conſp. Med. p. 743.

Coſtiveneſs in *Infants* is a much more dangerous complaint, ſubjecting them to many diſorders. The common purgative ſyrups of roſes and peach-flowers are to be given in this caſe, as alſo emollient clyſters; and ſuppoſitories are to be applied, for which purpoſe nothing is ſo proper as a piece of parſley-root cut into a proper ſhape, and introduced after rubbing it over with butter. It is neceſſary, however, to diſtinguiſh this coſtiveneſs from a natural firmneſs of the ſtools when they are voided at moderate diſtances of time, and that without pain; for this is a very ſalutary habit in children, after the meconium is voided in the firſt ſtools: It ſhews a ſtrength in the child, and is to be accounted a good ſymptom.

Cutaneous eruptions. Theſe attend children in various forms, and are of very different kinds; but in all the ſame method of cure is to be uſed: The nurſe and child ſhould both take decoctions of ſaſſafras, and in the intermediate days laxatives with ſmall doſes of calomel. External applications to them muſt be very mild and innocent, ſuch are the oil of eggs mixed with an equal quantity of the oleum philoſophorum, and oils in which wall-flowers have been inſolated.

Aphthæ. In this complaint *Infants* are found to have their tongues covered over with a white ſkin or film, and much ſwelled or inflated, and the internal part of the mouth ſore. This diſorder ſometimes ariſes from internal heat, ſometimes from the frequency and eagerneſs of the child's ſucking. The mouth in this caſe is to be wiped and cleanſed frequently with a rag dipped in wine and honey, or with a coarſer cloth dipped in ſyrup of mulberries; and if there be any febrile heat attending it, gentle alexipharmics and laxative ſyrups are to be given internally, and repeated as often as is found neceſſary.

Convulſions. Theſe are cauſed in children by ſeveral different means, and therefore require a different treatment. If they ariſe from a repreſſion of ſweats, the common alexipharmics are to be given, and in the intermediate times ſmall doſes of mercurius dulcis. If they are owing to acrimonious humors in the bowels, they are to be cured by gentle doſes of ſyrup of rhubarb, and powders of calcined cryſtal, and other abſorbents, with a little of ſweet almonds. When they are cauſed by abundant ſeroſities, valerian roots and aurum fulminans, are greatly recommended. When they are epileptic, and return very frequently, cinnabar is to be given freely in powders; and when they are owing to worms, mercurius dulcis is the beſt of all remedies.

It is to be obſerved in general, that of the diſeaſes of children the far greater number are wholly owing to external cauſes, very few of them to any internal fault in the conſtitution. The principal of theſe external cauſes, are the following:

1. Changes of the temperature of the air. Theſe are brought on in regard to *Infants* at the nurſe's pleaſure, and it is often thrown into too profuſe ſweats by a cloſe room and too warm covering, and perhaps in the midſt of this ſweat is immediately taken from under that covering, and expoſed to the open air. To this are owing moſt of the catarrhal affections to which *Infants* are ſubject, and their fevers and cutaneous eruptions of the ſeveral kinds.

2. Improper food and drink are another great ſource of the diſeaſes of *Infants*. Nurſes frequently ſtarve children, and more frequently cram them with much more food than is neceſſary; and beſides theſe irregularities in regard to quantity, errors in the quality are not leſs fatal. A thin and bilious milk throws them into gripings of the bowels, and bilious diarrhœas; and milk when too thick gives them ſtuffings or ſtoppages at the breaſt, and ſometimes ſuffocative catarrhs. And finally, the milk of a perſon, who has a remaining taint of the venereal diſeaſe, ſubjects the child to breakings-out, and ulcers of many kinds. *Junker*'s Conſp. Med. p. 747.

3. Motion and reſt improperly managed are alſo the ſources of many of the complaints of children. Nothing is more prejudicial to the health of a child, than that frequent cuſtom of idle nurſes of rocking a child to ſleep, whether it will or not; the violent and continual motion in this caſe often gives the child a vertigo, which it never afterwards gets rid of.

The binding children too tight in their dreſs, is alſo another great cauſe of diſorders, by obſtructing the due motions of nature in the circulation of the blood. The ſetting children too early on their feet, and compelling them to walk too early, is alſo the cauſe of many miſchiefs. And nothing is more miſchievous than the frequent diſturbing them out of their ſleep: This makes them peeviſh, and torpid, and ſleepy at other times.

4. The ſuppreſſion of the natural excretions is alſo the origin of many diſorders; and though this may ſometimes happen from an innate cauſe in the *Infant*, it much oftner is owing to the perverſeneſs of the nurſe in feeding on acid foods, or ſuch as are hard of digeſtion; and expoſing the child, as well as her own breaſts to the cold air, when they are hot.

Infants, from the great tenderneſs of their parts, are much more ſubject to the ſeverity of diſeaſes, than grown perſons; yet experience ſhews us, that they uſually get through them with leſs danger. An inſtance of this is evident in the ſmall-pox, from which people in general eſcape much better when young, than at any other time. Convulſions, violent hiccoughs, and ſevere and almoſt continual crying, are obſerved very often to be fatal to children in the firſt ſix weeks; but are much leſs dangerous afterwards: And convulſions become habitual to children, tho' they are often very frequent in their returns upon every ſlight occaſion, yet they are found much leſs dangerous than in other caſes. In general, all diſeaſes come to a ſhorter period in *Infants*, than in grown perſons.

Moſt of the diſtemperatures of children are to be cured by gentle correctives and evacuants; and of theſe, the very mildeſt in their operation are always to be choſen. Vomits are very ſeldom neceſſary to be given to children; but when it is neceſſary to provoke their ſtomachs to throw up their contents, the putting the finger to the throat will uſually prove ſufficient to ſet them to reaching; or if this fail, a little ſyrup or conſerve of peach-bloſſoms will take effect.

Mercurius

Mercurius dulcis, or calomel, is an extremely ſafe and valuable purge for children, provided that they have no fever; it is to be given from one grain, to three or four. In caſes of diſorders from the retropulſion of cutaneous humors, this does more good than could well be expected from any medicine. *Junker*'s Conſp. Med. p. 751.

Manna, infuſions of ſena, and ſmall doſes of ſyrup of buckthorn, may alſo be given as purges to children, where there is no fever joined with their complaints; but where there is a feveriſh diſpoſition, rhubarb is to be preferred to all other things. In violent gripings, and pains attended with crying out, terrors and tremblings, and acrid ſtools, mucilaginous medicines often prove of more ſervice than the common abſorbents. Worms in *Infants*, when alive in the bowels, often bring on atrophies and convulſions; and when dead and putrified, they occaſion many malignant effects, with convulſions, and often unaccountable ſymptoms. When alexipharmic or diuretic medicines are found neceſſary, it is always much better to give them to the nurſe than to the child; but antimony-diaphoretic, when faithfully prepared, is a medicine of great power, and yet ſo ſafe that it may be given to the *Infant*. Narcotic medicines are to be given with the utmoſt caution; a ſingle grain of theriaca ſeems as proper as any thing for this purpoſe. Cinnabar in ſmall doſes is found to be an excellent remedy in convulſions; but if it be given too freely, it generally loads the ſtomach.

INFANT, in law, if it appear that an *Infant*, under the age of diſcretion could diſtinguiſh between good and evil, as if one of nine or ten years of age ſhould kill another, and hide the body, or himſelf, *&c.* by the law of England he may be convicted, and condemned, *&c.* But the judge in prudence will reſpite the execution. *Hawk*, P. C. b. 1. c. 1.

INFERIÆ, in antiquity, ſacrifices offered to the Dii manes, or the ſouls of deceaſed heroes and illuſtrious perſons; or even any relation or perſon whoſe memory was held in veneration. *Pitiſc.* Lex. Ant. in voc.

INFERIOR (*Cycl.*)—INFERIOR *Courts of Record*, in Engliſh law-writers, is uſed as a general name for corporation-courts, courts-leet, and ſheriffs-torns. *Hale*, Analyſ. p. 36. 2 Inſt. 143. 4 Inſt. 263. See the article *Inferior* COURTS.

Moſt courts are ſubordinate to ſome other; but for diſtinction ſake the term *Inferior-court* is by Sir Matthew Hale, and others, applied in the manner here mentioned. *Hale*, ibid.

INFERIOR *Penis*, in anatomy, a name given by Spigelius to one of the muſcles of the penis, generally called the *Accelerator* by the moderns; and by Veſalius, and others of his time, *Primus penis*. See the article ACCELERATOR, *Cycl.*

INFERNAL-*Salt*, a name given by Hoffman, and ſome other of the chemical writers, to nitre; they have alſo called it *cerberus chemicus*.

INFERTILITY. See the article FERTILITY.

INFIBULATION, *Infibulatio*, in medicine. See the article ANCTERIASMUS.

INFINITESIMALS. In the method of *Infiniteſimals*, or of infinitely ſmall quantites, the element by which any quantity increaſes or decreaſes is ſuppoſed to be infinitely ſmall, and is generally expreſt by two or more terms; ſome of which are infinitely leſs than the reſt, which being neglected as of no importance, the remaining terms form what is called the difference of the propoſed quantity. The terms that are neglected in this manner, as infinitely leſs than the other terms of the element, are the very ſame which ariſe in conſequence of the acceleration, or retardation, of the generating motion, during the infinitely ſmall time in which the element is generated; ſo that the remaining terms expreſs the element that would have been produced in that time, if the generating motion had continued uniform, as is farther explained in the article FLUXION.

Therefore thoſe differences are accurately in the ſame ratio to each other, as the generating motions or fluxions. And hence, though *infiniteſimal* parts of the elements are neglected, the concluſions are accurately true, without even an infinitely ſmall error, and agree preciſely with thoſe that are deduced by the method of fluxions.

In order to render the application of this method eaſy, ſome analogous principles are admitted, as that the infinitely ſmall elements of a curve are right lines, or that a curve is a polygon of an infinite number of ſides, which being produced give the tangents of the curve, and by their inclination to each other meaſure the curvature. This is as if we ſhould ſuppoſe that when the baſe flows uniformly, the ordinate flows with a motion which is uniform for every infinitely ſmall part of time; and increaſes or decreaſes, by infinitely ſmall differences at the end of every ſuch time.

But however convenient this principle may be, it muſt be applied with caution and art, on various occaſions. It is uſual therefore, in many caſes, to reſolve the element of the curve into two or more infinitely ſmall right-lines; and ſometimes it is neceſſary (if we would avoid error) to reſolve it into an infinite number of ſuch right-lines, which are *Infiniteſimals* of the ſecond order. In general, it is a *poſtulatum* in this method, that we may deſcend to *Infiniteſimals* of any order whatever, as we find it neceſſary; by which means any error that might ariſe in the application of it, may be diſcovered and corrected by a proper uſe of this method itſelf. See *Maclaurin*'s FLUXIONS, Art. 495—502.

It is alſo to be obſerved, that when the value of a quantity that is required in a philoſophical problem becomes in certain particular caſes infinitely great, or infinitely little, the ſolution would not be always juſt, tho' ſuch magnitudes were admitted. As when it is required, to find by what centripetal force a curve could be deſcribed about a fixed point that is either in the curve, or is ſo ſituated that a tangent may be drawn from it to the curve. The value of the force is found infinite at the center of the forces in the former caſe, and at the point of contact in the latter; yet it is obvious, that an infinite force could not inflect the line deſcribed by a body that ſhould proceed from either of theſe points, into a curve; becauſe the direction of its motion in either caſe paſſes through the center of the forces, and no force how great ſoever that tends towards the center could cauſe it to change that direction. But it is to be obſerved, that the geometrical magnitude by which the force is meaſured is no more imaginary in this than in other caſes, where it becomes infinite; and philoſophical problems have limitations that enter not always into the general ſolution given by geometry.

But altho' by proper care errors may be avoided in the method of *Infiniteſimals*, yet it muſt be owned that to ſuch who have been accuſtomed to a more ſtrict and rigid kind of demonſtration in the elementary parts of geometry, it may not ſeem to be conſiſtent with perfect accuracy, that, in determining the firſt differences, any part of the element of the variable quantity ſhould be rejected, merely becauſe it is infinitely leſs than the reſt; and that the ſame part ſhould be afterwards employed for determining the ſecond and higher differences, and reſolving ſome of the moſt important problems. Nor can we ſuppoſe, that their ſcruples will be removed, but rather confirmed, when they come to conſider what has been advanced by ſome of the moſt celebrated writers on this method, who have expreſſed their ſentiments concerning infinitely ſmall quantities in the preciſeſt terms; while ſome of them deny their reality, and conſider them only as incomparably leſs than finite quantities, in the ſame manner as a grain of ſand is incomparably leſs than the whole earth; and others repreſent them, in all their orders, as no leſs real than finite quantities. And altho' it appears from what has been ſaid in this article, that a ſatisfactory account may be given for the brief way of reaſoning that is uſed in the method of *Infiniteſimals*; while nothing is neglected without accounting for it; and that the harmony between the method of fluxions and that of *Infiniteſimals*, thus appears more perfect.

And however ſafe and convenient this method may be, yet ſome will always ſcruple to admit infinitely little quantities, and infinite orders of *Infiniteſimals*, into a ſcience that boaſts of the moſt evident and accurate principles, as well as of the moſt rigid demonſtrations. It is therefore proper, that this extenſive and uſeful doctrine ſhould be eſtabliſhed on unexceptionable principles. See the articles FLUXION, and LIMIT. See alſo Mr. *Maclaurin*'s Treat. of Fluxions in the Introduction, pag. 39, 40, *&c.* and Book 1. Art. 495, to 502.

INFINITO, in the Italian muſic, is uſed for ſuch canons or fugues, as may be begun again and again: Whence they are alſo called *perpetual fugues*. See the article FUGUE, *Cycl.* & *Suppl.*

IFFLAMMABILITY *of Oils with Acids*. Among the many ſurpriſing phænomena which the world owes to the late improvements in chemiſtry, there is none which has more attracted the admiration of the generality of mankind than that remarkable one of the producing actual flame, by mixing two liquors both cold to the touch; the acid ſpirits of minerals, and the chemical oil of vegetables.

Becher is the firſt author who has publiſhed an account of this phænomenon. He obſerves, in his phyſica ſubterranea, that oil of vitriol which is a very ſtrong acid liquor, with oil of turpentine which is a very ſulphureous one, produces a violent heat, and actual fire or flame. Becher giving no farther account of the proceſs than this, ſeveral of the ſucceeding chemiſts tried the experiment, but all without ſucceſs. At length Borrichius explained it, with all the neceſſary particulars, and the effect according to his directions has been ſometimes produced; tho' the great uncertainty of a thouſand little accidents, all of which muſt neceſſarily concur to the producing the flame, has made it often miſs even in the moſt careful hands. The method of Borrichius is this, mix in a glaſs veſſel four ounces of freſh drawn and highly rectified oil of turpentine, with ſix ounces of aqua fortis newly made and carefully prepared; cover the veſſel, and ſhake the two liquors well together. After they have ſtood together half an hour, open the veſſel, and there will proceed out of the mouth of it large quantities of flame mixed with great clouds of ſmoke. The experiment will not ſucceed however unleſs the liquors are freſh made, and the veſſel be expoſed to the heat of the ſun. And many who

have ſucceeded amiſs in trying the experiment from their neglect of certain circumſtances which appeared trifling to them, have cenſured both authors as relating untruths. But Mr. Geoffroy, by repeated experiments, at length found the truth of the aſſertion, and became able at any time to enflame ſuch mixtures, but found that ſpirit of nitre was the acid which ſucceeded beſt; and that of all oils thoſe of the foreign exotic vegetables, which are thick and heavy, were moſt readily inflamed by it. Mr. Tournefort produced actual flame, and that of a ſtrong red colour, by mixing ſpirit of nitre and oil of ſaſſafras in equal quantities; but he try'd without ſucceſs the ſame experiment with many of our European oils, and indeed with the foreign oil of cloves. After this, however, Mr. Homberg ſucceeded in the attempt with oil of cloves, and with all the aromatic oils of the Indian vegetables. Mem. Acad. Par. 1702.

After this, Mr. Rouviere found the means of ſucceeding in it with the ſpirit of nitre and the fœtid oil of guaiacum, in which experiment the ſpirit not only ſet fire to the oil, but made a ſort of volcano in it, raiſing up a maſs of ſpungy matter to the height of two inches above the ſurface of the veſſel, in which it was made. All theſe experiments however do not prove the truth of Borrichius's experiment in the literal words, ſince none of theſe gentlemen were ever able to produce fire with oil of turpentine, with the aſſiſtance of any acid whatever; there required for this an aqua fortis deflegmated in the higheſt degree. Mem. Acad. Par. 1726.

Mr. Geoffroy at length prepared a ſpirit of nitre ſo perfectly deflegmated, that it would always give flame with oil of ſaſſafras or oil of cloves; this he prepared by mixing four parts of clay with one of nitre. The clay and the nitre for this proceſs muſt be both perfectly dried, and muſt be mixed while yet hot and put into the retort; after this, the ſpirit which comes firſt over muſt be ſeparated, as it yet contains ſome phlegm; the ſucceeding ſpirit muſt be kept alone, for this purpoſe. This is too ſtrong for the common uſes in the metallic ſolutions, but it always ſucceeds in giving fire with the oils. Another acid which the ſame author has deſcribed as capable of producing the ſame effect, is an aqua fortis made too ſtrong for the ſolution of metals: This is prepared by mixing equal quantities of vitriol calcined to a redneſs, while it is yet hot with an equal quantity of nitre dried and reduced to powder.

As this operation however is attended with its difficulties, the fumes ariſing on the mixture of the two ſalts greatly incommoding the artiſt, the ſame author deſcribes a third liquor, made by adding powdered nitre to concentrated oil of vitriol, and giving a conſiderable heat to the mixture. This without diſtillation yields a ſort of aqua fortis, which, tho' inferior in ſtrength to the former, yet will produce flame on mixing with the oil of guaiacum. Tho' this however will do without diſtillation, yet a diſtilled ſpirit prepared from three parts of dried and powdered ſalt-petre mixed with one part of oil of vitriol, with the help of a reverberatory fire is greatly ſuperior to it. This is a liquor ſo fuming, that it is ſcarce poſſible to keep it even in glaſſes ever ſo well ſtopped; and it very readily takes fire with all the aromatic oils of the Eaſt-Indian plants; but even this will not produce the ſame effect with oil of turpentine.

The firſt experiment which ſucceeded with Mr. Geoffroy in this particular, was this: He mixed in a ſmall retort an ounce of oil of vitriol with an ounce of fuming ſpirit of nitre, and pouring on this mixture two ounces of oil of turpentine, a thick ſmoke and a large quantity of flame were immediately produced, and this continued a long time till all the liquid matter of the mixture was conſumed; and there remained nothing but a ſmall quantity of a black light matter, reſembling a coal.

This ſucceſs and the ſimilitude of this mixture of acids, with the liquor diſtilled by the ſame author from vitriol and nitre, gave the hint for the following compound acid, which, more conſtantly and happily than any other, produces this wonderful effect.

Take two pounds of nitre dried and powdered, mix it with one pound of concentrated oil of vitriol, or of common oil of vitriol of a ſufficient ſtrength; diſtil this mixture in a retort with a reverberatory fire, and the liquor raiſed from it will be an aqua fortis capable of giving fire and flame with oil of turpentine, without any farther aſſiſtance.

Mr. Hoffman has alſo given the proceſs for another acid ſpirit, which produces the ſame effect; and which, though founded on the ſame baſis with the former, differs in ſome particulars. This is made by mixing in a retort equal quantities of purified nitre and oil of vitriol, and diſtilling the whole in a mild ſand heat. Mr. Geoffroy tried this and found it anſwer in every particular, and give fire with oil of turpentine even more readily than the inventor had declared; for he orders the ſhaking of the veſſel in which they are mixed, and then ſtanding ſome time; whereas Mr. Geoffroy on carefully repeating every article of his proceſs, found there was no occaſion for ſhaking the veſſel, nor that any time was required; but that the flame appeared inſtantaneouſly on making the mixture, and that in a more violent manner than could have been expected from ſuch an operation. In order to the ſucceſs of this ſurpriſing operation, however, no more is neceſſary than that the acids of nitre and vitriol ſhould be mixed; the manner of doing it is of no conſequence. But without the trouble of making either of theſe ſpirits, if common ſpirit of nitre well dephlegmated be mixed with a ſufficient quantity of oil of vitriol, it will give fire, and that very violently with oil of turpentine, or any other of the European oils of vegetables. The beſt veſſel to perform the experiment in, is that ſort of glaſs uſed for preſerving fruits in brandy, which is about a foot high, and three inches in diameter. Mem. Acad. Par. 1726.

Mr. Geoffroy ſucceeded in this manner in giving flame with oil of juniper, mint, fennel, the vulnerary herbs, and eſſence of lemons, notwithſtanding that they are much thinner fluids than the oils of the aromatic plants of the Indies. And this ſeems indeed a better method than the relying on any ſpirit of nitre by a particular diſtillation, ſince in that way there are a great many accidents which may prevent the ſucceſs of the experiments, and in this all is familiar and eaſy.

As all theſe experiments are attended with ſome expence, Mr. Geoffroy has endeavoured to reduce them to the cheapeſt and eaſieſt method that may be. Mr. Hoffman ſays, there muſt be at leaſt an ounce of the acid, and an ounce of the oil, to produce the effect; but Mr. Geoffrey has found it ſucceed very well with a dram of ſpirit of nitre, a dram of oil of vitriol, and three drams of oil of turpentine. The heavy oriental oils ſucceed with a ſmaller portion of acid; and it ſeems a general rule, that the lighter the oil is, the larger portion of the acid is required. Petroleum and naphtha, with the other inflammable mineral oils, might be ſuppoſed very fit for theſe experiments; but none of them ſucceed on the trial.

It is not only the oils of our European plants, as well as the Indian ones, that are to be ſet on fire by mixture with theſe acids; but the very natural balſams perform the operation in the ſame manner, and afford the ſame ſurpriſing phænomenon.

An ounce of common Venice turpentine will be immediately ſet on fire, by pouring on it a mixture of an ounce of ſpirit of nitre, and half an ounce of well rectified oil of vitriol. This is a very fine experiment, for the flame continues longer than that from any of the oils, and is rendered a more pleaſing ſpectacle by a great number of exploſions, which ſucceed one another at different diſtances of time.

Balſam of capivi and balm of Gilead, ſucceed in the ſame manner in the ſame doſes; and the balm of Gilead yields its flame with a very remarkable exploſion, and probably all the natural balſams will produce the ſame effect; but in order to ſucceed in the experiment, it is neceſſary to have them perfectly genuine and unadulterated.

The ſmoke and vapours that attend the flame in theſe experiments always diffuſe a very ſtrong ſmell of the ſubſtance that is employed; and the petroleum, tho' it will not yield a flame in this ſort of mixture, yet diffuſes a very remarkable ſmell of ambergreaſe; and the leaſt touch of the matter while fuming will give a ſmell of that perfume, which will laſt a very long time. Mem. Acad. Par. 1726.

INFLAMMATION (*Cycl.*)—A late author is of opinion, that the ophthalmia, angina, phrenitis, peripneumonia, pleuritis, hepatitis, nephritis, and rheumatiſmus, have all the ſame characteriſtic, and differ in nothing but the part affected; ſo that if one has a right knowledge of an *Inflammation* on an external part, its progreſs and proper remedies, and at the ſame time is throughly acquainted with anatomy and the animal œconomy, he cannot be at a loſs to diſtinguiſh and treat any of the diſeaſes belonging to this claſs. Medic. Eſſ. Edinb. Vol. I. p. 265.

Diſperſion of INFLAMMATIONS. See the article DISPERSION.

INFLEX-*Leaf*, *Inflexum Folium*, among botaniſts. See the article LEAF.

INFLUENT (*Cycl.*)—INFLUENT *Fever* is ſometimes uſed for a nervous fever. In this the warm regimen is thought uſeful by ſome, as low cooling drinks are in the effluent or in flammatory fever.

INFORMER, *Informator*, in law, a perſon that informs againſt, or proſecutes in any of the king's courts thoſe that offend againſt any law or penal ſtatute. *Blount*, *Cowel.*

INFRASPINATUS (*Cycl.*)—This is a triangular fleſhy and pretty broad muſcle, in ſome meaſure penniform, filling the whole *infraſpinal* cavity, or foſſa of the ſcapula. It is fixed in the poſterior half of the *infraſpinal* cavity, or foſſa, and to the correſponding part of the baſis of the ſcapula. From thence ariſe a great number of ſhort fleſhy fibres, which run more or leſs obliquely, and end in a middle tendinous plane, which terminates a little below the broadeſt part of the ſpine of the ſcapula, under the root of the acromium. The fleſhy fibres then leaving the bone, unite in one fleſhy maſs, which paſſing under the acromium over the articulation of the head of the os humeri, and adhering to the capſular ligament, terminates there in a broad flat tendon, which

which adhering alſo to the capſula, is afterwards inſerted in the greater middle ſurface of the great tuberoſity of the head of the os humeri. At the place where the fibres leave the *infraſpinal* foſſa under the acromium, there is a great quantity of fat, or adiſpoſe cells between the bones and the looſe portion of the fleſhy maſs. This muſcle appears double a little below the ſpine, and toward the baſis of the ſcapula, becauſe of the middle tendinous plane already mentioned. It ſeems likewiſe to be confounded with the teres minor, to which it is very cloſely joined; and its tendon is united on one ſide with that of the teres major; and on the other ſide with that of the ſupraſpinatus, and it is covered by the poſterior portion of the deltoides. *Winſlow*'s Anat. p. 183.

INFRIGIDANS, a term uſed by ſome of the writers in medicine, to expreſs the cerate of roſes.

INFUNDIBULIFORM (*Cycl.*)—INFUNDIBULIFORM *Flowers*, or *funnel-faſhioned flower*, in botany, a term uſed to expreſs one of the kinds of monopetalous or one-leav'd flowers. The reaſon of the name is their reſembling a funnel in ſhape, that is, having a narrow tube at one end, and a wide mouth at the other. There are properly two ſpecies of the funnel-ſhaped flowers: The one repreſents an inverted cone at its mouth, and the other being more wide and ſhallow looks more like a ſmall ſaucer. The firſt of theſe are more properly called funnel-ſhaped flowers, the others ſaucer-ſhaped ones, from their reſembling a ſaucer in their figure. See Tab. 1. of Botany, Claſs 1. *Tourn.* Inſt. p. 116.

INFUSION (*Cycl.*)—INFUSION *of laurel leaves*. See the article LAUROCERASUS.

INFUSION *of Sena*, *Infuſum Senæ*, a purging medicine in great uſe, but of a very diſagreeable flavour. The London Diſpenſatory orders however two methods of preparing it, by which it loſes at leaſt a great part of its nauſeouſneſs. The one is by diſſolving three drams of cryſtals of tartar in a pint of water, and pouring this boiling hot upon an ounce and half of ſena, and two drams of cardamum-ſeeds, and ſtraining it off when cold. This is a much better way than the common one, with ſalt of tartar. But the other is more elegant; it is this; take ſena an ounce and half, lemon-peel freſh an ounce, lemon-juice an ounce, boiling-water a pint; let it ſtand till cold, and then ſtrain it off. *Pemberton*'s Lond. Diſp. p. 257.

INGANNO, in the Italian muſic, is uſed when the compoſer, after having done every thing proper for making a cloſe or cadence, inſtead of ſo doing places a mark of ſilence in the place of the final note. This word is Italian, ſignifying deceit.

INGESTA, is uſed by ſome authors to expreſs all ſorts of aliment taken into the body.

INGROSSING *of a Fine*, is the making of the indentures by the chirographer, and delivery of them to the party to whom the fine is levied. F. N. B. 147. *Blount*.

INGUINAL *Ligament*. This, which has been alſo called from its diſcoverer *Ligamentum Fallopii*, is an aponeurotic, or ligamentary band, faſtened by one end to the anterior and ſuperior part of the os ilium, and by the other to the ſpine of the os pubis. The middle portion of it is very narrow, but it expands conſiderably towards both its extremities. It is cloſely joined to the muſcles of the abdomen, and to the aponeurotic faſcia of the thigh, but ſeems to be often wanting. *Winſlow*'s Anat. p. 124.

INGUINALIS, in botany, a name given by ſome to the plant more commonly called *aſter atticus*. See the article ASTER *Atticus*.

INHOC, or INHOKE, in our old writers, is uſed for any corner or part of a common field ploughed up and ſowed with oats, &c. and ſometimes fenced in with a dry hedge, in that year wherein the reſt of the ſame field lies fallow and common. It is called in the north of England an *Intock*, and in Oxfordſhire a *Hitchin*. And no ſuch *Inhoke* is now made without the joint conſent of all the commoners, who in moſt places have their ſhare by lot in the benefit of it, except in ſome manors where the lord has a ſpecial privilege of ſo doing. *Kennet*'s Paroch. Antiq. 297, &c. and his Gloſſary. The word is Saxon, compounded of *In*, within, and *hoke*, a corner.

INHUMATION, (*Cycl.*) in chemiſtry, a method of digeſting ſubſtances together, by burying the veſſel in which they are put in horſe-dung, or in a dry ſandy earth expoſed to the ſun.

INJECTION, or INJECTING, (*Cycl.*) in ſurgery, the throwing in ſome liquor or medicine into a vein opened by inciſion. This practice, and that of tranſfuſion, or the conveying the arterial blood of one man, or other animal, into another, were once greatly practiſed, but are now laid aſide.

The method of *injecting* is this: A vein is to be opened in the arm with a lancet as in bleeding, and the ſmall pipe of a ſyringe being introduced at the oriſice, the liquor intended to be mixed with the blood and contained for that purpoſe in the body of the ſyringe, is to be forcibly *injected* or thrown into the vein upwards or toward the heart; which done the oriſice is to be ſecured with compreſſes and bandage as in bleeding. *Heiſter*'s Surgery, p. 304.

Whether this practice of *injecting* proper medicines into the blood may not be found of uſe in apoplexies, quinſies, hydrophobia, &c. is worthy to be tried by repeated experiments. Purman performed it upon himſelf with great ſucceſs, once curing himſelf of an itch, and once of a fever by it. And Elſholtz has written a treatiſe profeſſedly on the ſubject.

The method of *injecting* liquors into the blood of living animals, is ſaid to be the invention of Sir Chriſtopher Wren. His method was by making ligatures on the veins, and opening them on the ſide of the ligature towards the heart; then putting into them ſmall ſyringes or quills faſtened to bladders, in the manner of clyſter-pipes, containing the matter to be *injected*. Mr. Boyle ſoon made the experiment upon dogs, with infuſions of opium and crocus metallorum. All which he circumſtantially deſcribed, in his Uſefulneſs of Experimental Philoſophy, part. 2, eſſ. 2. Phil. Tranſ. N° 7. p. 128, 129.

Many diſorders of particular parts are no way curable, unleſs the parts affected are *injected* with a proper liquor, by means of a ſyringe and a proper tube. The method of performing this, is too obvious to need any directions; but theſe general cautions are neceſſary in regard to it, that the ſyringe or tube be applied tenderly and carefully to the parts, eſpecially in very ſenſible or nervous parts, to avoid giving the patient any pain; and that the liquor to be *injected*, be neither too hot nor too cold.

In ulcerations and inflammations of the uvula, tonſils, and fauces, *Injections* are generally uſeful; but care muſt be taken to preſs down the tongue with a ſpatula, or with the flat end of a ſpoon, and having introduced the ſyringe two or three fingers breadth into the mouth, the *Injection* is to be carefully and gently thrown in at ſeveral times. In gonorrhœas, *Injections* are often neceſſary, to allay the heat and ſoreneſs of the urethra, and to waſh out the matter. The ſafeſt and beſt *Injections* on this occaſion, are warm milk, and barley-water ſweetned with ſugar, honey, or ſyrup of marſhmallows; and towards the end a little ſaccharum ſaturni diſſolved in plantane-water. *Heiſter*'s Surgery, p. 317.

Anatomical INJECTIONS. Theſe are coloured in order to make the parts more conſpicuous. Mr. Monro uſes red and green chiefly. For the red, vermillion finely levigated muſt be got. For the green, diſtilled verdigreaſe is beſt; becauſe its colour is brighter than that of the common ſort, and it never runs into knots, and alſo diſſolves in oily liquors.

To make the fine *Injection*, pour a pint of the oil of turpentine on three ounces of vermillion, or verdigreaſe; ſtir them well with a wooden ſpatula till they be thoroughly mixed, and then ſtrain all through a fine linnen rag.

The coarſer *Injection* is thus made; take tallow *lb.* i. white-wax *oz.* v. oil of olives *oz.* iii. melt them over a gentle fire, then add of Venice turpentine *oz.* ij. when this is diſſolved, ſprinkle in of vermillion or verdigreaſe *oz.* iii. then paſs all through a warm linnen cloth. When you deſign to make it run far in the veſſels, add ſome oil of turpentine immediately before you uſe it.

As to the practice of *Injections*, we refer to the Medic. Eſſ. Edinb. Vol. 1. art. 9.

INIMBOY, in botany, a name by which ſome authors have called the Acacia Glorioſa, the tree which produces the bonduch or bezoar nuts. *Marggr.* p. 12.

INK (*Cycl.*)—Writing *Ink* is commonly made of copperas and galls; but other aſtringent plants may ſerve the ſame purpoſe, ſuch as oak-bark, red-roſes, log-wood, or ſumach. Mr. Boyle ſeems to doubt whether all aſtringent vegetables will do the ſame. *Boyle*'s Works abr. Vol. 1. p. 57.

Filings of iron put into ſeveral of the common vegetable juices turn them inſtantly as black as *Ink*; and hence it ſhould ſeem that vitriol only acts in the making *Ink* as a ſubſtance containing iron; which always gives a black colour to an infuſion of galls, or the like vegetable ſubſtances, and that the more deep, as it is more divided in its particles by acids. According to this rule, all thoſe vitriols which have iron for their baſis, and all ſolutions of iron in vitriolic, ſulphureous, or aluminous acids, muſt make *Ink* with galls, or a like infuſion; and the blue vitriol of Cyprus, and ſuch others as have copper for their baſis, muſt have no ſuch effect on theſe infuſions; and both theſe deductions are confirmed by experience.

In examining ſeparately the two principles of which the atramentitious vitriols are compoſed, that is, their vitriolic acid, and their baſis of the matter of iron, it appears, that the acid alone being mixed with an infuſion of galls, will never make *Ink*; whereas the baſis alone, that is filings of iron, will always do it in a little time. Hence it appears, that the acid has no ſhare in the effect, and that the whole is owing to the ferrugineous matter in the vitriol reviving again into iron. The manner in which this revivification of iron is ſo ſuddenly performed, on the mixing vitriol and the infuſion of galls, ſeems to be, that this infuſion acts as an abſorbent on the acid which had before reduced the iron to vitriol, and the ferrugineous particles being thus freed from the acid by which they were transformed into vitriol, appear again in their native form, and have the ſame effect upon the infuſion that ſimple or pure iron would have. Mem. Acad. Par. 1707.

A proof that the acids of the vitriol leave the particles of the iron in the pores of the moleculæ of the galls ſuſpended in the infuſion, and that to this reviving of the iron alone is owing the black colour of the liquor, is this; that if after the *Ink* is thus made a little freſh acid or ſpirit of vitriol be added, the particles of iron immediately receive it, which could not be, if the acid they had before poſſeſſed were not taken from them. The conſequence of their receiving this new acid is their being again diſſolved and reduced to the form of vitriol, ſo that their revivification is deſtroyed; and as this alone occaſioned the black colour of the *Ink*, this alſo diſappears, and the liquor becomes limpid and clear; vitriol in the ſtate of vitriol not being able to make a ſolution of galls black, nor that ſolution to turn vitriol into iron a ſecond time, when it has already abſorbed as much of the acid which reduced it to that ſtate as it could.

It is on this principle that verjuice, lemon-juice, and other vegetable acids take out ſtains of *Ink* from linnen; thoſe ſtains depending on the effect of plain iron, and theſe acids converting that iron into vitriol again.

It is plain from what has been advanced, that galls act as abſorbents in the making *Ink* with vitriol; nor is this the only inſtance in which they are able to act in the ſame manner; for they ſupply the place of the common abſorbents, ſuch as ſalt of tartar, lime-water, ſpirit of ſal ammoniac, and the like, in precipitating metallic ſolutions. So alſo are all the other vegetable infuſions which will make *Ink* with vitriol; but as galls make a better *Ink* than any other of the vegetable infuſions, ſo they alſo act much more powerfully than any other in the precipitating metals from their ſolutions.

It might be expected, that as galls act in the metalline ſolutions like ſalt of tartar, lime-water, and the like, ſalt of tartar and thoſe other ſubſtances ſhould act like galls in a ſolution of vitriol, and turn it into *Ink*; but the difference is, that while theſe act as mere abſorbents, and only take up the particles of acids in the vitriol, the galls act as abſorbents and ſulphureous bodies at once, taking up the acid particles and carrying them out of the ferrugineous ones, and by this means decompounding the vitriol, and leaving the iron of it revived and in the ſtate of iron. Mem. Acad. Par. 1707.

Any abſorbent or alkali, loaded with ſulphureous particles, will make *Ink* with a ſolution of vitriol in the manner of the infuſion of galls, tho' no ſimple abſorbent can. Thus the ſcoriæ of the regulus of antimony, without iron, diſſolved in a large quantity of water, give a liquor charged at once with an alkali, and with the ſulphur of antimony; and this liquor makes *Ink*, with a ſolution of vitriol, as well as galls.

In the ſame manner hot water poured upon quick-lime and orpiment, after ſtanding five or ſix hours, becomes a lime-water highly impregnated with the ſulphur of the orpiment; and this being like the other, at once an abſorbent and a ſulphureous body, acts like the former in the manner of galls, and turns a ſolution of vitriol into *Ink*. The nature of iron alſo confirms theſe opinions; we know it to be a very ſulphureous metal, and thence very ready to receive acids; and it is eaſy to conceive, that when it has once received them, and is converted into vitriol, nothing can diveſt it of them perfectly, and reſtore it to the ſtate of iron again, but a liquor equally ſulphureous, and equally ready to receive them.

Tho' many vegetable ſubſtances are able to ſupply the place of galls in the making of *Ink* with a ſolution of vitriol, yet all are not ſo; and the reaſon why the galls do it better than all the others that are ſo, is, that they are the greateſt and moſt powerful of all the vegetable abſorbents. The galls have alſo a glutinous property, which renders an infuſion of them capable of ſuſtaining the revived particles of iron. This is wanting in many of the other vegetables uſed on this occaſion; and ſuch tho' they immediately make *Ink* with a ſolution of vitriol by reviving the particles of iron, yet not being able to ſuſtain them when revived, they ſoon after ſink to the bottom, and the liquor becomes clear and limpid over them. A little gum arabic, or any thing of the like nature, added to the mixture, remedies this fault by giving them the glutinous quality of the galls; and after this the iron no more ſubſides, and the *Ink* remains good.

All vegetables are more or leſs proper to make *Ink* with a ſolution of vitriol, as they more or leſs approach to the nature of the galls, and are abſorbent and agglutinating. Of all the vegetable ſubſtances, none appear ſo good for the making *Ink* as that claſs of aſtringents, which act by thickening the humors, ſtrengthening the parts, and deſtroying the acids which irritate them. Of this kind are the cortex granatorum, balauſtines, ſumach, red roſes, acorns, and the leaves and wood of the oak; and finally, the galls. The virtues of all theſe ſubſtances in medicine depend wholly upon their being abſorbents and ſulphureous bodies, as the galls have been proved to be. The purging remedies on the other hand, produce no ſimilar effect. Infuſions of ſena, agaric, jalap, colocynth, tobacco, and white and black hellebore, have all been ſeverally tried in mixture with a ſolution of vitriol, and not one of them give the liquor any blackneſs, nor ſeem to have any tendency toward it. This confirms what has been already obſerved; for theſe purging medicines have no abſorbent quality, but, on the contrary, they all contain active and pungent ſalts, on which their purgative virtue depends. Mem Acad. Par. 1707.

On the other hand, rhubarb and myrobalans which have an aſtringent virtue, which they exert after their purging, muſt conſequently contain ſome abſorbent and agglutinating particles, and accordingly infuſions of theſe turn the ſolutions of vitriol into *Ink*.

Theſe experiments are not limited in their uſe to the making of *Ink* alone, but may be extended much farther; for if, as it appears very certain, no vitriol can make *Ink*, but ſuch as contains iron; and no vegetable can make *Ink* with that vitriol, but ſuch as poſſeſſes an aſtringent virtue; theſe two ſubſtances become teſts to one another, and may ſerve to find out the virtues of unknown ſubſtances. For inſtance, any unknown vegetable may be tried by its infuſion in mixture with a ſolution of vitriol; if it make it black, it will be known to be an aſtringent; if not, otherwiſe. And in any vitriol the teſt may be eaſily made whether it contains iron; ſince if it does, it will become black in ſolution with galls; if otherwiſe, it will not. All the vitriols of copper, or the common blue kind, and the reſt, having no power of changing an infuſion of galls into *Ink*. Mixtures of blue and green vitriol make a reddiſh *Ink*; and probably all thoſe native vitriols which make an *Ink* of the ſame reddiſh colour, contain a quantity of copper, which is the baſis of blue vitriol, mixed with their iron.

Sympathetic INKS. Every ſort of liquor with which a perſon may write ſo that the letters do not appear till there is ſome particular means uſed to give them a colour different from that of the paper, are called by the name of *ſympathetic Inks*; and of theſe there are a great many kinds deſcribed in the writings of Baptiſta Porta, Lemery, and other authors.

All theſe *Inks* may be regularly diſtributed into different claſſes, according to the different means which are to be uſed to make them appear; and theſe are in general the four following: 1. By giving a new liquor or the vapour of a new liquor a place on the paper, on which the letters are written with the naturally inviſible *Ink*. 2. By expoſing the paper to the air, by which means the letters at firſt inviſible will appear. 3. By paſſing gently over the letters a matter of ſome remarkable colour reduced to a fine powder. And 4. By expoſing the paper to the fire.

This laſt is by much the beſt method, and is ſo general, that it may be prudently uſed to all papers ſuſpected of containing any ſecret writing, as it ſeldom fails to diſcover it. All the common *Inks* of this kind however, when they have been once made to appear, either by fire or by any other method, can never be made to diſappear again; but there is one kind deſcribed by Mr. Heliot, in the Memoirs of the Academy of Sciences of Paris, and ſince tried many times with us, and elſewhere, which, tho' the letters it gives are in themſelves inviſible, and appear like thoſe of ſome other of theſe *Inks*, on their being held to the fire, yet they after that will fade and diſappear on the paper again, and may be re-produced in this manner ſeveral times. This therefore is the firſt known *Ink* of a fifth general claſs, of which future reſearches may diſcover perhaps more.

Of the firſt claſs of *ſympathetic Inks*, or thoſe which do not appear till the paper on which they are written be made to imbibe another liquor, or the vapour of another liquor, are the following kinds:

1. Mr. Lemery's orpiment kind. This is compoſed of different liquors; the letters are to be written with a ſolution of lead or litharge in diſtilled vinegar. This being dried in the air, not at the fire, does not appear at all upon the paper; if this be rubbed over with a pencil dipped in a ſolution of orpiment in lime-water, or if the paper be only made to receive the vapour of that water, the letters immediately appear and are at firſt yellow, and afterwards become black. Theſe may be made to diſappear again, if the paper be rubbed over with an acid liquor, ſuch as aqua fortis or ſpirit of nitre, and may be again made to appear, if before the paper be dried a ſolution of orpiment be again rubbed over them. It is eaſy to perceive, that all theſe effects are produced by ſucceeding ſolutions and precipitations.

2. The golden *ſympathetic Ink*. This is made by diſſolving in aqua regia as much gold as that menſtruum can take up, and then adding to the liquor five or ſix times as much water; in another veſſel there muſt be ſome tin diſſolved in aqua regia, and when that menſtruum has alſo taken up as much of the metal as it can, there is to be added to it an equal quantity of common water. The letters muſt be written on white paper with the ſolution of gold, and the writing being dried in the ſhade the letters will not appear, at leaſt not for ſeven or eight hours afterwards; dip a pencil in the ſolution of tin, and rub that over the ſolution of gold with which the letters were written, and they will appear of a beautiful purple.

It might be ſuppoſed, that any other metals which were ſoluble in the ſame acid menſtruum would equally produce this effect; but experiment ſhews, that this is not the caſe,

and

and ſilver and copper, tho' both ſoluble in aqua fortis, yet produce no change of colour by theſe precipitations made by mixing the ſolutions of them on paper; and this example of ſuch an effect in the ſolutions of gold and tin, is an exception to the general rules in the ſolutions of metals, and their effects on one another.

The purple colour of theſe letters may be again effaced by rubbing ſome ſimple aqua-regia over the paper, and may be made to appear again by rubbing over that the ſolution of tin. Kunkel, Caſſius, and Orſchal, with ſome other writers, made the firſt ſteps toward this diſcovery, by their attempt to give cryſtal, by means of gold, the colour of the oriental rubies. There are beſide theſe mineral preparations, ſome vegetable ones, which give the ſame phænomena, but theſe are the more certain.

Of the ſecond-kind of *ſympathetic Inks*, or thoſe which appear on being expoſed only to the air, is the golden *Ink* made by adding to a ſolution of gold in aqua regia, ſo much water that the liquor ſhall not ſtain a white paper; letters written with this will not appear till the paper has been expoſed ſome hours to the open air, and they will then begin to acquire a colour by degrees till they at length become of a deep violet colour tending to black.

If, inſtead of expoſing the paper to the air, it be kept in a box cloſe ſhut up, or cloſely folded in other paper, it will remain inviſible two or three months; but at the end of that time it will begin to appear, and will by degrees become of a deep violet colour. So long as the gold remains united to its diſſolvent, it is yellow; but the acid that diſſolves it being of a volatile nature, the greater part of it evaporates, and leaves no more than is juſt neceſſary to colour the calx of gold which remains upon the paper.

The ſecond of theſe is the ſilver *Ink*, made by a ſolution of ſilver in aqua-fortis, weakned by diſtilled water till it will not ſtain the paper. Letters written with this will be inviſible for three or four months, if ſhut up in a box; but if it be expoſed to the ſun it becomes legible in about an hour, becauſe by this means the evaporation of the acid is accelerated. The letters written with this *Ink* are of a ſlate colour; and that from the ſulphureous nature of the aqua fortis, every thing that is ſulphureous blackening ſilver. This blackiſh colour, however, is not permanent; for the ſulphureous part finally evaporating, the letters are left to their natural appearance, and are of a true ſilver colour, if the ſilver that was uſed was fine, and the place open.

In this claſs there may alſo be placed ſeveral metallic diſſolutions; as that of lead in vinegar, and of copper in aqua fortis, which give at length a browniſh colour upon the paper; as alſo the ſolution of tin in aqua regia, of mercury in aqua fortis, of iron in vinegar, of emery and ſeveral of the pyritæ in ſpirit of ſalt. But all theſe, tho' they give letters which are after ſome time legible on being expoſed to the air, are alſo made to appear inſtantly on the paper, on holding them to the fire. Each of theſe ſolutions gives its own particular colour; but they have all this diſadvantage, that in time they eat away the paper, and the letters are ſeen in the ſhape of ſo many holes.

Of the third claſs of *Ink*, or that which appears on rubbing over the paper with a brown or black powder, are almoſt all the glutinous expreſſed juices of plants, which are themſelves of no remarkable colours, the milk of animals, or any other thick and viſcous fluids. To uſe theſe, the letters muſt be written on a white paper, and when dry there is to be thrown over them the fine powder of any coloured earth, or other ſuch ſubſtance; and the writing will afterwards appear coloured, becauſe its viſcous quality remains ſufficiently in it for the entangling and retaining this fine powder, tho' it falls eaſily off from every other part of the paper. Mem. Acad. Scienc. Par. 1737.

Of the fourth claſs, or thoſe *Inks* which become viſible on holding them to the fire, there are a vaſt number, and indeed all infuſions, the matter of which is readily burnt to a ſort of charcoal by a little fire, will anſwer this purpoſe. The neceſt of this kind is the ſal armoniac *Ink*, made by diſſolving a ſcruple of ſal armoniac in two ounces of fair water. Letters written with this ſolution are inviſible on the paper till it is held before the fire, or has an iron a little heated paſſed over it. The rationale of this is, that the inflammable part of the ſal armoniac is burnt to a charcoal by a heat which is not ſufficient to ſcorch the paper; and this is the caſe with all the reſt of this claſs. The letters written with this ſolution are, however, of no great duration; for the ſalt being apt to moiſten in the air, the letters ſoon ſpread, and run together in a confuſed manner.

The fifth claſs of *ſympathetic Ink*, contains only one yet known kind.

This, tho' in itſelf inviſible, becomes of a bluiſh green when held to the fire, and this colour diſappears again as the paper cools, and is to be produced again on holding it again to the fire; and this for a long time, and a repeated ſeries of trying; it may alſo, according to the different manner of treating it, be made to appear blue, green, yellow, red, and of ſome other colours.

A certain German chemiſt ſhewed the Academy at Paris a ſalt of a roſe-colour, which became blue on holding it to the fire, and at the ſame time ſhewed the ore from which he procured the ſalt, which he called an ore of marcaſite, a name given by many to the biſmuth ore. He added, that this was the mineral from which the fine blue ſmalt of Sneeberg was prepared, and that no other ore but this afforded it, and that he made the tincture from this mineral with aqua fortis, which he fixed with ſea-ſalt.

This was the ſubſtance of what the German declared, and from which Mr. Heliot took the hint for his diſcovery of this remarkable *Ink*. The ſalt was after many experiments at length found to be produced from an arſenic ore; and it was found, that all the cobalts and ores of biſmuth afford a tincture capable of theſe changes by fire.

The method of preparing it is this; pour upon two ounces of arſenic ore groſsly powdered, a mixture of five ounces of aqua fortis, and five ounces of common water; after the firſt ebullition is over, place the veſſel in a gentle ſand-heat, and let it ſtand there till no more air-bubbles ſeem to aſcend; after this increaſe the fire, ſo as to make the liquor boil for about a quarter of an hour; after this the liquor will become of a reddiſh colour, and when cold it is to be decanted clear off from the ſediment into a phial; and after ſtanding in that ſome time, is to be again decanted off from what is precipitated there; and ſo on for three or four times, till it is quite clear; for it muſt not be filtered leſt the acid ſhould take ſomething from the paper that might ſpoil the effects. When the liquor is clear, there muſt be added to it two ounces of white ſea-ſalt; this mixture is to be evaporated over a gentle ſand heat, till there remains only a dry ſaline maſs. When the liquor is grown hot, it changes from its orange colour to a fair red; and when the aqueous humidity is evaporated, it becomes of a beautiful emerald colour, and from this, as it dries up, it changes by degrees to a dirty green like that of verdigreaſe in the cake. As it becomes nearly dry, it muſt be ſtirred about with a glaſs-rod or peſtle, to keep it from uniting into a maſs; and it moſt not be kept over the fire till perfectly dry, becauſe by that means the colour is often loſt, and the ſalt from green becomes of a duſky yellow; but if it be taken from the fire while it is green, it gradually becomes reddiſh as it cools, and finally is of a beautiful roſe-colour.

This is the ſalt the German produced before the Academy of Paris. This ſalt is to be put into another veſſel with a quantity of ſimple diſtilled water, and this is to be ſet alſo in a warm digeſtion, till there remains nothing but a white powder precipitated to the botom, which is the ſtony part of the ore uſed in the preparation, the ſalt having been all taken up by the water. If the firſt quantity of water does not take up all the ſalt, but leaves the precipitate coloured, it muſt be poured off and more put on, till all the ſalt is diſſolved. Eight or nine ounces of water is the uſual proportion to the ſalt made from an ounce of the tincture; and if the ore that was uſed has been a good one, this quantity of liquor will be of the colour of the lilac flowers. If the ore has contained copper, which is the caſe in a great many of the biſmuth ores, the liquor will ſtill produce its effects as a *ſympathetic Ink*; bnt it will be of a bad colour; and if look'd on in the bottle it will appear of different colours according as it is held with regard to the light, like the infuſion of the nephritic wood. This liquor does not retain its virtue ſo long upon the paper as that which has been made from a purer ore, and which in the bottle appears the ſame in all lights.

The manner of uſing this *ſympathetic Ink*, is this: Write with it on a fine and ſmooth paper, or draw with a black lead pencil the figure of a plant or tree on the paper, then trace over the ſame lines with this liquor; let it dry in the open air, and then rub off the black lines with bread, and the paper will appear altogether fair, tho' the lines made by the *Ink* are in reality ſunk deep into it. On holding this paper to the fire the lines will all appear, and the figure of the plant or the letters will be painted in a beautiful bluiſh green, which will continue ſo long as the paper is warm; but when it is cold again, they will wholly diſappear. The lines therefore diſappear much ſooner in winter than in ſummer; and in very hot weather it is often neceſſary to lay the paper on a marble, or other very cold body, in order to produce this effect. At any time if the paper be ſcorched in the experiment, the colour of the lines will not diſappear again, even if ice be laid upon them. If the writing be expoſed for three or four days to a humid air, the lines will appear of a fine pale red. If the impregnation of the ore of biſmuth, inſtead of ſea-ſalt, have alum added to it, and the whole proceſs be continued as before deſcribed; and if letters be written with the red liquor as it is taken out of the veſſel, the letters will not appear even on holding it to the fire; but if the paper be wetted over with a clear ſolution of marine ſalt, and then left to dry, and afterwards held to the fire, the letters will appear blue. The ſame alſo will be the effect, if the writing be expoſed to the vapour of hot ſpirit of ſalt. When this preparation is thus made with alum, inſtead of common ſalt, the liquor never becomes green, but continues red, and never changes colour in the drying,

drying, or afterwards. The green colour ſeems to be wholly the effect of the ſea ſalt; for not only this aluminate impregnation, but others in which other ſalts had been employed, were always found to be of a different colour.

Glauber's ſalt uſed inſtead of common ſea ſalt, left the maſs red in the ſame manner as alum did. Nitre added inſtead of ſea ſalt, gave the precipitate or dried ſalt of a beautiful purple colour, which became white on the inſtant that water was poured upon it, and a roſe coloured tincture was drawn from it, which gave lines or letters on paper, which continued inviſible as long as they were cold, but aſſumed a beautiful red on holding the paper to the fire; which colour they retained no longer than while the paper continued warm, diſappearing afterwards in the ſame manner with the green colours made by the ſea ſalt; and if a ſimple ſolution of ſea ſalt be rubbed over the paper, and ſuffered to dry, and the paper be afterwards heated, the lines appear blue. Borax has the ſame effect in this preparation with the nitre. All theſe experiments were made with the neutral ſalts; but in order to try what would be the effects of alkalies in the mixture, Mr. Heliot added to three ounces of the impregnation of the ore in aqua fortis, pure ſalt of tartar, till the ebullition ceaſed; but the conſequence of this was no great precipitation, but merely the ſubſiding of a ſmall white ſediment; this mixture being evaporated nearly to a dryneſs, the remaining maſs, ſo long as it was warm, appeared of a beautiful purple; but this became paler as it dried, and turned white in an inſtant on pouring water upon it. This, diſſolved in water in the manner of the others, gave lines on paper of a faint roſe colour, which appear'd or diſappear'd in the manner of thoſe made by the other ſolutions, according as the paper was hot or cold; and the wetting the paper with a ſolution of ſea ſalt, had the ſame effects on this as on the others, making the lines appear blue on holding to the fire. Mem. Acad. Par. 1737.

Indian INK. The Chineſe have often attempted to uſe this in their porcelain, to give the colour of black to the figures traced on white veſſels, but it has been a vain attempt; for however beautiful and ſtrong the figures might appear when firſt laid on, and even when the veſſels were dried, it all diſappear'd on the baking, and they came out quite white as they were put in. The colours for this uſe muſt be ſuch as can penetrate the varniſh, and endure the fire. Mineral colours alone are found to have theſe qualities, and theſe alone therefore are to be employed; ſuch light ones as this black burning off from the ſurface, and wholly diſappearing. Obſ. de les Coutumes de l'Aſie. p. 329.

INLAGATION, *Inlagatio*, a reſtoring of one out-lawed to the protection of the law, and benefit of a ſubject. *Bract.* lib. 3. tract. 2. c. 14. Leg. Canut. par. 1. c. 2.

The word comes from the Saxon *In-lagiam*, i. e. *inlagare*. Terms of law. *Blount*, *Cowel*.

INLAGH, *Inlagatus*, he that is of ſome *frank-pledge*, and not out-lawed. It ſeems to be the contrary to *Utlagh*. *Bract.* tract. 2. lib. 3. c. 11. Terms of law.

INLEASED, in our old writers, ſignifies entangled or enſnared; it is uſed in the champion's oath. 2 Inſt. 247. *Blount*.

INN, or INNER, in the manege, is applied differently, according as the horſe works to the right or left upon the volts, or as he works along, by a wall, a hedge, or the like. For along or by a wall, the leg that is of a ſide with, or next the wall is the outer, and the other the *in* or *inner* leg. And if upon volts, the horſe works to the right, the right heel is the *inner*, and the left the outer heel, and ſo of the other parts of the body, furniture, &c. The direct contrary of this will happen, if the horſe works to the left.

INNOMINATA *Oſſa*. See the article OSSA *innominata*.

INOCULATION, or INOCULATING, *(Cycl.)* in gardening, an operation in the propagation of trees, uſually practiſed on all ſtone fruit, and commonly known by the name of *budding*. Peaches, nectarines, cherries, plums, &c. as alſo oranges and jeſamines, ſucceed very well this way, and it is indeed preferable to any other for fruit trees in general.

The method of performing it is this: The operator muſt be provided with a ſharp penknife having a flat haft, the uſe of which is to raiſe the bark of the ſtock to admit the bud, and ſome ſound baſſinat, which ſhould be ſoaked in water to encreaſe its ſtrength, and make it more pliable. Then having taken off cuttings from the trees to be propagated, a ſmooth part of the ſtock muſt be choſen, which if intended for dwarfs, muſt be about five or ſix inches above the ground, but if for ſtandards, it ſhould be as many feet high. A horizontal cut is then to be made croſs the rind of the ſtock, and from the middle of that another ſlit muſt be made ſtrait downward of two inches in length, that the whole may have the figure of the letter T, but theſe muſt not be cut too deep. Then cutting off the leaf from the bud, but leaving its foot-ſtalk remaining, a croſs-cut is to be made on it about half an inch below the eye, and the bud is to be ſlit off with part of the bark to it, in form of an eſcutcheon. The wood then muſt be taken out of the ſlip of the bud, without pulling the eye of the bud out with it, for if this happens, the bud muſt be thrown away as uncapable of ſucceeding. When the bud is thus prepared, the bark of the ſtock is to be gently raiſed with the flat haft of the penknife, and the eſcutcheon of the bud muſt be ſlipp'd in, and placed very evenly between the bark and the wood, cutting off any part of the rind of the bud which may be too long for the ſlit made in the ſtock. The whole is then to be gently tied up, beginning at the lower part of the ſlit, and taking great care not to injure the eye of the bud, which is to be left out at the ſlit. In three weeks or a month the bud will ſhew that it is joined, and then the tying round the ſtock muſt be looſened; and in the March following, the ſtock muſt be cut off about three inches above the bud, ſloping it that the wet may run off. To this part of the ſtock the ſhoot proceeding from the bud is to be tied, leſt the winds ſhould looſen or diſplace it; and when the tree has ſtood one year in this ſtate, the ſtock muſt be cut down cloſe to the bud.

The ſeaſon for *inoculating* is from the middle of June to the middle of Auguſt, according to the forwardneſs of the trees. When the buds are formed at the ends of the ſhoots of the ſame year, it is a proof that the tree is fit for the purpoſe; the firſt tree that comes in ſeaſon to be *inoculated* is the apricot, and the laſt the orange tree: And in doing this, choice ſhould always be made of a cloudy day, that the ſun may not dry up the buds too quick; and in ſome very tender plants, a part of the wood in the ſcutcheon of the bud ſhould be left in. *Miller*'s Gardener's Dict.

It is ſaid by many, that ſuch trees as are *inoculated* in the month of February, will continue always free from worms, both themſelves and their fruit; but this is a thing not confirm'd by experience. Another error in theſe things is, the opinion that a cyon taken from a young tree which has never yet bloſſomed, will never bear fruit; experience proves that it will; but our gardeners chooſe rather to take their cyons from ſuch trees as have already borne. Phil. Tranſ. N°. 2.

In the *Inoculations* made upon fruit trees, it is obſervable, that a little vegetable bud, often not ſo big as a pea, is able ſo to tranſmute all the ſap which arrives at it; that tho' this ſap be already in the root, and in its paſſage upwards, determined by nature's intention, as is ſaid, to the production of fruit natural to the ſtock, it ſhould yet, by ſo ſmall a vegetable ſubſtance, be ſo far changed, as to conſtitute a fruit quite otherwiſe qualified than the genuine product of the tree; which at the ſame time, is actually produced by thoſe other portions of the like ſap, that happened to nouriſh ſuch prolific buds, as are the genuine offſpring of the ſtock; ſo that the ſame ſap, which in one part of a branch conſtitutes a cluſter of haws, in another part of the ſame branch may conſtitute a pear. And what is farther remarkable, not only the fruits made of the ſame ſap often differ from one another in ſhape, bigneſs, colour, odour, taſte, and other obvious qualities, but tho' the ſap itſelf be a wateriſh and almoſt inſipid liquor, yet it is not only convertible by buds of ſeveral natures into different fruits, but in one and the ſame fruit, the tranſmuted ſap ſhall by different textures, be made to exhibit very different, and ſometimes contrary qualities. As when a peach-bud not only changes the ſap which comes to it, into a fruit very different from that which the ſtock naturally produces, but into parts very different from one another in the ſame fruit.

From *Inoculations* therefore we learn, that a liquor ſeemingly homogeneous, may, by being variouſly ſtrained, be tranſmuted into bodies endowed with new ſcents, colours, taſtes, ſolidity, medicinal virtues, and many other qualities, manifeſt and occult. *Boyle*'s Works abr. Vol. I. p. 250.

INOCULATION, in medicine *(Cycl.)*—The Chineſe ſeem to have had the method of *inoculating* the ſmall-pox, long before it was introduced into this part of Europe. Their method of proceeding is this; they gather the ſcabs which come off from an healthy child, who has had the ſmall-pox in a favourable way, and keep them well ſhut up in a china-cup, till there is occaſion for them; then taking four ſmall ones, or two large ones, and putting a grain of muſk between them, they roll them in a little cotton, and thruſt this tent into the child's noſe, where it remains till the ſymptoms of infection begin to appear. The child is to be more than a year old. If the puſtules appear on the firſt day of the fever, the child almoſt certainly dies; if on the ſecond, the event is uncertain; if they do not ſhew themſelves till the third day, the patient probably recovers. Letr. Edif. & Cur. Tom. 20.

INOSARCION, in natural hiſtory, a name given by the old Greek and Roman authors to a peculiar ſpecies of emerald, called alſo by ſome the Chalcedonian emerald. The great diſtinction of this from all the other kinds of this gem, was its not being of the pure, clear, and unvarying colours of the others, but having thick veins in it, which gave peculiar refractions and reflexions to the light; and tho' the ſtone was in itſelf wholly green, yet when viewed in ſide-lights, theſe veins gave all thoſe changeable colours that ornament the feathers of a peacock's tail, or the neck of a pigeon.

INSAG, in natural hiſtory, a name given by the people of the Philippine iſlands, to one of the ſeveral ſpecies of Parrots, common in their woods. The *Inſag* is a very beautiful bird; its body is of a very bright green, and its head of a fine florid red.

INSCHI, or INSCHI *Kna*, in the materia medica, a name given by ſome authors to the common ginger.

INSECTS (*Cycl.*) make one of the claſſes of animals, the characters of which are, that their body is covered with a ſort of bony ſubſtance inſtead of ſkin, and their heads are furniſhed with antennæ, called horns. *Linnæi* Syſtem Nat. p. 83.

Eyes of INSECTS. The bounty of nature in giving eyes to theſe ſmall animals is amazing; they have often beſide the reticular large eyes, which make ſo conſiderable a part of the bigneſs of the head, other ſmall ones placed triangularly above or below them. Theſe reticulated eyes however are the moſt amazing of all, and are in a manner common to the whole *Inſect* world. Many authors have deſcribed them, but none ſo accurately as Reaumur in his hiſtory of *Inſects*. He has given his deſcriptions from the eyes of the butterfly kind, but they equally ſerve as the general deſcriptions of all the reſt. *Reaumur*'s Hiſt. Inſect. vol. 1. P. 1. p. 261.

Theſe reticulated eyes always form a part of a ſphere: This in ſome ſpecies is a larger, and in others a ſmaller portion; and conſequently ſome are more, and others leſs prominent, and they are larger or ſmaller in proportion to the ſize of the head in the different ſpecies. The external covering of theſe eyes, which by its poſition and uſes may be called the cornea, has a ſort of gloſs on it, which often ſhews all the rainbow colours, as it is differently turned to the light: And the colour that makes the baſis of theſe, and appears the general colour of the eye in a common light, is black in ſome ſpecies, brown in others, and in others grey. Sometimes a changeable aſſemblage of ſeveral colours ſerves in the place of a ſimple one, even in this view. A view of theſe eyes by the naked eye ſhews us that their ſurface is not even or ſmooth, but dotted all over; but when we bring them before the microſcope, the ſtructure is found to be truly wonderful. The whole ſurface then appears to be reticulated, and the ſeveral meſhes of the net all regularly of the ſame ſize. The middle of each meſh is not empty but filled with a globular body, the ſurface of which ſtands up above the level of the reſt, ſo that the whole cornea or external ſurface of the eye, appears no other than a multitude of little globular bodies, ſtuck into a ſubſtance proper to retain them in their proper places; and the matter in which they are placed forms a rectilinear figure ſurrounding them, which is ſquare in ſome ſpecies, and hexangular in others. The whole cornea may be therefore compared to a glaſs cut into a number of convex faces; or in properer terms, the cornea may be ſaid to be compoſed of a prodigious number of cryſtallines, arrang'd in a beautiful order cloſe together. The number of cryſtallines that go to the formation of one of theſe eyes, is ſcarce to be conceiv'd; but as different authors have been at the pains of counting them in different *Inſects*, and as our own obſervations may at any time evince the truth of each calculation, there is no doubt of the reality of them. Lewenhoeck counted 3181 in the ſingle eye of a beetle, and 8000 in the eye of a fly. Mr. Puget, an author of great accuracy, counted 17325 in the eye of a butterfly; and Malpighi, from the moſt careful obſervations, and analogy with the parts of other animals, declares each of theſe to be a diſtinct and ſeparate eye; ſo that inſtead of the vulgar opinion of a butterfly's having no eyes, we find it has in reality no leſs than 34650. And the ſucceeding obſervations of the curious in microſcopes, have found that every one of theſe eminences in the cornea of *Inſects*, has all the neceſſary parts, and performs all the offices of an eye.

The accuracy of the Abbé Catalan, and after him of ſeveral others, has yet gone farther in the obſervation of theſe eyes. They have pick'd out a ſingle one from the net, and making it clean, have examined and found it to have all the properties of an eye. The whole cornea may alſo be cut off, and waſh'd clean on the inſide by means of a ſoft pencil and warm water; and when perfectly clean'd in that manner, it becomes beautifully tranſparent, and if held up in the apparatus of a microſcope, and pointed againſt any object, it multiplies and diminiſhes it in ſize in a manner not to be deſcribed, and with a beauty not eaſily conceiv'd. A ſingle ſoldier viewed thro' it, gives the appearance of an army of pigmies; and the arches of a bridge are ſo multiplied in number, and appear ſo elegantly diſpos'd over and about one another, as that they make an object of beauty ſcarce to be deſcrib'd. The light of a candle viewed thro' it, is ſeen elegantly multiplied into an immenſe number of candles; and indeed none of the common multiplying glaſſes, nor any that can be made by art, can ever ſhew ſuch a number of faces. *Reaumur*'s Hiſt. Inſ. vol. 1. P. 1. p. 267.

The exiſtence of theſe numerous cryſtallines is then a point no longer to be doubted, and authors have gone yet farther in their obſervations and gueſſes concerning them. Lewenhock diſcovered the bundles of optic nerves which ſerve theſe ſmall lenſes; and Reaumur ſuppoſes theſe nerves to ſupply the place of all that is wanting behind the lenſes, for the organiſation of an eye compleat for viſion; and he thinks that the tunica choroides being of different colours in different *Inſects*, is the reaſon why we ſee their eyes of different colours.

We ourſelves ſee objects with two eyes at once, and yet thoſe objects appear ſingle to us; and the ſame mechaniſm that makes us ſee them ſo, may make the *Inſect* claſs ſee them ſingle alſo, tho' they ſee them thro' many thouſands of eyes at once.

The uſes of theſe numerous eyes to theſe ſmall animals are obvious; and as they are in continual want of food, and in continual fear of enemies, it is extremely proper that they ſhould be well prepared to be aware when either the one or the other is near. It has been ſuppoſed by many naturaliſts, that the eyes in theſe corneæ are ſo ſmall and convex, that they can only ſerve the creature to ſee very near objects, and muſt magnify them extremely; but obſervation ſhews that a ſingle eye of theſe held in the focus of a microſcope, ſerves with the lens in that apparatus to ſee diſtant objects diminiſhed. We alſo know, that two convex lenſes of great power, may be ſo combin'd as to ſhew diſtant objects very diſtinct, and diminiſhed in ſize, not magnified; ſo that we find ſuch eyes may be made to ſerve ſuch purpoſes, and we have no reaſon to doubt, but that what we are able to do by art, is much better done in them by nature.

Among all the naturaliſts who have been converſant in microſcopes, none could miſs obſerving and admiring ſuch a wonderful ſtructure and organiſation as that of theſe parts; all have obſerv'd them, but ſome have been of opinion that they are not really eyes; there is however no doubt, but that parts ſo beautifully and nicely organis'd, muſt ſerve to ſome ſenſation, and to what other ſenſe except that of ſeeing, can their frame and ſtructure ſeem to point? Mr. De la Hire was one of the firſt who doubted whether theſe reticulated parts were eyes; for obſerving that flies had beſide theſe three lucid points in the front of their heads, he concluded that thoſe points were eyes, as indeed they certainly are; and taking it for granted that three eyes of this kind were enough for ſuch an *Inſect*, he concluded that the other reticular bodies were not eyes; but it having been ſince obſerved, that all *Inſects* have not theſe other ſmaller eyes diſcovered by Mr. De la Hire, and particularly that the whole butterfly claſs wanted them, and therefore that ſomething elſe certainly ſupplied their place, and what ſhould do that but theſe reticular eyes?

A fly is indeed ſurprizingly furniſhed by nature with the organs of ſight; it has two large and reticulated bodies, each of which contains many thouſands of eyes; and beſide theſe, has not barely three, but has twelve, fifteen, or more of theſe ſingle brilliant eyes, placed in ſeveral parts of its head.

The ſpider has alſo a great number of theſe lucid or brilliant ſingle eyes, and they are placed in different parts of the head, and are of different ſizes, ſo that it ſhould ſeem as if nature has furniſhed them with different eyes, ſuited to different purpoſes, ſome being of uſe to ſee near objects, and others the more diſtant; and that theſe creatures inſtead of eyes deſtined like ours for the ſame purpoſes, had microſcopes and teleſcopes always in readineſs for their ſeveral occaſions.

In the butterfly claſs, there are ſeveral which have a great number of hairs growing on the reticulated bodies, placed on the ſides of the head; theſe hairs have been urged by thoſe who were unwilling to allow the reticulated bodies to be eyes, as a great objection to the received opinion of their being ſo: But the anſwer is eaſy, that tho' if each of theſe reticulated bodies was a ſingle eye, the viſion muſt neceſſarily be troubled by ſuch a number of hairs growing in the midſt of them; yet as they appear to be in reality each compos'd of a vaſt multitude of eyes, theſe hairs may perhaps ſerve only in the office of eyelids to them, and that their breaking off a part of the rays of light may be no injury to viſion, but even neceſſary to eyes of ſo tender a ſtructure. *Reaumur*'s Hiſt. Inſect. vol. 1. P. 1. p. 273.

Anatomical uſe of INSECTS. The *Inſect* world affords us numerous uſes, and thoſe many of them ſuch as no one would at firſt thought imagine, and which no other operations or operators could ſo well effect. In the minutiæ of anatomy, where knives cannot be introduced, the maggot or the ant may be employed with great ſucceſs. Skeletons of fœtus's have been prepared by burying them in an ant-hill, and that in ſo accurate and perfect a manner, that all who have ſeen them, have admired by what means they could be ſo nicely finiſhed; and the ſecret of the great Ruyſch, by which he cleared away the parenchymatous ſubſtance from his vaſcular preparations, was of this kind. After injecting the veſſels of any part with wax, all that remained to the compleating theſe preparations, was the taking off the parenchymatous or fleſhy matter from between and among them. Other anatomiſts of his time did this by the knife, or by maceration in water, and other liquors; but it appeared a ſort of magic to them, that his were always not only much ſooner executed, but to a greater nicety and perfection than theirs ever poſſibly could be. His method was only to put a number of the common fleſh-eating maggots, to the ſubſtance; and theſe regularly eat away all the fleſh, their heads getting into crevices which no inſtrument could reach, and the whole ſubſtance of the injection remained unhurt, as their ſoft bodies could glide between its niceſt parts without injuring them; and the wax being no food for them, was in no danger of being eroded, even in its ſmalleſt pieces. The ſeveral

ſizes of the worms or maggots bred from the eggs of different flies were of great uſe in the perfecting the preparations; for while the larger ſort eat the more fleſhy parts, where the veſſels are large and but few in number, the middle-ſiz'd maggots got into the interſtices of the more vaſcular parts, and the moſt minute of all, which are uſually alſo the moſt numerous, kept about the ſurface, and eat away between and among the capillary veſſels. *Hebenſtreit* de Vermibus Anatomicor. adminiſtris.

The maggots produced from flies are not the only animals fit for this kind of buſineſs. There are ſeveral ſpecies of beetles of the ſmaller kinds, whoſe eggs hatch into a ſix-leg'd worm, which eats as much and as nicely as the fly-maggots. All theſe may be employed very ſucceſsfully to the preparations of the parts of animals.

Theſe nice anatomiſts are not confined to animal ſubſtances: They often exert their power alſo on vegetables. Many of them feed on the leaves and fruits of plants; and ſome ſpecies of theſe work ſo nicely, that they eat away all the outer membrane and internal parenchymatous ſubſtance of the leaves, ſo as only to leave the net-like plexus of veſſels ſtanding. Yet theſe being unhurt ſhew the true figure of the leaf, and are a ſort of vegetable ſkeletons, but very poorly imitated by art in the common way, by long macerations in water; this method uſually deſtroying and waſhing away many of the ſmaller veſſels, which the tender mouths of theſe creatures ſpare. If they exert their ſkill often upon leaves in this manner, they do it alſo ſometimes with equal if not greater ſucceſs upon fruits. As in the leaves, thoſe which have the tendereſt parenchyma and the firmeſt ribs, ſucceed beſt; ſo alſo it is in fruits. The leaves of the ruſcus or butcher's-broom, are often found thus beautifully anatomis'd; and of all fruits, none ſucceeds ſo well as that of the ſtramonium, or thorn-apple. Where-ever this plant grows in any plenty, the fruit toward autumn while it is yet full of juice is attacked by a ſmall worm, which eats away all the parenchyma, and leaves every veſſel ſtanding in its place; and this not only in the outer coat of the fruit, but in the very inner cells of the ſeeds. Theſe veſſels remain exactly in the ſhape of the fruit, and, growing white with the air, exhibit the moſt elegant and beautiful ſkeletons imaginable, while yet ſtanding on the plant. The animal which effects this, is a hexapode worm produced from the egg of a ſmall beetle; and differs very little from ſome of thoſe which ſo elegantly eat away the fleſhy parts from the injected anatomical preparations. Theſe are gregarious animals like ſome ſpecies of the ſmaller caterpillars, and numbers of them are always at work together on the ſame leaf or fruit, ſo that the ſkeleton is ſoon made. They begin by piercing a number of little holes into the ſubſtance of the leaf, and thence burrow under the integument till they meet one another; and this being done all over the leaf, they leave it, and go to work upon another.

Transformation of INSECTS. See the article TRANSFORMATION.

INSECTS *in Amber*. Scarce any thing in natural hiſtory has more perplexed the writers on that ſubject, than the finding *Inſects* intombed in amber. Naturaliſts were, for a long time not well acquainted with the true nature and origin of the ſubſtance itſelf; and while they made erroneous conjectures about it, there was no great hope of their falling into the true account of its receiving theſe creatures. Pliny mentions a lizard, and Martial a whole viper buried in amber; and Mercatus in the Metallotheca Vaticana, and ſome other writers, have deſcribed and figured ſmall fiſhes in it. The account of a whole viper muſt needs be a mere chimera; and the other large animals, which are pretended to be buried in it, the effect of fraud. Some artful perſon finding means to ſplit the amber, and making a hollow to receive the creature, cloſed it together again, perhaps by means of heat, and then poliſhed over the ſurface to conceal the cheat.

Tho' the larger animals are not to be expected to be found naturally included in amber, yet we have daily and inconteſtible proofs, that *Inſects*, and thoſe of ſeveral kinds, continually are ſo. *Hartman*'s Hiſt. Succin.

There is one very eaſy way of diſtinguiſhing alſo whether theſe are real and natural curioſities, or whether art has been concerned in them; which is by examining at what depth in the maſs the creature lies. *Inſects* naturally embedded in amber, are always found near its ſurface, or at leaſt, there are few found otherwiſe. The artificially buried creatures are always lodged in or near the center. The reaſon of this is plain; for the artiſt knows that the deeper the creature lies, the better his art will be concealed; and that if he had lodged it near the ſurface, the natural tranſparence of the thin plate of amber which lay over it, would have ſhewn the fallacy by bringing the artificial hollow too near the eye. Phil. Tranſ. N° 248. p. 21.

The too great beauty, ſolidity, and perfection of the piece of amber, in which an *Inſect* lies, is alſo a very great reaſon to ſuſpect that there is fallacy in the caſe. When the artiſt is at the pains of introducing a fly into a piece of amber, it is moſt worth his while to chuſe out a fine ſolid and tranſparent piece for it; becauſe it will ſell beſt when done, and will bear his working on it better than a coarſe and ſhattery one. But nature who has not quite ſo much conſulted the fancy of the purchaſer, generally has lodged theſe animals, or parts of them, in the leſs ſolid pieces of amber, and ſuch as have flaws and cracks. A perfectly uniform and ſolid piece of amber with an inſect in it, may generally therefore be condemned as artificial; for the natural amber that has theſe creatures embodied in it, is uſually compoſed of a number of cruſts or coats, but imperfectly cohering together, and has often cracks and clefts in it reaching to the ſurface, and the legs or wings or ſome part of the included *Inſect* often hangs out from the ſurface. When a piece of coarſe amber is found with an *Inſect* thus bedded in it, the whole may be concluded the work of nature alone, and the ſpecimen a truly valuable curioſity. There are ſome finer that are natural, but they are very ſcarce. The *Inſects* really buried by nature in amber make a very different appearance, in regard to the manner of their preſervation; for ſome of them are ſeen in all their beauty and natural ſplendor; others have nothing of this, but have a coat of ſhining amber thinly ſpread over them, and the whole maſs covering that, they reſemble amber-flies in other amber; but a great many are foul and imperfect. Phil. Tranſ. N° 248. p. 21.

Their poſtures alſo, are as various as their appearance; ſome ſeem as if they had been torpid or dead, when taken into the amber; others have the appearance of having been taken in alive, their limbs being extended, and the whole creature appearing as if ſtruggling hard to get out of the priſon. Some pieces of amber contain a ſingle and perfect *Inſect*, others have a mutilated *Inſect* or a part of one only, and the ſingle leg or wing of a fly is more common than any thing elſe; but on the other hand, there have been found pieces of amber, containing each a large number of *Inſects*, and thoſe ſometimes all of the ſame ſpecies, ſometimes different. *Hartman*'s Hiſtoria Succini.

Theſe are the general appearances of the real and of the fictitious curioſities of the amber kind. The reality of many is unqueſtionable; and many authors in order to account for their coming there, had recourſe to the ſuppoſition of amber's being the reſin of ſome ſpecies of tree. They thought, that as this reſin ran down the trunk, the fly might be taken and included in it; but this is not only a falſe account of the origin of amber, but if it were true, it would not clear up the point: for of all the reſins which we know, and which are continually dropping from trees, where *Inſects* in abundance are alſo found, we never ſee any of them thus intomb'd. Philoſ. Tranſ. N° 248. p. 23.

Others, who ſaw the weakneſs of this argument, have aſſerted, that thoſe things which appear to be *Inſects* in amber, are not really ſuch, but that we miſtake the cracks and flaws in the amber for real bodies. But this ſuppoſition is eaſily proved to be equally erroneous, by examining the bodies themſelves in broken pieces of the amber; in which they will be found really and truly animal remains, and in every part of the ſame internal ſtructure with that of the animal itſelf. The true account of the matter is, that the amber itſelf is a foſſile ſubſtance and bitumen condenſated into a ſolid body, and that this is done in the earth.

We often find, that flies, bees, ants, and other *Inſects*, in bad weather betake themſelves to the ground, and bury themſelves alive remaining in a torpid ſtate, perhaps during the whole winter, perhaps for a ſhorter period of time. During this time amber is formed by the condenſing a fluid bitumen into a ſolid ſubſtance; and if while fluid it falls on the places where the *Inſects* lie, it muſt needs incorporate them into itſelf, and ſhew them in its hardned ſtate. The greater part of the *Inſects* found naturally included in amber, are of thoſe kinds which we know do thus hide themſelves in the earth in winter. And it is from hence, that the generality of *Inſects* in amber are found in a contracted poſture, ſuch as they lie in during their ſtate of reſt. Some few indeed ſeem as if they had ſtruggled in order to ſet themſelves at liberty; theſe are probably ſuch as were entangled in the tough bitumen, either at the time of their firſt coming into the earth, or near the period of their ſtay there, when they either had not yet fallen into the torpid ſtate of the others, or were rouſing out of it. Some pieces of amber are ſhewn indeed in the cabinets of the curious, containing flies in very lively poſtures, and ſome with the male and female in coition. The firſt of theſe are to be greatly ſuſpected as impoſtors, and the latter wholly condemned as ſuch. For the time during which the creatures are buried under ground, and half dead with the cold, is certainly not the ſeaſon for propagation. See the article SUCCINUM.

Aquatic INSECTS. There is an *Inſect* of a very peculiarly amphibious kind, which Mr. Reaumur has accurately deſcribed in the Memoirs of the Paris Academy. Many animals are aquatic for a part of their lives, and paſs the reſt on dry land; but this ſingular creature always contrives to have its head and tail both in the water, and the intermediate part of its body out. To conceive the manner in which this is effected, we muſt conſider its figure. It is compoſed, like

many other of these small animals, of several rings or joints; it has eleven of these between its head and its tail; they are all roundish, and very well resemble a string of beads. The creature is almost always in a bending figure representing a syphon; its head and tail are always placed near one another, while the body is elevated and forms an arch above them. The head, the tail, and the ring joining to the tail, are the parts constantly kept in the water; and the nine other rings, or at least seven of them, lie upon dry land. The constant habitation of the animal, is at the edges of standing waters. It constantly draws back if more of the body is wetted, and plunges in deeper if less than the allotted portion is so. The animal is not more than two thirds of an inch long: it is therefore much better distinguished when kept in a vessel of water, than while it is in a pond. The uneasiness of the creature at being too much or too little immersed, is easily seen; for if the vessel be sloped so as to drain the water from it, it very speedily follows it down the side of the vessel; and if it be sloped the contrary way, so as to make the water cover it too far, it as readily climbs up to get in part out of the reach of the water. Its manner of moving is very particular; for neither the head nor the tail seem concerned in it, but the highest part or sixth ring of the body, which in its crooked state makes the summit of the arch, is what moves first, and draws all the other parts to follow it, the creature continuing in its bended posture while it moves. It does not move by vermicular progression, as some animals do; but has regular feet. These indeed are so small as not to be distinguishable without the assistance of glasses; but when seen, they are found to be one of the great singularities of the animal. Mem. Acad. Par. 1714.

The feet, contrary to their position in all other animals, are in this creature placed upon its back. Hence the creature naturally lies down upon its back as other creatures do upon their bellies, and as it lies the mouth and the anus turn upwards. But this is not peculiar to this animal, for there are some flies, and other water *Insects*, which always swim upon their backs, and have their mouths pointed upwards, that they may take their food, which is usually placed above them; and the same reason is to be given in regard to this *Insect*. Its feet are ten in number, placed on the separate rings, two on a ring. There are only four between the sixth ring and the head; but these are larger than the other six. They are very short, and much resemble the slender legs of silk-worms, or other caterpillars; and their extremities are in the same manner flatted, and armed with numbers of little hooks. The four first legs are bent towards the head, and the other six are bent the contrary way, or towards the tail. There is great providence in this disposition of them; for as the creature is usually in an arched posture and moves in that figure, the ten legs tho' they are placed contrary ways in regard to the head, are all placed in the same direction in regard to the sixth ring, which is as the head to other animals, the part which begins all motion. By this disposition of the legs the animal has a greater variety of motion, than any other creature; for in an extended posture it can run with equal swiftness backwards or forwards, by using the one or the other set of its legs; and in its arched position it can, beside the common motion forwards, move sideways either to the right or left with great facility, which is of great use to it when it wants to change its place, by moving only a little way. Beside all those motions, it has also the power of swimming like other worms, which it exerts by turning and twisting its body about when it is by any accident plunged all over in the water. This, however, seems an unnatural position to it, and it never seems to get into it but by constraint, and then always gets out of it again as soon as it can, by swimming to the side. It is almost continually feeding, tho' its morsels are but small, being only such animalcules as microscopes discover in waters.

The belly of this *Insect* is of a deeper brown than its back, and the rings have on this side certain spots surrounded with short hairs, in the manner of the tracheæ of several *Insects*, and probably they serve the animal for the same purpose of respiration. The back is white and transparent, and its rings have none of these marks; but they beautifully shew by their transparence what passes in the body of the animal. There may be observed near the anus a pipe, or circular canal, like the piston of a syringe, which is continually playing, and approaching to or receding from the anus. The same sort of motion is also perceived within the third ring of the body, in a pipe or canal, which seems only a continuation of the former, and possibly the heart of the creature is situated there. Mem. Acad. Par. 1714.

Musk-INSECT. See the article MUSK.

Hearts of INSECTS. See the article HEART.

INSIDIANT *Diseases*, a term used by some authors, to express such diseases as shew no evident symptom, but remain latent a long time in the body, and are ready to break forth in an unexpected manner, and as it were by surprize.

INSTEP, in the manege, is that part of the hinder leg of a horse, that corresponds to the shank in the fore-leg, extending from the ham to the pastern joint.

INSTITA, a word used by the chirurgical writers, for a fillet or other bandage of that kind; and by medicinal writers, for that sort of flat worms bred in the intestines, called by many the tape-worm, or flat-worm. *Cast.* Lex. Med. in voc.

INSTITUTORES, in botany, that set of authors in this science who have laid down certain settled rules, axioms, and institutions in it. *Linnæi* Fund. Bot. p. 2.

INSTRUMENT (*Cycl.*)—*Pocket*-INSTRUMENTS, in surgery. See the article POCKET.

INSUFFLATIO, a term used by some writers in medicine, to express the blowing into any part, in order to convey the fumes of medicines into it.

INSULTUS, a word used by the writers in medicine to signify the access of the paroxysm in intermittent diseases; or sometimes the first invasion of a disease.

INTEGRANT *Parts*, in philosophy, the similar parts of a body, or parts the same and of the same nature with the whole; as filings of iron are the *integrant* parts of iron, and have the same nature and properties with the bar they were filed off from. The chemists distinguish in their resolutions of bodies between the dividing or resolving them into *integrant* parts like these; and what they call constituent parts, that is, dissimilar parts, or the principles of the bodies they work upon. Thus when crude mercury is dissolved in aqua-fortis, tho' held imperceptibly in the menstruum, yet when that menstruum is diluted with water and a copper plate is suspended in it, the menstruum leaves the mercury to work upon the copper, and the mercury subsides unaltered and in its own natural form; the mercury therefore, in this operation, was only divided into its *integrant* parts, or small parcels of the same nature and properties of the whole; but when artificial cinnabar is resolv'd or divided into crude mercury and sulphur, neither of these are of the same nature and properties with the cinnabar, and are not its *integrant* but its constituent parts. This therefore is the dividing a body into its constituent parts or principles. *Shaw*'s Lectures, p. 15.

INTEGRUM *Folium*, among botanists. See the article LEAF.

INTENSUM *Diatonum*. See the articles DIATONIC, and GENUS.

INTENTION, (*Cycl.*) *intentio*, ἐπίτασις, in the antient music, was used to denote the passage of the voice from grave to acute. *Aristoxen.* p. 10—13. *Aristid.* Quint. p. 8, 9. *Gaudent.* p. 2, 3. *Euclid.* p. 2. Edit. Meimbom.

INTER *Canem & Lupum*, in law, words used formerly in appeals, to signify that a crime was committed in the twilight, i. e. *inter diem & noctem*, &c. This part of a day has divers other denominations: Thus, in some parts of England they call it *mock-shadow*, corruptly *muck-shade*; and in the north, *day-light's gate*; others say, *betwixt hawk and buzzard*. *Cowel*, *Blount*.

INTERCAPSULARIA, in anatomy, a name given by some writers to the cavities between the scapulæ and the vertebræ.

INTERCEPTED *Axis*, in conic sections, is the same with what is otherwise called the *Abscissa*. See the article ABSCISSA, *Cycl.*

INTERCESSION, *Intercessio*, was used in antient Rome, for the act of a tribune of the people, or other magistrate, by which he inhibited the acts of other magistrates; or even in case of the tribunes, the decrees of the senate. *Veto* was the solemn word used by the tribunes when they inhibited any decree of the senate, or law proposed to the people[a]. The general law of these *Intercessions* was, that any magistrate might inhibit the acts of his equal, or inferior; but the tribunes had the sole prerogative of controuling the acts of every other magistrate, yet could not be controuled themselves by any[b].—[[a] *Middlet.* of Rom. sen. p. 160. [b] *Middlet.* ibid.]

INTERCIDENT *Pulse*, a term used by medical writers, to express a sort of pulse, in which between two regular strokes there is perceived a third irregular.

INTERCOSTAL (*Cycl.*)—INTERCOSTAL *Muscles*. These muscles are so many thin fleshy plates, two between every two ribs, an external and an internal, closely joined together with only a thin cellular web between them. The fibres of the external *Intercostals* are very oblique near the vertebræ; but this obliquity decreases insensibly as they approach the anterior extremities of the ribs. Their insertions begin at the ligaments, by which the ribs are fastened to the transverse apophyses. They are a little tendinous, and run a small space beyond the edge, on the outside of each rib. The fibres of the internal *Intercostals* are in general shorter and less oblique than the former; they fill almost entirely the interstices between the cartilaginous portions, and they are covered on the outside by a ligamentary membrane, the fibres of which running in an opposite direction to those of the muscles, have been mistaken for continuations of the external *Intercostals*, over which this membrane is also spread, only a little diminished in thickness.

Any portion of the breast of an animal may be boiled so much that the flesh easily parting from the bones, the ribs

may be drawn out, without disordering either the muscles or the membranes; but we are not for this reason to conclude, that all the *Intercostals* on one side of the breast make but one muscle; because the same reasoning might prove, that all the muscles which immediately surround the os femoris are but one; since by a like experiment, they together with the periosteum may be entirely separated from the bone, without breaking their fibres. *Winslow*'s Anatomy, p. 231. For the use of these in respiration, see the article RESPIRATION.

INTERCOSTAL *Nerves*. Dr. Walther has given a very minute description of the *Intercostal nerves*, and eighth pair. See Nov. Act. Erud. Lipsi. 1734. Feb. & ibid. 1736 Sept.

INTERCUS, a word used by some medical writers, to express that sort of dropsy more usually called an anasarca. See the articles DROPSY and ANASARCA.

INTEREST *(Cycl.)*—INTEREST, *Interesse*, in law, is commonly taken for a chattel real, as a lease for years, &c. and more particularly for a future term; in which case it is said in pleading, that one is possessed *de Interesse termini*: Therefore an estate in lands, is better than a right or *Interest* in them. But in legal understanding, an *Interest* extends to estates, rights, and titles, that a man hath in or out of lands, &c. so as by grant of his whole *Interest* in such land, a reversion therein, as well as possession in fee-simple shall pass. Co. Litt. 345. *Blount*.

INTERFERE, in the manege. A horse *interferes*, when the side of one of his shoes strikes against, and hurts one of the fetlocks. See the article FETLOCK.

INTERFEMINEUM, a word used by some to express the perinæum.

INTERLUNIUS *Morbus*, a name by which some authors have called the epilepsy, a disease often affected remarkably by the changes of the moon.

INTERMITTENT, or INTERMITTING *Fever (Cycl.)*—See the article FEVER.

INTERNUS *(Cycl.)*—INTERNUS *mallei*, in anatomy, a name given by some authors to one of the muscles of the ear. It is the *musculus Internus auris* of Cowper, and is very properly called by Albinus *tensor tympani* from its use. Spigelius calls it simply the *Internus*.

INTEROSSEUS, in anatomy, a name given by Spigelius in his account of the muscles of the foot, to a muscle called by Albinus the *flexor brevis pollicis pedis*, and by Winslow the *thenar* and *flexor brevis*.

INTERRING, or INTERMENT *(Cycl.)*—See the articles BURIAL and BURYING.

INTERSEPTUM, a word used by some writers to express the uvula, and by others the septum narium.

INTERSPINALES *(Cycl.)*—INTERSPINALES *dorsi*, in anatomy, a name given by Albinus to certain muscles of the back, not mentioned by the old writers in anatomy, but called by Winslow and other of the modern French writers, *les petits epineux du dos*; as the *Interspinales* lumborum of the same author, are the *epineux des lombes*.

INTERSPINALES *lumborum*, in anatomy, a name given by Albinus to some muscles not mentioned by the generality of writers, but called by Winslow the *epineux des lombes*, or *spinales lumborum*.

INTERTRANSVERSARII *dorsi*, in anatomy, a name given by Albinus and others of the late anatomists, to certain small muscles of the back, not observed by the old writers on these subjects, but called by the French *les petits transversaires du dos*.

INTERTRANSVERSARII *lumborum*, in anatomy, a name given by Albinus to those muscles of the loins, which Douglas also calls the *Intertransversales*, and Winslow and the other French writers *transversaires des lombes*.

INTERVAL, in music *(Cycl.)*—*Intervals* are founded on certain ratio's or proportions expressible in numbers, which may all be analysed into the prime numbers 2, 3, and 5. And all *Intervals* may be found from the octave, fifth and third major, which respectively correspond to those numbers. These are the musicians elements, from the various combinations of which, all the agreeable variety of relations of sounds result. This is the modern system, and a late author[a] assures us, it may be looked on as the standard of truth; and that every *Interval* that occurs in music is good or bad, as it approaches to, or deviates from what it ought to be, on these principles. He observes, that the doctrine of some of the antients seems different. Ptolemy, for instance, introduces not only the primes 2, 3, 4, 5, but also 7 and 11, &c. Nay, he seems to think all fourths good, provided their component *Intervals* may be expressed by super-particular ratio's. But these are justly exploded conceits; and it seems not improbable, that the contradictions of different numerical hypotheses, even in the age of Aristoxenus, and their inconsistency with experience, might lead him to reject numbers altogether[b].—[a Dr. *Pepusch*. ap. Phil. Trans. N°. 481. p. 267, 268. b Id. Ibid.]

Mr. Euler defines an *Interval*, the measure of the difference of an acute and grave sound. Tentam. Nov. Theor. Music. p. 72. and p. 103.

Suppose three sounds *a*, *b*, *c*, of which *c* is the most acute, *a* the most grave, and *b* the intermediate sound. From the preceding definition, it appears that the *Interval* between the sounds *a* and *c*, is the aggregate of the *Intervals* between *a* and *b*, and between *b* and *c*. Therefore if the *Interval* between *a* and *b*, be equal to that between *b* and *c*, which happens when $a : b :: c : d$, the *Interval* between *a* to *c*, will be double the *Interval a* to *b*, or *b* to *c*. This being considered, it will appear that *Intervals* ought to be expressed by the measures of the ratio's, constituting the sounds forming those *Intervals*: But ratio's are measured by the logarithms of fractions, the numerators of which denote the acute sounds, and the denominators the grave. Hence the *Interval* between the sounds *a* and *b*, will be expressed by the logarithm of the fraction $\frac{b}{a}$, which is usually denoted by $l\frac{b}{a}$, or, which comes to the same, $lb - la$. The *Interval* therefore of equal sounds, *a* to *a*, will be null, as $la - la = o$. The *Interval* called an octave or diapason, will be expressed by the logarithm of 2; and the *Interval* of the fifth or diapente, will be $l\frac{3}{2} = l3 - l2$. From whence it appears, that these *Intervals* are incommensurable; so that no *Interval*, however small, can be an aliquot part, both of the octave and fifth. The like may be said of the *Intervals* $l\frac{3}{2}$ and $l\frac{5}{4}$, and others whose logarithms are dissimilar. But *Intervals* expounded by logarithms of numbers, which are powers of the same root, may be compared—Thus, the *Interval* of the sounds 27 : 8, will be to the *Interval* of the sounds 9 : 4, as 3 is to 2: For $l\frac{27}{8} = 3l\frac{3}{2}$, and $l\frac{9}{4} = 2l\frac{3}{2}$. *Euler*, ibid. p. 74.

But tho' the logarithms of numbers, which are not powers of the same root, be incommensurable, yet an approximating ratio of such may be found. Thus the measure of the octave is $l2 = 0.3010300$, and the measure of the fifth is $l3 - l2 = 0.1760913$. Hence the *Interval* of the octave will be to that of the fifth, nearly as 3010300 to 1760913; which ratio being reduced to smaller terms, in the method explained under the head RATIO, will give us these simpler expressions for the ratio of the octave and fifth, 2 : 1, 3 : 2, 5 : 3, 7 : 4, 12 : 7, 17 : 10, 29 : 17, 41 : 24, 53 : 31, which last is very near the truth. *Euler*, ibid. p. 75.

In like manner *Intervals* may be divided into any number of equal parts: for this purpose we need only divide the logarithm of the proposed *Interval* into the same number of parts, and then find its correspondent number by the tables. The ratio of the number so found, to unity, will give the required ratio of the divided *Interval* to its proposed part. Thus let the third part of an octave be required; its logarithm will be $= 0.1003433 = \frac{1}{3}l2$: The ratio corresponding nearly to this will be, 63 : 50, or less accurately, 29 : 23, or 5 : 4, which last expresses the third major; and this is by the less knowing taken for the third part of an octave, and seems to be such on our harpsichords and organs, where from C to E is a third, from E to G♯ another, and from G♯ or A♭ to *c* another third. But the more intelligent know, that G♯ and A♭ ought not to be reputed the same sound, since they differ by a diesis enharmonica, which is nearly equal to two commas. *Euler*, ibid.

Mr. Euler has inserted a table of *Intervals* in his *Tentamen Novæ Theoriæ Musicæ*: He supposes the logarithm or measure of the octave to be 1.000000, whence the logarithm of the fifth will be 0.584962, and the logarithm of the third major will be 0.321928; from these the measures of all other *Intervals* may be found. But as it has been customary for musicians to measure their *Intervals* by commas, we shall here insert a table of *Intervals* with their measures in commas; where we suppose the logarithm or measure of the comma $\frac{81}{80}$ to be 1.00000: hence the logarithm of the octave $\frac{2}{1}$ will be 55.79763, that of the fifth 32.63952, and lastly that of the third major 17.96282. From these all the other *Intervals* may be found in the manner expressed in the table; where the first column shews the names of the several *Intervals*; the second the proportions of sounds forming these *Intervals*; the third the composition of these proportions from the primes 2, 3, and 5. The smaller figures marked above, and somewhat to the right of the larger, indicate the power to which the number expressed by the larger figures is raised. Thus $\frac{2^{17}\,3}{5^8}$ shews that the seventeenth power of 2 multiplied by 3, and divided by the eighth power of 5, will produce $\frac{393216}{390625}$ in the second column, and that this is the proportion expressing the *Interval* called *eschaton* in the first column. The fourth column of the table contains some simple signs of some of the *Intervals*, as *h* for *hyperoche*, *d* for *diesis*, &c. and the fifth column shews how the *Intervals* arise from others: Thus, over-against semitone major, I find in the fourth column *S*, which is here only an arbitrary mark for this semitone; and in the fifth column I find $s + d = \text{IV} - \text{III}$, which signifies that the semitone major is equal to the sum of the semitone minor and diesis, or to the difference between the fourth and third major. Observe, that the comma is marked by a dot (.); when this is placed over the letter or other symbol, it signifies that the *Interval* is supposed to be heightened by a comma; and on the contrary, when the point is placed below, it signifies that the *Interval* must be diminished by a comma: Thus $\dot{t} = T$ signifies that the

the tone-minor increaſed by a comma is equal to a tone-major, and vice verſa, T = *t* ſhews that the tone-major diminiſhed by a comma is equal to the tone-minor. The ſigns +, —, =, are here taken in the ſame ſenſe, as in algebra, to ſignify addition, ſubſtraction, and equality. So likewiſe the dot placed between two numbers, or between a number and the ſymbol of an *Interval*, ſignifies that the *Interval* is to be multiplied by the number. Thus 2. IV ſhews that the fourth is doubled; and thus, 7^b = VI + S = 2. IV = VIII — T, ſhews, that the leſſer flat ſeventh is equal to the ſixth major and ſemitone-major, or alſo to two fourths, or to the octave when the tone-major has been taken from it. Laſtly, the ſixth column of the table ſhews the meaſures, or logarithms of the ratios in the ſecond column. Theſe are not the common logarithms of the tables where 1.0000000 is the logarithm of 10. But here 1.00000 is aſſumed as the logarithm of $\frac{81}{80}$ or of the comma, as before mentioned. Theſe logarithms are eaſily derived from the common, of the larger tables of Vlacq. or Briggs. Thus the logarithm of 2, or the octave = 0.3010299957; the logarithm of $\frac{3}{2}$, or of the fifth = 0.1760912590; and laſtly, the logarithm of $\frac{5}{4}$, or of the third major = 0.0969100130. Now theſe logarithms being ſeverally divided by the logarithm of $\frac{81}{80}$, or of the comma = 0.0053950319; the quotients will give the number of commas in an octave = 55.79763; in a fifth = 32.63952; and in a third major = 17.96282. Hence all the reſt may be found by addition and ſubſtraction only. Here follows the Table.

A TABLE of Muſical *Intervals*, with their Meaſures.

Names of the *Intervals*.	Proportions expreſſing the *Intervals*.	Compoſition of the Proportions from 2, 3, and 5.	Simple Signs.	Complex Signs to ſhew the Compoſition of *Intervals*.	Meaſures by Commas.
Eſchaton	$\frac{393216}{390625}$	$\frac{2^{17}3}{5^8}$		$d-b=2d-s=3d-S$	0.53222
Diaſchiſma	$\frac{2048}{2025}$	$\frac{2^{11}5}{3^45^2}$		d	0.90917
Comma	$\frac{81}{80}$	$\frac{3^4}{2^45}$	.	$T-t$	1.00000
Comma of Pythagoras	$\frac{531441}{524288}$	$\frac{3^{12}}{2^{19}}$		$6T-VIII$	1.09083
Hyperoche	$\frac{3125}{3072}$	$\frac{5^5}{2^{10}3}$	b	$s-d=S-2d$	1.37695
Enharmonic Dieſis, or diminiſhed ſecond	$\frac{128}{125}$	$\frac{2^7}{5^3}$	d	$S-s$	1.90917
Semi-tone Minor, or leaſt Chromatic Dieſis	$\frac{25}{24}$	$\frac{5^2}{2^33}$	s	$t-S=d+b=III-3^b$	3.28612
Limma of the Greek Scale, or deficient Semi-tone Major	$\frac{256}{243}$	$\frac{2^8}{3^5}$		$S=IV-2\dot{T}$	4.19529
Leſſer Limma, or redundant Semi-tone Minor	$\frac{135}{128}$	$\frac{3^35}{27}$		$\dot{s}=T-S$	4.28612
Semi-tone Major	$\frac{16}{15}$	$\frac{2^4}{3\cdot5}$	S	$s+d=IV-III$	5.19529
Apotome of the Greek Scale	$\frac{2187}{2048}$	$\frac{3^7}{2^{11}}$		$T-S=\ddot{s}$	5.28612
Greater Limma, or redundant Semi-tone Major	$\frac{27}{25}$	$\frac{3^3}{5^2}$		$\dot{S}=T-s$	6.19529
Double Semi-tone Minor	$\frac{625}{576}$	$\frac{5^4}{2^63^2}$		$2s=t-\dot{d}$	6.57224
Greateſt Limma, or redundant double Semi-tone Minor	$\frac{1125}{1024}$	$\frac{3^25^3}{2^{10}}$		$s+\dot{s}=T-d$	7.57224
Tone-Minor	$\frac{10}{9}$	$\frac{2\cdot5}{3^2}$	t	$S+s=T=IV-3^b=III-T$	8.48141
Tone-Major	$\frac{9}{8}$	$\frac{3^2}{2^3}$	T	$\dot{t}=V-IV$	9.48141
Diminiſhed Third	$\frac{256}{225}$	$\frac{2^8}{3^25^2}$		$t+d=2S$	10.39058
	$\frac{144}{125}$	$\frac{2^43^2}{5^3}$		$T+d=3^b-s$	11.39058
Superfluous Second	$\frac{125}{108}$	$\frac{5^3}{2^23^3}$		$t+s$	11.76753
	$\frac{75}{64}$	$\frac{3\cdot5^2}{2^6}$		$T+s=3^b-d$	12.76753
Trihemitone of the Greek Scale, or deficient third Minor	$\frac{32}{27}$	$\frac{2^5}{3^3}$		$3^b=t+S=IV-T$	13.67670
Third Minor	$\frac{6}{5}$	$\frac{2\cdot3}{5}$	3^b	$T+S=V-III$	14.67670
Trihemitone Major	$\frac{4096}{3375}$	$\frac{2^{12}}{3^35^3}$		$3S=T+S+\dot{d}$	15.58587
Extreme diminiſhed Fourth	$\frac{768}{625}$	$\frac{2^83}{5^4}$		$3^b+d=IV-2s$	16.58587
Third Major	$\frac{5}{4}$	$\frac{5}{2^2}$	III	$III=V-3^b$	17.96282
Ditonus of the Greek Scale, or redundant third Major	$\frac{81}{64}$	$\frac{3^4}{2^6}$		$\dot{III}=2T$	18.96282
Diminiſhed fourth	$\frac{32}{25}$	$\frac{2^5}{5^2}$		$III+d=IV-s$	19.87199
Superfluous third	$\frac{125}{96}$	$\frac{5^3}{2^53}$		$III+s$	21.24894
Fourth	$\frac{4}{3}$	$\frac{2^2}{3}$	IV	$III+S=VIII-V$	23.15811
Redundant fourth	$\frac{27}{20}$	$\frac{3^3}{2^25}$		$\dot{IV}=3^b+T$	24.15811
Superfluous fourth	$\frac{25}{18}$	$\frac{5^2}{2\cdot3^2}$		$IV+s$	26.44423
Semidiapente of the Greek Scale	$\frac{1024}{729}$	$\frac{2^{10}}{3^6}$		$IV+S$	27.35340

Tritonus,

Tritonus, or falſe fourth	$\frac{45}{32}$	$\frac{3^2 5}{2^5}$		IV + ṡ = V − S	27.44423
Semidiapente, or falſe fifth	$\frac{64}{45}$	$\frac{2^6}{3^2 5}$		IV + S = V − ṡ	28.35340
Tritonus of the Greek Scale	$\frac{723}{512}$	$\frac{3^6}{2^9}$		3T = V − S = IV + s̈	28.44423
Diminiſhed fifth	$\frac{36}{25}$	$\frac{2^2 3^2}{5^2}$		V − s = 2.3^b	29.35340
Deficient fifth	$\frac{40}{27}$	$\frac{2^3 5}{3^3}$		V̇ = IV + t	31.63952
Fifth	$\frac{3}{2}$	$\frac{3}{2}$	V	IV + T = III + 3^b	32.63952
Superfluous fifth	$\frac{25}{16}$	$\frac{5^2}{4^2}$		V + s = 2. III	35.92564
Sixth Minor	$\frac{8}{5}$	$\frac{2^3}{5}$	6^b	V + S = VIII − III	37.83481
Sixth Major	$\frac{5}{3}$	$\frac{5}{3}$	VI	V + t = VIII − 3^b	41.12093
Hexachord of the Greek Scale, or redundant ſixth Major	$\frac{27}{16}$	$\frac{3^3}{2^4}$		V̇I = V + T = VIII − 3̇	42.12093
Leſſer / Greater diminiſhed ſeventh	$\frac{128}{75}$	$\frac{2^7}{3 \cdot 5^2}$		6^b + S = 2.IV − s = 7^b − s	43.03010
	$\frac{216}{125}$	$\frac{2^3 3^3}{5^3}$		6^b + Ṡ = 7̇^{b} − s	44.03010
Leſſer / Greater ſuperfluous ſixth	$\frac{125}{72}$	$\frac{5^3}{2^3 3^2}$		VI + s	44.40705
	$\frac{225}{128}$	$\frac{3^2 5^2}{2^7}$		VI + ṡ = VIII − 2S	45.40705
Leſſer / Greater ſeventh Minor	$\frac{16}{9}$	$\frac{2^4}{3^2}$	7^b	VI + S = 2.IV = VIII − T	46.31622
	$\frac{9}{5}$	$\frac{3^2}{5}$	7̇^{b}	VI + Ṡ = V + 3^b = VIII − t	47.31622
Seventh Major	$\frac{15}{8}$	$\frac{3 \cdot 5}{2^3}$	VII	VI + T = VIII − S	50.60234
Diminiſhed Octave	$\frac{48}{25}$	$\frac{2^4 3}{5^2}$		VII + d = VIII − s	52.51151
Superfluous Seventh	$\frac{125}{64}$	$\frac{5^3}{2^6}$		VII + s = VIII − d	53.88846
Octave	$\frac{2}{1}$	$\frac{2}{1}$	VIII	VIII = V + IV	55.79763

The limma, apotome, trihemitone, ditonus, ſemidiapente, and tritonus, mentioned in this Table, by the names of limma, apotome, &c. of the Greek ſcale, are ſuch as are either mentioned by the antients, or at leaſt occur in their ſcale, where fourths are divided into two tones and a limma, and where the octave conſiſted of five tones and two limmas.

The term *redundant* in the Table, is applied to ſuch *Intervals* as exceed the truth by a comma; and ſuch as fall ſhort of the truth by a like quantity, are called *deficient*. *Intervals* that exceed true diatonic *Intervals*, by a ſemitone-minor, are ſaid to be *ſuperfluous*; and thoſe which fall ſhort by the ſame quantity, are ſaid to be *diminiſhed*. Where an *Interval* exceeds a true diatonic *Interval* by the quantity of two ſemi-tones minor, we have called it an *extreme ſuperfluous* Interval: And if it falls ſhort by the ſame quantity the appellation of *extreme diminiſhed* Interval is given it. Thus, if from A to D aſcending be a true fourth, and from D to *a* a true fifth, then, if D be ſuppoſed raiſed by a comma, from A to Ḋ will be a redundant fourth, and from Ḋ to *a* a deficient fifth. From A to D♯ will be a ſuperfluous fourth, and from D♯ to *a* will be a diminiſhed fifth. In like manner, from A to D^b, will be a diminiſhed fourth; and from D^b to *a*, a ſuperfluous fifth. From A to D♯♯ (D double ſharp) will be an extreme ſuperfluous fourth, and from A to D^{bb} (D double flat) will be an extreme diminiſhed fourth. In like manner, from D♯♯ to *a* will be an extreme diminiſhed, and from D^{bb} to *a*, an extreme ſuperfluous fifth. Such *Intervals* are not to be met with in the practice of muſic; but if the diviſion of the octave into 31 parts were once eſtabliſhed, as it ought for the perfection of muſic, ſuch *Intervals* as theſe here mentioned will neceſſarily occur in the ſcale. Vid. Phil. Tranſ. N° 481. p. 273, 274. See the article GENUS.

This Table, among other uſes, will facilitate the examination of any propoſed ſcale, or *Interval*. Suppoſe, for inſtance, it were required to examine ſome of Ptolemy's diviſions of the fourth, as his Diatonicum molle, which he makes $\frac{8}{7} \times \frac{10}{9} \times \frac{21}{20} = \frac{4}{3}$. Take the logarithm of $\frac{8}{7}$ from the common tables, and divide it by the logarithm of $\frac{81}{80}$, the quotient will be 10.75, which gives the meaſure or number of commas, and its parts contained in an *Interval* expreſſed by $\frac{8}{7}$. Look for the neareſt meaſure of *Intervals* to 10.75 in the table, it will be found to be 10.39058, which anſwers to the *Interval* of two ſemitones major, or of the diminiſhed third as practitioners call it. But Ptolemy's exceeds this by 0.36, or about $\frac{1}{3}$ of a comma. The next *Interval* in Ptolemy's diviſion is $\frac{10}{9}$, which is a true tone-minor. The third is $\frac{21}{20}$, which will be found to be 3.93 commas, that is a ſemi-tone minor and 0.64 of a comma, or a ſemi-tone minor redundant by near $\frac{2}{3}$ of a comma. But this is much out of tune. In the common, and in Huygens's temperatures the ſemi-tone minor is increaſed only by about $\frac{1}{4}$ of a comma. Vid. *Ptolem.* Harmon. p. 92. ap. *Wallis* Oper. Tom. 3.

Diminiſhed INTERVAL, in muſic. See the article DIMINISHED *Interval*.

INTERVALS, in huſbandry, a term uſed to expreſs the ſpaces left between the ſeveral rows of plants ſown or ſet in a garden or field. The method of horſe-hoeing huſbandry, ſo ſtrongly recommended by Mr. Tull, is objected to by many, on account of the largeneſs of the *Intervals* which are to be left between the rows of corn. Theſe are required to be about five foot wide; and it is thought that ſuch wide ſpaces are ſo much loſt earth, and that the crop is to be ſo much the leſs for it. But it is to be obſerved, that the rows of corn ſeparated by theſe *Intervals* need not be ſingle, they may be double, triple, or quadruple, at the pleaſure of the farmer; and four rows thus ſtanding as one will have the five foot *Interval* but one fourth of its bigneſs as to the whole quantity, and it will be but as fifteen inch *Intervals* to plants in ſingle rows. Corn that is ſown irregularly in the common way, ſeems indeed to cover the ground better than that in rows; but this is a mere *deceptio viſus*, for the ſtalks of corn are never ſo thick as when they come out of one plant, or as when they ſtand in a row, and a horſe-hoed plant of corn will have twenty or thirty ſtalks in a piece of ground of the ſame quantity, where an unhoed plant will have only two or three ſtalks. If theſe ſtalks of the hoed plant were ſeparated and planted over the *Intervals*, the whole land would be better covered than it is in the common way; and the truth is, that tho' theſe hoed fields ſeem to contain a much leſs crop than the common ſown fields, yet they in reality do contain a much greater. It is only the different placing that makes the ſown crop ſeem the larger, and even this is only while both crops are young. *Tull*'s Horſehoeing Huſbandry.

The *Intervals* are not loſt ground, as is uſually ſuppoſed, but when well horſehoed they are all employed in the nouriſhment of the crop, the roots of the plants in the adjoining rows ſpreading themſelves thro' the whole *Interval*, and drawing ſuch nouriſhment from it, that they increaſe accordingly. When the plants ſtand in the ſcattered way, as in common ſowing, they are too cloſe to one another; each robs its neighbours of part of their nouriſhment, and conſequently the earth is ſoon exhauſted, and all the plants half ſtarved. The cloſe ſtanding of them alſo prevents the benefit of after-

tilling,

tilling, as the hoe cannot be brought in, nor the ground by any means ſtirred between them to give it a new breaking, and conſequently afford them new food.

Experiments have abundantly proved, that in large grounds of wheat where the different methods have been tried, thoſe parts where the *Intervals* were largeſt have produced the greateſt crops, and thoſe where hoeing was uſed without dung have been much richer, than thoſe where dung was uſed without hoeing. If it were poſſible that plants could ſtand as thick, and thrive as well over the whole ſurface of the ground, as they do in the rows ſeparated by theſe large *Intervals*, the crops of corn ſo produced would be vaſtly greater than any that have been heard of; but the truth is, that plants receive their growth not according to the ground they ſtand on, but to the ground they can extend their roots into; and therefore a ſingle row may contain more plants than a large *Interval* can nouriſh, and therefore the ſame number that ſtand in that row, and no more than theſe could be nouriſh'd if ſcattered over the whole *Interval*; and they would be much worſe nouriſhed in that way, becauſe while the *Interval* is void, the earth may be ſtirred about them, and new roots will be formed in great numbers from every one broken by the inſtruments, and new nouriſhment laid before theſe roots by the breaking the particles of earth, by which the plants will have ſupplies that they cannot have when ſcattered over the whole ſurface, becauſe the ground is then all occupied, and cannot be moved between the plants.

The horſe-hoeing which takes place in theſe large *Intervals*, and is to be repeated ſeveral times: once or twice are of great advantage, but the oftner it is repeated the better the crop will ſucceed. In the beginning, or while the plants are young, it is to be done only in the middle of the *Interval*, that the roots of the tender plants may not be injured by coming too near them; but in the grown plants the hoe may be brought very near their roots without any fear of harm from it; and tho' the larger roots are many of them broken off by it, they are ſo ſoon ſupplied with new ones, that no ill conſequence was ever known to attend it. Poor land tho' it be ever ſo light, ſhould have many hoeings; for the plants receive but little nouriſhment from its natural poſture, and it is therefore neceſſary to make a continual ſupply of the artificial. The young roots multiplied by the breaking of the old ones with the hoe, are fuller of lacteal mouths for receiving of nouriſhment, than the old ones; and it is therefore no wonder, that the faſter theſe are propagated the better the plant thrives. And there is a diſadvantage in the plants of corn ſown in the common way, which is, that their ſtalks being as numerous, or nearly ſo at firſt as afterwards, they very quickly exhauſt the ground, while the plants in rows with *Intervals* between have much fewer ſtalks at firſt, and only increaſe in number as their roots are increaſed by the cutting, and the nouriſhment increaſed alſo by the ſame operation. *Tull*'s Horſehoeing Huſbandry, p. 36.

The earth about the ſown plants in the common way ſoon hardens and ſhuts out the benefits of the atmoſphere, whereas in the other way the hoe keeps it ſoft and open, ready to receive all the benefits of rains and dews; and tho' the crop of corn from the hoed *Interval* way ſhould be twice as large as the other, the land is yet left twice as rich for the next crop.

It is impoſſible to bring theſe calculations to mathematical rules, but it is very certain that a ſown crop ſucceeding a large undung'd hoed crop, is much better than a ſown crop that ſucceeds a ſmall dung'd ſown crop; and experience ſhews that poor worn-out heath-ground will produce four ſucceſſive good hoed crops, the latter all better and better till the whole is become at length good ground by the benefit of the hoeing, in ſpite of the nouriſhment drained out by the potatoes.

The wider the *Intervals* are, the more earth may be divided; for the row takes up the ſame room with a wide or a narrow *Interval*; and therefore with the wide the unhoed part bears a leſs proportion to the hoed part than in the narrow.

There are many ways of hoeing with the hoe-plow, but there is not room to turn two deep and clean furrows in an *Interval* that is narrower than four foot eight inches; for if it want much of this breadth, one at leaſt of theſe furrows will reach and fall upon the next row, which will be very injurious to the plants, except of grown ſaint-foin or ſome other ſuch plants, which can bear to have the earth pulled over them with a harrow.

All ſoils and all ſituations are not equally proper for this method of planting in rows, with large *Intervals* and hoeing between. The lighteſt ſoils ſeem the beſt for it, and the tough and wet clays the worſt.

Such grounds as lie on the ſides of hills are alſo leſs proper than others, for this work.

This method is not ſo proper in common fields, but that not in reſpect of the ſoil, but of the huſbandry of the owners, who are uſually in the old way, and change the ſpecies of corn, and make it neceſſary to fallow every ſecond, third, or fourth year.

INTESTINES (*Cycl.*)—*Wounds of the* INTESTINES. When a large wound is made in the cavity of the abdomen, which not only lets out the *Inteſtines*, but alſo divides ſome part of them; the wounded part of the *Inteſtines* are always to be ſtitched up before they are returned, by which means the wound heals the more readily; and the diſcharge of chyle and fæces into the cavity of the abdomen is prevented, from which dangerous ſymptoms would otherwiſe have enſued. And altho' wounds of the *Inteſtines*, eſpecially of the ſmall guts, admit of little or no hopes of a cure; yet as the great guts ſometimes admit of the ſuture with advantage, it is better to uſe a doubtful remedy, than none. Small wounds of the *Inteſtines*, however, or ſuch as do not exceed the diameter of a gooſe-quill, are by no means to be ſtitched, but left to nature; by which means there is much greater hopes of ſucceſs, than from irritating them with the ſuture; but large wounds of the *Inteſtines*, tho' they ſeldom admit of cure, yet it is always to be attempted by means of the glovers ſuture, before the *Inteſtine* is returned. To perform this, you are to be provided with a ſmall needle threaded with ſilk, an aſſiſtant ſhould take hold of one part of the gut by a fine piece of linnen well air'd; while the ſurgeon ſhould hold the other part in his left hand, and ſew up the whole wound after the glover's manner, leaving very ſmall ſpaces, not more than the twelfth of an inch each between each of the ſtitches. The laſt ſtitch in this operation muſt be faſtned with a knot, but the other end muſt hang out about a foot out of the abdomen, by means of which the ſilk may be drawn out when the *Inteſtine* is healed. After this is performed, the wound of the abdomen is next to be taken care of, and ſtitched up, keeping the lower or depending part of the wound open with a tent, till all the preternatural fluids are diſcharged out of the cavity of the abdomen, and till the union of the wound in the *Inteſtine* ſhall give leave to draw away the ſilk with which the ſuture was performed on it.

As the modern ſurgeons, however, have found that few are ſaved who have received any large wound in the *Inteſtines*, and that in thoſe few who do recover, the wounded parts, from the fineneſs of the coat of the gut do not properly unite, but rather adhere to the inner part of the peritoneum, or to the omentum, or to ſome other of the *Inteſtines*, they rather chuſe now to let alone the operation of the ſuture of the gut, and ſubſtitute a gentler method of cure. They paſs a waxed thread thro' a fine needle, and with this they faſten the wounded part of the *Inteſtine* to the internal orifice of the wound in the abdomen. The thread that in this caſe hangs out of the abdomen, is to be ſo firmly fixed by the application of ſticking plaiſters to the wound, that the *Inteſtine* cannot recede from the part to which it was faſtened, nor can it evacuate any of its contents into the cavity of the abdomen. When this operation is well performed, the *Inteſtine* eaſily adheres to the internal part of the abdomen, and the patient ſuffers infinitely leſs pain and hazard, than from the former way of making the ſuture. The ſame method of cure alſo is the proper one for wounds of the ſtomach, where they are within the reach of the hand, and it is ſometimes crowned with ſucceſs. *Heiſter*'s Surgery, p. 56.

Loſs of Subſtance in the INTESTINES. Where any part of the *Inteſtines* is carry'd away, the caſe is plainly deſperate, and 'tis indeed wonderful that perſons thus wounded have not all died upon the ſpot, or in the operation of making the ſuture, till ſome of the late eminent ſurgeons obſerved that the lips of the *Inteſtines* ſo wounded, would ſometimes unexpectedly adhere to the wound in the abdomen, and took this hint from nature toward a cure in ſuch deſperate caſes. Whenever a ſurgeon therefore is called in a caſe of this kind, after diligently examining the ſtate of the upper part of the *Inteſtine* which has ſuffered the loſs of ſubſtance, he ſhould ſtitch it to the external wound; for by this means the patient may not only be ſaved from inſtant death, but there have been inſtances where the wounded *Inteſtine* has been ſo far healed, that the fæces which uſed to be voided by the anus, have been voided by the wound in the abdomen. And this, tho' from the neceſſity of wearing a tin or ſilver pipe, or keeping cloths conſtantly upon the part to receive the excrement, may ſeem to be very troubleſome; yet it is ſurely far better to part with one of the conveniencies of life, than to part with life itſelf; beſide the excrements that are voided by this paſſage, are not ſo offenſive in ſmell, as thoſe voided per anum.

The ſame method of cure may conveniently alſo be put in practice, where any part of the *Inteſtine* is mortify'd, by having been thruſt out of the abdomen; for in this caſe if you tie up the meſenteric arteries, the corrupted or mortify'd part of the *Inteſtine* may be cut off, and the remaining ſound part made to adhere to the wound of the abdomen. And it is ſurely better to try this method and ſave if it be only a few by it, than to leave all in this unhappy ſituation to periſh without help. *Heiſter*, p. 65.

We have inſtances of mortified pieces of the *Inteſtines* in the Herniæ cut away, and a cure made by keeping the extremities of the gut near to each other, and near to the rings of the muſcles, with a ſtitch through the meſentery. The

ends of the *Inteſtines* grew to the peritoneum, new fleſh was extended along this membrane, and joined the extremities together. The ſoldered part of the gut is always ſtraitned, and therefore thoſe who are cured in this caſe ought to guard againſt too full meals and indigeſtion. See Mem. de l'Acad. de Chirurg. Tom. 1.

INTESTINES *of Fiſhes*. The guts in fiſhes are very different in the ſeveral kinds in length, proportion, and figure; in ſome fiſh the *Inteſtine* is ſtrait and ſimple, and is carried directly from the ſtomach to the anus, as in the conger, ſyngnathus and petromyzon; in others it is only once returned upwards, as in the cyprini, ſalmons, pearch, and many others. In others it is variouſly contorted and revoluted, in the ſame manner as in land animals. We have inſtances of this in the ſparus, dolphin, mullet, and ſword-fiſh. *Artedi* Ichthyolog.

In length there are many very eminent differences. In the petromyza, *&c.* the whole *Inteſtinal* canal is not ſo long as the body of the fiſh. In the cyprini of many kinds it is about the ſame length with the body of the fiſh; and in others it is greatly longer, as in the ſpari, mullets, *&c.*

INTESTINAL *Fever*, *Febris Inteſtinalis*, in medicine, a name given by Heiſter to a peculiar ſpecies of acute fever paſſed over in ſilence by the generality of authors; but by ſome called the meſenteric fever, and by our Sydenham the new fever, *nova febris*. This differs from other acute fevers, in that it is attended always with a diarrhœa, which however is ſalutary, and which it is very dangerous to ſtop, and in that it is not relieved by the attemperating or diaphoretic medicines uſeful in other fevers, much leſs by the hot ſudorifics; all theſe things exaſperate and make it worſe, and the only things that give relief in it, are gentle cathartics, and vomits that operate without violence. This fever, therefore, evidently ſhews the error of thoſe haſty reaſoners, who declare, that all acute fevers are to be cured by diaphoretics.

This peculiar ſpecies of fever, tho' unknown to many of the late writers, and called by Sydenham a new diſtemper, was not unknown to the antients. Hippocrates has left many things concerning it; as have alſo the later Greeks, and Celſus: And among the moderns, Duret, Sennertus, Foreſtus, Riverius, Etmuller, Baglivi, Stahl, Hoffman, and Lanciſci, have all met with it, tho' they have given but very ſhort and imperfect deſcriptions of it in their writings.

The generality of thoſe who have written of this fever have refer'd it to the malignant kinds, from its being uſually attended with ſevere and uncommon ſymptoms from the beginning, or from ſuch being brought on in the courſe of an irregular treatment. The common method of curing fevers by diaphoretic medicines bringing on in this, anxieties and ſtraitneſs of the præcordia, with pains about the ſtomach, loſs of appetite and deliriums, with efflorescences of various kinds, particularly petechial ſpots; and theſe ſymptoms are not unfrequently attended with death. But it is to be obſerved, that diſeaſes are to be carefully diſtinguiſhed in their own ſymptoms, thoſe which the phyſician brings on being often very different from what nature would offer.

Theſe fevers have their ſeat in the ſtomach and *Inteſtines*; or if they have it any where elſe, it appears at leaſt that their origin, which is in a putrid colluvies, is always much more eaſily educed and evacuated by theſe, than by any other paſſages. Many of the diſtempers mentioned by authors under peculiar names, are properly to be refer'd as to their cauſes to this ſpecies of fever. The dyſenteric fever is abſolutely of this kind, and many of the petechial ones. The catarrhal fevers alſo, are referable to this kind; and the continual quotidian and tertian, with the fevers deſcribed by the antients under the names of *hemitritæus*, *aſſodes*, *elodes*, *epiala*, and *lipyria*, with the *tritophyæ* nearly allied to the *hemitritæi*, and by ſome authors confounded together, the words being uſed as ſynonymous. *Heiſter*'s Compend. Med. p. 83. ſeq.

Symptoms of INTESTINAL *Fevers*. Theſe are frequent ſhiverings when the patient is firſt ſeized with the diſtemper, which return at different and irregular intervals. After theſe the tongue, teeth, and fauces are covered with a foul and viſcid phlegm, the tongue in particular often looking yellowiſh, and blackiſh with it; the patient perceives a continual diſagreeable taſte in his mouth from this, and the people who are about him an ill ſmell. There is always a diarrhœa attending theſe fevers, and the fæces voided in it have a peculiarly offenſive ſmell. The hypochondria are always diſtended, and often in pain; the patients are attended with violent tremblings in their ſleep, ſo that they are frequently waked in terrors and uneaſineſs; and in tenderer ſubjects theſe alſo are very frequent, while waking. Pains in the head and neck are alſo a conſtant attendant of this diſtemper, and ſeem to take their origin from ſpaſms. The urine in the beginning of the diſeaſe is of a natural ſtate and colour, and afterwards becomes turbid, and depoſits a muddy ſediment during the whole courſe of the diſtemper.

Theſe are the conſtant ſymptoms of theſe fevers; but beſide theſe there are ſometimes other very violent ones, ſuch as violent anxieties of the præcordia, pains in the ſtomach and in the ſide reſembling thoſe of a pleuriſy, a loſs of ſtrength, a violent internal heat, and a continual convulſive or tremulous motion of the hands, with a ſubſultus tendinum, hiccough, and cold ſweats; which are all extremely dangerous ſymptoms, and preſage a fatal period to the diſtemper.

Beſide theſe, which are the common and the additional ſymptoms of theſe fevers, there are yet ſome others often ſeen in them, which are merely accidental, and are owing to the improper management of the patient. It is a common error to give hot and ſudorific medicines in theſe caſes, the conſequence of which is, that the peccant matter which was lodged before in the primæ viæ is propelled into the blood, and not being able to make its way through the pores it appears under the ſkin in form of petechiæ or purple ſpots, or of papulæ of a purple or reddiſh colour; ſometimes of a livid or blackiſh. Under this circumſtance, which is wholly owing to the ignorance of the preſcriber, the diſtemper gets the name of a petechial or a purple fever. Sometimes the ſame methods ſend the matter to the ears, where it occaſions deafneſs; ſometimes to the parotids and maxillary glands, where it forms tumors, inflammations, and abſceſſes of a very bad ſort; and, finally, if it be tranſferred to the brain, violent deliriums and phrenitis are the certain conſequence. Thus, according as this matter happens to be driven by this improper treatment to a more or leſs noble part of the body, it gives the ſymptoms of a more or leſs dangerous diſeaſe; and very frequently the patient ſeems to have a pleuriſy, or peripneumony, or an inflammation of the liver, ſpleen, or *Inteſtines*, while in reality the cauſe of the diſeaſe is all the while the ſame; and there is no difference, but that of the matters ſettling on one or another part. *Heiſter*'s Compend. Med. p. 97.

The Method of Cure. All hot medicines muſt be avoided, and the diſcharge of the peccant matter by the diarrhœa promoted by glyſters and by purging medicines. Some adviſe aloes, and other medicines of that kind; others ſena and manna; ſome the purging ſalts; but moſt prefer rhubarb, given in often repeated ſmall doſes. Large draughts of the lubricating decoctions, ſuch as barley-water and water-gruel, are to be given, and emulſions of ſweet almonds and of the cold ſeeds. Small quantities of oil of ſweet almonds are alſo to be given at times, and juleps of the cooling waters and ſyrups moderately acidulated, and powders of nitre, cinnabar, and the common abſorbents, as crabs-eyes and the like, are to be given to take off the pains and ſpaſms, and to attemperate the acrid matter. Bleeding in this fever is not neceſſary, unleſs in plethoric habits, and in thoſe caſes it muſt be done on the acceſs of the diſeaſe, for if done after the third or fourth day it is uſually found to do more harm than good.

The diet in theſe fevers is not to be ſo very thin and weak, as in other acute fevers, but moderate nouriſhment is to be allowed, that the patient may hold his ſtrength ſufficiently to go through it; in the beginning of the diſeaſe however, the patient has uſually an averſion for food, and then it is not to be forced upon him; but when the ſtomach begins to require it, then it is to be given in moderate quantity; and great care muſt be taken that nothing aſtringent or difficult of digeſtion be allowed, but light and innocent meats, and with theſe a little good wine to promote digeſtion. Some alſo have given frequent vomits, by ſmall doſes of ipecacuanha in theſe fevers, and that with very good ſucceſs; and it is remarkable, thot the purple fever mentioned by Stahl, and others, as peculiarly affecting lying-in women, and being very frequent in Saxony for a long time, was by Dr. Wagner, and others, cured by this method: Its origin being found to be a viſcous matter putrifying in the ſtomach and *Inteſtines*; and therefore the diſtemper being properly one of theſe *inteſtinal* fevers, was curable by the ſame methods with them, that is by emptying the primæ viæ.

Some, as Baglivi and Burchard, have called theſe fevers *meſenteric fevers*; but improperly, according to Heiſter, L. c. p. 85.

INTESTINALIS *Sphincter*, in anatomy, a name given by Winſlow to a muſcle of the anus, called by Albinus *ſphincter internus ani*. It is called by Riolan, and others, *ſphincter cutaneus*, and *ſphincter ſuperficialis*.

INTESTINUM *Cæcum*. The fiſh kinds have in general a great number of theſe *cæca*; they are called by the ichthyologiſts *Inteſtinula cæca*, and *appendices pylori*. They are always placed about the pylorus, and the beginning of the *inteſtinal* canal, and ſeem by their number and appearance to contribute not a little to the digeſtion of the food. They are very different in the ſeveral kinds of fiſh, in number, figure, and proportion. 1. In ſome fiſh there are none of them. The cetaceous fiſhes in general are without them, and the cartilaginous of many kinds alſo want them. In the ammodytes or ſand-eel there is only one *cæcum*, and this ſeems the only fiſh that has it ſingle. In many of the pleuronecti they are two in number, and very ſhort. The pearch, ſpari, *&c.* have five, ſix or ſeven of them, and all conſiderably large ones. In ſome fiſh there are eight, ten, or twelve of them, as in the catti, and ſome of the ligyri. In the herring and anchovy, there are ſeventeen or eighteen of them. Some, but not many fiſh, have twenty or more, not arriving

at thirty. The gadi, and ſome other fiſh have thirty; and the coregones and ſalmons, at leaſt ſixty of them. The clupea or thriſſa of authors has at leaſt eighty of them; and the ſword-fiſh, the tunny, the mackrel, and many others, have more than a hundred of them, or have them indeed without number. Their differences in figure are alſo very great. In ſome fiſh they are long and narrow, as in the ſalmons, gadi, and clupeæ. In others, they are very ſhort and thick, as in the pleuronecti, and oſmerus. In the greateſt part of fiſhes they are much ſmaller than the reſt of the guts; but in the mullet and ſand-eel they are nearly as large as the *Inteſtine* itſelf. It is remarkable, that theſe appendices to the pylorus, or *Inteſtine*, are not only found in fiſhes, but in ſome inſects. Dr. Tyſon found three or four of them in that ſpecies of inſect called the blatta. *Artedi*'s Ichthyology. See the article BLATTA.

INTRADA, in the Italian muſic, is uſed to denote an *entry*, and is much the ſame as *prelude*, or *overture*. See the articles PRELUDE, and OVERTURE, *Cycl.*

INTRENCHMENT, in the art of war, all ſorts of works made to fortify a poſt, againſt an enemy. See the article RETRENCHMENT, *Cycl.*

It was a maxim amongſt the Romans, that even in their moſt haſty marches they *intrenched* every night.

INTRITA, a name given by ſome authors to the maltha, a liquid bitumen uſed by the antients inſtead of mortar in building. See the article MALTHA.

INTRODUCTOR, in antiquity, was particularly uſed for an officer, who introduced the Athletæ to the Stadium, or place where they were to contend.

INTRUSIONE, a writ brought againſt an *Intruder*, by him that hath fee-ſimple, *&c.* New Nat. Brit. 453. *Blount*, *Cowel.*

INVADIATUS, in our old writers, a perſon accuſed of any crime, which not being fully proved, he was put *ſub debita fide juſſione*, and called *Invadiatus*. *Blount.*

INVECTIVE, in rhetoric, differs from reproof, as the latter proceeds from a friend and is intended for the good of the perſon reproved; whereas *invective* is the work of an enemy, and entirely deſigned to vex and give uneaſineſs to the perſon againſt whom it is directed. *Voſſ.* Rhet. L. 3. p. 420.

INVOLUCRUM, among botaniſts, expreſſes that ſort of cup which ſurrounds a number of flowers together, every one of which has beſide this general cup its own particular perianthium. The *Involucrum* conſiſts of a multitude of little leaves diſpoſed in a radiated manner. See the article CALYX.

JOA *Muſchata*, in botany, a name uſed by ſome authors for the chamæpitys or ground-pine. *Ger.* Emac. Ind. 2.

JOHNSWORT, or St. JOHN'S-WORT, *Hypericum*, in botany, *&c.* See the article HYPERICUM.

JOINTS (*Cycl.*)—The ſuppleneſs that the *Joints* may be brought to by long practice from the time of infancy, is ſurpriſing. Every common poſture-maſter at a country-fair ſhews us a great deal of this; but the moſt wonderful inſtance we have ever had of it, was in the perſon famous in London fifty or ſixty years ago, whoſe name was Clark, and commonly called Clark the poſture-maſter. This man had found the way by long practice to diſtort many of the bones, which no body before had ever thought it practicable to alter the poſition of; and had ſuch an abſolute command of his muſcles and *Joints*, that he could almoſt disjoint his whole body; ſo that he once impoſed on the famous Mullens by his diſtortions, ſo far that he refuſed to undertake his cure, as ſuppoſing him beyond relief. But, to his amazement, he had no ſooner given him over, than the man reſtored himſelf to the figure and condition of a proper man, with no diſtortion about him. See Phil. Tranſ. N° 242. p. 262.

JOINT-*Cartilage*, or ARTICULATING-*Cartilage*. An *articulating cartilage* is an elaſtic ſubſtance, uniformly compact, of a white colour and ſomewhat diaphanous, having a ſmooth poliſhed ſurface covered with a membrane, harder and more brittle than a ligament; but ſofter and more pliable than a bone. Philoſ. Tranſ. N° 469. p. 515.

When a *Joint-cartilage* is well prepared by the anatomiſt, it feels ſoft, and yields to the touch; but, as ſoon as the preſſure is taken off, reſtores itſelf to its former equality of ſurface. Its ſuperficies, examined by a glaſs, appears like a piece of velvet. If we endeavour to peel off the matter of the cartilage in ſeveral lamellæ, we find it impracticable; but if we uſe a certain degree of force, it ſeparates from the bone in ſmall pieces, and we never find the edge of the remaining part oblique, but always perpendicular to the ſubjacent ſurface of the bone. If we view this edge thro' a microſcope, it appears like the edge of a piece of velvet; that is, it is ſeen to be a maſs of ſhort and nearly parallel fibres, riſing from the bone and terminating at the ſurface of the cartilage; and the ſurface of the bone itſelf is plan'd out into a number of ſmall circular dimples in which the bundles of theſe fibres are fixed. Thus we may very aptly compare the ſubſtance of the cartilage to the pile of velvet, and the ſurface of the bone to the web of ſilk which is the baſis of it.

In both ſubſtances the ſhort threads or filaments ſink in waves on being preſſed, but by the power of elaſticity they both recover their perpendicular direction as ſoon as they are no longer ſubjected to a compreſſing force. Theſe perpendicular fibres, doubtleſs, make the greateſt part of the ſubſtance of the cartilage in its natural ſtate. In the beſt preparations they ſeem to make up the whole; but it is probable, that in the recent ſtate there were a number of tranſverſe fibrils ſerving to connect theſe erect ones together, and form the whole into a ſolid body; and that theſe periſh in making the preparation.

We are told by anatomiſts, that cartilages are covered with a membrane called perichondrium. If they mean the cartilages of the ribs, larynx, ear, *&c.* there indeed ſuch a membrane is very conſpicuous; but the perichondrium of the ſmooth *articulating cartilages* is ſo delicately thin, and ſo firmly braced upon the ſurface, that there is great room to doubt whether it has been rightly underſtood, or demonſtrated.

This membrane has, however, been raiſed by ſome late anatomiſts in pretty large pieces, after macerating, and it is found to be a continuation of that fine ſmooth membrane which lines the capſular ligament folded over the end of the bone; for when that ligament is inſerted on the neck of the bone, or between the inſertion of the ligament and the border of the cartilage, it is very conſpicuous, and may be pulled up with a pair of pincers; but where it covers the cartilage it is connected ſo cloſe, that it is not to be traced while recent, without the greateſt care and delicacy. In this particular it reſembles that membrane which is common to the eye-lids and the fore-part of the ball of the eye, and which is looſely connected with the albuginea, but ſtrongly attach'd to the cornea. From this deſcription it is plain, that every *Joint* of the human body is inveſted with a membrane, which forms a compleat bag, and gives a covering to every thing within the articulation, in the ſame manner as the peritonæum, inveſts not only the parietes but all the contents of the abdomen. Phil. Tranſ. N° 469. p. 517.

The blood-veſſels of the cartilages are ſo ſmall, that they do not admit the red globules of the blood, and conſequently they remained unknown till they were diſcovered by the modern diſcovery of injections, by which the whole vaſcular ſyſtem is filled with a liquid wax, coloured ſo as to be diſtinguiſhed from all other things: nor even by this method are we able to demonſtrate the veſſels of the true cartilaginous ſubſtance in adult ſubjects. But the fat, the glands, and the ligaments will be red with injected veſſels, while not one coloured ſpeck appears on the cartilage itſelf. Yet it is evident, that there are veſſels there, ſince in very young ſubjects after a ſubtile injection they become ſufficiently obvious. By this means their courſe is alſo diſcovered, and is found to be as follows.

All round the neck of the bone there are a great number of arteries and veins which ramify into ſmaller branches, and communicate with one another by frequent anaſtomoſes like thoſe of the meſentery. This might be called the *circulus articuli vaſculoſus*, the vaſcular body of the *Joint*. The ſmall branches of the veſſels divide into ſtill ſmaller ones upon the adjoining ſurface in their progreſs to the center of the cartilage; and we are very ſeldom able to trace them into its ſubſtance, becauſe they terminate abruptly at the edge of the cartilage in the ſame manner with the veſſels of the albuginea of the eye, when they arrive at the cornea. The larger veſſels which compoſe the vaſcular circle plunge in by a great number of holes, and diſperſe themſelves into branches between the cartilage and the bone. From theſe again there ariſes a crop of ſhort twigs, which ſhoot toward the outer ſurface. Whether theſe ſerve for nouriſhment only to the part, or whether they do not pour forth a dewy moiſture of ſervice to the functions of the part, it is not eaſily determined. It is to be obſerved however, that the diſtribution of the blood-veſſels to the articulating cartilages, is very peculiar, and ſeems calculated for the obviating of great inconveniencies. Had they run to the outer ſurface, the preſſure and motion of the two cartilages muſt infallibly have occaſioned frequent obſtructions and inflammations, which would ſoon have rendered our motions painful, and at laſt have deprived us of them; but by creeping round the cartilaginous brim where there is little friction, or under the cartilage where there is none, they are perfectly well defended from theſe accidents. Philoſ. Tranſ. N° 469. p. 518.

It would be very happy, if we could trace the nerves of the cartilages; but in relation to theſe organs we are obliged to be ſatisfied with mere conjecture, as to their exiſtence here, as well as in many other parts of the body. And tho' from the great inſenſibility of cartilages ſome perſons have ſuppoſed, that they were furniſhed with no nerves at all, yet when we conſider that theſe veſſels ſeem neceſſary to the growth and preſervation of any part, we muſt be forced to acknowledge their exiſtence in this, tho' we can neither ſee them nor be ſenſible of their effects.

The *articulating cartilages* are moſt happily contrived to all the purpoſes of motion in the parts. By their uniform ſurface they move upon one another with eaſe; by their ſoftneſs, ſmoothneſs and ſlipperineſs, their abraſion is prevented,

which elſe muſt have happened from ſuch frequent uſe. By their flexibility, the contiguous ſurfaces are always nicely adapted to one another, and the friction diffuſed equally over the whole; by their elaſticity the violence of any ſhock which may happen from running, jumping, or other violent motions, is broken and gradually ſpent; and as the courſe of the cartilaginous fibres appears calculated chiefly for this laſt advantage, we need only, to illuſtrate it, to reflect upon the difference of riding a chamber horſe of wood, and a real one, whoſe motions are ſoftened in all reſpects by the cartilages placed in the *Joints*.

The inſenſibility of the articulating cartilages is wiſely contrived by the great author of our frame, ſince it is wholly owing to this that the neceſſary motions of the body are performed without pain.

An ulcerated cartilage is generally allowed, by the beſt chirurgical writers from Hippocrates to the preſent time, to be a very troubleſome diſeaſe, and one that is more difficult to cure than a caries of the bones; and that when a cartilage is deſtroyed, it is never to be recovered again, is alſo a generally eſtabliſhed opinion. Hildanus in particular, in treating of the diſeaſes of theſe parts, has obſerved, that where a cartilage is by any means deſtroyed, nature uſually ſupplies its place by a callus thrown out from the bone, and that thus a bony anchyloſis, or immoveable continuity, is produced in the place of a moveable *Joint*. In the examining the diſeaſed *Joints*, either after death or amputation, Mr. Hunter obſerves, that he uſually found, according to the nature and ſtage of the diſeaſe, the cartilages in ſome parts reddiſh and lax, and in others ſoft and ſpongy; or that they were raiſed up in bliſters from the bone, or quite eroded, and perhaps the extremities of the bones carious; and finally, ſometimes a bony anchyloſis formed, as Hildanus reports; but that he never ſaw, or indeed heard of, an exfoliation from the ſurface of the cartilage. Now if we compare the texture of the cartilages, and their morbid appearances together, all theſe diſeaſed ſtates will admit of as rational ſolution, as thoſe of perhaps any other part of the vitiated œconomy. Phil. Tranſ. N°. 469. p. 521.

It appears from maceration of the cartilages, that their tranſverſe fibrils are extremely tender and diſſoluble, and that the coheſion of the parts of the ſtrait fibres is ſtronger than their coheſion with the bone. When a cartilage, therefore, is inflamed, and ſoaked in purulent matter, the tranſverſe, or connecting fibres, will ſooneſt give way, and the cartilage will become more or leſs red and ſoft. If the diſorder goes on a little longer, the cartilage does not throw off a ſlough, but ſeparates from the bone where the force of the coheſion is leaſt, and where the diſeaſe ſoon arrives, by reaſon of the thinneſs of the cartilage. When the bone is thus expoſed, the matter of the ulcer, or motion of the *Joint*, corrodes or abrades the bony fibres, and if the conſtitution is good, theſe will ſhoot out a callus, which either cements together the oppoſite bones of the articulation, or fills up the cavity of the *Joint*, and for the future prevents all motion: but if unfortunately the patient labours under a bad habit of body at the time, the malignancy having got root in the bone, will gain ground every day, and the caries will ſpread, till at laſt the only relief will be found the cutting off the limb.

JOINT *Water*, a term uſed by our farriers, for what the old writers in medicine have called hydarthros; a running of a clear ichor from the *Joints*, when they are either wounded or ulcerated; it is common in the diſeaſes of horſes.

JOINTE E, in the manege. See the article HANDFUL.

JOINTRESS, or JOINTERESS, ſhe that hath an eſtate ſettled upon her by the huſband, to hold during her life, if ſhe ſurvives him.

JON, in natural hiſtory, the name of a gem deſcribed by Pliny, and ſaid to be brought from the Eaſt Indies; he deſcribes it as being of a purple or violet colour, but rarely very deep in the tinge. It ſeems to have been a ſpecies of amethyſt.

JONÆ *Piſcis*, the *Jonas Fiſh*, a name given by many authors to the common ſhark, the *canis carcharias* of authors. It has this name from an opinion, that it was the fiſh which ſwallowed up the prophet of that name. But there are many objections to ſuch an opinion. See the articles CANIS and LAMIA.

JONKS, or JONQUES, in ſhip-building, veſſels very common in the Eaſt Indies, about the bigneſs of our fly-boats, but differing in form of building, according to the various methods of the nations in thoſe parts.

JONTHLASPI, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the cruciform kind, conſiſting of four leaves. The piſtil ariſes from the cup, and becomes at length a flat orbicular clypeated fruit, containing only one cell, which holds a flat and orbicular ſeed.

The ſpecies of *Jonthlaſpi*, enumerated by Mr. Tournefort, are theſe: 1. The hoary diſcoide mountain *Jonthlaſpi*, with yellow flowers: And 2. The little ſpiked lunated *Jonthlaſpi*. The firſt of theſe is called, by many authors, ſimply a *thlaſpi*, and the other a *lunaria*. *Tourn.* Inſt. p. 210.

IO PÆAN, among the antients, an exclamation uſed on account of a victory, or ſome proſperous event. Hoffman thinks that *Io Pæan* is a contraction of the Hebrew *Jao*, from *Jehovah*, and פנה, *reſpexit*; and was the ſame with *Jehovah Penoch*, i. e. *Dominus reſpiciat in nos*. Something like this exclamation ſtill remains among the *Symerones*, a people of the Weſt Indies, who on any joyful occaſion frequently cry out *Yo Peho*. *Hoffm.* Lex. in voc.

JOURNCHOPPERS, in our old writers, regrators of yarn; which formerly, perhaps, was called *Journ*. They are mentioned in the Stat. 8 Hen. 6. c. 5. *Blount*, *Cowel*.

JOY (*Cycl.*)—This paſſion has been found to increaſe the perſpiration and urine of human bodies. See the article PERSPIRATION.

JOZO, in zoology, the name of a ſmall ſea-fiſh, of the ſea-gudgeon or rock-fiſh kind, common in the Mediterranean, and called *gobius albus* by ſome authors.

It is ſmaller than any other ſpecies of the gobius, and has larger and rougher ſcales. It is of a paler and ſomewhat bluiſh colour, and the rays or nerves of its foremoſt back fin ſtand out beyond the edge of the fin itſelf, in form of hairs or briſtles. Its ſides are divided by a line running along each, from the gills to the tail, compoſed of ſmall oblong black ſpots. All the fins in this ſpecies are edged with blue, and the belly-fins are wholly blue. It is brought to market at Rome and Venice. *Willughby*'s Hiſt. Piſc. p. 207.

IPECACUANHA (*Cycl.*)—The bark of *Ipecacuanha* is ſaid to be preferable to its root, as an emetic; acting equally well, and with equal ſafety in a ſmaller doſe, either in powder, or infuſion. Six grains of the bark, infuſed for a night in an ounce and a half of old rheniſh, proves a good emetic. See Phil. Tranſ. N°. 476. Sect. 10.

The brown *Ipecacuanha* yields, by diſtillation, a ſmaller quantity of oil than the grey, and the laſt portion of the ſpirit which comes over with the oil, on urging the fire to the greateſt violence, tho' it be conſiderably acid to the taſte, yet does not ſeem to contain leſs, but rather more volatile particles than the ſpirit drawn in the ſame manner from the grey. On mixing the ſpirits of both kinds alſo with ſalt of tartar, the volatile parts of that from the brown, eſcape with more rapidity than thoſe from the ſpirit of the grey, and affect the noſe more ſenſibly.

It is rational to conclude from hence, that if the brown *Ipecacuanha* contains leſs oil than the grey, it alſo contains leſs reſin; and that as this laſt portion of ſpirit contained more volatile parts, it muſt naturally be expected that it ſhould prove more violent in its operation than the grey. This obſervation alſo, which is countenanced by fact, may in ſome degree favour the opinion of thoſe who affirm, that the purgative virtues of medicines are excited by a volatile ſalt, and that they are more or leſs violent, as they contain more or leſs of this ſalt.

The brown *Ipecacuanha*, as well as the grey, will afford two ſorts of extracts, a reſinous and a ſaline one; but both theſe are yielded in a ſmaller quantity from the brown than from the grey, and conſequently the reſiduum is alway greater from the brown. Eight ounces of the grey *Ipecacuanha* yield, with ſpirit of wine, ten drams of the reſinous extract; the ſame quantity of the brown, treated in the ſame manner, yields only ſix drams. From the reſiduum of this quantity of the grey kind, thus diveſted only of its reſin by the ſpirit, there may be procured, by a watery ſolvent, two ounces of a ſaline extract; but the reſidue of the ſame quantity of the brown will yield only five or ſix drams of this extract, by the ſame treatment. The reſidue of the grey, thus diveſted of its reſinous and ſaline parts, will weigh four ounces; and the reſidue of the brown, after the ſame treatment, will weigh near ſix ounces. Hence it is very evident, that the active principles are much more abundant in the grey than in the brown kind of this uſeful root.

If the proceſs of this analyſis be varied, and the watery menſtruum uſed firſt, the proportion of the ſaline extract will be greatly increaſed by it, and that of the reſinous greatly diminiſhed; eight ounces of the grey *Ipecacuanha*, thus treated, yielding three ounces and a half of ſaline extract, and only thirty-ſix grains of the reſinous one afterwards by ſpirit of wine; and the ſame quantity of the brown yielding one ounce and three drams of the ſaline extract, and only twenty-four grains of the reſinous one, by means of ſpirit of wine afterwards uſed. From all this it is eaſy to perceive, that the brown *Ipecacuanha* contains much leſs of the active parts, and much more of the terreſtrial than the grey; and yet it is equally certain from trial, that the brown is much more violent in its operation than the grey.

This ſeems a perplexing ſort of paradox; but to explain it we muſt remember, that the virtues of medicines are not to be meaſured by their bulk nor their weight, the moſt powerful of all acting in the ſmalleſt quantities. It has been obſerved, that the laſt portion of ſpirit drawn from the brown is more pungent and ſtrong than that from the grey; and probably this part of the root has as much power to irritate the internal parts of the inteſtines as the reſinous parts.

Small doſes of *Ipecacuanha* are recommended in diarrhœas of a more ſimple kind, as well as in dyſenteries; and in the fluor albus, we hardly know a better medicine.

IPECATI *Apoa*, in zoology, the name of a Braſilian ſpecies of duck, called *pata* by the Portugueſe; the word in that language expreſſing gooſe. It is nearly of the ſize of the gooſe, but is exactly of the ſhape and figure of the common duck. The head, neck, belly, and lower part of the tail, are white, and the back, wings, and top of the head, of the fine green colour of the necks of our drakes; and its belly has ſome few black variegations. And over the origin of the beak there is a fleſhy tubercle, which is black, variegated with white ſpecks. Its legs and feet are of a browniſh grey. The male ſeems to be diſtinguiſhed from the female, in this ſpecies, by its having ſome long feathers of its wings of a ſhining brown. It is very common in the Braſilian rivers, and is fleſhy and well taſted. *Marggrave*, Hiſt. Braſ.

IPECA GUACA, in zoology, the name of a Braſilian ſpecies of duck. It is of a middle ſize between the duck and gooſe, and is kept tame there for breeding and eating. It is a very beautiful colour'd bird. It has a very elegant red ſpot on the middle of its head. Its whole upper part is of a very beautiful white like the ſwan. Its legs and feet are yellow. It will fatten as well on dry land as when it has the uſe of water, and lays a vaſt number of eggs. *Piſo*, Hiſt. Braſil.

IPECU, in zoology, the name of a Braſilian bird of the woodpecker kind, called by Mr. Ray, *picus varius Braſilienſis*. It is of the ſize of a common pigeon. Its head is of a very gay and beautiful red, and has a very beautiful creſt of feathers of the ſame colour on it. Its neck is black, but has a very broad white line on each ſide. Its wings are black on the outſide, and red within. Its tail is black; and its belly and thighs are mottled with black and white. Its beak is ſtrait, and very hard and ſharp, and it pierces the bark and wood of trees with it, in the ſame manner as the European kinds. *Marggrave*, Hiſt. Braſ..

IPERAQUIBA, in zoology, a name by which ſome have called the *remora*, or ſucking fiſh, called alſo by the Portugueſe, *piexe pogador*, and *piexe pioltho*. Ibid. p. 117.

IPPOSELINUM, or HIPPOSELINUM, in botany, a name given by the antients to the plant from the roots of which the fineſt myrrh was obtained by inciſion. Some alſo have called this plant *ſmyrnium*; but it is evident, that it could not be the ſame with the *Hippoſelinum* or *ſmyrnium* of our authors, which is the herb Alexanders, ſince the juices of this plant have no reſemblance to myrrh. Dioſcorides calls the plant *ſmyrna*, and diſtinguiſhes it from the *ſmyrnium* of thoſe times; but others have made the *ſmyrna* and *ſmyrnium* the ſame.

IRACUNDUS *Muſculus*, in anatomy, a name given by ſome authors to one of the muſcles of the eye, called alſo the *rectus exterior* and *abducens*. It is one of the *quatuor recti oculi* of Albinus, and is called by him and Douglaſs, as well as many others, the *abductor*. See the article ABDUCTOR, *Cycl.* and *Suppl.*

IRINGIUM, a name given by ſome of the old writers on the materia medica, to a root called *ſecacul* by the Arabians, and which, from the ſimilitude of the Latin name with the word *eryngium*, many have ſuppoſed to be the ſame root which was well known to the Greeks and Romans in medicine, and ſtill is in great repute with us on the ſame occaſions. The interpreters of Aviſenna and Serapion always render the word *ſecacul* by *Iringium*, never by *eryngium*; and, according to their accounts, it was a root much reſembling ginger in ſhape, and was brought from the Eaſt Indies, and ſuppoſed to have the virtue of promoting venery.

We at this time eſteem the *eryngium* a provocative, and it is kept candied, and eaten for that purpoſe: But this, probably, is only an error founded on our ſuppoſing it the ſame with the *Iringium* of the Arabians; for Dioſcorides, who gives a full account of the virtues of his *eryngium*, which is the ſame with ours, ſays nothing of its poſſeſſing any ſuch quality; and the Greeks, at his time, were as famous for finding out the virtues of plants in this reſpect, as the eaſtern nations are at preſent, tho' not quite ſo credulous. It is poſſible that the *Iringium* may be the ſame with the *ginging* or *ginſeng*, ſo famous in the Eaſt at this time for the ſame virtues. See the article GINSENG.

IRIS (*Cycl.*)—When the aqueous humour of the eye is evacuated at a wound or ulcer of the cornea, there is danger of the *Iris* growing to it. To prevent this, the patient is to be expoſed to the light from time to time, till the cornea is again raiſed by the aqueous humour. The light occaſions a motion in the *Iris*, which may prevent its adheſion. *Demours*, ap. Med. Eſſ. Abr. V. 2. p. 508.

IRIS, the *flower de luce*, in the Linnæan ſyſtem of botany, a diſtinct genus of plants, under which that author comprehends the *Iris*, the xyphion, the ſiſyrinchium, and hermodactylus of Tournefort, as all plants of the ſame genus, the characters of which are; that there is no flower cup, but ſome ſingle ſpathæ interwoven with one another, imbricated, dividing the flowers from one another, and remaining after the flowers are fallen off. The flower is divided into ſix parts; the petals are long, and obtuſe; the three exterior ones are bent back; the three interior are erect and acute, and the whole number joined at their lower ends. The ſtamina are three pointed filaments lying on the bent petals; and the antheræ are oblong, ſtrait, and depreſſed. The germen of the piſtillum is oblong, and is placed below the receptacle. The ſtyle is ſingle, and very ſhort. The ſtigma very large, and divided into three parts; the ſegments, which reſemble ſo many petals of a flower, are broad, and bent back, and preſs upon both the petala and ſtamina; the extremities of theſe are bifid. The fruit is an oblong angular capſule, with three cells and three valves. The ſeeds are many in number, and very large. See Tab. 1. of Botany, Claſs 9.

In ſome of the plants of this genus the capſule is trigonal, in others hexangular. *Linnæi* Gen. Plant. p. 11.

The characters of *Iris*, according to Tournefort, are theſe: The flower is liliaceous, conſiſting of one leaf, and being of a tubular ſhape at the bottom: Hence it is expanded and enlarged, and forms ſix parts, three of which point upwards, and three downwards. The piſtil ariſes from the bottom of the flower, and is furniſhed with three petals, which are arched, and ſo bent down upon the reflex leaves of the flower, that they reſemble a ſort of palate. The flower-cup finally becomes an oblong fruit, which opens into three parts at the end, and is ſeen to be divided into three cells, which contain roundiſh and ſometimes flattiſh ſeeds. To this it is to be added, that the root is fleſhy, oblong, and of the creeping kind, and not covered with coats.

The ſpecies of *Iris*, enumerated by Mr. Tournefort, are theſe: 1. The common wild or German *Iris*. 2. The common garden broad-leav'd *Iris*, with purpliſh blue flowers. 3. The garden *Iris*, with pale blue flowers. 4. The little pale blue-flower'd garden *Iris*, with a white covering. 5. The white German garden *Iris*. 6. The white Florentine *Iris*. 7. The common Illyrian *Iris*. 8. The very large-flower'd black and white *Iris*. 9. The little broad-leav'd *Iris*, with white flowers and blue edges. 10. The little broad-leav'd *Iris*, with white flowers, and pale purple edges. 11. The many-flower'd blue Aſian *Iris*. 12. The purple Aſian *Iris*. 13. The reddiſh flower'd ſcentleſs *Iris*. 14. The *Iris* with the ſmell of the oxycantha. 15. The great broad-leav'd Roman blue *Iris*. 16. The great Dalmatian *Iris*, with a pale violet-colour'd flower. 17. The bluiſh purple Conſtantinople *Iris*. 18. The many flower'd blue Damaſcus *Iris*. 19. The broad-leav'd ſweet-ſcented German *Iris*. 20. The broad-leav'd German *Iris*, with the ſmell of elder flowers. 21. The broad-leav'd German *Iris*, with deep yellow flowers. 22. The broad-leav'd German *Iris*, with white and purple flowers. 23. The broad-leav'd *Iris*, with the ſmell of the oxycantha. 24. The broad-leav'd Pannonian *Iris*, with double flowers. 25. The broad-leav'd *Iris*, with green and white flowers. 26. The broad-leav'd *Iris*, with naked ſtalks. 27. The broad-leav'd *Iris*, with white flowers, ſtreaked with red. 28. The broad-leav'd Dutch *Iris*, with the ſmell of elder. 29. The variegated broad-leav'd elder-ſcented *Iris*. 30. The greater purple-flower'd broad-leav'd *Iris*, with the elder ſcent. 31. The broad-leav'd *Iris*, with whitiſh ſtriated flowers. 32. The low broad-leav'd purple *Iris*. 33. The two-flower'd *Iris*, with ſmall flowers, ſmelling like lilly of the valley. 34. The great-flower'd Illyrian *Iris*. 35. The ſmall Dalmatian *Iris*, with pale purple flowers. 36. The yellow-flower'd garden *Iris*. 37. The variegated yellow garden *Iris*. 38. The yellow-flower'd Tripoli *Iris*, with extremely long leaves. 39. The common wild marſh *Iris*, with yellow flowers, called the yellow *flag-flower*. 40. The wild yellow flag-flower, with ſhorter and bluiſh green leaves. 41. The pale wild yellow *Iris*. 42. The wild ſtinking *Iris*, called *xyris*, and ſtinking *gladwin*. 43. The narrow-leav'd meadow ſtinking *Iris*, or *gladwin*. 44. The taller narrow-leav'd not ſtinking *Iris*. 45. The lower narrow-leav'd meadow *Iris*. 46. The narrow-leav'd ſea *Iris*. 47. The leſſer narrow-leav'd ſea *Iris*. 48. The narrow-leav'd garden *Iris*, with changeable colour'd flowers. 49. The narrow-leav'd garden *Iris*, with whitiſh flowers, marked with ſtreaks of red. 50. The narrow-leav'd *Iris*, with two colour'd flowers. 51. The greater narrow-leav'd *Iris*, with the ſmell of a plum. 52. The leſſer narrow-leav'd *Iris*, with the plum ſmell. 53. The two-flower'd dwarf *Iris*, with large deep purple flowers. 54. The low *Iris*, with blackiſh purple flowers. 55. The low *Iris*, with variegated flowers. 56. The low *Iris*, with a blackiſh purple flower. 57. The low *Iris*, with plain purple flowers. 58. The low *Iris*, with white flowers, and ſtreaks and edges of blue. 59. The low Pyrenean *Iris*, with greeniſh yellow expanded leaves. 60. The low Pyrenean *Iris*, with green expanded leaves, variegated with blue. 61. The little low *Iris*, with a bluiſh purple flower. 62. The low *Iris*, with red flowers. 63. The low dwarf *Iris*, with variouſly painted flowers. 64. The low *Iris*, with purple and yellow flowers. 65. The low *Iris*, with pale and whitiſh flowers. 66. The leſſer dwarf *Iris*, with variegated flowers. 67. The leſſer *Iris*, with white flowers. 68. The dwarf *Iris*, with yellow flowers. 69. The dwarf *Iris*, with duſky yellow flowers. 70. The low *Iris*, with pale yellow flowers. 71. The low *Iris*, with white flowers, variegated with veins of many colours. 72. The

The dwarf French ſtone *Iris*. 73. The broad-leaved low ſtone *Iris*. 74. The larger leaf-leſs ſtone low *Iris*. Tourn. Inſt. p. 360.

The Florentine dry *Iris*, or orrice root, is an expectorant and attenuant. It is given with ſucceſs in aſthmas, and many other diſorders of the breaſt and lungs. The doſe is from ten to fifteen grains in powder. The juice of the freſh root of our *Iris*, is an excellent medicine in dropſies; and the beſt way of giving it is with white wine, an ounce or two for the doſe, which muſt be taken every two or three days. It works both by vomit and ſtool, and diſcharges a very great quantity of phlegm.

We have a great many ſpecies of this plant preſerved in gardens, and moſt of them very beautiful; their roots are tuberous, and increaſe very faſt, and all the ſpecies are eaſily propagated by parting them. The beſt ſeaſon for doing which, is in Auguſt, when their flower leaves are decayed, and the whole plant begins to change colour; but this ſhould always be done when the weather is moiſt, ſo that if the month of Auguſt ſhould prove very dry, it ſhould be deferred till September, though it is beſt to do it ſooner if it can be. They all love a ſhady and moiſt place. If too much dung is uſed to the ground, it rots their roots; and if they ſtand expoſed to the ſun, their flowers are but of very ſhort duration. They ſhould be taken up once in two years, to prevent their extending their roots too far, for they are very apt to ſpread, and to harbour all ſorts of vermin.

The curious may raiſe the ſeveral ſpecies from their ſeeds, which if taken from the choiceſt flowers, and cultivated with care, uſually afford a fine variety in the flowers of the plants they produce. They ſhould be ſown ſoon after they are ripe on an eaſt border; they will come up in ſpring, and the year following will flower. *Miller*'s Gard. Dict.

IRIS *lutea paluſtris*, the *yellow flag flower*. The common people of Scotland have found out a uſe of this plant, which has eſcaped the moſt accurate writers on botany. In that country the common ink is made of it. They cut ſome of theſe roots into thin ſlices, and either boil or infuſe them in water till the liquor is highly tinged with them; they then pour it clear off; and then putting into it the blade of a knife, or any other piece of iron, they rub it hard with a rough white pebble common there, and by degrees the liquor becomes black; they continue rubbing it till it is as deep a black as they require, and it is a tolerable good ink. Philoſ. Tranſ. N° 117.

The juice of this plant mixed with ſyrup of buckthorn, is reckoned an effectual hydragogue. See Med. Eſſ. Edinb. vol. 5. art. 8.

IRIS is alſo a name given by ſome authors to a peculiar ſpecies of ſpring cryſtal, remarkable for its giving the rainbow colours in reflection. This, however, being a property more or leſs found in all the kinds of ſprig cryſtal, and theſe much reſembling one another, it became applied to ſprig cryſtal in general; and *Iris*, inſtead of being the name of a peculiar ſpecies, was underſtood as a ſynonymous term for common cryſtal. Dr. Hill has, however, from the accounts of the authors who firſt gave a name to this body, aſcertained it to be properly the denomination of a peculiar ſpecies of ſprig cryſtal, which he has diſtinguiſhed by the name *ellipomacroſtylum albidum*, *pyramide longiſſima*, or whitiſh ſprig cryſtal, with a very long pyramid, which is found in great abundance in Germany, Italy, and England, adhering to the ſurfaces of fiſſures in ſtone quarries. *Hill's* Hiſt. of Foſſ. p. 179.

IRIS *Marina*, the *Sea Rainbow*. This elegant appearance is generally ſeen after a violent ſtorm, in which the ſea-water has been in vaſt emotions. The celeſtial rainbow has great advantage over the marine one in the brightneſs and variety of the colours, and in their diſtinctneſs one from the other; for in the ſea rainbow there are ſcarce any other colours than a duſky yellow on the part toward the ſun, and a pale green on the oppoſite ſide. The other colours are not ſo bright or ſo diſtinct as to be well determined, but the ſea rainbows are more frequent and more numerous than the others. It is not uncommon to ſee twenty or thirty of them at a time at noon-day. Obſerv. ſur l'Aſie, p. 292.

IRON (*Cycl.*)—It would ſcarce have been believed, till experiments confirmed it, that *Iron* makes a part of almoſt all ſorts of ſubſtances. Mr. Geoffroy attempting to produce *Iron* by chemiſtry out of ſeveral ingredients, into which it may be decompoſed, wanted firſt to find ſuch as in themſelves contained no *Iron*. He found that the aſhes of all vegetable bodies whatever, contained more or leſs of that metal; and Mr. Lemeri afterwards, in his analyſis of honey, found *Iron* in the calcined caput mortuum of that ſubſtance, many particles of it adhering to a knife that had been touched on a magnet. Mem. Acad. Par. 1706.

This had much puzzled the thoughts of the chemiſts, when Mr. Lemeri at length attempted to account for it in this manner. All earth is impregnated with a ferrugineous or vitriolic matter, and this therefore muſt be received into the roots of plants in their growth, and make a part of their ſubſtances. It is, however, in too ſmall a quantity, and in particles too much diſſeminated, to ſhew itſelf in the ſtalks or leaves of the plant; but when the whole has been calcined, the fire collecting together its ſeparated particles, they then form ſmall maſſes which act as *Iron*, and apply themſelves to the magnet.

Beſides this, the ſame author gives another explication of this phænomenon, according to which he ſuppoſes that there was abſolutely no *Iron* in the plant itſelf in its natural ſtate, but that the fire in calcining the aſhes, has converted a part of them into that metal.

The firſt of theſe has the faireſt appearance of truth, but before it can be determined with any degree of certainty which, or if either be right, it ſeems neceſſary to be perfectly informed whether there may not be in nature other particles of matter, beſide thoſe of *Iron*, capable of being attracted by the magnet. This, however, there ſeems at preſent no poſitive argument to ſupport, or reaſon to ſuppoſe; and on the other hand, it is not only in all vegetable aſhes that particles of *Iron* are diſcovered by the magnet, but in animal ones; the aſhes of caſtor having been found by the younger Lemery to contain alſo *Iron* in as large a proportion as thoſe of honey and of vegetables.

To try whether theſe particles attracted by the magnet in the aſhes of vegetables were really *Iron*, this author collected a ſmall quantity of them together by means of a knife touched on the magnet, and expoſing them to the focus of the great burning-glaſs belonging to the then duke of Orleans, they were found to be melted by that heat in the ſame manner as common *Iron*, and to be attended with all the ſame circumſtances in the ſeveral ſtates of fuſion and diſſipation. It ſparkled greatly while ſoft, and finally was reduced to a ferrugineous earth or bole, in all reſpects the ſame with that ſeparated by the ſame means from filings of *Iron*, or from the magnet. When this matter is thus proved to be real *Iron*, the doubt how it is able to get into the minute veſſels of plants, is cleared, by conſidering that *Iron* is not only preſent in all earth, but is alſo very eaſily diſſolved by all ſorts of ſalts, and takes different forms with every one, according to its ſeveral nature. When it is found in earths which contain an acid analogous to that of vitriol, ſulphur, or alum, it becomes converted into a ſalt known by the name of vitriol; and what objection can there be againſt the ſuppoſing that this ſalt, when diſſolved in a ſufficient quantity of water, is received into the veſſels of plants growing in the earth where it abounds; and we cannot doubt the diviſibility of the particles of *Iron* in the ſtate of this ſalt, being great enough to make it capable of paſſing even into the moſt minute veſſels of plants, when we conſider that a grain of vitriol diſſolved in nine thouſand times its own weight of water, is capable of giving colour to the whole, and with it a ſenſible taſte of the metal from which it had its origin.

The ſpecific gravity of *Iron* has been by ſome ſuppoſed to be a reaſon againſt the believing its aſcent in the veſſels of plants; but this appears of no weight, when we conſider that all flowers are found, on a chemical analyſis, to contain earth, and that earth is heavier than *Iron* in the ſtate of vitriol; and that the metals in the ſtate of vitriols, do often riſe in vapour, and that without any great heat, is plain from this experiment, that if blue, green, and white vitriol be put together into a box, and covered down, the natural evaporations of each falling confuſedly on the others, will change the colour of every one on their upper ſurface, while that which touches the bottom of the box remains unaltered. If vitriol be put into an earthen veſſel, and water poured on it in ſmall quantity only to moiſten it, the *Iron* loaded with its acids, will be found in a little time to aſcend up the ſides of the pot to the top. This is a ſecond proof that *Iron* in the ſtate of vitriol is to be raiſed or ſublimed with great eaſe. There is, however, beſides theſe, yet another more convincing.

When ſpirit of nitre is poured upon filings of *Iron*, there ariſes an ebullition attended with ſo great heat that the hand can ſcarce be held upon the outſide of the veſſel. After the ebullition the liquor becomes red, and greatly loaded with the diſſolved *Iron*. If oil of tartar be added to this liquor, there is raiſed a moderate ebullition, and the mixture ſwells greatly. After this there are found a number of branches very beautifully arranged on the ſides of the veſſel, and theſe continue to form themſelves under the eye, while there is no fermentation nor ebullition in the liquor. Theſe curious figures at length cover the whole ſurface of the veſſel, and riſing over the rim of it, fall on the outſide, and cover that alſo. This beautiful vegetation may be varied a great many ways by the different proportions of the ingredients; but in every proceſs it ſhews how very eaſily *Iron* may be made to aſcend upwards, and that to great heights; and when we conſider the power of the heat of the ſun, and of the ſuction of the roots of plants, which are in a manner ſo many ſyphons acting together upon the juices of an earth, among which there are particles of *Iron* thus diſſolved; we are not to wonder that *Iron* is conveyed into the veſſels of the plant, or found afterwards in its aſhes. The wonder would be, that there ſhould be any vegetable aſhes which did not afford *Iron*, but that does not appear yet to have been found in regard to any. Mem. Acad. Par. 1706.

On expoſing a piece of *Iron* of a dram weight to the focus of the great burning-glaſs, it became immediately red-hot; then its ſurface was covered with a blackiſh ſcum, looking like pitch or bitumen. If the *Iron* be taken away in this ſtate, this black matter is found to have formed a thin cruſt which covers it, and eaſily falls off on ſtriking on the backſide of the *Iron*; and the ſurface of the *Iron*, which was covered by it, appears whiter than this metal uſually does. This covering is, according to Mr. Homberg, a part of the oily matter of *Iron*, which always ſeparates itſelf from that metal when it is about to melt, and remains ſome time before it is evaporated. If the piece of *Iron* be continued longer in the focus, on a piece of charcoal, it ſoon perfectly melts, and throws out very bright ſparks; theſe are very numerous, and ſometimes are diſcharged to a foot diſtance. If theſe ſparks are caught upon paper, they appear upon examination to be ſo many globular particles of *Iron*, and are for the moſt part hollow. If the *Iron* be continued yet longer in the focus, it diſſipates intirely in form of theſe ſparks, and nothing remains of it.

This ſparkling of the *Iron* appears to be wholly owing to the ſulphureous part of the charcoal acting upon the oily part of the *Iron*; for if it at any time happens that the ſurfaces are ſeparated by a bed of aſhes, the *Iron* then ceaſes to ſparkle, and remains in a quiet ſtate of fuſion; but if by any accident the bed of aſhes is diſcompoſed, and the *Iron* becomes touched again by the charcoal, it immediately ſparkles as before. The aſhes are ſometimes vitrified by the heat, and then they either mix among the melted metal, and make together a ſort of half vitrified maſs, or elſe the glaſſy matter of the aſhes ſwims on the ſurface of the melted *Iron* in round globules; theſe are ſometimes clear and tranſparent, ſometimes opake and obſcure, according as they contain more or leſs of the metal. If after the melted *Iron* has been ſuffered to cool upon the charcoal, it be again expoſed to the focus of the glaſs upon a piece of ſtone, it then will ſparkle very violently, and wholly diſſipate itſelf, which it otherwiſe would not have done, if it had not been before fuſed upon the charcoal.

If ſteel and *Iron* be expoſed together to the focus of the glaſs upon a piece of ſtone, they both become red-hot and melt, but never ſparkle; they emit large fumes, and the metal becomes thin like oil, and if taken away in this ſtate, they fix, when cold, into regulus's uſually of a ſtriated texture. Theſe metals would be vitrified in a little more time in the focus, but the matter which they are laid upon vitrifies alſo, and by that means there is a confuſion of the two ſubſtances. The regulus before mentioned is a ſort of half vitrified matter; it is very brittle, and of an obſcure duſky brown, and is no longer in the ſtate of *Iron*; but as it has been reduced to this ſtate merely by depriving it of its oil or ſulphur, it may be again reſtored to its ductility and true metalline ſtate, by giving it again a ſulphureous matter of the ſame kind. This may be done by laying it in the focus again upon a piece of charcoal, which will reſtore its oil to it: in this caſe it melts readily, and remains a long time in fuſion without ſparkling, but at length it begins to ſparkle as common *Iron*; and if taken away at that time, it is found to be common *Iron* again, only ſomewhat whiter and more compact than before. Mem. Acad. Par. 1709.

It appears from the whole, that *Iron* contains an oil or ſulphureous principle, which is what renders it bright, malleable, and fuſible; that this oil is carried off from the metal by the ſun's heat, when it is held ſome time in fuſion, nay, and that this oil is even carried off in ſome degree by a common fire, which though not capable of melting *Iron*, yet reduces its ſurface in large pieces into a reddiſh ruſt. The metal diveſted of this oil by the ſun, appears a reguline matter, not unlike antimony in colour, and ſeems a half vitrified ſubſtance; and there ſeems no doubt but that this would be perfectly vitrified, if there were any way of holding it a ſufficient time in the focus, without melting the ſubſtances alſo on which it is ſupported. This glaſſy, or reguline matter requires only a ſmall quantity of oil to be reſtored to its priſtine ſtate of metal, and it readily receives this oily matter from charcoal; whence it ſeems no raſh inference that the oil of charcoal, and that of *Iron*, are ſubſtances not very different in their nature, ſince the one can thus replace the other; but there is evidently ſome difference, ſince the *Iron* filled with the oil of charcoal ſparkles in this trial; whereas common *Iron* does not ſo till laid upon charcoal and melted on it, in which ſtate it probably loſes ſome of its own ſulphurs, which are replaced from the charcoal.

Of all the metals *Iron* is the only one which ſparkles in the focus of the burning-glaſs, and this is probably owing to the prevalence of a vitriolic ſalt in it, which is very greedy of ſulphurs; and to this alſo it is probably owing that *Iron* conſumes the charcoal on which it is fuſed, much more quickly than any other metal. Id. ibid.

IRON, in medicine, is ſaid to have greater virtues than any of the other metals, which is not to be wondered at, as being the only one that is in a manner ſoluble in the human body. All the other metals, whether hard or ſoft, poiſonous or ſalutary, nay, even fluid mercury itſelf, ſwallowed in their crude ſtate, paſs out of the body again unaltered; but this is not the caſe with *Iron*, its crude filings are often taken as a medicine, and are always ſo much acted upon by the juices, as to produce conſiderable effects. It is ſo eaſily wrought upon out of the body alſo by fire, and by different menſtruums, that it becomes an aperient or aſtringent, as it is differently treated; and is, under proper management, greatly ſuperior to all other medicines in chronic caſes.

Its virtues internally were not unknown to the antients; Dioſcorides attributes an aſtringency and aperiency both to it, and preſcribes it in hæmorrhages. He alſo recommends its ruſt, or *crocus martis*, in ſuppreſſions of the menſes; though he on the other hand preſcribes wine or water, in which red-hot *Iron* had been quenched, as an aſtringent in dyſenteries, diarrhœas, and weakneſſes of the ſtomach.

It ſeems to act in the human body principally by means of its vitriolic ſalt; and if we rightly underſtand the nature of that ſtyptic ſalt, we ſhall not be at a loſs to comprehend how a metal that abounds ſo with it, acts in two ſuch different manners, while both ariſe from the ſame principle, though they ſhew themſelves in various forms.

Every preparation alſo of *Iron* is both aperient and aſtringent in degree; and the only difference between them is, that ſome of them operate more ſtrongly one way, ſome the other. Thoſe in more frequent uſe at preſent are, 1. The crude filings reduced to an impalpable powder. 2. The ſalt or vitriol of *Iron*, called *ſal martis*. 3. The *crocus martis aperiens*. 4. *Tinctura martis cum ſpiritu ſalis*, 5. *Flores martiales*, or flowers of *Iron*. 6. The *vinum chalybeatum*. Theſe are all accounted aperients. Among the aſtringents the two capitals ones are, 7. The *crocus martis aſtringens*; and 8. The *tinctura antiphthyſica*, or, as it is called in the New London Diſpenſatory, *tinctura ſaturnina*.

How to gild *Iron* with water-gold. See the article GILDING.

IRON *Furnaces*. Theſe furnaces as they are employed in running the moſt difficult of fuſion of all metals, ſo they are of all others contrived the largeſt, and capable of carrying heat to the greateſt degree. When they are to be uſed, they are firſt filled up to the top with coals; and the lower part being lighted; the top, and all other parts of the furnace where the air could have paſſage, are cloſed firmly up with *Iron* plates laid one over another. The conſequence of this is, that the fire is put out, and the whole is kept in this ſtate ten or twelve days. At the end of this time the furnace is opened, and the coals are found all black, without a ſingle ſpark of fire in any part, yet extremely hot, and reduced to a tenth part of their quantity. When the furnace has been thus opened about a quarter of an hour, the matter begins to take fire of itſelf by the mere contact of the air. The firſt appearance of this is very remarkable, there ariſes a very bright flame from ſome of the coals, which plays about their ſurface, and ſpreads itſelf from one to another, without the appearance of the leaſt ſpark of fire in any part of any of the coals. The ore of the *Iron* is for the firſt day put only in the middle of the furnace, and that but in ſmall quantity; the next day more, and every day afterwards more and more is put on, and by degrees it is ſpread over the whole ſurface of the furnace to the edges. This is the method of working the ore to the utmoſt advantage, and with the moſt diſpatch. The whole proceſs for one furnace of ore is finiſhed in about eight days from the time of the opening the top; all the uſe of the firſt quantity of coal, is only thoroughly to warm the ſides and walls of the furnace; and it is after this to be kept carefully ſupplyed with fuel, and the ore only ſpread out toward the ſides as the extreme heat, moſt ſenſible in the center, encreaſes. If too much be laid on of the ore at firſt, there is always a loſs from the quantity of metal. The quantity of the coals neceſſary to any given quantity of ore, differs in proportion to the advantageous or faulty ſtructure of the furnace. In the very beſt conſtructed ones, the weight of the coals and of the ore need be no more than equal. The flame which makes its way out of the bottom of the furnace, is of different colours, according to the nature of the ore and of the coals; ſometimes red, ſometimes yellow, and ſometimes green. That which iſſues out from the top of the furnace is of a red colour, and aſcends in a ſort of ſpiral line reſembling the ſound of diſtant falls of waters as it mounts up. With all the care that can be taken to heat the ſides of the furnace, and to keep them hot, the middle is always greatly the hotteſt, and the ore ſooneſt runs into metal there. *Swedenborg* de Ferro & Igni.

IRON *Ore*. In the *Iron* works in Staffordſhire, after the ore is dug, before it be fit for the furnace, they burn or calcine it on the open ground with ſmall charcoal, wood, or ſea coal, to make it break into ſmall pieces, which will be done in three days. *Plott*, Nat. Hiſt. Staff. c. 4. n. 21.

This they call annealing or fitting it for the furnace. *Hought.* Collect. N° 271. See IRON *Furnaces*, ſupra.

Iron may be procured from its ore in a cloſe veſſel in the following manner: Roaſt for a few minutes in a teſt, placed under a muffel in a pretty ſtrong fire, two centners of *Iron* ore groſsly powdered, that the volatile particles may be in part diſſipated, and the ore ſoftened in caſe it be too hard.

When it is grown cold, beat it to a very fine powder, and roaſt it a ſecond time in a ſtronger fire till it emits no ſmell, then take it out of the fire.

Compoſe a flux of three parts of the common white flux, and one part of powdered glaſs, and add of ſandiver and coal-duſt of each one half part. Add of this flux three times the quantity of the roaſted ore, and mix the whole very well together; then take a good crucible well luted within, and put into it the ore mixed with the flux; cover it with common ſalt, and ſhut it cloſe with a tile, and with lute applied to the joints. Put the common wind furnace upon its bottom part, having a bed made of coal-duſt; introduce into the furnace a ſmall grate ſupported on its iron bars, and a ſtone upon it whereon the crucible may ſtand; ſurround the whole with hard coals, not very large, and light them at top. Make the fire very ſtrong, and continue to add freſh fuel, that the veſſel may never be naked at top. When the fire has thus been continued in its full ſtrength for an hour, take out the veſſel, and ſtrike on the floor where it ſtands, to collect all the particles of *Iron* into a body, and when cold break the veſſel, and you will find the pure *Iron*. *Cramer*'s Art of Aſſaying, p. 338.

Several attempts have been made to run *Iron* ore with pit-coal, but we meet with no account of the ſucceſs of ſuch attempts: However, Mr. Maſon informs us, that at Colebrook Dale in Shropſhire, Mr. Ford makes *Iron* brittle or tough as he pleaſes, from *Iron* ore and coal, both got in the ſame dale; there being cannon thus caſt, ſo ſoft as to bear turning like wrought *Iron*. Phil. Tranſ. N° 482. Sect. 6.

IRON-*Wort*, in botany. See the article SIDERITIS.

IRREDUCIBLE *Caſe*, in algebra, is uſed for that caſe of cubic equations where the root, according to Cardan's rule, appears under an impoſſible or imaginary form, and yet is real. Thus in the equation, $x^3 - 90x - 100 = 0$, the root, according to Cardan's rule, will be $x = \sqrt[3]{50 + \sqrt{-24500}} + \sqrt[3]{50 - \sqrt{-24500}}$, which is an impoſſible expreſſion, and yet one root is equal to 10; and the other two roots of the equation are alſo real. Algebraiſts, for two centuries, have in vain endeavoured to reſolve this caſe, and bring it under a real form; and the queſtion is not leſs famous among them, than the ſquaring of the circle is among geometers.

It is to be obſerved, that as in ſome other caſes of cubic equations, the value of the root, tho' rational, is found under an irrational or ſurd form; becauſe the root in this caſe is compounded of two equal ſurds with contrary ſigns, which deſtroy each other; as if $x = 5 + \sqrt{5 + 5 - \sqrt{5}}$; then $x = 10$; in like manner, in the *irreducible* caſe, when the root is rational, there are two equal imaginary quantities, with contrary ſigns, joined to real quantities; ſo that the imaginary quantities deſtroy each other. Thus the expreſſion: $\sqrt[3]{50 + \sqrt{-24500}} = 5 + \sqrt{-5}$; and $\sqrt[3]{50 - \sqrt{-24500}} = 5 - \sqrt{-5}$. But $5 + \sqrt{-5} + 5 - \sqrt{-5} = 10 = x$, the root of the propoſed equation.

Dr. Wallis ſeems to have intended to ſhew, that there is no caſe of cubic equations irreducible, or *impracticable*, as he calls it, notwithſtanding the common opinion to the contrary.

Thus in the equation $r^3 - 63r = 162$, where the value of the root, according to Cardan's Rule, is, $r = \sqrt[3]{81 + \sqrt{-2700}} + \sqrt[3]{81 - \sqrt{-2700}}$, the doctor ſays, that the cubic root of $81 + \sqrt{-2700}$, may be extracted by another impoſſible binomial, *viz.* by $\frac{9}{2} + \frac{1}{2}\sqrt{-3}$; and in the ſame manner, that the cubic root of $81 - \sqrt{-2700}$ may be extracted, and is equal to $\frac{9}{2} - \frac{1}{2}\sqrt{-3}$; from whence he infers, that $\frac{9}{2} + \frac{1}{2}\sqrt{-3} + \frac{9}{2} - \frac{1}{2}\sqrt{-3} = 9$, is one of the roots of the equation propoſed. And this is true: But thoſe who will conſult his Algebra, p. 190, 191, will find that the rule he gives is nothing but a trial, both in determining that part of the root which is without a radical ſign, and that part which is within: And if the original equation had been ſuch as to have its roots irrational, his trial would never have ſucceeded. Beſides, it is certain, that the extracting the cube root of $81 + \sqrt{-2700}$, is of the ſame degree of difficulty, as the extracting the root of the original equation $r^3 - 63r = 162$; and that both require the triſection of an angle for a perfect ſolution. See M. de Moivre in the Appendix to Saunderſon's Algebra, p. 744, ſeq.

For Cardan's rule. See the article *Cubic* EQUATION.

IRREDUCTIBLE *Caſe*, in algebra. See the article IRREDUCIBLE.

IRREGULAR *Leap*, (*Cycl.*) in muſic. See the article LEAP.

ISABELLA, in conchyliology, the name given by the French naturaliſts to the beautiful pale-brown voluta, ſo much eſteemed in the Dutch cabinets.

ISAGON, in geometry, is ſometimes uſed for a figure conſiſting of equal angles.

ISAMBLUCIS, in natural hiſtory, the name of a genus of foſſils of the claſs of the ſelenitæ, but of the columnar, not the rhomboidal kind. See Tab. of Foſſils, Claſs 2.

The word is derived from the Greek ἴσος, equal, ἀμβλὺς, obtuſe, or blunt; and κίων, a column; and expreſſes a body in form of an obtuſe or blunt column, the ſides of which are all equal to one another. This diſtinguiſhes it from the genus of the *iſchnambluces*, or thin columnar ſelenitæ, two of the ſides of which being broader than the others, make it of a flatted form. The ſelenitæ of this genus conſiſt of ſix ſides, and two obtuſe or abrupt ends; and all their ſides being very nearly of the ſame breadth, they much reſemble broken pieces of the columns of ſprig cryſtal.

The bodies of this genus, as well as the reſt of the columnar ſelenitæ, are ſubject to a longitudinal crack, which ſometimes admitting a ſmall quantity of clay, ſhapes it into the figure of an ear of graſs. *Hill's* Hiſt. of Foſſ. p. 121. See the article SELENITES.

Of this genus there are only two known ſpecies, 1. A whitiſh one, very much reſembling a broken ſprig of cryſtal, found among the white tobacco-pipe clay near Northampton. And, 2. A ſhort and pellucid one, with ſlender filaments; this is found in the ſtrata of yellow clay in Yorkſhire, and ſometimes lying on the ſurface of the earth. *Hill's* Hiſt. of Foſſ. p. 139, 140.

ISATIS, *Woad*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of four leaves, and is of the cruciform kind; the piſtil ariſes from the cup, and afterwards becomes an unicapſular oblong fruit, compreſſed at the ſides, and containing only one oblong ſeed. See WOAD.

The ſpecies of *Woad*, enumerated by Mr. Tournefort, are theſe: 1. The broad-leaved, or manured *Woad*. 2. The narrow-leaved, or wild *Woad*. And, 3. The ſmall wild Portugueſe *Woad*. *Tournef.* Inſt. p. 211.

ISATODES, a word uſed by Hippocrates, and ſome other of the old writers, to expreſs a greeniſh colour of the bile diſcovered in the ſtools, which reſemble the colour of the herb *iſatis*, or woad. This was eſteemed an indication of a highly depraved bile.

ISCHÆMON, in botany, a name uſed by many authors for the graſs called *gramen mannæ*, manna graſs, or Ruſſia ſeed. *Park*'s Theat. p. 78.

ISCHÆMON was alſo a word uſed by the antients to expreſs any thing given as a remedy in hæmorrhages, or other fluxes of blood, whether from wounds or otherwiſe.

ISCHÆMUM, in botany, the name by which Linnæus calls the *ſchænanth*, or camel's hay. This makes a peculiar genus of plants, the characters of which are theſe: It has male and female flowers, diſtinct from one another. The male flower is very ſmall, and always ſtands upon the glume of the cup of the female flower. Its cup is a bivalve glume, with no awns, and containing only one flower; the flower is another bivalve glume of the ſize of the cup, and without awns. The ſtamina are three ſhort capillary filaments, and the antheræ ſimple; the female flower is larger; its cup is a large bivalve glume, placed within the common glume, and terminated by a twiſted awn, or beard between each valve. The flower is a ſmall double glume; the piſtil conſiſts of an oblong germen, and two reflex ſtyli; all the glumes of the cup, flower, &c. continue to ſurround and encloſe the ſeed; and they never drop it out till forced from them, each containing one ſeed. *Linnæi* Gen. Plant. p. 527.

ISCHAS, in botany, a name given by Cluſius and ſome others, to thoſe ſpecies of tithymal or ſpurge which have tuberous or knobby roots, and are called by others *apios*. See the article TITHYMALUS.

ISCHENIA, Ἰσχηνία, in antiquity, anniverſary ſports celebrated at Olymphia in memory of Iſchenus the grandſon of Mercury and Hierea; who, in a time of famine, devoted himſelf to be a ſacrifice for his country, and was honoured with a monument near the olympian ſtadium. *Potter*'s Archæol. Græc. l. 2. c. 20. tom. 1. p. 407.

ISCHIO-CAVERNEUX, in anatomy, a name given by Winſlow, and other of the French anatomiſts, to a muſcle of the penis, called alſo by ſome the *poſterior* and *collateralis penis*, but now generally named, from its office, the *erector*. See the article ERECTOR, *Cycl.*

ISCHIO-CAVERNEUX is alſo applied by the ſame authors to a muſcle of the female pudenda, called by ſome the *muſculus clitoridis*, and *clitoridis manifeſtus muſculus*, and by Cowper and Albinus, from its office, the *erector clitoridis*.

ISCHIUM (*Cycl.*)—This is the loweſt portion of the *os innominatum*, as alſo of the whole trunk. It is divided into the body, the tuberoſity, and the ramus or branch.

The body of the *os iſchium* forms the loweſt and greateſt part of the acetabulum, and ſends out an apophyſis backward, called the ſpine of the iſchium. The tuberoſity is very thick, unequal, and turned downward; and it is on this part that the whole body reſts when we ſit. It appears cartilaginous, becauſe of the dried and hardened remains of the tendons. The whole convex portion of it is originally an appohyſis, of which the marks are obliterated ſooner in ſome ſubjects than in others: three muſcular impreſſions may be diſtinguiſhed in it.

The branch of the *Iſchium* is a kind of thin flat production, or apophyſis, which aſcends forward from the curvature of the

the tuberoſity of the os pubis, and it is often covered in part by a continuation of the epiphyſes of the tuberoſity.

Theſe three parts of the *Iſchium* taken together, form a large opening, which makes the greateſt part of the foramen ovale. Three other notches are remarkable in this bone; one poſterior between the tuberoſity and the ſpine, for the paſſage of the internal obturator muſcle, which is a little cartilaginous, and divided into three or four ſuperficial channels; one lateral between the tuberoſity and the acetabulum, for the paſſage of the external obturator muſcle; and one anterior at the edge of the acetabulum for ligaments. *Winſlow*'s Anatomy, p. 71.

ISCHNAMBLUCIS, in natural hiſtory, the name of a genus of foſſils of the claſs of the ſelenitæ, but one of thoſe which are of a columnar form, not of the common rhomboidal one. See Tab. of Foſſils, Claſs 2.

The word is derived from the Greek, ἰσχνὸς, thin, ἀμβλὺς, blunt or obtuſe, and κίων, a column; and expreſſes a body in form of a thin or flatted column, with obtuſe ends.

The characters of this genus are, that the bodies of it are of a flatted columnar form, and octohedral in figure, conſiſting of ſix long planes, and two abrupt or broken ends. The whole being of a flatted figure. The top and bottom planes are much broader than the reſt; the four other planes, called the ſides, are narrower than theſe, but are uſually of very nearly the ſame breadth with one another, as are alſo theſe tops and bottoms, ſo that the whole figure comes very near an hexhedral priſm. *Hill*, Hiſt. of Foſſ. p. 121.

The bodies of this genus very frequently have a long crack reaching their whole length, and clay often getting into this, ſpreads itſelf into the form of an ear of ſome of the graſſes, and has been miſtaken for a real ear of graſs.

Of this genus there are only four known ſpecies. 1. A flat, broad, and pellucid kind, found in Northamptonſhire, Leiceſterſhire, and Yorkſhire, at conſiderably great depths in blue clay. 2. A dull rough-ſurfaced and thicker kind, found in many parts of Kent, and in great plenty in the cliffs of Sheppey iſland. 3. A dull longitudinally ſtriated kind, found in the clay-pits of Yorkſhire and elſewhere, and frequently marked in the middle with the figure of an ear of graſs. And 4. A thick, rough, and ſcaly kind, frequent on the ſhores of Sheppey iſland, and both in the clay-pits and on the ſhores of Yorkſhire. This alſo has frequently the repreſentation of an ear of graſs. Ibid. p. 136, 137, 139.

ISCHNOPHONIA, a word uſed by ſome authors to expreſs that weakneſs and ſhrilneſs of the voice which attends perſons in ſome diſeaſes; more uſually, however, it is underſtood to expreſs a ſtammering or imperfection in the ſpeech.

ISCHURIA (*Cycl.*)—See the article SUPPRESSION *of Urine*.

ISCUSTOS, a word uſed by the writers of the middle ages as the name of a gem, but ſeeming to be only a corrupt way of ſpelling aſbeſtos. Albertus ſays it was of a yellowiſh colour, and found in Spain, and that its fibrous texture made it capable of being wrought into cloth, which when thrown into the fire, was not conſumed, but only cleaned by burning. See the article ASBESTOS.

ISING-GLASS (*Cycl.*)—A ſtrong glue is made of *Iſing-glaſs* diſſolved in ſpirit of wine. See the articles GLUE and ICHTHYOCOLLA, *Cycl.* and *Suppl.*

ISINGLAS *Fiſh*, the Engliſh name of the fiſh from which the drug called *ichthyocolla* or *iſinglaſs* is made. It is a ſpecies of the *accipenſer* or ſturgeon, and is diſtinguiſhed by not having any of the tubercles which the body of the common ſturgeon has. See the article ACCIPENSER.

ISIR, or IXIR, a name uſed by ſome of the chemical writers for an elixir.

ISIS, in botany, a term uſed by Linnæus to expreſs a genus of ſea-plants, comprehending all thoſe which are branched and incruſtated, and which have a ſimple ſurface.

ISKA, a name given by the antients to a light kind of agaric growing to the old ſtumps of the oak, hazel, and other trees. This being a very light kind of fuel, was uſed by the antients in the manner of a cautery, as we have of late learned from the Indians to uſe moxa or the down of mugwort leaves.

ISLAND (*Cycl.*)—Kircher tells us of a very remarkable change of the face of the earth in the eaſtern parts of the world, by the coalition of ninety-nine *Iſles* into one larger one, under the ſame extent of ſurface which they had while divided by the ſea. But we are to obſerve, that no abſolute dependance is to be given to what he affirms of the miraculous things of China. His ſtory of the leaves of trees turning into black birds, is a proof that he took many abſurd things, on the credit of people whom a philoſopher ought not to have believ'd. *Kircher*, China illuſtrata. See the article BLACK-*Birds*.

Floating ISLANDS. Hiſtories are full of accounts of *floating Iſlands*; but the greater part of them are either falſe, or founded on exaggerations. What we generally ſee of this kind is no more than the concretion of the lighter and more viſcous matter floating on the ſurface of water in cakes, and, with the roots of plants, forming congeries of different ſizes, which not being fixed to the ſhore in any part, are blown about by the winds, and float on the ſurface. Theſe are generally found in lakes, where they are confined from being carried too far; and in proceſs of time ſome of them acquire a very conſiderable ſize. Seneca tells us of many of theſe *floating Iſlands* in Italy; and ſome later writers have deſcribed not a few of them in other places. But however true the hiſtories of theſe might have been at the time when they were wrote, there remain very few proofs of their truth at this time, theſe *Iſlands* having either diſappeared again, or been fixed to the ſides, in ſome part, in ſuch a manner as to have made a part of the ſhore. Pliny tells us of a great *Iſland* which at one time ſwam about in the lake cutilia, in the country of Reatinum, which was diſcovered to the old Romans by an oracle; and Pomponius tells us, that in Lydia there were ſeveral *Iſlands* ſo looſe in their foundations, that every little accident ſhook and removed them. Herodotus ſpeaks alſo very largely of the lake Chemnis in Ægypt.

ISLAND *Cryſtal*, a body famous among the writers of optics for its property of a double refraction; but very improperly called by that name, as it has none of the diſtinguiſhing characters of cryſtal, and is plainly a body of another claſs. Dr. Hill has reduced it to its proper claſs, and determined it to be of a genus of ſpars, which he has called, from their figure, *parallellopipedia*, and of which he has deſcribed ſeveral ſpecies, all of which, as well as ſome other bodies of a different genus, have the ſame properties. Bartholine, Huygens, and Sir Iſaac Newton, have deſcribed the body at large, but have accounted it either a cryſtal or a talc; errors which could not have happened, had the criterions of foſſils been at that time fixed; ſince Sir Iſaac Newton has recorded its property of making an ebullition with aqua fortis, which alone muſt prove that it is neither talc nor cryſtal, both thoſe bodies being wholly unaffected by that menſtruum.

It is always found in form of an oblique parallellopiped, with ſix ſides, and is found of various ſizes, from a quarter of an inch to three inches or more in diameter. It is pellucid, and not much leſs bright than the pureſt cryſtal, and its planes are all tolerably ſmooth, tho' when nicely view'd, they are found to be waved with crooked lines made by the edges of imperfect plates. What appears very ſingular in the ſtructure of this body is, that all the ſurfaces are placed in the ſame manner, and conſequently it will ſplit off into thin plates, either horizontally or perpendicularly; but this is found, on a microſcopic examination, to be owing to the regularity of figure, ſmoothneſs of ſurface, and nice joining of the ſeveral ſmall parallellopiped concretions, of which the whole is compoſed, and to the ſame cauſe is probably owing its remarkable property in refraction. *Hill*, Hiſt. of Foſſ. p. 333.

It is very ſoft and eaſily ſcratched with the point of a pin; it will not give fire on being ſtruck againſt ſteel; and ferments, and is perfectly diſſolved in aqua fortis. It is found in *Iſland* from whence it has its name; and in France, Germany, and many other places. In England fragments of other ſpars are very often miſtaken for it, many of them having, in ſome degree, the ſame property. *Hill*, Hiſt. of Foſſ. p. 334. See the article ANOMORHOMBOIDIA.

ISLAND *Fiſh*, in the fiſh trade, a name given to the common cod-fiſh when it has been caught and preſerved in *Iſland*. *Willughby*, Hiſt. Piſc. p. 166. See the article COD-FISH.

ISLEBEIANUS *Lapis*, in natural hiſtory, a name given by authors to a kind of blackiſh ſlate, very heavy, not very hard, and eaſily ſplitting into thin flakes. It is dug near Iſleb in Thuringia, whence it has its name, and is much of the nature of that ſort of black ſlate which we have common in England, lying over the coal ſtrata.

As our ſlate of this kind contains uſually leaves of fern and other plants, this foreign kind contains the impreſſions of ſeveral kinds of fiſhes, ſo exactly delineated in ſhape, and with the fins, ſcales, and all other parts ſo perfect, that the ſpecies are eaſily known. All theſe impreſſions and delineations are, however, ſo flat and thin, and have taken up ſo little room in the ſtone, that they ſeem rather to have been the ſkins and exuviæ of fiſh, than the whole bodies of them; but this is not wonderful when we conſider how eaſily the bodies, and even the bones of fiſhes, may be diſſolved; and that theſe exuviæ are lodged in a ſubſtance which contains a vitriolic ſalt, very capable of effecting ſuch a ſolution. It is eaſy to conceive, that this and other ſuch ſalts, while in a ſtate of ſolution in water, before the concretion of the matter of this ſtone into a hard maſs, might make that water a menſtruum capable of thus diſſolving the bodies and bones of fiſhes, while the outer ſkin and ſcales being much tougher, and of a very different nature, might eſcape the effects of them. It is well known that the fins and ſcales, and other external parts of fiſhes, are much more capable of bearing maceration in water, than the internal ſubſtances of them; and it is eaſy to conceive that theſe, after having withſtood that power in the water, would at length ſubſide down among the muddy matter that was to form ſome of the ſtrata of this ſlate: The motion of the water would not fail to expand theſe ſkins, tho' ever ſo thin, into the true and exact ſhape of the whole fiſh; and when thus laid along upon the ſurface of the new formed ſtratum, the next quantity of the ſame matter that ſubſided would form another ſtratum, which falling evenly upon the former, would cover it, and on the following concretion of both, the

figure of the fiſh would be beautifully preſerved between two plates or flakes of a fiſſile ſtone.

The ſcales of moſt of the fiſhes, preſerved in this *Iſleb* ſtone, are ſquare or rhomboidal, and do not terminate round as thoſe of moſt of the other fiſhes do, ſome of theſe have their natural appearance and complexion, being of a whitiſh or pearly hue, and very bright and ſhining; others are copper-colour'd, ſome yellow, and ſome green; but whether theſe have been the natural colours of the ſcales, while on the body of the fiſh; or whether they have acquired them while lying in the earth among the various ſorts of mineral matter with which they are lodged, ſeems not eaſy to determine; tho' the latter ſeems the more probable conjecture. The ſcales are uſually very fair and well preſerved, as are alſo the heads and fins, with the tail and coverings of the gills, which are all more durable and hard than the reſt of the fiſh. *Woodw.* Cat. Foſ. vol. 2. p. 23.

It is very remarkable, that as in theſe ſlates of *Iſleb* preſerving fiſhes, the external parts only are preſerved, the bones and fleſh being waſted; ſo, on the other hand, in thoſe foſſile fiſhes brought from Syria, the ſkins and ſcales are wanting, and the ſkeletons are principally the part preſerved. In ſome of theſe the bones are not clean, ſmall parcels of the fleſh being found petrified among them; but this fleſh is ſtripped of the ſkin. The ſtone in which theſe Syrian fiſhes are preſerved is alſo very different from the *Iſleb* ſlate, being whitiſh or greyiſh, and very hard. The ſtones of this kind found on mount Libanus, where they are very common, have very fine delineations of the ſtar-fiſh compleat. Id. Ibid.

ISNARDIA, in the Linnæan ſyſtem of botany, the name of a genus of plants, the diſtinguiſhing characters of which are theſe: The cup is a perianthium, formed like a bell, ſlightly divided at the extremity into four pointed ſegments. It has no petals. The ſtamina are four filaments, growing out of the middle of the cup. The antheræ are ſimple, The germen of the piſtillum is incloſed in the ſubſtance of the cup. The ſtyle is ſimple, and longer than the ſtamina; and the ſtigma is thick and large. The fruit is made out of the baſis of the cup, which is ſquare, and has four cells. The ſeeds are few in number, and of an oblong figure. *Linnæi* Gen. Plant. p. 51.

ISOPSEPHUS, Ισόψηφος, in antiquity, an appellation given to judges, who had equal juriſdiction and authority; it was likewiſe applied to a caſe where the votes were equal on both ſides. Another ſenſe is given to it, *viz.* when the letters of different words made up the ſame ſum, they were ſaid to be ἰσοψηφα ἐημαλα; for the Greeks had no other cyphers to number with but the letters of their alphabet; ſo that α ſignified one, β two, γ three, &c. But beſide words, the antients had likewiſe whole verſes of this kind; and'tis pretended that there are ſeveral ſuch verſes in Homer. Hiſt. Acad. Inſcript. vol. 3. p. 311. ſeq.

ISOPYRUM, in botany, the name of a genus of plants deſcribed by Linnæus, the characters of which are theſe: There is no cup; the flower conſiſts of five petals, equal in ſize, of an oval figure, ſtanding open, and very ſoon falling after they are opened. The nectaria are five; they are all of the ſame ſize, and are tubular and very ſhort; their margin is oblique and undivided, and they ſtand within the baſe of the flower. The ſtamina are numerous capillary filaments, ſhorter than the flower. The antheræ are ſimple. The germina of the piſtil are two; they are of an oval figure. The ſtyles are ſimple, and of the length of the germina; and the ſtigmata are obtuſe, and of the length of the ſtamina. The fruit is compoſed of two lunulated pods, each containing a ſingle cell, in which are ſeveral ſeeds. It is evident, by theſe characters, that this genus differs from the aquilegia, hellebore, and thalictrum, with one or other of which authors have been uſed to confound it. *Linnæi* Gen. Plant. p. 245.

ISORA, in botany, the name given by Plumier to a genus of plants, called by Linnæus, helicteres. *Plumier* 37. See the article HELICTERES.

ISPIDA, the *King-Fiſher*, in ornithology, a very beautiful bird frequenting waters, and feeding on fiſh. It builds in deep holes in the banks of rivers, and lays five, or according to ſome, nine eggs. It much approaches to the picus or woodpecker, in many things, but wants its great character, which is the having two toes behind. The legs of this bird are very ſhort, and are black before, and red behind. Its colours, particularly its green and blue, which are its general ones, are extremely bright and beautiful. *Ray*'s Ornithology, p. 101.

This name is given by Linnæus to the bird called the *merops*, or bee-eater. This makes, with that author, a diſtinct genus of birds of the order of the picæ. The diſtinguiſhing character of which is, that the middle toe has three joints joined to the outer toe, and but a ſingle one joined to the inner one. *Linnæi* Syſt. Nat. p. 45.

ISSONG, in botany, a name given by the people of Guinea to a ſpecies of plant, which they infuſe in water, and afterwards boil, and then waſh the head with it, as a cure for all kinds of the head-ach. It is a plant deſcribed by the botanical writers under the name of *Piſum veſicarium fructu nigro, alba macula notato*, the bladder pea, with a black fruit marked with a white ſpot; and called by the people of Malabar, where it alſo grows very plentifully, *ulinga*. It is alſo found in Barbadoes and Jamaica, and is there called *parſley*. Philoſ. Tranſ. N°. 232.

ISSUES (*Cycl.*)—The moſt ready method of making *Iſſues*, is by inciſion, and that in the following manner: Firſt mark the proper place with ink; then elevating the integuments between the thumb and fore-finger, make an inciſion thro' them, either with the ſcalpel or lancet, big enough to admit a pea, which being inſerted, and covered with a plaſter and compreſs, nothing more is wanting but the roller to compleat the operation. Then the wound is to be cleanſed every morning and evening, and dreſſed with a freſh pea, and it will, by degrees, in a day or two, degenerate into a little ulcer, diſcharging daily a quantity of purulent matter, which ſhould be carefully wiped off at every dreſſing.

The method by cauterizing is practiſed by ſome, and is done in this manner: The iron, to be made red hot, is ſmall and rounded, and is included in a caſe, that the ſight of it may not terrify the patient. This caſe is preſſed upon the part, and then the red hot iron within is thruſt down to the ſkin, and made to burn; the burn is to be dreſſed with baſilicon till the eſchar falls off, and then the little ulcer that is formed is to be filled with a pea, and then dreſſed as before. Tho' this method of making *Iſſues* is the more ſevere and painful, it muſt be alſo the moſt efficacious, as the pain and cauterization muſt neceſſarily cauſe an afflux of humours to the part, and make a conſiderable revulſion, though there are very few patients that will bear it. *Heiſter*'s Surgery, p. 314.

The laſt method of making *Iſſues* is by cauſtic medicines. This is to be done in this manner: Firſt a piece of plaſter is to have a hole cut in its middle, and to be ſo placed on the part, that the whole may be placed upon the part marked with ink for the *Iſſue*. A piece of the common cauſtic is then to be applied to the hole in the plaſter, and retained cloſe down upon the ſkin, with ſome ſcraped lint, a ſmall compreſs, and a large plaſter: And laſtly, with a larger compreſs and bandage. After ſix or eight hours the cauſtic is to be taken off, and the eſcar dreſſed as that made by burning. See the article BURN.

Which ever way an *Iſſue* be made, it ſhould be dreſſed at leaſt twice every day, if it runs well, and at each dreſſing a freſh pea muſt be put in, and covered with a clean plaſter, and retained by a proper bandage and compreſs. Some uſe, inſtead of rollers or fillets for *Iſſues*, a leather ſwath faſtened with claſps, and others uſe peas of ſilver or wood inſtead of common ones to dreſs them with, but the difference is not material. When the iſſue has done its buſineſs, and is to be dried up, little more is required to this than the taking away the pea, without which it heals up of itſelf in a little time.

ISTHMUS, (*Cycl.*) in anatomy, is a paſſage in that part of the medulla oblongata of the brain, which lies between the cerebrum and cerebellum, and which reaches from the place called *anus* to the fourth ventricle. The upper part, or cover of this conduit, or paſſage, which is betwixt the teſtes and the foremoſt vermicular proceſs of the cerebellum, and to which two it is tied at its two ends, and to the proceſſes which come from the cerebellum to the teſtes at its ſides, is called *valenta major*; it is of a medullary ſubſtance, and its uſe is to keep the lympha from falling out above the nerves in the baſis of the ſkull. *Harris.*

ITAIARA, in zoology, a name by which ſome have called a Braſilian fiſh, of the turdus kind, of great beauty, and a very delicate taſte, more uſually known bp the name *juruncapeba*. *Ray*'s Ichthogr. p. 325. See the article JURUNCAPEBA.

ITALIAN (*Cycl.*)—ITALIAN *Marble*, a name uſed by our artificers for two or three of the variegated marbles, of great beauty, commonly wrought into chimney-pieces and other ornamental things. *Hill*, Hiſt. of Foſ. p. 473.

The name is a very indeterminate one, many of the plain, as well as the variegated marbles, being from Italy, and indeed many of the variegated ones which have other peculiar names, tho' known to be brought from Italy, being never called by it; ſo that if any meaning is to be fixed to the word at all, it muſt be ſaid to mean ſuch of the variegated foreign marbles as are not diſtinguiſhed by any other peculiar title. The artificers chiefly comprehend, however, under this name, five ſpecies: 1. The common purple and white variegated one. This is a very beautiful maſs, and in general moderately fine, but of very different degrees of purity and hardneſs in its different parts. It is, in general, white, vein'd, ſpotted, and variegated with purple; but, in ſome blocks, the purple makes the ground, and the white the variegation, and in moſt it is variegated beſide with ſpots of pale red and brown, ſometimes of yellow, and ſometimes of a greeniſh brown. This is the moſt common marble of Italy. 2. A brown and white friable one. This emulates the figure of the former in the diſpoſitions of its veins, but is only of a white ground, vein'd with a duſky brown, and is the ſofteſt of all the marbles. The white part of it appears compoſed of granules, looſely hung together, and, on a near view, much reſembles loaf ſugar of the fineſt kind, and if ſcraped with a knife, readily falls away in large granules like ſand. This is alſo common in Italy. 3. A hard variegated blue and white

white marble. This is a ſomewhat coarſe marble, of a rough grain, and of a looſe ſhattery texture, and is variegated with a duſky blue, and a pearl colour or bluiſh white, each making uſually an equal part of the maſs. This is very common in Italy, and great quantities of it are imported hither. 4. A fine black and yellow one, the yellow veins appearing like ſtreaks of gold. This is much eſteemed and uſed. And 5. A purple and yellow one, of great beauty, and very great price. This has of late been ſold at a higher than ordinary rate. *Hill*, Hiſt. of Foſſ. p. 476, 477, 478.

ITEA, in botany, a name uſed by the antients in general to ſignify the willow; but by ſome of the Greek writers it is alſo uſed as a name for the pine.

ITHYNTERION, ἰθυντηριον, in antiquity, a ſtaff of laurel, which prophets uſually carried in their hands, otherwiſe called *ſceptron*. *Pott.* Arch. Græc. l. 2. c. 12.

ITINERARIUM, in ſurgery, a name given by Hildanus, and many other writers, to a ſtaff uſed in the operation of cutting for the ſtone.

ITING, in natural hiſtory, a name given by the people of the Philippine iſlands to a bird common among them, and ſeeming, by the deſcription, to be of the woodpecker kind. It is of the bigneſs of the ſtarling. Its wings and tail are black, as are alſo its legs and beak. Its back and belly are ſilver-colour'd. Its head is bald, or deſtitute of feathers, except that there runs all along it a ſtrait row of ſhort black plumes, forming a line from the beak to the neck. It builds in the hollow trunks of the palm trees, and feeds on various kinds of fruits. It is a very noiſy bird, but its voice is not diſagreeable. People ſay this bird has but one ſtrait gut.

IVAPECANGA, in botany, a name given by ſome authors to the climbing plant, of which the ſarſaparilla, uſed in medicine, is the root. *Marggrave*, p. 11. *Piſo*, p. 258.

JUCADICE *Arbor*, in botany, a name by which ſome authors have called the *canella alba*, or wild cinnamon-tree. *Nieremberg*, p. 294.

JUDAICUS *Lapis*, (*Cycl.*) in natural hiſtory. This ſtone has by many been ſuppoſed to be a foſſile body in its native figure, but is really the remains of a ſpine of an echinus, filled with a plated ſpar. It is of the figure of an olive, and is fluted and ridged, and furrowed longitudinally in a very beautiful manner. It is very common in Syria, and is ſometimes found with us. *Hill*, Hiſt. of Foſſ. p. 652. See the article SPAR.

JUDAS *Tree*, in botany. See the article SILIQUASTRUM.

JUDDOCK, in zoology, the name commonly given, in England, to a ſmall ſpecies of ſnipe, called by authors, *gallinago minima*, and in ſome places with us, the *ged*, or *jack* ſnipe. It is but of about half the ſize of the common ſnipe. Its rump is of a purpliſh blue, like that of the back of a ſtarling, all the ends of the feathers being alſo whitiſh. The long ſhoulder-feathers are brown, yelloviſh, and blackiſh blue. The neck is variegated with brown, white, and pale red. The breaſt and belly are white. It is commonly found among ruſhes, and in watery places. *Ray*, Ornithol. p. 214.

JUDGE (*Cycl.*)—By the law of England, all *Judges* muſt derive their authority from the crown, by ſome commiſſion warranted by law. The *Judges* of the king's-bench, common pleas, and the barons of the exchequer, are all (excepting the chief juſtice of the king's-bench, who is created by writ) appointed by patent. Formerly they held their places only during the king's pleaſure: But now, for the greater ſecurity of the liberty of the ſubject, by a ſtatute of Wil. 3. [a] their commiſſions are to be *quandiu ſe bene geſſerint*. Tho' upon an addreſs of both houſes of parliament, they may be lawfully removed [b].—[[a] 12 and 13 Wil. 3. c. 2. [b] Ibid.]

Judges muſt exerciſe their authority in a legal manner, and hold their courts in their proper perſons, for they cannot act by deputy, nor any way transfer their power to another, as the *Judges* of eccleſiaſtical courts may.

The *Judges* are bound by oath to determine according to the known laws and antient cuſtoms of the realm. Their rule herein muſt be the judicial deciſions, and reſolutions upon the various caſes that have occurred, and not their own arbitrary will and pleaſure, or that of their prince. Vid. Stat. 13 Edw. 3. c. 1. 20 Edw. 3. c. 1, 2.

Judges are free from all proſecutions for any thing done by them in court, which appears to have been an error of their judgment. But for wilful corruption, they have been complained of to the ſtar-chamber formerly [a]; and may now be called to an account in parliament [b].—[[a] Vid. *Vaughan* 139. [b] 1 *Hawk.* P. C. 139. 12 *Coke* 24.]

It has been ſaid, that ſcandalous reflections on the *Judges* in Weſtminſter-hall are within the ſtatute of *ſcandalum magnatum*. V. *Vaugh.* ibid.

It was formerly enacted, ſtat. 33 Hen. 8. c. 24. that none ſhould be juſtices of aſſiſe within the county where they were born, or do inhabit; but this is repealed by a late ſtatute, 12 Geo. 2. c. 27.

By the common law, the patents of *Judges* were determined by the death of the King, in whoſe name they are made. But by ſtatute 7 & 8 Wil. & Mar. c. 27. & 1 Ann. c. 8. it is enacted, that every commiſſion, civil and military, ſhall remain in full force for the ſpace of ſix months next after the demiſe of the King, unleſs ſuperſeded by his ſucceſſor. It was formerly held, that by a juſtice's acceptance of any new name of dignity, his commiſſion was determined; but this was remedied by ſtatute 1 Edw. 6. c. 7. But it has been doubted, whether the dignity of baronet, created ſince that ſtatute, is within the equity of it. *Croke* Car. 104.

JUGERUM, a Roman meaſure, the double of the *actus quadratus*. It was a ſquare of 120 Roman feet. The *Jugerum* was divided into 12 *uncias*, and the *uncia* into 24 *ſcrupulæ*. Its proportion to the Engliſh acre is as 10000 to 16097. Treat. Pract. Geom. p. 87.

JUICE (*Cycl.*)—JUICES *of Plants*. Moſt *Juices* of vegetables coagulate when expoſed to the air, whether it be that they are drawn out of the plant by wounds, or that they naturally run out; tho' what is called naturally running out, is generally the effect of a wound in the plant, from a ſort of cancer, or ſome other internal cauſe. The flowers of the St. John's wort, and the leaves of the rorella, or ſundew, afford us purple blebs and veins, and large drops of a clear fluid, yet it does not ſeem certain that theſe are coagulated *Juices*. The ſmall green leaves, forming the cup of the flower of the common erect tutſan St. John's-wort, are ſurrounded with purple bleds, and the points or tops of the leaves alſo have each two or three ſuch blebs, all containing a purple *Juice*; yet the ſtalk of this plant, being cut and ever ſo nicely examined, does not ſhew to the naked eye, nor even to the microſcope, any veſſels containing ſuch a purple fluid. Whence it may appear not improbable, that what is thus found in ſmall blebs is a matter ſeparated by coagulation only from the reſt of the *Juice* of the flower. Philoſ. Tranſ. N°. 224. p. 366.

In the common St. John's wort the edges of all the leaves of the flower are ſurrounded with theſe purple blebs, and the ſtalk, tho' round, has a double edge, one on each ſide, and the blebs or bags are to be ſeen riſing on theſe edges of the ſtalk. The cup of the flower has ſeveral purple veins, yielding a purple *Juice*, and the leaves of the flower have alſo ſome ſuch veins, and even the apices all contain a purple matter.

In the ſquare-ſtalk'd St. John's wort, commonly called St. Peter's wort, the edges of all the leaves, from the top to the bottom of the ſtalk, are ſurrounded with rows of theſe purple bags, and the apices of the flower are ſo many purple bags; but the cup and the petals of the flower have but very few purple veins in this ſpecies.

In the *hypericum pulchrum tragi*, or upright elegant St. John's wort, the leaves and ſtalks have no purple blebs, but only the cup and the flower have them. Theſe *Juices* alone are what give the red colour to the oil of St. John's wort kept in the ſhops. And it is worthy a ſtrict enquiry, what they really are, and by what means produced.

Diverſe parts of the ſame plant yield different *Juices*. The ſame veins, in their courſe thro' the different parts of the plant, yield *Juices* of a different appearance. Thus the milky *Juice* in the root of the cow parſnep is of a brimſtone colour; but in the ſtalk it is white.

Among thoſe *Juices* of vegetables which are clammy, and readily coagulate, there are ſome which readily break with a whey. The great wild lettuce, with the ſmell of opium, yields the greateſt plenty of milky *Juice* of any known Engliſh plant. When the ſtalk is wounded with a knife, the *Juice* flows readily out like a thick cream, and is white and ropy; but if theſe wounds be made at the top of the ſtalks, the *Juice* that flows out of them is daſhed with a purple tinge, as if cream had been ſprinkled over it, with a few drops of red wine, and has ſome veins. Some little time after the letting this out, it becomes much more purple, and thickens, and finally the thicker part of it ſeparates, and the thin whey ſwims at the top. Herein the *Juice* of this plant exactly reſembles the blood of animals, which tho' a ſimple fluid, when drawn from the veſſel, yet ſoon ſeparates into a thick cake, and a thin fluid, or ſerum.

The whey, or thin part of this ſeparated matter, is eaſily preſſed out from the curd by ſqueezing between the fingers, and the curd then will remain white, and, on waſhing in fair water, becomes like rags. The purple whey, for in this part all the colour is lodged, ſoon dries into a cake of the ſame colour, and may be crumbled between the fingers into a purple powder. The white curd being dried, and kept ſome time, becomes hard and brittle. It breaks with a ſhining ſurface like reſin, and is inflammable, taking fire at a candle, and burning all away with a ſtrong flame. The ſame thick part being held over a gentle heat, would draw out into tough long threads, melting in the manner of wax. Philoſ. Tranſ. N°. 224.

The purple cake, made from the whey, is wholly different from this, and when held to a candle, ſcarce flames at all, but burns to a black coal. The whole virtue of the plant ſeems alſo to conſiſt in this thin part of its *Juice*, for the coagulum or curd, tho' looking like wax or reſin, has no taſte at all, whereas the purple cake made from the ſerum is extremely bitter, and of a taſte ſomewhat reſembling that of opium.

It is poſſible that the artifice of bees may conſiſt, in a great meaſure, in the ſeparating in this manner the thick and the

thin parts of the *Juices* of peculiar plants, the curd or thick part of which being glutinous and inſipid, may ſerve them as wax, and the thin part may make their honey.

The throat-wort, ſpurge, and many other plants, replete with milky *Juices*, are of this kind, and their *Juice*, when let out, ſeparates into curd and whey. But this, though a common law of nature, is not univerſal; for there are many plants which yield the like milky *Juices* which do not ſeparate and break into curds and whey, but coagulate all together into one ſimple maſs. The white *Juice* of the *ſonchus* never ſeparates, but dries into an uniform cake; the common red wild poppy bleeds freely with a milky *Juice*, and the heads or capſules of ſeed bleed not leſs than the reſt of the plant, even after the flower is fallen. This *Juice*, on being received into a ſhell or other ſmall veſſel, ſoon changes its white to a deep yellow colour, and dries into a cake which ſeems reſinous and oily, but no whey ſeparates from it.

It ſeems by the experiments on the *Juice* of the opium lettuce before mentioned, that theſe milky liquors are of a mixed kind, and compoſed of different fluids, of various and perhaps of contrary qualities; ſo that if the curd part be ſimple and harmleſs, the whey may be a powerful medicine, and ſo of the reſt: But in theſe which do not ſeparate in this manner, we are forced to take the whole together, unleſs ſome way may be found of ſeparating them by art. Perhaps the ſetting them in wooden veſſels, and after a time adding freſh *Juice* to them, may do it; and poſſibly the adding a little calf's runnet may be able to effect it.

The tragopogon, or goat's-beard, when wounded, bleeds freely a milky *Juice*; it is at firſt white, but becomes immediately yellow, and after that more and more red; at length it is wholly of a duſky red. It never ſeparates but dries together into one cake, and is oily and reſinous, but of an inſipid taſte. The great bindweed bleeds freely alſo a white *Juice*; the flowers, as well as the ſtalks and leaves, afford this liquor. It is of a ſharp taſte, and as many of the purging plants are of this claſs, it would be worth trying whether this milk be not purgative.

Theſe *Juices*, as well as the generality of others which bleed freely from plants, are white like milk, but there are ſome of other colours. The *Juice* of the great celandine is of a fine yellow; it flows from the plant in the thickneſs of cream, and ſoon dries into a hard cake, without any whey ſeparating from it. Another yellow *Juice* is yielded by the ſeed veſſels of the yellow centaury, in the month of July, when the ſeeds are full grown. This is of a fine yellow colour, and very clammy; it ſoon hardens altogether into a cake, no whey ſeparating from it; it ſticks to the fingers like birdlime, and is of the colour of pale amber, and will never become harder than ſoft wax, if dried in the ſhade; but if laid in the ſun it immediately becomes hard like reſin. Theſe cakes burn like wax, and emit a very pleaſant ſmell.

The great angelica alſo yields a yellowiſh *Juice* on being wounded; and this will not harden at all, but if kept ſeveral years will ſtill be ſoft and clammy, drawing out into threads like wax, or half melted reſin.

Another kind of *Juices*, very different from all theſe, are thoſe of a gummy nature; ſome of theſe remain liquid a long time, and are not to be dried ſooner without the aſſiſtance of heat; the others very quickly harden of themſelves, and are not inflammable. The gum of the *Juice* of rhubarb leaves ſoon hardens, and is afterwards ſoluble in common water, and ſparkles when put into the flame of a candle. Theſe two qualities ſhew that theſe gums have a watery part in them, and they melt alſo in the flame of a candle, and become ductile; and this ſhews that they have alſo the curdy part, though this does not ſeparate from the whey in drying, as in ſome other caſes. Theſe do not ſparkle in the flame ſo much as ſome others which contain more water; and their not burſting out into an actual flame, ſhews that they want oil.

The cluſters of the common honeyſuckle are full of a liquid gum; they frequently throw this out, and it falls upon the leaves, and retains its own form there; the red hairs of the ſundew are all terminated by large bladders of a thin watery fluid: This is alſo a liquid gum, it ſticks to the fingers, and draws out into long threads, and this ſtands the force of the ſun all day. In the center of each of theſe dew drops, there is a ſmall red bladder which ſtands immediately on the ſummit of the red hair. This is of the nature of the blebs on the leaves and flowers of the St. John's wort, containing a purple *Juice* which may be ſqueezed out of it. The pinguicula, or butter-wort, has alſo ſome gummy liquid matter on its leaves. It does not ſtand upon ſuch long hairs as that of the ſun-dew, but it is in much greater quantity. The hairs of the leaves of theſe two plants ſtand on the upper ſides of the leaves, and are very thick ſet there, while the under ſide is ſmooth. This is a ſingularity not obſervable in any other plant, at leaſt of our own growth. Vid. *Liſter*, in Philoſ. Tranſ. N° 224. and *Lowthorp*'s Abridg. vol. 2. p. 696, ſeq.

Mr. Boyle tells us that the fumigated *Juices* of plants may be ſucceſsfully preſerved by adding a ſmall quantity of the white coagulum, made by the pure ſpirits of wine and urine. See the article OFFA *alba*.

Oily JUICES. Some plants yield *Juices* which are of a manifeſtly oily nature, which, being rubbed between the fingers, are not at all clammy, but make them glib and ſlippery; and theſe *Juices* do not harden at all on being expoſed to the air. If the ſtalk of elecampane be wounded, there flows out a plain oily *Juice* ſwimming upon a watery one. The ſtalks of hemlock alſo afford the ſame oily liquor ſwimming upon the other; and the common white mullein, if the leaves are pulled off in the month of June, yields the ſame ſort of oil very freely along with its watery *Juice*. The berries of ivy, the bay, juniper, dogberry tree, and the fruit of the olive, when wounded, ſhew their oil in the ſame manner floating on the watery *Juice*.

Some of theſe oily *Juices*, ſoon after they are let out of the plant, coagulate and harden into a kind of reſin. Our ivy yields ſuch a *Juice* very abundantly; and the *Juice* of the ſmall purple-berried juniper is of the ſame kind, being hard and fat, and not very gummy.

If the bark of the common ivy be wounded in March, there will ooze out a tough and greaſy matter of a yellowiſh colour; if this be taken up between the fingers, it feels not at all gummy or ſticking, but melts in handling into a ſort of oil, which in proceſs of time hardens and cruſts upon the wounds, and looks like brown ſugar; it burns with a laſting flame, and ſmells very ſtrong. The tops of the wild lettuce, and the leaves growing near the tops, if examined with a magnifying-glaſs, ſhew a great number of ſmall bladders or drops of an oily *Juice* of a browniſh colour, hardening into a kind of reſin; they are eaſily wiped off when of any ſize, and are truly an oily *Juice* hardened a little. It is probable alſo, that the fine blue flower or powder called the bloom, upon the ſurface of our common plums, is no other than ſuch an oily *Juice* exſudating from their pores in ſmall particles, and hardening into a ſort of reſin. The leaves and ſtalks of the common Engliſh mercury, are all over covered with ſmall tranſparent drops looking like pearls; and if the plant is taken into the hand, theſe feel rigid and greaſy. The leaves of the ſtinking orach abound alſo with the ſame ſort of drops, and theſe are only ſmall portions of the oily *Juices* of the plant, which are continually exſudating through its pores, and harden into theſe reſiny pearls. Phil. Tranſ. N° 224.

The ſap or *Juice* of trees appears to be very different, according to the ſpecies or genus of the tree, as we find by experiments, or by their ſpontaneous exſudations. The extravaſations of ſap in the plum and cherry kind, being all clammy, and hardening into a gum like gum-arabic; and on the other hand, thoſe of the vine, the oak, and many other trees, being thin as water. The clammineſs of the ſap in trees, ſeems one of the great things that renders them hardy, and not liable to injuries from cold, *&c.* In the hard froſts, thoſe trees which have watery *Juices* periſh, and even ſplit and cleave of themſelves; while thoſe which have gummy and viſcous *Juices* eſcape. In our gardens the vines crack and burſt with the froſt, while the plums, cherries, peaches, and other gummy trees, ſtand without any damage or danger; and in the fields no trees ſo readily ſplit in ſevere froſts as the oaks, which though the hardeſt wood of all our timber trees, yet has of all the moſt thin and watery *Juices*.

The trees which have deciduous leaves, have in general thinner and more watery *Juices* than the evergreens; to the freezing of theſe, or their decay from want of due heat, and other accidents, is owing the decay and fall of thoſe leaves, while the others remain in their places, though not encreaſing, or no new ones growing, the *Juices* remaining unaltered, though ſtagnated in the veſſels, and ſafe from injury, though waiting the ſun's heat to put them in motion. The earlier or later germination of trees and plants of different kinds, is probably owing alſo to the ſame cauſe. The thineſt *Juices*, as they are ſooneſt injured by cold, ſo they are probably ſooneſt influenced alſo by heat; and that warmth may make them move, and prepare the plant for growing, which could ſcarce begin to attenuate the tough and gummy ones. Phil. Tranſ. N° 165. See the article SAP.

Concrete JUICES, in mineralogy, a name given by many authors to ſuch ſubſtances found in the bowels of the earth, as have once been in a ſtate of fluidity, and are capable of being rendered fluid again by art, by means of heat, moiſture, or other common agents.

Others apply the word *concrete* to all thoſe ſubſtances which may be ſeparated from fluids by chemical operations, whether they are afterwards ſoluble in them again or not; ſuch are the particles of ſpar ſeparated from water by a ſlow diſtillation, and remaining at the bottom of the veſſel.

The concrete *Juices* of the earth are ſuppoſed to be the principal things which give the virtue to mineral waters; for thoſe which receive no concretion, and are only mingled with the waters in their paſſage through that part of the earth where they are evaporated, on the waters being expoſed to the air, tho' they may give a briſkneſs to it, while entire in it, yet are not to be ſuppoſed to give the principal virtues. Theſe fluid and volatile *Juices* all fly off in the analyſes of the waters,

ters, but the concrete *Juices* are more permanent, and leave certain ſediments which render them viſible and palpable, after the diſtillation of the waters with which they are mixed. When theſe happen to be ſimple, and of the ſame ſpecies with thoſe known in a ſolid ſtate, it is eaſy to deduce the virtues of the waters from them, and to know what muſt be the effect of ſuch fluids as carry ſpar, ſulphur, vitriol, or other well known ſubſtances, into the blood; but it ſeldom happens that theſe things are thus contained ſimple and entire in the waters, they are often blended variouſly with one another, and often not the whole of the known body is contained, but the principles that conſtitute ſome part of it, ſuch as the acid of vitriol without its metalline part, the baſis of ſea ſalt without its acid, and ſo of the reſt.

Salts and earths are evidently the moſt ſenſible and the moſt common matters which are mixed with water, and it is from them in general that the medicinal ſprings take up their virtues. There is ſcarce any earth that does not contain ſome ſort of mineral ſalt, capable of being waſhed out by water, tho' it be generally in imperceptible quantities; but where the earths are richer in theſe ſalts, the waters not only take them up, but carry alſo with them the ſeveral finer particles of the earth itſelf in which they are bedded, and riſing up at ſome ſmall diſtance from the place they make medicinal ſprings, of virtues anſwerable to the peculiar ſpecies of the ſalt that was lodged there. We are always able to ſeparate, by analyſis, the ſalts and the earths of the mineral waters; but when we have done this, we are not arrived at the end of the taſk, for they are often ſuch mixed ſubſtances, that we can neither know them perfectly as they are, nor ſeparate them.

The four moſt known and frequent of thoſe concrete *Juices* which are called ſalts, are alum, nitre, vitriol, and culinary ſalt; but the examination of the waters of different medicinal ſprings ſhews us, that there are in the earth others very different from theſe, and that perhaps in great numbers. There is in Aſia a native alkali ſalt, or natrum, and in all the mineral waters we celebrate, there is a peculiar ſalt ſeparable by evaporation, which is nearer allied to this than to any of the other four, to one or other of which it has uſed to be the cuſtom to reduce all ſalts; and yet different even from this in ſome reſpects. Beſide this thoſe *Juices* of the ſaline kind, whoſe diſpoſition to concretion is not yet finiſhed, and whoſe ſtate is, as it were, but in embryo, or the firſt ſtage of being, are not to be known, when ſeparated from the waters to which yet they may have perhaps given virtues greater than the concrete, in what we call its more perfect ſtate, might have given: Nay, even thoſe that are more formed, and are already concreted, or in a ſtate capable of concretion, have not ſimple and homogeneous ſubſtances in each of the ſpecies. The ſalt that is called culinary ſalt, is obſerved to have two different portions mixed together; the one is condenſed and cryſtallized by cold and in moiſture, after the evaporation of a part of the water wherein this ſalt hath been diſſolved; and the other will not be cryſtallized nor condenſed, but by a total evaporation of the water. The portion of this ſalt that is cryſtallized by cold and in moiſture, is the moſt ſulphureous, and by its ſulphureity it will mix itſelf with the ſulphureous ſalt of calcin'd tartar reſolved in a moiſt air, or in common water, without turbidneſs, and without coagulation; but that portion of this common ſalt which is not condenſed but by the total evaporation of the water which had diſſolved it, hath an acidity which inſtantly coagulates the ſalt of tartar diſſolved, and all other ſalts in the ſame ſtate which are ſulphureous and nitrous. It is evident, that while this ſalt is in its embryo ſtate, the one or the other alone of theſe two very different ſubſtances of which it is contained, may be mixed with the waters of a ſpring, and communicate virtues different from thoſe which the whole body of the ſalt would have done. This ſalt alſo being procured by evaporation of the water, or by any other analyſis of it, could not be known or referred to the common ſalts, and much leſs if in the earth, as may very eaſily happen, it ſhould be united with ſome one of the conſtituent parts of ſome other ſalt, in the ſame diſunited or unfaſhion'd ſtate.

The vitriol which in a moiſt air yields an efflorescence upon ſulphureous marcaſites, has likewiſe a juicy portion, condenſible only by a total evaporation of its aqueous humidity; this is of a very acrimonious taſte, of an unctuous ſubſtance, and eaſily runs to water in a moiſt air. This juicy portion of vitriol is very different from that which ſhoots and condenſes in the fluid liquor, by means of the cold. Theſe cryſtals are pure vitriol acid, auſtere, and on being mixed with the ſulphureous and nitrous ſalts, a great quantity of earthy matter precipitates out of them; but the other portion will mix itſelf with theſe ſalts in ſolution, without turbidneſs or emotion, not having, like the former, that acidity upon which the ſulphureous or nitrous ſalts can act; which is exactly contrary to what happens to common ſalt, of which the firſt portion is the moſt ſulphureous, and the latter portion the moſt acid. Nitre is alſo like the reſt compoſed of two different ſaline portions, the one more ſulphureous, which cryſtallizes with the cold, and in moiſture, and the other, which remains diſſolved after all the cryſtals are obtained, and which cannot be obtained in a dry form, but by the evaporation of all the humidity. This is leſs ſulphureous than the other part obtained in cryſtals, and has ſome acidity which the other has not.

The firſt embryos of mineral ſalts are nothing elſe but vapours or *Juices* not concreted, but totally volatile or vaporable; of theſe ſome may be condenſed, and in part fixed by the action of fire, or diſengaged from their matrices, and made capable of concretion by means of the air, as is obſerved in certain nitrous, aluminous, and vitriolic ſalts. The ſulphureous part, which is formed in the lime, made of certain hard ſtones burnt in the fire, which is generally allowed to be a ſpecies of nitre, has certainly its ſeminal being in theſe crude ſtones, and in that ſtate of its firſt being, is very different from that which we find after it has paſſed the fire, which from cold and coagulative, changes into cauſtic and reſolutive. This cold and coagulative quality of this ſtony ſalt, in its firſt ſtate, manifeſts itſelf ſufficiently in the waters of certain rock ſprings, which are very limpid and cold, and breed cold and ſchirrous tumours under the throats of thoſe people who ordinarily drink them, as in the Alps, *&c.*

This ſeminal matter of this ſalt then is wholly altered in its nature by fire, and is rendered ſulphureous and cauſtic as nitre. Fire is able to exalt and alter the ſtate of being of this ſalt, but it is no more able to produce it in theſe ſtones, than in the ſhells of oyſters, *&c.* of which alſo a lime is made, which yields a ſalt not more ſulphureous, than this. *Du Clos*, Obſerv. ſur les Eaux Miner.

The ſeminal being of alum and vitriol muſt, in the ſame manner, exiſt in thoſe ſubſtances out of which thoſe ſalts are extracted by water, after they have been calcined by fire, or expoſed to a ſlower calcination in the open air. They are not found in theſe ſtones before theſe proceſſes, yet it is ſufficiently evident that the fire and air could not produce them, but could only exalt them there.

All theſe varieties to which the ſeveral mineral ſalts are liable in their different ſtages, and in which they may be abſorbed together, and united by water under the earth, do not only render the judging of the mineral waters, which partake of them by analyſiſes very uncertain, but even, in many caſes, perplex and confound us, by the very means by which we hope to underſtand them.

Mineral JUICES. Many countries afford theſe, and give marks by them of treaſures that might be turned to great account, were the proper manner of aſſaying them known; which is by firſt properly reducing them to a dry ſubſtance, ſo as to come at the ſolid matter they contain. With a view to the diſcovery of metallic veins, the erection of ſalt-works, vitriol-works, alum-works, borax-works, and the like, the curious on this ſubject may find many excellent hints for further diſcoveries in the cloſe of Agricola's work, *De re metallica*; and the view is farther carried on by Boyle, Beccher, Stahl, and Homberg. The royal academy of Paris have alſo given ſome hints that may be of uſe, in their memoirs; and ſome practical things are recorded in the Philoſophical Tranſactions.

We have accounts in the Philoſophical Tranſactions of white and thick fluids like cream, found in mines at very great depths, and containing mineral particles. The bottoms of our coal-pits ſometimes afford this liquor in very large quantities. And ſome of the iron mines in Shropſhire, particularly that called the white mine near Hales in that county, affords a great quantity of this ſort of *Juice*. It is thick as cream, white, and of a ſweetiſh taſte, but with a vitriolic twang behind it. This is contained in the nodules of iron ſtone, which are here a ſort of enhydri, very large, compoſed of thick cruſt, and ſome of them holding near a hog's-head of this ſort of liquor. Phil. Tranſ. N°. 100. See the article ENHYDROS.

JUICE *of Tar*. See the article TAR-*Water*.

JUJUBES (*Cycl.*)—There are ſeveral ſpecies of this tree preſerved in the gardens of the curious. They are propagated by planting their ſtems in pots of light earth, ſoon after the fruit is ripe, and in winter they ſhould be preſerved under a common hot-bed frame, where they may be defended from the ſeverer froſts, and in ſpring the pots ſhould be plunged into a moderate hot-bed. When the young plants are come up, they ſhould be enured to the open air by degrees, and in June they may be removed out, and placed under the ſhelter of a warm hedge. In this place, they ſhould remain till the beginning of October, when they are to be removed into the green-houſe, or elſe placed under a hot-bed frame, that they may be preſerved from the froſts. During the winter they ſhould have as much air as the ſeaſon will permit, and be watered at times, tho' this muſt be very cautiouſly done after they have ſhed their leaves. In the March following, before they begin to ſhoot, they are to be tranſplanted each into a ſeparate pot of light earth, and they ſhould then be plunged into a moderate hot-bed, and watered and ſhaded till they have taken thorough root; and in May they are to be removed thence into the open air. They muſt be houſed in winter till they are about four years old, and then may be tranſplanted into the naked ground, and will ſtand our winters. *Miller*'s Gardener's Dict.

JUJUB, *Zizyphus*, in botany. See the article ZIZYPHUS.

JULEP (*Cycl.*)—*Camphor* JULEP, *Julepum e Camphora*, a medicine preſcribed in the late London Diſpenſatory, and ſeeming the beſt calculated of any thing of the kind, to communicate the virtues of camphor to water. It is made thus: Take camphor a dram, fine ſugar half an ounce, boiling water a pint. Grind the camphor with a little ſpirit of wine till it is ſoftened, then add the ſugar, and by degrees perfectly unite theſe; finally add the water by a little at a time, and when the whole has ſtood in a covered veſſel till it is cold, ſtrain it off. *Pemberton*, Lond. Diſp. p. 286.

JULIA, in ichthyology, a name given by Salvian and Gaza to the *Ioulos* of the Greeks, called *julis* by the Latin writers in general, and by the Italians, *donzellina*. It is a ſpecies of the labrus, according to Artedi, and is diſtinguiſhed by that author from the other fiſh of that kind, by the name of the variegated labrus of a palm long, and having two larger teeth in the upper jaw. See the article LABRUS.

JULIS, in zoology, the name of a ſmall fiſh, caught principally about Genoa, and ſold in the markets, being a very delicately taſted fiſh. Its uſual ſize is about the length and a little more than the breadth of a finger. In ſhape it approaches to the long-bodied turdi, but is longer, ſlenderer, and its back leſs ridged. Its ſcales are ſmall, and adhere very cloſely to the fleſh, and its colours are ſo various and lively, that it exceeds, in this particular, even the turdi. Its back, from the head to the tail, is of a duſky and ſomewhat blackiſh hue. Along the middle of the ſides there runs a broad blue line, and immediately under this a yellow or ſaffron-colour'd one; and the belly is of a bluiſh white or pearl-colour. Its eyes are ſmall, and their iris red. Its mouth ſmall. Its teeth ſtrong and ſharp; and its lips thick and fleſhy. Its back fin reaches from head to tail. Its anterior rays are ridged and prickly, the reſt ſoft and flexile, and its colours very lively and beautiful; its bottom being yellow, its middle red, and its top blue. Its tail is blue, with an admixture of red, and is not forked. *Rondelet.* de Piſcib. l. 6. c. 7. p. 180. *Aldrovand*, de Piſc. l. 1. c. 7.

The males of this ſpecies are very beautifully painted. Their backs are green, and their heads have variegations of yellow and red. Its ſides have very broad ſerrated lines of a fine gold yellow, and its back fin has ſeveral large ſpots of blue and red. They are fond of human blood, and will ſeize upon the legs of people who walk naked into the water. *Geſner*, de Piſc. p. 549.

JULUS. See the articte GALLY-*Worm*.

JUMENTA, in the Linnæan ſyſtem of zoology, the claſſical name of one of the orders of quadrupeds; the character of which is, that the teeth of the creatures are irregularly placed, and in a different manner from thoſe of the other four orders of quadrupeds. Of this order are the elephant, the hippopotamus, the ſorex or mus araneus, the horſe, and the hog. *Linnæi* Syſtem. Naturæ, p. 40.

JUNCAGO, *Ruſh Graſs*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged into a circular form. The piſtil ariſes from the center of the flower, and finally becomes a fruit or capſule, which, when ripe, opens at the bottom, and is found to be compoſed of three vaginæ, each of which contains one oblong ſeed.

There is only one known ſpecies of this genus, which is the common *Juncago*, called by many *Gramen Spicatum*, and *Triglochin*. *Tourn.* Inſt. p. 266.

JUNCI *Lapidei*, in natural hiſtory, the name given by authors to a ſpecies of foſſile coral, of the tubularia kind, and compoſed of a congeries of ſmall tubules, which are uſually round and ſtriated within. See Tab. of Foſſils, Claſs 7.

JUNCO, in zoology, the name of a bird called in Engliſh the greater reed ſparrow. It is almoſt as large as a thruſh. Its beak is oblong, and ſomewhat crooked, the upper chop being blackiſh, and the under white. Its tongue is bifid and jagged, and its mouth yellow within. Its throat, breaſt, and belly are of a whitiſh yellow; near the tail it is more yellow than elſewhere, and its back is of a yellowiſh brown, with a faint greyiſh caſt. It has a white line over its eyes, a little yellowneſs under the wings, and a very ſtiff and rigid tail like the woodpecker. Its legs are remarkably ſhort and ſtrong. It always lives among reeds, and climbs and ſticks to them, as the woodpecker does to the branches of trees. Its feet, however, are not formed like thoſe of that bird, but have only one toe behind. It feeds on the beetles and other inſects which are found among the reeds, and ſings very agreeably and ſweetly. *Ray*, Ornithology, p. 99.

JUNCO is alſo uſed by Bellonius for a bird ſeeming, by his deſcription, the ſame with what we call the *ſtint*. See the article STINT.

JUNCUS, the *Ruſh*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, conſiſting of ſeveral petals, diſpoſed in a circular form. From the center of the flower ariſes a piſtil, which finally becomes a trigonal fruit or capſule which opens three ways, and uſually contains a number of roundiſh ſeeds.

The ſpecies of *Ruſh*, enumerated by Mr. Tournefort, are theſe: The ſharp or pointed *Ruſh*, with ſorghum heads. 2. The ſharp *Ruſh*, with ſpread panicles. 3. The longer ſharp *Ruſh*, with ſpread panicles. 4. The ſmooth or ſoft *Ruſh*, with conglomerated heads. 5. The larger *Ruſh*, with a bending top. 6. The ſmaller *Ruſh*, with bending tops, called by many, the trifid *Ruſh*. 7. The hairy *Ruſh*, with heads like thoſe of pſyllium, called by many the ſmall hairy graſs or cyperus graſs. 8. The great broad-leav'd wood *Ruſh*, commonly called the broad-leav'd wood graſs. 9. The low erect marſh *Ruſh*. 10. The low creeping marſh *Ruſh*. 11. The *Ruſh* with jointed leaves, and umbellated flowers. 12. The jointed-leav'd *Ruſh*, with umbellated and paniculated flowers. 13. The mountain water *Ruſh*. 14. The ſmall roundiſh-fruited *Ruſh*, or *Ruſh*-graſs. 15. The narrow leav'd hairy *Ruſh*, with white paniculated flowers. And 16. The leaſt leafy *Ruſh*. *Tourn.* Inſt. p. 246.

JUNGERMANNIA, in botany, the name of a genus of plants called by Dillenius, *lichenaſtrum*, and ſome of the ſpecies are called by Micheli by this name; others by that of *muſcoides*. The characters of the *Jungermannia* are theſe: It produces both male and female flowers; and theſe are often found both upon the ſame plant. The male flower ſtands upon a long pedicle, which ariſes from a ſort of cup or caſe on the leaf. This has no cup, no petals, nor any ſtamina, but is only one ſingle anthera or apex, which is at firſt of an oval figure, but being compoſed of four valves, it opens when ripe into four ſegments, and remains in this ſtate a long time upon the plant. The female part of fructification, as it may be much more properly called than flower, conſiſts only of ſeeds, ſo far as we are able to obſerve, for there is no appearance of either cup or petals; but the ſeeds are found in ſome ſpecies ſingly, in others in cluſters on different parts of the leaves. *Linnæi* Gen. Plant. p. 506. *Micheli*, Nov. Gen. p. 54.

JUNIPA, in botany, the name of a tree of the Caribbee Iſlands, and ſome other places, the fruit of which is ſaid to yield a juice as clear as water, yet yields a fine violet-colour'd dye, and being rubbed twice on the ſame place, makes it black. This tincture, it is ſaid, cannot be got out by ſoap, or any other method of cleanſing, but after nine or ten days diſappears of itſelf. It is ſaid alſo by the ſame authors, that hogs and parrots, feeding on this fruit, have their fleſh and their fat all tinged throughout of a violet colour. *Ligon.* America.

JUNIPER, (*Cycl.*) *Juniperus*, in botany, the name of a genus of trees, the characters of which are theſe: The male flowers are of the amentaceous kind, conſiſting of a number of ſmall leaves, loaded with many apices. The fruit are round berries, containing angular kernels, and in them oblong ſeeds. To this it is to be added, that the leaves are plain and ſimple, not like thoſe of the cypreſs, which is the character that diſtinguiſhes this from the cedrus.

The ſpecies of *Juniper*, enumerated by Mr. Tournefort, are theſe: 1. The common ſhrubby *Juniper*. 2. The tree *Juniper*. 3. The ſmall mountain *Juniper*, with broad leaves and oblong berries. 4. The great *Juniper*, with blue berries. And 5. The great *Juniper*, with reddiſh brown berries. *Tourn.* Inſt. p. 589.

The confuſion in names that has ariſen from the calling ſome of the *Junipers* by the name of cedar, is as old as Theophraſtus. In the days of this author the Greeks plainly did not diſtinguiſh between the names *Juniper* and cedar, but applied them indifferently to the ſame trees; and all the authors ſince have more or leſs given into it. The Greeks uſed alſo the word *thyon* as the name of both the one and the other of theſe trees. This *thyon* ſeems originally to have been the name of a kind of ſavin, uſed in the ſacrifices of the Greeks; but the reſemblance between this tree and the *Juniper*, called at that time the cedar, which was probably the ſame with our cypreſs-leav'd *Juniper* of theſe times, occaſioned its being called by the ſame name with it; and from thence all the other kinds of *Juniper* were called cedars; and this word thyon, as well as the others of *Juniper* and cedar, became indiſcriminately uſed as the name of all the kinds of this tree. Among the Greeks we find the *Juniper* called the wild cypreſs; and among the Arabians it is called the wild cedar. Myrepſus uſes the words *Juniper* and wild cedar as ſynonymous, and makes them the ſame with the citrus of the Romans. Some authots, ſince the diſcovery of America, have called the Weſt Indian *Junipers* by the name of *Cedrus Atlantica*; and we at preſent call thoſe of Virginia, and other places, by the names of Virginian and Bermudas cedars. The Spaniards have confounded the ſeveral ſpecies of *Juniper* and cypreſs under the name *Enebro*, though it was originally only uſed to expreſs the *Junipers* commonly ſo called; and the ſmall cedars, which are alſo *Junipers* of one kind or other; and in this ſenſe it made no real confuſion upon the whole. The reader is always to examine the context in his author, when he meets with the word cedar in any language, for it runs thro' a great many with very little variation, before he can know whether the cedar of Lebanon or the common *Juniper* be meant by this name.

Theophraſtus, in his time, tells us, that the world diſtinguiſhed two kinds of cedar, which they called the Lycian and the Phœnician; but he tells us, that ſome aver'd at that time, that theſe were the ſame ſhrub, and that both of them were of the ſame nature with the *Juniper*. This author him-

ſelf tells us, that the only difference between the *Juniper* and cedar, was in the leaves, for that the leaves of the cedar were hard, ſharp, and prickly, and thoſe of the *Juniper* ſofter; and that the *Juniper* tree grew much higher than the cedar. It is plain from this, that the Greeks had no idea of the cedar of Lebanon under this name, but that their cedars were only *Junipers* of peculiar ſpecies, and of the nature of our Virginian and Bermudas cedars. The Greeks in general, after the time of this author, called both theſe trees by the name of cedar, only ſometimes they diſtinguiſhed them by calling the low kind *oxycedrus*, the prickly cedar, becauſe of its prickly leaves.

JUNKES, on board a ſhip, is uſed to ſignify old hawſers.

JUNO, in aſtronomy, a name given by ſome to the ſecond ſatellite of Jupiter. *Lowthorp*'s Abrid. Phil. Tranſ. vol. 1. p. 408.

IVORY (*Cyl.*)—A green dye may be given to *Ivory* by ſteeping it in aqua fortis tinged with copper or verdigreaſe.

And by converting the aqua fortis into aqua regia, by diſſolving a fourth part of its weight of ſal ammoniac in it, *Ivory* may be ſtained of a fine purple colour. *Boyle*'s Works abr. vol. 1. p. 133.

Ivory has the ſame medicinal virtues with hartſhorn; its ſhavings too, like thoſe of hartſhorn, boil into a jelly with water, which has the ſame reſtorative quality. See the article HARTSHORN, *Cycl.* and *Suppl.*

Foſſile IVORY. The abundance of elephants teeth found buried in different parts of the world, and many of thoſe parts ſuch as no elephant is ever known to have lived in, have given great amazement to naturaliſts.

The long tuſks, which are what we call *Ivory*, are the only teeth the vulgar are acquainted with in this creature, yet even theſe, in their foſſile ſtate, have often been miſtaken for horns, or other animal parts. The grinders of this animal are ſo enormouſly large, and of ſo ſingular a ſhape, that it requires ſome knowledge in natural hiſtory to diſcover them at ſight, and many have miſtaken them when imperfect, for parts of a petrified ſhell-fiſh of the nautilus kind, their root being hollowed all along, and armed with an indented ridge on each ſide, in the manner of the back parts of ſome ſhells of that and of the cornu ammonis kind.

We are not to wonder that the teeth of elephants are found more frequently than any other bones of the animal, ſince their uſe in the creature required that they ſhould be harder than any other bone, and that hardneſs has preſerved them in places where the other bones have periſhed. The different ſtate in which theſe teeth are found, is wholly owing to the different juices abounding in the earth in the place where they were depoſited, ſome of thoſe juices being of power to preſerve, others to deſtroy them; ſome eating them inſenſibly away, ſome as it were calcining them by ſlow degrees, and others rendering them greatly more hard and durable than before. Mem. Acad. Par. 1727.

Count Marſigli, and ſome other writers, have thought it an eaſy ſolution of the queſtion of the teeth and bones of elephants being found in countries where elephants are not naturally found, that we owe them to the Romans, who bringing them over for their uſe in war, buried them wherever they happened to die. But Sir Hans Sloane expreſſes himſelf very juſtly againſt this opinion: He obſerves, that of the remains of elephants found in Europe, nothing is ſo common as the *Ivory* tuſks. Now, as he well obſerves, the Romans held *Ivory* in the higheſt eſteem, and it ſold among them at a great price; wherefore had they been the buryers of theſe elephants, they would certainly have taken away the *Ivory* tuſks firſt. It is certain, therefore, that accidents, and not deſign, have buried theſe bones, and that accident can have been no other than ſome prodigious inundation. Woodward is deſirous of making the univerſal deluge to have done all this, but that ſeems not neceſſary to be ſuppoſed in every caſe. Sir Hans Sloane gives an enumeration of the moſt curious of theſe pieces of foſſile *Ivory*, which his own cabinet contained, and of ſome others of the moſt remarkable, mentioned by authors; from which we may form a very diſtinct idea both of the nature of the bodies themſelves, and of the places where they are uſually met with. See Philoſ. Tranſ. N° 403. p. 458.

One of theſe is compoſed of coats or layers, like the annual circles or rings in the trunks of trees. The large piece, which was the baſe of the tooth, is compoſed in this ſpecimen of nine ſuch coats, ſome of which have about a tenth of an inch in thickneſs, which, allowing for the conic cavity within, which is ſomewhat more than the thickneſs of either of the ſides, gives the whole tooth at the baſe three inches in diameter. Toward the ſmaller end of the tooth, theſe nine coats were found to grow together, and form only two or three, which are conſiderably thick.

In the baſe of the tooth, each of the nine coats may, with care, be ſeparated into a great number of others which are not thicker than common parchment. The manner of theſe teeth falling to pieces, is alſo a proof of their being of this coated ſtructure, for they always fall into hollow fragments which are parts of theſe coats. This ſtructure is alſo ſometimes diſtinguiſhed in the recent teeth of the elephant, which when diſeaſed will ſometimes exfoliate, or throw off pieces in form of coats of the ſhape of a part of the tooth, but as thin as paper, and eaſily breaking on the lighteſt touch.

The power of ſubterranean calcinations to render things of this kind brittle, is alſo remarked by the ſame author from Moreton's hiſtory of Northamptonſhire, in the inſtance of a foſſile tuſk of an elephant which was in the whole at leaſt ſix foot long, and had preſerved its natural whiteneſs, though rendered ſo brittle as to fall into ſeveral pieces in the digging. This was dug up near Little Bowden in Northamptonſhire; and the ſtrata of the place where it lay, were as follows: 1. Vegetable mould fourteen inches. 2. Loam a foot and half. 3. Large pebbles, with a ſmall mixture of earth among them, two foot and a half. 4. Blue clay; in the upper part of this laſt ſtratum, the tooth was found. *Moreton*'s Hiſt. of Northamptonſhire.

Sir Hans mentions another elephant's tuſk very intire and ſound, found in Siberia. It is of a brown colour, and is hollow at the bottom, as all elephant's teeth are: This is five foot ſeven inches long, ſix inches in diameter at the baſe, and its weight forty-two pounds. The like are common in Siberia and many parts of Ruſſia, and are ſo little injured, that they are uſed as *Ivory*, and are ſuppoſed to be the teeth of a vaſt animal called the *mammouth*, which they think lives under ground. Ludolfus, however, ſays, that the more ſenſible people among the Ruſſians allow theſe to be the teeth of elephants, and ſay that they were brought to their country, and buried there by the univerſal deluge. One of theſe teeth is in the collection of curioſities of Peterſburg, and weighs one hundred and eighty-three pounds. They are found very plentifully in the high banks of rivers, which break and fall down in large pieces after froſts. The inhabitants, who have an opinion of their belonging to a ſubterranean animal, pretend that the creature dies as ſoon as ever it ſees the light, which they ſay ſometimes happens to it when it comes abruptly to a precipice, ſuch as the ſteep bank of a river, which they ſay is the reaſon why they are ſo frequently found in thoſe places. They pretend that they have ſometimes found the intire ſceletons with the fleſh yet remaining on the bones, and a thouſand other fabulous accounts of this imaginary animal, are given in the hiſtories of that country. Cornelius Le Brun, in his travels through Ruſſia to the Eaſt-Indies, mentions vaſt numbers of elephant's teeth found lying on the ſurface of the earth near Veronitz, which puzzle people to imagine how they came there: The Czar's opinion, he ſays, was, that Alexander the Great, when he paſſed the Tanais or Don, advanced as far as Koſtinka, a ſmall town eight werſts from thence; and that, probably, many of his elephants dying there, theſe teeth are the remains of them. Phil. Tranſ. N° 403. p. 468.

JUPATUMA, in zoology, a name by which ſome call a very remarkable American animal, known among us by the name of the *opoſſum*. *Marggrave*, Hiſt. Braſil. See OPOSSUM.

JUPUJUBA, the Braſilian name of a bird of the woodpecker kind, more commonly known by the name *japu*. See the article JAPU.

JUQUER. This plant is found in Braſil, and is of a poiſonous nature; but if we may credit Piſo, its root is its antidote. *Boyle*'s Works abridg. vol. 1. p. 14.

JURIS UTRUM, in law, a writ which lies for the parſon of a church, whoſe predeceſſor hath alienated the lands and tenements thereof. Terms of Law. *Blount*, *Cowel.*

JURUCUA, in zoology, the Braſilian name of a ſpecies of tortoiſe. This has feet almoſt in the ſhape of wings, the fore ones about ſix inches long, the hinder ones conſiderably ſhorter; its tail is ſhort, and of a conic figure; its eyes large and black; its mouth has no teeth, but reſembles the beak of a bird. It frequently grows to four foot long, and about three in width; its ribs are faſtened to the ſhell, and are eight on each ſide; the middle ones of theſe are the longeſt, the fore and hinder ones being the ſhorter. The fleſh and eggs of this ſpecies are very delicately taſted; they lay their eggs in holes on the ſea ſhore, covering them over with ſand, and leaving them for the ſun to hatch them. There are uſually a great many very odd figures, like geometrical lines, running in various directions on the ſhell; the whole ground of the ſhell is uſually black and very gloſſy, adorned with yellow variegations; but this is no certain character of the ſpecies, the varieties in the colouring of theſe ſhells being very great. *Ray*'s Syn. Quad. p. 256.

JURUNCAPEBA, in zoology, the name of a ſea fiſh of the turdus or wraſſe kind, caught about the ſhores of the Braſils, and called alſo *Itaiara*. It is uſually about five or ſix inches long, and about a third part of its length in breadth; its mouth is extremely large and wide, and of a ſomewhat triangular figure; its eyes are large, and their pupil white, their iris red. It has a long back fin, the anterior rays of which are prickly, the others not ſo; its ſcales are ſo evenly arranged that it ſeems ſmooth, and its colour all over is a very beautiful red; its belly having many white ſpots, and its ſides a great number of them of different ſizes, black, brown, and red; its fins are all red, and ſpotted with black. It is caught among the rocks, and is a very delicate fiſh for the table. *Marggrave*'s Hiſt. Braſil.

JURURA, in zoology, the name of a ſpecies of tortoiſe common in the Braſils. It is a ſmall kind, ſeldom exceeding ten fingers breadth in length, and eight or nine in length, and is of an elliptic figure; its under ſhell is about nine fingers long, and four and a half broad, and is flat; it can at pleaſure hide its whole body in the ſhell, or thruſt out its neck to three fingers breadth diſtance; the head is thick and long, the noſe elevated and pointed; the mouth is large, and the eyes black; it has four long claws on its feet; its tail is ſhort and pointed, and its ſkin is rough and ſcaly. The upper ſhell is brown, the lower yellow; its eggs are white and round, and about half the ſize of a hen's egg, and are very well taſted. *Ray's* Syn. Quad. p. 258.

JUS (*Cycl.*)—Jus *Gladii* is mentioned in our Latin authors, and the Norman laws, where it ſignifies a ſupreme juriſdiction, *Camd.* And hence it is, that at the creation of an earl, he is ſaid to be *gladio-ſuccinctus*, to ſignify that he had a juriſdiction over the county of which he was made earl. See PLEAS *of the Sword*, *Cycl.*

JUSQUIAMUS, in botany, a name uſed by ſome authors for the hyoſcyamus or henbane. *Ger.* Emac. Ind. 2.

JUSSIEUA, in botany, the name of a genus of plants deſcribed by Linnæus, the characters of which are theſe: The perianthium is ſmall, and ſtands upon the germen of the piſtil; it is compoſed of five leaves, which join at the baſe, and are of a pointed oval figure. The flower conſiſts of five oval expanded petals; the ſtamina are ten very ſhort and ſlender filaments, the antheræ are roundiſh, the germen of the piſtil is oblong, and ſtands under the cup; the ſtyle is capillary, the ſtigma is flat, and capitated and marked with fine ſtriæ. The fruit is oblong, thick, and coronated, and opens longitudinally when ripe; the ſeeds are numerous, and ſtand in ſeries. *Linnæi* Gen. Plant. p. 186. Hort. Malabar, vol. 2. p. 51.

JUSSIEVIA, in botany, a name given by Houſton to a genus of plants deſcribed by Linnæus under the name of *jatropha*. See the article JATROPHA.

JUSTICIA, the name given by Houſton to the plant, which is called *adhatoda* by Tournefort, and *echolium* by Rivinus. The name *Juſticia* is preſerved by Linnæus, and the plant in his ſyſtem is a diſtinct genus. The characters of this are, that the cup is an extremely ſmall perianthium compoſed of one leaf, divided into five ſegments at the end, erect, narrow, and acute; the flower is a ſingle petal, forming a gibbous tube, with a gaping mouth, the upper lip of which is oblong, and has a rim round its edge; the under one is of the ſame length, and is bent backward, and obtuſely trifid or divided into three ſegments. The ſtamina are two pointed filaments, and are hid under the upper lip of the flower; the antheræ are erect and bifid at their baſe. The fruit is a capſule, oblong, obtuſe, narrow at the baſe, containing two cells with two valves, and a ſeptum placed in a contrary direction to the valves. The ſeeds are roundiſh. *Linnæi* Gen. Plant. p. 4.

JUSTICIAR, in our old laws, an officer inſtituted by William the Conqueror as the chief officer of ſtate, and who principally determined all pleas civil and criminal. He was called in Latin, *capitalis juſticiarius totius Angliæ*. *Maddox* Hiſt. of the Excheq. c. 9.

JUSTICIARII, in church hiſtory, an appellation given to heretics who boaſt much of perfect righteouſneſs, and deſpiſe others; ſuch were the Phariſees among the Jews, and the Novatians and Donatiſts among the Chriſtians. *Hoffm.* Lex. in voc.

Magiſter JUSTICIARIUS, a judge in the kingdom of Naples, who has ſupreme juriſdiction in all caſes of treaſon, and pleas of the crown, and finally determines all appeals; he has four aſſeſſors. *Hoffm.* Lex. in voc. *Juſticiarius.*

JUSTICIARY *Court*, in Scotland. The court of *Juſticiary*, has ſupreme juriſdiction in all criminal cauſes. It came in place of that of *juſtice Eyre*, or *juſtice general*, which was laſt in the perſon of the earl of Argyle, who tranſacted for it with king Charles I. and was made juſtice general of all the iſlands; which raiſing great debates between him and ſome hereditary ſheriffs there, the juriſdiction was taken away in 1672, and this court of *Juſticiary* erected inſtead of it, conſiſting of a juſtice-general, alterable at the king's pleaſure; a *juſtice clerk*, and five other *judges*, who are likewiſe lords of the ſeſſion.

This court commonly ſits on mondays, and has an ordinary clerk, who has his commiſſion from the juſtice clerk. They have four ordinary macers and a doomſter, appointed by the lords of ſeſſion.

The form of proceſs is this, the clerk raiſes a libel or indictment, by a bill paſſed by any of the lords of that court, at the inſtance of the purſuer againſt the defender or criminal, who is committed to priſon immediately after citation. When the party, witneſſes, and great aſſize (or jury of forty-five men) are cited, the day of appearance being come, fifteen of the great aſſize are choſen to be the aſſize upon the pannel (or priſoner at the bar). The aſſize ſits with the judges to hear the libel read, witneſſes examined, and the debates on both ſides, which is written verbatim, in the adjournal books. The king's advocate pleads for the purſuer, being the king's cauſe, and other advocates for the pannel. The debates being cloſed, the judges find the libel or indictment either *not relevant*; in which caſe they deſert the diet, and aſſoil or abſolve the party accuſed: Or elſe they find the libel *relevant*; in which caſe the aſſize or jury of fifteen is removed into a cloſe room, none being allowed to be preſent with them; where they chuſe their own chancellor and clerk, aud conſider the libel, depoſitions, and debates, and bring in their verdict of the pannel ſealed, guilty or not guilty. If not guilty, the lords abſolve; if guilty, they condemn, and order the ſentence of condemnation to be pronounced againſt the criminal by the mouth of the doomſter. *Chamberlain's* Preſent State of Great Brit. p. 385. The lords of *Juſticiary* likewiſe go circuits twice a year, *viz.* in May and October, into the country, which is divided into three circuits, the ſouth, weſt, and north, where aſſizes are held, and criminals tried, as mentioned above.

JUSTICIES, in law, a writ directed to the ſheriff in ſome ſpecial caſes, by virtue of which he may hold plea of debt in his county court for a large ſum, whereas otherwiſe, by his ordinary power, he is limited to ſums under forty ſhillings. F. N. B. 117. *Kitch.* 74.

JUTRA, in botany, a name uſed by ſome authors for the tree whoſe fruit is the tamarind of the ſhops. *Piſo*, p. 157.

IVY, *Hedera*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, or compoſed of ſeveral leaves arranged in a circular order. The piſtil ariſes from the cup, and finally becomes a roundiſh berry, containing ſeeds gibboſe on one ſide, and flat or ſmooth on the other.

The ſpecies of *Ivy* enumerated by Mr. Tourneſort are theſe: 1. The common *Ivy*. 2. The poetic, or Dionyſian *Ivy*. And, 3. The American tree *Ivy*, with ſpear-pointed leaves. *Tournf.* Inſt. p. 612.

Ivy is a very well known plant, and it is very certain, from all the writings of the antients, that they, when they wrote with propriety, meant the ſame plant by the word *Hedera* that we do at this time. There is, however, in Pliny, a paſſage which has appeared unintelligible to his commentators in general, and ſeemed to point out ſome other plant as known to the antients by the name *Hedera*, beſides our *Ivy*. See the article CISTUS.

Ground-IVY, *Hedera Terreſtris*. The leaves of the common ground-ivy are found ſometimes to produce on their under part certain galls, or round protuberances, of a fleſhy texture and green colour, of the ſize of nutmegs, or ſometimes larger. Theſe are in ſome years ſo common in France, that the poor people eat them either raw or roaſted, and find them a wholeſome food.

It is well known that the leaves of the oak afford very often protuberances of a like kind, or ſoft galls, called oak apples. Theſe, however, are not eatable, becauſe of the auſtere taſte of the juice of the tree. The common ſage alſo produces ſuch galls or apples very frequently in the warm countries, and theſe are ſo common, ſo large, and ſo well taſted, that they are in ſome places brought to the market. All theſe galls have the ſame origin, they are all produced by the eggs of a fly, which hatch into a worm or maggot that feeds on the juices of the plant. On opening theſe galls at a proper time, the maggot is always found within. See the article GALLS.

Ground Ivy is an attenuant and diſſolvent, and famous, both externally and internally, as a vulnerary. It is much uſed by way of tea in diſorders of the breaſt and lungs, and is ſometimes an ingredient in the pectoral decoction. It is eſteemed a ſpecific in eroſions and ulcerations of the viſcera, and particularly of the kidneys and lungs; with which intention its juice has been given people in conſumptions. Lindanus praiſes it in an *empyema* and *vomica pulmonum*, and recommends it to ſuch as void blood and purulent matter by urine. It is alſo ſaid to be good in bruiſes, and to cure the head-ach: But notwithſtanding all this, it is left in great meaſure to the common people.

Petrified IVY. In places where the incruſtations of moſſes and other vegetables happen, *Ivy* is one which very frequently undergoes the ſame fate. The beauty and elegance of the *petrified Ivy* of Derbyſhire with us, has been long famous. In the mountains near matlock baths in that county, there are many grotto's which afford great quantities of this *petrified Ivy*, as it is called, and of other incruſtations of the ſame kind. The beauty of theſe caverns is ſcarce to be conceived; their roofs are hung with ſtalactitæ and ſtalagmitæ, in form of cluſters of grapes, and the incruſted plants are many of them ſo delicate and tender that they fall to pieces under the touch. It is very common in theſe places to ſee *Ivy* creeping along the rock; in ſome parts the ſame branch will be found only incruſted in the common way; in other parts the ſtony matter will ſo penetrate its pores, that the wood and leaves ſhall appear wholly petrified, and in others the ſame branch ſhall be yet freſh and vegetating.

Hazel trees often make a part of theſe incruſtated matters, and appear in this ſtate very beautiful, their roots and branches being in ſome parts only thinly incruſted, in others more thickly and firmly petrified. Among theſe alſo, as in the *Ivy*, there are

continually ſhooting up a number of young branches, which after a time will all ſhare the ſame fate. Philoſ. Tranſ. N°. 456. p. 353.

Nothing can give a more lively and beautiful idea of the whole buſineſs of petrifaction, than this appearance of the ſeveral ſtates or ſtages of it in the *Ivy*, and other vegetables in theſe places. It is evident, that in theſe places not only the water diſtilling out of the rocks is able to depoſit ſtony matter on the vegetables, *&c.* in form of incruſtations, but even the ſteams and exhalations being highly ſated with theſe ſtony particles, are capable of working the ſame effect. This is evidently the caſe in regard to ſeveral pieces of the incruſtated *Ivy*, which have never been in the way of water, and yet are as compleatly covered with ſtone as the reſt; and this is the only method in which the ſtony matter is conveyed into the internal parts of the plants that are really petrified in theſe places. For experience ſhews in regard to theſe, that they are not petrified firſt, and afterwards incruſted, but it is plain, that the incruſtation is made firſt, and that afterwards, when in a long ſpace of time the vegetable matter within is periſhed and waſted away, the cavity that it leaves, by this means, is filled up afterwards with the ſame ſtony matter. It is evident that this inner part of the petrifaction was not formed while the vegetable yet exiſted by the inſinuation of ſtony matter into its pores, but that it is a mere maſs of ſtone added afterwards, ſince it has never any the leaſt trace of the inner ſtructure of the vegetable: And this ſtony matter, tho' uſually much more firm and ſolid than the outer cruſt, muſt in many caſes have been formed merely by vapours, as it is in places where water is never found to come on any occaſion. The water of ſome ſprings may be ſo loaded with ſtony matter, as perhaps by penetrating the pores of wood, and other lax bodies, to encreaſe greatly their ſpecific gravities, yet ſurely it is contrary to the laws of matter to ſay, that there are any hidden properties in that water capable of changing the bodies put into it, into other bodies ſpecifically different. A piece of wood put into one of theſe ſprings may in time loſe its texture and coherency, by the admittance of heterogeneous particles of different attractions; but the cauſe of coherency in the parts of the original body muſt ceaſe and be diſſolved, before it can be ſaid to become a part of any other body whatever. Afterwards, indeed, the ſpace that was poſſeſſed by the parts of the original body, may be ſupplied by thoſe of the new one, ſo as to make in time an uniform ſtone in the ſhape of the original plant; but if this petrified plant be ſtill kept in the place, where the ſame petrifying quality continues to act upon it, it will loſe even that ſhape, and become a part of that body which is contiguous to it, and ſo a great number of theſe plants thus petrified, arranged near to one another, will compoſe large maſſes, and perhaps whole ſtrata of ſtone. This is clearly the caſe in regard to many of the lime-ſtone rocks about the places where the petrified *Ivy* is found; and perhaps it might be carried ſo far as to ſtrengthen our conception about the general formation of the ſtrata of lime-ſtone and marble; that appearing to be every where (notwithſtanding that Dr. Woodward diſpatches them much more expeditiouſly) but eſpecially in the Peak of Derbyſhire, ſuch a petrifaction as has been deſcribed, only perfectly finiſhed. Philoſ. Tranſ. N°. 456. p. 356.

IVY *Reſin*, in the materia medica, is brought from Perſia, and ſome other of the hot countries, where alone it is to be found in any conſiderable quantity. Mr. Ray, indeed, mentions ſome of it having been found on *Ivies* in Worceſterſhire, and other authors in other parts of Europe; but theſe are only ſingular inſtances of what may happen, our ſhops being obliged to be ſupplied from the Eaſt.

The antient Greeks were acquainted with this reſin, which they called *lacryma hederæ*, as ſome alſo do to this day. It is ſaid to be emollient and detergent, and to make a noble balſam for freſh wounds; but is never uſed by us with theſe intentions. The Perſians eſteem it much as an aſtringent.

IXALOS, in natural hiſtory, a name given by the Greek writers to the creature which we call the chamoy goat.

IXIAS, in botany, a name given to the chamæleon thiſtle, of the white kind; and in the materia medica of the antients, to a poiſon, againſt which they have preſcribed many remedies. The uſe of ſynonimous words among the antients has given great occaſion to error and confuſion in the writers of later times; and this is a very remarkable inſtance of it. An explication of this confuſion is neceſſary, in order to the underſtanding either of Pliny, or of almoſt any other author who has happened to mention the poiſon *Ixias*, or the chamæleon thiſtle. It is to be obſerved, that the words, tho' ſynonymous with us, are not truly ſo in the original Greek, the one being a ſubſtantive of the feminine gender, always uſed alone, and with the particle ἡ prefixed to it, and the other being a maſculine adjective, and always introduced by the particle ὁ, and prefixed to the word chamæleon. The word *Ixias*, when uſed as a ſubſtantive, and having the particle ἡ prefixed to it, ſignifies no other than the common bird-lime which was in uſe at their times as well as now, and was eſteemed, if given internally, one of the ſlow poiſons. Galen ſays, it was one of thoſe which took time to perform its fatal office; and Dioſcorides and others inform us, that the manner of its killing the perſon to whom it was given, was by clogging and gluing up the inteſtines, ſo that nothing could paſs thro'. In this ſenſe bird-lime was eſteemed a poiſon, and when the word *Ixias* was uſed as a ſubſtantive of the feminine gender, and written ἡ ἰξιας, it always was meant as the name of this ſubſtance alone.

The female chamæleon thiſtle, or, as ſome call it, the white chamæleon thiſtle, was found in thoſe countries ſometimes to exſudate near its root a ſort of gummy juice, which was ſo like bird-lime in its quality of tenacity, that it was called by the ſame name by theſe authors, and the plant which was found to produce it was diſtinguiſhed from the other by the addition of a word to its name, expreſſive of this glue. In calling it the glue chamæleon, or bird-lime chamæleon, they could uſe no other word than that by which they expreſſed ſuch a ſubſtance, and therefore they called it the *Ixias* chamæleon. This, however, they always expreſſed by both words together, and by prefixing the particle ὁ denotative of the gender, to denote the word *Ixias* there to be an adjective ſignifying viſcous, and not the name of bird-lime: They wrote it on this occaſion ὁ ἰξιας χαμαιλέων, and by Theophraſtus it is called ἰξινη ακανθη. If this name had been uſed by all the writers, as well as by this great author, there could have been no confuſion between things in themſelves ſo unlike as the chamæleon thiſtle and common bird-lime; yet Pliny has tranſlated as belonging to the chamæleon thiſtle all that the Greek writers have ſaid of bird-lime; and others, looking upon him as a good authority, have branded a very innocent plant with the name of a poiſon. The roots of the white chamæleon being eſculent, and its gum, tho' like bird-lime in viſcoſity, yet being inoffenſive to the human body. See the article CHAMÆLEON.

IXOPUS, in botany, a name given by Cordus, and ſome other authors, to the chondrilla or ſuccory. *Ger. Emac. Ind.* 2.

IXORA, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are, that the calyx is a ſmall erect perianthium, divided into four ſegments, and remaining when the flower is fallen. The flower conſiſts of one petal, which is a ſlender, cylindric, and very long tube, with a flat border, divided into four ſegments, of an oval figure. The ſtamina are four very ſhort and crooked filaments, placed in the notches of the flower. The antheræ are oblong. The germen of the piſtillum is roundiſh. The ſtyle is ſlender, and of the length of the tube; and the ſtigma is bifid. The fruit is a roundiſh berry, containing only one cell, in which are four ſeeds, convex on one ſide, and angular on the other. *Linnæi* Gen. Plant. p. 27.

JYNX, in zoology, the name of a bird of the woodpecker kind, called alſo the *torquilla*, and in Engliſh, the *wry-neck*. It is a little ſmaller than a lark. Its beak is of a bluiſh colour, and is not ſo ſtrong and thick as in moſt of the woodpecker kind. It can at pleaſure raiſe the feathers of its head into a ſort of creſt, and is a very beautifully variegated bird. Its colours are a pale grey, or aſh-colour, a white, a browniſh red, a deep plain brown, and black. Its head is grey, and is variegated with tranſverſe black lines. Its belly and breaſt have a caſt of yellowiſh in the grey, and are in like manner variegated with black lines. Its breaſt is white, with the ſame variegation. Its back is black, and the reſt of the colours are beautifully mottled on its wings. It has a very whimſical way of turning and twiſting its neck about, and bringing its head over its ſhoulders, whence it had its name *Torquilla*, and its Engliſh one of *wry-neck*. It feeds on ants, which it very dexterouſly transfixes with the bony and ſharp end of its tongue, and then draws them into its mouth. *Ray*, Ornithol. p. 95. See Tab of Birds, N°. 13.

IZTICHUILOTLI, in natural hiſtory, the American name of a ſtone found in New Spain, and ſome other places; it is very hard, of a beautiful black, and takes a fine poliſh. The Americans are very fond of it as a gem, and wear it by way of ornament; but they attribute no medicinal virtues to it.

De Laet mentions an American ſtone in his poſſeſſion, which was cut by the Indians into a flat oval plate, and was of a beautiful black, but with two round ſpots of a ſilvery white. He ſuppoſes this to have been the *uterinus lapis*, and probably it was either that ſtone, or of the ſpecies here mentioned.

IZTICPASO-QUERZALIZTLI, in natural hiſtory, the name given by the natives of ſome parts of America to a ſtone famous for its virtues in curing the colic, and many other diſeaſes, externally applied: It is of a beautiful green colour, and is by Ximenes ſuppoſed a coarſe ſpecies of emerald; but is more properly a very fine kind of *lapis nephriticus*, of a pale green colour, very hard, and more pellucid than the other ſpecies of that ſtone, but yet always ſhewing that greaſy look on being poliſhed, which characterizes all the nephritic ſtones. It is uſually found in large maſſes, and the Indians cut it into flat pieces, which they apply to the navel in the colic, and in other diſeaſes, to the part affected, and ſuppoſe it has great power in promoting a diſcharge of the noxious humours. *De Laet.*

IZTLI, in natural hiſtory, the American name of a ſpecies of ſtone, of which the natives made their weapons of war, *&c.* before they knew the uſe of iron. It is called by De Laet and other authors, *lapis novacularum*. See the article NOVACULARUM *Lapis*.

K.

KAALING, in natural hiſtory, the name of a ſpecies of ſtarling, common in China, and not unfrequent in the Philippine iſlands. It is black, but its eyes, legs, and beak are yellow. It is eaſily kept tame, and may be taught both to ſing and talk. It eats rice and inſects in its wild ſtate; but when kept in a cage will feed very heartily on bread, and all kinds of fruits.

KABANI, in the oriental offices, a perſon who ſupplies the place of what we call the notary publick. All obligations that are valid are drawn by him; and he is likewiſe the public weigh-maſter, and every thing of conſequence ought to be weighed before him. *Pocock*'s Egypt. p. 170.

KABBALA. See CABBALA.

KABBOS, in zoology, the name of an Eaſt Indian fiſh of the muſtela kind. It grows to about two feet long, has no ſcales, but feels ſmooth and ſoft, like the eel, and is of a brown colour; the noſe or ſnout much paler than the reſt, and ſpotted with black. The head is obtuſe, and the eyes placed very near the extremity of it. *Ray*'s Ichthyolog. Append. p. 4.

KÆADAS, Καιαδας, among the Lacedæmonians, a dungeon for throwing their criminals into. It was of the ſame nature with the Athenian *Barathron* or *Orygma*. *Potter*, Tom. 1. p. 135. See BARATHRON and ORYGMA.

KÆKURIAGHAKA, in botany, a name uſed by ſome authors for the tree which affords the gum elemi of the ſhops. *Herm.* Muſ. Zeyl. p. 48.

KAFER *Aliheud*, in the materia medica, the name given by Aviſenna to the drug we call *bitumen Judaicum*, or Jews pitch. What this author gives us under this head, is principally tranſcribed from Dioſcorides; but it appears that the Arabian has confounded, in his account, the piſſaſphaltum with the aſphaltum or Jews pitch, which the original author keeps ſeparate, and to which he attributes different virtues, and of which he gives different hiſtories. Dioſcorides tells us, that the piſſaſphaltum was generated in the mountains of Epidaurus and other places, and waſhed down into the ſea or rivers by the torrents that ſucceeded rains, and that the aſphaltum was generated in the bottom of the ſea. Aviſenna tells us, that the *kafer aliheud* was ſometimes produced on mountains, and ſometimes in the ſea; and hence it appears, as well as from other inſtances, that he has deſcribed both together under the ſame name of *bitumen Judaicum*.

The great reſemblance in ſound between this word *kafer* and *kofer*, which is the name of camphor, has been the occaſion of great errors among the commentators on the works of the Arabians in general. Averrhoes deſcribes this drug in the ſame manner that Aviſenna and the reſt do; but his interpreters, inſtead of rendering his words *bitumen Judaicum*, have rendered them *Camphora Indica*; hence the being produced in the ſea, and the healing of burnt wounds are attributed to camphor, though wholly different both from its real hiſtory and true virtues.

KAGHU, in botany, a name by which ſome authors have called the cajou, or caſhew tree, the fruit of which affords us the caſhew nuts. *Herm.* Muſ. Zeyl. p. 37. See ACAJOU.

KAIEBACA *Dabari*, in botany, the name uſed by ſome authors for the arnotto or urucu, called orleana or orellana by other authors. *Ger.* Emac. p. 1554.

KAIMACHAN, among the Turks. See CAIMACAN, *Cycl.*

KAKILE, a ſpecies of *eruca*. See the article ERUCA.

The original ſenſe of this word was not the plant now named by it; but the *ſoldanella* or ſea bindweed. This was one of the plants uſed in the making the potaſhes, or alkali ſalt for glaſs and ſoap making, when thoſe manufactures were firſt brought into uſe; and it had both the names from that ſalt. The *kakile* from *kali*, and the *ſoldanella* from *ſoder* or *ſolda*, another name of that ſalt. Dioſcorides calls this *crambe thalaſſia*, and we find the ſame name turned into Latin and ſtill preſerved, and the plant called *braſſica maritima*, and in Engliſh the ſea cabbage.

KAKOUSA, in botany, a name by which ſome authors have called the tree, which affords the gum elemi uſed in medicine. Hort. Beaum. p. 35.

KALD, a word uſed by Rulandus to expreſs vinegar.

KALED, a word uſed by ſome of the chemical writers to expreſs volatile.

KALI, *Glaſſwort*, (*Cycl.*) in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, compoſed of ſeveral leaves arranged in a circular form. The piſtil ariſes from the center of the flower, and finally becomes a fruit of a membranaceous ſtructure, and roundiſh figure, and containing only one ſeed, which is twiſted or wreathed like a ſnail ſhell, and uſually covered with the leaves of the flower.

The ſpecies of *kali* enumerated by Mr. Tournefort are theſe. 1. The greater *kali* with the ſnail like ſeed. 2. The prickly *kali* with longer and narrower leaves. 3. The prickly *kali* with ſhorter and broader leaves. 4. The woody Sicilian *kali* with membranaceous flowers. 5. The ſhrubby Spaniſh *Kali* with tamariſk leaves. 6. The ſhrubby Spaniſh *kali* with broom like leaves. 7. The ſhrubby Spaniſh *kali* with very narrow hairy leaves. *Tourn.* Inſt. p. 247.

This plant abounds greatly with ſea ſalt, its juices being properly a ſaline, not an inſipid aqueous fluid; but the difference between the produce of this plant when green and when dry, is wonderful in chemical experiments. If diſtilled while freſh and green, it yields an inſipid water; if a pound of it be gathered freſh and hung up to dry, it will yield only three ounces of the dried plant; this being burnt, is more difficult than any other ſubſtance of a ſeeming like texture to be reduced to aſhes; and the aſhes finally produced from this quantity burnt in a potter's kiln, will yield only a dram and half of a whitiſh ſalt, and this will but ſlightly ferment with aqua fortis. Four ounces of the freſh herb being boiled in water, and that water carefully evaporated, there will be formed near three quarters of an ounce of pure ſea ſalt in its own natural cubic form faſtened to the bottom and ſides of the veſſel; and when no more ſalt will ſhoot, the remaining liquor being carefully diſtilled, encreaſing the fire to a proper degree, the water will firſt paſs over, and then a dry volatile ſalt will be raiſed and ſtick to the top and ſides of the veſſel. The ſalts being purified, there will be found as the reſult of the experiments, that this herb, while growing, contains about one fifth part of its weight of common ſalt. The herb which had been thus boiled being dried, and afterwards again boiled in four or five pints of water, and that decoction evaporated to half the quantity, the liquor will yield ſeveral different ſmells, as that of a honey comb, that of cabbage, and other pot-herbs. And after all this, the boiled herb being left to putrify, yields the ſmell of animal excrements, and in the ſame manner becomes the reſort of flies, and yields a proper place of habitation, and food for numbers of worms hatched out of the eggs of thoſe winged inſects. *Henkel*, de Affinit. Veget. et Miner.

All the experiments that can be made with the cubic cryſtals of ſalt, formed in the evaporated decoction of this herb, prove them to be common ſalt; and the volatile ſalt raiſed afterwards by fire from that liquor, in which no more of this cubic ſalt would cryſtallize, is found to be a high alkali by its fermenting with the acid ſpirits. The juice of this plant, when it has been ſet by in order to ſhoot, and all its ſea ſalt has been ſeparated from it by that means, being dried away by evaporation, and the remainder calcined; there is found at laſt a dry and earthy ſubſtance, which has ſomewhat of a lixivial taſte, but does not run to a liquor by being expoſed to the air. This calcined ſubſtance, being mixed with any of the acid ſpirits, but particularly with that of vitriol, becomes of a beautiful blue colour, not inferior to the fineſt ultramarine.

If the recent herb *kali* be ſet to ferment with common water, it yields, in the different ſtages of fermentation, ſeveral very different ſmells; firſt that of pickled cabbage, afterwards that of earth-worms killed in ſpirit of wine, and afterwards that of fiſh and dried herrings. If this matter be after all this diſtilled, it yields a ſpirit very much reſembling the finer ſpirit of tartar, and afterwards an empyreumatic oil, exactly reſembling thoſe of animal ſubſtances; but what is remarkable is, that there can be no volatile ſalt extracted from this putrefied maſs by any art. The reſiduum yields a potaſh, which effervеſces violently with acids, and with the vitriolic acid, becomes a ſal enixum; with aqua fortis, it makes nitre; with ſpirit of ſalt it affords common ſalt, ſuch as that ſpirit was diſtilled from; and with all the acids of whatever kind under proper management, it yields the blue colour before mentioned, approaching more or leſs to the fine colour of the ultramarine, according to the nature of the acid and the proceſs. The ſalt extracted from purified potaſh, made in this manner, is of a greeniſh caſt like native borax, and the remainder, after the extracting of this ſalt on mixing and digeſting with aqua fortis, will become a ſoft gelatinous matter of a truly metallic taſte.

KALKABRE, a name given by ſome of the barbarous writers to *gagates*, or *jet*.

KAMAN, in natural hiſtory, a name given by many authors to a ſtone found about the burning mountains, and at ſome times uſed to engrave ſeals on. It is deſcribed as a white ſtone variegated with ſeveral colours.

KAMAR, a word uſed by ſome writers in chemiſtry to expreſs ſilver.

KAMINE, a name given by ſome to the butter-ſtone. See BUTTER-*ſtone*.

KANFOR, a word uſed by ſome chemical writers to expreſs tin. See the article TIN.

KANNAWAKERAKA, in botany, a name uſed by ſome authors for the tree which produces the gamboge, or gutta gamba of the ſhops. *Herm.* Muſ. Zeyl. p. 26.

KAOLIN, the name of one of the two ſubſtances, which are the ingredients of China ware. The other, which is called *petuntſe*, is eaſily vitrifiable, and this *kaolin* is ſcarce at all ſo. Whence the fire compoſes from a mixture of them both a ſemivitrification, which is China ware.

Mr. Reaumur had an opportunity of examining this ſubſtance, not in its native ſtate, but only in form of ſmall bricks, made out of a paſte of the powder of the native *kaolin* and water. He found it of a white colour, and ſprinkled all over with fine glittering particles; but theſe he did not judge to be fragments of a different ſubſtance mixt among the maſs, as are the ſmall flakes of talc in our clays and ſands; but that the whole maſs was compoſed of ſome ſtone reduced to powder and made into a paſte with water, and that theſe larger ſpangles were only coarſer particles of the powder; the examination of which he promiſed himſelf would diſcover what the ſtone was of which they were formed. And this was the more worthy a diligent enquiry, ſince the *petuntſe* might eaſily be ſupplied by many of our own earths and ſands; nothing being required of that but a ſubſtance eaſily running into a white glaſs. But the difficulty of vitrifying this other ingredient, renders it a thing much more difficult to be ſupplied by one of the ſame nature among ourſelves. The compariſon of theſe, with other mineral ſubſtances, ſoon proved that they were of the nature of talc; or, in other words, that *kaolin* was talc powdered, and made up into a paſte with water. And to be aſſured whether the whole maſs was talc powdered, or any thing elſe with a mixture of talc, he ſeparated the particles of the *kaolin* by water, and found the ſmall ones wholly the ſame with the larger, and that the larger, when reduced to powder alone, made with water a paſte wholly the ſame with the *kaolin*. It is well known, that the fragments of talc have a great reſemblance to the pearly part of ſome ſhell fiſhes; and hence unqueſtionably has ariſen the opinion of porcelain being made of ſea ſhells; ignorant perſons having ſeen the talc or *kaolin*, and taken it for ſhelly matter. Talc has not yet been ſucceſsfully uſed in any of our European manufactures of porcelain; but it is eaſy to ſee, from many unanſwerable reaſons, that ſince China porcelain is made of a mixture of a vitrifiable and an unvitrifiable matter, nothing is ſo likely to ſucceed with us in the place of the laſt of theſe as talc.

1. We know no ſubſtance in the foſſile world ſo difficult to reduce to glaſs as talc, which if put into the ſtrongeſt of our fires, in a crucible, is not to be vitrified, nor even calcined. 2. We know no ſubſtance which keeps ſo much brightneſs after having paſſed the fire as talc, or is of ſo pure a white; whence we may alſo learn that it is not to the *petuntſe* alone, that the China ware owes its whiteneſs, but that the *kaolin* is inſtrumental to the giving it that colour. 3. Talc is tranſparent, nay, and in ſome degree keeps its tranſparence after the action of the moſt violent fire. If we are to make porcelain of a vitrifiable, and an unvitrifiable matter mixt together, yet it is neceſſary that the unvitrifiable one ſhould retain its tranſparence, otherwiſe it would obſcure the maſs; and talc is therefore the only known ſubſtance qualified for this purpoſe. Perſons who have been at the China works, ſay, that the porcelain is made of equal quantities of *petuntſe* and *kaolin*, and it is therefore a juſt and exact ſemivitrification. 4. Talc is well known to have a great flexibility or toughneſs, and as it is found to preſerve this even after it has paſſed the fire; it is very probable, that it is owing to this property of the *kaolin*, that the China ware is ſo much leſs brittle than glaſs. Mem. Acad. Par. 1727.

It has been before obſerved, that we may eaſily in Europe be provided with different ſubſtances, which will, in our porcelain manufactures, ſupply the place of the *petuntſe* of China, and talc appears equally qualified to ſerve inſtead of the *kaolin*. For this purpoſe we may uſe the common Muſcovy talc, or iſinglaſs, uſed by our miniature painters, to cover their pictures inſtead of glaſs, and, by the curious, to preſerve objects for the microſcope; or perhaps the Venetian talc of the druggiſts, would ſucceed even better; at leaſt the proceſs is ſo rational as to be extremely well worth trying.

KAPAMARA, in botany, a name by which ſome authors have called the caſhew nut tree, the acajou, and acajuiba of other writers. Hort. Malab. V. 3. p. 65. See ACAJOU.

KAPNAJICORAKA, in botany, a name given by ſome authors to the tree which produces the gamboge, or *gutta gamba* of the ſhops. *Herm.* Muſ. Zeyl. p. 26.

KAPRILI, a word uſed by ſome chemical writers to expreſs ſulphur. See SULPHUR.

KARABITUS, a word uſed by the Arabian phyſicians to expreſs a delirium.

KARADRE, a name given by the writers of the middle ages to a ſtone, of which they record many imaginary virtues, ſuch as the rendering people amiable, ſprightly, and the like. They deſcribe it to have reſembled cryſtal, but with a mixture of a duſky white. It ſeems to have been a foul kind of pebble cryſtal.

KARENA, a term uſed by Paracelſus, to expreſs a very minute quantity of any liquid. He explains it, by calling it a twenty-fourth part of the ſmalleſt drop: but this is a very indeterminate ſort of meaſure.

KASAM, a word uſed by ſome chemical writers to expreſs iron. See the article IRON.

KATIMIA, a word uſed by ſome chemical writers to expreſs tutty, and by others for the lapis calaminaris.

KATOU-*alou*, in botany, a name uſed by ſome authors for the *ficus Indica*, the arched Indian fig-tree. Hort. Malab. V. 3. p. 73. See FICUS.

KATOU *Carva*, in botany, a name by which ſome authors have called the tree, whoſe leaves are the tamalapatra, or Indian leaf of the ſhops. Hort. Malab. V. 5. p. 109. See the article MALABATHRUM.

KATOVINDEL, in botany, the name given by the authors of the *hortus Malabaricus*, to a genus of plants, called by ſome *elate*, and by Linnæus *phœnix*. Hort. Malab. V. 3. p. 23. See PHOENIX.

KAYL, a word uſed by ſome writers to expreſs ſower milk.

KAYSIR, a word uſed by ſome to ſignify the froth of the ſea, and by others for the pumice ſtone, ſuppoſed to be generated of that froth.

KAZDIR, a word uſed by ſome chemical writers to expreſs tin. See the article TIN.

KEALE, ſmall fragments reſembling chips or broken pieces of ſtone of various kinds; ſome of lime-ſtone, others of free-ſtone, and others of rag-ſtone, found mixed among the earth, of the upper ſtratum in many parts of this kingdom, and giving that ſoil the name of *kealy*; hence, ſome of theſe pieces of *keale* are thin and flat like bits of ſlate. *Moreton's* North. p. 41.

KEALY *ſoil*, in agriculture, is uſed by the huſbandmen for a ſort of land, plentifully ſtrewed with *keale* or *kale*.

KECKLE, on board a ſhip. When the cables gaul in the hawſe, or the bolt ropes do ſo againſt the ſhip's quarter, the ſeamen wind ſome ſmall ropes about them; and this is called *keckling*.

KEDGER, or KEDGE-*anchor*, in a ſhip. See ANCHOR.

KEDRELÆON, *Cedrelaion*, in the materia medica of the antients, an oil taken from the *pix cedri*, or pitch of the cedar tree.

Erotian, and many of the old Greek authors have confounded together the two ſubſtances mentioned by the phyſicians of moſt account; the *cedrium* or *cedria*, and the *cedrelaion* or *cedrelæum*. Theſe were not the ſame ſubſtance, though generally ſuppoſed to be ſuch; but the *cedrium* was a kind of liquid pitch or tar obtained from the cedar wood by burning; and the *cedrelæum* was a liquid oil, that ſeparated itſelf from this *cedrium* or tar, while it was kept boiling over the fire, and was collected by locks of wool dipped into it.

Dioſcorides plainly diſtinguiſhes the two ſubſtances, and in the very formation of the word from *cedria* or *cedrium*, we may underſtand the nature of the ſubſtance expreſſed by it. For as *cedrelæum* was formed from *cedrium*, ſo was *piſſælæum* from *pix*; and as the one expreſſed the ſubſtance ſaved in the boiling of pitch, ſo the other ſignified that which was ſaved in the boiling of *cedrium*, or the pitch of the cedar. Pliny indeed confounds the *cedrelæum* and *piſſælæum* as one ſubſtance; and where he tranſlates Dioſcorides on the virtues of medicines, he often renders that *piſſælæum* which he finds in his author *cedrelæum*. But this is not ſurpriſing; ſince he knew ſo little of theſe ſubſtances, as not only to ſuppoſe them the ſame, but to give an account of their being obtained from the fruit of the cedar, not from its wood. In another place, indeed, he tells us, that this liquid ſubſtance was made from the *cedrium*, or pitch of the cedar, and that it was more efficacious than the common *piſſælæum*. This confuſion of Pliny, in regard to the oil of pitch, and that of the *cedrium*, is evidently owing to his miſtaking the name, by which the Greeks diſtinguiſhed the latter oil from the name of a tree. Inſtead of *cedrelaion*, he has written *credelaton*, and ſuppoſes it a large kind of cedar tree. When he had thus loſt the only name of the *cedrelæum*, it is no wonder that he confounded the ſubſtance with another, ſo like it, as the common oil of pitch or *piſſælæum* was.

KEEL (*Cycl.*)—KEEL-*haling*, or KEEL-*raking*, in the ſea language, is a puniſhment inflicted at ſea on very great offenders, who are drawn underneath the very *keel* of the ſhip. See DUCKING, *Cycl.*

KEEL-*rope*, a hair rope running between the *keelſon* and the *keel* of a ſhip, to clear the limber holes when they are choaked up with ballaſt, &c.

KEELAGE, *killagium*, a privilege to demand money for the bottoms of ſhips reſting in a port or harbour. Terms of law, *Blount*.

KEELING, a name uſed in ſome Engliſh writers for the common codfiſh. *Willughby*'s Hiſt. Piſc. p. 160. See the articles ASELLUS and CODFISH.

KEELSON, in a ſhip, the next piece of timber to the *keel*, lying right over it next above the floor timber.

KEEPITHEJA, in botany, the name by which ſome authors call the tree, on the branches of which the gum lacca of the ſhops is uſually found. *Herm.* Muſ. Zeyl. p. 11.

KEIKEM, in the materia medica, a name given by the Arabian writers to a gum uſed in their time for the making of varniſh.

Gum lacca is generally ſaid to be the ſubſtance meant by it, but Aviſenna ſeems to expreſs by it every thing that was uſed as varniſh. Thus he ſometimes means by it the gum ſandarach, and ſometimes amber. The *gum cancamum* of the Greeks is alſo certainly often meant by it; but this is ſcarce to be mentioned as an explication of the word, it being almoſt as general a term as itſelf, and ſtanding with many of the old authors for ſandarach, gum lacc, and amber, as well as for the gum properly expreſſed by it. In ſhort, all the gums uſed in making varniſh, are in general called by the names of any one of them, and thus vernix, ſandarach, cancamum, and lacca, are made ſynonymous words, and either ſtands for each of the things ſignified by all the words.

KEIRAN, in the oriental learning, the Perſian, and Arabic name for the planet Saturn, according to Salmaſius. See the article CHIUN.

KEKIO. See the article FERN-*oil*.

KELMESAN, in botany, a name given by ſome authors to the acacalis, or wild carob tree. *J. Bauhine*, V. 1. p. 439.

KELP, in the glaſs trade, a term uſed for a ſort of pot-aſhes uſed in many of their works, particularly for the cryſtalline metal. It is the calcined aſhes of a plant, called by the ſame name, and in ſome places ſea thongs or laces, a ſort of thick leaved fucus or ſea wrack: the *alga anguſtifolia vitrariorum* of John Bauhine. This plant, if kept moiſt a little after gathering, will ſhew afterwards, though long kept, its white ſalt upon the ſurface of its leaves. This plant is thrown on the rocks and ſhores in great abundance, and in the ſummer months is raked together, and dried as hay in the ſun and wind, and afterwards burnt to the aſhes called *kelp*, which are uſed not only in the glaſs, but in the alum works. *Merret*'s Notes on Neri, p. 263.

KEMA, in natural hiſtory, a name given by Leo Africanus, and other writers of the African hiſtory, to a ſort of ſubterranean production of the vegetable kind, greatly eſteemed as a delicious food. The Arabian writers on medicine have often mentioned it, and that under names ſufficiently reſembling the modern African appellation, ſuch as *camahe*, *camah*, *kemah*, and *camba*. Leo Africanus alſo calls them *terfez* in ſome places, and aſcertains their being the ſame thing, by telling us, that the *terfez* were called by the Arabian phyſicians *camba*. There has been much diſpute about what theſe really were: ſome have ſuppoſed them to be the *zelem* of the antient Arabians; but erroneouſly, for that was a fruit. Some have thought them the roots of the *tarſi*, or *traſi*, called *avellanda* by the Spaniards, from their likeneſs to a hazel nut in ſhape; and others have ſuppoſed them the ſame with our earth-nuts, or the roots of the bulbocaſtanum. But Scaliger declares againſt this, and tells us from Leo Africanus, that they are found as large as a quince, and of a moſt delicious flavour. He adds, that the inhabitants call them *camba*, but the Arabian phyſicians have ſoftened the word into *kemah*. We ſee, by the preceding obſervation, how little truth there is in this account of the names. Leo tells us that theſe roots, as he calls them, are produced in the deſarts of Numidia in vaſt abundance, and are carefully ſought after by the people of all the neighbouring country, and are eaten ſtewed in milk and water. We find no account of any plant growing up from theſe, but, on the contrary, are told, that they ſend up no part above the ſurface of the earth. From this, and from their delicious flavour, it is eaſy to ſee that they are not the roots of any plant, but a fine kind of ſubterraneous muſhroom, or truffle. Theſe are white on the outſide, and lie generally pretty deep in the earth. *Scaliger*, Exerc. 93.

KEMUM, in botany, a name uſed by ſome authors for the cuminum, or cummin; the plant which produces the cummin ſeeds of the ſhops. *Ger.* Emac. Ind. 2.

KENAM, or KELAM, in the materia medica, the name the Chineſe give to the fineſt ſweet ſcented calambac wood. *Dale*, Pharm. p. 448. See CALAMBAC.

KENKS, in the ſea phraſe, are doublings in a cable or rope, when it is handed in or out, ſo that it does not run ſmooth; or when any rope makes turns, and does not run ſmooth, and clever in the block, they ſay it makes *kenks*.

KENNE, in botany, a name uſed by ſome authors for the liguſtrum, or privet. *Ger.* Emac. Ind. 2.

KENNE is alſo uſed by ſome writers for a ſtone, as they call it, generated in the corners of the eyes of a ſtag, and poſſeſſing many medicinal virtues. This is doubtleſs what we now call the *lacryma cervi*, or ſtags tears.

KENNETS, in our old writers, a ſort of coarſe Welch cloth, mentioned in the Stat. 33 Hen. VIII. c. 3. *Blount*.

KENNETS, in a ſhip, are ſmall pieces of timber nailed to the inſide of the ſhip, unto which the tacks and ſheets are belayed, (as they call it) *i. e.* faſtened.

KERATOPHYTUM, a name by which Boerhaave expreſſes the black coral, called alſo *antipathes*, *lithophyton*, and *pſeudocorallium*. *Boerh.* Ind. A. 6.

KERF, is the notch or ſlit that is made by the ſaw between two pieces of wood, when they are ſawing aſunder.

KERFE-KARUMFEL, in the materia medica, a name given by Aviſenna, and others, to the wood of the clove tree, as the wood of the cinnamon tree was called *kerfe darſini*; and many others in the ſame manner.

KERMES (*Cycl.*)—The *kermes* is the moſt famous, and moſt valuable creature of its kind, and is properly an inſect of the gall-inſect claſs, and of that genus whoſe figure reſembles a ſphere, from which a ſmall Part had been cut off. This ſpecies is found on a particular kind of the ilex, known by the name of the *ilex aculeata cocciglandifera*. This never ariſes beyond the height of a ſmall ſhrub, and is very plentiful in the uncultivated parts of Provence and Languedoc, and in ſome other Places; as in Spain, in the iſlands of the Archipelago, and particularly in Crete. The peaſants make their harveſt of theſe animals, from off theſe ſhrubs, at the proper ſeaſon; and though the hiſtory of this drug is a ſubject well worthy the attention of every naturaliſt, yet it is but of very late years that it has been enquired into with any degree of accuracy. Meſſrs. de la Hire and Sedileau opened a way to the knowledge of it, by their hiſtory of the gall-inſect of the orange tree; but all the advantages that might have been expected thence were not ſoon obtained, nor was the reſemblance and ſtrict analogy between the flat and the ſpherical gall-inſects ſo ſoon obſerved, as might have been expected.

The *kermes*, when at its full growth, appears a ſmall ſhell fixed to the branches of this ſhrub, or ſeems a purſe or bag, the covering of which is ſufficiently ſtrong, bright and ſhining, and of the colour of a ripe plum, and covered with the ſame ſort of whitiſh powder, as that fruit is when ripe. This powder the people of the place call the flower of the *kermes*. Thoſe who have never ſeen *kermes*, otherwiſe than in the ſhops of the druggiſts, may naturally think it of a reddiſh brown; but this is not its natural colour, but is the effect of the vinegar they uſe for its preſervation; that remaining on the branches, and which has not been affected by vinegar, having nothing of this colour, but exactly that of ripe ſloes in the hedges.

The people in the places where the *kermes* is produced, know it in three different ſtates, according to the ſtages of its growing. Its firſt ſtate is toward the beginning of March; at this time they term it the ſetting worm. It is at this ſeaſon as ſmall as a grain of millet, and it ſeems to ſome, that this is the ſeaſon at which it begins to fix itſelf in its place, after having run about at its liberty during the winter on the ground; but it is much more probable, that this is the ſeaſon only at which it begins to acquire a ſenſible bulk, and quits the leaves of the tree to fix itſelf on its branches. Viewed in this ſtate with the microſcope, it appears of a fine bright red, and has all about, and under its belly, a downy ſubſtance, which ſerves it for a bed. It has alſo ſome parcels of the ſame cottony matter on its back, and where that is not ſo covered, the microſcope diſcovers ſeveral ſmall ſpecks of the colour and brightneſs of burniſhed gold.

The next, or ſecond ſtage of its growth, is in the month of April. The people of the country then diſtinguiſh it by the term of the worm which has hatched; but their manner of expreſſing themſelves is very irregular, ſince all that they mean by this is, that the creature has now acquired its full growth, and perfect ſhape. It is in this ſtate round, and of the bigneſs of a pea; but its ſize is by no means exactly determinable, being larger or ſmaller, according to the favourableneſs of the ſoil and ſeaſon. Its ſkin is at this time become firm, and the downy matter, which was before laid on it at intervals, and in little bundles, is now equally ſpread all over it, and lies in form of powder on its whole ſurface, and it now appears no other than as a ſhell, or bag full of a reddiſh liquor, reſembling a pale coloured blood.

The third ſtage of its growth is toward the end of May; and at this ſeaſon there are found in this bag, or, more properly ſpeaking, in the belly of the animal, eighteen hundred, or two thouſand ſmall round bodies. Theſe are its eggs, which, in the natural courſe of things, coming afterwards to hatch, would afford ſo many animals of the ſame ſpecies. Theſe eggs are not more than half the ſize of poppy-ſeeds, and are all full of a pale red juice; and viewed by the microſcope, are ſeen ſpangled over with a vaſt number of gold coloured ſpangles. The ſkin of the belly of this creature contracts inward, and approaches to the back as theſe eggs are diſcharged, and the eggs by this means find a place within the ſhell made by the body of the animal; as is the caſe in all the reſt of the gall-inſect claſs.

There are two kinds of *kermes*; the one, that which has been already deſcribed, which is of the colour of a plum, and which lays red eggs. The other is whitiſh, or ſomewhat reddiſh, and is covered in the ſame manner as the

other

other with a white powder, and lays its eggs in the ſame manner. Its growth is the ſame with the other, and at the ſame ſeaſons, and its eggs are white.

The young inſects produced from both theſe ſpecies are very like, and have a conſiderable reſemblance to wood-lice, or millepedes, as indeed have the young of all the gall-inſect claſs. They differ however in colour: thoſe which are produced from the red eggs are themſelves red; they are flat in ſhape, and ſomewhat more pointed behind than at the head; their back is convex, with a round arched prominence. This kind has ſeveral ſhining gold coloured ſpangles, and is ſtriated on the back, and has ſeveral tranſverſe lines acroſs the belly. It has ſix legs, and two horns nearly as long as its body, and a tail ſplit into two, or forked, the divided parts being nearly as long as its horns, and its eyes are black and ſhining.

The young ones produced from the white eggs, are of a dirty white; their back is ſomewhat flatter than that of the others, and the ſpangles on them, viewed by the microſcope, appear of a ſilver colour, not of a gold. There are a much ſmaller number of theſe white than of the red *kermes*, and the people of the country call them the mother of the *kermes*. There are alſo among the *kermes* ſeveral found containing, inſtead of theſe eggs, the nymphs of two kinds of ſmall flies, which regularly are produced from them, and have both a power of hopping or jumping. The one ſpecies of fly is of a fine jet black, and the other is of a dirty white. One of theſe is a white winged fly, alike, in all reſpects, to the gall-inſect fly, and is, without all doubt, the male *kermes*; though this very obſervation of a fly being produced from ſome of the *kermes*, has been one great occaſion of believing the *kermes* to be a true gall.

According as the winter has been more or leſs mild, the harveſt of *kermes* is the more or leſs plentiful; and the people always preſage themſelves a fine ſeaſon, when the ſpring has been free from froſts and fogs. It is obſerved, that the loweſt and oldeſt ſhrubs are always the fulleſt of this inſect; and the *kermes* produced on thoſe trees which are in the neighbourhood of the ſea, is always larger and finer than that from the inland places.

The merchants who purchaſe the *kermes*, always wet it with vinegar, and afterwards expoſe it to the heat of the ſun, or to an equal heat from the fire, to deſtroy all the young inſects hatched, or in a ſtate near hatching, in it.

It is no uncommon thing to have two harveſts of *kermes* in a year. Thoſe of the latter ſeaſon are ſmaller, and leſs valuable, than thoſe of the firſt, and are found not on the branches, but on the leaves of the ſhrub; which is juſt analogous to the cuſtom of the gall-inſects of all other kinds; all which about this age leave the branches to feed on the leaves, where their yet tender trunks can find an eaſier entrance. See Tab. of Inſects, N° 30.

From this analogy between the *kermes*, and other inſects of the ſame claſs, it ſhould ſeem worth while to try, whether ſome of thoſe may not poſſeſs the ſame virtues in medicine, at leaſt, if not in the arts. It is certain that the common oak produces a red gall-inſect of the very ſhape of the *kermes*, and of the colour of the paler ones. *Reaumur*, Hiſt. Inſect. p. 45.

KERMES *mineral.* The *kermes mineral* was a preparation of Glauber, which the king of France bought of Mr. de la Ligerie, and made public in 1720. That receipt was in the following form. Take a pound of Hungarian antimony, broken into thin pieces, according to the direction of its ſpicula; four ounces of nitre, fixed by charcoal; and a pint of rain water: boil them two hours; then filtre the warm liquor, and when it cools, the *kermes* precipitates. The ſame antimony undergoes the ſame operations with the remaining liquor, to which three ounces of fixed nitre, and a pint of water, is added. In a third boiling, two ounces of nitre, and a pint of water, are to be added to the former lixivium. The *kermes* thus obtained is about a dram, and is well edulcorated by waſhing it with water, and burning ſpirit of wine on it; then it is dried for uſe.

Mr. Geoffroy ſhews, by many experiments, that the *kermes* is the reguline part of the antimony, joined to a ſort of *hepar ſulphuris*. He teaches us a much eaſier way of preparing this medicine, thus. Mix intimately the fine powder of two parts of antimony, and one of any fixed alkaline ſalt; melt thoſe materials in a crucible; then having powdered them while hot, boil them two hours in a large quantity of water; after this, paſs the hot liquor through paper, receiving it into a veſſel, in which there is hot water, the *kermes* ſeparates when it cools. The groſſer parts, which do not paſs through the paper, are to be boiled again, and filtrated as before; and the operation is to be repeated a third time, by which ſix or ſeven drams of *kermes* may be got out of every ounce of antimony. He ſays, he has ſeen effects like to thoſe of mild *kermes* from antimony, reduced to ſuch a fine powder, that none of the ſhining ſpicula are to be ſeen; and that the magiſtery of antimony, made by pouring ſpirit of nitre, or aqua regia, on the powder of antimony, and then edulcorating the maſs with water, has the ſame effects as *kermes*. Mem. de l'Acad. des Sciences 1734, 1735.

Half a grain, or a grain of this powder, given every three or four hours, produces no violent effects; but by encreaſing the doſe, it may be made to vomit, purge, and ſweat. Some commend this medicine as the moſt univerſal reſolvent, and deobſtruent; aſſuring us, that it almoſt infallibly cures pleuriſies, peripneumonies, aſthmas, catarrhs, anginæ, ſmall-pox, and many other diſeaſes. Others are as poſitive, that it heats and thickens the blood, thereby increaſing obſtructions, and is particularly hurtful in all inflammatory diſeaſes.

This preparation was famous in France, and known by the name of *poudre des Chartreux*, becauſe a Carthuſian monk, who got it from Mr. de la Ligerie, firſt brought it into vogue. See Hiſt. de l'Acad. des Sciences 1720. and the Memoirs for the ſame year, where it is ſaid, that Glauber was looked upon as the firſt inventor of this remedy.

Its effects, like that of many other antimonial preparations, is very various, which is frequently owing, as Mr. Geoffroy obſerves, to the different manner and care in making it. He adds, that the more the *kermes* contains of a regulus eaſily revivified, the more it proves emetic. He alſo ſhews how to make a cinnabar with the *kermes* and mercury, and to diſengage the vitriolic acid from the *kermes*. See Mem. de l'Acad. des Sciences 1734.

KERN, in the Engliſh ſalt works, a word uſed to ſignify the cryſtallizing, or ſhooting of ſalt in the brine, when ſufficiently evaporated in the boiling pan.

This word is alſo uſed by the ſeamen for the firſt forming of the bay ſalt, made by the ſun's heat in the iſles of May, *&c.* See SALT.

KERN *ſtone*, in natural hiſtory, a name given by the common people of many parts of England to a peculiar ſort of ſtone, which is found on the ſides of hills in ſandy countries, where the hills are rocky. Pyran ſands afford a great many ſtones of this kind; and the manner of their formation is thus. The rocks in the ſides of the hills are continually covered over with the looſe ſand, which the winds toſs up, and the ſparry matter continually ouzing out of the pores of theſe ſtones, with the wet, cements the grains of ſand together. When one cruſt is thus formed, another is ſoon added, and ſo on, till the whole maſs is of a conſiderable thickneſs; and the ſpar ſtill ſerving as the general cement, the whole is held together, though but in a looſe way, yet ſo as to reſemble a ſort of ſtone. The little grains of ſand are ſtill viſible in all parts of this ſtone, and are what induced the people to call it *kern ſtone*, as they call theſe *kerns*, or *kernels*. This account of the origin of the ſtone is eaſily proved, by puting a ſmall piece of it into aqua fortis, for this diſſolves the ſpar, or cement, and the ſand is left looſe.

KERUGHA, in botany, a name uſed by ſome authors for the ricinus, or palma Chriſti. *Germ.* Emac. Ind. 2.

KESTREL, the Engliſh name of a hawk, called alſo the *ſtannel* and the *windhover*, and by authors the *tinnunculus* and *cenchris*. It builds with us in hollow oaks, and feeds on partridges and other birds. *Ray*'s Ornithol. p. 50. See TINNUNCULUS.

KETMIA, in botany, the name of a genus of plants; the characters of which are theſe. The flower conſiſts of one leaf, and is broad and open at the mouth, and very like the mallow flower. From the cup there riſes a piſtil, which is fixed in the manner of a nail to the lower part of the flower, and afterwards ripens into a fruit, which is divided into ſeveral cells, and opens at the ſummit, ſhewing a number of ſeeds.

The ſpecies of *ketmia* enumerated by Tournefort are theſe. 1. The ſmooth ſhrubby *ketmia*, called by authors *ketmia ſyrorum*. 2. The violet purple flowered ſmooth leaved *ketmia*. 3. The variegated red and white flowered ſmooth *ketmia*. 4. The yellow flowered Syrian *ketmia*. 5. The poplar leaved African *ketmia*. 6. The poplar leaved African *ketmia* with green ſtalks, and leaves hoary underneath. 7. The purple flowered bladder *ketmia* with leaves divided into three ſegments, called by many authors the *trefoil alcea*, or *bladder alcea*. 8. The poplar leaved Indian *ketmia* with a compreſſed orbicular fruit. 9. The lime leaved Indian *ketmia*. 10. The cotton leaved Indian *ketmia* with an acid taſte like that of ſorrel. 11. The mallow leaved tree *ketmia* of America with the taſte of ſorrel. 12. The Chineſe *ketmia* with a roundiſh leaf and ſingle flower. 13. The Chineſe *ketmia* with a roundiſh leaf and double flower. 14. The purple marſh *ketmia*. 15. The painted leaved *ketmia* with rough hairy ſtalks and a ſtellated fruit. 16. The Indian *ketmia* with a ſpear pointed leaf and hard fruit. 17. The large vine leaved Indian *ketmia*. 18. The vine leaved Indian *ketmia* with a horned fruit. 19. The ſmall flowered vine leaved Ægyptian *ketmia*. 20. The vine leaved Indian *ketmia* with a pendulous yellow flower. 21. The Ægyptian *ketmia* with perfumed ſeeds, called by authors *bell muſchus*, and *abel moſch.* 22. The American hairy *ketmia* with yellow flowers and perfumed ſeeds. 23. The fig-leaved Braſilian *ketmia* with a long ſulcated fruit. 24. The prickly Indian *ketmia* with fingered leaves. 25. The prickly American *ketmia* with a large

large purple flower. 26. The perennial *ketmia* of Sicily, with perfumed deeply ſerrated leaves. 27. The common bladder *ketmia*, commonly called the *bladder alva*. 28. The African bladder *ketmia*. 29. The purple flowered ſhrubby American *ketmia*, with leaves like thoſe of the mulberry. 30. The various flowered American *ketmia*, with large heart faſhioned leaves. 31. The large angular leaved American *ketmia*, with a rough clypeate fruit. *Tournefort.*

There are a great many different ſpecies of this plant propagated in gardens, where moſt of them grow to be ſhrubs of ſix or ſeven feet high; and, in the time of their flowering, which is during a great part of the latter end of the ſummer, they make a very beautiful figure. They may all be propagated by ſowing their ſeeds in February or March on a bed of light earth: they muſt be ſuffered to remain in theſe beds till the following ſpring, being well weeded, and often watered in the ſummer. In the March following the plants are to be tranſplanted into beds of the ſame ſort of earth, ſetting them at about ten inches diſtance every way; here they are to remain two years more, being well weeded and watered in the time; and in the March following they ſhould be carefully removed to the places where they are to remain. They muſt be taken up carefully, without injuring the roots; the ground muſt be well watered where they are planted, and ſome muck ſhould be laid about their roots, to prevent the ground's drying too faſt.

Some chooſe to propagate them by ſuckers from the old roots, but this is by no means adviſeable, as the plants this way raiſed are never ſo well rooted, and are always ſubject to produce great numbers of ſuckers themſelves, which render them very unſightly. *Miller*'s Gardners Dict.

KETRAN, KITRAN, or ALKETRAN, a name given by ſome of the Arabian authors to the oil of cedar, called by the Greeks *cedria*. We have of later times formed the word *cedranum* upon this, and it has ſince been applied to the zopiſſa of the antients, a compound made of pitch and wax melted together, and uſed for the covering the bottoms of ſhips.

KETTLE, in the art of war, a term the Dutch give to a battery of mortars, becauſe it is ſunk under ground.

KETTLE-*drums* are formed of two large baſins of copper or braſs, rounded at the bottom, and covered over with vellum or goat-ſkin, which is kept faſt by a circle of iron, and ſeveral holes faſtened to the body of the drum, and a like number of ſcrews to ſcrew up and down, with a key for the purpoſe. The two *drums* are kept faſt together by two ſtraps of leather, which go through two rings, and are faſtened, the one before and the other behind the pommel of the *kettle* drummer's ſaddle. They have each a banner of ſilk or damaſk, richly embroidered with the ſovereign's arms, or thoſe of the colonel, and are fringed with ſilver or gold; and to preſerve them in bad weather, they have each a cover of leather. The drum-ſticks are of crab-tree or other hard wood, of eight or nine inches long, with two knobs on the ends, which beat the drum head and cauſe the ſound. The *kettle-drum* with trumpets is the moſt martial ſound of any; each regiment of horſe has a pair.

KETTLE-*drummer*, a man on horſeback appointed to beat the *kettle-drums*, from which he takes his name.

He marches always at the head of the ſquadron, and his poſt is on the right when the ſquadron is drawn up.

KEVELS, or CHEVILS, in a ſhip, are ſmall pieces of timber nailed to the inſide of a ſhip, unto which the tacks and ſheets are belayed or faſtened.

KEY *(Cycl.)*—KEY-*ſtone*, in an arch, is the ſtone placed at the top or vertex of an arch, to bind the ſweeps of the arch together.

KEYRI, in botany, a name uſed by ſome for the common wall flower. *Park.* Theat. 625.

KIBRIC, a word uſed by ſome chemiſts as a name for the philoſopher's ſtone; others expreſs by it, what they call the parent, or firſt matter of mercury, and all fuſible and liquifiable ſubſtances.

KIBRITH, a word uſed by ſome chemical writers as a name for ſulphur. See SULPHUR.

KIBRIUS, a word uſed by ſome chemical writers as a name for arſenic.

KICKER *againſt the ſpurs*, in the manege. See RAMINGUE.

KIDDERS, thoſe that badge, or carry corn, dead victuals, or other merchandiſe, up and down to ſell: every perſon being a common badger, kidder, lader or carrier, *&c.* ſays the ſtat. 5 Eliz. c. 12. And they are called *kiddiers* 13 Eliz. c. 25. *Blount.*

KIDDLE, or KIDEL, *Kidellus*, a dam or wear in a river, with a narrow cut in it, for the laying of pots, or other engines to catch fiſh.

The word is antient, for in *Magna Charta*, c. 24. we read, *omnes* kidelli *deponantur per Thameſiam & Medweyam & per totam Angliam, niſi per coſteram maris.* And by king John's charter, power was granted to the city of London, *de* kidellis *amovendis per Thameſiam & Medweyam.* A ſurvey was ordered to be made of the wears, mills, ſtanks and *kidells* in the great rivers of England. 1 Hen. IV. Fiſhermen of late corruptly call theſe dams *kettels*; and they are much uſed in Wales, and on the ſea-coaſts of Kent. Terms of law. *Blount.*

KIDDOW, in zoology, the moſt common Engliſh name of the lomwia, a webfooted bird, common on our ſhores, and called in different places the guillemot or guillem, and the ſea hen, and ſkout. See LOMWIA.

KIDNEY *(Cycl.)*—KIDNEYS *of fiſh.* Fiſh of all kinds have *kidneys*, but they differ extremely in the ſeveral genera. All the cetaceous fiſhes, and many of the cartilaginous kinds have two *kidneys*, as quadrupeds have. In moſt of the ſpinoſe kinds, they are found concreted into one. In the ſpinoſe fiſhes they are oblong and extended throughout the whole length of the abdomen. In the cetaceous fiſhes they are of a roundiſh oblong figure as in quadrupeds; and as to their ſituation, the ſpinoſe fiſh in general have them extended all along the back bone, and the cetaceous kinds are on the contrary in the lower part of the belly: they are very long and large in the ſpinoſe kinds, and very ſmall and ſhort in the cetaceous. The urinary bladder is generally ſituated in the lower part of the abdomen in theſe creatures, and often lies upon the rectum. There are generally two ureters by which the urine is ſecreted from the *kidneys* into it: but the urethra through which the urine is to be diſcharged from the bladder, is leſs obvious in the ſpinoſe fiſhes. In the cetaceous kinds, it is plainly to be followed either into the vulva, or *foramen ſeminis. Artedi.* Ichthyolog.

KIDNEY-*Beans*, in botany. See PHASEOLUS.

KIGGELARIA, in botany, the name given by Linnæus to a genus of ſhrubs, ſuppoſed from ſome faint reſemblance in the external figure to be a kind of bay, and deſcribed by Sterbius under the name of *lauri ſpecies.* The characters of the genus are theſe. It produces ſeparate male and female flowers. The male flower has for its cup, a hollow one leaved perianthium, divided into five oval and pointed ſegments, which are concave. The flower conſiſts of five hollow lanceolated petals, which are a little longer than the cup, and form with it a figure like that of a ſort of pitcher. The nectaria are five obtuſely trilobate glandules, the middle lobe being longer than the reſt; they are coloured, and grow one to each petal near its baſe. The ſtamina are ten extremely ſmall filaments, the antheræ are oblong, but ſhorter than the cup; and their tops burſt open with two holes in the female flower. The cup and petals are the ſame as in the male. The germen of the piſtil is roundiſh, and the ſtiles are five in number of a ſimple figure, and the ſtigmata are obtuſe. The fruit is a round and rough coriacious capſule, containing one cell and made up of five valves. The ſeeds are very numerous, they are of a roundiſh figure, and each inveſted in its own peculiar membrane within the capſule. *Linnæi* Gen. Pl. p. 483. *Sterb.* p. 12.

KIJON, in antiquity, a name for Saturn, according to Salmaſius and Kircher. See CHIUN.

KILCH, in zoology, a name uſed by ſome for a ſpecies of fiſh of the albula kind, caught in the lakes of Germany, of a fine firm fleſh and delicate flavour, and ſeems very little if at all different from the ferra. *Geſner*, de Piſc. p. 1107. See the article FERRA.

KILLAS, in natural hiſtory, a name given by the people who dig in the mines of Cornwal, to a kind of greyiſh white earth, which is of great hardneſs, and ſeems to approach very much to the nature of the *ludus Helmontii* of ſome kinds, only that it is ſomewhat leſs hard than that, and has nothing of the ſepta or partitions, that make the character of that foſſil. This earth contains ſo great a quantity of ſpar, that it ferments with acids very ſtrongly, though that ſpar being once diſſolved, and the earthy part of the ſubſtance only left, it will no longer ferment with theſe menſtruums; whence it is evident, that its terreſtrial matter is not alkaline, though the ſpar it contains is ſo.

This is the certain character of what is called *killas* in many parts of Cornwal, where it lies in ſtrata of two, three, or more feet thick, and often beſide this is laid on each ſide of the vein of tin or other ore. But in ſome other parts of England the miners uſe the ſame word to expreſs a kind of white brittle and ſhattery ſtone, ſomewhat like the flag ſtone with which they cover houſes in Northamptonſhire, and many other counties.

KILLAS is alſo uſed as the name of a ſlaty ſtone of various colours, ſpangled all over with talc in ſmall flakes in the place where they uſe it. In this ſenſe, they generally expreſs themſelves, when talking of the earth deſcribed above, by the phraſe *white killas.* They alſo ſometimes call this flaky ſtone by the name *Delvin.*

KILLKENNY *Marble*, a fine black marble full of ſhells, and coralloide bodies, and much uſed in chimney pieces, *&c.* See CORALLOIDE *Marble.*

KILLOW, or CULLOW, an Engliſh name for a black earth of a very remarkable ſtructure, ſeeming of a mixed nature between the marbles, ochres, and clays, and uſually containing a large quantity of the matter of the common vitriolic pyrites or ink ſtone, which gives it a very ſharp unpleaſant taſte, and makes it, when thrown on the fire, emit a ſlight blue flame of a ſulphureous ſmell, and calcined to a deep red. It is common in many parts of England, Wales, and

and Ireland. It is lighter than any of the other clays, though that is the genus to which it moſt properly belongs; and it is of an uneven ſurface, and ſhattery ſtructure. *Hill*'s Hiſt. of Foſſ. p. 34.

KILLYTH-STALLION, in our old writers, is where lords of manors were bound by cuſtom to provide a ſtallion for the uſe of their tenants mares. *Spelm.* Gloſſ. *Blount.*

KILN *(Cycl.)*—KILN *for tin ore.* The place where the tin ore is roaſted in order to burn away the mundic, and other ſulphureous matters that are mixed with it, is called the *tin kiln.* This is of a very plain ſtructure, its hearth or floor is made of one large ſtone, and this is covered with another ſupported at ſix inches height above it. The uppermoſt has a hole in the middle through which the ore is poured on the under one, and when it is diſtributed over it in a bed of three or four inches thick, it is burnt by means of a fire of furze buſhes kept underneath, and communicating with the ſpace between the two ſtones by an aperture behind; the lower ſtone not reaching the wall by ſix inches.

When the ſulphur is all burnt away by the fire, and the flame is no longer blue, the whole bed of roaſted ore is thruſt off the ſtone by the rake into the aperture behind, through which it falls into the open fire. The fire is kept up with new buſhes, and there is a new bed of ore thrown in at the hole above. Thus the fire is kept up day and night, and ſupplies of freſh ore made through the hole by the black tin brought from the buddles of waſhing troughs. When the lower part of the furnace is filled up with the ore thrown into it, there is a hole behind the *kiln* through which this ore, and the coals and aſhes are all raked out together, and left in the open air to cool; and the whole maſs thus raked out, will ſometimes be ſeveral days in cooling, the mixture of coals among it keeping it red hot for a conſiderable time. When it is taken away from behind the furnace, it is waſhed again before it is put into the melting furnace. It is obſerved, that the different ores require for this laſt operation a different proportion, and different ſort of fuel. The moor tin, that is, ſuch ore as is dug up in the moory countries, melts beſt with moor coal charred; but that dug on the hills is found to run beſt with a mixture of charcoal and peat in equal quantities. The ſtones uſed for the *kilns* are always moor ſtone. Phil. Tranſ. N° 69.

Brick-KILN. See BRICK.

KIMBULA, in zoology, the name of a ſpecies of crocodile found in the iſland of Ceylon, and of a very beautiful variegation of colours, being mottled all over with extremely elegant black ſpots ſhining with the gloſs of black velvet. *Ray*'s Syn. Quad. p. 263.

KINAKINA *Aromatica*, in the materia medica, a name by which ſome authors have called the *cortex eleutherii*. *Geoffr.* Tract. p. 307.

KING *(Cycl.)*—The *king* of England, though he be intruſted with the whole executive power of the law, yet he cannot ſit in judgment in any court; but juſtice and the laws muſt be adminiſtred according to the powers committed and diſtributed to the ſeveral courts. 4 Inſt. 70, 71. 2 Inſt. 103.

KING, among Hebrew grammarians, is an appellation given to a ſpecies of accents anſwering to our colon. See the article ACCENT, *Cycl.*

KING *of the mullets.* See MULLUS *imberbis.*

KING *of the quails.* See ORTYGOMETRA.

KINGS-*Bench (Cycl.)* —This court was always ambulatory, and removed with the *king* wherever he went: hence the writs returnable into this court are *coram nobis ubicunque fuerimus in Anglia*; and all records there are ſtiled *coram rege*, as it is ſtill ſuppoſed to have always the *king* himſelf in perſon ſitting in it; from whence it obtained the name of the court of *king's-bench*, and hath always retained a ſupreme original juriſdiction in all criminal matters, for in theſe the proceſs both iſſued, and was returnable into this court; but in treſpaſs it might be made returnable into either the *kings-bench*, or common-pleas; becauſe the plea was criminal as well as civil. V. 4 Inſt. 70. 2 Inſt. 24. *Co. Lit.* 71. *Cromp.* of Courts. 78. 1 Rol. Abr. 94.

This court is often termed the *cuſtos morum* of all the realm, and wherever it meets with an offence contrary to the firſt principles of juſtice, and of dangerous conſequence, if not reſtrained, it may adapt a proper puniſhment to it [a]. For the better reſtraining ſuch offences, it has a diſcretionary power of inflicting exemplary puniſhment on offenders, either by fine, impriſonment, or other infamous puniſhment, as the nature of the crime, conſidered in all its circumſtances, ſhall require. It may make uſe of any priſon which ſhall ſeem moſt proper; and it is ſaid, that no other court can remove or bail perſons condemned to impriſonment by this court [b]. [[a] 2 *Hawk.* P. C. p. 6. [b] 2 *Hawk.* P. C. p. 7.]

An act of parliament, appointing, that all crimes of a certain denomination ſhall be tried before certain judges, does not exclude the juriſdiction of this court, without expreſs negative words; and therefore it has been reſolved, that 33 Hen. 8. c. 12. which enacts, that all treaſons, *&c.* within the king's houſe, ſhall be determined before the lord ſteward of the king's houſe, does not reſtrain the court of *king's-bench* from proceeding againſt ſuch offences. 2 Inſt. 549. 2 *Hawk.* P. C. p. 7.

But when a ſtatute creates a new offence, which was not taken notice of by the common law, and erects a new juriſdiction for the puniſhment of it, and preſcribes a certain method of proceeding, it ſeems queſtionable how far this court has an implied juriſdiction in ſuch a caſe. 2 *Hawk.* P. C. p. 7.

The judges of this court are the ſovereign juſtices of *oyer* and *terminer* [a], goal delivery, conſervators of the peace, *&c.* As alſo the ſovereign coroners [b]; and therefore, where the ſheriffs and coroners may receive appeals by bill, *a fortiori*, this court may. Alſo this court may admit perſons to bail in all caſes according to their diſcretion [c]. [[a] 4 Inſt. 73. 9 Co. 118. b. [b] 4 Inſt. ibid. [c] 4 Inſt. 74. Vaugh. 157.]

This court has not only a power to reverſe erroneous judgments, for ſuch errors as appear the defect of the underſtanding; but alſo to puniſh all inferior magiſtrates, and all officers of juſtice, for wilful and corrupt abuſes of their authority againſt the obvious principles of natural juſtice. Vid. 2 *Hawk.* P. C. p. 8.

This court being the ſupreme court of oyer and terminer, goal delivery, and eyre, its preſence ſuſpends the power, and avoids the proceedings of all other courts of the ſame nature in the county wherein it ſits, during its ſitting there. Vid. 2. *Hawk.* P. C. p. 8. 4 Inſt. 73. 3 Inſt. 27.

The civil ſide of the *king's-bench* commences on a ſuppoſition of a treſpaſs committed by the defendant in the county where it reſides, and that he is taken up by proceſs of this court, as the ſovereign eyre, and being committed to the marſhal, he may be declared againſt in any civil action whatſoever. The firſt proceſs therefore, is a bill either real or feigned, and ſo called, becauſe its foundation was the bill of complaint in court, touching the treſpaſs: in this is founded the *latitat*, which ſuppoſes that the defendant has eſcaped, and therefore iſſues in the *king*'s name, to apprehend the party wherever he may be found. Vid. New Abr. Law. Vol. 1. p. 595. and Title *Proceſs.*

KING-*piece*, in any building, is a piece of timber ſtanding upright in the middle, between two principal rafters, and having ſtrutts or braces going from it to the middle of each rafter.

KINNOR, in the Jewiſh antiquities, a muſical inſtrument, frequently tranſlated *cithara.* It was compoſed of a baſe or hollow ſounding belly, and of two branches raiſed perpendicularly on the two ſides of this belly. Above theſe branches was a piece of wood which went acroſs, and was faſtened to each of them. To this piece of wood were fixed three, ſix, or nine ſtrings, which made a very harmonious ſound as often as they were either play'd upon with the fingers, or touched with the bow. *Calmet*, Dict. in voc. *Cithara.* See CINYRA.

KIRATHE, a name of a weight mentioned by ſome authors equal to four grains.

KIS, in natural hiſtory, a name given by ſome people to the common pyrites; and by others to a peculiar kind of it, containing copper and a ſmall quantity of ſilver.

KISSINA, in botany, a name by which ſome authors have called the tree, whoſe wood is the *agallochum*, or lignum aloes of the ſhops. *Kempf.* Amœnit. Ex. p. 903.

KIST, a word uſed by Paracelſus as the name of a weight, equal to fourteen grains.

KITCHEN *Garden*, there are certain general rules always to be obſerved in the making this uſeful ſort of *garden*, which will render it much cheaper and more convenient than if undertaken at a venture without the conſideration of them.

It ſhould always be placed behind a houſe, that it may be both ſheltered and kept out of ſight, and always ſhould be as near as may be to the ſtables, that the dung may be ready, and coſt no great labour nor expence in carriage. A ſquare is the beſt figure for the ground; but this is not neceſſary, ſince all irregularities may be hid by the quarters. The ſoil muſt neither be very wet nor very dry, nor too ſtiff; and if there are any riſings in any part of the ground, they are by no means to be levelled, as they will be of great uſe for different crops of ſeveral things. It muſt be fully expoſed to the ſun, and by no means overſhadowed by trees. The quantity of ground is to be wholly proportioned to the ſize of the family it is to ſupply; for a ſmall one of an acre of ground will be enough, and there ſeldom requires more than three or four acres. It ſhould be walled all round with walls twelve feet high for the reception of fruit trees, and the ground ſhould be ploughed up three or four times before any thing is planted in it.

If the ſoil be ſtiff, it muſt be manured with ſea-coal aſhes, the cleanſings of the ſtreets of large towns, or ſea ſand, as alſo with rotten wood, and decayed and putrefied vegetables. On the contrary, if it be light, and warm, it muſt be manured with rotten neat's dung; and if horſe dung be uſed, it muſt be always very well rotted firſt.

The ſoil muſt be at leaſt two feet deep, and there muſt be a ſupply of water, which, if it can be contained in baſons, or reſervoirs, will be very convenient and advantageous.

As ſoon as the walls are built, the firſt thing to be done is the laying out the borders under them, which ſhould be ten or twelve feet broad; and on thoſe which are expoſed to the ſouth, the early crops are to be planted, and the later on thoſe to the north. No large or deep rooting plants ſhould ever be ſet near the roots of the wall-fruit trees, but the beans and peas, required to be early, ſhould be planted in other parts of the *garden*, and ſheltered by moveable reed hedges, which will ſcreen and forward them as well as the walls. The next thing to be done, is the laying out the ground into quarters. Theſe ſhould never be too ſmall, but in a little *garden* it is better to have only a few of them. They muſt be ſurrounded with eſpaliers of fruit trees, and have walks turfed between them, which in a ſmall *garden* ought to be ſix feet wide, in a large one ten; and on each ſide the walk there ſhould be allowed a border of three or four feet broad, between its edge and the eſpaliers. On theſe borders ſmall ſallading, or any thing that does not remain long, nor root deep, is proper to be ſown. If the walks are covered with lime rubbiſh or ſand, inſtead of being turfed, it will be an advantage to the fruit in the eſpaliers, though it takes off from the beauty of the *garden*. The beſt figure for the quarters is either a ſquare, or an oblong; but when the nature of the ground does not admit this, they may be triangular, or of any other form. The ground in theſe quarters ſhould never be ſown, or occupied by the ſame crop, for two years together; and when any part of the ground is not uſed, it ſhould be trenched up in ridges, to receive the better the benefit of the dews.

In one of the quarters which is neareſt the ſtables, and is moſt defended from bad weather, ſhould be the beds for cucumbers, melons, and other productions of the hot-bed; and it is a very good method to ſurround that part with a reed hedge, which both ſhelters and hides the beds from ſight. This ſquare ſhould always be large enough for the beds of two years.

The moſt important points of culture and management are the well digging and manuring the ſoil, and the giving a proper diſtance to each plant. The quarters and dunghills are both alſo to be kept clear of weeds, for if they are ſuffered to ſcatter their ſeeds on the dunghills, it is in vain to root them out of the *garden*, as they will be continually renewed from thence. *Miller's* Gardner's Dict.

KLIMIA, or CLIMIA, in the materia medica, the name given by the Arabian writers to the *lapis calaminaris*. Aviſenna and Serapio never call it by any other name. Some pronounce the word *calimia*. Hence the modern Greeks have formed their *celimia*, which is the name of the ſame ſubſtance; and our *calaminaris* is evidently deduced from the ſame original.

KLINKETS, in fortification, a ſort of ſmall gates made through paliſadoes for ſallies.

KLIP *fiſh*, in zoology, a name by ſome authors ſuppoſed to mean the *lupus piſcis*, or wolf fiſh, and by others the common cod fiſh.

Of the former opinion is Fabricius, who ſuppoſes the lupus ſo called, becauſe it is able to climb up rocks, or generally lies hid among rocks; the word *klip* in the German ſignifying a rock. Of the other is Schonfeldt, who ſuppoſes the cod has its name of *klip fiſh*, or rock fiſh, from its being uſually dried upon the rocks. *Willughby*, Hiſt. Piſc. p. 130.

KLIP *fiſh* is alſo a name by which the Dutch in the Eaſt-Indies call a flat fiſh caught frequently on thoſe ſhores, and ſometimes called alſo *ſoldaten viſch*, or the ſoldiers fiſh. It ſomewhat reſembles the bream in ſhape. Its general ſize is about ſix or ſeven inches in length, and it is of a very white and ſilvery hue. It differs very greatly, however, from the bream in many particulars. The nerves of its back fin are prickly as in the pearch; its tail is pointed, not forked; and the iriſes of its eyes yellow. It is one of the fineſt fiſh of the Eaſt-Indies. Its fleſh is very firm, and falls into large pieces, when dreſſed, like that of the cod, and is very well taſted. *Ray's* Ichthyogr. Append. p. 6.

KNAPWEED, *Jacea*, in botany. See JACEA.

KNAVE (*Cycl.*)—KNAVE-*line*, in a ſhip, a rope faſtened to the croſs-trees, under the main or fore-top, whence it comes down by the ties to the ram-head, and there it is reeved through a piece of wood of about two feet long, and ſo is brought to the ſhip's ſide, and there haled up taught to the rails.

KNAUTIA, in botany, a name given by Linnæus to the plant called by Boerhaave, and others, *lychni-ſcabioſa*. This makes in the Linnæan ſyſtem a diſtinct genus of plants, the characters of which are; that the calyx is a common perianthium, containing four flowers, and made up of four leaves; it is oblong, placed erect, and its ſegments are pointed, and ſet near one another. The whole complex maſs of flowers is equal and regular. Each ſingle flower is monopetalous, and unequal. The petal is formed into a tube for the length of the cup, and has an irregular mouth with four ſegments, the outer one being large, and of an oval figure. The ſtamina are four filaments, longer than the tube of the flower, and inſerted in the receptacle. The antheræ are oblong, and lie regularly on theſe. The germen of the piſtil is placed below the receptacle of the flower. The ſtyle is ſlender, and as long as the ſtamina, and the ſtigma is thick and bifid. The ſeeds are ſingle, ſquare, and hairy at the tops. *Linnæi* Genera Plantarum. p. 23.

KNECK, in the ſea language, the twiſting of a rope or cable, as it is veering out.

KNEE. The mucilaginous glands of the *knee*, which lie near the edges of the patella, are very remarkable: they are diſpoſed in fringes, and ſupported by a great quantity of fatty matter, which in ſome meaſure makes one maſs with them. This common maſs is contained within the capſular ligament, and on the ſide of the joint is covered by a very fine membrane, which likewiſe lines the inner ſurface of the ligament. The glandulous ſubſtance is eaſily diſtinguiſhed from the fat by the reddiſh colour of the capillary veſſels, which ſurround the glands. The ſuperior portion of this maſs is, as it were, ſupported by a ſmall ligament, fixed in the anterior part of the great common notch of the condyles of the os femoris, and which from thence runs to the upper part of the patella. There are alſo other mucilaginous glands, both above and below the edges of the ſemilunar cartilages, and likewiſe in the ham: ſome of theſe ſerve for the joint, and the others for the crucial ligaments. Theſe laſt lie in folds formed by the internal membrane of the capſular ligament, which give particular coverings to the crucial ligaments, and to the other bundles of ligamentary fibres near them. *Winſlow's* Anatomy, p. 131.

Luxated KNEE. A luxation of the *knee* is a receding of the tibia from under the femur. The leg is ſometimes thus luxated from the baſis of the thigh bone, on the outſide, ſometimes on the inſide, and ſometimes backward, but very rarely or never forwards, unleſs it be forcibly driven with great violence that way; for the patella is bound againſt the articulation forwards, by the ſtrong tendons of the muſcles which extend the leg; nor is it indeed eaſy for the bones of the leg to be wholly diſplaced from that of the thigh, ſo as to make a perfect luxation of the *knee*, by reaſon of the great ſtrength of the ligaments, and the two deep ſinuſes, which receive the head of the thigh bone, unleſs thoſe ſtrong ligaments ſhould happen to be broken aſunder at the ſame time. This is the reaſon alſo why people, who ſuffer a perfect luxation of the *knee*, are generally tortured with the moſt violent and excruciating pains, and convulſions; and if they eſcape the miſchiefs uſually attending ſuch ſymptoms, they are generally troubled afterward with a lameneſs and ſtiffneſs of the joint; but ſlight or imperfect luxations of this joint are uſually very ſpeedily and eaſily cured. The patient in this caſe is to be ſeated on a bed, bench, or table, and one aſſiſtant is to hold the thigh firmly above the knee, and another ſtrongly to extend the leg, while the ſurgeon replaces the bones by his hands and knee, in their natural places. If the hands and ſlings are not ſufficient, in this caſe, to make a proper extenſion, recourſe muſt be had to the pullies, generally uſed on ſuch occaſions; but in children and young perſons, great care muſt be taken not to make the extenſion ſo violent, as to ſeparate the epiphyſes from the bones, to which they are, in ſuch ſubjects, not yet firmly united. After the luxation is properly reduced, the *knee* is to be bound up with a proper bandage, and placed in a frame or caſe, ſo as to be kept at reſt for a proper time. *Heiſter*, p. 172.

KNEE, in the manege, is the joint of the fore quarters, that joins the fore thigh to the ſhank.

KNEES, in a ſhip, thoſe crooked pieces of timber, bowed like a *knee*, that bind the beams and futtocks together, being bolted faſt into them both. Some of theſe ſtand right up and down, ſome along ſhip. They are uſed about all the decks; ſome ſawed or hewed to that form, and others naturally ſo, which are certainly beſt for ſervice.

KNEE *of the head*, in a ſhip, the ſame with the cut-water. See CUT-*water*.

KNEE-*Timber*, in a ſhip, the ſame with the *cut-water*, which is called the *knee of the head*.

KNETTLES, in the ſea language, a name the ſeamen give to two pieces of ſpun yarn put together untwiſted.

KNEVELS, in a ſhip. See CHEVILS.

KNIGHTEN-*Gild*, in our old writers, a *gild* or company in London, conſiſting of nineteen knights, which king Edgar founded, giving them a portion of void ground lying within the walls of the city, now called Portſoken-ward. *Stow*, 151.

KNOTS (*Cycl.*)—KNOTS, in gardening, a term uſed to expreſs the rudiments of the firſt branches of plants, as they grow up from the ſeed. Thus in the melon, the two firſt leaves or ſeed leaves, are called the ears, and the branches, that grow from them, are called according to the order of their growth, the firſt, ſecond, and third *knots*. Mr. Quintiny's famous method of raiſing the beſt melons, depended principally on the cutting off every third *knot* of the plant as they grew up. Phil. Tranſ. N°. 45.

KNOTS, on board a ſhip, are of ſeveral ſorts; the chief of theſe are, the *wale-knot*, which is ſo made with the lays of a rope, that it cannot ſlip, and ſerves for ſheats, tacks, and ſtoppers. The *bow-line-knot* is ſo firmly made, and faſtened to the

the crengles of the ſails, that they muſt break, or the ſails ſplit, before it will ſlip; and laſtly, the *ſheep-ſhank-knot*, which ſerves to ſhorten a rope without cutting it, which may be preſently looſened.

KNOT-*Graſs*. See POLYGONUM.

KNOTT, in zoology, the name of an Engliſh bird of the ſnipe kind, not known among authors by any particular Latin name, unleſs it be the *calidrys nigra*, or black calidrys of Bellonius, which is doubtful from his deſcription; and ſaid to have obtained its Engliſh name from Canute, one of the kings of this iſland, who was particularly fond of it.

It is ſeldom of more than two ounces and a half in weight. Its head and back are of a greyiſh brown; its rump is variegated with black and grey; its breaſt and belly are white, and its ſides browniſh, in ſome, but not in all the birds of this ſpecies: there is on each ſide of the head a white ſtreak, running from the angles of the beak to the eyes. The long feathers of the wings are black and white; and the tail, which is two fingers breadth and a half in length, has its feathers tipped with white at the ends. Its beak is a finger's breadth and a half long, and is black, but it is ſtronger than any other of the ſnipe kind. Its eyes are large, and its legs are green. They appear in Lincolnſhire and Yorkſhire in the beginning of winter, and remain there ſome months, always keeping about the ſea ſhores. *Ray*'s Ornithol. p. 224.

KNOWLEDGE (*Cycl.*) may be uſefully diſtinguiſhed into three kinds; hiſtorical, philoſophical, and mathematical.

Hiſtorical KNOWLEDGE is merely the *knowledge* of facts, or of what is or happens in the material world, or within our own minds. Thus, that the ſun riſes and ſets, that trees bud in the ſpring, that we remember, will, &c. are inſtances of *hiſtorical knowledge*.

Philoſophical KNOWLEDGE is the *knowledge* of the reaſons of things, or of what is or happens. Thus he has a *philoſophical knowledge* of the motion of rivers, who can explain how it ariſes from the declivity of the bottom, and from the preſſure which the lower part of the water ſuſtains from the upper. So likewiſe the ſhewing how, and by what reaſon, deſire or appetite ariſes from the perception or imagination of its object would be *philoſophical knowledge*.

Mathematical KNOWLEDGE is the *knowledge* of the quantity of things, that is, of their proportions or ratios to ſome given meaſure. Thus he who knows the proportion of the meridian heat of the ſun at the ſummer ſolſtice to its meridian heat at the winter ſolſtice, might ſo far be ſaid to have a *mathematical knowledge* of the ſun's heat. So likewiſe he has a *mathematical knowledge* of the motion of a planet in its orbit, who can diſtinctly ſhew, how from the quantity of the impreſſed and centripetal force the velocity of the planet is produced; and how from the action of this double force, the elliptical figure of the orbit ariſes.

Theſe three kinds of *knowledge* differ evidently, it being one thing to *know* that a thing is; another, the reaſon why it is; and a third, to *know* its quantity or meaſure.

It is alſo evident, that hiſtorical *knowledge*, though extenſively uſeful, and the foundation of the reſt, is the loweſt degree of human *knowledge*. Thoſe who aim at the greateſt certainty ought to join *mathematical* with *philoſophical knowledge*. Nothing can more evidently ſhew that an effect ariſes from a certain cauſe, than the *knowledge* that the quantity of the effect is proportional to the force of the cauſe. Beſides, there are many things in nature, the reaſons of which depending on certain figures or quantities, are not aſſignable but from mathematical principles. Vid. *Wolf*. Diſc. Prelim. Logic. Cap. 1 & 2.

Philoſophical knowledge is attended with advantages not to be expected from mere hiſtory. See PHILOSOPHY.

KODDA *pail*, in botany, a name given by Plumier, and in the *hortus Malabaricus* to a genus of plants, called by Linnæus *piſtia*. *Plumier*, Gen. 39. Hort. Malab. Vol. 11. p. 32. See PISTIA.

KOHLMULEN, in ichthyography, a name given by ſome to the *aſellus flaveſcens*, or yellow cod, called by others *blank* and *gelbe*. *Willughby*'s Hiſt. Piſc. p. 173. See the article BLANK.

KOKOB, in zoology, the name of a ſpecies of ſerpent found in the Weſt Indies, and very fatal by its bite. It is ſmaller than our viper, and of a brown colour, variegated with green and red ſpots.

KOLERUS, a name given by Paracelſus to an old dry ulcer.

KOLLOW, a name given in ſome parts of England to a black earth, being of the nature of a coarſe ochre, which is found in Derbyſhire, Wales, and many other places. It has obtained its name from the old Engliſh word *collow*, which ſignifies grime, or blacking of any kind.

KOLTO, a name given by ſome writers to the *plica polonica*.

KOMMANICK, in zoology, the German name for the large creſted lark common in many parts of Germany, but not known in England. It is larger than our common lark, and has a much larger and longer beak. Its back is of a greyer colour, and leſs ſpotted than in the common lark, and its rump is ſcarce ſpotted at all. Its creſt is very beautiful, and is compoſed of eight, ten, or twelve feathers much darker coloured than the reſt, and the bird cannot only raiſe and depreſs, but can ſpread and contract them at pleaſure. It very ſeldom is ſeen high in the air, and never makes any long ſtay there, but is moſt frequently ſeen about the banks of rivers. *Aldrovand*. de Avib.

KONNARUS, a name given by Agathocles in Athenæus to a plant of Arabia, which the deſcription ſhews to be the ſame with the *ſaduc* of the later Arabians, the fruit of which is called *nabac* or *nabech*.

This tree is the *lotus* of Dioſcorides and the *acanthus* of Virgil, whoſe berries he mentions. The fruit of this tree is like a cherry, but ſmaller, and is ground to powder by the Africans when dried. It is very well known to all who are acquainted with the writings of the old phyſicians, that the berries of the *lotus* or *nabac* were ground down, by the Egyptians and other nations where they grew, to a fine powder for medicinal uſes. They were aſtringents, and uſed both externally in pultices and fomentations, and internally in decoctions and other forms where aſtringents were required. *Athenæus*, p. 61.

KORACHORYNCHUS *Indicus*, in zoology, the name of a ſea-fiſh of the Eaſt Indies, called by the Dutch the *raeven beck*. It has its name from its noſe reſembling the beak of a raven or crow, and is about ſeven inches long; its back and tail are red, and its belly yellow; it has alſo on each ſide two pale yellow longitudinal lines, running from the gills to the tail. It is a wholeſome and well taſted fiſh. *Ray*'s Ichthyograph. Append. p. 2.

KOS, in the Jewiſh antiquities, a meaſure which held the quantity of four cubic inches, and ſomething over. This was the cup of bleſſing, out of which they drank when they gave thanks after ſolemn meals, as on the day of the paſſover. — *Exod.* xxv. 29. — *Calmet*, Dict. Bibl. in voc. *Cyathus*.

KOUANIN, in the Chineſe language, the name of a tutelary deity of women. The Chineſe make great numbers of the figures of this deity in white porcelain, and ſend them to all parts of the world, as well as keep them in their own houſes. The figure repreſents a woman with a child in her arms. The women, who have no children, pay a ſort of adoration to theſe images, and ſuppoſe the deity they repreſent to be of power to make them fruitful. It has been ſuppoſed, by many Europeans, that theſe images were meant to repreſent the Virgin Mary, with our Saviour in her arms, but this is an idle opinion; the Chineſe having been fond of this figure in all times that we have an account of. The ſtatue always repreſents a handſome woman, very modeſtly attired. Obſerv. ſur les Coutumes de l'Aſie.

KRUTZVOGEL, in zoology, the German name for the loxia or croſs bill.

KUHUL, a word uſed by ſome chemical writers to expreſs lead ore.

KURUNDU, or KURUDU, in botany, a name by which ſome botanical authors have called the cinnamon tree. *Herm*. Muſ. Zeyl. p. 12.

KUSBORAH, in botany, and in the materia medica, a name uſed by ſome authors, particularly Averrhoes, for the plant or ſeed of coriander. *Ger*. Emac. Ind. 2.

KYMOLEA, a word uſed by ſome writers, to expreſs the foulneſs or muddy ſubſtance, which gathers about a ſtone uſed for cutting or grinding other bodies.

L.

LA, in the Italian muſic, a ſyllable by which *Guido* denominated the laſt ſound in each hexachord, if it begins in C it anſwers to our *a*, if in G to *e*, if in F to *d*.

LABADISTS, a ſect of religioniſts, followers of the opinion of Jean de Labadie, who lived in the laſt century, and was cotemporary with Mad^lle Bourignon.

Some of his tenets were, that 1. God could and did deceive men. 2. That in reading the ſcriptures greater attention ſhould be given to the internal inſpiration of the holy Spirit than to the words of the text. 3. That baptiſm ought to be deferred till mature age. 4. That the good and the wicked entered equally into the old alliance, providing they deſcended from Abraham, but that the new admitted only ſpiritual men. 5. That the obſervation of Sunday was a matter of indifference. 6. That Chriſt would come and reign a thouſand years on earth. 7. That the euchariſt was only a commemoration of the death of Chriſt, and that tho' the ſymbols were nothing in themſelves, yet that Chriſt was ſpiritually received by thoſe who partook of them in a due manner. 8. That a contemplative life was a ſtate of grace, and of divine union during this life, the ſummit of perfection, &c. 9. That the man whoſe heart was perfectly content and calm, half enjoys God, has familiar entertainments with him, and ſees all things in him. 10. That this ſtate was to be come at by an entire ſelf-abnegation, by the mortification of the ſenſes and their objects, and by the exerciſe of mental prayer. See Journ. des Scavans for Oct. 1727, where we have ſome account of Labadie and his followers, which were moſtly women; and with ſome of which, it has been ſaid, he took criminal liberties. See *Baſnage*, Annales des Provinces Unies, Tom. 2. cited in Journ. des Scav. l. c.

LABARIFERI, among the Romans, ſtandard-bearers, who carried the *labarum*. *Danet*, in voc. *Signa*. See LABARUM, *Cycl.*

LABDACISM Λαβδακισμὸς, in rhetoric, the too frequent repetition of the letter L, as *ſol et luna luce lucebant*, and *alba levi lactea*. *Voſſ.* Rhet. l. 4. p. 45.

LABDANUM, in the materia medica. See LADANUM, *Cycl.*

LABELLED *line*, in heraldry, a term uſed by ſome to expreſs the line in certain old arms, called more uſually urdee or champagne. Others apply the ſame word to expreſs the patee or dovetail line, called alſo the inclave line by Morgan. It ſomewhat reſembles the joint called a dovetail by our joiners, and its points, as they proceed from the ordinary, whether chief or feſs, reſemble the ends of labels. See URDEE and PATEE.

LABEO, in ichthyology, a name given by the old Latin writers to the fiſh, uſually called *cheilon* and *chelon*. See the article CHELON.

LABER, a word found in Serapion, and uſed there as the name of an aromatic drug. The commentators have been much perplexed, to find the reaſon or etymology of the word, as it appears no where elſe in the writings of the antients. It ſeems to be no other than a wrong ſpelling of the word *ſaber* or *ſebar*, ſometimes alſo written by the Arabians *cebar*, which is a name of the lignum aloes.

LABERINTH. See LABYRINTH.

LABIATED *flowers*, in botany, a term for a very large ſeries of flowers; the diſtinctions of which are, that they are monopetalous, and are in their lower part formed into a pipe or narrow tube, and in their upper become widened into one or two lips. The cup of theſe flowers conſiſts of one leaf, and is uſually tubular, and reſembles a paper cone; and their piſtil is ſurrounded with four embryos, which ripen into a fruit, compoſed of four ſeeds, and kept incloſed in the cup; by this they are diſtinguiſhed from the perſonated flowers, whoſe fruit is an oblong capſule; and they differ from the rotated flowers of borrage, and the like, in that they have ſome ſort of reſemblance to the opening of a mouth of ſome animal. See Tab. 1. of Botany, Claſs 1. *Tourn.* Inſt. p. 177.

A BIATED *leaf*. See LEAF.

LABINÆ, in natural hiſtory, a term uſed by the authors, who have written of Swiſſerland, and other mountainous countries, to expreſs thoſe vaſt maſſes of ſnow, which ſometimes fall from the hills, and bury houſes, or even whole towns; and when hardened by the froſts, as is often the caſe, into ſolid ſubſtances, they overthrow woods, villages, and whatever ſtands in the way of their courſe, as they roll down the ſteep ſides of the precipices in their way. Some authors have alſo extended the word to a larger ſenſe, and made it expreſs the falling of vaſt rocks, or parts of mountains, and their rolling down in the ſame manner into the flat country: this is a miſchief very frequent in the ſame places, after froſts, and often very fatal. *Wagner's* Hiſt. Helvet.

LABIUM *ſuperius attollens*, in anatomy, a name given by Spigelius to the muſcle, called by Albinus, Winſlow, and others, *zygomaticus major*.

LABORANT, in chemiſtry, the perſon that attends on and works under a chemiſt, while he is about any proceſs or experiment.

LABORATORY *(Cycl.)*—Dr. Shaw, who has taken great pains to bring the ſtudy of chemiſtry more into uſe in England, than it has hitherto been, has explained the eaſyneſs of its operations in general, and attempted a means of making its practice leſs expenſive, by introducing in the place of that vaſt number of furnaces, and other contrivances, figured and deſcribed by the generality of writers on the ſubject, a *portable laboratory*, by means of which alone all the chemical operations may be commodiouſly performed. This *laboratory*, fitted for its ſeveral purpoſes, is figured in the plate of chemical furnaces and veſſels, to which we refer the reader. See Tab. of Chemiſtry, N° 31. *ſeq.*

Its contrivance is ſuch, that not only compleat courſes of chemical experiments and operations may be commodiouſly performed by its means; but all the medicines may be prepared, in ſuch quantities, as to ſupply not only the demands of a family, but of an apothecary's ſhop, in moderate buſineſs. The firſt perſon who planned out this ſort of furnace was Beccher, and the ſcheme executed by Dr. Shaw is an improvement on that attempt. This *laboratory* conſiſts of two parts beſide the furnace: theſe are the apparatus and the materia chemica, which are deſcribed under the heads APPARATUS *chemicus*, and MATERIA *chemica*.

The furnace has four principal parts. 1. The cover. 2. The ring. 3. The body, and 4. The foot. The general office and uſe of the cover is to check, ſuppreſs, and throw back the heat and flame, that the fuel may not waſte itſelf too faſt, as it otherwiſe would do to very little purpoſe in many of the operations; for the action of the fire being not momentary but ſucceſſive, the more it is kept in, and directed upon the ſubject, the more it is able to perform its effect, and that with the leſs expence or deſtruction of it. In order to increaſe the draught to the fire, and ſqueeze the air the more forcibly through the body of the fuel, there is a moveable funnel or chimney, which may occaſionally be fixed to the orifice, in the top of the cover left for that and many other uſes. See the Figure, *ubi ſupra*.

The ring is the place or ſeat of many operations. The body to be worked upon by the fire is frequently lodged in it; and, in other caſes, it helps to enlarge the furnace, and renders it capable of operations it could not otherwiſe perform. The body of the furnace ſerves to contain the fuel, and is the common ſeat of the operations by the fire, in the running metals from their ores; and in theſe and many other the like caſes, it performs the office of a crucible as well as fire place, and contains the ſubject mixed along with the fuel, as is practiſed at the ſmelting houſes. To this body there belong three ſeveral grates, which may be placed at different heights therein, according to the nature of the operation, and the diſtance required between the ſubject and the fire. Laſtly, the foot is of two kinds, and is not only of uſe in ſupporting the reſt of the parts, but it receives the aſhes of the fuel, and the melted matter that may, in any of the operations, run down from the ores of metals; or, on other the like occaſions, when the fire liquates any thing above. The more immediate appurtenances of this furnace are fuel and bellows. The general fuel is to be charcoal; or, as there is a contrivance for a vent or flue in the body of the furnace, common ſea-coal may be employed, and the ſmoak directed up the chimney of the room, in which the furnace is to ſtand. The ſtructure of this furnace is alſo very well fitted for a lamp, which is a ſort of heat, highly convenient for ſome curious digeſtions and calcinations, and by this means thoſe operations, which would otherwiſe require an athanor, may be conveniently performed, and that in the moſt accurate manner.

The number of chemical proceſſes that may be performed by this furnace is not eaſily reckoned up; but it may not be improper to add an account of the ſeveral ſtates, into which it is to be put for the performing them.

The moſt ſimple ſtate of the furnace is a combination of its two lower parts, the body and the foot. When theſe are put together it is fit for fuſion by the naked fire, where the matter to be melted is to be mixed among the fuel; as for inſtance, in the running the ores of lead, tin, or iron, which may thus, in the quantity of many pounds at a time, be ſeparated from their droſs, and purged for uſe, as exactly as at the mine works, or ſmelting houſes, either with the aſſiſtance of the bellows, or without, as the nature of the ore requires. By barely placing a grate in the middle of the body, the inſtrument becomes a melting furnace for a crucible, wherein all the operations that require a fire of fuſion, animated either by the air, or bellows, are performable with ſuch advantages as cannot be had in the common wind, or blaſt furnaces made for this purpoſe. When only

the body of the furnace with its middle grate is ſet upon the foot, it anſwers all the purpoſes of a ſhop-furnace uſed by the apothecaries for decoction, inſpiſſation, extraction, and the like purpoſes, where a naked fire only is required, and certain diſtillations and ſublimations may alſo be performed conveniently by it.

It may in this ſtate alſo be conveniently made to ſerve the purpoſes of a *balneum mariæ*, an aſh heat, a ſand heat, or a ſtill ſtronger one for digeſtion and ſublimation, by only ſetting on it in this ſtate a veſſel of water, or one filled with aſhes, ſand, or iron filings; and thus ſeveral operations requiring the ſame kind of heat may be carried on at the ſame time. If inſtead of a common pan or veſſel to hold water, ſand, *&c.* the ring or third part of the furnace, be ſet on furniſhed with its ſet of pots, the whole is then a furnace fitted for that ſort of diſtillation called diſtillation in *capella vacua*, where the retorts are contained in the cavity of the pots, and locked down therein without any viſible medium between. By this means many operations may be performed in the diſtillation and ſeparation of bodies, that could not be worked upon to ſo much advantage by any other method. Particularly the rectification of the ſtrongeſt acid ſpirits, is very eaſily and conveniently performed this way at very little expence.

If an iron pan be placed in the room of the ring juſt mentioned, the inſtrument is then a calcining furnace, where ores of metals may be roaſted, and lead, antimony, and the like bodies may be conveniently reduced to aſhes.

If the loweſt grate be uſed inſtead of the middle one, then either a cold ſtill, or, as it is generally called, a hot one may be put into the body, and worked in the common manner with its head and refrigeratory. Thus all the cordial waters may be made ſpirits, may be rectified, and the eſſential oils diſtilled by the ſame means, as well as by the common fixed ſtills.

The laſt part or cover of the furnace, may ſometimes be applied to the ring, ſometimes only to the body of the furnace without the ring. The inſtrument in this caſe becomes a proper reverberatory furnace, and is uſeful for cæmentation, cupellation, and the eſſaying of ores; and for diſtilling with a fire of ſuppreſſion, that is, where the fire is placed above as well as below the ſubject, and the veſſel that contains it.

A furnace of this nature has numerous advantages, not only over all the chemical furnaces in common uſe, but even over thoſe of the moſt celebrated ſtructure and contrivance, deſcribed by authors on particular occaſions, not excepting thoſe of Glauber and Vigani. Thoſe nicely contrived furnaces are generally adapted to ſome few particular purpoſes, and yet this eaſy kind anſwers in experiment thoſe very purpoſes better; and at the ſame time is of general uſe on all the other occaſions of chemiſtry. Experience has ſhewn, that it is better for the various uſes of Glauber's philoſophical furnaces, than thoſe very furnaces themſelves, though made for theſe very purpoſes; and for the higher operations as they are called of metallurgical chemiſtry. For example, to obtain a pure ſpirit of ſalt in plenty, Glauber orders the ſalt to be thrown upon the fire, and has contrivances to catch the riſing vapour; but this is a tedious way, and turns to very little account in practice, nor is the matter much improved by quenching the coals in a brine of ſea ſalt, and afterwards burning them for their fume; but all that can be expected from theſe aukward contrivances, may be had commodiouſly from the furnace here deſcribed, where the fire being animated by bellows, cauſes the fire to burn more free, and the fuel to yield the ſpirit it was impregnated with much more quickly and eaſily, than in the furnace contrived by that author for the purpoſe, while the fuel is ſupplied by the door without any diſturbance to the operation. *Shaw*'s Eſſ. on a Portable Laboratory.

There are many other curious philoſophical experiments, which can be no way ſo well done as with this kind of furnace, and many ſcarce at all without it. It is excellently fitted alſo for enamelling, making of paſtes, ſtaining of glaſs, and making the artificial gems. And beſide theſe and a number of other curious uſes; it is extremely well fitted for all the common purpoſes of fires. Any artizan who requires fire in whatever manner in his buſineſs, may contrive to apply it in this manner as he will; the offices of a common ſtone in a kitchen, may alſo be very well ſupplied by it, and the warming a room or vault, is as well done by it as by any of the common contrivances of ſtoves, ovens, and other things, made purpoſely for that uſe.

The outer caſe of the furnace is to be made of good plate iron of a conſiderable thickneſs, formed in ſeparate pieces of the figures expreſſed in the plate, and its ſize may be ſuch as the operator chuſes; obſerving only a due proportion in its ſeveral parts. The inner ſides of all the parts muſt be lined at leaſt an inch thick with a proper luting, which muſt be carefully laid on and gently dried, the cracks which happen in the drying, being filled up with more of the ſame luting. Windſor loam alone may be uſed to this purpoſe, but the author himſelf recommends the following mixture. Take a buſhel of Windſor loam, four quarts of brickduſt, two quarts of powdered green glaſs, two quarts of iron filings, four handfuls of cow-hair, and eight handfuls of horſe-dung, theſe are all to be beat together, and a ſufficient quantity of bullocks blood added, to make the whole into a ſtiff and uniform paſte, which is to be carefully ſpread over every part of the furnace that the fire can touch.

LABOUR, in the ſea language, is uſed when a ſhip rolls and toſſes much.

LABRAX, in zoology, a name given by ſome to the lupus or ſea wolf, called in Engliſh the Baſſe. *Willughby*'s Hiſt. Piſ. p. 272. See the article BASSE.

LABRUS, in ichthyology, the name of a genus of fiſhes, the characters of which are theſe. They are of the acanthopterygious tribe. The branchioſtege membrane on each ſide contains ſix ſlender and flat bones, when the fiſh is full grown; but in the young ones, five only can be counted. The teeth are large, and are placed in the jaws, and on three bones in the fauces, the upper ones hard and two in number, the lower one ſingle, the palate and tongue are ſmooth. There are thick and fleſhy lips covering the teeth. The membrane of the back fin, contains in its fore part double rays ariſing from each baſe of theſe two, the one is prickly, the other ſoft and inoffenſive. The colour is generally beautiful and in moſt of the ſpecies elegantly variegated. The tail is generally undivided; the ſcales are large, ſoft and ſmooth; and there are no appendices to the pylorus. *Artedi* Gen. Piſc. 27. The ſpecies of this genus enumerated by Artedi are theſe. 1. The *labrus* with the ſnout turning upwards, and with the tail circular at the end. This is the *turdus vulgaris*, and *tinca marina*, or ſea tench of authors, and is called by our people in Cornwall, the wraſſe or old wife fiſh. 2. The green *labrus* with a blue line on each ſide. 3. The black *labrus* called by authors the *merula*. 4. The elegantly variegated *labrus* with the pectoral fins rounded at the ends. This is the *pavo* of Salvian. 5. The oblong green *labrus* with gold coloured iriſes. 6. The blue and yellow *labrus* with very large fore teeth. 7. The four toothed green *labrus* with a forked tail. 8. The ſmall variegated *labrus* with two large teeth in the upper jaw. 9. The *labrus* with the lower jaw longeſt with a forked tail, and variegated with tranſverſe black lines. 10. The *labrus* variegated with purple, blue, yellow, green, and black. This is called by ſome authors the *ſcarus varius*.

The word *labrus* is truly Roman, and is uſed in the ſame ſenſe by Ovid and others, being probably derived from the word *labra*, lips; this fiſh having remarkable thick and prominent lips.

LABRUSCA, in botany, a name uſed by the old authors for black bryony. *Ger.* Emac. Ind. 2.

LABUYO, in natural hiſtory, a name given by the inhabitants of the Philippine iſlands, to a bird very common among them, and called by us the Urogallus. See UROGALLUS.

LABYRINTH (*Cycl.*)—*Labyrinth*, in gardening, is a part of the ground ſo planted and diſpoſed, as to render it difficult when any one is in it to find the way out, and in the attempting to get out, there are to be as many ſtops and diſappointments laid in the way as poſſible; the center alſo is to be made difficult to be found. There are two general ways of making them; the firſt is with ſingle hedges, and this is what has been moſt practiſed in England; and this may be beſt where there is but a ſmall ſpot of ground allowed for the making them, but where there is room enough, the double hedges are greatly the moſt eligible, and theſe are beſt of all when there is a wood-work between them. The walks in *labyrinths* ſhould be gravelled, and ſhould by no means be made too narrow. Theſe are to be ſet with iron beams, and the paliſadoes ought to be twelve or fifteen feet high. *Labyrinths* are only proper for large gardens, and the fineſt in the world is ſaid to be that of Verſailles. *Miller*'s Gard. Dict.

LAC, *milk.* See MILK.

LAC *Lunæ* (*Cycl.*)—Dr. Plot gives this foſſil as a mark of good lime ſtone; but it has been obſerved, that two quarries in Ireland where *lac lunæ* was found, were of building ſtone, but would not burn into lime. Phil. Tranſ. N° 477. Sect. 9. See AGARIC, *Cycl.* and *Suppl.*

LACCA, *Gum Lacc.* The method of obtaining the fine red laque uſed by painters from this ſubſtance, is by the following ſimple proceſs. Boil the ſtick *lacc* in water, filtre the decoction, and evaporate the clear liquor to a dryneſs over a gentle fire. The occaſion of this eaſy ſeparation is, that the beautiful red colour here ſeparated, adheres only ſlightly to the outſides of the ſticks, broke off of the trees along with the *gum lacc*, and readily communicates itſelf to boiling water. Some of this ſticking matter alſo adhering to the *gum* itſelf, it is proper to boil the whole together, for the *gum* does not at all prejudice the colour, nor diſſolve in boiling water. So that after this operation, the *gum* is as fit for making ſealing wax as before; and for all other uſes which do not require its colour. *Shaw*'s Lect. p. 178.

A tincture of *gum lacc* may be thus prepared. Take two ounces of *gum lacc*, reduce it to a fine powder; and make it into a ſtiff paſte with oil of tartar per deliquium; ſet this in an open glaſs to dry by a gentle heat, then remove it to the open air, that it may relent and grow ſoft, then dry it again, and repeat this two or three times, at the

end of which the hard body of this reſin will be found reſolved into a purple liquor. This may yet again be dried, and when dried muſt be reduced to powder, which powder will afford a fine ſtrong tincture to ſpirit of wine, being boiled in it in a tall glaſs in a ſand heat for two or three hours. And by this proceſs ſtrong tinctures may be made from myrrh, amber, gum, juniper, &c. which will yield no tincture of ſtrength to ſpirit of wine alone, if treated in the uſual way. *Shaw*'s Lect. p. 203.

LACCIA, in ichthyology, a name given by Paulus Jovius to the ſhad, or, as we ſometimes call it, the mother of the pilchards. See the articles THRISSA and CLUPEA.

LACCOPEDON, a word uſed by the old medical writers to expreſs the lax part of the ſcrotum.

LACCOS, Λακκος, among the Greeks, a ditch or trench uſed inſtead of an altar, when ſacrifices were to be offered to the ſubterranean or infernal Gods. *Potter*, Archæol. Græc. l. 2. c. 2. Tom. 1. p. 192. See ALTAR.

LACEDÆMONIUM *Marmor*, in the natural hiſtory of the antients, the name of a ſpecies of *marble* very hard, and of a beautiful green colour. It is a very cloſe, even, and compact *marble*; of a fine ſtrong and bright green, and when poliſhed, is the brighteſt of all the green *marbles*, and is remarkable for this, that the colour is not regularly and equally diffuſed through the whole maſs, but leaves in it many ſpots and lines very bright and pale, and ſome much deeper than the general colour, though there is no colour but green, in the whole, only in different ſhades and degrees, ſome parts approaching to black and others to whiteneſs.

It was originally found only in Ægypt, and there not in entire ſtrata, but in large pieces waſhed off from the ſtrata, and ſometimes left on the ſurface, ſometimes buried in the earth, and was greatly valued. It has been ſince found in Italy and Germany, and in England. About five miles from the hot wells at Briſtol there is a ſtratum of it, whence it might be had in conſiderable quantities. Its beauty would ſoon recommend it if it were once known: and though hard to cut, it would make amends for that by the high poliſh it would take. *Hill*'s Hiſt. of Foſ. p. 469.

LACERTA, *the lizard*. See LACERTUS.

LACERTA *Chalcidica*, in zoology, the name of a ſpecies of *lizard*, more uſually known by the name *ſeps*. See SEPS.

LACERTA *Volans*, a ſpecies of *lizard*, which lives on trees, feeding on ants, flies and other inſects, and doing no injury to man or any other large animal. It has membranes on its ſides, which ſerve the office of wings, in carrying it from one tree to another, and has been called by Geſner the dragon or winged ſerpent.

LACERTUS, in ichthyography, the *lizard* fiſh, a name given by ſome writers to a fiſh of the cuculus kind, much reſembling the common mackerel, in ſhape and in taſte, and more uſually called *trachurus*. *Geſner* de Aquat. p. 290. See TRACHURUS.

LACERTUS is alſo uſed for a fiſh of the garfiſh kind, or *acus oppiani*, but larger than the common ſpecies, and called by the Italian fiſhermen *aguglia imperiale*, or the imperial garfiſh, and by the fiſhermen of England, particularly in Cornwall, the *girrock*, in diſtinction from the common kind which they call *ſkipper*. It is thicker in proportion to its length than the common garfiſh, and has a ſhorter and ſharper ſnout, and inſtead of teeth, has only its jaws ſerrated like a file. It is a ſcarce fiſh, but is more firm in its fleſh than the common garfiſh. *Rondelet*. de Piſ. p. 32.

LACERTUS, the *lizard*, in zoology, the name of a large genus of animals, comprehending all thoſe quadrupeds which are oviparous, and have long tails continued from their bodies. The term oviparous is to be underſtood however in a larger ſenſe, expreſſing ſome among theſe, which though they have true and proper eggs within them, yet never depoſit them as ſuch, but keep them in their bodies till they are hatched, and bring forth living young ones. Some of the ſerpents, as well as ſome of the *lizards*, are of this kind, and the obſervation is as old as Ariſtotle, who calls the creatures, whoſe generation is of this kind, *internally oviparous, externally viviparous*. See Tab. of Quadrupeds and Serpents, N° 30. *ſeq.* and *Ray*'s Syn. Quad. p. 261.

LACERTUS *Orbicularis*, in zoology, the name of a very ſingular ſpecies of *lizard*, which is not long and ſlender like the reſt, but broad and rounded. *Hermandez* Lib. 9. c. 46. See the article TOPAYAXIN.

LACERTUS *Squammoſus*, in zoology, a name given by authors to a ſpecies of *lizard*, more eminently ſcaly than any other kind. The general length of this creature is about a yard and half. His head from the noſe end to the fore feet, is not above three inches; he has no neck; his trunck from the fore legs to the hinder, is not above ten inches and a half, but his tail is exceeding long, not meaſuring leſs than a yard and a half quarter; the back part of his head is near two inches over; his noſe about an inch, his body nearly four inches, and his tail very taper, but ending in an obtuſe end; the under part of the tail is flat, the upper part hyperbolic; the fore legs, contrary to what they are in other *lizards*, are longer than the hinder, theſe being not above three inches and a half in length, and thoſe more than four. The claws of the fore feet are alſo longer, thoſe of the hinder being but about half an inch long, thoſe of the fore ones near an inch; there are on each foot four toes and a heel behind. He is all over, except his throat and belly, and the lower part of his fore legs, and the inward part of the hinder ones, covered with ſcales very thick, and in ſolidity equal to the hardeſt bone. The baſes of the ſcales are of blackiſh yellow, the reſt of a pale yellow, like that of old ivory. They are ſtriated from the baſe to the cone, and are diſpoſed alternately in the manner of the ſcales of fiſhes. In the body there are ten or eleven in each rank, and on the tail about five; the largeſt are near two inches broad, but the ſmalleſt, not more than a quarter of an inch. They are flat on the forehead, the back and the fore part of the tail, but on the edges of the tail they are doubled into an acute angle. It is ſaid to be a very tame and inoffenſive animal. *Grew*'s Muſ. Soc. R. p. 46.

The throat and belly of this animal are beſet with hairs, and Mr. Ray ſuppoſes it from that, to belong to the viviparous quadrupeds, notwithſtanding that its ſhape has always made it be ranked among the *lizard* kind. It is preſerved in the muſeums of the curious, but we are not acquainted with the part of the world it lives in. *Ray*'s Syn. Quad. p. 275.

LACERTUS *Subterraneus*, the underground *lizard*, a very diſagreeable and dangerous ſpecies of *lizard*, found in the Antilles iſlands, and ſome other places. They are often met with by the people who dig in marſhy places, and are of a very formidable aſpect; they are about ſeven inches long. Their back is covered with black gloſſy ſcales, with a few grey ones, mixed here and there among them, and they look ſleek and gloſſy as if rubbed over with oil; the belly is no leſs ſcaly than the back, and their ſkin is of a yellowiſh colour. The head is ſmall and ſharp, and the mouth opens very wide, and is armed with very numerous and ſharp teeth; their eyes are very ſmall. As ſoon as they are dug up, and thrown on the ground, they immediately dig their way in again, with their feet, which are prepared for that purpoſe, and armed with ſharp claws; and when they are once in they burrow their way like moles wherever they pleaſe. They do great miſchiefs to the inhabitants in their gardens and plantations, burrowing horizontally at ſmall depths, and deſtroying the roots of every thing they meet with. Their bite is eſteemed as dangerous as that of the moſt poiſonous ſerpent. *Rochefort*, Hiſt. des Antill.

LACERTUS *viridis*, the *green lizard*, a very beautiful creature, which is common in many parts of Italy, and is ſometimes found in Ireland. It is conſiderably larger than our land eft, and of a very beautiful green. See Tab. of Quadrupeds and Serpents, N° 30. and *Ray*'s Syn. Quad. p. 263.

LACERTUS *alter ſphincteris*, in anatomy, a name given by Santorini, and ſome others, to one of the muſcles of the anus, now generally known by the name of the *levator ani*. The *muſculus ſedem attollens* of Veſalius, and *latus* of others. The thin termination of this muſcle, not the whole, is underſtood by this name.

LACERUM *folium*, among botaniſts. See LEAF.

LACHNIS, in natural hiſtory, the name of a genus of foſſils, of the claſs of the *fibrariæ*; the characters of which are, that they are fibroſe bodies, not elaſtic, and compoſed of ſhort and abrupt fibres, or filaments.

The word is derived from the Greek λαχνη, a hair or ſhort capillament or fibre. See Tab. of Foſſils, Claſs 1.

The bodies of this genus are divided into thoſe which are compoſed of larger and broader, and thoſe which are compoſed of ſmaller and narrower filaments. Of the firſt of theſe there are ſix ſpecies known among us; and of the other, four. Thoſe of the firſt are, 1. A pale fleſh coloured very gloſſy kind, found in the marl pits of Derbyſhire, and of little value. 2. A gloſſy greeniſh white kind, found alſo in the ſame county in a greeniſh marl. 3. A greyiſh white with thick filaments, common in the hills of Yorkſhire. 4. A dead looking white one common in Derbyſhire and Leiceſterſhire. 5. A very gloſſy white one in the clay pits of Yorkſhire; and 6. A dull fleſh coloured one in the Derbyſhire marl pits, which, as well as ſome others of theſe, makes a very good gypſum with very little trouble. *Hill*'s Hiſt. of Foſſ. p. 93—98.

Thoſe of the ſecond ſort, or the narrow threaded ones are, 1. A very gloſſy pale red one, found in great plenty on Mendip hills, and burning very freely to fine plaiſter. 2. A blueiſh white one common in the marl pits of Staffordſhire, though not regarded as a thing of any value by the owners of the pits. 3. A gloſſy greeniſh grey one common on the ſhores and in the cliffs of Yorkſhire. And 4. a very bright greeniſh white kind, found in great plenty in Derbyſhire, and frequently uſed for burning into plaiſter. It is very certain, that moſt of the reſt, from the quantities they are found in, might be made a very profitable thing to the owners of the pits where they lie, though they are in moſt places neglected. *Hill*'s Hiſt. of Foſſ. p. 98, 99, 100, 101.

LACINIATED *leaf*, in botany. See LEAF.

LACRYMA *cervina*, in natural hiſtory, a little round and hard bone, ſaid to grow in the great corner of a ſtag's eye after a certain age. Some alſo preſerve under this name a thickened excretion from the inner angle of that creature's eye, in colour and conſiſtence reſembling myrrh, or ear-

wax,

wax, long hardened in the ear. This is of a ſtrong and very diſagreeable ſmell, like the ſweat of the ſame animal, and is affirmed to be ſudorific and alexipharmic. *Grew*'s Muſ. p. 21.

LACRYMA *jobi*, in botany. See DIOSPIROS.

LACTARIA, *milk wort*, a name uſed by ſome botanical authors for the tithymal or ſpurge. This plant has been ſo called on account of its *milk* like juice. *Ger.* Emac. Ind. 2.

LACTEAL *fevers*, a term uſed by medical writers, to expreſs what the women call milk fevers, that is ſuch fevers as attend the difficult ingreſs of milk to the breaſts in lying-in-women.

LACTEUS *lapis*, in natural hiſtory, a name given by ſome authors to the *galactites*. See GALACTITES.

LACTIFEROUS, an epithet applied to ſuch plants as abound with a milk like juice, ſuch as the tithymal, ſow-thiſtle, and many others.

LACTUCA, *lettuce*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the ſemi-floſcular kind, being compoſed of a number of ſmall ſemi-floſcules, ſtanding on the embryo ſeeds, and contained in a common oblong and ſlender ſcaly cup. The embryos finally become ſeeds winged with down. To this it may be added, that there is a peculiar appearance, in all the *lettuces*, which eaſily diſtinguiſhes them from all the other genera of the plants with ſemi-floſcular flowers.

The ſpecies of *lettuce* enumerated by Mr. Tournefort are theſe. 1. The common garden *lettuce*. 2. The endive leaved *lettuce*. 3. The *lettuce* with ſpotted leaves. 4. The great variegated, headed and cultivated Auſtrian *lettuce* with a ſweet ſmell, commonly called the clove *lettuce*. 5. The long ſweet *lettuce*, called the Roman *lettuce*. 6. The jagged *lettuce* with curled leaves. 7. The broader leaved curled *lettuce*. 8. The *lettuce* with oblong pointed leaves. 9. The common headed garden *lettuce*. 10. The greater headed garden *lettuce* with duſky green leaves. 11. The wild *lettuce* with thorny ribs to the leaves. 12. The Italian wild *lettuce* with a prickly middle rib and bloody ſpots on the leaves. 13. The great opium ſcented wild *lettuce*. 14. The wild *lettuce* with the ſtalk covered with leaves, called by ſome the *viſcous ſuccory*. 15. The blue flowered dwarf perennial *lettuce*. 16. The white flowered dwarf perennial *lettuce*. 17. The wild *lettuce* with narrow jagged leaves. 18. The prickly, ſhrubby Spaniſh ſea *lettuce*. 19. The dandelion leaved mountain *lettuce*. 20. The blue flowered mountain *lettuce* with broad jagged leaves. 21. The white flowered mountain *lettuce* with broad jagged leaves. 22. The tall broad leaved Canada *lettuce* with a greyiſh flower. 23. The tall narrow leaved Canada *lettuce* with a pale yellowiſh flower. *Tourn.* Inſt. p. 473. See LETTUCE.

LACTUCA *marina*, *ſea lettuce*, in botany, a name uſed by ſome authors for the *lichen marinus*, commonly called oiſter green. Chabræus 572.

LADA, in botany, a name given by ſome authors to the plant which produces the common black pepper. *Piſo*, Mant. arom. p. 492.

LADDERS, in a ſhip, are uſually three.

1. The *entring ladder* is in the *waſte*, and made of wood.

2. The *gallery ladder* made of ropes, is hung over the gallery or ſtern of a ſhip, and ſerves to enter by, out of the boat, when the weather is foul, and the ſea high.

3. The *bolt-ſprit-ladders* are at the beak-head made faſt over the bolt-ſprit, to get upon it, and are only uſed in great ſhips.

Cart-LADDERS. See the article CART.

LADIES *ſmock*. See the article CARDAMINE.

LADIES *ſlipper*, in botany. See CALCEOLUS.

LADLE *of a gun*, the inſtrument wherewith the powder is put into the piece.

It is made of a plate of copper bowed in form of a half cylinder, rounded at one end, the other being fixed upon a long ſtaff; this filled with powder, the gunner carries, with his left hand, under the end of it, to keep the powder from falling out, till he enters it in the muzzle of the piece; when he has carried the powder home to the charged cylinder, he turns the *ladle* that the powder may fall out, and withdraws it.

Ladles are fitted to the bore of each gun, and hold powder ſufficient for the charge.

LADONIS, in the materia medica of the antients, a name given by ſome to the laurus or bay tree. We find the word in a compoſition preſcribed in Galen, from the works of ſome of the empirics of his time, but it never was uſed by the more regular authors.

LADRE, in the manege. See the article DULL.

LÆNA, among the antients, a thick ſhaggy upper garment. See the article CHLÆNA.

LAERTA, in natural hiſtory, a name given by authors to a ſpecies of veſpa or waſp, whoſe ſting is ſaid to be fatal: but this is an erroneous opinion. This waſp is larger and longer bodied than the common kind, but ſmaller than the hornet. It ſeems of a very irritable diſpoſition, attacking animals of any kind that come in its way.

LAGANUM, in natural hiſtory, the name of a genus of the *echini marini*, of the general claſs of the placentæ. The characters of the *lagana* are, that they have their mouth in the center of the baſe, and their aperture for the anus in its third region; that their ſuperficies is whole, and their edges waved. Of this genus there are five known ſpecies. 1. A ſmall very white one, with a ſinuous and fimbriated edge. 2. A larger, with a ſinuous edge, jagged in two places. 3. Rumphius's flat echinus. 4. A ſmaller and thinner than that; and 5. Plot's echinites deſcribed by Liſter, which beſide the fine ſtriæ has an almoſt innumerable ſeries of fine circular rings. *Klein*'s Echinod. p. 31.

LAGINE, in natural hiſtory, a name given by Pliny to a climbing plant, of the nature of that from which ſcammony was obtained, but ſmaller, and thence called by ſome *ſcammonea parva*, the ſmaller ſcammony. The antient Greeks have called this plant *jaſine*; and it appears very probable, that the word *lagine* here mentioned by Pliny is but a corruption of that name.

LAGOCEPHALUS, in zoology, the name of a ſpecies of orbis or globe fiſh. It is about a foot long and half a foot high. Its head is ſomething like a hare's, the forehead plain and almoſt ſquare, an inch and three quarters broad; the eyes round, above three quarters of an inch over and ſtanding high; the noſtrils three quarters of an inch before the eyes, and from theſe to the noſe end is a little above an inch. Each chap is, as it were, divided into two great teeth of three quarters of an inch broad. The fins are five in number; the ſkin membranous and limber on the back, head, upper ſides and breaſt, and round about his tail ſmooth and bald, and on his belly and lower part of his breaſt armed with little ſhort prickles; and there are undulated and crooked lines running along his back and ſides. *Grew*'s Muſeum Soc. Reg. p. 108.

LAGOPUS, in zoology, the name of a bird of the partridge kind, called by many the *rabolane*, and diſtinguiſhed from all other birds of this kind, by the thick covering of its legs and feet; it is a little larger than a tame pigeon; its beak is ſhort, ſtrong, and a little hooked, like that of the other gallinaceous fowls; and over its eyes there are naked ſpaces, of a fine red, and full of fleſhy protuberances. The males have a black line on each ſide the head, which the females have not; all the reſt of the body, the tail only excepted, is as white as the pureſt ſnow. Its tail conſiſts of ſixteen feathers, and is white, variegated with grey and black. Its legs and feet are very thick, covered even to the claws, with a fine, ſoft, and warm feathers; its claws are very long and ſharp, and its toes have a hairyneſs underneath. It ſpends its life on the mountains, in regions which are for the greateſt part of the year covered with ſnow. Its food is vegetable matter, the leaves of heath, whortles, and other ſhrubs. Its fleſh is very delicate and much valued. *Ray*'s Ornithol. p. 127.

LAGOPUS *altera*, in zoology, the name of a bird of the gallinaceous kind, and approaching to the *lagopus* or rabolane in many reſpects, more commonly known by the name of the *gorcock*, *moncock*, or *red game*. Some authors indeed have uſed the name *lagopus altera*, for the otomo, a bird ſeeming not eſſentially to differ from the *lagopus*. *Ray*'s Ornithol. p. 128. See the articles GORCOCK and OTOMO.

LAGOUDI, a name given by the Indians to the tree, which produces the leſſer galangal root of the ſhops. See the article GALANGAL.

LAGRIMOSO, in the Italian muſic, is uſed to ſignify a plaintive manner of ſinging or playing.

LAKES (*Cycl.*)—The *lake* Neſs in Scotland has been commemorated by many writers, but never with any degree of judgment, till Mr. Fraſer gave a perfect account of it to our Royal Society. It never freezes though the winters be ever ſo ſevere, and is full of ſprings in almoſt every part; and its waters, in the time of the ſevereſt froſts, run fluid, and ſmoaking for ſix miles down the river into which they are diſcharged, while every thing is frozen about them. The river runs very ſlowly notwithſtanding, and from this ſmoak of the water there is raiſed a ſort of fog which overſpreads the whole country for ſeveral miles. There is a mountain near the ſide, of two miles perpendicular height from the *lake*; and on the ſummit of this mountain there is another *lake*, which has no ſpring viſibly running into it, nor any outlet, and yet always keeps of the ſame degree of fulneſs, ſummer and winter. Due weſt from the river into which the lower *lake* diſcharges itſelf, there is an opening of ſea or frith of two miles long and ſix miles wide; the middle of this is ſometimes dry, and it is then eaſily ſeen that this was once dry land, and an inhabited country. There are found there large bodies of trees felled, and lying ſtrait along: the wood of theſe is black but it is very ſound, and there are many tumuli, or heaps of ſtones, to be ſeen under water in different parts of the frith, one of which is acceſſible at low water, and there have been found in it urns, which prove that they have been all burying places. Phil. Tranſ. N° 253. p. 231.

As the ſea waſhes away the banks of this frith, there is found in many places a large quantity of wrought timber; beams of fourteen, or more feet long, with the marks of the axe and other inſtruments upon them; and at the depth of

ſixteen feet, in the ſteep banks of the neighbouring river Beuly, there are found oak trees and pieces of burnt timber. We find by this, that the face of the whole country hereabouts is very different from what it was ſome ages ago; and there ſeems ſome reſemblance between the preſent face of things here, and that in the bogs of many parts of England. The trees found buried in theſe were felled by the conquering Romans, and perhaps theſe are of ſome ſuch origin.

We have many ſingularities offering to our view in the *lakes* of our own country: that of their freezing at peculiar ſeaſons is not one of the leaſt. There is a little *lake* in Straherrick in Scotland, which never freezes over before the month of February, though the froſts be ever ſo intenſe; but after the firſt part of this month, one night's trifling froſt will cover it all over with ice, and a ſecond night will induce it to a very conſiderable thickneſs. There are alſo two other *lakes* in the ſame county, the one called *Loch Monar*, which is conſiderably large, yet always keeps up the ſame rule of freezing over in February with every little froſt, but never before that month be the ſeaſon ever ſo rigorous; and the other in Straglaſh, which is as remarkable for a contrary quality. This lies in a ſort of bottom, between the ſides of two very high hills, and is itſelf conſiderably above the level of the reſt of the country. This *lake* freezes continually. It has always ice in the middle, even in the hotteſt ſummer months, though it thaws about the edges. The ſun by reflection from the hills on each ſide of this *lake* gives a very conſiderable heat; and there are many other *lakes* in the ſame ſort of ſituation, in the neighbouring country, which yet have nothing of this phænomenon; ſo that this, and the property of the other *lakes*, muſt be owing to ſomething peculiar to themſelves, not to their ſituation, or other accidents. The herbage about the ſides of this laſt mentioned *lake* is in a ſort of perpetual ſpring all the year round, and is much eſteemed by the country people, being found to fatten cattle more in a week, than the beſt land in the country beſide will do in a fortnight. The *lake* is very deep, and the water does not manifeſt any particular quality. Phil. Tranſ. N° 114.

The ſtrange effect of ſome *lakes* on their water being diſturbed, are recorded by many writers with an air of truth; but are to be examined, with great caution, before they are credited. Wagner, in his hiſtory of Swiſſerland, quotes no leſs than thirty-five authors, who ſay, that a water there called the *lake* of Pilate is of this kind, and that it cauſes tempeſts, rain, thunder, *&c.* if any thing be caſt into it; but the truth is, that it is a very tame puddle, ſcarce deſerving the name of a *lake*; and it is proved, by experience, that no conſequence at all attends the throwing it into confuſion by any means whatever. *Wagner*'s Hiſt. Helvet.

Subterranean LAKES. That there are in many places immenſe *ſubterranean lakes*, can ſcarce be doubted, becauſe we ſee them in ſome places; but their effects are often perceived where they are not ſeen, and puzzle the people who attempt to account for thoſe effects upon other principles. The famous Zirchnitzer *lake* in Carniola, which fills and empties itſelf, at times, in an impetuous manner, bringing up with its waters fiſh, and even wild fowl, communicates with another immenſe *ſubterranean lake* in the mountain Javornick; and according to its filling or emptying, the upper one is alſo filled and emptied. The grotto *podſpetſchio*, in the ſame country, gives another inſtance of ſuch a *ſubterranean lake*. The people of the neighbouring country enter the ſide of the mountain where this *lake* is by a ſmall opening, through which they go to a cavern of a great width and heighth; and at the end of this is a ſmall opening again, through which they go on to the edge of a vaſt ſubterranean piece of water. They go with torches, and find the water very clear and fine. It is ten cubits deep at the edge, and doubtleſs is much more in the middle. The water runs into this *lake* by a large channel, and runs out of it again by another, falling down a precipice into another *lake*, and that with ſuch a noiſe, that the report of a piſtol cannot be heard near it. Stones thrown in every way are heard to fall into water, and there is great reaſon to ſuppoſe the *lake* a German mile long; for at that diſtance there is another water diſcovered through ſuch another cleft of the rock, which ſtands at the ſame horizontal height as this, and is ſubject to the ſame accidents at the ſame times. This vaſt body of water ſometimes all runs off in a few minutes and leaves the baſon dry, and after ſome weeks it fills again with a frightful noiſe. As theſe accidents always happen to both the waters above-mentioned at the ſame time, they appear very plainly to be only the two ſides of the ſame *lake*. Phil. Tranſ. N° 191.

We have in England many of theſe reſervoirs, the water of which is always remarkably clear and cold, and is ſo loaded with ſpar, that it generally encruſts things very quickly that are put into it; and when raiſed into vapours, as a part of it ſometimes is, by the ſubterranean heat, or carried up with other vapours, ſtops at the cieling of the vaults, and there forms ſtalactitæ and other ſuch concretions. In many of theſe *lakes* alſo are found the round balls of ſpar, called ſtalagnitæ. They are compoſed of ſeveral cruſts gathering round ſome central nucleus, and often exceed the ſize of a ſchool boy's marble. Phil. Tranſ. N° 144.

In Pen-Park hole in Glouceſterſhire there is a remarkable inſtance of this, that ſtrange cavern containing one of the largeſt of the *lakes* in our kingdom. The hole itſelf was accidentally diſcovered by ſome miners, who were digging for lead ore; it is twenty nine fathoms deep from the ſurface, and is a vaſt cavern of the ſhape of a horſe-ſhoe, ſurrounded with rugged rocks and rough walls of earth, containing in the midſt a river or *ſubterranean lake* of twenty fathom broad and eight fathom deep, of the ſame cold and petrifying water with the other reſervoirs of this kind. The people of the country have an opinion that this water ebbs and flows with the tide, but it is an error. The water is higher in winter and lower in ſummer; but the decreaſe is ſlow and gradual at the proper ſeaſon, and ſo is the increaſe, never happening at any other time. There is in one part of the cieling of this cavern a vaſt hole, in at which ſome miners have crept, and ſaid they found lead ore very fine, and in great quantities; but an idle opinion of ſpirits prevents their purſuing the diſcovery. The flooring of this vaſt cavern is all of a white ſparry ſtone, ſpangled over with lead ore; and the rocks, which hang over head, are all glazed, as it were, with ſpars very bright and pellucid, and of very elegant figures. The higheſt part of the roof is nineteen yards above the level of the water, and there are two large rocks in it, all covered with mud at ſuch times as the water is not above them, as in ſummer it never is. The paſſages down into the hole, and the ſide cavities, are all covered with that ſort of ſpar, which uſually attends lead ore, and there is no living creature found in the place except ſome bats. The air in the deepeſt part is clear, and the place leſs damp than might be expected.

LAKE, or LAQUE, a preparation of different ſubſtances into a kind of magiſtery for the uſe of painters. One of the fineſt and firſt invented, of which was that of *gum lacca* or *laque*, from which all the reſt, as made by the ſame proceſs, are called by the common name *laques*.

The method of preparing theſe, in general, may be known by the example of that from the curcuma root of the ſhops, called turmeric root, the proceſs for the making of which is this. Take a pound of turmeric root in fine powder, three pints of water, and an ounce of ſalt of tartar: put all into a glazed earthen veſſel, and let them boil together over a clear gentle fire, till the water appears highly impregnated with the root, and will ſtain a paper to a beautiful yellow. Filtre this liquor, and gradually add to it a ſtrong ſolution of roch alum in water, till the yellow matter is all curdled together and precipitated: after this pour the whole into a filtre of paper, and the water will run off and leave the yellow matter behind. It is to be waſhed many times with freſh water, till the water comes off inſipid, and then is the beautiful yellow, called *laque* of turmeric, and uſed in painting. *Shaw*'s Lectures, p. 178.

In this manner may a *laque* be made of any of the tinging ſubſtances that are of a ſomewhat ſtrong texture, as madder, logwood, *&c.* but it will not ſucceed in the more tender ſpecies, as the flowers of roſes, violets, *&c.* as it deſtroys the nice arrangement of parts, in thoſe ſubjects, on which their colour depends.

A yellow *lake* for painting is to be made from broom flowers in the following manner. Make a lee of pot-aſhes and lime reaſonably ſtrong; in this boil at a gentle fire freſh broom flowers till they are white, the lee having extracted all their colour; then take out the flowers, and put the lee to boil in earthen veſſels over the fire; add as much alum as the liquor will diſſolve; then empty this lee into a veſſel of clean water, and it will give a yellow colour at the bottom. Let all ſettle, and decant off the clear liquor. Waſh this powder, which is found at the bottom, with more water, till all the ſalts of the lee are waſhed off; then ſeparate the yellow matter and dry it in the ſhade. It proves a very valuable yellow. *Neri*'s Art of Glaſs, p. 162.

LAMAC, a word uſed by ſome authors to expreſs gum arabic.

LAMARE, a word uſed by ſome of the chemical writers as a name for ſulphur.

LAMB (*Cycl.*)—LAMB *earth*, in huſbandry, is a whitiſh ſtony loam. The name ſeems only a corruption of the word *loam earth*. It is a clay, with an admixture of that ſort of ſtony matter which uſually conſtitutes lime ſtone, of fragments of lime ſtone, and of many ſmaller pieces of a ſtony matter, of a leſs firm concretion. Theſe ſtones are all of much the ſame colour with the earth, and the whole eaſily breaks and moulders upon putting water to it. It has uſually an admixture of ſea ſhells alſo in it, and, while in the ſtratum, is ſo hard as ſcarce to be cut by a ſpade. It is in great eſteem in many counties of England for making the earthen floors of barns, and other ſuch uſes. *Moreton*'s Northampt. p. 67.

LAMBENT *fire*. See the article FIRE.

LAME, in the manege, is uſed in ſeveral phraſes of that art; as *lame of an ear*, called in French *boiteux de l'oreille*, is ſaid of a horſe, when he halts upon a walk or trot, and keeps

keeps time to his halting with the motions of his head: for all *lame* horſes do not keep time in that manner.

LAME *of the bridle*, is uſed by way of raillery to ſignify the ſame thing.

LAMIA, in zoology, a name uſed by ſome authors for the *ſhark*. *Rondelet*, de Piſc. See SHARK.

LAMIODONTES, in natural hiſtory, the name given by Dr. Hill to the foſſile teeth of ſharks, called by the generality of authors *gloſſopetræ*, or ſtony tongues, a name founded on an erroneous opinion, of their having been the tongues of ſerpents turned into ſtone.

The ſeveral ſizes of the teeth of the ſame ſpecies, and thoſe of the ſeveral different ſpecies of ſharks afford us a vaſt variety of theſe foſſile ones. Their uſual colours are black, blueiſh, whitiſh, yellowiſh, or brown, and in ſhape they uſually approach to a triangular figure. Some of them are ſimple, others are tricuſpidate, having a ſmall point on each ſide the large one. Some of them are very long, others ſhorter, and ſome very broad in proportion to their length; others as remarkably ſlender and narrow. Many of them alſo are quite ſtrait, though ſeveral are found crooked. Theſe laſt are not bent any one particular way, but all ways and in all directions, ſome inward, ſome outward, others ſideways, and of theſe ſome to the right and others to the left. Many of them alſo have their edges plain, others ſerrated, and that more or leſs deeply; and ſome are undulated, or waved in the manner of a flaming ſword at their edges, and ſlightly ſerrated on theſe undulations. They are as various alſo in ſize as figure, ſome being found of four or five inches long, and the ſmaller of leſs than a quarter of an inch. See Tab. of Foſſils, Claſs 8. *Hill*'s Hiſt. of Foſſ. p. 644.

They are moſt uſually found with us in the ſtrata of blue clay, though ſometimes alſo in other ſubſtances, and are frequent in the clay pits of Richmond and other places. They are very frequent alſo in Germany, but no where ſo plentiful as in the iſland of Malta. Ibid. p. 643.

The Germans attribute many virtues to theſe foſſile teeth; they call them cordials, ſudorifics, and alexipharmics: and the people of Malta, where they are extremely plentiful, hang them about their childrens necks to promote dentition. They may poſſibly be of as much ſervice this way as an anodyne necklace; and if ſuſpended in ſuch a manner, that the child can get them to its mouth, may by their hardneſs and ſmoothneſs be of the ſame uſe as a piece of coral.

LAMIOLA, in ichthyology, a name by which ſome authors have called the maltha or *ſorrat*, a kind of ſhark. *Willughby*'s Hiſt. Piſc. p. 50. See MALTHA.

LAMIOLA is alſo the name given by the modern Italians to a fiſh, called in Cornwal the *tope*. It is a ſpecies of the *ſqualus*, called by the generality of authors *galeus canis*, and by Artedi the *ſqualus*, with the noſtrils placed near the mouth, and with the ſmall foramina near the eyes.

LAMIUM, *deadnettle*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of the labiated kind. The upper lip is hollowed in form of a ſpoon, and the lower is divided only into two ſegments, and reſembles the figure of a heart; both of them are alſo marginated, and reſemble the jaws of ſome animal. The cup of the flower is tubular, and is divided into five ſegments; from this ariſes the piſtil, which is fixed in the manner of a nail into the hinder part of the flower, and is ſurrounded by four embryos, which afterwards become four triangular ſhaped ſeeds, which ripen in the cup. *Tourn.* Inſt. p. 183.

The ſpecies of *lamium* enumerated by Mr. Tournefort are theſe. 1. The roundiſh leaved ſtinking *deadnettle*, which is the *galeopſis* of Dioſcorides. 2. The leſſer red flowered roundiſh and ſtinking *lamium*. 3. The red flowered long leaved *lamium*. 4. The common white flowered *lamium*, called *archangel* and white *deadnettle*. 5. The *lamium* with leaves marked round with white lines. 6. The pellitory leaved *lamium*. 7. The purple flowered mountain *lamium* with deeply divided leaves. 8. The common little red *lamium* with jagged leaves. 9. The *lamium* with leaves ſurrounding the ſtalks, called *henbit*.

Theſe are all the ſpecies which this author can allow to be genuine *lamiums*, but others have accounted many more, reckoning ſeveral of the caſſidæ, the galeopſis, and baum kind, as of this genus. See GALEOPSIS, *&c.*

The flowers of *deadnettles* have been greatly recommended in the fluor albus in women, and againſt floodings of the menſes. It is alſo ſaid to be a great vulnerary, and good in obſtructions of the viſcera.

LAMIUM *exoticum*, in botany, a name given to a ſpecies of *caſſida*. See CASSIDA.

LAMNE, in ichthyology, a name given by Appian, and ſome other of the old Greek authors, to the common *ſhark*, or as we uſually call it the white *ſhark*, the *lamia* and *canis carcharias* of authors. This is properly a ſpecies of *ſqualus*, and is accurately diſtinguiſhed by Artedi under the name of the *ſqualus*, with a flat back, and with numerous teeth ſerrated at the edges. See SQUALUS.

LAMP (*Cycl.*)—The flame in a *lamp* never conſumes the wick, till the wick be expoſed to the air by the *flames* falling downward; and from hence it may be inferred, that a way found out to keep the fuel, and conſequently the flame at the ſame height upon the wick would make it laſt a long time. Many ways have been deviſed to arrive at this, but it ſeems only poſſible to be done, in any degree of perfection, by hydroſtatics. Thus, let a *lamp* be made two or three inches deep, with a pipe coming from the bottom almoſt as high as the top of the veſſel; let it be filled ſo high with water as to cover the hole of the pipe at the bottom to the end, that the oil may not get in at the pipe, and ſo be loſt. Then let the oil be poured in, ſo as to fill the veſſel almoſt brim full, which muſt have a cover pierced with as many holes as there are wicks deſigned. When the veſſel is thus filled, and the wicks are lighted, if water falls in by drops at the pipe, it will always keep the oil at the ſame height, or very near; the weight of the water being to that of the oil as 20 $\frac{8}{11}$ to 19, which in two or three inches make no great difference. If the water runs faſter than the oil waſtes, it will only run over at the top of the pipe, and what does not run over will come under the oil, and keep it at the ſame height. Phil. Tranſ. N° 245, p. 388.

Perpetual LAMP. The teſtimonies of Pliny, St. Auſtin and others, have led many to believe, that the antients had the invention of *perpetual lamps*: and ſome moderns have attempted to find out the ſecret, but hitherto in vain. Indeed it ſeems no eaſy matter to find out, either a *perpetual wick*, or a *perpetual oil*. The curious may read Dr. Plot's conjectures on the ſubject in the Philoſophical Tranſactions, N°166, or in Lowthorp's abridgment, Vol. 3. p. 636. But few, we believe, will give themſelves the trouble of ſearching for the ſecret, when they conſider, that the credulity of Pliny and St. Auſtin was ſuch, that their teſtimony does not ſeem a ſufficient evidence to induce us to believe, that a *lamp* was ever contrived to burn for 1000 or 1500 years; much leſs is it credible, that the antients had the ſecret of making one burn for ever.

LAMPERN, a river fiſh of the *lamprey* kind found in many parts of England, particularly in Oxfordſhire and the neighbouring counties, and there called the *pride of the Iſis*. The Latin authors call it the *lampetra parva* and *muſtela fluviatilis*. It is a ſmall fiſh, of a browniſh or blueiſh black upon the back, and a fine ſilver white on the belly. Its mouth is circular or elliptic, and furniſhed with ſix or ſeven teeth, and over theſe a ſmall ſemi-circular bone. In the middle of the head it has a hollow or ſmall tube, like the whale; the uſe of this is to admit the water and air, while the mouth is applied cloſe to the rocks; its gills are ſeven holes on each ſide, and has two fins on the back. *Willughby*'s Hiſt. Piſc. p. 104. *Geſner*, p. 706.

The word *lampern* is uſed by the common people in England for one ſpecies of the *lampetra*, and is not to be confounded with the other called the *lamprey*, or the *lamprey eel*. The near alliance in ſound between the two words *lampern* and *lamprey* has deceived ſeveral, to ſuppoſe they meant the ſame fiſh; and even ſome authors have not diſtinguiſhed them, but the determinate ſenſe of the words is this: they are the names of two fiſh, both of the genus of the *lampetra*, according to the generality of writers, and of the *petromyzon*, according to the new ſyſtem of Artedi. The *lampern* is that ſpecies of the genus, which is called by Geſner and Willughby the ſmall river *lampetra*, the *lampetra parva fluviatilis*. It is the *lampetra ſubcinerea*, or the greyiſh *lampetra*, and *muſtela* of the old Latin authors, as Pliny, *&c.* Caſſiodore has called it *exormiſtos*; and Albertus, *muræna*. Dr. Plot calls this ſpecies the *pride of the Iſis*, from its being found in great plenty and perfection in that river. It is the *neunaugen* of the Germans.

The *lamprey* is the fiſh called, by the ſame authors, either ſimply the *lampetra*, or the *lampetra major*, *lampetra marina*, or *lampetra maculoſa*.

The *lampern* has many other names among writers, ſuch as *pricka* and *pryk*, from the German name *pryk*; and *nattingus*, from the *natting* of the Swedes. But with all theſe variety of names, there were none that could diſtinguiſh the two fiſh from one another, till Artedi adapted names to them, and called the firſt, or *lampern*, the *petromyzon*, with only one row of very ſmall teeth in the verge of the mouth, beſide the lower larger ones; and the other, or the *lamprey*, the ſpotted *petromyzon*, with about twenty rows of teeth. *Artedi*, Gen. Piſc. p. 90. See PETROMYZON and LAMPETRA.

LAMPETRA, the *lamprey*, in zoology, a fiſh of the anguilliform kind, diſtinguiſhed from all the reſt by having a round or oval mouth, placed at the end of the ſnout, and having no fins either at the gills or belly. This is the character of the *lampetra* genus, of which there are ſeveral ſpecies. The *lampern*, *lamprey eel*, *brick*, *mucu*, *&c.* *Ray*'s Ichthyog. p. 104. See LAMPERN, &c.

LAMPETRA *Indica*, in zoology, the name of an Eaſt-Indian fiſh of the *lamprey* kind, caught in ſtanding waters, and called by the Dutch there *bont ael*, and *neegen oog*, or nine eyes. *Ray*'s Ichthyogr. Append. p. 4. See the article BONT-*ael*.

LAMPREY-*eel*, the Engliſh name of the common *lamprey*, or *lampetra*. Its back is of a blackiſh hue, with ſome an-

gular whitiſh ſpots. The ſkin is tough, but much thinner than that of the eel. Its mouth is rounded, and it lays ſo faſt hold of rocks, or wood, with this, that it ſeems to ſuck them, and ſticks ſo firmly, as not to be eaſily removed. It can however contract this mouth lengthwiſe, and ſhut it at pleaſure. It has a white ſpot in the middle of its forehead, between the eyes, and before that a hole, ſurrounded with a thin membrane, by which it admits the water and air, while its mouth lies cloſely on the rock. The gills are placed within ſeven round holes on each ſide, and the edge of its mouth is ſurrounded with a range of ſhort fibrillæ, which have by ſome been miſtaken for teeth; but are really of no other uſe, than to affix its mouth the more firmly. Its teeth are placed within its mouth, and there are twenty rows of them, the inner ones being the larger. Theſe are diſpoſed in rows from the center toward the circumference, and are five, ſix, or ſeven in a row.

It is a fiſh that equally lives in ſalt and freſh water. In the month of March it commonly runs up into the rivers, and is then moſt valuable for the table, as being fat and full of eggs. *Geſner*, de Aquat. p. 696.

The *lamprey-eel* is the *echeneis* of Oppian, and ſome other of the old Greek writers, and the *galaxias* of Galen. It is very different from what we call the *lampern*, though of the ſame genus. See LAMPERN and LAMPETRA.

LAMPRILLON, or LAMPREYON, a name by which ſome authors have called that particular ſpecies of *lamprey*, which we by way of diſtinction call *lampern*. *Willughby*, Hiſt. Piſc. p. 104. See LAMPERN.

LAMPSANA, *nipplewort*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is compoſed of a number of ſemifloſcules, placed on the embryo's, and contained in a one leaved jagged cup, which finally becomes a ſtriated ſeed veſſel, containing narrow and pointed ſeeds.

There is no other ſpecies of this plant, but the common *nipplewort*. *Tourn.* Hiſt. p. 479.

LAMPUGA, in zoology, a name given by ſome authors to the fiſh more uſually known by the name of *ſtromateus*. *Willughby*, Hiſt. Piſc. p. 156. See the article STROMATEUS.

LAMPUGO, in ichthyography, a name given by many to the *hippurus*, a ſea fiſh, caught on the coaſt of Spain, and ſuppoſed by ſome to be the ſame with the *dorado*. *Willughby*, Hiſt. Piſc. p. 213. See HIPPURUS.

LANARIA, or *Herba* LANARIA, in botany, a name given by the antient Romans to a plant called *ſtruthium* by the Greeks, and uſed in the cleanſing of wool. The plant was of the thiſtle kind, and had large roots, and very prickly leaves. Some have ſuppoſed that the *chaſcuſa* of the antients was the ſame with the *lanaria herba*, or *ſtruthium*; but this appears to be a great error, for the *chaſcuſa* of the Greeks is the *antirrhinum* of the Latins, which Pliny deſcribes to have leaves like flax.

LANATA, in botany, a name given by Cordus, and ſome other authors, to the *aria Theophraſti*, or *white beam tree*. *Ger.* Emac. Ind. 2.

LANCARIM *ſpring*, the name of a medicated water of Glamorganſhire. It has its name from a town near which it riſes, and has been very long famous in the place for the cure of the king's evil. The body of water is about an ell broad, and runs between two hills covered with wood. About twelve yards from this ſpring the rill falls from a rock of about eight or nine feet high, with a conſiderable noiſe. The ſpring is very clear, and riſes out of a pure white marl. The cures that have been performed there are proofs of a real power in the water; but there is ſome queſtion, whether the water, or its motion and coldneſs does the good; for the people, who come for relief, always drink of the ſpring, and bath the part afterwards in the fall below. It is generally ſuppoſed that the lime-ſtone rocks communicate a virtue to it, by which it cures internally; but it has been often found, that the holding a limb diſordered with the evil in the ſtrong current of a mill tail, has cured it; and there is the ſame advantage in the fall of this water. Philoſ. Tranſ. N° 233.

LANCEA *Chriſti*, in botany, a name given by ſome authors to the *ophioglоſſum*, or adder's tongue, a ſmall herb found in moiſt places, with a ſingle ſtem of ſeeds. *Ger.* Emac. Ind. 2.

LANCEARII, in middle age writers, ſoldiers whoſe chief weapon was the lance. They were in great eſteem formerly. *Pitiſc.* in voc.

LANCEOLA, in botany, a name given by ſome authors to that ſpecies of plantain called *rib-wort*, or *plantago quinquenervia*, by moſt authors. *Ger.* Emac. Ind. 2.

LANCEOLATED *leaf*, among botaniſts. See LEAF.

LAND (*Cycl.*)—*Clay* LAND. The *clay lands* in different parts of England are of different colours, as blue, black, yellow, white, and red. Of theſe the black and the yellow are every where found the beſt for corn; the red is very good, but the white and the blue are the worſt. Some of the blue in particular is of ſuch a ſtubborn nature and diſpoſition, that nothing can ſubdue it; and is ſo greedy and voracious, that nothing will ſatiate it, without the utmoſt induſtry. Some *clay lands* are more pinguid, and others more ſlippery, but all of them are very tenacious of water upon the ſurface, where it ſtagnates and chills the plant, inſtead of penetrating and nouriſhing it; and in dry ſeaſons they become ſo hard, that the dews cannot penetrate them. Wheat, barley, grey peaſe, and horſe beans, are the principal produce of theſe ſort of lands; and that the farmer may know which of his untried *lands* are of this kind, he muſt obſerve their natural productions, and if he finds gooſe-graſs, or chavers, with wild tanzy, great daiſies, thiſtles, May weed, and ſome red poppies, he may be aſſured the *land* that produces them is of this kind.

Some of theſe *clays* will bear exceeding good crops of clover, or rye graſs, and if well manured and fed, they will anſwer the expence by the richneſs of the crop. The beſt manures for them are dung, particularly horſe dung, aſhes, lime, ſoot, pigeons dung, malt duſt, and the dung of ſheep, by the folding them upon the *land* in different places. *Mortimer*'s Huſbandry, p. 68.

Clays hold the manure that is beſtowed on them better than any other *lands* whatever, and yield the beſt grain of any, eſpecially where there is a mixture of lime-ſtone with them. It is the common practice of the farmers of England to ſow theſe *lands* at firſt breaking up with black oats; they then fallow them, and after this ſow them with wheat or barley, and the etch crop with either oats, peaſe, or beans.

Bog LAND. See BOG.

Chalk LAND. See CHALK.

Chiſley LAND. See CHISLEY.

Gravelly LAND. See GRAVELLY.

Marſh LAND. See MARSHES.

Meadow LAND. See MEADOW.

Sandy LAND. See SAND.

Wood LAND. See WOOD.

Burning of LAND. See BURNING.

Incloſing of LAND. See INCLOSING *of land*.

Overflowing of LANDS. See OVERFLOWING.

LAND *layed*, at ſea. They ſay the *land is layed*, when a ſhip is juſt got out of ſight of the *land*.

LAND *mark*, at ſea, is any mountain, rock, ſteeple, wind-mill, a tree, or the like, near the ſea-ſide, which ſerve to direct ſhips, paſſing by, how to ſteer, ſo as to avoid certain dangers, be they rocks, ſhoals, whirlpools, *&c.*

LAND *ſhut in*, at ſea. When another point of *land* hinders the ſight of that which a ſhip came from, then they ſay the *land is ſhut in*.

LAND *to*, at ſea. When a ſhip lies ſo far from the ſhore, that ſhe can but juſt ken *land*; then ſhe is ſaid to lie *land to*.

LAND *turn*, at ſea, is a wind that blows from the ſhore, in the night, at certain times, in moſt hot countries.

Setting the LAND, at ſea, is obſerving by the compaſs how it bears.

Head LAND, or *Point of land*, in the ſea language, is that which lies farther out into the ſea than the reſt. See POINT, CAPE, *&c. Cycl.*

LANE, in the military art, is uſed when men are drawn up in two ranks facing one another. This is called *making a lane*, and is generally done in the ſtreets through which a great perſon is to paſs, as a mark of honour. But ſoldiers are often drawn up in this manner, when an offender is to run the gauntlet, each having a ſmall wand or ſwitch in his hand, to whip him as he paſſes.

LANGUENTE, in the Italian muſic, is uſed to denote a languiſhing and ſoft manner of ſinging.

LANIS *de creſcentia Walliæ traducendis abſque cuſtuma*, *&c.* an antient writ that lies to the cuſtomer of a port, to permit one to paſs wool without paying cuſtom, he having paid it before in Wales. Reg. Orig. 279. *Blount*, *Cowel.*

LANISTA, in antiquity, is ſometimes uſed to ſignify an *executioner*, but more frequently for a maſter-gladiator, who taught the uſe of arms, and had always people under them, ready to exhibit ſhews of that kind. For which purpoſe, they either purchaſed gladiators, or educated children, that had been expoſed, in that art. *Pitiſc.* in voc.

LANISTA was alſo uſed to denote one who taught game-cocks to fight.

LANIUS, in zoology, the name of a ſpecies of ſhort winged hawk, called in Engliſh the *butcher bird*. It is the ſmalleſt of all the European birds of prey, yet is very fierce and deſtructive. Its beak is all the way ſtrait, except juſt at the end, where it is ſlightly hooked, and its tail faſhioned like that of the magpye, the outer feathers being the ſhorteſt, the reſt gradually longer; for which reaſon ſome have called it the *pica*. The antients called it the *tyrannus*, and in Engliſh we ſometimes alſo call it the *ſhrike*.

There are three ſpecies of the *lanius*: 1. The common larger kind, called the *mattageſs*. 2. The ſmaller, called the *fluſher*. See the articles MATTAGESS and FLUSHER. And 3. The *lanius minor*, or grey little butcher bird. See Tab. of Birds, N° 5. and *Ray*'s Ornitholog. p. 52.

LANIUS *minor cinereus*, the little grey butcher bird, the name of a very ſmall ſpecies of the *lanius*. It has a white ſpot on each ſhoulder, and a tranſverſe black ſtreak over the top of the beak. Its head is of a pale brown, and its back

back brown while young, but afterwards of a pale grey; its rump is white, and its breaſt and belly of a pale greyiſh hue. Its beak is ſtrait all the way to the point, where it is a little hooked. It is common in Italy and elſewhere, and is a very great deſtroyer of the wrens, and other ſmall birds. *Ray*'s Ornithol. p. 55.

LANNARET, in zoology, a hawk of the long winged kind, the male of the *lannarius*, which being ſmaller than the female, is called *lannaret*, while that is called ſimply the *lannar*. *Ray*'s Ornithol. p. 48. See LANNARIUS.

LANNARIUS, in zoology, the name of a bird of the long winged hawk kind, called in Engliſh the *lannar*, and the male the *lannaret*. Its beak and legs are blue, and its head and neck variegated with large ſtreaks of black and white. Its back, wings, and tail are not variegated, unleſs with a few ſmall white ſpots, and its wings, when extended, are ſeen ſpeckled underneath with ſmall round white ſpots. Its neck is very ſhort, as are alſo its legs. It is common in France, and abides the whole year there, and is very docile, and ſerves to all the purpoſes of hawking. In Italy the ſpecies ſeems ſomething different, having much of a yellowiſh brown about the ſhoulders, and being indocile, and of no uſe in ſporting. *Ray*'s Ornithol. p. 48.

LANNIERS, or LANNIARDS, in a ſhip, are ſmall ropes reeved into the dead mens eyes of all the ſhrowds and chains. Their uſe is to ſlacken, or ſet taught the ſhrowds. The ſtays alſo of all maſts are ſet taught by *lanniers*. That rope, which faſtens the ſtopper of the halliards to them, is alſo called a *lannier*.

LANSPESSADE, in military affairs. See the article ANSPASSADE, *Cycl.*

LANTANA, in botany, the name given by Linnæus to a genus of plants comprehending the *camara* of Plumier, and the *myrobatindum* of Vaillant, with the *pſeudoviburnum* of Rivinus. The characters are theſe. The cup is a very ſhort one leaved perianthium of a tubular cloſe figure, very lightly divided into four ſegments at the edge, and remaining after the flower is fallen. The flower conſiſts of one petal. The tube is cylindric and ſlender, and longer than the cup; it is a little oblique; the verge is plain, obtuſe, and very ſlightly divided into five ſegments. The ſtamina are four extremely minute filaments; they ſtand in the center of the flower, and two of them are a little ſhorter than the other two. The antheræ are roundiſh. The germen of the piſtil is roundiſh. The ſtyle is capillary, and of the length of the ſtamina, and the ſtigma ſtands like a wedge on the top of the ſtyle, in an oblique manner. The fruit is an unilocular drupe of a roundiſh figure. The ſeed is a nut of a roundiſh, but ſomewhat pyramidal figure, containing two cells, in each of which there is an oblong kernel. The eſſential character of this genus is in the very remarkable figure of the ſtigma. *Linnæi* Gen. Pl. p. 303. *Plum.* 2. *Dillen*, Hort. Elth. p. 56, 57. *Vaillant*, A. G. 1722. *Rivin.* 1. 172.

LANTERNS *(Cycl.)* are uſed at ſieges in the night time, upon the batteries; but theſe muſt be blind or dark *lanterns*. There is always great proviſion of them in all ſtore-houſes.

LANTERN *fiſh*, the Engliſh name of a fiſh of the ſoal kind, but ſmaller, and ſmoother to the touch, called in Latin *arnogl ſſus*. *Willughby*, Hiſt. Piſc. p. 102.

LANTERN *fly*, in natural hiſtory, the name of a very ſingular kind of inſect produced in the Weſt-Indies, and carrying a ſtrong light with it in the night. The ſtructure of the trunk in this inſect is of the ſame kind with that of the cicada, and as it wants the power of making the noiſe for which the cicada is ſo famous, it belongs, according to Mr. Reaumur's diſtinctions, to that ſpecies of inſect called the *procigale*, or *procicada*.

The glow-worm, and the luminous beetles, with all the other luminous inſects we are acquainted with in this part of the world, diffuſe their light from a part which is near the extremity of the body, and under the belly, but the *lantern fly* gives it from its head. It differs alſo greatly in the degree of light; for this, in all the inſects we are acquainted with, is very feeble; whereas, in this fly it is ſo ſtrong, that Mrs. Morian, who is the firſt that well deſcribed it, ſays ſhe could read a ſmall print in a dark night by the light that one of them gave. The eyes of this creature are placed very near the part from which the light iſſues, and it is commonly ſuppoſed, that the uſe of the light is to ſhew the creature the objects it paſſes by in its flight; but if we conſider the effect of a light ſo placed, in regard to ourſelves, we ſhall find that it would by no means anſwer the ſame purpoſe to us. If our whole forehead was covered with a lambent flame in the night, it would rather blind us, than ſhew us any diſtant objects. The head of this creature, ſtrictly ſpeaking, is very ſhort, not exceeding the length of one of the rings of the body, if it be meaſured from its joining with the corcelet to its joining with the *lantern*; but if that part be accounted a portion of the head, then the head is equal in length to the whole body. This *lantern* is wider than it is deep, or thick, and has near its origin a large protuberance, which gives it a bunched or humped look. There are ſeveral tubercles and lines on it of a reddiſh colour. The ground colour is an olive brown, and underneath it has one large rib running all the way along it, from end to end, and dividing it into two, and by the ſides of that there are ſome others. Theſe are all reddiſh, and thoſe neareſt the edges have ſmall rows of ſpines running along them. Over each of the eyes there is a round granulated prominence, which ſeems to have been a collection of ſmaller eyes; and if ſo, the animal is ſupplied with the organs of viſion in a different manner from all other known creatures. But there requires an examination of the creature on the ſpot, and while alive, in order to find out this. The upper pair of wings are not perfectly tranſparent, they are dotted with white in ſome places, and are variegated near their origin with ſeveral blackiſh ſpots. The under pair are more tranſparent than the upper, they are much ſhorter, and are broader than the others. Theſe have each a large and beautiful round ſpot near the extremity, reſembling that on the wing of the peacock butterfly. The colours of the circles of theſe eyes are brown and olive; the laſt colour very bright and clear, the other very duſky and obſcure. The ſpots are ſo large, that they appear very beautiful. *Reaumur*, Hiſt. Inſ. Vol. 9. p. 247.

LANTERNISTS, a name aſſumed by the academicians of Toulouſe. See ACADEMY, *Cycl.*

LAPACTICS, a term uſed by the old writers in medicine to expreſs ſuch things as purged by ſtool, or at leaſt gently looſened the belly. It was ſometimes applied to the cathartic medicines, and ſometimes to thoſe foods which were of this tendency. *Caſt.* Lex. Med. in voc.

LAPARA, a word uſed by ſome writers to expreſs the flanks, or that part which is ſituated on each ſide the body, between the ſpurious ribs and the hips. *Caſt.* L. Med. in voc.

LAPATHUM, *dock*, in botany, the name of a genus of plants; the characters of which are the ſame with thoſe of ſorrel, [ſee SORREL] but that the leaves of the *dock* kind have not that acid taſte which thoſe of the ſorrel have.

The ſpecies of *dock* enumerated by Mr. Tournefort are theſe. 1. The common garden *dock* with oblong leaves. 2. The ſharp pointed *dock* with plane ſmooth leaves. 3. The ſharp pointed *dock* with curled leaves. 4. The ſharp pointed *dock* with red, or red veined leaves, commonly called the *bloody dock*. 5. The ſharp pointed *dock* with gold yellow flowers. 6. The leaſt *dock*. 7. The water *dock* with diers weed leaves. 8. The *dock* with leſs pointed leaves. 9. The broad leaved garden *dock*, called *monks rhubarb*. 10. The round leaved Alpine *dock*. 11. The round leaved Alpine *dock*, with the pedicles, and the middle ribs of the leaves, of a beautiful green. 12. The great water *dock*. 13. The leſſer water *dock*. 14. The elegant ſinuated *dock*, called the *fiddle dock*, from the ſhape of its lower leaves. 15. The ſtinking ſea *dock*. *Tourn.* Inſt. p. 504.

The great water *dock* has been long famous in medicine. Muntingius wrote a whole treatiſe on it, under the title of *de Britannica antiquorum vera*. The roots are principally uſed, and are ſaid to be of great ſervice in the jaundice, in the herpes, and eryſipelas, and in the diſpoſing inveterate ulcers to heal. It is alſo ſaid to be a ſovereign remedy in quinzies. *Lemery*, Dict. des Drog.

The *lapathum acutum*, or ſharp pointed leaved *dock*, is as eminent, as an antiſcorbutic, and a cleanſer of the blood. It is alſo uſed externally in ointments againſt the itch, and other cutaneous foulneſſes.

The common ſorrel, which is another ſpecies of the *lapathum*, is well known as a gentle acid, a cooler, and ſubaſtringent. It is excellent in fevers, in which it cools the mouth, and allays thirſt. Schroder goes ſo far as to recommend a conſerve of the freſh leaves in the plague, and in all peſtilential, petechial, and malignant fevers. *Dale*. See SORREL.

LAPHIATI, in zoology, the name by which the people of Lemnos call a ſpecies of ſerpent, ſuppoſed by Bellonius to be the ſame with the *elaps*, or *elaphis* of the antients. See ELAPS.

LAPIS *(Cycl.)*—LAPIS *Arabicus*, in the natural hiſtory of the antients, the name of a ſtone of a fine white colour, reſembling the pureſt ivory, and which, though naturally of a firm, ſolid, and compact texture, yet, when burnt, became light, porous, and ſpungy, and aſſumed the figure and appearance of a pumice; and was uſed like it in the compoſitions of the antient phyſicians for cleaning the teeth. *Hill*'s Theophraſt. p. 51.

LAPIS *æroſus*, in natural hiſtory, a name given to ſeveral ſorts of ſtones, and other foſſils, which had lain in the neighbourhood of copper mines, and been impregnated with particles of copper, though not in a ſufficient degree, to be thought worthy the name of *copper ores*. See LAPIS *atramentarius*, infra.

The ſame ſort of ſtones were alſo ſometimes called *chalcites*, which made ſome confuſion, as it gave occaſion to confound them with the true *chalcitis*. See CHALCITIS.

LAPIS *aſſius*, in the natural hiſtory of the antients, the name of a ſtone, called alſo *ſarcophagus*, from its power of conſuming fleſh.

It was a ſtone much uſed among the Greeks in their ſepultures, and is recorded to have always perfectly conſumed the fleſh of human bodies, buried in it, in forty days. This property it was much famed for, and all the antient naturaliſts mention it. There was another very ſingular quality alſo in it, but whether in all, or only in ſome peculiar pieces of it, is not known; that is, its turning into ſtone any thing that was put into veſſels made of it. This is recorded only by Mutianus and Theophraſtus, except that Pliny had copied it from theſe authors, and ſome of the later writers on theſe ſubjects from him. The account Mutianus gives of it is, that it converted into ſtone the ſhoes of perſons buried in it, as alſo the utenſils which it was, in ſome places, cuſtomary to bury with the dead, particularly thoſe which the perſon, while living, moſt delighted in. The utenſils this author mentions, are ſuch as muſt have been made of very different materials; and hence it appears that this ſtone had a power of conſuming only fleſh, but that its petrifying quality extended to ſubſtances of very different kinds. Whether ever it really poſſeſſed this laſt quality has been much doubted, and many, from the ſeeming improbability of it, have been afraid to record it. What has much encouraged the general diſbelief of it, is, Mutianus's account of its taking place on ſubſtances of very different kinds and textures; but this is no real objection, and the whole account has probably truth in it. Petrifactions in thoſe early days might not be diſtinguiſhed from incruſtations of ſparry and ſtony matter on the ſurfaces of bodies only, as we find they are not with the generality of the world even to this day; the incruſtations of ſpar on moſſes and other ſubſtances in ſome of our ſprings, being at this time called by many *petrified moſs*, &c. and incruſtations, like theſe, might eaſily be formed on ſubſtances encloſed in veſſels made of this ſtone, by water paſſing through its pores, diſlodging from the common maſs of the ſtone, and carrying with it particles of ſuch ſpar as it contained; and afterwards falling in repeated drops on whatever lay in its way, it might again depoſit them on ſuch ſubſtances, in form of incruſtations. By this means, things made of ever ſo different matter, which happened to be encloſed, and in the way of the paſſage of the water, would be equally encruſted with, and in appearance turned into ſtone, without regard to the different configuration of their pores and parts.

The place from whence the antients tell us they had this ſtone was Aſſos, a city in Lycia, in the neighbourhood of which it was dug; and De Boot informs us, that in that country, and in ſome parts of the Eaſt, there are alſo ſtones of this kind, which if tied to the bodies of living perſons, would in the ſame manner conſume their fleſh. *Hill*'s Notes on Theophraſtus, p. 14.

LAPIS *atramentarius*, the *copper ſtone*. See PYRITES.

LAPIS *Bononienſis*, the *Bolonian ſtone*. The art of preparing this ſtone ſo as to make it ſhine in the dark, has been ſuppoſed by many to be long loſt in its utmoſt perfection, and indeed that there were but few people who were ever truly poſſeſſed of it. The whole is, however, deſcribed at large in Hook's Philoſophical Collections, by Sir Marc Antonio Cellio, and in a book of the ſame author, publiſhed at Rome in 1680, expreſsly on that ſubject.

The principal places near Bolonia, where this *ſtone* is found, are, 1. At Pradalbino. 2. In a ſmall brook near the village Roncania, where it is found among a large quantity of a white ſtone like ſal armoniac, and an eruginary ſtone, which yields a vitriolic efflorescence: theſe are probably a fibroſe talc, and a pyrites. And 3. At Monte Patemo, which is the moſt noted place of all for theſe *ſtones*; and thoſe found here are ſaid to ſucceed beſt in the operation. The ground where it is found is barren, and abounds with ſmall globular gold coloured pyritæ. The *ſtone* is found moſt eaſily after rain; when the earth being waſhed away, the ſeveral maſſes of it appear as bright as burniſhed ſilver, or with the glittering of talc, reſembling the gloſs of a looking glaſs. Il Foſoro de *Marc. Anton. Cellio.*

The *ſtone* is of no certain figure, but is ſometimes round, ſometimes oblong and cylindric, ſometimes lenticular; the laſt kind uſually proves the beſt of all, as being more ſhining and tranſparent. They are uſually as big as an orange, and ſometimes are found of five pound weight, and are very light, conſidering their bulk. They are of various colours; ſome are aſh coloured, ſome of a ſky blue, ſome of a ferrugineous colour, others yellow, others greyiſh white, and ſome almoſt perfectly white. The beſt for uſe are the ſky coloured and the white. When this *ſtone* is prepared, it affords an efflorescence, in which lies its principal virtue of receiving light; which it does, either from the ſun, the moon, the common day light, or a flame, but in different degrees. When carried into the dark, it appears exactly like a burning coal, and the light it gives is ſufficient to read by, if the letters be placed near the *ſtone*. It does not retain its light long, but requires often renewing; and when well prepared, its virtues will laſt five or ſix years, but ſeldom longer. The way of ſeeing it to the greateſt advantage, is after the eye has been kept for ſome time in a dark room, and the ſtone is brought in there immediately from being held in the ſun.

The beſt method of preparing it is this: make a cylindric furnace of iron or copper plates, ſeven inches in diameter, and as many in height. Line the inſide of it with a ſtrong lute, ſo that the inſide may be ſix inches wide in the clear hollow: at the top of this there are to be made four notches of 2 ¼ inches deep, and 1 ½ inch wide; to this make ſuch a cylindrical part of the ſame diameter, but a little higher, and make at the bottom two aſh-holes, or air-holes, big enough to put in one's hand. Line this, as the other, with good lute, and give it a bottom of lute, that it may the more ſtrongly reflect the heat, and make a cover for the top, lining it in the ſame manner with lute: into this furnace put an iron wire grate near the bottom, to ſuſtain the coals, and freely admit the air. On this grate lay ſome pieces of lighted charcoal, and on theſe put others not lighted, all broken to the ſize of a walnut, or thereabouts. Some of the ſtones muſt be powdered, and thoſe which are to be calcined muſt be dipped in ſtrong aqua vitæ, and while wet rolled in this powder. Theſe ſtones, thus covered, muſt be laid upon the bed of charcoal cloſe to one another, and another bed of charcoal, in the like ſmall pieces, muſt be laid over them up to the top of the furnace. The cover of the furnace is then to be put on, and the fire lighted. When the charcoal is all burnt away, and the whole is cold, take out the ſtones, and taking out the cruſt from them, wrap them up in ſilk, and keep them in a cloſe box for uſe.

The cruſt which is taken off from the ſtones is to be preſerved; it ſhines as well as the ſtone, and is to be beat to powder, and rubbed over any thing that is to be made to ſhine; the thing being firſt daubed over with the white of an egg: this will make it ſtick on, and the whole will ſhine like the ſtone.

The furnace here deſcribed is not abſolutely neceſſary to the ſucceſs of the operation; but it is convenient to know the quantity of charcoal neceſſary to give the ſhining quality to the ſtone, ſince an over heat deſtroys it, and too ſmall a degree is not ſufficient to raiſe it.

LAPIS *caudæ cancri*, in natural hiſtory, a name given by Geſner, and ſome other writers, to the foſſile ſhells, ſince called *tubuli marini concamerati*, and by ſome *polythalamii* and *ortho-ceratitæ*. See the article TUBULUS *concameratus*.

Colicus LAPIS. See the article COLIC-*ſtone*.

LAPIS *corneus*, *horn ſtone*, a name given by many of the German authors to flint, which ſome of them have alſo very improperly called pyrites, or the fire ſtone, becauſe it is uſed to ſtrike fire with.

Butner, in his *corallographia ſubterranea*, has a remarkable ſyſtem in regard to flint. He is of opinion, that all flints are foſſile corals. He ſets out with a juſt principle, *viz.* that of thoſe things found under ground exactly reſembling animals, vegetables, or parts of them, which may be now found recent, living, or growing, not one is of true mineral origin; but that they are in reality ſtones, formed in or upon the very ſhells they repreſent. As it is very eaſy to find corals that reſemble our common flints, and as many of the branched, and oddly figured flints, found in our chalk pits, have ſomething of the external ſhape of ſome of the ſpecies of white corals; he concludes, that they were originally ſuch, and have been only altered into the ſtate and ſubſtance we find them in, by time. The trunk and branches of the white corals may be found very nicely repreſented in ſome of the oblong ramoſe flints found in ſtrata of chalk; and in theſe, as well as in thoſe now found in the ſea, ſome of the branches are intire, and ſome are truncated. The inner ſubſtance of the corals, and that of theſe flints, is ſmooth, hard, and uniform; and the flints have a white thin cruſt on their outſide as the corals have. Theſe are the [a] principal foundations on which he has built his new opinion. But it is to be obſerved, that the reſemblances of flints and corals are but very ſlight and ſuperficial, and we have no proof from their internal ſtructure of their being at all alike.

[a] Vid. *Butner*, Corallog. Subter.]

LAPIS *divinus*, a ſpecies of jaſper, ſo called from its imaginary virtues, as a diuretic and expeller of poiſons. It is found in the ſhores of the Ganges and other parts of the Eaſt Indies.

The Turks are extremely fond of it in their curious works, particularly for the handles of their ſabres.

LAPIS *Hyenius*. See HYENIUS *Lapis*.

LAPIS *Hybernicus*, a foſſile of the ſlate kind, ſo ſtrongly impregnated with alum as to deſerve the name of an alum ore; it often contains alſo a portion of vitriol, and is found in many parts of Ireland, as well as in ſeveral of our own counties.

It is given in powder as a ſtyptic in all kinds of hæmorrhages with ſucceſs; but, as it owes all its virtues to alum, it might be full as prudent to give this ſalt in its ſtead.

LAPIS *Iſlebeianus*. See ISLEBEIANUS *Lapis*.

LAPIS *Judaicus*. See JUDAICUS *lapis*.

LAPIS *lazuli*. The method of making the Venetian counterfeit *lapis lazuli* is this. Melt in a pot, in a glaſs-houſe furnace, equal quantities of the faireſt lattimo, and the whiteſt cryſtalline glaſs; when this is in fuſion, mix into it, by ſmall parcels at a time, the blue ſmalt uſed by the painters; make frequent proofs of the colour, and when it is right let the whole ſtand twelve hours, and then work it. If the metal riſe in the pot, put in a piece of leaf gold to keep it down; this makes a fine plain blue ſubſtance, repreſenting the plain blue parts of the true natural *lapis lazuli*. *Neri*'s Art of Glaſs, p. 117.

Lapis lazuli ſtands recommended againſt apoplexies, epilepſies, melancholy, and quartan agues; but its violent operation, as a purgative and emetic, has frighted people out of the uſe of it; and the preſent practice takes no notice of it in any of the above intentions. The chemical writers give us proceſſes for magiſteries, tinctures, and elixirs of *lapis lazuli*, but they are wholly out of uſe.

LAPIS *lucis*, the *ſtone of light*, in the materia medica of the Arabs, a name given to the braſſy marcaſite or pyrites. The Arabians have adopted this. Aviſenna ſuppoſes this ſubſtance to be called ſo, becauſe it was uſed after calcination for diſeaſes of the eyes. It is very probable, that where vitriolic medicines take place, the caput mortuum of this foſſile, which is only a colcothar of vitriol, may be of uſe. But its virtues in this reſpect can never be ſuppoſed ſo eminent, as to have entitled it to the pompous name it bears. It ſeems more probable, that it was called the *ſtone of light*, either from its glittering appearance where freſh broken, or from its giving large ſparks of fire, when ſtruck againſt a ſteel. It was from this quality that it obtained the name of pyrites or fire ſtone. It giving fire on the colliſion with ſteel much better than flint does.

LAPIS *luminis*, is uſed by ſome authors, in the ſame ſenſe as *lapis lucis*, that is, for the *pyrites*. De Laet. de Lap. See LAPIS *lucis* ſupra.

LAPIS *Lydius*. See LYDIUS *lapis*.

LAPIS *muſicalis*, the *muſic ſtone*, in natural hiſtory, a name given by Mr. Sivers, to a ſtone found in Pruſſia, carrying naturally on it all the muſical characters found on the ſhell, commonly called the muſic ſhell. He deſcribes the ſtone, which ſeems to have been a ſingle ſpecimen, as being of a greyiſh colour, and of the matter of the common finer ſand ſtones, ten inches in length, and ſeven in breadth. The lines which expreſs thoſe of the common ruled muſic paper are continued lengthway through the ſtone, and are of a reddiſh colour; as are alſo the marks expreſſing the notes, which are partly of the common modern character, and partly of that kind uſed by the Monks in their writing muſic on vellum. There ſeems to be no regular origin aſſignable to this ſtrange ſtone; and as this author is the only one who ever met with it, it is much to be ſuſpected that either fraud or fancy has had a great ſhare in the matter.

LAPIS *Nephriticus*. See NEPHRITICUS *lapis*, *Cycl.*

LAPIDES *Picti*, in natural hiſtory, a term uſed by Langius, to expreſs ſuch ſtones as are found with the delineations of fiſhes, trees, and ſhells, as well as leaves of ferns and other plants, very perfectly repreſenting the things themſelves, but ſcarce at all ſtanding out above the ſurface of the ſtone, and having in themſelves ſcarce any thickneſs. The foſſile bodies, which have been once parts of animals or vegetables, and are thence called by authors extraneous foſſils, have uſually the ſame thickneſs, that the natural bodies, whoſe figures they repreſent, have. Thus our *ſnail*, *wilk*, and other ſea ſhells which we find buried in ſtone, uſually are not only as long, but as thick as thoſe now found recent in the ſeas; but it is very certain, that the figures of fiſhes found in ſtone are often mere lineaments, and only repreſent figures traced out with a pencil, not the bodies of the fiſh themſelves buried in the ſtone. Theſe laſt are what this author ſeparates from the common kinds, under the names of *lapides picti*; and we find ſomething of this kind among the ſhell claſs as well as the fiſh; ſome of our own black ſlate ſtones being full of ſcallop ſhells, and *cornua ammonis*, which have ſo little thickneſs, that twenty beds of them lie over one another, in the compaſs of the ſixth of an inch.

We have been uſed to attribute this to preſſure; but however well this might ſerve to explain the flatneſs of the repreſentation of a fiſh in a hard ſtone, as it is not difficult to imagine ſo ſoft a body eaſily compreſſed by ſo hard a one; yet it ſeems ſtrange, that in a ſoft and crumbly ſtate, ſuch friable bodies as ſhells are, ſhould have been thus flatted, and yet not broken to pieces. The opinion of Langius is, that in theſe caſes the body of the animal is not there, but that as when a branch of roſemary, or any other plant, is carefully burnt, the aſhes will perfectly preſerve its form, though their whole ſubſtance might be reduced by preſſure to the thinneſs of a piece of paper; ſo in theſe caſes the body of the animal repreſented has been decayed and corrupted, but that ſome of its remaining principles, its ſulphurs, as he ſuppoſes, might preſerve its exact lineaments to the ſtone, as we ſee them. It is difficult to conceive that theſe bodies ſhould be thus diſſolved, while in a ſtate of ſuch perfect reſt, as that not one lineament ſhould be loſt, or one ſmall part ſeparated from the reſt, and carried away from ſo ſoft a maſs; but till ſome future writer ſhall advance a better ſyſtem, this may deſerve a place. The other kind of *lapides picti*, or painted ſtones, are thoſe which give delineations of rivers, trees, houſes, and the like; of this kind are the mocoa ſtone, and the florentine marble. It is very evident, that the bodies repreſented are not here, in reality, but the whole configuration is owing to the natural veins of the ſtone, and the coaleſcence of the ſeveral ſmaller maſſes of which each large ſtone is compoſed, and to the vapours from within the earth, getting into the natural fine cracks in the ſtones, and tinging their ſides with blackneſs. *Lang.* Hiſt. Lapid. Helvet.

LAPPAGO, in botany, a name given by the old Roman authors, to the plant we call aparine, or clivers, or ſome herb nearly allied to it.

Many of the modern Greeks have been erroneouſly of opinion, that the *lappago* of the Romans was the ſame with the *pheos* or *hippopheos* of the Greeks; but it is evident, that the *pheos* of the Greeks was a prickly ſhrub. Theophraſtus abſolutely deſcribes it as ſuch, and Dioſcorides yet more at large; yet Gaza interprets the *pheos* of the firſt author *lappago*, though that was, by all account, only a low herbaceous plant. The *lappago* of the Romans is no where ſaid to be a prickly plant. Pliny ſays it reſembles the anagallis, a ſmall and tender herb; but that it is more branched, and has more numerous and rough leaves. Dioſcorides ſays, that the antirrhinum is like the anagallis in ſtalks and leaves, and Theophraſtus reſembles the ſame plant to the aparine. Pliny's account of the antirrhinum is different indeed from this; but though many have, for that reaſon, ſuppoſed the text both in Theophraſtus and Dioſcorides corrupt, it appears to be right in both; and the whole matter is, that the antirrhinum of the Greeks, and antirrhinum of the Romans were two different plants; but both theſe and all the other deſcriptions given of the *lappago*, and the reſemblances mentioned between it and other plants, and compariſons of other plants to it ſeem to expreſs, that it was a very rough and tenacious plant, having ſeveral leaves growing from every joint, and bearing a fruit; which, by reaſon of its roughneſs, and its property of ſticking to peoples clothes, had ſome reſemblance to the *lappæ*, or burs, as we call them, which grow upon the common burdock.

Pliny tranſlates the aparine of Theophraſtus, where he copies his accounts from that author, ſometimes by the word *lappago*, tho' ſometimes by *lappa*; hence, it ſhould ſeem, that *lappago* and *lappa* were eſteemed ſynonymous terms at that time. Theophraſtus has peculiarly deſcribed the flower and fructification of the aparine; and Pliny has in his way tranſlated the account, uſing the word *lappa* as the name for aparine. In another part of the ſame book he tranſlates it *lappago*, where he mentions two kinds of it, the ſoft and the rough, which he calls *mollugo* and *aſperugo*. The *mollugo* ſeems to have been the ſame plant we ſtill call by that name, an herb reſembling the aparine in its whole exterior face, and manner of growing, but being wholly ſmooth. The name *aſperugo* here plainly meant the common aparine or clivers, but we have ſince appropriated it to another plant.

LAPPULA, in botany, a name given by ſome to the great caucalis, or rough fruited ſtone parſley. *J. Bauhin*, V. 3. p. 80. See CAUCALIS.

LARBASON, a word uſed by ſome authors as a name for antimony. See ANTIMONY.

LARGE, in the manege. A horſe is ſaid to go *large*, or wide, when he gains or takes in more ground in going wider from the center of the volt, and deſcribing a greater circumference. To make a horſe go *large* you muſt give him the aid of your inner heel. See ENLARGE.

LARGE, in muſic. See CHARACTER, *Cycl.*

LARGHETTO, in the Italian muſic, ſignifies a movement ſomething ſlow, yet a little quicker than *largo*.—V. Broſſ. Muſ. Dict. in Voc. See LARGO.

LARGO, in the Italian muſic, a ſlow movement, one degree quicker than *grave* and two than *adagio*. See ADAGIO and GRAVE.

LARIX, the *larch tree*, in botany, the name of a genus of trees, the characters of which are theſe. The flower is of the amentaceous kind, being compoſed of a number of apices; but it is barren, the embryo fruits appearing in other parts of the tree. Theſe finally become a ſort of cones, compoſed of a number of ſcales affixed to an axis, and containing under them a number of foliated ſeeds. To this it is to be added, that the leaves grow many together out of the ſame theca. *Tourn.* Inſt. p. 586.

The ſpecies of *larix* enumerated by Mr. Tournefort are theſe. 1. The common *larch tree*. 2. The oriental *larix* with round obtuſe fruit. 3. The American *larix*, with leaves growing, five out of the ſame theca; and 4. The Canada *larix* with very long leaves.

There are two ſpecies of this tree cultivated in the gardens about London; the one is the common kind, the other has white rudiments to the fruit. They are propagated by ſowing in March on a bed of light earth expoſed to the morning ſun. The ſeed muſt be covered half an inch thick

with fine light earth, and the beds watered at times, when the weather is over dry. In about ſix weeks the plants will appear; they muſt at this time be carefully guarded from the birds, and not expoſed to the ſun or winds, and muſt be kept clear of weeds and watered.

In the latter end of April the following year they may be removed into beds of freſh earth, placing them at ten inches diſtance every way. They are to be kept here two years, and ſuch of them as ſeem to bend muſt be tied up to a ſtake to keep them upright. They may afterwards be planted in the places where they are to remain. They thrive well on the ſides of barren hills, and make a very pretty figure there.

LARK, *Alauda*, in zoology. See ALAUDA.

The *lark* is not only a very agreeable bird for the cage, but it is alſo a very hardy one; it will live upon almoſt any food, ſo that it have once a week a freſh tuft of three leaved graſs put into the cage with it.

The *ſky* and *woodlark* differ in the time of their breeding; the former not producing her young ones till May, the latter hatching them in March. In winter it is common to ſee vaſt flocks of *ſky larks*; and yet, it is obſerved, that there are fewer of their neſts found in the ſeaſon, than of any birds that is in any degree common among us. The *ſky lark* ſometimes builds among corn, ſometimes among high graſs, and ſeldom has more than three young ones at a brood, ſcarce ever more than four; ſo that it is the more wonderful whence the large flights we ſee come. The young may be taken out of the neſt at a fortnight old, and are ſo hardy, that they will eaſily be brought up. The beſt food is ſheeps heart chopped with egg, and afterwards oatmeal, bruiſed hempſeed, and bread, with a little egg among it. They ſhould have clean ſand at the bottom of the cage, but they need no perches.

The common way of taking *larks* is in the night, with thoſe nets which are called *trammels*. Theſe are uſually made of thirty ſix yards in length, and about ſix yards over, with ſix ribs of packthread, which at the ends are put upon two poles of about ſixteen feet long, and made leſſer at each end. Theſe are to be drawn along the ground by two men, and every five or ſix ſteps the net is made to touch the ground, otherwiſe it will paſs over the birds, without diſturbing them, and they will eſcape. When they are felt to fly up againſt the net it is to be clapped down, and then all are ſafe that are under it. The darkeſt nights are the propereſt for this ſport, and the net will not only take *larks* but all other birds, that rooſt on the ground, among which are woodcocks, ſnipes, partridge, quails, field-fares, and ſeveral others.

In the depth of winter people ſometimes take great numbers of *larks* by nooſes of horſe hair. The method is this: take a hundred, or two hundred yards of packthread; faſten at every ſix inches a nooſe made of double horſe hair; at every twenty yards the line is to be pegg'd down to the ground, and ſo left ready to take them. The time to uſe this is when the ground is covered with ſnow, and the *larks* are to be allured to it by ſome white oats, ſcattered all the way among the nooſes; they will ſoon fly to theſe, and in eating will be hung by the nooſes. They muſt be taken away as ſoon as three or four are hung, otherwiſe the reſt will be frighted; but though the others are ſcared away juſt where the ſportſman comes, they will be feeding at the other end of the line, and the ſport may be thus continued a long time.

Sea LARK, in ornithology. See HIATICULA.

LARKSPUR, in botany. See DELPHINIUM.

There are eleven ſpecies of this plant cultivated in the gardens of the curious, for the beauty of the flowers; and beſide theſe a number of other varieties produced by a careful management of the ſeed ſaved from good flowers. They are to be raiſed by ſowing the ſeeds in autumn ſoon after they are ripe. Some ſow them in ſpring, but the plants are thus never ſo ſtrong, nor are the flowers ſo large. When the young plants have got a little ſtrength, they ſhould either be pulled up, or tranſplanted, ſo as to have them at ten inches diſtance every way. They will now require no farther care, but will flower in June. *Miller*'s Gardners Dict.

LARUS, the *Gull*, in the Linnæan ſyſtem of zoology, is the name of a diſtinct genus of birds of the anſer order. The characters of which are a pointed bill, feathered thighs, and feet placed not very far behind. *Linnæi* Syſtem. Natur. p. 46.

The general characters of this genus, according to Mr. Ray, are theſe. They are all, except a very few, web footed, their beak is long, narrow, ſtrait, and a little hooked at the end, their noſtrils are oblong, their wings long and ſtrong, their legs ſhort, and their feet ſmall. Their body is very light, and covered with a thick plumage. They are great flyers, very clamorous and noiſy, and feed on fiſh. There are properly two ſubordinate genera of theſe birds; the firſt is of thoſe which are large, and have an even not forked tail, and have a tubercle in the lower chap of their bill. The other of the ſmaller ones, which have all forked tails, and have no tubercle in their lower chap. Of the firſt genus are the *great gull*, the *herring gull*, the *ſea mall*, the *ſea meb*, the *tarrock*, the *pewit*, the *gannet*, the *cataracta*, the *martinazzo*, the *coddy moddy*, the *winder meb*, the *cepphus*, the *brown fern*, and the *gaviota*: and of the ſecond, or ſmaller kind, are the *ſterna*, the *fiſcherlin*, the *ſcarecrow*, and four ſpecies of the *larus fidipes*; all which ſee under their ſeveral heads. *Ray*'s Ornithol. p. 261.

LARUS *fidipes*, in zoology, the name of a peculiar kind of bird, accounted by many to be of the *larus*, or gull kind, but having its feet not webbed, as in the other birds of that genus, but the toes looſe, as in land fowls. There are four known ſpecies of this bird. 1. A black one, ſomewhat ſmaller than the common ſea ſwallow, and having a forked tail. 2. A black kind with a greyiſh white breaſt and belly, and remarkable for the great length of its wings. 3. A grey kind, of the ſize of a blackbird, with a very long tail, and very ſhort wings. And 4. A brown one, with yellow ſpots. The firſt and the laſt of theſe are common on our own coaſts; the two others are deſcribed by Aldrovand. They all feed on fiſh. *Ray*'s Ornitholog. p. 270. Vid. ſupra.

LASANON, a word uſed by different authors in very different ſenſes; ſome applying it to the trivet commonly uſed in kitchens; others to a cloſe-ſtool; and others, among whom are Hippocrates and the antient phyſicians, for a ſort of chair, contrived for a woman in labour to ſit in, as being ſo made, that the weight of the child, when born, ſhould help to draw away the ſecundines.

LASER *cyreniacum*, in the materia medica, a name ſuppoſed to be given by the antient Greeks to the gum we at this time call *aſſa fœtida*. The word *aſſa*, or, as it was originally written, *aſa*, was evidently formed on the *laſer* of the Greeks; but there was alſo an *aſa* mentioned by the old authors very different from this, being a fragrant and ſweet ſcented gum: and indeed, though Aviſenna and Serapion, and many of the authors of the middle ages, have determined the *laſer cyreniacum* to be our *aſſa fœtida*, yet it is but a ſuppoſition, and that ſo ill founded, that it will not bear a critical examination. The *laſer* of the antients was of a very agreeable and fragrant ſmell, not of the ſtinking one of our *aſſa*. Dioſcorides attributes to it a very pleaſing ſmell, and expreſsly ſays that it had nothing of the ſmell of the leek or onion kind, for which our *aſſa fœtida* is ſo remarkable. Theophraſtus quotes ſome authors, much older than himſelf, to the credit of the ſweet ſmell of *ſilphium* of Cyrene, which is the plant whence the *aſſa* of their times was produced, and even the poet Ariſtophanes calls it the ſweet ſcented gum. The miſunderſtanding ſeems to have ariſen about this gum, from the naming another thing by its name in after times. This ſweet gum was evidently the *laſer* and *aſa*, or *aſſa*, of the antient Greeks; and the *ſilphium* was the plant which produced it. This plant grew in Cyrene, and furniſhed it a long time, but in the days of Pliny it was in a manner loſt. The people of Cyrene found it more profitable to feed their cattle upon the *ſilphium*, than to gather its gum. We hear of the great eſteem, in which the fleſh of cattle fed on the *ſilphium* was among the antients, and have wondered at it, that ſo ſtinking a plant as that muſt be, which yields *aſſa fœtida*, could give a good flavour to the fleſh of cattle; but we find by this account, that the *ſilphium* was not a ſtinking plant, and that the *aſa* of thoſe times was a very ſweet and fragrant gum, not a ſtinking one, like what we now call by that name.

Pliny continues to tell us, that by the feeding cattle on this plant, it was ſo perfectly deſtroyed, in a courſe of years, that there had been, of a long time, only one plant of it ſeen, and that reckoned ſo great a curioſity, that it was ſent as a preſent to the emperor Nero.

When Cyrene no longer afforded the *ſilphium*, it was fought for in other places, and the Romans had a gum of the ſame name with that of the Cyrenian from Armenia, Media, and Perſia. This, however, was very different from the original medicine. This was of a diſagreeable ſmell, and though of a much hotter and more firey taſte than the Cyrenian, yet came very ſhort of it in its virtues. The original *aſa*, or *laſer*, had the ſmell of myrrh, but more mild and agreeable; and the *aſa* of ſucceeding times had that of leeks or garlick, and thence was diſtinguiſhed by the name *ſcorado laſerum*.

LASERPITIUM, *laſerwort*, in botany, the name of a genus of the umbelliferous plants; the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral heart faſhioned petals diſpoſed in a circular order on a cup, which finally becomes a fruit compoſed of two ſeeds, gibboſe on one ſide, and ornamented with four large foliaceous wings, which are ſometimes curled, and ſometimes plain.

The ſpecies of *laſerpitium* enumerated by Mr. Tournefort are theſe. 1. The French *laſerworts*, or *laſerpitium* of Marſeilles. 2. The *laſerpitium* with very narrow and oblong leaves. 3. The ſtinking *laſerpitium* with brittle angular leaves. 4. The ſelinum like *laſerpitium* with curled ſeeds. 5. The broad leaved *laſerpitium* with a narrow and hollow umbel. 6. The broad leaved not ſinuated *laſerpitium*. 7. The narrow leaved not ſinuated *laſerpitium*. 8. The daucus like *laſerpitium* with viſcous ſeeds. 9. The *laſerpitium* with broad lobated leaves. 10. The great round leaved Alpine

Pine *laſerpitium*. 11. The great large leaved *laſerpitium* with curled ſeeds. 12. The low *laſerpitium* with ſmallage leaves, and purple flowers. 13. The low *laſerpitium* with ſmallage leaves and white flowers. 14. The *laſerpitium* with long and divided lobes. *Tourn.* Inſt. p. 324.

LASHED, a ſea term ſignifying *made faſt*. Thus they ſay the carpenter ought to take care that there be ſpare yards *laſhed* faſt to the ſhips ſides; *i. e.* faſtened there to uſe on occaſion.

LASKETS, or LATCHES, in a ſhip, are ſmall lines, like loops, faſtened, by ſowing into the bonnets and drablers, in order to lace the bonnets to the courſes, or the drablers to the bonnets.

LAST, (*Cycl.*) in the marſhes of Kent, a court held by the twenty four jurats, and ſummoned by the bailiffs; wherein orders are made to lay and levy taxes, impoſe penalties, *&c.* for the preſervation of the ſaid marſhes. *Hiſt. of imbanking and draining*, fol. 54. *Blount.*

LATERALIS *morbus*, a name given by ſome writers to the pleuriſy.

LATERALIS *naris muſculus*, in anatomy, a name given by many authors to that muſcle of the face which Albinus has called, from its office, the *levator labii ſuperioris alæque naſi*. It is alſo called the *obliquus naſi*.

LATERCULUM, among the Romans, was uſed for a roll or liſt of all the magiſtrates and military officers under the Roman emperors, with an account of their reſpective offices and fees. *Pitiſc.* in voc.

LATEX, in chemiſtry, a name by which Van Helmont has, in ſome of his writings, called the famous menſtruum, which he boaſts Paracelſus and himſelf to have been poſſeſſed of, and which he uſually calls *alkaheſt*. See ALKAHEST.

LATH *bricks*, a particular ſort of *bricks* made in ſome parts of England of twenty two inches long, and ſix inches broad, which are uſed in the place of laths, or ſpars, ſupported by pillars in *caſts*, for the drying of malt. This is an excellent contrivance; for, beſide that they are not liable to fire as the wooden *laths* are, they retain the heat vaſtly better; ſo that being once heated, a very ſmall quantity of fire will keep them ſo. *Plot*'s Oxfordſhire, p. 257.

LATHRÆA, in botany, the name given by Linnæus to the plant called by Tournefort *clandeſtina*. This, in the Linnæan ſyſtem of botany, is alſo a diſtinct genus of plants; the characters of which are: That the cup is compoſed of one leaf, ſtanding erect, and repreſenting a bell, with its rim deeply divided into four ſegments. The flower is compoſed of a ſingle petal, in form of a tube, longer than the cup, with a gaping and bellied mouth. The upper lip of the flower is hooded, and is broad and concave, with a narrow crooked extremity; the under one is ſmaller, crooked, obtuſe, and divided into three parts. The ſtamina are two pointed filaments, of the length of the flower, hid beneath the upper lip. The antheræ are two on each filament, obtuſe above, and narrower below. The piſtillum has a roundiſh germen, a thread-like ſtyle of the ſame length with the ſtamina, and placed in the ſame manner with them, and a truncated ſtigma. The fruit is a roundiſh, obtuſe, but pointed capſule, divided into two cells, having two valves, and is very elaſtic. *Linnæi* Gen. Plant. p. 9. See CLANDESTINA.

LATHYRIS, in botany, a name given by many authors to a ſpecies of tithymal, or ſpurge, commonly known by the name of *tithymalus latifolius*, the broad leaved ſpurge, and called by ſome alſo *cataputia*.

LATHYRUS, in botany, the name of a genus of plants; the characters of which are theſe. The flower is of the papilionaceous kind. The piſtil ariſes from the cup, and finally becomes a pod, in ſome ſpecies, of a cylindric, and in others of a flatted form, containing ſometimes cylindric, and ſometimes angular ſeeds. To this it is to be added, that the ſtalks are flat and ridged, and have on each ſide a foliaceous wing, and the leaves ſtand only two on each rib; theſe are placed oppoſite to one another, and the rib itſelf ends in a tendril.

The ſpecies of *lathyrus* enumerated by Mr. Tournefort are theſe. 1. The cultivated *lathyrus* with a white flower and white fruit. 2. The purple flowered garden *lathyrus*. 3. The common large wild *lathyrus*. 4. The greater wild *lathyrus* with a blackiſh purple flower. 5. The broad leaved *lathyrus*. 6. The broad leaved *lathyrus* with white flowers. 7. The great narrow leaved french *lathyrus*. 8. The narrow leaved *lathyrus* with a ſpotted ſeed. 9. The orobus podded *lathyrus* with a very beautiful large red flower. 10. The American variegated *lathyrus* with very narrow leaves. 11. The creeping tuberoſe rooted field *lathyrus*. 12. The vetch leaved yellow flowered wild *lathyrus*. 13. The blue flowered annual *lathyrus*. 14. The yellow flowered bœtic *lathyrus*. 15. The yellow flowered Spaniſh *lathyrus*. 16. The broad leaved yellow *lathyrus*. 17. The hairy podded narrow leaved *lathyrus*. 18. The broad leaved annual *lathyrus* with a hairy jointed pod. 19. The *lathyrus* with extremely narrow leaves and round ſeeds. 20. The *lathyrus* with extremely narrow leaves, and angular ſeeds. 21. The narrow leaved red flowered *lathyrus*. And 22. The ſcarlet flowered *lathyrus* with graſs like leaves. *Tournefort*, Inſt. p. 396.

LATIBULUM, a word uſed by ſome medical writers for the fomes, or latent matter, which is the occaſion of fevers and other diſorders.

LATION, is uſed by ſome for the tranſlation, or motion of a body from one place to another.

LATI-TENDINIS *muſculus*, in anatomy, a name given by Spigelius and others to a muſcle called, by Winſlow, *muſculus faſciæ latæ*, and by Albinus the *muſculus vaginæ femoris*. See MEMBRANOSUS, *Cycl.*

LATOMIA, λατομια, in antiquity, a famous priſon or dungeon at Syracuſe, cut out of the ſolid rock.

It was the work of the tyrant Dionyſius. Cicero calls it a vaſt magnificent work, ſunk into the ſolid rock to a wonderful depth; and ſays, that nothing could even be imagined more ſecure for the confinement of priſoners. *Pitiſc.* Lex. Ant. in voc.

The word *latomia* ſignifies a quarry, from λας, a ſtone, and τεμνω, to cut.

Latomia was alſo the name of a dungeon at Rome near the priſon called *Tullianum*. *Pitiſc.* l. c.

LATTIMO, in the glaſs trade, a name for a fine milk white glaſs. There are ſeveral ways of making it, but the beſt of all others is this. Take four hundred weight of cryſtal fritt, and ſixty pound of calcined tin, and two pound and a half of prepared manganeſe; mix theſe well with the fritt, and ſet them in a pot in a furnace to melt and refine. At the end of eighteen hours this will be purified; then caſt it into water, purify it again afterwards in the furnace, and make a proof of it. If it be too clear, add fifteen pound more of calcined tin; mix it well with the metal, and let it ſtand one day to purify; it will then be of a whiteneſs ſurpaſſing even that of ſnow, and is fit to work into veſſels. *Neri*'s Art of Glaſs, p. 98.

LATTIN, a name by which we uſed to call the plates of iron covered with tin, and now uſually called tin, of which our mugs, and ſuch other things, are made. The method of preparing theſe plates of tin, as they are called, is as follows. Plates of iron are prepared of a proper thinneſs; theſe are cut into ſquares fitted to receive the tinning, but it is not every kind of iron that will ſerve to this purpoſe, but only ſuch as is moſt of all diſtenſible, eaſily beating out to any degree of thinneſs when hot, and malleable even when cold, without danger of flying to pieces. Of this the Germans have large quantities, which they always ſelect for this purpoſe. This ſort of iron is firſt formed into ſquare bars of an inch in diameter; theſe they beat out a little into flatneſs, and then cut into pieces, which they call *ſemelles*, or *ſoles*. They fold theſe together, and having made them into parcels, containing forty pieces each, they beat them all at once with a hammer, which weighs ſix or ſeven hundred weight. When they have done this, the principal part of the whole work is to prepare the leaves, now beat out to a proper thinneſs, ſo as that they ſhall readily receive the tin; for if there be but the ſmalleſt particle of duſt on them, or only the ſlighteſt ruſt in any part, the tin will never fix there.

This ſmoothing of the plates may be brought about by filing them, but that would be too expenſive, wherefore they do it by ſteeping them in acid waters. Thus preparing a great number at a time, they leave them in this liquor till the ſurface is a little preyed upon by it, and then they are ſcowered with ſand, which makes them very ſmooth and fine. By this means a woman cleans more plates in an hour, than the moſt expert workman can do in many days. Mr. Reaumur, to whom the world owes the diſcovery of this proceſs, mentions ſeveral waters, any one of which will ſucceed, but the Germans themſelves uſe nothing but common water, made eager with rye. This they make a great ſecret of, but the preparation is very eaſy. After they have ground the rye groſsly, they leave it to ferment in common water for ſome time; and they are thus ſure of a ſharp and eager menſtruum, excellently fitted for their purpoſe. With this liquor they fill certain troughs, or tuns, and into theſe they put ſeveral bundles of the plates of iron: and to make the liquor be more eager, and act the better on them, they keep it in ſtoves, where it has little air, and is kept warm with ſmall charcoal fires. The workmen go into theſe vaults once or twice a day, to turn the plates, that they may be the better wrought upon by the acid, and to take out thoſe which are moſt wrought upon, and put in others in their room. The more acid the liquor is, and the warmer the ſtove, the ſooner the plates are cleanſed: it requires, however, at leaſt two days to effect this, and oftener ſomething more.

This was the method which the German labourers, employed in the tin works in France, always made uſe of, in order to prepare the iron to receive the covering of tin; but the authors finding that this was a very laborious employ, and that the heat in the ſtoves was ſo great, that they could hardly bear it, propoſed ſome other methods in the place of this, which were attended with much leſs trouble,

and as ſmall an expence, if not leſs, and theſe, upon trial, were found to ſucceed equally well.

Having obſerved that the iron leaves, or plates, are covered with a ſmall layer of a ſort of ruſt which they contract in the fire, and which the acid liquor took very little hold of; he judged it might be better to expoſe the plates to ruſt, in order to the cleanſing them eaſily of it; as ruſt is always accompanied with a ſort of fermentation, and the particles of ruſt, found on the ſurface of the iron, would be ſure to raiſe up every thing in their way. To this purpoſe he ſteeped the plates of iron in waters, in which were ſeparately diſſolved alum, common ſalt, and ſal armoniac. Some other plates he did not ſteep in theſe liquors, but only juſt dipped them in, and then expoſed them to the air to ruſt. All theſe liquors, thus uſed, cauſed the iron to ruſt very freely, but the ſal armoniac beſt of all. After two days, during which every plate had been dipped into this menſtruum only twice or thrice, he ordered both theſe, and thoſe which had been left ſteeping during the ſame ſpace of time, to be ſcowered; and on comparing them together, it was found, that thoſe which had been dipped, and expoſed to the air, became much cleaner than thoſe which had been all the time ſteeped. The ruſt covered all the ſurface in the latter, without raiſing the ſcale; whereas, in the former, the ſurface was raiſed into bliſters of ruſt, which carried it wholly off with them. Theſe diſſolvents, though very weak, are obſerved to produce the deſired effect, as well as ſtronger, which muſt be much dearer; but among the latter he prefers vinegar in France, which ſucceeds very well, and being plentiful there, is very cheap. This operates ſo quick on the iron, that the plate need only be once dipped into it, and immediately taken out again, and ſet in a moiſt place, where it will ruſt in eight and forty hours. If the dipping is repeated three or four times, the ruſting will be ſtill more expeditious, and eſpecially if a ſmall quantity of ſal armoniac be diſſolved in the vinegar, about a pound to the puncheon. This will make a very efficacious menſtruum, the vinegar diſſolving iron very well, and the ſal armoniac ruſting it ſooner than any other ſalt. This, however, muſt be uſed very moderately, and the plate muſt be ſteeped in cold water afterwards, to take off any particle that might yet remain upon it, otherwiſe it would be ſubject to ruſt after it was tinned.

There are ſeveral other ways of making iron ruſt, as keeping it in a moiſt cellar, expoſing it to the dew, ſprinkling it with ſimple water, or, which is ſtill better, with water, in which ſal armoniac has been diſſolved, ſeveral times a day; and in thoſe countries where the pyrites is common, the vitriolic waters, which partake of it, will do it very well. This water may be prepared at little or no expence, only by heaping up large quantities of the pyrites, and letting it moulder in the air, then putting it into common water, and making a lixivium of it.

The leaves of tin, when they are finiſhed, are always found to be more bright and gloſſy on one ſide than on the other, which is owing to the plates of iron having always ſeveral roughneſſes on one ſide, where it has been moſt expoſed to the hammer. Theſe roughneſſes are what are principally to be eaten down by the menſtruums; for which reaſon Mr. Reaumur greatly prefers ſprinkling, or wetting them, to ſteeping; becauſe in ſteeping, as both ſides are equally expoſed to the force of the menſtruum, the ſmooth ſide muſt be conſequently eaten away too far, while the other is but eaten barely enough; this occaſions a loſs of the iron, which the author propoſes to ſave by ſprinkling, or ſimply wetting, as then the bad ſide only might be ſubjected to the action of the menſtruum.

There are two other cautions, very neceſſary to be obſerved in this part of the work. The firſt is in the management of the plates, before they come to be prepared; which is, in the beating of them, to turn them continually about, ſo that all parts of every plate may be equally extended. And the other is, to plunge them into ſome ſoft clay, or fullers earth, before they are heated, that they may not ſolder themſelves together.

Which ever method of ruſting the plates be uſed, it is always neceſſary to ſcower them with ſand as ſoon as it is done; and when they are thus cleaned, they muſt be immediately plunged into water, to prevent their ruſting again, and they are to be left in this water till the inſtant in which they are to be tinned, or, in the language of the workmen, *blanched*. The people employed in this part of the operation, are called *blanchers*, and the others who, aſſiſt at the cleaning the plates, the *ſealers*. The blancher makes as great a ſecret of his art, as the ſealer does of his, and it was with great difficulty that Mr. Reaumur obtained it. The manner of doing it is this.

They flux the tin in a large iron crucible, which has the figure of an oblong pyramid with four faces, of which two oppoſite ones are leſs than the two others. The crucible is heated only from below, its upper part being luted with the furnace all round. The crucible is always deeper than the plates, which are to be tinned, are long; they always put them in downright, and the tin ought to ſwim over them.

To this purpoſe artificers of different trades prepare plates of different ſhapes, but Mr. Reaumur thinks them all exceptionable. But the Germans uſe no ſort of preparation of the iron, to make it receive the tin, more than the keeping it always ſteeped in water till the time; only when the tin is melted in the crucible, they cover it with a layer of a ſort of ſuet, which is uſually two inches thick, and the plate muſt paſs through this before it can come to the melted tin. The firſt uſe of this covering is to keep the tin from burning; as if any part ſhould take fire, the ſuet would ſoon moiſten it, and reduce it to its primitive ſtate again. The blanchers ſay, this ſuet is a compounded matter. It is indeed of a black colour, but Mr. Reaumur ſuppoſed that to be only an artifice to make it a ſecret, and that it is only coloured with ſoot, or the ſmoke of a chimney; but he found it true ſo far, that the common unprepared ſuet was not ſufficient; for after ſeveral attempts, there was always ſomething wanting, to render the ſucceſs of the operation certain. The whole ſecret of blanching, therefore, was found to lie in the preparation of this ſuet; and this he at length diſcovered to conſiſt only in the firſt frying, and burning it. This ſimple operation not only gives it the colour, but puts it into a condition to give the iron a diſpoſition to be tinned, which it does ſurpriſingly.

The melted tin muſt alſo have a certain degree of heat, for if it is not hot enough, it will not ſtick to the iron; and if it is too hot, it will cover it with too thin a coat, and the plates will have ſeveral colours, as red, blue, and purple, and upon the whole will have a caſt of yellow. To prevent this, by knowing when the fire has a proper degree of heat, they might try with ſmall pieces of iron; but, in general, uſe teaches them to know the degree, and they put in the iron when the tin is at a different ſtandard of heat, according as they would give it a thicker or a thinner coat. Sometimes alſo they give the plates a double layer, as they would have them very thickly covered. This they do by dipping them into the tin, when very hot, the firſt time, and when leſs hot, the ſecond. The tin, which is to give the ſecond coat, muſt be freſh covered with ſuet, and that with the common ſuet, not the prepared. Philoſ. Tranſ. N° 406. p. 634.

LATUS, in zoology, the name of a fiſh of the coracinus, or umbra kind, caught in the Nile, and in the Adriatic and Mediterranean ſeas. It much reſembles the common coracinus, but is larger, and has not the beard which hangs from the chin in that ſpecies, and its body is ſomewhat rounder. It is eſteemed a very delicate fiſh. *Rondelet.* de Piſc. p. 130.

LATUS, (*Cycl.*) in anatomy, a name given by many authors to one of the muſcles of the anus, now generally called the *levator ani*.

LATUS *muſculus*, in anatomy, is alſo a name given by Riolanus, and others, to a muſcle called by Albinus *latiſſimus colli*, and by others *platyſma myodes*, and *quadratus genæ*. Part of this muſcle ariſing from the cheek, is called by Santorini the *muſculus riſorius novus*. See QUADRATUS.

LATUS-*pulſus*, a *broad pulſe*, a term uſed to expreſs that ſort of *pulſe*, in which the artery is very ſenſibly dilated at every ſtroke.

LAVACRUM, in botany, a name given by ſome authors to the common wild teaſel, or *dipſacus ſylveſtris major*. *Ger.* Emac. Ind. 2.

LAVARETUS, in zoology, the name of a ſmall fiſh called by ſome the *gang-fiſh*, and the *rhingau*, and by Marggrave the *curimata*. It ſeems of a middle nature, between the trout and herring kind, and is caught in vaſt quantities in the months of March and April, in ſeveral of the lakes in Germany, and is pickled, and ſent to different parts of the world. It ſeldom grows to more than four inches long, and the figure of its body is like that of the herring, flatted, broad, and oblong. Its back is black, and its belly white. It has two fins upon the back; the one near the head, and of the common kind; the other near the tail, and of the nature of the generical fin of the truttaceous fiſhes, free from rays or nerves, and fat. Its tail is forked, and it has a pair of fins under its gills, and another pair on the belly. Its head is bright, and in a manner pellucid, and is marked with black ſpots. *Willughby*, Hiſt. Piſc. p. 183.

LAUDICOENI, among the Romans, applauders, or perſons who, for a reward, attended the rehearſal of plays and orations, in order to raiſe, or join in the acclamation. See ACCLAMATION and APPLAUSE.

LAVENDULA, *lavender*, in botany, the name of a genus of plants; the characters of which are theſe. The flower conſiſts of one leaf, and is of the labiated kind. The upper lip is erect, roundiſh, and uſually bifid; the lower is divided into three ſegments. The piſtil ariſes from the cup, and is fixed, in the manner of a nail, to the hinder part of the flower. This is ſurrounded by four embryo's, which afterwards become ſo many ſeeds, ripening in the cup of the flower. To theſe marks it may alſo be added, that all the ſpecies of *lavender* bear their flowers in compact ſpikes at the tops of their branches.

The ſpecies of *lavender* enumerated by Mr. Tournefort are theſe. 1. The ſhort ſpiked greyiſh broad leaved Indian *lavender*. 2. The woolly Spaniſh broad leaved *lavender*. 3. The common broad leaved *lavender*. 4. The white flowered common *lavender*. 5. The narrow leaved *lavender*. 6. The white flowered narrow leaved *lavender*. 7. The cut leaved *lavender*. 8. The longer, and more elegantly cut leaved *lavender*. 9. The *lavender* with crenated leaves. 10. The American ſhrubby *lavender* with broad crenated leaves. *Tourn.* Inſt. p. 198.

We have three or four ſpecies of this plant in our gardens, all which are propagated by planting their cuttings, or ſlips, in April, in a place where they may be ſhaded. They muſt be watered till they have taken good root, which will be in about two months; after which they may be planted out where they are to remain. They thrive beſt in an open ſituation, and gravelly ſoil. They grow faſter in richer ground, but they are there very ſubject to be deſtroyed in hard winters, and their flowers are never ſo well ſcented. See LIMONIUM.

The flowers and ſummits of this plant are, in a very eminent degree, cephalic and nervine. They are given in palſies, vertigoes, lethargies, and tremors of the limbs. The compound ſpirit, diſtilled from them, is famous in theſe, and many other the like caſes.

LAVER-*bread*, a ſort of food made of a ſea plant, otherwiſe called the *oiſter-green*, or *ſea-liverwort*. It is ſaid to be uſed in the county of Glamorgan, and other parts of Wales.

LAUGHER, a name given to a particular ſpecies of pigeon, called by Moore the *columba ridens*. It is about the ſize of the common pigeon, and much of the ſame make; but it has a very bright pearl coloured eye, almoſt white, and is a mottled red, or blue. They are ſaid to be brought from Jeruſalem, and the country thereabouts. When the cock of this ſpecies courts the hen, he has a guttural cooing, not unlike the guggling of a bottle of water, when poured out haſtily; and after this he always make a noiſe, not unlike laughing, from the ſingularity of which he has obtained his name. *Moore*'s Columbarium, p. 45.

LAVIGNON, the name of a French ſhell fiſh, common on the coaſt of Poitou. It is of the *chama* kind, having a very thin pair of ſhells for its covering, which are eaſily cruſhed to pieces between the fingers, and which never can ſhut cloſe, in the manner of the oiſter or muſcle, or other common bivalve ſhells. The fiſh therefore always buries itſelf in the mud by way of ſecurity. The ſhells are very ſmooth and poliſhed, eſpecially on the inſide, and they are naturally white. This colour they always retain within, though their outer ſurface is often tinged black by the mud.

They are often buried five or ſix inches deep in the mud, but it is always eaſy to know where they are, becauſe they muſt keep a free communication with the water above; and this is done by means of a round aperture, of about a tenth of an inch diameter, which opens from the ſurface of the mud to every ſhell fiſh. Very often there are two of theſe apertures to one fiſh, and uſually they are found in great numbers together; the fiſh generally living in the neighbourhood of one another. When the ſhells of this fiſh are opened to their utmoſt width, it is eaſy to ſee a ſort of arm with which each is furniſhed, in the manner of the common muſcle, for its progreſſive motion. This part ſerves them to bury themſelves in the mud, and to raiſe themſelves out of it again, when they are inclined to ſeek a new habitation; unto which it makes its way in a more ſpeedy manner than would eaſily be thought.

When the creature is plunged to its proper depth under ground, it yet receives the benefit of the water above, by means of two pipes, or proboſcides, which have each a double aperture at their ends. Theſe take in water, and throw it out again, alternately, for the uſes of the animal, and either of the two is indifferently qualified to anſwer either purpoſe. Theſe pipes make the round apertures, which are ſeen over the places where the fiſh are buried; for as ſoon as they have entered the mud, the continual motion of the water ſmooths over the top of the hole, and the creature is deprived of the advantages of the water above, till it open a communication again by one, or both theſe pipes. The fiſh has a power of lengthening, or ſhortening theſe pipes at pleaſure, and, when it pleaſes, takes them wholly into the ſhell. It can alſo move them about, and turn them to any direction, and often they raiſe them above the ſurface of the bottom, the level with which is their uſual height; and when they are thus exerted, they draw them ſeveral ways about, and mark with them ſeveral irregular furrows about their holes. Mem. Acad. Par. 1710.

LAVIN, in natural hiſtory, a name given by the people of the Philippine iſlands to a ſpecies of hawk, a bird of great beauty, being variegated all over with yellow, black, and white. They call it alſo *ſicub*. See SICUB.

LAUNCEGAYS, in our old writers, a kind of offenſive weapons, now diſuſed, and prohibited by the ſtatute 7 Rich. II. c. 13. *Blount.*

LAUNCH, (*Cycl.*) a term uſed in ſeveral ſea phraſes, as *launch out the capſtan bars*, that is, put them out; *launch aft*, or *foreward on*, that is, when things are ſtowed in the hold, to put them more aft, or foreward on; *launch, ho!* that is, when a yard is hoiſed high enough, hoiſe no more; or in pumping, if the pump ſucks, pump no more.

LAUNDER, in mineralogy, a name given in Devonſhire, and other places, to a long and ſhallow trough, which receives the powdered ore after it comes out of the box, or coffer, which is a ſort of mortar, in which it is powdered with iron peſtles.

The powdered ore, which is waſhed into the *launder* by the water from the coffer, is always fineſt neareſt the grate, and coarſer all the way down. See DRESSING *of ore*.

LAURACES *lapis*, in natural hiſtory, the name of a ſtone ſaid to be of great virtues againſt the head-ach, but not known among us, nor deſcribed by the antients.

LAUREL, in botany. See LAURO-CERASUS.

This tree is very eaſily propagated, by planting cuttings of it in September, in a cool ſhady border, where they will very ſoon take root, and the year afterwards are to be removed into beds, and placed at two or three feet diſtance; and when they have ſtood here three years, they will be fit for tranſplanting into the places where they are to ſtand. The beſt ſeaſon of making this laſt removal is April. This is the better method when they are deſigned for dwarfs; but if they are intended for high trees, they ſhould be raiſed from berries, as they then always grow much faſter. The berries ſhould be ſown as ſoon as they are ripe, covering them an inch thick with earth, and the young plants will appear the ſpring following, when they ſhould be cleared of weeds, and watered in dry weather. The next year they ſhould be tranſplanted, and ſet at a foot diſtance; and when they are two years older, may be removed to the places where they are to remain. *Miller*'s Gard. Dict. in voc.

Laurel berries are held to be carminative, emollient, and reſolvent. They are given internally in ſuppreſſions of urine and the menſes, in colics, in pains after delivery, and in all nervous complaints. Externally they are uſed in emollient cataplaſms and fomentations.

Spurge LAUREL. See LAUREOLA.

LAUREL *water* has been diſcovered to be of a poiſonous quality. See LAURO-CERASUS.

LAURENTINA, in botany, a name given by Matthiolus, and ſome other authors, to the bugula, or bugle. *Ger.* Emac. Ind. 2.

LAUREOLA, the ſmall *ſpurge laurel*, in botany, is the ſame with the *thymelæa* with *laurel* ſhaped leaves. See the article THYMELÆA.

Laureola is a very rough purge; it operates both upwards and downwards, and uſually carries off a great quantity of matter, but it is apt to erode, and inflame the ſtomach and inteſtines. The leaves are ſomewhat milder than the bark of the ſtem; that of the root is ſtrongeſt of all. Many have given it in drops with ſucceſs; but it is ſo rough and dangerous a medicine, that while there are others capable of anſwering all the purpoſes intended by it, it is unpardonable to bring it into uſe.

LAURO-CERASUS, the *laurel*, in botany, the name of a genus of trees, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals arranged in a circular form. The cup is hollowed, and funnel faſhioned, and from it there ariſes a piſtil, which finally becomes a fruit, reſembling a cherry, ſoft, and encloſing a ſtone with a roundiſh kernel. *Tourn.* Inſt. p. 629.

The ſpecies of *laurel* enumerated by Mr. Tournefort are theſe. 1. The common *laurel*, and 2. The ſmaller Portugal *laurel*.

The diſtilled water and the infuſion of the leaves of the *lauro-ceraſus* are poiſonous; both the water and the infuſion having been obſerved to bring on convulſions, palſy, and death, when taken by the mouth, or anus.

This was diſcovered by the accident of two women dying ſuddenly at Dublin, after drinking ſome of the common diſtilled *laurel* water. Several experiments were then made on dogs, and communicated to the Royal Society by Dr. Madden, and afterwards confirmed by Dr. Mortimer, which plainly ſhewed the poiſonous effect of *laurel* water. See Phil. Tranſ. N° 418, 420.

The *lauro-ceraſus* being an ever-green, and abounding with a warm eſſential oil, it was at firſt imagined that other ever-greens might partake of the ſame poiſonous quality. But by Dr. Madden's experiments made on the leaves of the yew tree, and on box leaves no ſuch quality appeared. Phil. Tranſ. N° 418.

The expreſſed juice of *laurel* leaves had the like poiſonous effects with the diſtilled water and the decoction.

Several things were tried as antidotes to this poiſon, as *bole*, *vinegar*, and *milk*. The two former did little good, but the dog which drank the milk recovered, without any bad ſymptoms.

LAUROTAXA, in botany, a name uſed by Columna and ſome other authors for the narrow leaved kind of *ruſcus*, or butcher's broom, called by others *biſlingua*. See the article RUSCUS.

LAURUS, the *bay*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is compoſed

of only one leaf, which is hollowed into the ſhape of a baſon, and divided into many ſegments at the edges; from the bottom of the flower ariſes a piſtil, which finally becomes an oval fruit, or berry, having under its back an unicapſular ſeed veſſel, containing ſeeds of an oval figure.

The ſpecies of *bay* enumerated by Mr. Tournefort are theſe. 1. The broad leaved *bay*. 2. The common *bay*. 3. The common *bay* with double flowers. 4. The common *bay* with undulated leaves; and 5. The narrow leaved *bay*. *Tourn.* Inſt. p. 597.

We have ſeveral ſpecies of this tree cultivated in the gardens about London: they are all propagated by ſowing the berries, or by laying down the tender branches, which will take root in one year's time, and may then be tranſplanted into beds for a year or two, or even placed at once where they are to remain.

If they are to be raiſed by ſowing, the berries muſt be gathered when ripe, which is in January, and kept in dry ſand till the beginning of March, when they muſt be ſown in a bed of rich dry earth, well ſheltered from the north and eaſt winds. The bed muſt be levelled, and then furrows of an inch deep made along it, at eight inches diſtance; into theſe the berries are to be dropped about two inches aſunder, and covered with earth; and if the ſeaſon prove very dry they muſt be watered: they will come up in about two months, and ſhould be ſuffered to remain in theſe beds two years. They ſhould then be tranſplanted into a bed of earth well dug, and ſet at eighteen inches aſunder; this ſhould be done in April, and they ſhould be well watered, and the ground covered with ſome muck about their roots. They muſt be trained up ſtrait, by tying them to ſtakes, and their under ſhoots pruned off, to make them advance in height. Theſe trees are proper to plant on the warm ſides of hills, where they may be ſheltered from the north and north eaſt winds. In open ſituations, the *bay* tree will ſometimes indeed loſe all its verdure in ſevere winters and appear dead, and many trees have on this occaſion been dug up and burnt; but this is a raſh and very wrong practice; for uſually, if they are ſuffered to remain they ſhoot freely again, and after another ſeaſon are found as lively as ever. *Miller's* Gardners Dict.

LAURUS *Alexandrina*, in botany, a name given by many authors to ſome of the larger ſpecies of *ruſcus*, or butcher's broom. See RUSCUS.

LAWNS. Theſe ſpacious plains make a noble figure before grand houſes, and the great rule in regard to their dimenſions, is to make them as large as the ground will permit, but they ought never to be leſs than fifty acres. *Lawns* ought always to lie open to the front of the houſe, and be open to the neighbouring country, not pent up with trees; and the moſt happy ſituation is, when the beſt rooms of the houſe front the eaſt, and the *lawn* lies immediately before them; becauſe the ſun, in an afternoon, in this caſe, ſhines on the proſpect, and at the ſame time not into the rooms. The beſt ſituation for a *lawn*, except this, is on the ſouth ſide of a houſe; for if on the weſt, it expoſes the houſe to too much wind, and if on the north too much open to the cold. It is beſt therefore to plant trees and wilderneſſes on the weſt and north ſides of houſes. The beſt figure for a *lawn* is ſquare, and it is beſt left quite open; but if it is to be bounded by walks, there ſhould be rows of lime trees planted at proper diſtances, on each ſide, but the end ſhould be left open, unleſs it ſink very much from the houſe. A circular *lawn* is a very agreeable proſpect, and a triangular one not amiſs, but then the angle leading to the front of the houſe muſt not be too acute. If the country beyond the *lawn* do not afford an agreeable proſpect, the end ſhould be blocked up with an amphitheatre of trees, which will have a very beautiful effect. *Miller's* Gardners Dict.

The lime is a very proper tree for bounding *lawns*, becauſe it grows in a good ſhape, and if carefully planted will thrive on any good ſoil. The elm is alſo very proper, having a large and very green leaf. The beech, cheſnut, and cherry tree alſo are very proper, where the ſoil will ſuit them; and the fir and pine kind where they can live are of peculiar value, as affording a green proſpect in winter as well as ſummer.

LAWSONIA, in botany, a name given in honour to the late Dr. Lawſon to a genus of plants, before called *alhen* by Dr. Shaw, and *henna* by Ludwing. The characters of the genus are theſe. The perianthium is ſmall and permanent, and is divided into four parts. The flower conſiſts of four petals, of an oval pointed figure, which ſtand expanded. The ſtamina are eight capillary filaments of the length of the flower, they ſtand in pairs within the petals. The antheræ are roundiſh. The germen of the piſtil is roundiſh, the ſtyle is ſimple, permanent, and of the length of the ſtamina, and the ſtigma is capitated. The fruit is a globoſe capſule, terminating in a point; it contains four cells, in which are ſeveral angular pointed ſeeds. *Linnæi* Gen. Plant. p. 163. *Shaw's* Travels. *Ludw.* 143.

LAY (*Cycl.*)—LAY *fee*, *feodum laicum*, land held in fee from a *lay* lord, by the common ſervices to which military tenure was ſubject, as diſtinguiſhed from the *eccleſiaſtical* holding in *Frankalmoign*, diſcharged from thoſe burdens. *Ken.* Gloſſ.

LAYERS (*Cycl.*)—The propagating trees by *layers* is done in the following manner: the branches of the trees are to be ſlit a little way, and laid under the mould for about half a foot; the ground ſhould be firſt made very light, and after they are laid they ſhould be gently watered. If they will not remain eaſily in the poſition they are put in, they muſt be pegged down with wooden hooks: the beſt ſeaſon for doing this is, for ever-greens, toward the end of Auguſt, and for other trees, in the beginning of February. If they are found to have taken root, they are to be cut off from the main plant the ſucceeding winter, and planted out. If the branch be too high from the ground, a tub of earth is to be raiſed to a proper height for it, and ſome bare off the rind, and others twiſt the branch before they lay it, but this is not neceſſary in all caſes.

The end of the *layer* ſhould be left about a foot out of the ground, and the branch may be either tied tight round with a wire, or cut upwards from a joint, or cut round for an inch or two at the place; and it is a good method to pierce ſeveral holes through it with an awl, above the part tied with the wire. *Miller's* Gardners Dict.

LAZARI *morbus*, a name given by ſome writers to the *elephantiaſis*.

LAZIVRAD, in natural hiſtory, one of the oldeſt names by which we find the *lapis lazuli* expreſſed in authors. They uſed this equally for the ſtone itſelf, and for the colour prepared from it; and, in after times, every blue colour became called by the ſame name. From this were derived the other names of *lazurad*, *lazuri* and *azure*, as well as *lazuli*, now its common name. Aviſenna deſcribes the *lapis lazuli* under the name of *alazarad*, and his interpreter renders this *de lapide lazuli ſive armenio*, making them to be the ſame thing. But they ſtrictly are not ſo, though nearly allied to one another. See LAPIS *lazuli*.

LAZULI *lapis*. See LAPIS *lazuli*.

LEA *of yarn*, is uſed in ſome parts of England for a certain quantity of *yarn*. At Kidminſter it ought to contain 200 threads, on a reel four yards about. Stat. 22 & 23 Car. 2. *Blount*.

LEACH *brine*, a word uſed by the Engliſh ſalt workers to expreſs the brine, which runs out from the ſalt, when it ſtands in the baſkets to drain, immediately after being taken out of the pan; and alſo the liquor left in the pan, when no more ſalt will ſhoot. This is alſo called the *mother brine*, and *bittern*. In the German ſalt works they always throw this liquor away. In our *brine* ſalt works in Cheſhire they always preſerve it, and add it to the next boiling; and in the Newcaſtle, and other ſea water ſalt works, they ſave it for the making the bitter purging ſalt, called Epſom ſalt.

LEAD (*Cycl.*)—The method of ſeparating *lead* from its common fuſible ore by aſſaying, is this: beat the ore into a coarſe powder, like grains of coarſe ſand; weigh two docimaſtical centners of this powder, and put it into a teſt. Put upon this a tile, or elſe another teſt; the ore muſt be ſpread wide all over the bottom of the teſt. Roaſt it in a fire moderate at firſt, but afterwards encreaſed, ſo far as to make the teſt red hot; leave it thus for a few minutes, then take off the tile, and in a ſhort time the ore will change its blackiſh to a yellowiſh colour. This ſhews that great part of the ſulphur is now diſſipated.

Beat this roaſted ore into a fine powder, and add twice as much of the black flux, and of filings of iron not ruſty, and of ſandiver, of each half a centner; powder all theſe in a mortar to mix them well; then put them into a crucible large enough to contain twice or three times as much; cover them over a quarter of an inch thick with common ſalt, and preſs all down with a finger; put a tile, on a ſmall crucible, and ſtop the joint with a lute that will bear the fire; then dry the veſſel with a moderate heat. Then put the crucible into a wind furnace, and heap coals upon it, covering it ſome inches high. When the crucible is red hot you will hear the ſalt crackle, and this will be ſucceeded by a gentle hiſſing noiſe; ſo long as this laſts keep the ſame degree of fire, but when it is over, increaſe the fire till the whole maſs is melted, which will be done in a quarter of an hour, in a moderate melting fire. Then take out the crucible, put it upon the hearth of the furnace, which muſt be very dry, ſtrike it a few times with a hammer, to get all the *lead* together in the bottom; when it is cold take it out, and you will find by the weight of the regulus how much *lead* the ore contains. *Cramer's* Art of Aſſaying, p. 287.

This metal may be procured from its ore, of whatever kind that be, by a ſtratification with charcoal. The method of doing it in aſſay is this: take for a docimaſtical centner of the ore a hundred half ounces, or three pounds and four half ounces, that by this means each half ounce may ſtand in lieu of the docimaſtical pound; beat this to a coarſe powder, or lumps not larger than a pea. Put it at firſt into a large earthen or iron frying-pan, and heat it firſt by a gentle fire, which muſt be encreaſed gradually, that the greateſt part of the ſulphur may be diſſipated. Now have at hand a melting-furnace, with its bed made of lute and duſt of charcoal. Apply to this, on the outſide, another bed, joined to it by lute, that the matter running out of the inferior hole, when open, may be received into it. Surround this outer bed with burning and freſh coals, and fill the whole furnace with the ſame fuel, that it may be dried.

dried. Then with a pair of bellows excite the fire for a quarter of an hour, then put in the ore at ſeveral times; nor will it be amiſs to add to it ſome ſcales of iron; but the ore muſt be put in ſo as to be above the coals, facing the hole, through which the blaſt of the bellows is made; but let it not touch the wall of the furnace. Fill the furnace at leaſt two thirds with charcoal, and let it be in pieces of a moderate bigneſs; and after every portion of ore is put in, add a larger of charcoal above it. When all the ore is put in, continue to blow till all the fire is conſumed; then pour water upon the foremoſt bed, drop by drop, to cool the *lead* gathered in it, and ſee among the ſcoriæ if there be any *lead* lodged among them; and if there be, ſeparate it, and weigh all together, and you will from this know the value of the ore, and what the ſmelter may obtain from it. *Cramer*'s Art of Aſſaying, p. 298.

This metal, as in common uſe, always contains ſome ſilver, which is not in quantity enough to be worth the charges of ſeparating. The moſt common proportion is not more than two drams to a centner. This, though of little conſequence on any other occaſion, is carefully enquired into by the aſſayers of the ores of metals, particularly in regard to the ores of ſilver, for the ſeparation of which from its ore *lead* is employed; and it occaſions a very great error, when its computation is neglected, in eſtimating the value of an ore from the aſſay. This encreaſing ſilver is therefore always ſubtracted by the more accurate aſſayers; and in order to do this with the leſs trouble, a large quantity of *lead* is granulated at once for this uſe, and mixed by ſifting; then the uſual quantity employed in the aſſaying an ore is to be tried alone in a copel, and the bead of ſilver it affords carefully preſerved. After this, when the bead produced from a ſilver ore is weighed; that bead of ſilver, given by the *lead*, is to be put into the oppoſite ſcale among the weights, and then the weights balancing the bead, will, without more trouble, give the weight of the ſilver from the given quantity of its ore. *Cramer*'s Art of Aſſaying, p. 216.

All the metals may be conſidered in certain circumſtances, as acting in the manner of menſtruums on one another, and of theſe none has ſo much power as *lead*. When *lead* is expoſed to a moderate fire in an earthen veſſel, the ſurface of the melted maſs is ſoon covered with ſcoriæ, in form of a thin ſkin of many colours: when the fire is ſo far increaſed as to make the veſſels quite red hot, this ſkin melts a little, and is thrown to the ſides of the veſſel in form of a furfuraceous matter, of various yellowiſh or whitiſh colours, called litharge. After this the melted *lead* ſmoaks, and ſmall drops, reſembling the firſt ſcoriæ riſe, and ſwim like globules of oil upon the ſurface; theſe are one after another added to the litharge at the ſides; and if the fire be kept in this degree, the whole ſubſtance of the *lead* is finally turned into litharge.

If copper be added to *lead* thus ſmoaking, it cauſes a much briſker ebullition than before, and the copper burſts, and divides, and ſeems to become one homogene maſs with the *lead*; this maſs is brittle, and if made with equal parts of *lead* and copper, reſembles tempered ſteel when broken. Gold and ſilver melted thus with *lead* become brittle alſo, and gold becomes pale by the ſmalleſt admixture of it.

Tin and *lead* melt together with a fire ſtrong enough to melt the *lead* alone; but when this is increaſed, ſo as to make the veſſels red, the tin immediately riſes up above the *lead*, in form of little whitiſh duſty hillocks, ſo that the whole looks as if aſhes had fallen into the veſſel; and the tin thus calcined, when cold, is variegated in colour, with white, yellow, and red. *Lead*, ſo long as it keeps its metallic form, can never be made to join with iron, though urged by ever ſo violent a fire.

The ſemi-metals are all eaſily melted with *lead* by fire, and if added in too large a quantity they take away its malleability.

Lead and all its products turn into glaſs by a ſtrong fire; and this glaſs, or in the place of it litharge melted with ſtones, and other vitrifiable ſubſtances, makes them run into glaſs with a much leſs fire than they otherwiſe would do; and if a very large quantity of this glaſs or litharge be added, they become ſo far attenuated as to run through the ſides of the veſſels. Lime ſtones ſuffer the ſame change by means of this matter; and the incombuſtible ſtones, with proper management, are ſubject to the ſame fate; but unleſs theſe proceſſes are carefully conducted, the litharge or glaſs of *lead* gets away alone through the veſſel. Among the metals litharge facilitates the fuſion of copper and iron by the fire, but it conſumes a conſiderable quantity of them, and runs itſelf with what it poſſeſſes into glaſs; and finally, the whole tin and its calx are with difficulty vitrified by glaſs of *lead*, and they loſe nothing by it: but if gold and ſilver are very frequently melted with litharge, they will at length be found to have loſt a little of their weight; but this ſmall quantity is not deſtroyed, but may, by the proper operations, be again regained out of the litharge.

It has been proved, by the experiments of different chemiſts, that *lead* contains a real running mercury. Kunkel and Becher both ſeparated mercury from it; and Mr. Groſſe, of the Paris academy, has juſtified their experiments by producing the ſame effect; by means not only very different from theirs, but abſolutely oppoſite and contrary. They ſuppoſe that the mercury contained in *lead* is fixed there, either by acids or by ſulphurs, and therefore they uſed alkaline materials to diſengage and ſupport it. On the contrary, Mr. Groſſe uſed only acids, and by means of theſe procured a pure running mercury from this metal. His method was to diſſolve thin plates of *lead* in ſpirit of nitre, weakened with an equal quantity of water. He then obſerved a grey coloured powder precipitate, which when tried on gold or copper, ſhewed itſelf to be mercurial, and even in the powder he ſaw ſmall globules of quickſilver. Mem. de l'Acad. des Scienc. 1733.

As there could be no poſſibility of the acids forming mercury with *lead*, it is very plain that it muſt have been originally there.

In the trying *lead* by the teſt of the burning glaſs, a piece of that metal laid on a charcoal very readily melts, and afterwards wholly diſſipates itſelf in fumes; if it be placed on a piece of ſtone it fumes very much, and becomes at length a thin fluid reſembling oil, or melted reſin; and this liquor, in cooling, fixes itſelf into a ſort of glaſs, which has this peculiar quality, that it is always compoſed of plates, or ſcales, in the manner of talc; it is of a greeniſh or yellowiſh colour, with ſome reddiſh ſpots, and is very ſoft to the touch. If it be kept longer in the focus of the glaſs it ſpreads abroad upon the ſtone, and by degrees penetrates its ſubſtance, and promotes its fuſion. If the common calx of *lead*, red *lead*, or litharge, be uſed inſtead of plain *lead* in this experiment, the event is the ſame. The whole becomes a thin fluid matter, which in cooling affords a flaky glaſs, like talc. Mem. Acad. Paris 1709.

If this talcky glaſs of *lead* be expoſed to the ſame focus, laid on a piece of charcoal, it preſently melts, and re-aſſumes the form of *lead*; and, if then taken away, and ſuffered to cool, is no way different from common *lead*. If the calx of *lead*, or red *lead*, or litharge, be in the ſame manner melted in the focus of the burning glaſs on a piece of charcoal, they in the ſame manner immediately re-aſſume the form of *lead*.

It appears from the whole that there is in *lead* an oily inflammable matter, which is eaſily driven off, either by the ſolar or by a common fire; that the baſis of *lead*, which appears alone, when this is driven off, is a ſcaly or talcky earth; and that this oily matter of *lead* is no way different from the oils of vegetables, ſince the oil of charcoal is able perfectly well to ſupply its place, and to reſtore this talcky earth to the form of *lead* again.

Lead is well known to be in its natural ſtate a metal ſo little ſonorous, that it is even a proverbial expreſſion uſed to any metal that is leſs ſonorous than others, that it is almoſt as mute as *lead*.

Mr. Lemery, however, once ſhewed Mr. de Reaumur, and afterwards to the academy of ſciences at Paris, a lump of *lead*, which had been left in one of his veſſels, after ſome chemical operation, which when ſtruck, gave a very loud and acute ſound.

Mr. Lemery had no occaſion afterwards to repeat the experiment, which had afforded him this remarkable *lead*, and left it to Mr. Reaumur to diſcover the manner of doing it, who luckily hit upon it, without the difficulty he had expected from the reſearch; and, it appears, that we have a thouſand times met with ſonorous *lead*, without knowing it to be ſo. This property is not the effect of any particular operation, but is found in all *lead*, which after fuſion has taken a certain form, and this a form which accident almoſt always gives it on that occaſion. The common way of melting *lead*, in order to the caſting it into moulds, is in iron ladles; it very rarely happens, that all that is melted in the ladle is caſt into the mould, but a ſmall quantity remains, which ſoon forms itſelf into a maſs in the ladle, and this maſs is always ſoronous. Its figure is uſually either that of the ſegment of a ſphere or of a ſpheroide, and it is plane or flat on one ſide, and convex on the other: this is all it ſeems to have of regularity. The ladles are generally very irregular, and a thouſand other accidents occur, which prevent the *lead*'s receiving any determinate form. The maſſes are irregularly convex on the under ſide, and on the upper there is commonly a protuberance, which is ſometimes in the center, but much more frequently on one ſide. The maſſes of this kind, examined by Mr. Reaumur, were in general of about three inches diameter, and of about a third of an inch in thickneſs; theſe were all very ſonorous. There are, doubtleſs, certain proportions of their thickneſs to their diameter, which may make them more or leſs ſonorous, but all are conſiderably ſo: nor is the being caſt in a ladle any eſſential accident to the rendering them ſonorous, ſince pieces of the ſame ſhape caſt in ſand are equally ſo with thoſe from the ladle; and hence it will be eaſy to caſt *lead* into different moulds of earth, with all the varieties of ſpheroidal figures, and thence learn what is the proportion that moſt aſſiſts the ſound. Poſſibly alſo figures of a different kind may prove ſonorous; but Mr. Reaumur tried one convex on each ſide, and found it to have no ſound

at

at all. Larger and thicker disks of *lead* are sometimes found sonorous, but never so much so, as the figures first described. There are also two circumstances, in which the mass from the ladle itself is not sonorous; the one is, when it is covered with a coarse spungy crust, and the other, when its edges are extremely thin for any considerable space. The scum is prevented, by carefully taking it off while the metal is in fusion; and when the edges are as thin as paper, as is frequently the case, there is nothing farther necessary, than to pare them carefully off. The sound is always found to become more and more clear, as they are cut away. This is easily tried, and it is readily determined how far these edges are to be pared down, by placing the mass in equilibrio, on the top of a finger, and striking it with a key, or any other hard body, nay even with another piece of *lead*.

It is very evident then, that it is the being cast in a certain form that renders *lead* sonorous, notwithstanding the natural softness of its parts; and that in such circumstances, in spite of this obstacle, it makes very quick vibrations. It is not the form, however, which does this alone, since pieces of the same figure, made by hammering and cutting, have no more sound than *lead* in any other shape; the fusion therefore, and the casting or cooling from fusion in this shape, is an essential point. The external figure is necessary, but there is also requisite an internal configuration of the parts of the metal, which bare hammering or cutting can never give; nay, so far from giving the reality of sounding to *lead*, hammering is able to take it from it; for all these naturally sonorous casts of *lead* become greatly more dead and dull on being hammered, or struck upon by any hard body.

The author of these observations has, in another place, given an account of the arrangement, which the particles of all metals take in their cooling from a state of fusion; and has observed, that in *lead* the particles arrange themselves into a sort of fibres in this action. It was easy to conclude from hence, that this arrangement of the particles of the *lead* might be that which rendered a cast of such a figure sonorous; this was easily tried, since, if it was so, the disturbing these fibres in their arrangement must impair, or destroy the sounding; but experiment shews such a conclusion to be too hasty, and that the *lead*, though it be shook about in the ladle during the time of its cooling, or injured in the arrangement of its parts by any other means, yet does not lose any thing of its sonorous quality. Though the arrangement of the parts of this metal into fibres be not, however, the occasion of its becoming sonorous, yet it is easy to observe, that these fibres are composed of several arrangements of granules; and these may be still continued, in their natural state, during the cooling, though they are prevented by the motion from running into their natural arrangements. Thus the shaking the matter while cooling may, by preventing the concretions of these fibres, do no injury to the sound, while the blows of a hammer, which must evidently destroy the figure of these granules, may naturally be supposed wholly to take it off; since this quality plainly depends upon the vibrations of the particles of the metal on being struck; and these granules, while in their own natural figure, and disposed in a mass of a determinate shape, may easily be conceived to be capable of a vibration, which they can no longer exert, when they are beaten flat, intermingled with one another, and that the figure of the mass they form is altered.

These speculations are not without their use. It is not to be supposed indeed, that any form, into which *lead* can be cast, can make it capable of answering the purpose of the more sonorous metals in bells, *&c.* but it is very probable, that the casting metals, naturally sonorous, into a shape, or figure, which alone can render a metal, naturally mute, highly sounding, would make their sounds greatly more perfect, more loud and clear. Experiment alone can determine this, and distinguish what is only probable, and what is true. It should seem that the present form of bells, which doubtless had their origin from the observing that pots, and other vessels, made for more immediately necessary uses, gave a great sound; and thence, when bells were to be made, they cast them, as nearly as conveniently might be, of that figure. Had they had equal opportunities of observing the sonorous quality of metals cast into the shape of segments of spheres, it is very probable that all the bells in the world had now been of that form. The figure of bells, used at present, is indeed very convenient for the suspending them in churches; but there is great reason to suppose that a proper metal, cast into the form above-mentioned, would be more fit than in any other for house clocks, where a great sound is required. As the artist is limited to size in this, and in many other things of a like kind, there is great reason to believe this sonorous quality of *lead*, in a certain form, may give very useful hints for the curious artificer to improve the common practices upon. It appears from the whole, that bells may be made of *lead*, which would be sufficiently sonorous, but they would not be lasting. Their figure must necessarily be that of a segment of a sphere, thickest in the middle, and becoming gradually thinner towards the edges; and the true proportion of this decrease of thickness might be easily found by experiments, and when found, would probably prove this metal to be more sonorous than it is yet found to be. It appears also from the whole, that *lead* is a metal naturally sonorous, though that was never supposed before; that there is one peculiar form, in which it is most so; and that we destroy this property by hammering it, which destroys those granules on which its vibrations depend. Mem. Acad. Par. 1726.

LEAD, in medicine. This metal is celebrated by some chemical writers for its great medical virtues; but after all, it seems to be a metal which ought to be given internally with the greatest caution, and to be rather calculated for outward application. Its ore is so poisonous, that the steam, arising from the furnaces where it is worked, infects the grass of all the neighbouring places, and kills the animals which feed on it. Its best preparation is *saccharum saturni*; which, though able to do great good in hæmorrhages, and some other cases, is apt, however, to bring on colics of so violent a kind, that the remedy often proves worse than the disease.

The preparations of *lead*, most in use, are, 1. Minium, or red *lead*. 2. Litharge. 3. Plumbum ustum, burnt *lead*. 4. Ceruss. And 5. Saccharum saturni, sugar of *lead*. See MINIUM, LITHARGE, *&c. Cycl.* and *Suppl.*

Balsam of LEAD, an external medicine, greatly famed for its effects in old and sharp ulcers. It is made by mixing one ounce of sugar of *lead* with two of oil of turpentine, and setting this mixture in a sand-heat till the salt is dissolved. By this means the oil acquires a red colour, and is called *balsam of lead*.

Black LEAD, in mineralogy. See BLACK *lead*.

Burnt LEAD, *plumbum ustum*, is only intended for external use. It has the same virtues ascribed to it, in ointments and plasters, as litharge or minium. Mixed into an unguent with lard alone, it makes a good ointment for the piles.

Calcined LEAD. See GLASS *of lead*.

Cohesion of LEAD. When one mass of *lead* is applied to another, with both surfaces smooth, its cohesion is very extraordinary. Dr. Desaguliers tried it with two balls of *lead*, the one weighing two pounds, and the other one pound; from each of which having cut a small segment of only the diameter of a quarter of an inch, he pressed them together with his hands, giving them a twist, to make the surfaces touch as closely as could be. These supported one another, and the weight of sixteen pounds; but a little more separated them. When examined, after they were separated, the touching surfaces were found not to exceed a tenth of an inch in diameter. But it is to be observed, that on repeating the experiment, the weight required to separate the balls was never twice exactly the same; as indeed it never is in any of the experiments of this kind, and that from very obvious reasons.

Glass of LEAD. See GLASS *of lead*.

Mock LEAD, a name given to a glittering substance found in *lead* mines. See GALENA *inanis* and BLENDE.

Native LEAD. See PLUMBUM *nativum*.

Red LEAD. See MINIUM.

LEAD *ore*. Mr. Boyle observes there is great difference, discernible by the eye, between different *lead ores*. Some is so like steel, that the workers call it *steel ore*. And this being of more difficult fusion than ordinary, they mix it with other *ore*, by them called *firm ore*, when they commit it to the furnace. He says, he likewise took notice of an *ore*, which, for its aptness to vitrify, and serve potters to glaze their vessels, the miners call *pottern ore*, and sell it dearer than other *ore*. *Lead ore* often yields silver, but not always. Mr. Boyle mentions some *lead ore*, he tried, so rich, as to yield seventy *per cent* of *lead*; yet did not, though tried by one of the most expert artists, give one grain of silver. *Boyle*'s Works Abr. Vol. 1. p. 156.

The poisonous quality of this *ore* is such, that the people who live in the countries where it is dug, and near the places where it is washed, can keep neither dog nor cat, nor any kind of fowl, but all die in a short time; and it has been known that a little house, in which *lead ore* had been kept for some time, though afterwards made very clean, and bedded with fern, yet calves being then put into it, all have died in a very short time; and it is a too common melancholy observation, that children are often known to die strangely and suddenly about these places. If any sort of cattle are known to eat of the grass on which the steam, that arises from the melting of *lead*, falls, they are always observed to die a while after. Philosophical Collections, N° 2. p. 6.

Sugar of LEAD. See SACCHARUM *saturni*.

LEAD, among bowlers. See BOWLING.

LEAD, in the manege, is a term used to express the part that begins any motion first. A horse going in a streight line, always *leads*, or cuts the way with his right foot. This is called in French *entamer le chemin*. See ENTAMER.

LEAD *walling*, in the salt works, on the salt springs in some parts of England, is the term used for that quantity of brine that is necessary for twenty four hours boiling in one house.

The whole government of the works is in the hands of certain lords, who proportion the quantity to be worked by theſe *lead wallings* to the ſeveral perſons who work it. At Namptwich, in Cheſhire, two hundred and ſixteen *lead wallings* belong to all the owners of the pit, and no tradeſman, batchelor, or widow, can rent more than eighteen *lead wallings*. All is under the directions of four ſworn officers, choſen every year, and theſe appoint how much ſalt ſhall be made each year, and how many houſes ſhall work at a time. *Ray*'s Engliſh Words, p. 142.

LEAD-*Wort*. See PLUMBAGO.

LEADERS, in the military art. See FILE-*leaders*.

LEÆNA, the *lioneſs*. See LIONESS.

LEAF (*Cycl.*)—The *leaves* of trees and plants afford the curious in microſcopic obſervations many very beautiful objects.

All *leaves* are full of innumerable veſſels, which convey perſpirable juices to the pores for their diſcharge. Whether there be any circulation in them, is not yet determined; but as their juices all become ſtiff and coagulated, when let out, it is probable that they have ſome motion, which keeps them fluid while in the veſſels of the plant.

The pores in the *leaves* of plants are almoſt innumerable. Mr. Lewenhoek found an hundred and ſeventy two thouſand and ninety pores on one ſide of a *leaf* of box. The *leaves* of rue ſeem full of holes, like a honey comb; all the kinds of St. John's wort appear likewiſe ſtuck full of pin holes to the naked eye, but the microſcope diſcovers, that the places where thoſe holes ſeem to be, are really covered with a very thin and white membrane. The backſide of the herb mercury looks as if rough caſt with ſilver, and all the ribs are full of white round tranſparent balls, faſtened by ſlender ſtalks, like ſo many grapes. A ſage *leaf* appears like a rug, or ſhag, full of knots and tufts of ſilver thrums, and embelliſhed with fine round cryſtal beads, or pendants, and theſe faſtened by ſlender foot ſtalks. The back ſide of a roſe *leaf*, and particularly of that kind called *ſweet briar*, appears diapered with ſilver. Every one knows, that the *leaves* of ſtinging nettles are thick ſet with ſharp prickles, which penetrate the ſkin when touched, and occaſion heat, pain, and ſwelling. Theſe ſymptoms were imagined formerly to be owing to the prickles being left in the wounds they make, but the microſcope diſcovers ſomething much more wonderful in this plant, and ſhews that its prickles are formed for acting, in the ſame manner as the ſtings of animals. For every one of them is found to be a rigid body, hollow, and terminating in a very fine point, with an opening near its end. At the bottom of this prickle there lies a pellucid bag, containing a limpid liquor, which, upon the leaſt touching the prickle, is ſquirted out at the little outlet, and if it enters the ſkin, produces the miſchiefs beforementioned by the pungency of its ſalts. And hence it is, that the *leaves* of nettles, when they have been dried a little in the ſun, ſting ſcarce at all. *Baker*'s Microſcope, p. 259.

The *leaves* of plants are of the utmoſt conſequence to the life of the whole. Air evidently paſſes in at the *leaves*, and goes through the whole plant, and out again at the roots. If the *leaves* have no air, the whole plant will die, as is eaſily proved by the air pump; but in theſe experiments, if the *leaves* be left on the outſide of the receiver, and parted by a hole cemented with wax, and have air, the plant will thrive, and grow, though its roots and ſtalk are kept in vacuo in water. The *leaves* of plants perform the neceſſary work of altering the water received in at the roots, into the nature of the juices of the plant; and hence it is, that the life of the plants depend ſo immediately upon their *leaves*. The huſbandman often ſuffers for want of this knowledge. A crop of ſaint foin is a very valuable thing, and its root being perennial, will yield him encreaſe many years; but it is often deſtroyed at firſt, by ſuffering it to be indiſcreetly fed upon by the ſheep, which eating up all the *leaves*, the root remains without the means of a ſupply of air, and the whole periſhes.

Leaves being thus neceſſary to plants, nature has, in all perennial plants, provided a reverſionary ſtock of them. The *leaves* of theſe plants are always formed in autumn, though they are not unfolded till the following ſpring. They then open and encreaſe gradually, in proportion to the motion of the ſap, and the quantity of pabulum it then receives to be circulated. Theſe *leaves* may alſo, though not wholly appearing out of the bud, be ſufficient for the extremely ſmall motion of life, which the ſap of perennial plants, that drop their leaves, has in winter. *Tull's* Horſe-hoeing Huſbandry, p. 10.

Dr. Grew obſerved the formation of theſe autumnal *leaves*; but beſide theſe, there is another ſet of them formed in the ſpring, and expanding about Midſummer. Theſe are of infinite ſervice to many particular trees, particularly to the mulberry, as they ſave its life when the ſpring *leaves* have been all eaten up by the ſilk worms. People who ſtrip that tree for the food of theſe animals find, however, that ſome caution is neceſſary, in order to make the new ſupply of ſpring *leaves* ſave the life of the tree. For if they pull off the old *leaves* downward, ſtripping away ſtalk and all, the tree often dies, but if they pull them upwards, the tree lives without hurt; becauſe the ſtalk, in this caſe, is left, and often a piece of the bottom of the *leaf* upon it. Theſe ſerve, in ſome degree, in the place of the whole *leaves*, till the new ones are formed.

It is certain that no plant, to which nature has allotted *leaves*, can live without them, but will certainly die if they are pulled off as ſoon as they appear. The common graſs of our meadows and paſtures might ſeem an exception to this general rule; but it is to be conſidered, that though the ſheep eat this down very cloſe, and take off its *leaves* as ſoon as they grow, yet when it is thus devoured by cattle, it is only in the *leaf*, very little of it growing up into ſtalk at that time, and therefore leſs ſap is to be purified, and conſequently leſs of the operation allotted to the *leaves* required; and there is a conſtant ſucceſſion of new *leaves* growing up in the place of the old ones, and many of theſe being too ſhort to be bitten off, ſerve in the place of thoſe which are eaten.

The figure of the *leaves* of plants may be repreſented by holding one in the ſmoke of reſin, camphor, a candle, *&c.* whereby the *leaf* acquires a blackneſs, which when preſſed on white paper, gives the exact ſize, ſhape, and particular ramifactions of the fibres. This method may be of uſe to botaniſts, when they have no ſkill in drawing. *Boyle*'s Works Abr. Vol. 1. p. 132.

The *leaves* of plants have ſeveral diſtinctions among botaniſts, according to their ſhape and diviſion, each of which has its peculiar name. See Tab. of Leaves.

Aculeated LEAF, is that whoſe ſurface is covered with cartilaginous points, ſharp, rigid, and ſtrong enough to wound any tender part of the fleſh; and which adhere but ſlightly to the *leaf*, and may be eaſily ſeparated from it.

Acuminated LEAF, one terminated by a pointed and ſharp extremity, like an awl.

Acute LEAF, that which terminates in a ſharp point.

Alated LEAVES, are thoſe divided into, or compoſed of ſeveral compleat pinnated *leaves*, whether equal or unequal uniform or difform, as in the orobus, and other the like plants.

Alternate LEAVES, thoſe which do not ſtand oppoſite, but one over another, all the way up the ſtalk.

Amplexicaule LEAF, expreſſes a *leaf*, the baſe of which extends itſelf in ſuch a manner, that it environs, and ſurrounds the ſtalk every way. In this caſe, the *leaf* is generally of a ſagittated, or heart-faſhioned ſhape, and is ſeſſile.

Articulated LEAVES, thoſe which grow one on the top of another.

Bifid LEAF, one divided into two parts at the top. When a *leaf* is thus divided into three parts, it is ſaid to be *trifid*; when into four, *quadrifid*, and ſo on. *Multifid* expreſſes a *leaf* divided into a great number of ſegments.

Bigeminate LEAF, one formed of a double conjugation of leſſer *leaves*.

Binated LEAF, *binatum folium*, a kind of compound *leaf*, formed only of two folioles on one petiole.

Bipartite LEAF. See *Quinque partite* LEAF, infra.

Canaliculated LEAF, one which is hollowed all the way of its length with a channel.

Carnous LEAF, one which is full of pulp, or of a fleſhy ſubſtance, contained between the membranes which form the upper and under ſurface.

Cartilaginous LEAF, that whoſe edge is ſurrounded with a kind of cartilage, or border, thicker than the reſt, but of the ſubſtance of the *leaf*.

Cauline LEAF, that which grows not immediately from the root, but on the ſtalk of a plant.

Ciliated LEAF, one ſurrounded all the way with parallel hairs, or filaments, ſo as to give ſome reſemblance of the hairineſs of the eye-lids.

Compound LEAF, is that which is divided to the middle rib into ſeveral ſegments, and ſeems made up of ſeveral ſmaller *leaves*, as in liquorice, *&c.*

Compound leaf expreſſes, in general, a *leaf* that is formed of ſeveral other leſſer ones. In this large ſenſe, however, it is diviſible into ſeveral kinds. 1. The *compound* ones, properly and diſtinctly ſo called. 2. The *decompound*. And 3. The *ſupradecompound*. Of each of which in its place.

In deſcribing theſe kinds of *leaves*, the whole *leaf*, which is the reſult of the combination, is called *folium*, and the ſmall *leaves*, which together compoſe it, are called *foliola*.

Compound leaf, properly ſo called, is only formed of one ſeries of foliola, or of one compoſition.

Compreſſed LEAF, one with the mark of an impreſſion on both ſides.

Concave LEAF, one whoſe middle is ſunk or hollowed.

Conferta FOLIA, *leaves* placed in cluſters, or ſo cloſe to one another, that it is not eaſy to diſcover their exact ſituation.

Connata FOLIA, leaves cohering together, or whoſe baſes unite, ſo as to form but one body.

Convex LEAF, one whoſe middle riſes into a protuberant form.

Cordated

Cordated LEAF, expreſſes one of an ovated ſhape, hollowed a little on each ſide at the baſe.

Obverſely cordated LEAF, one of the ſame figure with the former, but affixed to its petiole not by the cordated part which is the baſe in the former, but by the oppoſite end.

Cordato-ſagittated LEAF, a *ſagittated leaf*, the ſides of which are convex.

Crenated LEAF, *crenatum folium*, that whoſe edges are furniſhed with indentings which are contiguous to one another, and are neither turned toward the point nor toward the baſe.

Acute crenated LEAF, a *crenated leaf*, in which the indentings are ſharp at the ends.

Obtuſe crenated, that whoſe indentings terminate obtuſely.

Criſp LEAF, *criſpum folium*, that which is undulated or folded over and over at the edge, which muſt alſo be in ſome manner divided, not entire, *viz.* either dentated, ſerrated, or lacerated.

Cuneiform LEAF, one of the ſhape of a wedge; or, the length of which greatly exceeds its breadth, and the lower part of which grows ſmaller all the way.

Decompoſite LEAF expreſſes a *leaf*, the common petiole of which divides itſelf twice before it is furniſhed with *leaves*.

Decurrent LEAF, one which adheres immediately to the ſtalk or branch of a plant, without any pedicle; and, which has its lower part extended and running along the branch.

Deltoide LEAF, one with four angles, whereof thoſe of the ſummit are farther diſtant from the center than thoſe of the ſides.

Dentated LEAF, one whoſe edge is beſet with horizontal points of the ſame matter with the *leaf* itſelf, and diſtinct and ſeparate one from another.

Depreſſed LEAF, one which has the mark of an impreſſion on one ſide.

Digitated LEAF, expreſſes a compound one, formed of a number of ſimple foliola, placed regularly on a common petiole: in a ſtrict ſenſe, however, it is uſed only to expreſs ſuch a *leaf* as is compoſed of more than four foliola.

Duplicato-pinnatum, or *pinnato-pinnatum*, expreſſes a *leaf* compoſed of ſeveral others, each of which is itſelf compoſed of ſeveral ſmaller leaves or foliola.

Duplicato-ternated LEAF, one conſiſting of *leaves*, which are themſelves compoſed of three leaves each.

Emarginated LEAF, that which has a little indenting on the ſummit. *Obtuſely emarginated*, is the term when the two points which form the indenting are obtuſe: when they are acute, it is ſaid to be *acutely emarginated*.

Enſiform LEAF, a compreſſed *leaf* of the ſhape of a ſword, which is thin, and edged as it were on the ſides, and which has a high rib running down its middle.

Erect LEAF, one ſo ſituated as to make an acute angle with the ſtalk.

Eroſe LEAF, *eroſum folium*, a *leaf* which has ſeveral ſinuſes in its diſk, and alſo in the edge or border.

Faſciculate LEAVES, expreſſes *leaves*, many of which ariſe together from the ſame point.

Floral LEAF, expreſſes one found near the flower, and which never appears but with the flower.

Frondes expreſſes *leaves* conſiſting of ſeveral other *leaves*, and forming the whole plant; as is the caſe in the fern-kind, in which the fructification being on the back of the *leaves*, the ſingle *leaf* makes the whole plant.

Haſtated LEAF, one in form like a ſpear's point: this expreſſes a triangular *leaf*, the ſides and the baſe of which are both hollowed, ſo as in ſome meaſure to give the reſemblance of a *leaf* compoſed of three parts.

Hirſutum folium. See *Piloſe* LEAF, infra.

Hiſpid LEAF, one whoſe ſurface is covered with more thick and rigid hairs than the *piloſe leaf*. See *Piloſe* LEAF, infra.

Horizontal LEAF. See *Patent* LEAF, infra.

Jagged LEAF. See *Laciniated* LEAF, infra.

Imbricated LEAF, *imbricata folia*, *leaves* placed over one another in the manner of the tiles of a houſe, or like the ſcales of fiſhes.

Inflex LEAF, *inflexum folium*, that which in growing from its baſe, turns its point again toward the plant.

Intire LEAF, *integrum* or *indiviſum folium*, a *leaf* which is not cut in with any ſinus in its diſk.

The term *integerrimum* applied to a *leaf*, denotes that it is free from all diviſions or ſinuations of any kind in the border any more than in the diſks.

Lacerated LEAF, *lacerum folium*, a *leaf*, the edge of which is compoſed of ſegments of different ſhape and figure.

Laciniated LEAVES, are thoſe which are very deeply cut in, though not quite to the middle rib, yet are divided into ſeveral jagged portions, theſe are called alſo jagged *leaves*; and of this kind are thoſe of the horned poppy, ragwort, and the like.

Lanceolated LEAF, that which is ſhaped like a ſpear's point, or which is oblong, and growing ſmaller and narrower from the middle to the extremity where it terminates in a point.

Lanigerous LEAF. See *Piloſe* LEAF, infra.

Linear LEAF, one the two ſides of which run almoſt parallel to one another: the *linear leaves* are uſually narrow, and ſomewhat broader in the middle than at either end.

Linguiform LEAF, a linear *leaf* in ſhape of a tongue, which is obtuſe, fleſhy, depreſſed, convex on the under ſide, and uſually cartilaginous at the edge.

Lunulated LEAF, one in form of a creſcent: it is a ſuborbicular *leaf* hollowed at the baſe, with two curvilinear angles in form of circles at its hinder part or baſe.

Lyrated LEAF, *folium lyratum*, one in form of a lyre; or, it is a compound *leaf*, formed of a ſimple one, which divides itſelf in its lower part in ſuch a manner, that the inciſions below make ſegments which ſtand out from the body of the *leaf*, and are detached from the larger ſegment, which forms the upper part.

Membranaceous LEAF, one merely compoſed of membranes with no pulp between.

Naked LEAF, *nudum folium*, expreſſes a *leaf* whoſe ſurface is ſmooth and equal, without any particular marks.

Natant LEAF, one which floats upon the ſurface of the water.

Nervoſe LEAF, one whoſe veſſels are ſimple, and extend themſelves parallelly from the baſe toward the ſummit, without any ramifications.

Nitidum folium, expreſſes a *leaf* of a ſmooth and gloſſy ſurface, looking as if poliſhed by art.

Oblong LEAF, one the length of which is many times equal to its breadth, and the extremities of which are both too narrow to form ſegments of circles.

Obtuſe LEAF, one terminated by the ſegment of a circle. When the ſummit of a *leaf* is obtuſe, but terminated by a fine ſharp point, affixed as it were upon it, it is ſaid to be *obtuſum cum acumine*.

Obverſely ovated LEAF, *obverſè ovatum folium*, a *leaf* of the ſame figure with the ovated *leaf*, only fixed to the petiole by its ſmaller end.

Orbicular LEAF, one of a round figure, the breadth of which is equal to its length, and every part of its edges equally diſtant from the center.

Oval LEAF, one approaching to round, but too long for its breadth; its diameter, at both extremities, is equal to the two ends, forming the ſame ſegments of circles: this might be more diſtinctly called elliptic.

Ovated LEAF, *folium ovatum*, expreſſes a *leaf*, the ſhape of which is like that of an egg; or, which is longer than broad, and the baſe or lower part of which forms the ſegment of a circle, though the other extremity is too ſmall to be in proportion to it.

Palmated LEAF, one in form of an open hand: this expreſſes a *leaf*, divided into ſeveral ſegments, from the top down to the middle, or to the baſe.

Panduriform LEAF, one of the ſhape of a violin: this is an oblong *leaf*, larger at both ends than in the middle, where it is deeply cut, in a rounded manner.

Papilloſe LEAF, one whoſe ſurface is covered with little roundiſh protuberances, or veſicles.

Patent LEAF, one which ſtands almoſt ſtrait out from the ſtalk, or nearly at right angles with it. When it forms perfectly right angles, it is called *horizontal*.

Peltated LEAF, expreſſes a *leaf*, the petiole of which is affixed to the diſk, and not to the baſe, or to the edge of the *leaf*.

Pentagonal LEAF. See *trigonal* LEAF, infra.

Perfoliate LEAF, that whoſe diſk is pierced by the ſtalk, the branch, or the peduncle; and does not any where touch or adhere to its edges.

Petiolate LEAF, one affixed to a plant by means of a peculiar pedicle, which in the caſe of a *leaf* is called *petiole*, though in caſe of fruit a *peduncle*. See PETIOLE, *&c.*

Piloſe LEAF, one whoſe ſurface is furniſhed with hairs ſo large and long, as to be diſtinguiſhable by the eye ſeparately. The ſame idea is alſo expreſſed by the term *hirſutum*, *villoſum*, and *lanigerum*.

Pinnated, or *pennated* LEAF, one formed in manner of a wing, and compoſed of two ranges or ſeries of folioles, annexed to the two ſides of one common oblong petiole.

Of the *pinnated leaves* there are ſeveral kinds: 1. The *pinnated* with an odd one: this expreſſes the *pinnated leaf*, when beſides the two ſeries juſt mentioned, there is an odd *leaf* at the extremity of the petiole. 2. The *pinnated abrupt leaf*, in which there is neither an odd *leaf*, nor a tendril at the end of the petiole. 3. The *oppoſitely pinnated*, which is when the folioles ſtand oppoſite to one another on the common petiole. 4. The *alternately pinnated*, when the folioles ſtand not oppoſitely but alternately. 5. The *interruptedly pinnated*, in which the folioles are irregular and unequal in ſize or ſituation. 6. The *cirro-pinnated*, the extremity of whoſe petiole has one or more tendrils, inſtead of an odd *leaf*. 7. The *decurrently pinnated*, in which the folioles extend beyond their proper baſe in going down the petiole, and as it were make it alated. 8. The *membranaceous pinnated*, of the ſame form with the laſt, but with the petioles themſelves membranaceous and articulated. 9. The *conjugated pinnated leaf*, when the whole compound *leaf* conſiſts of only two folioles on the petiole: this kind of *pinnated*

leaf may be either abrupt, cirrated, membranaceous in the petiole, or ſtipulated.

Pinnatifid LEAF expreſſes one divided into ſeveral parts in form of alæ; or which has three, four, or more lateral ſinus's ſeparated by long horizontal ſegments.

Plicated LEAF, one from the baſe or petiole of which there run at ſeveral diſtances veſſels or fibres, which extend themſelves to the extreme ſides, and ſome of which raiſe and others depreſs the diſk of the *leaf* in an alternate order, making acute angles.

Præmorſe LEAF, *præmorſum folium*, a *leaf* which is truncated and terminated by an acute ſinus at the ſummit.

Quadrifid LEAF. See *bifid* LEAF, ſupra.

Quaternate LEAVES. See *ternate* LEAVES, infra.

Quina FOLIA. See TERNATE.

Quinquangular LEAF, one with ſtrait ſides and five angles.

Quinquefoliate LEAF, is a compound *leaf* of the ſame form with the *trifoliate*, but made up of five ſegments; ſuch are the *leaves* of cinquefoil, &c.

Quinquepartite LEAF, one which is ſeparated into five parts down to the very baſe, ſo as to ſeem made up of five ſeparate *leaves* till cloſely examined. In the ſame manner a *leaf* is ſaid to be *bipartite*, &c. when it is divided into two, three, &c. parts.

Radical LEAF, that which grows immediately from the root of a plant not from the ſtalk.

Radicant LEAF, one which puſhes out roots from its ſummit, as ſome of the ferns do.

Radicated LEAF, *folium radicatum*, one which puſhes out roots from its diſk or lower ſurface.

Ramoſe LEAVES, thoſe which are ſtill more divided than the winged or alated *leaves*, and compoſed of one ſeries farther in their diviſion. Of this ſort are the *leaves* of female fern, and the like. Or,

Ramoſe leaf is one which grows not on its main ſtalk, but on its branches.

Ramuloſe LEAF, a kind of compound *leaf*, in which there are ſeveral foliola ſuſtained on a branched petiole.

Reclinate or *reflex* LEAF, one which has its ſummit lower than its baſe.

Reniform LEAF, one of the ſhape of a kidney; or, it is a *leaf* of a ſuborbicular figure, hollowed a little at the baſe, but without any angle.

Repanded LEAF, *folium repandum*, a *leaf*, the border of which is marked all round with ſhort lobes, each making a ſegment of a circle, with obtuſe ſinus's.

Retuſe LEAF, *retuſum folium*, a *leaf* whoſe extremity is terminated by an obtuſe line.

Revolute LEAF, *folium revolutum*, a *leaf*, the upper part of which rolls itſelf downward.

Round LEAF, *teres folium*, one which is not flatted as moſt are, but is of a cylindric figure, except the point.

Rugoſe LEAF, that whoſe veins are ſunk deep, and between which the membranous and fleſhy part of the *leaf* riſes in irregular forms, ſo as to give upon the whole a wrinkled ſurface.

Sagittated LEAF, one formed like the iron head of an arrow. This is the triangular *leaf* hollowed at its baſe for the inſertion of the petiole.

Scabrous LEAF, that which has ſeveral irregular prominences on its ſurface.

Semamplexicaule LEAF, one reſembling the *amplexicaule*, but with its lobes at the baſe too ſmall to entirely ſurround the ſtalk.

Seminal LEAF, that which appears firſt from the ſeed of a plant, and is uſually different from the reſt.

Serrated LEAF, *folium ſerratum*, that whoſe edge or border is notched like a ſaw, or furniſhed with points which make acute angles, and placed one bending toward another, and all toward the top.

Retrorſum ſerratum folium expreſſes a *leaf* whoſe edge is furniſhed with the ſame ſort of indentings, but in which they are turned backwards, or all look toward the baſe of the *leaf*.

Obſolete ſerratum folium expreſſes a *leaf* indented in the ſame manner, but the indentings obtuſe and weak.

Folium duplicato-ſerratum denotes a *leaf ſerrated* as the firſt, but with the ſerratures large, and their edges *ſerrated* again with indentings of the ſame kind.

Seſſile LEAF, one which riſes immediately from the ſtalk without any pedicle.

Simple LEAF, is that which is whole, or not divided to the middle rib, or ſeeming made up of different ſmaller *leaves*; as in ſage, mint, &c.

Simple leaf is otherwiſe defined, that of which the petiole carries only one. See PETIOLE.

Sinuated LEAF, one which has a number of ſinus's on its ſides, but theſe ſeparated by lobes not very long, nor themſelves indented or notched at the edges.

Sinuato-dentated leaf expreſſes a *leaf* like the former, but with the lateral lobes of a linear figure.

Retrorſum ſinuatum folium, a *leaf* with ſinus's at the ſides, and with the lobes which divide them, pointed and turned toward the baſe like the beards of an arrow.

Sparſe LEAVES, thoſe which are placed irregularly over the ſeveral parts of the plant.

Spinoſe LEAF, that whoſe diſk or edge is armed with cartilaginous points ſo firmly affixed, that they cannot be ſeparated without injuring the *leaf* itſelf.

Stellate LEAVES, thoſe which grow more than ſix at a joint, and are arranged like the rays of a ſtar,

Striated LEAF, one with a number of longitudinal furrows on its ſurface.

Subrotund LEAF, that approaching to the figure of the orbicular *leaf*, but departing from it, either in being too long, or too broad, or prominent, in ſome one or more parts. Vid. ſupr.

Subular LEAF, that which grows at the ramifications, or under that part of the ſtalk, from whence there grows one on ſeveral branches.

Subulated LEAF, one of the ſhape of an awl. This expreſſes a *leaf* oblong and narrow, broadeſt at the baſe, and thence gradually decreaſing, till it terminate in a point.

Sulcated LEAF, one which has a great number of ridges all round it, with obtuſe ſinuſes.

Supradecompoſite LEAF, one which has the common petiole divided more than twice, before it is charged with *leaves* or foliola.

Ternated LEAF, a compound one, conſiſting only of three *leaves* on a common petiole.

Ternate alſo expreſſes *leaves* which grow three at a joint, ſurrounding the ſtalk. When there are four or five, they are called *quaterna* and *quina*, and ſo on.

Tetragonal LEAF. See *Trigonal* LEAF, infra.

Tomentoſe LEAF, one whoſe ſurface is covered with hairs ſo ſhort and fine, that the eye does not diſtinguiſh them ſingly, though the *leaf* in general is evidently downy, both to the ſight and the touch.

Triangular LEAF, one compoſed of three rectilinear ſides, and three angles, the two inferior ones of which are on a level with the baſe.

Trifid LEAF. See *Bifid* LEAF, ſupra.

Trifoliate LEAF, is a compound *leaf* made up of ſegments placed in the ſame order as in the digitated *leaf*, but theſe ſegments are uſually ſhort, and are always three in number. Of this ſort are the *leaves* of clover, graſs, &c.

Trigonal LEAF, one much like the triquetrous, only that in this the ſeveral faces are each hollowed in form of channels, and the ribs are ſharp and membranaceous.

A *leaf* that has, inſtead of three ribs or edges, four or five, is in the ſame manner called *tetragonal*, *pentagonal*, &c.

Trilobous LEAF, one divided into three lobes. This is a *leaf* divided juſt down to the middle into three parts, which ſtand apart from one another, and are ſurroundedat the edges.

Tripartite LEAF. See *Quinquepartite* LEAF, ſupra.

Triplicato-ternatum, or *ternato-ternatum*, a *leaf*, the petiole of which divides three times into three branches, before any *leaves* or foliola are placed on it.

Triquetrous LEAF, expreſſes a *leaf* which has three faces or ſides, all flat. This is uſually alſo ſubulated, or grows ſmaller gradually from the baſe to the point.

Truncated LEAF, that whoſe ſummit or point ſeems to have been cut off, or is terminated by a ſtrait line in a tranſverſe direction.

Tubuloſe LEAF, one which is hollow within, and makes a kind of tube.

Vaginans expreſſes a *leaf*, the baſe of which is formed like a cylinder, and ſurrounds the ſtalk, as is the caſe in many of the graſſes.

Venoſe LEAF, that on the ſurface of which there are a vaſt number of branched veſſels, which frequently unite in an odd manner one with another.

Villoſe LEAF. See *Piloſe* LEAF, ſupra.

Undulated LEAF, that whoſe exterior part of the diſk is of more extent than a circle of the ſame diameter, ſo that the edges are neceſſitated to riſe and fall in a regular manner.

Indian LEAF, in botany. See TAMALAPATRI.

LEAVES, in watchmaking, is uſed for the notches of its pinion. See PINION, *Cycl.*

LEAK, at ſea, is a hole in the ſhip, through which the water comes in. A ſhip is ſaid to *ſpring a leak* when ſhe begins to *leak*, or let in the water.

The manner of ſtopping a *leak* is, to put into it a plug wrapt in oakum, and well tarred, or in a tarpawling clout, which keeps the water out; or nailing a piece of ſheet lead on the place.

Seamen ſometimes ſtop a *leak* by thruſting a piece of ſalt beef into it. The ſea water, ſays Mr. Boyle [a], being freſher than the brine imbibed by the beef, penetrates into its body, and cauſes it to ſwell ſo, as to bear ſtrongly againſt the edges of the broken plank, and thereby ſtops the influx of the water.—[a] Works Abr. Vol. 1. p. 147.

A ready way to find a *leak* in a ſhip, is to apply the narrow end of a ſpeaking trumpet to the ear, and the other to the ſide of the ſhip where the *leak* is ſuppoſed to be; then the noiſe of the water iſſuing in at the *leak* will be heard diſtinctly, whereby it may be diſcovered. See Philoſ. Tranſ. N° 201.

LEAO, in natural hiſtory, a mineral ſubſtance approaching to the nature of the *lapis lazuli*, found in the Eaſt-Indies, and

and of great uſe in the Chineſe porcelain manufacture, being the fineſt blue they are poſſeſſed of. This ſtone is found in the ſtrata of pit coal, or in thoſe of a yellowiſh or reddiſh earth in the neighbourhood of the veins of coal. There are often found pieces of it lying on the ſurface of the ground, and theſe are a ſure indication, that more will be found on digging. It is generally found in oblong pieces of the ſize of a finger, not round, but flat. Some of this is very fine, and ſome coarſe, and of a bad colour. The latter is very common, but the fine ſort is ſcarce, and greatly valued. It is not eaſy to diſtinguiſh them at ſight, but they are found by experiment, and the trying one piece is generally ſufficient for judging of the whole mine; for all that is found in the ſame place, is uſually of the ſame ſort.

Their manner of preparing it for uſe is this: They firſt waſh it very clean, to ſeparate it from the earth, or any other foulneſs it may have; they then lay it at the bottom of their baking furnaces; and when it has been thus calcined for three or four hours, it is taken out and powdered very fine in large mortars of porcelain with peſtles of ſtone faced with iron. When the powder is perfectly fine, they pour in ſome boiling water, and grind that with the reſt, and when it is thoroughly incorporated, they add more, and finally pour it off, after ſome time ſettling. The remainder at the bottom of the mortar, which is the coarſer part, they grind again with more water, and ſo on, till they have made the whole fine, excepting a little dirt or grit. When this is done, all the liquors are mixed together, and well ſtirred. They are ſuffered to ſtand two or three minutes after this, and then poured off, with the powder remaining in them. This is ſuffered to ſubſide gradually, and is the fine blue they uſe in their beſt works, our common ſmalt ſerving for the blue of all the common low priced China ware. Obſervat. ſur les Coutumes de l'Aſie, p. 326.

It is plain that this ſtone is a ſort of *lapis lazuli*, and the ultramarine blue, uſed by our painters, is made in a manner not wholly unlike this. It is much to be wiſhed that England were well ſearched for ſuch a ſtone as this *lead*, ſince our mines in Derbyſhire afford many blue ſubſtances, which have not been ſufficiently conſidered; and if it ſhould be found that either this, or any other European nation, produces it, it will be a fine diſcovery, as we ſhould not only have the means of giving a fine colour to our own manufactures of this kind, but we might trade with it in China to a vaſt advantage. If England does not poſſeſs it, it is very probable that Germany does, the mines there affording an almoſt inexhauſtible ſtore of coloured ſtones; and this being certainly no other than the ſtony matter of ſome cryſtalline nodule, accidentally tinged with ſome particles of copper. See LAZULI *lapis*.

LEAP, (*Cycl.*) in muſic, is when the ſong does not proceed by conjoint degrees. For inſtance, when there is an interval of a third, fourth, fifth, &c. between two notes, the Italians call it a *leap*, *ſalto*.

It is to be obſerved that there are two kinds of *leaps*, regular and irregular, called by the Italians, *ſalti regolari & irregolari*.

The *regular leaps* are thoſe of a third major, or minor, whether natural or accidental, fourth, fifth, ſixth minor, and octave, and theſe either aſcending or deſcending.

Irregular leaps are the tritone, ſixth major, ſeventh major, the ninth, tenth, and in general all beyond the compaſs of an octave; at leaſt in vocal muſic.

Beſides theſe there are others which may be uſed, but with diſcretion; ſuch as the diminiſhed fourth, the falſe fifth, and flat ſeventh. The difference between the regular and irregular *leaps* is, that the former are performed by the voice, without any great difficulty or effort; whereas the latter require more attention and pains to execute.

LEAP in fiſhing is uſed for a net, engine, or weel, made of twigs, to catch fiſh in. Stat. 4 and 5 Will. and Mary, cap. 23. *Blount*.

LEAP, in the manege, an air of a ſtep and a *leap*. See STEP, *Cycl.*

LEAPING-*horſe*, in the manege, is one that works in the high manege, or one that makes his *leaps* with order and obedience between two pillars upon a ſtrait line, in volts, caprioles, balotades, or croupades. Uſe excludes a gallop *a terra a terra*, and corvets, from the number of *leaps*; becauſe the horſe does not riſe ſo very high in theſe. Each *leap* of the horſe ought not to gain, or make above a foot and a half of ground forward.

LEAT, is uſed for a trench to convey water to, or from a mill. It is mentioned in the ſtatute 7 Jac. I. c. 19.

LEATHER (*Cycl.*)—Mr. Boyle ſpeaks of a method of preparing *leather* without any bark at all, and better than in the uſual way; but we do not find the proceſs of this in his works. *Shaw's* Abridg. Vol. I. p. 134.

LEATHER-*mouthed*, in ichthyography, a term uſed as the Engliſh for *malacoſtomous*, the diſtinctive epithet of ſuch fiſhes as have thick lips and no teeth in their jaws; as the carp, tench, bream, roach, &c. *Willughby*, Hiſt. Piſc. p. 129. See MALACOSTOMOUS.

LEBERIS, in ſome medical writers, a word uſed to expreſs the exuviæ of ſerpents, or the ſkins which ſnakes caſt off every year; theſe are by ſome greatly recommended for taking off freckles and ſun-burns from the face.

LEBNI, in the materia medica of the antients, a name given by ſome to ſtorax. Aviſenna has treated of this drug in three ſeparate chapters; in one under the title of *aſtarak*, in another under the title of *lebni*, and in the other under the title of *miha*, or *almiha*. This has led ſome to imagine theſe three words the names of three different drugs; but the author ſets this right, by explaining himſelf in the beginning of one of the chapters, that of *lebni*, in this manner: What is *lebni? Lebni* is *miha*. It ſeems, upon the whole, that *miha* was the general name of this drug, and that *aſtarak* and *lebni* were the names of particular kinds of it. The Greeks were very nice in diſtinguiſhing the ſeveral kinds of ſtorax, and the Arabians ſeem to have followed their example; nay, they have even borrowed ſome of the terms, by which they called the particular ſorts, as the *calamita*, and the reſt. The calamite ſtorax of the Arabians was not, however, the ſame with that of the Greeks, but only the refuſe of the preſſings of the liquid ſtorax; the *lebni* ſeems to have been the ſame with the *calamite* of the Greeks, and the aſtarak the ſame with their cymatian ſtorax.

The ſoft, or liquid ſtorax of the Greeks, ſeems to have been very common among theſe people, and they have called it *mel lebni*, the honey of ſtorax. This was a common word with them to expreſs any thing ſoft. See MEL.

LECANOMANTIA, Λεκανομαντεια, in antiquity, a kind of divination performed in a baſon with wedges of gold or ſilver. See HYDROMANTIA.

LECCIA, in zoology, a name given by ſeveral to a large fiſh caught in the Mediterranean, and known among the generality of writers by the name of *amia*; though by Aldrovand, and ſome others, called *glaucus*. *Willughby*, Hiſt. Piſc. p. 296. See AMIA and LECHIA.

LECH, in metallurgy, a term uſed by the miners to expreſs the gold ore which has been powdered, and waſhed, and afterwards run with the aſſiſtance of lime ſtone. The *lech* is afterwards burnt in a fire of charcoal, in order to render it fit for the ſeparation of the metal, by means of lead, which abſorbing and ſcorifying the extraneous matter, renders the gold pure.

LECHIA, in ichthyology, a name given by Paulus Jovius, and others, to the fiſh called by others *amia* and *glaucus*, and by the antient Greeks *amia* and *trocTus*. It is properly a ſpecies of the ſcomber, and is diſtinguiſhed by Artedi by the name of the *ſcomber* with two fins on the back, and with the laſt bone, or ray of the hinder fin very long. The Italians call it *leccia*, whence Jovius's name. *Paul. Jovius*, c. 7. p. 57.

LECITHOS, a word uſed by the old medical writers, and plainly ſignifying a ſort of pulſe, but authors have variouſly underſtood it; ſome applying it to the decorticated ſeed of the lentil; others to the meal of the ſame pulſe; and others to the fruit of a peculiar ſpecies of *aracus*, or wild vetch. The ſame word is alſo uſed by Hippocrates, ſometimes, to denote the yolk of an egg. This is one of the numerous inſtances, in which confuſion is brought into the world by theſe homonymies; for when Hippocrates applies the epithet *lecithodes* to the ſediment of the urine in ſome diſeaſed ſtates, it is not eaſy to determine from it, whether he means to compare it to the meal of lentils, or to the yolk of an egg. The ſame alſo is the caſe in regard to his applying it to the pus, or matter of certain ulcers.

LECTICA, among the Romans, a litter, or vehicle, in which people were carried. The *ſella* differed from the *lectica*, as being higher, and becauſe people always ſat in it; on which account the *ſella*, from the time it was firſt brought into uſe, was eſteemed the more honourable carriage of the two.

The *lectica* was alſo uſed as a *bier* for carrying out the dead, who were dreſſed in habits ſuitable to their quality and ſex. *Pitiſc.* in voc. See BURYING.

LECTICARII, among the Romans, ſervants who carried the *lectica*. See LECTICA.

LECTORES, among the Romans, ſervants in great men's houſes, who were employed in reading while their maſters were at ſupper. They were called by the Greeks *anagnoſtæ*. *Pitiſc.* in voc. See ANAGNOSTÆ.

LECTUS *igneus*, among the Romans, a kind of torture firſt invented by Decius. The bottom of it was ſet with ſerrated teeth, or ſpikes, and ſtrowed with ſalt; while melted tallow was poured from above on the unhappy tortured perſon. *Hofm.* in voc.

LEDGES, in a ſhip, ſmall pieces of timber lying athwart ſhips, from the waſte-trees to the roof-trees, which ſerve to bear up the nettings, or the gratings over the half deck.

LEECH, *hirudo*, in zoology, an oblong animal, deſtitute of feet,

feet, and of a black colour, with various ſpots and lines, and a mouth with three diſtinct openings.

The creature is common in ſtanding waters, and is in frequent uſe in the practice of phyſic, often ſupplying the uſe of the lancet in bleedings. The beſt to be choſen for this uſe are the ſmall ones, and of thoſe, ſuch as have the moſt diſtinct lines on their backs. *Dale*, Pharmac. p. 355.

The hiſtory of this animal, and the ſtructure of its parts, by means of which it becomes uſeful to us, in ſupplying very happily the place of the lancet, with every other particular circumſtance of its life and food, have been very accurately given by Mr. Morand, in the Memoirs of the Academy of Sciences in the year 1739.

The more vulgarly known particulars of this animal are briefly mentioned by this gentleman; ſuch are the cutaneous annules of its outer coat, the beautiful arrangement of the ſeveral rays, the colours, the pyramids, and points, with which it is ornamented; the avidity with which this creature ſeizes the fleſh of animals; the manner of its applying its mouth; the vermicular motion obſerved within it while ſucking, which reſembles the common motion of deglution; the time they have been known to live in the water without any viſible food; and the faculty they have in common with many other animals, of moving when cut into ſeveral pieces: Theſe the author ſuppoſes already ſufficiently known, and paſſes on to what is leſs ſo, the ſtructure of its inner parts.

The part of this animal, by which it pierces the ſkin of any creature to get at its blood, is generally called, ſimply, its mouth, but it really conſiſts of five different parts, which are confounded under that general name. Theſe are two regular lips, a cavity, which is properly the mouth, certain inſtruments to pierce with, others which ſerve it for ſucking, and finally a ſort of throat, or œſophagus, through which it ſwallows the blood. When the *leech* is in a ſtate of reſt, its upper lip forms a regular ſemicircle, and the lower a portion of a much larger circle.

When the creature lengthens its head to move, the ſemicircle of the upper lip becomes two oblique lines, the junction of which makes a ſaliant angle, which the creature applies to whatever it would fix itſelf to. That angle is marked by a regular black ſpot on the outer edge of the lip. The extreme ſoftneſs of the fibres of this part makes it very ſerviceable to the animal, in that it readily aſſumes any figure, according to the occaſion of ſeizing any thing ſolid, in order to move the reſt of its body; or on the fleſh of an animal, to give opportunity to the piercing inſtruments to exert their force and action.

Whether it be for either of theſe purpoſes, that the creature fixes its mouth, the two lips regularly fix, and make in this ſtate a ſort of acetabulum, like the hollow of the tail. This may be ſeen in their fixing on the ſides of a glaſs veſſel in which they are kept, and the mouth, or aperture between the lips, is diſtinctly ſeen. This mouth is formed, like the lips, of ſuch extremely ſupple fibres, that it takes the figure of the part to which it is applied, and fixes perfectly cloſe to it. When the lips are fixed on the fleſh, in order to ſuck, this little mouth continues moveable under them, and ſearches over the compaſs of fleſh, incloſed in the larger circle of the lips, for the ſpot where it will be eaſieſt to draw much blood.

Within this mouth is placed the inſtrument for the piercing the ſkin, which is more than the meer ſucker of the gnat, or the like kind of flies; ſince the quantity of blood to be ſucked, by the *leech*, is greatly larger, and the aperture of the veſſel muſt therefore alſo be larger. The ſhape of this weapon may be diſcovered by examining the wound it leaves. This is compoſed of three cuts, making three rays, which uniting in a center, make equal angles one with another. This ſtructure of the wound is moſt diſtinctly ſeen when the ſwelling is gone down, and the ſkin is clean; and this is uſually on the fourth day after the application. The three openings are then plainly ſeen not to be punctures, but abſolute wounds, or cuts, as if made by a fine lancet. In examining the creature, the organ, deſtined for making the wound, is found to be placed between the aperture of the lips and the bottom of the mouth; and on cutting up the animal, and drawing the finger carefully over this part of it, there is felt a roughneſs like that of a fine file, which evidently is owing to ſome rough ſubſtance, of the hardneſs of bone. Theſe are, in reality, a number of fine and ſharp teeth, and when examined by a microſope, they are found to be diſpoſed in three ſeries on three ribs, or, as they may be called, jaws; each of which is placed along the middle of a ſtrong muſcle of its own length; and theſe correſponding regularly to a triangular opening, which the creature has in its mouth. When that has ſeized on a proper part for the getting blood, and is fixed, theſe muſcles exert their action, and ſtrike in the teeth through the ſkin.

Theſe are the inſtruments which pierce the ſkin, and the veſſel which is to afford the blood, and for the receiving it into the body of the animal. There is between theſe rows of teeth, or in the common center of the mouth, a ſmall aperture; and within this there is a little body to be diſcovered, which by its motion ſeems very plainly to be a tongue, and which probably acts as a piſton to take up the blood flowing from the triple wound, in the center of which it naturally ſtands, while the larger circle of the lips, &c. perform the office of the body of the pump, and the blood is eaſily, by this means, conveyed into the body of the animal. Finally, between the root of the tongue and the beginning of the ſtomach, there is a ſpace of two lines in length, in which it is eaſy to diſcover two different arrangements of fibres; the one ſet are flat and plain, the others are circular. Theſe evidently have a power of widening or contracting the cavity of the pump, and by that means facilitate its office; the plane ones contracting in length, to enlarge the capacity, and the circular ones determining the blood toward the ſtomach, by their power of contracting the hollow, when the blood is received. The blood from hence enters into a membranaceous ſort of ſack, which ſerves the animal for ſtomach and guts, and occupies the greateſt part of the body of the creature. If the air is admitted into the body by the mouth, it may be ſeen to make its way down a longitudinal canal, and fill, as it goes, a number of ſacks, or little bags, which are on each ſide. Theſe veſicules receive the blood, and becoming filled with it, ſwell out the body of the animal to a great ſize. It remains here many months, and nouriſhes the creature, and if any thing is excreted from it, it muſt be merely by an inſenſible perſpiration; ſince the creature has no anus, ſo far as can be yet diſcovereed, nor any aperture which can ſupply the place of one.

Leeches are able to live in oil; and when removed out of this liquor into water again, they throw off a tender ſkin, or film, of the regular ſhape of their body, and reſembling the ſkin of an eel in miniature. Their living in oil ſeems a proof, that their organs of reſpiration are not placed on the outſide of their bodies, as they are in many ſmall animals, which therefore die on being only rubbed over with oil. But the *leech* ſeems to reſpire by the mouth; and this may be the more plainly diſcovered, if the water, in which it is kept, be gently heated, for then the animal being uneaſy, breathes hard, and very viſibly.

The *leech* is a well known inſect, common in waters, and uſed to draw blood in medicine. The common ſtanding waters afford us two ſpecies of this inſect, a larger, called the *horſe-leech*, and a ſmaller, diſtinguiſhed from this not only in ſize, but by its whole ſurface, being covered with ſmall tubercles. The larger kind grow to five inches long, and is yelloviſh on the belly, and black upon the back. It is divided, in the manner of the earth-worm, into a number of annular joints, not leſs than an hundred, and is ſmaller toward the mouth, than toward the tail. The ſmaller kind has a broad ſtreak of a greeniſh black running down its back, and on each ſide of that a reddiſh line, and beyond theſe there are other lines formed of large black ſpots. The belly is blackiſh, with a caſt of green. This is the kind that ſhould be uſed in medicine, and is eaſily diſtinguiſhed from the other. Mr. Ray obſerves, that there are ſometimes found great numbers of young *leeches* ſticking in cluſters to the belly of the old one.

We have on the coaſt of Cornwall another inſect, much approaching to the nature of the *leech*. It is about ſix inches long, of a greyiſh colour, ſpotted with black, and is divided into about nineteen rings. It has a great number of a ſort of tubercles on the body, and is uſually found full of blood, or of a ſubſtance reſembling blood in colour. *Ray*'s Hiſt. Inſect. p. 3.

Bleeding with LEECHES. The method of bleeding by theſe animals was very early introduced into the practice of phyſic. *Leeches* ſhould always be choſen from clear and running waters; for thoſe from ſtagnant ones, and dirty ponds, ſeem to have ſomething malignant in their bite. The ſurgeons uſually chuſe ſuch as have ſlender heads, green lines on their backs, and bellies of a reddiſh yellow. But from whatever waters theſe creatures have been taken, the beſt method is to keep them many days in a glaſs of water, changing it often, that they may cleanſe themſelves.

Before the *leech* is applied to the ſkin, it ſhould be taken out of the water, and kept an hour in an empty cup, to drain itſelf, that it may thus be rendered thirſty and empty. They may be properly applied to the temples, or behind the ears, in diſorders of the head, and to the veins of the rectum in the blind piles. And applied to this part alſo, they often prove of great ſervice in hæmorrhages, or ſpittings of blood by the noſe, eſpecially when theſe have been occaſioned by a ſtoppage of the uſual diſcharges that way; though where this is not the caſe, they do great ſervice merely by revulſion.

Before the *leech* is applied, the ſkin muſt be well rubbed, till it become hot and red, and then either hold the *leech* by the tail to the part, or let it crawl of itſelf out of the cup upon it. By this means they readily lay hold; but if they refuſe, the blood of a chicken or pigeon ſhould be rubbed on the part; and if that does not allure them, they muſt be laid aſide as uſeleſs, and others taken in their ſtead.

If much blood is required to be drawn, the tails of the *leeches* may be cut off as they are ſucking, by which means, the blood they have already ſucked will be diſcharged, as well as what they continue to take in; for they will not let go their hold, but continue ſucking as before.

If they do not let go after a ſufficient quantity of blood is drawn, they are not to be pulled off, for that often occaſions tumors, and inflammations; but if a little ſalt be ſprinkled on the place, they quit their hold. The orifices ſhould be waſhed with warm wine, or water, and they uſually heal readily of themſelves. *Heiſter*'s Surgery, p. 312.

LEECH is alſo a name given by Boccone to a very particular water animal, which he found ſticking to the ſides of the *xiphias*, or ſword fiſh.

He calls it *hirudo*, or *acus cauda utrinque pennata*, and obſerves that it is ſlightly mentioned by Geſner, and by Johnſton, in their books of fiſhes. It is about four inches long. The belly is white and cartilaginous, and tranſparent. There is no regular head to be ſeen, but only a hollow ſnout, in the place of the head. This is covered with a very hard membrane, and differs extremely from the ſkin of the belly. This ſnout it thruſts up to the end into the body of the fiſh, and ſucks its blood with it. It has a tail ſhaped like a feather, and under it two ſlender filaments, or fibres, longer than its whole body. By means of theſe, when it is not faſtened to the body of the fiſh, it clings to ſtones, or ſea plants, to prevent its being carried away by the motion of the water; and when it is on the body of the fiſh, theſe ſerve it to hold much more faſtly with, than it otherwiſe could do. When it faſtens itſelf to the ſword fiſh, it always fixes on thoſe parts where the fins of the fiſh cannot come at it to diſturb it. Sometimes it adheres to the belly, ſometimes to the back, ſometimes to the tail, and often very near the head. The body of the creature is filled with ſlender tubes and pipes, by means of which it ſucks up the blood of the fiſh into the ſnout, which is a meer vacant tube, and from thence conveys it to the inteſtines. The whole body of the creature is formed of rings, which ſerve to draw up the tubes into the ſnout, and return them back upon occaſion. This creature miſerably afflicts the ſword fiſh, but it is itſelf as much tormented by an animal that preys on its blood and juices; this is a ſort of louſe, which is always found upon it. It is of a browniſh colour, and is generally found faſtened toward the tail of the creature, ſticking as firmly as a limpet to a rock. It is nearly of the bigneſs of a pea, and when cruſhed a little, will thruſt out ſeveral ſlender filaments. This *leech* is not found, ſo far as has yet been obſerved, on any other fiſh but the ſword fiſh; nor this louſe among other creatures, beſide this *leech*. Phil. Tranſ. N° 100.

LEEK, *porrum*, in botany. See PORRUM.

We have two kinds of *leek* commonly cultivated in our gardens, the one called the common *leek*, and the other a broader leaved one, commonly called the London *leek*. There are ſome reaſons to ſuſpect that theſe are only varieties of the ſame ſpecies of plant, both ariſing from the ſame ſeeds.

The method of propagating theſe is by ſeeds, and they are commonly ſown along with onions. The onions growing up firſt; and after they are pulled up, the *leeks* have time enough to grow to their ſize. *Miller*'s Gard. Dict.

LEEK-*head*, in the manege. See WART and PORIEAU.

LEER, (*Cycl.*) in glaſs making, a ſort of third furnace intended to anneal and cool, by proper degrees, the veſſels when made. This properly comprehends two parts, the tower and *leer*. The tower is that part which lies directly above the melting furnace, with a partition between them of a foot thick; in the midſt whereof there is a round hole, placed exactly over the furnace, through which the flame and heat paſs into the tower. On the floor of this tower the veſſels are ſet to anneal. There are two openings, by which the veſſels are put into this tower, and after ſtanding there ſome time, they are put into iron pans, which by degrees are drawn out all along that part of this furnace, which is properly called the *leer*; which is five or ſix yards long, that the veſſels may cool by degrees. This *leer* is continued to its tower, and arched all along, and is about four feet wide and high within. The glaſſes are cool by that time they are come to the mouth of this, which enters into a room where the glaſſes are placed when taken out. *Neri*'s Art of Glaſs, p. 243.

LEETCH *of a ſail*, in a ſhip, the outward edge or ſkitt of the *ſail* from the earing to the clew, or rather the middle of the *ſail* between theſe two.

LEETCH-*lines*, in a ſhip, ſmall ropes faſtened to the *leetch* of the top ſails (only) and then reeved into a block at the yard, juſt by the top ſail ties. Their uſe is to hale the *leetch* of the ſails, when the top ſails are to be taken in; which is always firſt done, and then the ſail can be taken in with the greater eaſe.

LEEWARD *ſhip*, at ſea, one that is not faſt by a wind, or which doth not ſail ſo near the wind, nor make her way ſo good as ſhe ſhould. See LEE, *Cycl.*

To *lay a ſhip by the lee*, or *to come by the lee*, is to bring her ſo that all her ſails may lie flat againſt her maſts and ſhrowds, and that the wind may come right upon her broad-ſide. The way to do which, if all a ſhip's ſails be abroad, is to bear up the helm hard to windward, to let riſe the fore jack, veer the main-ſheet, and take in the miſſen maſt, or at leaſt to peek it up, which is called *ſpelling the miſſen*.

LEEWARD *tide*, at ſea. See TIDE.

LEG (*Cycl.*)—In fractures of the two bones of the *tibia* and *fibula*, or either of them alone; the limb is to be extended, by aſſiſtants, both ways, while the ſurgeon replaces the bones, which done the limb is to be rolled up with the proper bandage, and retained in the moſt proper poſture. When both theſe bones are broken, they are ſeldom both broken juſt in the ſame place, but one a little higher than the other. If the *tibia* be broken alone, it is eaſily diſcovered by its lying ſo near the ſkin; but if the *fibula* alone, it is buried under ſo many muſcles that the fracture is not always ſo eaſily diſcovered, and the patient is ſo much leſs afflicted by it as to be ſometimes able to walk.

If a fracture of the *tibia* be accompanied with an external wound, this muſt be firſt well cleanſed, and the ſplinters of the bone carefully removed, and then the broken bone, by the help of a proper extenſion reduced to its proper place, the hæmorrhage ſtopped, and the whole bound up with the eighteen headed bandage; but if any fragments of the bone ſtick out, ſo as to hinder its reduction; they muſt be firſt removed by a pair of ſharp forceps, or if neceſſary a fine ſaw. The limb, when ſet, is to be laid in a proper frame, or in a caſe of ſtraw, renewing the dreſſing and bandage daily till the wound be healed. *Heiſter*, p. 136.

Ulcers in the LEGS. Although no part of the body is free from inveterate and obſtinate ulcers, yet the *legs* are found to be much more ſubject to them than the reſt. The general cauſes of ulcers in the *legs* are the ſame with thoſe of ulcers in other parts, a bad habit of body, too great a thinneſs and acrimony in the juices, and obſtructions of the menſes in women; to theſe alſo may be added calloſity of the lips of wounds, and caries of the bones within.

In perſons advanced in years, and naturally of a bad habit of body, it is moſt adviſeable not to attempt to heal theſe, ſince the effect of cure is often much worſe than the diſeaſe, and not unfrequently, even death itſelf: for theſe ulcers are, in many caſes, rather to be looked on as a relief to nature than a diſorder, as they ſerve to drain off a vaſt quantity of noxious humours from the body. This, however, ſhould not be extended to young robuſt habits, though bad, becauſe theſe may be corrected in ſuch ſubjects, and the firſt cauſe of the ſtubbornneſs of the ulcers removed by abſtinence, or a regular way of living, or by opening iſſues, with the help of internal remedies; and the cauſe thus removed, the ulcer may be removed with perfect ſafety: and though in old perſons theſe ulcers are not to be healed, yet palliative methods may be taken with them, to the great comfort of the afflicted perſons, that pain, and other violent ſymptoms may be removed, and the ulcer kept from ſpreading, or new bad ſymptoms from coming on.

Abſtinence and a ſtrict regimen are the great care, and gentle doſes of purging medicines are to be taken at times, and internal medicines, likely to do good in regard to the cauſe of the ulcer, may be alſo given: of this kind are eſſence of myrrh, balſam of peru, and the like. Externally, care muſt be taken to keep the ulcer perfectly clean; twice a day it ought to be dreſſed, and every time wiped clean from the ſanies; it ſhould then be dreſſed either with dry lint, or with lint dipped in a decoction of walnut leaves, or of birthwort, and over this a lead plaiſter, as that of the minium, or any of a like kind may be applied. Theſe ulcers treated in this eaſy manner will become very mild, of little trouble, and of great ſervice to the preſerving the life of the patient.

When inflammations and violent pains come on in theſe caſes, as they very frequently do from a blow, from cold, from dipping the *leg* in cold water, or from violent paſſions of the mind, or irregularity of diet, a linnen compreſs muſt be applied in this caſe dipped in Hungary water, or ſpirit of wine with camphor, or with a mixture of equal parts of lime water, and either of theſe liquors; theſe ſhould be applied warm, the patient ſhould be confined to his bed, and the limb carefully defended from the injuries of the external air, and ſmall liquors ſhould be frequently drank warm, to promote gentle ſweating; when the inflammation runs very high, and threatens a gangrene, great care is to be taken, and the methods uſed in inflammations and gangrenes regularly applied, otherwiſe there is the greateſt danger, that a ſphacelus, and death will be the conſequence.

When the ulcers dry up of themſelves in old people, nauſeas, horrors, and great weakneſs uſually ſucceed, which ſhew death at hand: in this caſe, the patient's ſtrength and ſpirits muſt be kept up as much as poſſible, and gentian, and florentine iris root muſt be applied in powder to the wound; and if theſe are of too little force, black hellebore root, either in powder or formed into little balls; and laſtly, powder of cantharides, or ſmall pieces of the common bliſtering plaiſter. If theſe applications ſucceed, and produce a running of the ulcer again, the methods before directed

muſt

muſt be again cautiouſly purſued; but if theſe fail of ſucceſs there is little hope of life. *Heiſter*'s Surgery, p. 253.

LEGS *of flies*. Theſe furniſh us with ſeveral diſtinctions for this large claſs of inſects. All flies have indeed ſix *legs*, but though they are the ſame in number, they differ ſufficiently in many other reſpects. Some flies have very long *legs*, and others as remarkably ſhort ones.

The gnats and tipulæ ſeem mounted on ſtilts, and by that differ from other flies, whoſe form of body is the ſame; but what is yet more obſervable, in regard to the *legs* of theſe inſects is, that though they are uſually all fixed to the corcelet, there are ſome ſpecies of flies which have the hinder pair faſtened to the rings of their body. *Reaumur*'s Hiſt. Inſ. Tom. 4. p. 143.

The *legs* of flies are often not only large or ſmall according to the ſize of the creature, but every portion of them comprized between two of the articulations, differs often from the other in length and thickneſs. What they all have in common, is, that the foot, or bottom part of them, on which the creature reſts itſelf, is always provided with at leaſt two claws, or hooks, which terminate in points ſo extremely fine, that they are able to lay hold of what appear to us the moſt ſmooth and poliſhed bodies.

The blue fleſh fly, and ſeveral other ſpecies, have alſo as it were two ſoles of feet; theſe are each of them nearly of a boat figure, and reſemble two ſmall balls; theſe touch at the part where they are connected to the foot, and leave between them an angular ſpace afterwards. Their external inferior ſurface is ſomewhat convex, and covered with very ſhort hairs very cloſely arranged; theſe hairs, like the points of the two claws, can find themſelves a paſſage into the pores of what appear to us the moſt poliſhed ſurfaces, and are of great uſe to the creatures, in their placing themſelves on vertical planes of glaſs.

Mr. Homberg has ſometimes found flies which could not walk upon glaſs in this poſition; and is of opinion, that theſe are ſuch, as by age had loſt the hairs from theſe balls on their feet. Thoſe alſo whoſe claws or hooks were become ſoft or blunt muſt find themſelves in the ſame ſituation: yet there are ſeveral ſpecies of flies which have not theſe balls; ſuch as the bee claſs, which yet are able to walk up our window glaſſes with great eaſe. *Reaumur*, Hiſt. Inſ. V. 4. p. 259.

LEG, in the manege, the member that ſupports a horſe's body, and performs the motion when he goes. Of the four *legs*, the two before have ſeveral parts, each of which has a peculiar name: ſo that by the name of fore-*leg*, we commonly underſtand that part of the fore-quarters that extends from the hough to the paſtern joint, and call it the ſhank; the part that correſponds to this in the hind-quarters is called the inſtep. But in common diſcourſe we confound the fore, and the hind-quarters; and without any diſtinction ſay the *four legs* of a horſe.

The French call a horſe *droit ſur les jambes*, i. e. ſtraight membered, or ſtraight upon his *legs*, when the fore part of the paſtern falls perpendicularly upon the *cronet*, and the ſhank and the paſtern are in a ſtraight line. See STRAIGHT and LONG-*jointed*.

The horſeman's legs are likewiſe of ſingular concern in the manege, for the action of theſe given ſeaſonably, and with judgment, conſtitutes one of the principal aids, which conſiſts in approaching more or leſs with the calf of the *leg* to the horſe's flank, and in bearing it more or leſs off as there is occaſion. This aid a horſeman ought to give very nicely, in order to animate a horſe: and it is ſo much the finer, that it is hidden and private: for in ſtretching the ham he makes the horſe dread the ſpur, and this fear has as much effect as the ſpur itſelf. See AID.

LEGS *of the martinets*, in a ſhip, is uſed for thoſe ſmall ropes, which are put through the bolt ropes of the main and fore ſail, in the leetch of each. They are above a foot in length, and at either end are ſpliced into themſelves: they have alſo a ſmall eye, into which the *martinets* are faſtened by two hitches, and the end is ſeized into the ſtanding part of the *martinets*.

LEGATE-*Note*, in the Italian muſic. Notes are ſaid to be *legate* when this ⌒, or this ⌣ mark is found over or under the heads of them. This is what we call *tying* them, and is done when they are properly but one note, but obliged to be ſeparated into two, becauſe part is found at the end of one bar, and the other part in the beginning of the following bar; or becauſe the two halves of a note are in different parts of the meaſure. See SYNCOPE.

LEGATO, in the Italian muſic, ſignifies confined or conſtrained by certain rules for ſome deſign; thus they ſay, *canone legato*, &c. See CANON.

LEGATORY, or LEGATARY, the ſame with *legatee* of a will. 27 Eliz. c. 16. *Blount*. It is derived from the Latin *legatarius*.

LEGER-*line*, in muſic, is uſed to ſignify a line, added to the ſtaff of five lines; when the aſcending and deſcending notes run very high or very low. We often meet with ſeveral of theſe lines both above and below the ſtaff.

LEGGIARDO, or LEGGIARDAMENTE, in the Italian muſic, is uſed to intimate, that the muſician is to ſing or play in a gay, briſk, and lively manner. See ALLEGRO.

LEGNA, Λεγνα, among the antients, a name given to the borders of the *Toga* and *Pallium*, that were on each hand; the extremities above and below being called *Ora*. *Pitiſc.* Lex. Ant. See ORA.

LEGUME, among botaniſts, a *pericarpium* of an oblong compreſſed figure, formed of two valves, joined by a viſible ſuture, both on the upper and under part, and having the ſeeds affixed to the upper limbs of the two valves in an alternate order. See PERICARPIUM.

LEIOBATUS, in ichthyology, a name given by Ariſtotle and Athenæus to a ſpecies of the ray fiſh, called by many of the old authors *bos marinus*, and by the later authors *lævi-raia*, or *raia oxyrynchus*. It is accurately diſtinguiſhed by Artedi, by the name of the variegated ray, with ten prickly tubercles on the middle of the back.

LEIOPODES, an epithet uſed by the old medical writers, to expreſs ſuch perſons who had feet perfectly ſmooth and even at the bottom, without the uſual hollow between the heel and the fore part of the foot.

LEITURGI, Λειτυργοι, among the Athenians, perſons of conſiderable eſtates; who, by their own tribe, or the whole people, were ordered to perform ſome public duty, or ſupply the commonwealth with neceſſaries at their own expences. *Potter*, Archæol. Græc. l. 1. c. 15.

LEMING, in zoology, the name of a creature of the rat kind, called by authors *mus Norwegicus*, the *Norway rat*. Olaus is the firſt author who has mentioned and deſcribed this creature, and from him Geſner, Scaliger, Johnſon, and the reſt, took their deſcriptions of it down to the time of Wormius, who took ſingular pains in giving its true hiſtory from his own obſervations. *Ray*'s Syn. Quad. p. 227.

It is a creature of the figure of the dormouſe, but has a ſmaller tail; it is uſually about five inches long, and its hair is very fine, and variegated with ſeveral colours; the lower part of the head is black; the crown yellow, and the neck and ſhoulders black again. The body is of a reddiſh tawney colour, but variegated with a great number of black ſpots of different figures, but uſually ſmall. The tail is ſcarce half an inch long, and very ſlender, and covered with a yellowiſh black hair.

It varies extremely in the order and diſpoſition of its ſpots; its noſe is ſharp, and its mouth ſurrounded by a great number of ſtiff hairs; among theſe there are twelve, which are much longer than the reſt, and are ſet at diſtances from one another; its mouth is ſmall, and the upper lip ſplit, and there are ſeen in this ſlit two very long teeth which are bent, and very ſharp; the eyes are ſmall and black, the ears are obtuſe and lie on the head, not ſtanding erect. The legs are ſhort, and the fore ones much ſhorter than the hinder pair; the creature is very ſwift in running, the toes of each foot are four in number.

LEMMA, in pharmacy, a term uſed to expreſs the huſk or ſhell of certain fruits, as the almond, and the like; and in general, whatever is taken off in decortication. Thus the huſks of oats, barley, &c. are the lemmata of thoſe ſeeds.

LEMMA is alſo a name given by ſome of the lower claſs of writers, in natural hiſtory, to an imaginary animal, which they deſcribe, as living in the woods of Aſia, and having the face of a woman and the body of a beaſt of prey.

LEMMA, in natural hiſtory, is alſo the name of a ſmall water plant well known to the antients, and called by Theophraſtus by this diſtinct name; but very improperly confounded by late writers among the duck weed kinds, and called by Bauhine, Ray, Parkinſon, and others, *lenticula paluſtris quadrifolia*, the four leaved duck weed; and by Petiver, in his gazophylacium naturæ & artis, *ſtratiotes paluſtris foliis lujulæ*, or the water ſoldier, with leaves like thoſe of wood ſorrel. Memoirs de l'Acad. Sc. Par. 1740.

Mr. Barnard Juſſieu has been at the pains of thoroughly enquiring into the nature and fructification of this plant, and to him alone we owe its true hiſtory. Its flowers having never been ſeen or regarded, till that gentleman gave an account of them in the memoirs of the academy of ſciences of Paris; and many of the more eminent botaniſts, from its different appearance when in the water and when out of it, having miſtaken it for two different plants. It indeed differs extremely from itſelf in three different ſituations in which it is found. It is ſometimes found in the middle of large ponds of freſh water, and is then very large, fair, and full; ſometimes it is found in ſhallow water, and is then conſiderably poorer, and ſometimes it is found on dry land, in which caſe it makes an extremely different figure; and is ſo ſtarved, and poor, as ſcarce to be known for the ſame herb.

The middle ſtate of theſe, that is when it grows in ſhallow water, ſeems its moſt natural appearance, and is the only condition in which it is found to produce its flowers and ſeeds. It is a ſpreading plant, its branches extend a great way far and wide; theſe ſend from their under part roots at certain diſtances, and from their upper four leaves ſuſtained by a long and ſlender ſtalk, and uſually there are ſeveral of theſe ſtalks from the ſame part of the plant, from

the ſame parts of the branches from whence the leaves ariſe; there are alſo ſeen to ariſe other very ſlender and very ſhort ſtalks which bear ſmall capſules, within which is encloſed the flower and afterwards the ſeed. The flowers are placed in ſeveral lodgments in this ſhell, and are compoſed of ſtamina and piſtils, but have no petals; the piſtils are various in number in the different flowers, from three to eight, the ſtamina are always very minute and very numerous. Memoirs Acad. Scien. Par. 1740.

Plukenet has deſcribed this plant a little differently from this writer, but the difference ſeems only owing to this, that Plukenet deſcribed one he found in deep water, whereas Mr. Juſſieu formed his account from the more ordinary and perfect appearance of the plant in ſhallow water, where alone it ripens its flowers and ſeeds. We have it not in England ſo far as is yet known, but it is common in the Eaſt and Weſt Indies and in France.

LEMNIAN *earth*, LEMNIA *terra*, a kind of bole or fine earth uſed in medicine, of which there are three ſpecies; the white, the yellow, and the red, but the red is moſt uſed. The characters by which they may be diſtinguiſhed from all other earths of the ſame colours are theſe.

Red *lemnian earth* is a denſe compact earth of a cloſe firm texture and pale red colour, and of a ſmooth and even, but not gloſſy ſurface. It does not break readily between the fingers, nor at all ſtains the hands, is not readily diffuſible in water, melts ſlowly in the mouth, is very aſtringent to the taſte, and when in its native ſtate is always ſomewhat harſh and gritty between the teeth; for what we find of it that is perfectly pure, and free from ſand, is ſuch as has been waſhed and ſeparated from it, all the genuine earth naturally containing ſome. It adheres firmly to the tongue, raiſes a ſlight efferveſcence with aqua fortis, and ſuffers very little change in a moderate fire. *Hill*'s Hiſt. of Foſſils, p. 13.

This is dug in the iſland of Lemnos, and in no other place ſo far as is yet known; and the fine and true earth only in one pit, which is opened once every year and no oftner, with great ſolemnity; and the earth, ſuppoſed ſufficient for the year's demand, is taken out and ſold to the merchants; ſome ſealed with various figures, other quantities unſealed; but, what is there bought unſealed is generally formed into ſmall maſſes, and ſealed before it is offered to ſale in Europe, the druggiſts always expecting to find *lemnian earth* ſealed. This is a very valuable earth, but is too often adulterated, frequently by the Turks upon the ſpot, either by mixing it with other earths, or another earth alone being ſold in its place, but more frequently in Europe, where every wholeſale dealer knows how to make a compoſition of our own clays, and properly tinge them with ochre, and afterwards give an impreſſion reſembling that of the genuine. Ibid.

The white lemnian earth is a fine bole of a very pure white, but of a ſomewhat lax texture, and leſs weighty than the other boles; it appears of a tolerably ſmooth ſurface, but feels ſomewhat duſty on rubbing; it ſcarce at all ſtains the fingers in handling, very eaſily crumbles to pieces, adheres ſtrongly to the tongue, and melts freely in the mouth, but like the red, leaves a ſandy harſhneſs between the teeth; this makes no efferveſcence with acids. It is dug in the iſland of Lemnos, and uſed in the German ſhops as an aſtringent and ſudorific. The antients knew this kind, but never uſed it in medicine, eſteeming the other ſuperior, but they employed it as the cimolia about cloaths. *Hill*'s Hiſt. of Foſſils, p. 2.

The yellow lemnian earth is a very valuable earth, common in the ſhops, and more than all the other ſubſtances of this kind ſubject to be counterfeited.

It is a very pure and fine earth, of a lively florid yellow, of a cloſe compact texture and ſmooth ſurface, conſiderably hard, and not at all ſtaining the fingers in handling. It ſticks firmly to the tongue, and melts pretty readily in the mouth, leaving not the leaſt harſhneſs between the teeth, and does not ferment with acid menſtrua. It is counterfeited two ways; the one by a yellow ochre, which may be diſcovered by its ſtaining the hands, and the other by a yellow clay; but this is eaſily known by its want of the true florid colour, and having all the characters of a clay not a bole. The genuine is found only in the iſland of Lemnos, and is the ſtratum next above the red. It is eſteemed a ſudorific, aſtringent and vulnerary. *Hill*'s Hiſt. of Foſſils, p. 8.

LENÆA, Ληναια, in antiquity, a feſtival of Bacchus, ſurnamed *lenæus* from ληνος, i. e. a vine preſs. Beſides the uſual ceremonies at feaſts ſacred to this God, it was remarkable for poetical contentions, and tragedies acted at this time. *Potter*, Archæol. l. 2. c. 20. T. 1. p. 412.

LENGTH, in the manege—*To paſſage a horſe upon his own length*, is to make him go round in two treads, at a walk or trot, upon a ſpot of ground ſo narrow, that the horſe's haunches being in the center of the volt, his own *length* is much about the ſemi-diameter of the volt; the horſe ſtill working between the two heels, without putting out his croupe, or going at laſt faſter or ſlower than at firſt. See the article VOLT.

LENS (*Cycl.*)—In the Philoſophical Tranſactions we have the figure of a machine for grinding *lenſes* ſpherically. It is a contrivance to turn a ſphere at one and the ſame time on two axes, interſecting each other at right angles, with an equal velocity and preſſure on each. See the Tranſactions, N° 459. Sect. 1.

LENS, the *lentil*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the papilionaceous kind, and from the cup there ariſes a piſtil, which finally becomes a ſhort rod, containing orbicular ſeeds, and thicker toward the middle than at the edges.

The ſpecies of *lentil* enumerated by Mr. Tournefort are theſe. 1. The common *lentil* with browniſh red ſeeds. 2. The common *lentil* with pale yellow ſeeds. 3. The common *lentil* with ſpotted ſeeds. 4. The common *lentil* with black ſeeds. 5. The greater *lentil*; and 6. The Hungarian *lentil*, with taller ſtalks and perennial roots. *Tourn.* Inſt. p. 390.

LENTA *febris*. See the article FEVER.

LENTES *lapideæ*, *foſſile lentils*, the name given by many writers to a very remarkable foſſile ſubſtance, uſually found immerſed in hard ſtones, and of a roundiſh but flatted ſhape, reſembling not unaptly a *pea* or *lentil* flatted by preſſure. They generally lie in great quantities in the ſame maſs of ſtone; and are of a very different appearance, when their ſides or ends are ſeen from that which they exhibit, when their flat ſurfaces come in view. They are generally ſuppoſed to be *lentils* petrified and bedded in ſtone, and as their ſides come in view in ſome parts of the maſſes, they are not perceived to be a part of the ſame ſubſtances, but are called the remains of ſeeds of other plants, and the whole ſtone is uſually named *lapis frumentarius*.

We are not to ſuppoſe, that ſo ſoft a body as the *lentil* ſeed, or a common *pea*, could be eaſily petrified and preſerved in its own form in ſtone; ſince if theſe ſoft ſubſtances were readily capable of ſuch a change, they are ſo very common in their recent ſtate, that they muſt be expected to be found in this *foſſile* condition very frequently alſo, and in great variety; this, however, is not the caſe. But this improbability is not all the reaſon we have to conjecture, that theſe are not what they are vulgarly ſuppoſed to be, that is, *foſſile* ſeeds; for a ſtricter examination of the things themſelves proves this to be impoſſible. Seeds, and other ſuch things, are of ſome determinate growth; the ſize of which we know, and are well acquainted with their internal ſtructure, which is only a farinaceous matter contained in a thick ſuperficial ſkin or covering.

On the contrary, theſe *foſſils*, when examined, prove to be of various ſizes, from the minuteſt ſpeck viſible to the eye, to near an inch in diameter, a ſize that no *lentil* could be ſuppoſed to arrive at. They are of two kinds; the one convex on both ſides, the other convex on one ſide only, and plain on the other. The firſt are thickeſt in the middle, and gradually leſſen in thickneſs all round, till they terminate in a thin edge; the others are juſt like the halves of theſe, when ſplit horizontally. Thoſe which are convex on both ſides, have uſually ſeveral crooked lines, riſing from the umbilicus on each ſide, and tending toward the circumference; and the flat ones, have uſually on the flatted ſide, a number of concentric circles, ſurrounding the umbilicus, and one another to the edge. When theſe are broken they are found to conſiſt of a number of caſes, or coats, one within another, all of the ſame ſhape with the outer one; and ſome of them are ſtriated or made up of tranſverſe fibres; they are plainly of animal origin, though they differ from all the parts of animals hitherto known. *Woodward*'s Cat. Foſſ. Vol. 2.

Dr. Woodward, in one place, ſuppoſes them to have been the looſe bones which are found in the heads of ſome ſea fiſhes, and are ſuppoſed to ſerve for hearing; but that they belong to ſome fiſh at preſent unknown, or that has not been yet examined in this particular: there is, however, another much more probable opinion, which he mentions afterwards, that they may have been opercula of ſhell fiſhes, of the nature of the umbilicus veneris, of which the fiſhes we know afford us a great variety; and the many others we are yet unacquainted with, may furniſh numbers of other kinds very different from all we do know.

Theſe bodies are found in a hard greyiſh ſtone, and ſome of the large ones which are flatted on one ſide, give great reaſon to judge that they are of this origin, as ſome of the large ones have on the flat ſide, a reddiſh line beginning at the center, and thence continuing in a ſpiral form, for eleven or twelve turns, till it reaches the edge of the ſtone. This is exactly the formation and lineation of the common umbilicus veneris, only that it has fewer ſpires. The ſtone called by authors *lapis numiſmalis*, is generally allowed to be of the nature of theſe opercula, and this differs very little from theſe large *lentes lapideæ*, as they are called.

LENTISCUS, the *lentiſk* or *maſtic tree*, in botany, the name of a genus of trees, very nearly allied to the terebinthus or turpentine tree in its characters, but differing in that the leaves are pinnated; but there is no ſingle leaf to terminate the end of each compound one. *Tourn.* Inſt. p. 580.

The ſpecies of the *lentiſk* enumerated by Mr. Tournefort

are theſe. 1. The common *lentiſk*. 2. The narrow leaved *lentiſk* of Marſeilles.

It does not ſeem certain that the *lentiſk* of the Arabians was the ſame with the tree which we call by this name. For they always mention the *lentiſk* as a ſpecies of turpentine tree; and when they have treated of it at large under that head, both Aviſenna and Serapion have, in other parts of their works, diſtinct chapters on the *maſtic*. The *lentiſk* which they deſcribe among the turpentine trees, was remarkable for its large fruit, and, as we find by Rawwolf, that there is a kind of turpentine tree growing at this time in Arabia, remarkable for the ſame character, it ſeems very probable that this was their *lentiſk*, and that they did not call the tree which produces the *maſtick* by that name, but only by that of the *maſtick tree*.

The antient authors in agriculture tell us, that the *lentiſk* tree has three ſeaſons of flowering and bearing fruit in the year, and that the times of ſowing and reaping were directed by theſe, and that the vigour of its growth denoted a plentiful harveſt, and its languiſhing condition a bad one. Aratus expreſſes all this very elegantly in verſe, and uſes the word *ſkinus*, σκινος, for what is tranſlated the *lentiſk*; but it is hard to ſuppoſe that the original author, who is Theophraſtus, from whom Aratus has tranſcribed the greateſt part of his work, ſhould ſay this of the *lentiſk*, which flowers in April, and ripens its fruit in October, and then flowers no more till the following ſpring.

The whole ſeems to be only intelligible this way. The word *ſkinus* is uſed by the antient Greeks, as the name of the eſculent kind of ſquill, as well as of the *lentiſk tree*; and this plant may very probably flower three times a year, being a vigorous bulb rooted herb, and a very quick grower. The ſame author (Aratus) uſes the flower of the ſquill, and the fruit of the *lentiſk*, in different parts of his work, as the preſages of ſowing and harveſt; and he expreſsly ſays, that the ſquill flowers produces fruit three times in the year. Since it is evident, therefore, that the word *ſkinus*, σκινος, ſignifies both a peculiar ſort of ſquill and the *lentiſk tree*; and ſince it is certain that the ſquill, in the countries where theſe authors wrote, does flower three times in the year, and that the *lentiſk* never does, nor ever can do ſo any where; it ſeems no raſh judgment to determine, that the antient Greeks, whenever they gave the *ſkinos* as the director for the ſowing or reaping corn, meant the ſquill by that word, never the *lentiſk tree*; though that happened to be called by the ſame name as this ſpecies of ſquill was, and by the Athenians, indeed, the ſquill in general.

The Latin writers, as they derived all theſe omens of the *ſkinus* from the Greeks, are not to be ſuppoſed to mean any thing but the ſquill in theſe directions to the farmer, even though they have erroneouſly rendered the word by *lentiſcus*. Cicero himſelf has fallen into this miſtake, quoting the abovementioned paſſage of Aratus, of the *ſkinos* bearing flowers and fruit three times in the year, and tranſlating it the *lentiſk*; but no authority can make us believe that this was ſaid of a tree, that can only flower and produce fruit once in the year. See SKINUS.

LENTISK-*wood*, *Lignum lentiſci*, is eſteemed aſtringent and balſamic, and is recommended in gonorrhœas and the fluor albus; but at preſent is little uſed.

LEO (*Cycl.*)— LEO, in botany, a name uſed by ſome authors for the *columbine*, or *aquilegia*. Columella, among others, calls it by this name. *Ger.* Emac. Ind. 2. See AQUILEGIA.

LEO, the *lion*, in zoology. See LION.

LEO-*pulex*, a name given by Mr. Reaumur to a ſpecies of inſect which feeds on the *pulex arboreus*, or common tree puceron, in the ſame manner that the creature, called the *formica leo*, does on the ants: This being alſo, like that, an animal, yet in an imperfect ſtate, and finally to be changed into a different creature, this author has kept up the remembrance of this analogy between them, by giving this a ſimilar name.

The *leo-pulex* is uſually bred among the herds of the pulices, which he devours moſt unmercifully. He is a worm of the hexapode, or ſix legged kind, and very ſoon arrives at the time of his change; after which he becomes a green fly with four wings. Another animal of this kind, and not leſs deſtructive of this ſmall race of animals, is a ſix legged worm of a whitiſh colour, and ſmaller than the former, which finally becomes a round bodied beetle.

Another ſpecies of theſe devourers this author calls *vermis hyſtrix*, the porcupine worm, from the vaſt number of ſpiculæ, or tender prickles, with which he is armed. This alſo finally becomes a round and ſmall beetle. *Reaumur*, Hiſt. Inſect. Tom. 1.

LEOCROCOTTA, in natural hiſtory, a name given by the antients to an animal, ſaid to be the ſwifteſt of all creatures in the world. Pliny, and ſome others, have called it *leucocrotta*, or *leucrocotta*, but theſe are only corruptions of the true name *leocrocotta*. It is deſcribed as a mungrel, or baſtard animal, unable to propagate its own ſpecies, and produced by the mixture of two different kinds of animals; being begotten upon the lioneſs by the male hyæna of ſome of the larger kinds.

Pliny tells us, in another part of his hiſtory, of this mixture of theſe two ſpecies, and ſays, that the animal produced between them was called the *crocotta*; whence we find, that the *crocotta* and the *leocrocotta* are the ſame animal, though deſcribed by moſt authors as two diſtinct ones.

In another place, however, he calls the creature produced between a dog and a female wolf, by this name, *crocotta*; ſo that this word is not always to be aſcertained in its ſenſe.

The *leocrocotta*, according to Pliny, has the head, neck, and breaſt of a lion, as alſo the tail. He adds, that it is one of the moſt voracious and deſtructive beaſts in the world, and that it imitates the human voice to draw men near it, that it may devour them; and that its jaw is one continued bone, without any diſtinction of teeth. The Greeks have not any where mentioned this animal, though they have in many places, and on many occaſions, named the *crocotta*, and upon the whole it appears to be one of thoſe animals, the exiſtence of which is much to be doubted.

The Latin authors have made ſome confuſion between this creature and the mantichora, attributing the things that have been ſaid of one to the other. See MANTICHORA.

LEONTESERES, in the natural hiſtory of the antients, the name of a ſpecies of agate, famous in early times for its imaginary virtues in taming the rage of wild beaſts, and not a little eſteemed among us for its beauty. It is the moſt variegated of all the agates. Its ground colour is yellow, and its variegations are flame colour, white, black, and green.

Sometimes it is one irregular congeries of all theſe colours, but more frequently it is very beautifully variegated with them in form of clouds and veins; the black and green particularly are uſually diſpoſed in concentric circles, round one or more points. It is found only in the Eaſt-Indies, and is very ſcarce. *Hill*'s Hiſt. of Foſſ. p. 487.

LEONTICE, in botany, the name given by Linnæus to that genus of plants which Tournefort and others have called *leontopetalon*. See LEONTOPETALON.

LEONTICE is alſo a plant mentioned by the antient Greeks, and called by them *cacalia*.

Dioſcorides tells us that it had theſe names in common, and that it was of great virtue in curing diſeaſes of the *aſpera arteria*, or wnid pipe.

This medicinal plant of the Greeks was very different from that we now call *cacalia*. Some have deſcribed it to have flowers like the oak, others like the olive tree, but the old manuſcripts of Dioſcorides all ſay, the flowers were like thoſe of bryony. Hence it could by no means be the *cacalia* of the moderns; nor is it eaſy to ſay, from ſuch ſhort and uncertain accounts, what it was.

LEONTIASIS, a name uſed by ſome authors for the elephantiaſis.

LEONTODERON, in natural hiſtory, a name given by ſeveral authors to a ſpecies of agate, of a plain yellowiſh colour, without variegations.

LEONTOPETALOIDES, in botany, the name of a genus of plants deſcribed by Dr. Amman; the characters of which are theſe. The flower is monopetalous, of the funnel faſhioned kind, and divided into ſeveral ſegments at the edge. This is ſucceeded by a bladder, or inflated fruit, which contains a number of oval ſeeds.

The plant is a native of the Eaſt-Indies; its root is tuberous, and two inches thick in the middle; it is grey on the outſide, and white within, and ſends out but few fibres. There uſually ariſe four ſtalks from each root. Theſe are very tall, and of a finger's thickneſs. Two of them uſually bear each one large and beautiful leaf, very thin in its ſubſtance, variouſly jagged, and of a beautiful green. The two others bear each a tuft of flowers, which are large and yellow, and ſtand in cups of a fine green, compoſed each of one leaf, divided into ſome ſegments at the end. Each flower is ſuſtained on a pedicle of about an inch in length. Theſe are ſucceeded by the fruit, which are green inflated bladders of an angular form, and of an inch diameter in the largeſt part, from whence they run to a point, where they are purple. The ſeeds are large, ſtriated, and of a pale brick colour. Act. Petrop. Vol. 8. p. 209.

LEONTOPETALON, in botany, the name of a genus of plants, called *leontice* by Linnæus. Its characters are, that the calyx is very ſmall and deciduous, and is compoſed of ſix leaves; the flower conſiſts of ſix petals of an oval figure, narroweſt at the baſe, the three interior ones being alternately ſmaller; the ſtamina are ſix very ſhort filaments; the antheræ are erect, formed of two valves, divided into two cells, and open lengthwiſe from the baſe to the apex, where they are firmly united; the germen is of an oblong, oval figure; there is no ſtyle; the ſtigma is obtuſe, and of the height of the ſtamina; the fruit is a large, globoſe, acuminated capſule, inflated, ſomewhat ſucculent, and containing only one cell. The ſeeds are globoſe and few in number.

There are only two ſpecies of *leontopetalon*, 1. The *leontopetalon* with tripartite leaves. And, 2. The ſimple leaved *leontopetalon*. Vid. *Linnæi* Gen. Plant. p. 146. and *Hill*'s Nat. Hiſt. Vol. 2. p. 377. ſeq.

The

The *artanita*, or *leontopetalon*, of the antients, is generally eſteemed a ſynonymous name for the *cyclamen*, or ſow bread, and is uſed as ſuch by moſt authors; but if the Arabian writers are underſtood of it in this ſenſe, it will be hard to reconcile their works with thoſe of the Greeks on the ſubject of this plant. See CYCLAMEN.

Aviſenna treats of the *artanita*, which he renders *cyclamen*, but the plant by no means agrees with the *cyclamen*, being the ſame with the *leontopetalon* of Dioſcorides and the Greeks; and after an account, which cannot belong to any plant but this, there follow the virtues properly belonging to the *cyclamen*. Aviſenna, who appears in all his writings to have been very well acquainted with plants, perceives his own error in this chapter, and lays the fault upon the tranſlator from the Greek. From this circumſtance we find, that the works of the Greek phyſicians were, in his time, tranſlated into the Arabic language; and that both this author, and Serapion, uſed theſe tranſlations, and not the originals. *Aviſenna*, Lib. 2. c. 62.

Aviſenna, in the abovementioned chapter, obſerves that the plant, known in his time by the name of *artanita*, had not the leaſt reſemblance with the *artanita* here mentioned, by the interpreter of Dioſcorides, whoſe works he uſed; but that it was plainly the *leontopetalon* of Dioſcorides, that was here deſcribed under that name. But in the remaining part of the chapter, we are let into another ſignification of the word *artanita*, which is, that it was among the Arabians a name given to the *ſtruthium* of the Greeks. Aviſenna ſays, that it was a plant of the thiſtle kind, armed with ſhort but very numerous thorns, and that its root was uſed in the cleanſing of wool. If this was the *artanita* of the times of Aviſenna, it is plain that the *artanita* of thoſe times was the *ſtruthium* of the antient Greeks, and the *herba lanaria* of the Latins, not the *candiſi*, as had been by ſome ſuppoſed. Pliny, from Theophraſtus, tells us alſo, that the *lanaria*, or *ſtruthium*, was a thorny plant.

The origin of this error ſeems not difficult to trace up from the earlier times; for in ſome of the old manuſcripts of Dioſcorides yet extant, with Arabic remarks, there ſtands the word *harthanithe* in Arabic characters againſt the *leontopetalon*. The old interpreter of this author, from whoſe Arabic tranſlation Aviſenna acknowledges that he took his account, has plainly given this name for the *leontopetalon*, though it belonged to the next chapter, which was of the *ſtruthium*; of which word it was the proper Arabic interpretation.

It ſeems that the two adjoining chapters had been joined into one, and that the Arabian interpreter not perceiving this, had given the ſynonymous names in the two languages amiſs. This is a thing that might eaſily happen in the copies of any of the Greek authors, where the chapters are not divided from one another, as in our books, by ſpaces, or the name of the ſubject treated of placed in capitals at the top; but only by a red letter, for the beginning of the name of the plant, about which a chapter was to treat. This only mark we find often omitted through the careleſsneſs of the copyiſts, and two chapters, or more, blended into one, both in the works of Dioſcorides and Theophraſtus.

This ſeems to have happened to the chapters of *ſtruthium* and *leontopetalon*, in the preſent inſtance. *Struthium* and *arthanita* we find, by Aviſenna, are names of the ſame plant, an herb whoſe roots were uſed in the wool trade; and the interpreter underſtanding the word *artanita* to mean *cyclamen*, gives the virtues of *cyclamen*, as belonging to it; and to compleat the error, adds the figure and characters of the *leontopetalon* from Dioſcorides, on account of its ſimilitude in ſome reſpects to the *cyclamen*. The roots both of the one and the other are black and tuberous, and like a turnep. See STRUTHIUM.

LEONTOPODIUM, *lion's* foot, in botany, a name given by ſome to a genus of plants, otherwiſe called *gnaphalium*. See GNAPHALIUM.

LEONURUS, *lions-tail*, in botany, the name of a genus of plants; the characters of which are theſe. The flower conſiſts of one leaf, and is of the labiated kind; the upper lip is imbricated, and much longer than the lower. From the cup there ariſes a piſtil, which is fixed, in the manner of a nail, to the hinder part of the flower; this is ſurrounded by four embryo's, which afterwards become ſo many ſeeds, and ripen in a long tubular huſk, which was the cup of the flowers.

The ſpecies of *leonurus* enumerated by Mr. Tournefort are theſe. 1. The ſideritis leaved perennial African *leonurus* with large purple flowers. 2. The catmint leaved annual American *leonurus* with ſmaller purple flowers. 3. The origanum leaved Canada *leonurus*. *Tourn.* Inſt. p. 187.

LEOPARD. This creature, when carefully examined, is found to be very like a cat; particularly its head, teeth, tongue, feet, and claws. Its actions alſo are all like a cat's; it boxes with its fore feet, as a cat does her kittens; leaps at its prey as the cat does; and will ſpit much in the ſame manner.

All the *leopard* kind, as they walk, keep the claws of their fore feet turned up from the ground, and ſheathed, as it were, in the ſkin of the toes, whereby they preſerve them ſharp for the ſeizing their prey.

Notwithſtanding the natural fierceneſs of the *leopard*, numbers of them are bred up tame, and kept for the Great Cham of Tartary's uſe, for the hunting of deer and other beaſts.

They are moſt numerous in Africa and Syria. *Grew's* Muſ. p. 12.

LEOPARD'S *bane*, in botany. See DORONICUM.

LEPA, in our old writers, a meaſure which contained the third part of two buſhels. Whence we derive a *ſeed-leap*. *Du Cange*. *Blount*.

LEPAS, in natural hiſtory, the name of a genus of ſhell fiſh, the ſame as *patella*. See PATELLA.

LEPASTRUM, in natural hiſtory, the name of a genus of foſſils, of the claſs of the *ſelenitæ*, compoſed of filaments arranged into broad plates, and thoſe diſpoſed in the form of a radiated ſtar.

The word is derived from the Greek λεπὶς, a ſcale or plate, and ἀστὴρ, a ſtar. *Hill's* Hiſt. of Foſſ. p. 123.

Of this genus there are two known ſpecies; the one a bright browniſh white kind, with thinner flakes, the other a white dull looking kind, with thick flakes. They are both found on the ſhores of Sheppey iſland in Kent, and form themſelves in the cavities of the ſeptariæ, called by authors *ludus Helmontii*; and the ſeptariæ with theſe affixed to them, have been accounted a ſeparated ſpecies of that body, and called the ſtarred waxen vein, or *ludus Helmontii ſtellatus*. The world in general has erred as to the origin of theſe beautiful foſſils, they having been ſuppoſed to be talcky ſpars; whereas, their want of elaſticity, the great character of talc, and their not fermenting with acids, which is the fundamental diſtinction of the ſpars, prove them to be not at all of the nature of either of theſe bodies; and experiments on them, plainly ſhew them to be a *ſelenites* of a particular kind. Ibid. p. 148.

LEPIDIUM, *dittander*, in botany, the name of a genus of plants; the characters of which are theſe. The flower conſiſts of four leaves, and is of the cruciform kind. The piſtil ariſes from the cup, and becomes at length a ſeed veſſel of a ſpear-pointed ſhape, and divided into two cells by an intermediate membrane, to which there adhere valves. The ſeeds contained in this capſule are uſually of an oblong figure.

The ſpecies of *lepidium*, enumerated by Mr. Tournefort, are theſe. 1. The common great broad leaved *lepidium*. 2. The low hoary field *lepidium*, called by many the *umbelliferous draba*, or Babyloniſh creſs. 3. The low leſs hoary *lepidium* of Aleppo. 4. The graſſy leaved *lepidium*, called by authors *iberis*, or *ſciatica creſs*. 5. The Spaniſh ſhrubby five leaved *lepidium*. *Tourn.* Inſt. p. 215.

LEPIDOCARPODENDRON, a name given by Boerhaave to a genus of plants, called by Linnæus *leucadendron*. See LEUCADENDRON.

LEPIDOTES, in natural hiſtory, the name of a ſtone carrying a reſemblance to the ſcales of fiſhes. The word has been uſed by ſome, as the name of thoſe ſtones which are compoſed of ſmall flakes, or ſcales of talc, and by others to expreſs the ſtones containing fiſh, or the impreſſions of fiſh, found in many parts of Germany.

LEPIUM, in natural hiſtory, the name of a genus of foſſils, of the claſs of the *gypſums*; the characters of which are, that the bodies of it are moderately hard, compoſed of very ſmall particles, and of a duſky hue.

Of this genus there is only one known ſpecies, and that is the leaſt valuable, and moſt impure of almoſt all the claſs of *gypſums*. It is of a rude, coarſe, and irregular ſtructure, a little ſoft to the touch, and in colour of a whitiſh grey; the two colours being irregularly blended in the different maſſes, and making ſome of a regularly deep colour, throughout great part of them, others merely white, with veins and ſpots of grey, and ſometimes there is mixed among this a greeniſh or reddiſh caſt. It is found in maſſes of ſix or ſeven inches in diameter, and of a very rugged ſurface. It ſplits horizontally more eaſily than in any other direction, and will neither give fire with ſteel, nor ferment with acid menſtrua, and is ſeen to be compoſed of irregularly ſhaped flattiſh particles.

It is found in great plenty in Germany, and is one of the many ſubſtances which, from their uſe in fuſion and caſting, the Germans called *ſpaad*. We have it in great plenty in Derbyſhire, and it is burnt into a ſort of plaiſter of Paris for the coarſer works; but it calcines very ſlowly and unequally. *Hill's* Hiſt. of Foſſ. p. 114.

LEPORARIA *aquila*, a name given by ſome authors to the *melanaëtos*, or black eagle, from his deſtroying great numbers of hares. *Willughby's* Ornitholog. p. 30.

LEPORINUM *genus*, in zoology, the name of a genus of animals, ſo called from their general reſemblance to the hare in ſhape, and other particulars; the characters by which they are diſtinguiſhed from other quadrupeds are theſe. They have feet divided into claws; they feed on vegetables; and

they

they have two very long teeth in the forepart of their mouths. *Ray*'s Syn. Quad. p. 204.

LEPRAS, in zoology, the name of a ſea fiſh of the turdus, or wraſſe kind, remarkable for the great variety and beauty of its colouring. It is ſeldom caught of more than five or ſix inches in length, and is conſiderably broad and flat. It ſometimes grows to a foot long, but that only in the ocean, never in the Mediterranean Sea, where it is uſually caught; and even there very rarely. It is ſpotted all over like the body of a leopard. It has only one long fin on the back, the anterior rays or ribs of which are prickly, the others ſoft and flexile; and this, as well as all its other fins, is ſpotted with blue, green, red, and yellow. Its body is alſo covered with ſpots and lines of the ſame colours, very beautifully diſpoſed, and the edges of all its ſcales are of a ſtrong red. Its mouth is ſmall; its teeth ſmall and ſharp; and it has the appearance of lips. Its ſcales are large, and its ſide lines finely arched and bent. Its head is leſs variegated than any other part of it, yet this has a number of red, green, and blue lines. Its eyes are ſmall and round, and their iris, as the fiſh turns them about, appears of a great variety of colours. It is one of the moſt beautiful fiſh of the Mediterranean, but is not much eſteemed at table, being of an inſipid and watery taſte. *Bellon.* de Piſc. *Geſner.* de Piſc. p. 559. See TURDUS.

LEPROSO *amovendo*, in law, an antient writ that lay to remove a *leper*, or *lazer*, who thruſt himſelf into the company of his neighbours in any pariſh, either in the church, or at other publick meetings, to their annoyance. Reg. Orig. 237. The writ lies againſt thoſe *lepers* that appear outwardly to be ſuch, by ſores on their bodies, ſmell, *&c.* and not againſt others: and if a man be a *leper*, and keep within his houſe, ſo as not to converſe with his neighbours, he ſhall not be removed. New Nat. Br. 521. *Blount*, *Cowel.*

LEPTODECARHOMBIS, in natural hiſtory, the name of a genus of foſſils of the claſs of the *ſelenitæ*.

The word is derived from the Greek, λεπτὸς, thin, δεκας, ten, and ῥομβὸς, a rhombic figure, and expreſſes a thin or ſlender rhomboidal body, conſiſting of ten planes, or ſides.

The characters of this genus are, that the *ſelenitæ* of it conſiſt of ten planes, each ſo nearly equal to that oppoſite to it, as very much to approach to a decahedral parallelopiped, but they never truly or regularly are ſo. Two of the planes in this genus, which may properly enough be called the top and bottom, are ever broader and flatter than the reſt, and theſe, though not regularly equal, uſually very nearly anſwer one another, as do alſo the other eight, in two ſets of fours.

There are four ſhorter planes meeting in ſomewhat acute angles, two and two, from the ends, or two ſhorter edges of the two flat and broad rhomboidal planes, called the top and bottom; and four longer meeting in more obtuſe angles from the ſides, or longer edges of the ſame rhomboidal planes.

As the broader and flatter planes, or the top and bottom, in this genus are not regularly equal to each other, ſo neither are the eight narrower to their oppoſites, but there are uſually differences both in their angles, and in the breadth of them.

Of this genus there are only five known ſpecies. 1. A thin, fine, pellucid, and ſlender ſtreaked one with tranſverſe ſtriæ, found in conſiderable quantities in the ſtrata of clay in moſt parts of England, particularly near Heddington in Oxfordſhire. 2. A thin, dull-looking, opake, and ſlender ſtreaked one, more ſcarce than the former, and found principally in Leiceſterſhire and Staffordſhire. 3. A thin fine ſtreaked one with longitudinal ſtriæ, found in the clay pits at Richmond, and generally lying at great depths. This has often on its top and bottom a very elegant ſmaller rhomboide, deſcribed by four regular lines. 4. A rough kind with thick tranſverſe ſtriæ, and a ſcabrous ſurface, very common in Leiceſterſhire and Yorkſhire. And 5. a very ſhort kind with thick plates, common in the clay pits of Northamptonſhire and Yorkſhire. *Hill*'s Hiſt. of Foſſ. p. 118 to 129.

LEPTOS *libanotis*, in the materia medica of the antients, a name given by ſome of the Greek writers to the ſmall frankincenſe, that is ſuch as came to their hands in ſmall flakes, broken from the larger maſſes in the gathering or packing up. This was alſo called *manna thuris*, the manna of frankincenſe, the word *manna* being of old uſed to expreſs any thing formed of granules, or ſmall pieces. The antients eſteemed this *leptos libanotis*, or *manna thuris*, when pure, beyond any other kind, for they always valued that frankincenſe moſt, which was drieſt and moſt brittle, and ſuch only as was ſo, could break off in theſe ſmall flakes. The medicine, however, ſoon grew ſubject to adulteration, and loſt its credit; for the duſt of the frankincenſe being allowed to be put up among this *manna thuris*, Dioſcorides tells us that in his time people, greedy of gain, had found the way to adulterate it, by adding, inſtead of this genuine duſt, the ſifted powder of the reſin of the pine tree.

LEPTUM, in antiquity, a ſmall piece of money, which, according to ſome, was only the eighth part of an obolus; but others will have it to be a ſilver or braſs drachm. *Pitiſc. Lex. Ant.* in voc.

LEPUS, the *hare*, in the Linnæan ſyſtem of zoology, makes a diſtinct genus of animals; the characters of which are, that the animals of it have feet made for running, with five toes on the fore ones, and four on the hinder, and have very long ears. Under this genus the author takes in all the creatures of the *hare* and rabbit kind. *Linnæi* Syſtem. Nat. p. 38.

What is moſt particular in the *hare* is, that the hinder legs are much longer than the fore ones, and are furniſhed with extremely ſtrong muſcles; by which means the creature, naturally defenceleſs, is furniſhed with a power of running very ſwiftly from whatever aſſails it. The head is roundiſh; the eyes prominent; and the upper lip ſplit. Its ears are very long; and it is ſaid to ſleep with its eyes open, for fear of danger. It lies hid all day, but in the night goes out in ſearch of food. *Ray*'s Syn. Quad. p. 204.

LEPUS *aqueus*, the *water hare*, a name given to the creſted diver, or colymbus of America, which is the ſame ſpecies with the larger European kind, though deſcribed by many authors as a different bird. It has the name of the *ſea hare*, or *water hare*, from its great nimbleneſs in the water. It is caught with much difficulty; and the Mexicans have a thouſand fabulous ſtories about it; as that it is able to call up the winds to overſet the boats of people who hunt it, that it has a jewel of great value in its heart, and the like ridiculous ſtories. *Ray*'s Orni. p. 257.

LESBIUM *marmor*, a name given by the antients to a ſpecies of marble of a blueiſh white, ſometimes uſed for vaſes and other ornamental works, but principally in the walls of public buildings.

LESSON, in the manege, is uſed for any piece of inſtruction in that art, whether given to the ſcholar or the horſe.

LET-*fall*, at ſea, the word of command for putting out a ſail, when the yards are aloft, and the ſail is to come down from the yard; but when the yards are ſtricken down, then the ſail is looſed below, before they hoiſe the yard.

Let-fall is not properly ſaid of top-ſails, becauſe they lie on the top; and therefore the word for them is, *Heave out your top-ſails*. Nor can it be applied to the miſſen; for the word is, *Strike the miſſen and ſet it*. So that in ſtrictneſs the term *let-fall* belongs only to the main-ſail, fore-ſail and ſprit-ſail, when their yards are hoiſted up aloft.

LETTER (*Cycl.*)— LETTERS *of marque*, in the Britiſh dominions, are to be granted by the admiralty. See PRIZES.

Aſſyrian LETTERS. See ASSYRIAN.

Hebrew LETTERS. See HEBREW.

LETTUCE, *lactuca*, in botany. See LACTUCA.

We have the ſeveral ſpecies of *lettuce* cultivated in the kitchen gardens about London, all of which are excellent ſallad herbs, and ſucceed one another in their ſeveral ſeaſons. The ſeveral kinds are, 1. The common *lettuce*. 2. The cabbage kind. 3. The Sileſia. 4. The Dutch brown. 5. The Aleppo. 6. The Imperial. 7. The green capuchin *lettuce*. 8. The Verſailles, or upright white cos *lettuce*. 9. The black cos. 10. The white cos *lettuce*. 11. The red capuchin *lettuce*. 12. The Roman *lettuce*. 13. Prince *lettuce*, and 14. The royal *lettuce*.

The firſt of theſe ſorts is very common in all gardens, and is commonly ſown for cutting very young, to mix with other ſalad herbs in ſpring; and the ſecond, or cabbage *lettuce* is only this, mended by culture. It may be ſown at all times of the year, but in the hot months requires to be ſown in ſhady borders. The cabbage *lettuce* may alſo be ſown at different ſeaſons to have a continuation of it through the ſummer. The firſt crop ſhould be ſown in February in an open ſituation; the others, at three weeks diſtance, but the later ones under covert, but not under the drippings of trees. *Miller*'s Gardners Dict.

The Sileſia, imperial, royal, black, white and upright cos *lettuces*, may be ſown firſt in the latter end of February or the beginning of March, on a warm light ſoil, and in an open ſituation; when the plants are come up, they muſt be thinned to fifteen inches diſtance every way, they will then require no farther care than the keeping them clear of weeds; and the black cos, as it grows large, ſhould have its leaves tied together to whiten the inner part. Succeeding crops of theſe ſhould be ſown in April, May, and June, and toward the latter end of Auguſt they may be ſowed for a winter crop, to be preſerved under glaſſes, or in a bed arched over with hoops and covered with mats.

The moſt valuable, of all the Engliſh *lettuces*, are the white cos, or the Verſailles, the Sileſia, and the black cos. The brown Dutch and the green capuchin are very hardy, and may be ſown late, under walls, where they will ſtand the winter, and be valuable, when no others are to be had. The red capuchin Roman, and prince *lettuce*, are very early kinds, and are ſown for variety, as are alſo the Aleppo ones for the beauty of their ſpotted leaves.

The milk of the common garden *lettuces* is hypnotic, while the root of the plant is cooling, diluent and nouriſhing. Dr. Aſton. ap. Med. Eſſ. Edinb. Vol. 5. art. 12.

LEVARE *antiphonam*, in the muſic of the Romiſh church, is to begin or open the firſt note of an anthem.

LEVA-

LEVATOR *ani parvus*, in anatomy, a name given by Riolanus, Douglaſs, and others, to a muſcle, called alſo by ſome *tranſverſalis penis* and *tranſverſalis urethræ*, and by Albinus *tranſverſus perinæi*.

LEVATOR *ani ſextus*, in anatomy, a name given by Riolanus and ſome others, to what was ſuppoſed by them to be a diſtinct muſcle; though, according to the later writers, it proves to be only a part of the ſphincter of the anus running into the perinæum. Some have alſo called this proceſs of the ſphincter the *dilatator urethræ* and *dilatator penis*.

LEVATOR *coccygis*, in anatomy, a name given by many to the muſcle, now generally known by the name of *coccygæus*. See COCCYGÆUS.

LEVATORES *breviores coſtarum*, in anatomy, the modern name introduced by Albinus for certain muſcles of the ribs, called by others the *ſupracoſtales*, the *ſur coſtaux* of the French, and the *ſcaleni quarti* by ſome. Steno was the firſt who called them *levatores coſtarum*, from their office; he is followed in this by Morgagni, and Albinus adding the word *breviores*, by way of diſtinction from ſome other longer ones, called *ſupracoſtales longi* by authors, has formed the modern name.

LEVATOR *internus*, in anatomy, a name given by Douglaſs, and ſome others, to a muſcle, now generally called only the *levator ani*.

LEVATOR *labii ſuperioris*, in anatomy, a name given by Albinus to a muſcle, called by Santorini and Winſlow the *inciſorius*, and by Cowper the *elevator labii ſuperioris*, and by Spigelius *alas naſi abducens*.

LEVATOR *menti*, in anatomy, a name given by Albinus to a muſcle of the face, called by Cowper and others *elevator labii inferioris*, and by ſome the *inciſivus inferior*. See the article INCISIVUS and ELEVATOR.

LEVATOR *palpebræ ſuperioris*, in anatomy, a name given by Albinus to a muſcle of the face, called by Cowper, Douglaſs, and the generality of writers, *aperiens palpebram*, and *aperiens palpebram rectus*.

LEVATOR *proſtatæ*, in anatomy, a name given by Santorini, and ſome others, to a muſcle, called by Winſlow, *proſtaticus ſuperior*, and by Albinus *compreſſor proſtatæ*.

LEVATOR *ſcapulæ proprior*, in anatomy, a long and pretty thick muſcle, about two fingers in breadth, lying above the ſuperior angle of the ſcapula, along the poſterior lateral part of the back of that bone. It is inſerted above, in the extremities of the tranſverſe apophyſes of the four firſt vertebræ of the neck by four fleſhy branches, ending in ſhort tendons. Sometimes the ſecond, ſometimes the third, or both; and ſometimes the third of theſe branches is wanting, theſe defects being made up by the largeneſs of the reſt: from thence theſe branches run down a little obliquely, and then uniting together, they are inſerted in the ſuperior angle of the ſcapula, and in the edge of its baſis from thence to the ſmall triangular ſpace, being there covered a little by the rhomboides. This muſcle is eaſily divided into two through its whole length. It is covered by the trapezius, and its inſertions in the neck are ſometimes mixed with thoſe of the neighbouring muſcles.

LEUCACHATES, in the natural hiſtory of the antients, the name of an agate, but that not a peculiar ſpecies, but only a particular appearance of the lead coloured agate, called *phaſſachates*. *Hill*'s Hiſt of Foſſ. p. 478. See PHASSACHATES.

LEUCACANTHA, in botany, a name uſed by Dioſcorides and the other Greek writers for the acacia tree, which produces the gum arabic, but it was alſo uſed for a kind of prickly plant, called alſo *amgaila* by ſome of the Arabians; as being a plant whoſe roots were knotted and jointed. Theſe joints were ſeparated and dried, and then uſed in medicine as cordiacs and carminatives, under the names of *bunk* or *bunken*. They were of a very agreeable aromatic ſmell, and very little taſte; and the antients always preferred ſuch of them as were yellow and light, rejecting thoſe which were heavy and white, and which wanted ſmell. It is not well known at this time what theſe roots were; but it is neceſſary, in order to the right underſtanding the works of the antients, to know that there were ſuch roots; and that though called by the ſame name with the gum arabic tree, they were of a very different nature.

The calling them *leucacantha* and *acantha arabica*, two common names for that tree, ſeems to have led others into the ſuppoſing them the ſame with that tree or its roots; and all the names of that tree have at one time or other been given to theſe roots; and all the names of theſe roots, or of the plant to which they belong, have been given to the acacia tree; ſo that in reading either the Greek or Arabian authors, where any of theſe words occur, the ſenſe of the context only can explain whether the acacia tree, or the bunken plant be meant by them. See AMGAILA and BUNK.

LEUCANTHEMUM, the *great daiſy*, in botany, the name of a genus of plants, the flowers and ſeeds of which are wholly the ſame with thoſe of the chryſanthemum or corn-marygold, except that the petals which compoſe the outer circle of the flower in this genus are always white.

The ſpecies of *leucanthemum*, enumerated by Mr. Tournefort, are theſe. 1. The common *leucanthemum*, or common *great daiſy*. 2. The common *great daiſy* with hairy ſtalks. 3. The great alpine *leucanthemum* with rigid leaves. 4. The great mountain *leucanthemum* with ſharp pointed leaves. 5. The mountain *leucanthemum* with obtuſe crenated leaves. 6. The *leucanthemum* with broad ſerrated leaves, and creeping roots. 7. The leſſer mountain *leucanthemum*. 8. The mountain *leucanthemum* with corn-marygold leaves. 9. The graſſy leaved *leucanthemum*. 10. The broad leaved great flowered *leucanthemum*. 11. The Alpine *leucanthemum* with coronopus leaves. 12. The alpine *leucanthemum* with very deeply divided leaves. 13. The little pyrenean *leucanthemum* with divided and hairy leaves. 14. The Portugal *leucanthemum* with jagged ſilvery leaves. 15. The Canary *leucanthemum* with corn-marygold leaves, and the taſte of pyrethrum. *Tourn.* Inſt. p. 492.

For the characters and different ſpecies of the common *daiſy*. See the article BELLIS.

LEUCELECTRUM, a name given by ſome authors to that ſort of amber, which is white and opake, and uſually of a fatty look. See SUCCINUM.

LEUCISCUS, in zoology, the fiſh commonly known in England by the name of the *dace* or *dare*.

It is diſtinguiſhed from other fiſhes by its reſembling the chub in ſize, but that it is ſmaller and whiter, and has a ſmaller head in proportion to its body. Its head is leſs flatted alſo, and its tail more forked, and its body thinner and flatter than that of the chub, but longer and narrower than that of the roach. It has no teeth in its jaws, but like the reſt of the leather mouthed fiſhes has them in the throat. It is very common in our rivers, and is a remarkably lively fiſh. They ſpawn in February, and the males at that time are ſpotted and ſcabby, as in the rudd, *&c.* and are in higheſt ſeaſon for the table in April and May, but they are never a very well taſted fiſh, or much eſteemed. See DACE.

LEUCOCROTTA, in natural hiſtory, the name given by many authors to a beaſt, ſuppoſed to be the ſwifteſt of all creatures in the world: others have called it *leucrocotta*, but the true name is *leocrocotta*. See LEOCROCOTTA.

LEUCODENDROS, in botany, a name given to the *ſilver pine-tree*. See *ſilver* PINE-*tree*.

LEUCOGÆA, in natural hiſtory, a name by which ſome authors have called the ſubſtance more uſually known by the name of *morochthus*, and called in Engliſh, French chalk, or Brianſon chalk. *Hill*'s Hiſt. of Foſſils, p. 22. See the article MOROCHTHUS.

LEUCOGRAPHIS, in natural hiſtory, the name uſed by ſome of the antient writers, for the ſubſtance commonly called *morochthus*, or French chalk. *Hill*'s Hiſt. of Foſſils, p. 22. See MOROCHTHUS.

LEUCOIUM, *wall-flower*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of four leaves, and is of the cruciform kind. The piſtil ariſes from the cup, and ripens into a long flatted pod, which is divided by an intermediate membrane into two cells, and contains a number of flattiſh rounded and marginated ſeeds.

The ſpecies of *leucoium*, enumerated by Mr. Tournefort, are theſe. 1. The great white *leucoium*. 2. The great white or hoary *leucoium* with greyiſh flowers. 3. The common purple *leucoium*. 4. The great ſcarlet flowered, hoary leaved *leucoium*. 5. The violet flowered *leucoium*. 6. The purpliſh red flowered *leucoium*. 7. The leſſer hoary *leucoium*. 8. The great hoary *leucoium* with double red flowers. 9. The great hoary *leucoium* with double purple flowers. 10. The great hoary *leucoium* with double blueiſh purple flowers. 11. The great hoary *leucoium* with double white flowers. 12. The great hoary *leucoium* with a flower variegated with irregular ſtreaks. 13. The great hoary *leucoium* with purple ſpotted flowers. 14. The great hoary *leucoium* with double variegated flowers. 15. The great purple flowered *leucoium* with blood coloured ſpots. 16. The great hoary double flowered variegated *leucoium* with leaves edged with ſilver. 17. The great double white *leucoium* with purple ſpots in the flowers. 18. The great double white *leucoium* with blood coloured ſpots in the flower. 19. The green leaved ſweet ſcented white flowered *leucoium*. 20. The great white ſpring flowering perennial *leucoium*. 21. The heſperis leaved *leucoium*. 22. The little ſpring ſea rocket leaved *leucoium* with white flowers. 23. The ſea *leucoium* with ſinuated leaves. 24. The white ſea *leucoium*. 25. The great yellow *leucoium* with bullated leaves. 26. The large flowered yellow *leucoium*. 27. The large flowered yellow *leucoium* with ſerrated leaves. 28. The common yellow *leucoium* or *wall-flower*. 29. The great double yellow *leucoium*. 30. The leſſer double yellow *leucoium*. 31. The double yellow *leucoium* with expanded flowers. 32. The double ferrugineous flowered *leucoium*. 33. The great double *leucoium* with flowers variegated with purple and yellow; and 34. The narrow leaved alpine *leucoium* with brimſtone coloured flowers.

Several ſpecies of this plant are propagated in gardens for the beauty of their flowers, where they are commonly called *ſtock july flowers*.

They are all to be propagated by ſeeds, and the beſt time for ſowing them is in the beginning of April. They muſt be ſown upon a border of freſh light earth, where they may enjoy the morning ſun; if they are expoſed to too much ſun, or ſown on too dry a ſoil, they are uſually deſtroyed while young by a ſort of fly, but there is a way of guarding againſt this, which is to ſow a few radiſhes on the ſame ground; for the flies being more fond of their leaves, will ſpare the others. The radiſhes, however, muſt not ſtand too thick, for that would weaken the plants.

When the young plants have got about ſix leaves, they ſhould be tranſplanted, to borders of light earth, where they may alſo enjoy the morning ſun; and here they ſhould ſtand at four inches diſtance, and be watered and ſhaded till they have taken root, and in the latter end of the Auguſt following they may be tranſplanted to the places in the flower garden, where they will flower the ſucceeding ſpring. This laſt tranſplanting ſhould, if poſſible, be done in a wet ſeaſon.

Theſe are but biennial plants, for which reaſon they ſhould be ſown every year; and it is a good method to exchange ſeeds annually with a perſon who raiſes good flowers in ſome other place. All the kinds may be propagated by ſlips and cuttings, but they never are ſo ſtrong, or flower ſo well this way, as when raiſed from ſeeds. *Miller*'s Gardners Dict.

LEUCOLIBANON, in the materia medica of the antients, a name given to the white *olibanum*, or frankincenſe, which they carefully diſtinguiſhed from the reddiſh or yellowiſh *olibanum*. This was alſo called *argyrolibanum*, or the ſilver coloured olibanum; and the yellow one *chalcolibanum*. This latter word is uſed in the Apocalyps of St. John, and is miſunderſtood ſo far, as to be tranſlated braſs, and ſuppoſed to be a kind of braſs from Mount Lebanon. See CHALCOLIBANON.

LEUCOLITHOS, in natural hiſtory, a name given by ſome of the Greek writers to the *pyrites argenteus*, or ſilvery pyrites. The antients had a great opinion of theſe foſſils in diſeaſes of the eyes; they uſed all the kinds of pyrites, or marcaſite, after calcination, for this purpoſe; but as they diſtinguiſhed four kinds of them, they attributed theſe virtues, in different degrees, to the different kinds; therefore they had recourſe to ſo many peculiar names for the diſtinguiſhing them; and the white kind was called *leucolithos*, to diſtinguiſh it from the duſky one called the iron pyrites, and the deeper and paler yellow kinds, called the gold and braſſy marcaſites.

LEUCOMA, Λευκωμα, among the Athenians, ſignified a public regiſter of the whole city, in which were written the names of all the citizens, as ſoon as they came to be of age to enter upon their paternal inheritance. *Potter*, Archæol. Græc. lib. 1. c. 13. Tom. I. p. 79.

LEUCOMÆNAS, in zoology, a name by which ſome have called the *ſmaris*, a ſmall fiſh caught in great plenty in the Mediterranean. *Willughby*, Hiſt. Piſc. p. 319. See the article SMARIS.

LEUCOPETALOS, in natural hiſtory, the name of a beautiful ſtone deſcribed by Pliny, as being of a fine gold yellow, variegated with white.

LEUCOPHAGIUM, a name given by ſome phyſicians to a ſort of medical aliment good in conſumptions, and other general decays. It is compoſed of ſweet almonds macerated in roſe water with the tender fleſh of a capon, all being finally boiled together to a pulp, capable of being paſſed through a ſieve.

LEUCOPIPER, in the materia medica, a name by which ſome authors have diſtinguiſhed the white pepper. Mant. Exot. p. 10.

LEUCORHŒA, a name given by ſome medical writers to the whites, or *fluor albus*, a very troubleſome diſeaſe to women. See FLUOR *albus*.

LEUCORODIUS, in zoology, a name by which ſome have called the *platea*, or ſpoonbill, a very remarkable kind of ſtork or hern. See PLATEA.

LEUCOSTAPHYLOS, in botany, a name given by ſome authors to the water elder, or *opulus*. *Ger.* Emac. Ind. 2.

LEVEN, in botany, a term uſed by Boccone for the milky juice contained in the globules placed at the tops of the ſtalks of red coral. Theſe round buttons are the only part of the coral, which are ſoft while under water, and from theſe the milky juice is eaſily expreſſed by a gentle ſqueezing between the fingers. The globules are each made up of five or ſix little cells, not communicating with one another, and each containing its own ſeparate quantity of this white and thick fluid. When the coral is newly taken up out of the ſea, this juice is of a ſharp, acrimonious, and aſtringent taſte; but when it has been ſome time expoſed to the air, it loſes the acrimony, and the aſtringency of the taſte only remains. This change in the taſte is made in ſix or eight hours, in hot weather, and the juice, in the ſame time, loſes its colour and conſiſtence, growing hard and brown. Philoſ. Tranſ. N° 100.

LEVIRATE, in the Jewiſh cuſtoms, a term uſed by authors who have written on the law and cuſtoms of the Jews, to denote particularly that law of Moſes, which obliges one brother to marry the widow of another, who died without children, and to raiſe up ſeed to him.

The word is derived from *levir*, which ſignifies, in Latin, the huſband's brother, or the brother-in-law; and the word *levirate* has been hence formed, to expreſs the law whereof we have been ſpeaking.

This law, which is an exception to that which condemns marriages between brothers and ſiſters, and between brothers-in-law, and ſiſters-in-law, ſeems to have been in uſe among the Hebrews and Canaanites before the time of Moſes; ſince Judah gives his firſt born Er, and Onan his ſecond ſon, ſucceſſively to Tamar, and obliges himſelf to give her likewiſe to Selah his third ſon. *Calm.* Dict. Bibl.

LEVISTICUM, in botany, a name given by ſome to *liguſticum*, or lovage. See LIGUSTICUM.

LEVITICI, in church hiſtory, a ſect of heretics who ſprung from the Gnoſtics and Nicolaitans. *Hofm.* Lex. in voc.

LEWING, in metallurgy, the ſifting the ores of metals in water. This is done in fine ſieves moved backward and forward under water; and is the method of ſeparating the finer part of the ores which had ſubſided among the larger lumps, under that part of it ſeparated for uſe in the various waſhings. The coarſer matter, left in the ſieve, is powdered again with the larger maſſes, and all thus ſifted together for the blowing-houſe. *Ray*'s Engliſh Words, p. 122.

LEXIARCHI, Λεξιαρχοι, at Athens, ſix officers, aſſiſted by thirty inferior ones, whoſe buſineſs it was to lay fines upon ſuch as came not to the public aſſemblies, and alſo to make ſcrutiny among ſuch as were preſent. *Potter*, Archæol. Græc. l. 1. c. 13. Tom. I. p. 79.

The *lexiarchi* kept a regiſter of the age, manners, and abilities of all the citizens, who were always enrolled at the age of twenty. Hiſt. Acad. Inſcrip. Vol. 4. p. 93.

LEYGAGER, is uſed for wager of law. Stat. 1 Car. I. c. 3. *Blount.*

LIBADION, in botany, a name by which Pliny, and ſome other authors, have called the *centaureum*, or centaury. *Ger.* Emac. Ind. 2.

LIBANIUM, in botany, a name given by Apuleius, and ſome other authors to the common *borago*, or borrage. *Ger.* Emac. Ind. 2.

LIBANOMANTIA, Λιβανομαντεια, in antiquity, a ſpecies of divination performed with frankincenſe; which, if it preſently caught fire, and ſent forth a grateful odour, was eſteemed a happy omen, and *vice verſa*. *Potter*, Archæol. Græc. l. 2. c. 14. Tom. I. p. 319.

LIBEL, in the law of Scotland, is uſed for a criminal accuſation.

LIBELLA, in natural hiſtory, the name of a very large genus of four winged flies, called by us *adder-flies* and *dragon-flies*. See FLY.

Theſe flies have all two very large and reticulated eyes, covering the whole ſurface of the head. They fly very ſwiftly, and prey upon the wing, being of great uſe to mankind, in clearing the air of innumerable little flies.

They are produced of ſeveral ſpecies of ſix-legged worms living in the waters, and figured by Mouffett, and other authors, under the name of *pulices* and *locuſtæ aquaticæ*. Mr. Ray deſcribes twenty three ſpecies of theſe flies. 1. The common greateſt *libella* with ſilvery wings. This is nearly three inches long, and is of a mixed colour of greeniſh and blackiſh. 2. The great *libella* with a long and ſlender body, and with yellowiſh wings. 3. The great *libella* with a long and ſlender body, of a lively green, inflated at both ends. 4. The common great *libella* with a ſhort and broad yellow body. 5. The great *libella* with a ſhort and broad blue body. 6. The great *libella* with a long and ſlender yellow body, and with no ſpots at the roots of the wings. 7. The great yellow winged *libella* with ſmooth ſhoulders. 8. The great *libella* with hairy ſhoulders and reticulated wings, and with a very beautiful red body, thicker toward the tail than elſewhere. 9. The middle ſized *libella* with a body partly of a green, and partly of a blue colour, with a row of large black ſpots in the middle. 10. The middle ſized *libella* with a blueiſh body, and wings all over of a blueiſh black. 11. The middle ſized *libella* with a blueiſh green body, and yellowiſh unſpotted wings. 12. The green bodied middle ſized *libella* with yellowiſh wings, marked with white ſpots toward the ends. 13. The green bodied middle fized *libella* with pale green wings. 14. The middle ſized *libella* with membranaceous ſilvery wings, with round brown ſpots in the middle. 15. The ſmall *libella* with reticulated wings, and with a green back with white joints. 16. The middle ſized *libella* with a white back, with two black ſpots at the joints. 17. The ſmall *libella* with reticulated wings, with a red back variegated with black ſpots at the joints. 18. The ſmall ſhort winged *libella* with a blue body, variegated with black ſpots. 19. The ſmall *libella* with ſhort wings, variegated with white and brown ſpots. 20. The ſlender weak *libella* with pellucid reticulated wings, marked with black ſpots. 21. The ſmalleſt *libella* with a body variegated with green and black. To theſe Mr. Ray adds two flies, he took in Italy, with large and long wings, which were reticulated, and of a browniſh colour, and were variegated with almoſt innumerable brown ſpots of various ſizes.

Moſt

Moſt of theſe ſpecies are found in Auguſt and September, in our fields and gardens, eſpecially near places where there are waters, as they have their origin from worms living in that element. The great ones uſually live all their time about waters, but the ſmaller are common among hedges, and the ſmalleſt of all are moſt frequent in gardens. The ſmaller kinds often ſettle upon buſhes, or upon the ground; but the large ones are almoſt always upon the wing, ſo that it is very difficult to take them. Their eyes are a beautiful object for the microſcope. *Ray*'s Hiſt. Inſect. p. 50.

The manner of this inſect's coupling with the female is a thing that has attracted the obſervation and admiration of multitudes, as they are frequently ſeen, in the hotter months, in that ſtate, flying together about the edges of waters.

Mr. Homberg, of the Academy of Paris, has taken great pains to inform the world of the whole ſecret of this ſtrange coitus, and of ſeveral other remarkable particulars in regard to the creature. The ſpecies in which he obſerved it is the common *libella* with a blue body, and large black ſpots on the wings; and is one of the middle ſize, between the largeſt and leaſt of theſe creatures, and very frequent in moſt places in June, July, and Auguſt.

He obſerves, that the male and female, in this ſpecies, are of the ſame ſize and appearance, but that the tail, or end of the body is larger in the female. The body of the male is of a bright violet colour, and the wings have each a large duſky ſpot near their extremity. This ſpot is really of the ſame violet colour with the body, but being deep, and on a very tranſparent body, it only ſerves to render it opake on a ſlight view. The females have bodies of a ſhining greeniſh grey, and their wings have not theſe ſpots. When this animal is at reſt, its wings are all placed erect, and ſo cloſe together, that they make the appearance of only one wing; which is a peculiarity in this ſpecies, the other *libella* carrying their wings always extended, as well when in a ſtate of reſt, as when flying. The head, in this ſpecies, is very large, in proportion to the body, and is joined to it only by a ſlender filament; and the belly is divided by ten articulations, which ſerve only to move it upwards and downwards, having no power of turning it ſideways. The part to which the wings are fixed is called the breaſt in animals of this kind; but in this creature the lungs are not ſituated there, but in the middle of the belly, which is ſeen continually riſing and falling at inſpiration and expiration. The laſt joint of the body of the male is a ring containing the anus, and this is furniſhed with two pair of hooks; the one pair outward and larger, the other inward and ſmaller: theſe the creature is able to open and ſhut as lobſters do their claws. The extremity of the belly of the female ſeems to conſiſt of two tubes, or pipes, one placed upon the other; the upper one is the anus, out at which it voids its excrements; the under one is the female part of generation, and the entrance to the womb of the animal. The womb is about a twelfth of an inch long, and has its origin at the lower part of the eighth ring of the body. Each of theſe tubes is furniſhed at the extremity with two ſmall points, as the anus of the male is with two pair of hooks; and theſe two pipes placed one over the other in the female, are the reaſon why the end of the body is not ſo large in the male as in this ſex.

When the male of this ſpecies finds the female ſiting upon a leaf, or ſtick, he ſeizes her as he flies, taking faſt hold of her with the hooks at the anus by the neck, or that part which joins the head to the breaſt, and immediately flies away with her, holding her fixed by the neck to the end of his tail. It would not be unnatural, on this occaſion, to imagine that there were one ſpecies of animal running away with another to devour it; but this thought muſt be of ſhort duration, ſince the female will be ſoon obſerved to make no attempts to get away; but, on the contrary, to contrive, as well as ſhe can, to be better carried, and that with leſs trouble to the male.

The male does not carry his bride far before he ſettles himſelf upon ſome plant, and raiſes his tail ſo, that the female may be brought to ſit eaſily under him upon the ſame plant. As ſoon as the female is thus ſeated, ſhe turns up her tail, and brings it between the legs of the male, then places it to a certain part of the breaſt of the male, in which are the organs of generation in that ſex. All this while the male keeps his hold of her neck with his forceps, or hooks. They uſually remain in this poſture about three minutes; and after that the male gently raiſing up his breaſt, they become ſeparated, and leaving the hold he had on her neck, at the ſame time, he flies away as he pleaſes. The female uſually remains on the place for half a quarter of an hour, and then ſhe flies away alſo. Mr. Homberg having obſerved the coupling of theſe animals thus far, was determined to examine the organs uſed in it by diſſection. To this purpoſe he caught ſeveral of them, and on the whole collected theſe obſervations.

The upper part of the body, as well in the male as female, is rounded, or convex, and the under part is ſo folded in the middle, as to make a kind of channel. The ſecond ring, in the body of the males, has a furrow, the edges of which are ſurrounded with hairs, and from the bottom of which, toward the breaſt, there ariſes a long black body, of the thickneſs of a hog's briſtle; at the end of this there is a ſmall white globule, which is hard, and very bright; this enters the breaſt, and ſeems to be the penis of the male. Its uſual poſition is horizontal, in the furrow of the body, and its white globule at the end may be always made to ſhew itſelf, by preſſing the body gently with a feather. The preſſing the tail of the animal, alſo makes it appear in the ſame manner. On cutting the breaſt of the animal tranſverſely, there appears a hollow cone, the baſe of which lies toward the body, and its apex runs to the root of this penis; and if a fine probe be puſhed into the hollow cone in the breaſt, the penis is always extended to its utmoſt length. This hollow cone ſeems the reſervoir of the ſemen of the male, and is only to be ſeen ſoon after the coupling with the female, when that ſemen has been ejected; it is then always to be ſeen hollow and empty, but at other times, when full, its parietes are ſo thin, that its ſhape is not to be diſtinguiſhed. The furrows, in which the penis is lodged, is no way different from that which runs all along the underſide of the body, and of which it is a continuation; only that it is deeper in this part, and is covered with hairs, which it is not elſewhere.

The female has the ſame furrow, but it is in her no deeper in this part than elſewhere, and has no hairs. The ninth ring in the female has, on its under part, an aperture, which is furniſhed at its edge with a little greyiſh ſubſtance, reſembling a ſmall wing, on each ſide. Theſe two wings ſerve to ſhut and open the paſſage to this aperture, at the pleaſure of the animal, and when ſhut they make a ſort of pipe before it. From the root of the eighth joint to the end of the ninth, there runs a ſmall elevation, at the extremity of which are placed two ſmall black horns. Theſe are very hard, and are about a twelfth of an inch long, and bent; their points are turned toward the anus: theſe conſiſt of a number of articulations, and conſequently are moveable every way. Theſe are generally hid under the little wings beforementioned, and are placed ſo cloſely and evenly together, that they ſeem only one little hook. It is eaſy to ſee that theſe little bodies may be of great uſe in the act of generation; they ſerve to open the female part at pleaſure, and to direct and fix it in the proper place for the male. When the female, in turning her body upwards, extends theſe hooks, and fixes them in the edges of the furrow, which runs along the body of the male, there is no more required than to ſlide them gently upwards, to bring the parts which they belong to exactly to the deſtined place. Mem. Acad. Par. 1699.

LIBELLA, among the Romans, was the tenth part of the *denarius*. See DENARIUS, *Cycl.*

LIBER, in vegetables, the bark or rind, principally of trees. This is to be conceived as conſiſting of a number of cylindric and concentric ſurfaces, whoſe texture is reticular, and in ſome trees plainly extruſible every way, by reaſon that the fibres are ſoft and flexible. While in this condition they are either hollow regular canals, or, if not ſo, they have interſtitial ſpaces, which ſerve the office of canals. The nutritious juice, which they are continually receiving, remains in part in them, and makes them grow in length and thickneſs, and ſtrengthens and brings them cloſer together; and by this means the texture, which was before reticular, becomes an aſſemblage of ſtrait fibres, ranged vertically, and parallel to each other; that is, as they are thus altered behind one another, they, by degrees, become a new ſubſtance more woody, and called *blea*. *Boerhaave*'s Chym. Not. p. 138. See BARK.

LIBERATE, in law, a writ that lies for the payment of a yearly penſion, or ſum of money, granted under the great ſeal, and directed to the treaſurer, chamberlains, and barons of the Exchequer, *&c.* for that purpoſe.

In another ſenſe it is a writ to the ſheriff of a county, for the delivery of poſſeſſion of lands, and goods extended, or taken upon the forfeiture of a recognizance.

Liberate is alſo uſed for a writ iſſuing out of the Chancery, directed to a gaoler for delivery of a priſoner, who hath put in bail for his appearance. F. N. B. 132. 4 Inſt. 116. Terms of the law. *Blount*, *Cowel.*

LIBERTATE *probanda*, in law, an antient writ that lay for ſuch as being demanded for villains offered to prove themſelves free; directed to the ſheriff, that he ſhould take ſecurity of them for their proving of their freedom before the juſtices of aſſize, and that in the mean time they ſhould be unmoleſted. F. N. B. 77. Terms of law. *Blount*, *Cowel.*

LIBERTATIBUS *allocandis*, in law, a writ lying for a citizen or burgeſs, impleaded contrary to his liberty, to have his privilege allowed. Reg. Orig. 262.

If any do claim a ſpecial liberty to be impleaded within a city or borough, and not elſewhere, there may be a ſpecial writ *de libertatibus allocandis*, to permit the burgeſſes to uſe their liberties, *&c.* Theſe writs are of ſeveral forms, and may be ſued by a corporation, or by any ſingle perſon, as the caſe ſhall happen. New Nat. Br. 509, 510. *Blount*, *Cowel.*

LIBERTY (*Cycl.*)—LIBERTY *of the tongue*, in the manege, is a void ſpace left in the middle of a bit, to give place to the tongue of a horſe, made by the bit's arching in the middle, and riſing towards the roof of the mouth. The bit, according to the various forms of the *liberty*, acquires different names; hence we ſay a *ſcatch mouth*, a *pignatelle*, i. e. with the *liberty* after Pignatelli's faſhion, and a *canon mouth*, with the liberty like a pigeon's neck.

In forging the bit, care muſt be taken not to make the *liberty* too high, leſt it hurt, or at leaſt tickle the palate, and make the horſe carry low.

LIBETHRIDES, in antiquity, a deſignation given to the muſes from Libethra a fountain of Magneſia, which was ſacred to them; but ſome derive the name from *Libethro*, a mountain of Thrace, in which was a cave likewiſe ſacred to them. *Hofm.* Lex. in voc.

LIBRATA *terræ*. This is the ſame with what in Scotland is called pound land of old extent.[—Tr. Pract. Geom. p. 87.]—See POUND *land*.

LICE, in zoology. See the article LOUSE.

LICHANUS, in the antient muſic, the name of one of the ſounds of a tetrachord. It was next to the nete. The word is Greek λιχανὸς, and ſignifies *index*. The reaſon of the appellation was, that the *lichanus* ſhewed whether, and how far the genus was *molle* or *intenſum*. For the more remote the *lichanus* was from the moſt acute ſound in the tetrachord, the more did the genus partake of the *molle*. And, on the contrary, the nearer the *lichanus* approached to this higheſt note, the genus was reckoned the more intenſe. Vid. *Wallis* Append. ad Ptolem. Harm. p. 160.

This is Dr. Wallis's account of the matter. And indeed, the reaſon of the name *lichanus* is not at all myſterious, if we conſider that the ſound of this chord was different in every one of the genera, whereas the ſound of the parypate remained the ſame in three different genera, and could not therefore be an index or characteriſtic of thoſe genera, which were, the *chromaticum toniæum*, the *diatonicum molle*, and the *diatonicum intenſum*. See CHROMATIC and DIATONIC.

LICHANUS *hypaton*, λιχανὸς ὑπατων, in the Greek ſcale of muſic, was the penultimate note of the hypaton tetrachord, and anſwers to *D ſol re* of Guido's ſcale. *Wallis* Append. ad Ptolem. Harm. p. 157. See DIAGRAM.

LICHANUS *meſon*, λιχανὸς μεσων, in the Greek muſic, was the penultimate note of the *meſon* tetrachord, and anſwers to Guido's *G ſol re ut*. Vid. *Wallis* Append. ad Ptolem. Harm. p. 157. See DIAGRAM.

LICHEN, *liverwort*, in botany, the name of a genus of moſſes, the characters of which are theſe. They have the moſt perfect fructification of all the moſſes, having evident flowers as well as ſeeds. Their flowering heads are of various figures, and have a number of monopetalous flowers in them, divided into a different number of ſegments; theſe have ſeveral filaments, and among them have a large quantity of a farina, which when examined by the microſcope appears of a globular figure. The ſeeds are produced in other parts of the plant, and are contained in certain cups, which ſtand without pedicles on the ſurface of the leaves; theſe are ſometimes on the ſame individual plant, with the flowering heads, but ſometimes they are on different plants of the ſame ſpecies.

Beſides theſe and the flowering heads, there are alſo in ſome ſpecies of *lichen*, certain other heads of the ſhape of a button ſtanding on pedicles, and containing neither flowers nor ſeeds; theſe are always found on ſuch plants as have no male flowers. The pedicles of theſe, as well as of the male flowers, are uſually naked, or without any covering at the baſe. To this it may be added, that the leaves of the *lichens* are leſs pellucid, and more like the leaves of the larger plants than thoſe of the other maſſes; and that they are of an irregular and indeterminate figure, ſpreading themſelves every way upon the ground, and ſending out roots from the underſide in various places. *Dillen.* Hiſt. Muſc. p. 516.

The *lichens* being a numerous family of plants, are by Dillenius divided into different orders.

The firſt order comprehends the pileated *lichens*, or ſuch as have not the ſtarry flowering heads of the more common kinds, of theſe there are only five known ſpecies. 1. The common great pileated and verrucoſe *lichen*, or muſhroom headed *liverwort*, this grows in great abundance on the clayey banks of rivers; it flowers in March and April. 2. The ſmaller muſhroom headed *liverwort* with crenated leaves. The leaves of this are uſually about an inch in length, and are moderately thick, ſomewhat concave, and pretty deeply notched at the edges. It is found on ſhady banks in many parts of England. 3. The muſhroom headed *liverwort* with narrow forked leaves. This grows on rocks and ſtones among other moſſes. It is not found in England. 4. The ſmall *liverwort*, with channelled leaves and fringed cups. This is found in large tufts on the northern mountains, it flowers in July, and uſually produces a great number of heads, which is contrary to the cuſtom of the other *liverworts*. 5. The pileated *liverwort* with lunulated ſeeds bearing leaves, and with heads finally becoming croſſed. This alſo grows in tufts on the damp ſides of hills and flowers in July. *Dillen.* Hiſt. Muſc. p. 521.

The ſecond order of the *liverworts* comprehends thoſe which have radiated or ſtellated heads. Of theſe the following are all the known ſpecies. 1. The great ſtar headed water *liverwort*. This grows on the banks of ditches, and in the ſides of wells, in which laſt place it is uſually of a more agreeable ſmell. It bears frequent cups on its leaves containing its ſeeds. 2. The ſmaller *liverwort*, with cups on the leaves, and with ſtellate and umbellated heads. This has much ſmaller leaves than the former, and is common in old walls. 3. The *liverwort* of America, with heads reſembling a duck's foot. This is found in the iſland of Martinico and in ſome other parts of America. It is of a very juicy or fatty ſtructure. Id. Ibid.

The third order of the *lichens* comprehends thoſe, the flowers and ſeeds of which are leſs accurately diſtinguiſhed than thoſe of the former kinds. Of theſe Dillenius mentions the following ſpecies. 1. The rock *liverwort* with grains like the ſeeds of the orobus. This is found in Italy, and ſome other countries, but not in England, ſo far as has been yet obſerved. 2. The dwarf *liverwort* with venous leaves, parting themſelves into two or three diviſions as they grow. This is deſcribed by Mr. Ray, in his hiſtory of plants, and is found in moiſt places on heaths. 3. The leaſt ſtar ſpread *liverwort* with ſharp divided leaves. This is found on Blackheath, and in other places about London. 4. The marſh *liverwort* with leaves divided like thoſe of rue. 5. The ſmall narrow leaved *liverwort* with plain ſegments, deſcribed by Micheli, under the name of *riccia*. 6. The greater checquered *liverwort* with the taſte of coriander. This is alſo deſcribed under the name of *riccia* by Micheli. 7. The middle ſized *liverwort* with deeply channelled leaves. This is alſo another of the *riccias* of Micheli, and is remarkable for its pyramidal fruit. 8. The little round headed marſh *liverwort*, called by Micheli *ſphærocarpos terreſtris minor*. 9. The heart cut *liverwort* with fringed leaves, found by Mr. Buddle, and by ſome called a ſpecies of *duckweed*. 10. The broad leaved green *liverwort* like the ſkin of a ſhark, with flowers at the edges of the leaves. 11. The *liverwort*, called by Ximenes *ychcacalotic*, or the cotton pod.

This is an American ſpecies of *liverwort* found by the ſides of rivers in hot places, and bearing ſtellated flowers like ours on ſhort and naked pedicles. It is of a cooling agreeable taſte, and is given in fevers, with good ſucceſs.

The Engliſh name *liverwort* expreſſes the good opinion the world has had of it in all diſorders of the liver. It is grown out of uſe with us at preſent, but the German phyſicians preſcribe it, and it is ſaid with ſucceſs in jaundices, and alſo in hectics. There are authors alſo who recommend it greatly in inflammatory fevers, in cutaneous eruptions, and in a gonorrhœa, but we have not ſo good accounts of the benefit received by it in theſe as in the other. Externally, it is recommended for ſtaunching the blood in freſh wounds; given in powder, in a doſe of about two ſcruples, it is excellent to ſtop the bleeding at the noſe, profluviæ of the menſes, or any other hæmorrhage; it acts by incraſſating the blood. There are ſome families in the weſt of England who prepare a medicated drink, which they pretend to be a cure for cancers, in which this plant is the principal ingredient. The antients recommended it as a remedy againſt laſſitude; they uſed it in baths and ointments. It has an Engliſh name, *cheeſe renning*, from its property of coagulating, or curdling freſh milk, and by a dry diſtillation it yields a manifeſt acid.

The grey ground *lichen* is famous for its virtues againſt the bite of a mad dog. It makes the baſis of the *pulvis antilyſſus* of the diſpenſatories. *Dale* Pharmac.

LICHENASTRUM, in botany, the name of a genus of plants of the moſs kind, ſo called from the *lichens* or *liverworts*, the flowers of which thoſe of this moſs ſomewhat reſemble. The characters of the *lichenaſtra* are theſe. The flower is naked, and of the antheraceous kind, globoſe at its firſt appearance, but ſoon after burſting open into a ſtellate or cruciform four leaved flower, or the reſemblance of one, much reſembling that of the galliums. This ſheds a fine duſt, or true farina, and is ſuſtained on a pedicle ſingly, and coming out of a theca or cup, which in ſome is undivided, in others is divided into two or more ſegments, repreſents a true flower. All the moſſes which have this ſort of flower are to be ranked in this genus, however widely they differ from one another in their external general form.

The firſt order of the *lichenaſtra*, according to Dillenius, contains thoſe with ſhoots and branches of a determinate figure; and of theſe the firſt ſeries conſiſts of ſuch as have leaves all ſet one way. Of theſe the following are all the known ſpecies. 1. The purple ſpoon leaved alpine *lichenaſtrum*. The leaves of this are auriculated, and hollowed like a ſpoon, it is found in the mountainous parts of Wales. 2. The upright branched *lichenaſtrum* with very ſmall round leaves. This has ſlender branches, and extremely thin and pellucid leaves, it is brought from Greenland. 3. The *ſcorpioide lichenaſtrum* with fine fringed leaves. This alſo is a na-

a native of Greenland, and very rarely is found in flower. 4. The fineſt leaved many flowered *lichenaſtrum*. This is an extremely ſmall ſpecies, it grows plentifully with us on Shooter's Hill. *Dillen.* Hiſt. Muſc. p. 486.

The ſecond ſeries of theſe *lichenaſtra* comprehends thoſe, which have their leaves ſet on each ſide the ſtalks, and reſemble in miniature the ſeveral kinds of the trichomanes and aſplenium. The firſt diviſion of theſe comprehends thoſe which have ſimple pinnæ, placed alternately againſt one another, and the middle rib naked.

The firſt ſubdiviſion comprehends thoſe which have whole pinnæ, or at the utmoſt ſuch as are only lightly crenated. Of theſe the following are all the known ſpecies. 1. The ſpleenwort-like *lichenaſtrum*, with thin ſet leaves. This grows among the other moſſes in ſhady places, and when it grows near clear running waters, uſually has a ſweet ſmell. 2. The ſpleenwort-like *lichenaſtrum*, with thicker ſet leaves. This grows in wet and ſhadowy places. 3. The trichomanes-like *lichenaſtrum*, with flowers from the middle and bottom. This flowers in April, and is not uncommon in wet places in woods. 4. The aquatic trichomanes-like *lichenaſtrum*, with a ſweet ſcent, commonly called the St. Winifred's well moſs. This is found in many parts of Devonſhire, and in ſome other places in wet grounds. 5. The ſhort creeping trichomanes-like *lichenaſtrum* with many flowers. This is found in many parts of England, and is eaſily diſtinguiſhed at a diſtance, when in flower, from the great number of the flowers. 6. The ſmall trichomanes-like *lichenaſtrum*, with flowers at the ends of the branches: this is common in ſhady places, and produces its heads in April. *Dillen.* Hiſt. Muſc. p. 487.

The ſecond ſubdiviſion of theſe *lichenaſtra* comprehends thoſe which have pinnæ cut into two or three ſegments, or as it were prickly. Of theſe the following are all the known ſpecies. 1. The larger hollow double ſtriped *lichenaſtrum*. This grows to two inches long, and is frequently found with its flowers in October and November, on heaths and in ſhady woods on the ſtumps of trees. 2. The ſmaller double ſtriped *lichenaſtrum* with blunter points. The pinnæ of this are ſhorter, more obtuſe, and leſs deeply cut in than thoſe of the former: it is common in wet and ſhady places. 3. The ſmalleſt double ſtriped *lichenaſtrum* with ſharper points. The branches of this are very ſhort, and it is very frequently found with a great number of flowers in April in ſhady woods. 4. The leaſt double ſtriped bifid *lichenaſtrum* with ſwollen ſheaths. This is not more than of half the bigneſs of the former. 5. The triple ſtriped *lichenaſtrum* with many branches. This is found on the Welch mountains. 6. The *lichenaſtrum*, with alternate, and as it were prickly pinnæ. *Dillen.* Hiſt. Muſc. p. 489.

The third diviſion of theſe *lichenaſtra* takes in thoſe which are pinnated and reſemble the trichomanes, but which have their middle rib hid, or covered by the auriculæ of the pinnæ, or elſe by ſecondary ones.

The firſt ſubdiviſion of theſe comprehends thoſe which have the middle rib covered by the auriculæ of the pinnæ. The following are the known ſpecies of this kind. 1. The *lichenaſtrum* with pinnæ, not ſerrated, but with very large auricles. This is of a ruſty colour, and does not creep, but grows tolerably erect. It is not unfrequent in woods. 2. The *lichenaſtrum* with ſmaller auricles and ſerrated leaves. This is found in ſome parts of Germany, but not in England. 3. The auriculated *lichenaſtrum* with round thick ſet leaves. This grows in large cluſters, yet is not erect, it is found on rocks in moiſt places. 4. The flat ear'd *lichenaſtrum* with narrow crooked leaves. This grows in tufts, its leaves are bent, and the ſtalks from half an inch to an inch and half in height, it is common in ſhady places, and flowers in April. 5. The auriculated *lichenaſtrum*, with hairy birds foot leaves. This has longer branches, and the leaves are leſs curled or bent than in the other ſpecies. It is found on the Welch mountains. *Dillen.* Hiſt. Muſc. p. 493.

The ſecond ſubdiviſion of theſe *lichenaſtra*, comprehends thoſe which have the lower part of their middle rib, covered with either one ſingle foliage, or with a ſeries of intermediate pinnæ. Of theſe the following are all the known ſpecies. 1. The *lichenaſtrum*, with a geniculated middle rib, and obtuſely trifid pinnæ. This is found on the Welch mountains, and is ſometimes ſingle ſtalked, ſometimes branched. 2. The greater *lichenaſtrum* with multifid leaves, and flowers from the extremities. This uſually grows in large tufts, and is ſometimes erect, ſometimes creeping; it is found in many parts of England. 3. The dwarf *lichenaſtrum* with multifid leaves, and with flowers growing from the bottom of the ſtalks. This in drying acquires an imbricated look, which it loſes again on being wetted. It is common by hollow road ſides. 4. The pennated fern-like *lichenaſtrum*. This is a ſort of miniature picture of ſome of the ferns, it grows in Patagonia.

The third ſeries of theſe *lichenaſtra*, comprehends thoſe which are imbricated, or have their pinnæ ſtanding cloſer upon, and lying over one another, and ſtanding leſs out from the ſurface of the ſtalks. The firſt diviſion of theſe takes in thoſe which have ſcales or pinnæ, as it were furniſhed with a ſecondary ſcale below. Of theſe the following are all the known ſpecies. 1. The large, flat, ſcaly *lichenaſtrum*. This is common on the barks of trees in almoſt all places, but it flouriſhes beſt in damp and ſhady parts of woods. 2. The leſſer convex ſcaly *lichenaſtrum*: this is commonly found mixed among the other in woods, but it is ſometimes ſeparate. It is while young of a beautiful green, but it ſoon loſes that colour, and becomes firſt brown, and afterwards of a blueiſh purple. 3. The leaſt flat *lichenaſtrum* with grey ſcaly leaves. This is found in the woods about Oxford and in many other parts of England, and is uſually met with among other moſſes, and creeping upon them. 4. The ſmalleſt herniaria leaved *lichenaſtrum*, deſcribed by Micheli. This is found in Italy. 5. The ſmalleſt round leaved *lichenaſtrum* with punctated leaves. This alſo is deſcribed by Micheli, and is found in Italy among other moſſes on the ſtumps of trees. *Dillen.* Hiſt. Muſc. p. 499.

The ſecond diviſion of theſe *lichenaſtra* contains thoſe which have the ribs or nerves of the branches, covered underneath by a ſort of ſecondary ſquammæ; of theſe the following are all the known ſpecies. 1. The ſcaly *lichenaſtrum*, reſembling the French tamariſk; this is found on rocks, and on the ſtumps of trees in many parts of England. 2. The ſmaller leſs round leaved, arbor vitæ-like *lichenaſtrum*. This grows on trees and walls in very thick tufts, and is very common both in England and North America. 3. The rounder leaved arbor vitæ-like *lichenaſtrum*. This alſo grows with us on the ſtumps of trees, but is leſs common than the former. 4. The imbricated *lichenaſtrum* with leaves like a curled fern. This grows to two inches high, and is found on barks of trees in Patagonia. *Dillen.* Hiſt. Muſc. p. 502.

The fourth ſeries of theſe *lichenaſtra* takes in thoſe, which are every way ſurrounded with leaves. Of this kind the following are the known ſpecies. 1. The elegant woolly fern-like *lichenaſtrum*. This is common about London in damp places. 2. The *lichenaſtrum* with various leaves. This is common in damp places in woods, and flowers in the ſpring. 3. The leaſt hoary *lichenaſtrum* flowering at the points. This is found in the woods of Germany, but has not yet been obſerved in England. 4. The alpine *lichenaſtrum* reſembling the ſilver bryum. This grows in very thick tufts, and is found on the Welch mountains. 5. The chocolate coloured alpine *lichenaſtrum* with ſcaly ſheaths. This alſo is found on the Welch mountains, and grows in thick tufts. 6. The duſky alpine *lichenaſtrum* with fine reflected leaves. This grows on the rocks in the higheſt parts of the Welch mountains, but uſually in damp places.

The ſecond order of theſe *lichenaſtra* comprehends thoſe which have leaves variouſly and indeterminately divided, which creep upon the ground, and have no ſtalks except the pedicles. Of theſe the following are all the known ſpecies. 1. The broad leaved *lichenaſtrum* with round heads growing out of the middle of the leaves. This is frequent on the ſteep banks of rivers, and in other damp places, it flowers in March. 2. The jagged *lichenaſtrum*, with oblong heads, growing near the ſegments of the leaves. This flowers in April, and is frequent about London. 3. The fine cut ambroſia-like *lichenaſtrum*: this is a ſmall ſpecies, and its leaves are always ſpread about the ground. It grows in woods and ſhady places in ſome parts of England, but is very ſcarce. 4. The germander like *lichenaſtrum* with multifid leaves. This is found in ſhady wet places. 5. The thin leaved forked *lichenaſtrum* with round hairy capſules. This grows in tufts, and is in ſome degree erect. It is found not unfrequently at the ſtumps of trees and on rocks, and flowers early in ſpring. 6. The little *lichenaſtrum*, with round, black and ſhining heads growing out of ſmall cups. This is a very elegant ſpecies, the leaves are lightly ſinuated, and have little cups, in many places, out of which grow the heads. It is found in wet ſhady places. *Dillen.* Hiſt. Muſc. p. 519.

The third order of the *lichenaſtra* comprehends a few ſpecies, of which the author was leſs perfectly informed than of the reſt, not having ſeen their heads, or abſolutely depending on the accounts of them. Theſe are, 1. The narrow floating forked *lichenaſtrum*. This always grows in ſtanding waters, and ſometimes floats on the ſurface, ſometimes ſinks deeper. 2. The *lichenaſtrum*, called by authors the branched and leafy marſh ulva. This ſomewhat reſembles the ambroſia *lichenaſtrum*, but is longer and more branched. 3. The *lichenaſtrum*, called by Micheli *jungermannia*, with branched ſtalks and flatted ſhoots, and hairy oval imbricated leaves laid in a double ſeries. 4. The *jungermannia* with a ſimple ſtalk, and leaves looſely imbricated, of an obtuſely oval figure, and reflected at the edges. Theſe two are mentioned by Linnæus in his flora laponica. *Dillen.* Hiſt. Muſc. p. 515.

LICHENOIDES, in botany, the name of a genus of moſſes, the characters of which are theſe. They are compoſed of parts of different figure and ſtructure, not ſimple and uniform as the byſſi; they have uſually no ſtalk, but grow on the branches of trees, on ſtones, and other bodies, either in

in form of a mere cruſt, or of leaves variouſly divided, and raiſed. They have tubercles on the ſeveral parts of theſe ſerving in the place of flowers or ſeeds, and growing cloſely upon the leaves without pedicles. Micheli has deſcribed the flowers and ſeeds of theſe plants from microſcopic obſervations, but theſe are too minute to form generical diſtinctions on. Theſe plants have the name *lichenoides*, from their reſemblance to the *lichen*, or liverwort, as they conſiſt, like it, of leaves diffuſed every way. They have hence been called by ſome *lichens*; but the difference between the two genera is very great, theſe having very imperfect flowers, the others the moſt perfect of all the moſſes.

The *lichenoides* are a very numerous genus, and are therefore divided into ſeveral ſubordinate ſeries, or orders.

Of the firſt order, or thoſe which have no leaves, but are merely cruſtaceous, the following are all the known ſpecies. 1. The cruſtaceous *lichenoides*, marked with lines reſembling foreign characters. The cruſt is white in this, and the lines ſlender and black. 2. The black dotted wrinkled *lichenoides*. The cruſt of this is white, and the ſpots ſmall and protuberant, and of a fine black. 3. The leprous brown knobbed *lichenoides*. The cruſt of this is very thin, and of a whitiſh grey; the tubercles are brown and large. 4. The yellow *lichenoides*, marked with lines reſembling the figures on a map. The cruſt is of a pale yellow, and very thin; the lines black. 5. The red knobbed *lichenoides*. This has no cruſtaceous bottom, but conſiſts only of ſmall red tubercles, reſembling ſmall fungus's. 6. The black lentil *lichenoides*. This grows on rotten wood. The tubercles are blackiſh, and of an oval figure; and it ſeems of a middle nature, between the *lichenoides* and fungus's. 7. The white tartareous ſcarlet dying *lichenoides*. This grows on the rocks in the mountains of Wales, and is compoſed of a hard and gritty cruſt, ſeeming almoſt of a ſtony nature, and much reſembling common tartar. This is whitiſh, and is ornamented, in ſeveral parts, with black tubercles. They boil this in urine, and it dies ſilk to a very beautiful red. *Dillen*, Hiſt. Muſc. p. 124.

The ſecond order of the *lichenoides* comprehends thoſe which have regular ſcutellæ appearing in manner of flowers; theſe are little hollowed cups, as it were, ſurrounded with a kind of rim. Of theſe the following are the known ſpecies. 1. The wrinkled wart *lichenoides*. This conſiſts of a thin cruſt of a blueiſh grey colour, beſet with ſmall wart-like protuberances; which, as they grow larger, aſſume the form of ſcutellæ, or little diſhes, hollowed pretty deeply. It grows on old trees, and on ſtones. 2. The ſcabrous *lichenoides* with tubercles reſembling crabs eyes. The cruſt is grey, and the tubercles grow to be wide ſcutellæ. This is uſed in dying, and is called by ſome *perelle*. 3. The meally rugged *lichenoides*. This firſt appears in form of a duſty ſubſtance, then it riſes into tubercles, and theſe finally become ſcutellæ. It grows on oak trees. 4. The meally tartareous *lichenoides* with brown ſcutellæ. This is compoſed of a thick cruſt, which is covered with a white farinaceous matter; the ſcutellæ are very broad, and have a white rim, but are brown in the middle. 5. The large leprous *lichenoides* with yellow plates. The cruſt of this is thick and wrinkled, the ſcutellæ broad, and of a pale yellow, with white rims. 6. The red ſpangled tartareous *lichenoides*. This has a thick cruſt, of a livid or blueiſh colour, the ſcutellæ are very broad, and have a ſilvery rim, being red in the middle. 7. The black ſpangled leprous *lichenoides*. The cruſt is thin, and of a greyiſh colour, the ſcutellæ ſome large, ſome ſmall, and all black. 8. The brown, or variouſly ſpangled leprous *lichenoides*. This makes its firſt appearance in form of ſmall grey tubercles, with a little brown hole in the center of each: theſe afterwards ripen into ſcutellæ. It is common on old walls, trees, *&c.* 9. The round grey cruſtaceous *lichenoides*. This is common on trees and old walls, and ſticks faſt to them all round. 10. The round yellow cruſtaceous *lichenoides*. This is extremely common on old walls, and the cruſt and ſcutellæ are both yellow. Ibid. p. 129.

The ſecond order comprehends the foliaceous *lichenoides*. Of theſe ſome are of a gelatinous ſubſtance, and have tubercles and ſcutellæ. Of this kind the following are all the known ſpecies. 1. The curled fleſhy ſea *lichenoides*. This reſembles the inteſtines of an animal, and is ſhort and thick, but not hollow, and is of a browniſh green colour, and jelly-like ſubſtance. It grows in ſea marſhes. 2. The wrinkled bats wing *lichenoides*. This is thin, membranaceous, and black. 3. The thin reticulated *lichenoides*. This is of a pale greeniſh colour, and has a great number of prominent veins diſpoſed in a reticular form. 4. The lobated jelly-like *lichenoides*. This is hollow, and divided into ſeveral lobes. It is of a greeniſh brown colour, and grows to ſtones. 5. The curled jelly-like *lichenoides*. This is of a greeniſh black colour, and is variouſly ſinuated. 6. The ear-like granulated gelatinous *lichenoides*. This grows to ſmall ſtones in garden walks. 7. The ſea ragwort leaved *lichenoides*. This is of a brown colour, and beautifully laciniated. 8. The imbricated jelly-like *lichenoides*. This is of a greeniſh colour. 9. The palmated jelly-like cluſtered *lichenoides*. This is found in woods in the winter months. 10. The opuntia-like jelly *lichenoides*. The leaves of this are narrow and thick. It is found in the mountains of Wales and Yorkſhire. 11. The broader opuntia leaved jelly *lichenoides*. The leaves of this are leſs wrinkled than thoſe of the former, and are of a duſky green, beſet all over with tubercles. 12. The horned and tranſparent *lichenoides*. This is ſometimes green, ſometimes purpliſh, and is compoſed of leaves growing into horns at their edges. It is common in ſpring among other moſſes on heaths. 13. The tranſparent endive leaved *lichenoides*. This is thin, and curled at the edges, and of a pale green, and is common among moſs. 14. The lettuce leaved tranſparent *lichenoides*. This is of a blueiſh green colour, and grows in Patagonia. 15. The criſp jelly *lichenoides* with flat leaves. This grows in cluſters, and its leaves ſpread every way about. 16. The criſp jelly *lichenoides* with ſmall upright leaves. This grows in ſmall tufts, and is of a bright pleaſant green. 17. The criſp jelly-like *lichenoides*, which ſeems as if prickly. This is of a blackiſh green, and is ſo nicely divided into ſegments at the edges, as to appear prickly. Ibid. p. 140 ſeq.

Of the gelatinous *lichenoides*, the following are the known ſpecies of the dry and more rigid kinds, which have regular ſcutellæ. 1. The common blue curled *lichenoides*. This is common on walls and old trees. 2. The ſmall leaved blueiſh *lichenoides* with hairy edges. This is common on the bodies of old oaks in Penſylvania. 3. The broad leaved *lichenoides* with hairy edges. The leaves of this are black underneath. 4. The ſaucer *lichenoides*. The leaves of this are much divided, grey on the upper ſide, and black underneath, and the ſcutellæ are large, and of a blackiſh red. 5. The larger ſea-green hairy *lichenoides*. The leaves of this are from one inch to two in length, and variouſly divided; the ſcutellæ grow at their edges, and ſtand on longiſh pedicles. 6. The ſmall grey hairy *lichenoides*. This is a very fine and tender kind, and the ſcutellæ are black. 7. The ſmall grey tree *lichenoides*, with black underſides to the leaves, and brown ſcutellæ, deſcribed by Micheli. 8. The blunt horned *lichenoides*. This grows on the ground, and ſtands ſomewhat erect. Ibid. p. 146.

Theſe have their ſcutellæ ſtanding on pedicles, more or leſs long; the following kinds have them applied cloſe to the ſurface of the leaves, and uſually of one colour: the leaves of theſe are more or leſs broad, and generally grow out from ſtones, or the branches of trees. 1. The grey flat black haired *lichenoides*. This grows to an inch in length, and the leaves are flatted, and edged with long black hairs. 2. The rough narrow leaved *lichenoides* with black ſpangles. The leaves of this are ſomewhat compreſſed and rigid, and are divided into five ſegments: the ſcutellæ are ſmall and black, ſurrounded with a thin edge of grey. 3. The bitter horned grey *lichenoides*. The leaves of this are narrow at the baſe, and wider toward the extremity: the ſcutellæ are rarely ſeen, but they are large, and black within. 4. The white prickly *lichenoides* with yellow ſcutellæ. This is divided into ſeveral ſegments, and is of a whitiſh colour, both on the upper and under ſide. 5. The white narrow horned *lichenoides*. The leaves of this are ſoft and tender, and have uſually a number of ſmall tubercles at their edges. 6. The common horned tree *lichenoides*. This is of a pale aſh colour, and is the moſt common of all the ſpecies: the trunks and branches of old trees are every where almoſt covered with it, and old pales and gates afford it in great abundance. 7. The ſmooth pitted endive leaved *lichenoides*. This does not grow on trees, but on ſtones, or on the ground, and has a baſis of a coarſe blackiſh cruſtaceous matter, from which it riſes in form of beautifully divided green leaves. 8. The black jagged, or fringed *lichenoides*. This is ſometimes compoſed of broader, ſometimes of narrower leaves, but they are always cut into jags and coarſe fringes at the extremities, in the manner of a farrier's apron. 9. The *lichenoides* which reſembles the fallopian tube. This is of a membranaceous ſubſtance, of a blueiſh green colour on the outſide, and white underneath: the ſcutellæ are broad, and ſtand near the edges. 10. The long leaved wrinkled ſtiff *lichenoides*. This is of a duſky greyiſh green, and is all over covered with ſcutellæ in the proper ſeaſon. It grows on the trunks of old oaks, and other trees. 11. The dyers *lichenoides* with ſhort and blunt horns. This is very like ſome of the ſea fucus's in the diviſion of its leaves; the leaves are whitiſh, and the tubercles very ſmall. It grows on the rocks in the iſland of Jerſey. 12. The flat dyers *lichenoides* with longer and ſharper horns. This alſo reſembles ſome of the fucus's in the diviſion of its leaves. It grows in large cluſters. It is common in the Eaſt-Indies, and is called by many authors *alga tinctoria*, and *rocella*, and is uſed in dying. See ROCELLA. 13. The coralliform channelled leaved *lichenoides*. This is of a whitiſh colour, and from an inch to three in length. Its ſcutellæ are ſmall, and grow about the edges and extremities of the leaves. 14. The fine cut warty *lichenoides*. This is divided at the edges into extremely fine ſegments, and is beſet toward the extremities with ſmall duſty tubercles. 15. The brown

brown rough *lichenoides* with ſtarry ſpangles, deſcribed by Micheli. Ibid. p. 158, 173.

Theſe have all their leaves, more or leſs, free; but there are ſome ſpecies which have them cloſely adhering, in every part, to the ſtone or wood on which they grow. Of this kind the following are all the known ſpecies. 1. The ſmalleſt fine cut *lichenoides*. This is extremely ſmall, and of a yellow colour: the ſcutellæ alſo are yellow. It grows on ſtones, and is common in many parts of Germany. 2. The brown ſmall cut *lichenoides*. The leaves of this are very narrow, and the ſcutellæ are black. 3. The grey ſmall cut ſtarry *lichenoides*. This grows frequently on the ſmall branches of trees. 4. The green blunt cut round *lichenoides*. This grows in a beautifully orbicular manner, the leaves are all collected in each plant into a ſort of circle, and the ſeveral ſingle plants grow in ſuch a manner together, as to form large circles. It grows on old trees. The ſcutellæ are black. 5. The green *lichenoides* with ſmall diſtorted leaves. This has leaves divided into very narrow ſegments, and grows on the barks of old trees. 6. The thin and ſoft agaric-like *lichenoides*. This is of a greyiſh colour, and grows on rocks. 7. The cartilaginous *lichenoides* with large ſpangles. The leaves of this are ſmall, but broad and rigid; they grow, like tiles, one over another; the ſcutellæ are very large, and of a yellowiſh tawney colour. 8. The greeniſh *lichenoides* with cheſnut coloured ſcutellæ. This has ſmall leaves collected into round tufts, the inner leaves of which are all the way ſmaller than the outer. It grows on rocks in the mountainous parts of England and Wales. 9. The common curled *lichenoides* with yellow leaves and plates. This is a middle ſized kind, and grows very frequently on trees and old walls. 10. The olive coloured *lichenoides* with ſmooth plates. This always grows in an orbicular form. Its leaves are very thin, and adhere firmly to the barks of trees. 11. The olive coloured *lichenoides* with watry ſcutellæ. The leaves of this are ſmaller, and more cut and divided than thoſe of the former. 12. The olive coloured *lichenoides* with wrinkled ſcutellæ. The leaves of this are of a ſomewhat greener hue than the former, and the ſcutellæ deeper. 13. The hairy purple ſtone *lichenoides*, called *cork*, or *arcell*, and by ſome *ken du*. The poor people uſe this in many places for dying, or ſtaining their linnen. 14. The black groenland cork, or *lichenoides*. The leaves of this are very ſmall, and finely divided, and the tubercles ſtand very thick and cloſe together. 15. The ſmooth bladder cork, or *lichenoides*. The leaves of this are not hairy at the edges, but are beſet with a great number of veſicles. 16. The common blueiſh grey pitted *lichenoides*. This is very common on old trees, and gates and pales. It very rarely produces the ſcutellæ. 17. The ſmooth endive leaved *lichenoides*. The leaves of this are green and curled at the edges, and black underneath. It grows on the ground in dry heathy places. 18. The wrinkled roſe leaved *lichenoides*. This is of a yellowiſh green colour, and is uſually expanded into the form of a roſe. It is common in many places both on walls and trees. 19. The bright green *lichenoides* with reddiſh diſhes. This grows frequently on old aſh trees in Ireland, and in ſome parts of England. 20. The pale blue ſcollopped leaved *lichenoides*. The leaves of this ſtand in thick cluſters, and are beautifully divided at the edges. 21. The ſooty *lichenoides* with ruſt coloured ſpangles. The leaves of this are ſoft and thin, and are divided into many ſegments: the ſcutellæ rarely appear. Ibid. p. 178, 194.

The third ſeries of the *lichenoides* takes in thoſe which are dry and peltated, or clypeated, which have tubercles of a roundiſh, or oblong figure, ſometimes flat, ſometimes convex, but never concave, nor ſurrounded with any rim or margin, in the manner of the ſcutellæ of the former kinds. The following are the known ſpecies of this kind of *lichenoides*. Firſt of ſuch as have the edges of the leaves, or their appendages, growing to the whole ſubſtance of the peltæ; that is, whoſe peltæ adhere by their whole inferior rim. 1. The rough villoſe *lichenoides* with ſmall peltæ or ſhields. The leaves of this are oblong, and divided into broad ſegments; the colour is a deep green at firſt, which turns to a browniſh red when dry. 2. The common grey or aſh coloured ground *lichenoides*, famous for the cure of the bite of a mad dog. 3. The dark coloured fingered *lichenoides*, with curled lettuce like leaves. This is uſually confounded with the former kind. It grows in the ſame places with that, and is indeed more common. The leaves are more rigid and thick in this ſpecies, and are divided into deeper ſegments, with curled edges turning inward. 4. The brown *lichenoides* with flat ſhields. This has variouſly ſinuated leaves, and grows frequently among graſs, and other moſſes, in dry places. 5. The livid *lichenoides* with reverſed brown ſhields. This is ſmaller, and its leaves ſhorter than the precedent kinds. 6. The fine green *lichenoides* with black warts. The leaves of this are ſhort and broad, and in the recent plant are of a good green. 7. The aſh coloured many fingered *lichenoides*. The leaves of this are an inch, or a little more, in length, narrow at their baſe, and broader toward the extremities; they are of a duſky greyiſh green, and the peltæ ſtand upon a ſort of pedicles, and are of a browniſh colour. 8. The double fingered tranſparent *lichenoides*. The leaves of this are about an inch long, divided into many ſegments, and of a whitiſh green colour. 9. The ſmall green *lichenoides* with flat black ſhields. The leaves of this are half an inch long, broad, ſmooth, and rigid. 10. The leaſt round leaved *lichenoides*. The leaves of this are flat, and lie cloſe upon the ground; they are green, and are the ſmalleſt of thoſe of all the *lichenoides*. 11. The eryngo leaved *lichenoides*. This is very rigid, and its leaves are variouſly ſinuated. 12. The finer eryngo leaved *lichenoides*. This is a tenderer plant than the former, and its leaves are more curled at the edges. Ibid. p. 204.

The ſecond diviſion of theſe *lichenoides* contains thoſe which have pileated heads or peltæ, ſuſtained on ſhort pedicles which are fixed to their middle. The known ſpecies of this kind are the following. 1. The common tree *lungwort*. This is a tough membranaceous ſubſtance of a browniſh colour, reticulated with a number of veins, and adorned with a great many peltæ at the edges. It is common on the bark of large woods. 2. The glaucous leaved *lungwort*, woolly on the underſide. The leaves of this are lobated or divided into broad obtuſe ſegments. 3. The buck's horn *lichenoides* ſpungy on the under ſide. The leaves of theſe ſpread upon ſtones, and grow to four or five inches in length. The peltæ are ſmall, and grow both on the edges and in the middle of the leaf. 4. The horny fimbriated *lichenoides* with heads like hair buttons. The leaves of this are about an inch long, and are uſually arranged in a circular manner. 5. The grey leathery *lichenoides* with black warts. This ſeldom exceeds an inch in length, the peltæ or warts are very ſmall. 6. The ſad coloured ſtiff *lichenoides* with black peltæ. This grows in a circular direction, and is about two inches in length in the largeſt leaves. 7. The chagrin *lichenoides*. This is black, and is granulated in the manner of the common chagrin leather. 8. The orange coloured *lichenoides* with black flat peltæ. This was found by Linnæus in Lapland. 9. The liverwort-like *lichenoides* with peltæ in ſockets. This is found on ſtones in ſome parts of England, and ſomewhat reſembles the preceding kind. 10. The round leaved peltated Lapland *lichenoides* with undivided edges, and leaves very hairy underneath. Ibid. p. 222.

To all theſe there are to be added ſome other ſpecies, the peltæ or ſhields of which very rarely, if ever appear, ſo that they have not yet been obſerved. 1. The grey cloudy leather-like *lichenoides*, yellow on the under ſide. This is found on moiſt rocks in ſome parts of England. 2. The imbricated, lead coloured *lichenoides*. The leaves of this are ſmall, and it grows in moiſt places on rocks. 3. The ſmall ſmooth rocky *lichenoides* with duſky leaves. This grows alſo in wet places. 4. The ſinged *lichenoides* with grey puſtules. This is one of the moſt elegant plants of this numerous tribe, and is found on moiſt rocks in ſome parts of France, and in ſome mountainous places with us. 5. The little yellowiſh ſtone *lichenoides* with pulpy leaves. 6. The ſmall green undivided *lichenoides* deſcribed by Micheli. 7. The ſmall green ſtone *lichenoides* with imbricated leaves deſcribed by the ſame author. And, 8. Haller's ſmall *lichenoides* with ſhort thick ſcales. As all theſe delight in watery places, it is much to be queſtioned whether they are not varieties of the other ſpecies, which had they grown in their natural dry ſoil, would have aſſumed their regular figure, and been furniſhed with their peltæ. Ibid. p. 229.

LICINIUM, a word uſed by many chirurgical writers to expreſs a tent.

LICNON, Λίκνον, in the Dionyſian ſolemnities, the myſtical van of Bacchus; a thing ſo eſſential to all the ſolemnities of this god, that they could not be duly celebrated without it. *Pott.* l. 2. c. 20. T. 1. p. 383. See DIONYSIA, *Cycl.*

LICNOPHORI, Λικνοφόροι, in the Dionyſian ſolemnity, thoſe who carried the *licnon*. See LICNON.

LICTORS, among the Romans, were officers who always attended the chief magiſtrates when they appeared in public. The duty of their office conſiſted in the three following particulars. 1. *Submotio*, or clearing the way for the magiſtrate they attended; this they did by word of mouth; or if there was occaſion by uſing the rods they always carried along with them. 2. *Animadverſio*, or cauſing the people to pay the uſual reſpect to the magiſtrate, as to alight, if on horſeback or in a chariot; to riſe up, uncover, make way, and the like. 3. *Præitio*, or walking before the magiſtrates; this they did not confuſedly, or all together, nor by two or three a-breaſt, but ſingly following one another in a ſtrait line. Their enſigns were the *faſces* and *ſecuris*. *Pitiſc.* in voc. See FASCES and SECURIS.

As to the number of *lictors* allowed each magiſtrate, a dictator had twenty-four, a maſter of the horſe ſix, a conſul twelve, a prætor ſix; and each veſtal virgin, when ſhe appeared abroad, had one.

LIENIS *infarctus*, in medicine. See the article SPLEEN.

LIFE (*Cycl.*)—LIFE *of animals*. Some contend that the *life* of animals is preſerved by the acid parts of the air mixing with the blood in the lungs; which parts diſſolve or atte-

nuate the blood and preſerve its heat, and by both theſe keep up the motion of the heart. See Dr. *Bryan Robinſon*'s Treat. of the Anim. Œconomy.

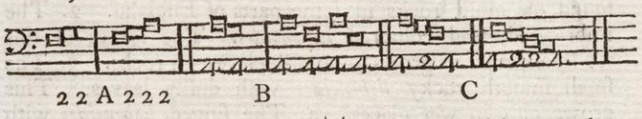
LIFE *eſtates*, in our law, are either for the life of the owner, or for the life of another, or others.

Annuity for LIFE. See the APPENDIX.

Prolongation of LIFE. See PROLONGATION.

LIFTING *pieces*, in a clock, are thoſe parts which lift up and unlock the detents in the clock part.

LIFTS, in a ſhip, ropes belonging to the yard arms of all yards. Their uſe is to ſtop the yard-arms, *i. e.* to make the end of the yards hang higher or lower, as occaſion ſerves. The top-ſail *lifts* ſerve as ſheats for the top-gallant yards, as well as for *lifts* to the top-ſail yards. The haling of theſe ropes is called *topping the lifts*: thus they ſay *top a ſtarboard*, or *top a port*, i. e. hale upon the ſtarboard or larboard *lift*. The *lifts* for the ſprit ſail yard, are called *ſtanding lifts*.

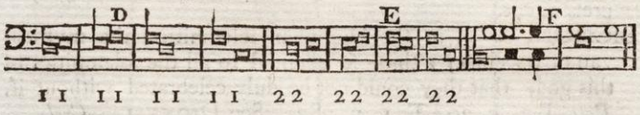


LIGAMENT (*Cycl.*)—LIGAMENTS *of the vertebræ*. Mr. du Vernoi has mentioned more *ligaments* of the vertebræ of the back, than are commonly deſcribed. See Comment. Acad. Petrop. Tom. VI.

LIGAMENTUM *peculiare ſtapides*, in anatomy, a name given by Schelhammer and ſome others, to what is properly a muſcle, and is called by Albinus *ſtapedium*, and by Cowper and others *muſculus ſtapides* and *ſtapedaceus*.

LIGATURE (*Cycl.*)—LIGATURE, *ligatura*, in the Italian muſic, ſignifies a tying or binding together of notes.

Hence ſyncopes are often called *ligatures*, becauſe they are made by the *ligature* of many notes. There is another ſort of *ligatures* for breves, when there are many of theſe on different lines, or in different ſpaces, to be ſung to one ſyllable.



To underſtand this, it muſt be obſerved, that only breves are capable of this ſpecies of *legature*, by reaſon their figure admits of their being placed ſo cloſe together, as to ſeem one character only, though placed on different degrees, unleſs there be occaſion to place a ſemi-circle either above or below them, to ſhew that they are tied. This kind of *ligature* regards common time only. Breves again muſt be conſidered as ſimple, as having a tail, and as being of different colours. Firſt, if they be ſimple 𝅜 and aſcend, they contain their natural quantity, *i. e.* each two ſemi-breves. Example A. But if they deſcend, then each is equivalent to four ſemi-breves, if only two follow one another, as in B. If there are three or four following ones, the firſt and laſt contain each four ſemi-breves, and thoſe in the middle but two, as in C.

2 2 A 2 2 2 B C

Secondly, if they have tails 𝅗𝅥, and the tail be turned upwards, the breves contain only one meaſure, as well aſcending as deſcending. See Ex. D. But if it be marked downwards, the breve then contains its natural quantity. See Example E. This ſpecies of *ligature* was invented only becauſe the minim being round, could not be uſed in this manner. And the ſemi-circle was not at that time in uſe.

It may be here remarked, that ordinarily the firſt breve alone of every *ligature* has a tail, and that uſually placed on the left ſide: laſtly, if they be of different colours, *i. e.* if the firſt be white, or open in the middle, and the ſecond black, the firſt contains a ſemi-breve, and the ſecond a pointed minim. Example F.

II II II II 22 22 22 22

Theſe are the principal *ligatures*, beſides which there are many others, for which ſee NOTA. *Broſſard.*

LIGATURES, in ſurgery, called alſo chords, bands, or ſtrings, are of different kinds, ſome fine, others coarſe and ſtrong, and are made either of flax, or hemp, or cloth, or ſilk, or horſe hair, according to the nature of the diſorder; for theſe things are almoſt conſtantly required. We uſe them to replace or extend bones that are broken or diſlocated; to tie the patients down in lithotomy, amputations, and operations of that kind; to tie up the veins in phlebotomy; to tie up arteries after amputations, or in large wounds; to ſecure the ſplints that are applied to fractures; to tie up the proceſſes of the peritoneum, with the ſpermatic veſſels in caſtration; and laſtly, in taking off warts, and other excreſcencies by *ligature*, and in all other operations of this kind. *Heiſter*'s Surg. p. 23.

LIGEANCE, *ligeantia*, is the true and faithful obedience of a ſubject to his ſovereign; and is alſo applied to the dominion or territory of the liege lord; thus children are ſaid to be born in or out of the *ligeance* of the king, *&c.* Stat. 25 Ed. 3. Co. Litt. 129. Terms of Law. *Blount*, *Cowel.*

LIGHT (*Cycl.*)—LIGHT *from diamonds and other bodies*. *Light* has of late ages become in a manner more common than it uſed to be among us. The chemical phoſphori have greatly increaſed its kinds, many electrical bodies are luminous, and many other bodies there are which are luminous without being electric.

The antient naturaliſts, and ſince their time, ſeveral other writers, at different periods of time, have been acquainted with many of theſe properties in ſeveral bodies, though very imperfectly. They have obſerved them too careleſsly, often exaggerated them in their accounts, and frequently deſtroyed the whole credit of the narration, by a mixture of falſity with the truth. M. du Fay, who laboured extremely in theſe diſquiſitions, has been at the pains of collecting all the accounts of this kind from authors, and ſeparating truth and probability from what is falſe or abſurd in theſe accounts, has with them given many experiments of his own to the academy of ſciences at Paris.

Among luminous bodies the diamond is to be reckoned, as ſome diamonds are known to ſhine in the dark. But on account of the feebleneſs of their ſplendor, it is neceſſary for the perſon, who is to obſerve them, previouſly to ſtay in the dark at leaſt a quarter of an hour; that the pupil of the eye may be dilated and enlarged, and ſo rendered capable of receiving a larger quantity of the rays of light. M. du Fay has alſo obſerved, that the eyes ought to be ſhut for this time, or at leaſt one of them; and that, in that caſe, the light of the diamond is afterwards only ſeen by that eye, which has been ſhut. Before the diamond is brought into the dark room, it muſt be expoſed to the ſun ſhine, or at leaſt to the open day light, to imbibe a ſufficient quantity of rays; and this is done in one minute, or even leſs; eight or ten ſeconds having been found to furniſh as much *light* as a ſtone is capable of receiving; and when brought into the dark its *light* continues about twelve or thirteen minutes, weakening all the while by inſenſible degrees. It is very remarkable, that in bodies ſo extremely ſimilar to each other as diamonds are, ſome ſhould have this property of imbibing the ſun's rays and ſhining in the dark, and that others ſhould not; yet ſo it is found to be by experiment, and the moſt nearly reſembling ſtones ſhall be found one to have this property, and another to be deſtitute of it; while the many of the moſt diſſimilar have this property in common. There ſeems to be no rule, nor even the leaſt traces of any imperfect rule of judging, which diamonds have and which have not this property; their natural brightneſs, their purity, their ſize, or their ſhape, contribute nothing to it; and all that has been yet diſcovered of the leaſt regularity among them, is, that all the yellow diamonds have this property. This may probably ariſe from their having more ſulphur in their compoſition, and therefore illuminating more readily, or emitting a more viſible flame.

The burning of diamonds is a term uſed among the jewellers; for putting them into a fierce fire, as they frequently do, when they are fouled with brown, or yellow, or the like; this always diveſts them of their colour, without doing them the leaſt ſenſible injury. M. du Fay having been informed of this common practice, formed a conjecture, that the difference of diamonds in their ſhining, or not ſhining in the dark, was owing to it; and that either all thoſe which had been burnt, or all thoſe that had not, were thoſe which alone ſhone in the dark. But this was found an erroneous conjecture; for two diamonds, one lucid in the dark, the other not, were both burnt, and afterwards both were found to retain the ſame properties they had before. It is not only the open ſun-ſhine, or open day-*light*, which gives to theſe diamonds power of ſhining in the dark; they receive it in the ſame manner, even if laid under a glaſs, or plunged in water or in milk.

M. du Fay tried whether it was poſſible to make the diamond retain, for any longer time, the *light* it naturally parts with ſo ſoon; and found, that if the diamond, after being expoſed to the *light*, be covered with black wax, it will ſhine in the dark, as well ſix hours afterwards as at the time it was firſt impregnated with the *light*. Mem. Acad. Scien. Par. 1735.

The imbibing *light*, in this manner, being ſo nice a property as not to be found in ſeveral diamonds, it was not to be ſuppoſed that it would be found in any other ſtones: accordingly on trial, the ruby, the ſapphire, and the topaz, were found wholly deſtitute of it, and among a large number of rough emeralds, one only was found to poſſeſs it. Such is the ſtrange uncertainty of theſe accidents.

All the other leſs precious ſtones were tried, and found not to poſſeſs this property of imbibing *light*, from the day-*light*, or ſun-ſhine, but they all became luminous, by the different means of heating, or friction; with this difference, that ſome acquired it by one of theſe methods, and others by the other; each being unaffected by that which gave the property to the other. The diamond becomes luminous by all theſe ways. Ibid.

LIGHT, in the manege. A *horſe* is ſaid to be *light*, in French *un cheval leger*, that is, a ſwift, nimble runner. We likewiſe call a horſe *light* that is well made, though he is neither ſwift nor active: for in this laſt expreſſion we conſider only the ſhape and make of a horſe, without regard to his qualities.

Light upon the hand; a horſe is ſaid to be ſuch, that has a good

good tractable mouth, and does not reſt too heavy upon the bit.

A coach horſe is ſaid to be *light*, when he ſtirs nimbly, and dreads the whip; or when he has a *light* trot.

LIGHT-*hand*. See the article HAND.

LIGHT *bellied*, in the manege. A horſe is thus called that commonly has flat, narrow, contracted ſides, which makes the flank turn up like that of a grey-hound.

LIGHTEN, in the manege. To *lighten* a horſe, or make him *light* in the fore hand, is to make him freer and *lighter* in the fore-hand, than behind. If you would have your horſe *light*, you ought to keep him always diſpoſed to a gallop, when you put him to a trot; and after gallopping ſome time, you ſhould put him back to the trot again.

LIGHTNING. In the diſſection of the body of a man killed by a ſtroke of *lightning* at Peterſburg, the abdomen and penis were found greatly inflated. The ſkin of the left ſide reſembled burnt leather; in the other parts of the body it was purple, except that on the neck, which was red as ſcarlet, and there was a ſmall hæmorrhage from the right ear: on the top of the head there was a ſmall wound, as if the fleſh had been torn away, but the ſkull was not injured; the head was found full of very fluid blood, every part of the brain being covered with it; and in the theca of the vertebræ there was a great quantity of ſerum. The lungs looked blackiſh and were collapſed; the heart had no blood in it, nor was there any in the veſſels about it; the gall bladder, and the urinary bladder, were both collapſed and wholly empty, and the ureters greatly diſtended with urine. Act. Petropol. VI. p. 383.

Lightning has been known to render iron magnetical. See Phil. Tranſ. N° 437. and N° 459. Sect. 11.

Artificial LIGHTNING. The phoſphorus, when newly made, gives a ſort of artificial *lightning* viſible in the dark, which would ſurprize thoſe who are not uſed to ſuch a phænomenon: the uſual method of keeping this preparation is under water, and if the coruſcations are deſired to be ſeen to the greateſt advantage, the glaſs in which it is kept ſhould be deep and cylindric, and not more than three fourths filled with water. The phoſphorus put into this water will ſend up coruſcations at times, which will pierce through the incumbent water, and expand themſelves with great brightneſs in the empty upper part of the bottle.

If we compare this artificial coruſcation to the real *lightning*, we ſhall find, that as in this the fire paſſes unaltered through the water, ſo in that the flaſhes of *lightning*, which come at intervals, paſs uninterrupted through the moſt denſe clouds, and are not obſtructed by the heavieſt ſtorms of rain, but like the beams of the ſun, or any other fire, paſs uninterrupted through glaſs and water. The ſeaſon of the weather, as well as the newneſs of the phoſphorus, muſt concur to produce theſe flaſhes; for they are as uncommon in winter as lightning is, but in warm weather both are very frequent.

The flame of *lightning* is generally inoffenſive, and does not, except under particular circumſtances, ſet fire to any thing that it falls upon; and, in like manner, the flaſhings of the phoſphorus through the water will not burn the fleſh, nor even fire the moſt combuſtible things; though the phoſphorus itſelf, like the *lightning*, under proper circumſtances, may be a very conſuming and terrible fire. The warmth of the air, or the immediate beams of the ſun will ſet fire to the condenſed body of the phoſphorus, and it then becomes this terrible fire; and in the ſame manner, *lightning* when condenſed and contracted, and wrapped up in a vehicle of air, ſo that it does not ſo eaſily diffuſe itſelf through the yielding æther, ſets fire to trees, houſes, or whatever it comes near.

The phoſphorus, while burning, acts the part of a corroſive, and when it goes out reſolves into a menſtruum, which diſſolves gold, iron, and other metals; and *lightning*, in the ſame manner, melts the ſame ſubſtances. From the whole, it appears that there is much more reſemblance between this phoſphorus and *lightning*, than between gunpowder or aurum fulminans, and that fire; though theſe have often been ſuppoſed to be nearly allied to its nature.

LIGNICENSIS *terra*, in the materia medica, the name of a fine yellow bole dug in many parts of Germany, particularly about Emeric in the circle of Weſtphalia, and uſed in cordial and aſtringent compoſitions. It is a common ſuccedaneum for the yellow Sileſian bole, where that is not to be had, and is generally eſteemed very nearly, if not abſolutely equal to it in its virtues. *Hill*'s Hiſt. of Foſſ. p. 8.

It is moderately heavy, naturally of a ſmooth ſurface, and of a beautiful gold colour. It eaſily breaks between the fingers, and does not ſtain the ſkin in handling, and melts freely in the mouth, but generally leaves a little grittyneſs between the teeth. It makes no efferveſcence with acids; and burns not to a red, but to a pale brown, and almoſt to a ſtone hardneſs.

Charlton (Foſſ. p. 5.) ſays it is more frequently known by the name of *terra ſigillata goltbergenſis*.

LIGNITES, the name of a ſtone deſcribed by Ludovicus Dulcis, as having the veins and appearance of wood, and the tranſparence of glaſs. He celebrates it for many imaginary virtues, nor does the ſtone itſelf indeed ſeem much leſs imaginary; this author, as De Boet obſerves, having deſcribed many ſtones which he never ſaw, and no ſmall number that never exiſted.

LIGNUM (*Cycl.*)—LIGNUM *campechianum*. See LOG-WOOD.

LIGNUM *colubrinum*. Garcias tells us of the wonderful effects of this drug againſt the bites of venomous ſerpents, and deſcribes two kinds of the plant which produces it; one having leaves like the pomegranate, and the other like the peach tree: theſe, he ſays, both grow in the iſland of Ceylon; and Acoſta mentions two other ſpecies of plants producing this wood, both different from either of thoſe deſcribed by Garcias, and both growing in Malabar. We have alſo accounts in the *geographus nubienſis* of another *lignum colubrinum*, different from theſe, growing in Æthiopia, and poſſeſſed of the ſame virtues againſt the bites of ſerpents as the others. This laſt is called in the Arabic *haud alhaic*, the plain verbal tranſlation of which is ſnake wood, or *lignum colubrinum*. He tells us, that it has ſome reſemblance in form to pyrethrum, and that the wood is always contorted.

Alha cararha is another of its Arabic names, and this is the word by which Aviſenna, and the other Arabian writers, interpret the *pyrethrum* of Dioſcorides; but it is not certain, whether the ſimilitude of ſounds between two or more Arabic words, may not have occaſioned ſome confuſion or error here. Dicæarchus, in his fragment of mount Pelion, deſcribes the root of a tree growing there, which is not only a ſovereign remedy for the bites of ſerpents, but even deſtroys them by its ſmell. This is alſo a *lignum colubrinum*; but whether the ſame with any of the others, or different from them all, we have not deſcriptions enough to determine.

It appears, upon the whole, that little can be depended on in the accounts of the medicine called *lignum colubrinum* by any author, unleſs he has himſelf experimented what he relates, and deſcribed the plant which produces the drug; for much imaginary virtue has been at all times given to many things againſt the bitings of ſerpents, and the *lignum colubrinum* of one author is not the *lignum colubrinum* of another. Every one having given this name to the thing which he ſuppoſed moſt deſerved it. Garcias tells a remarkable ſtory of a ſort of ferret, which he calls *quirl*, or *quirpele*; this creature, he ſays, is a continual enemy to the rattle ſnake, and often voluntarily attacks it in ſingle combat; but before it does this, he ſays, it always eats a quantity of the *lignum colubrinum*, and moiſtening its paws with the ſpittle, the creature rubs itſelf all over with it, and then attacks its enemy. The natural enmity between theſe creatures, of the weaſel kind and ſerpent, is recorded in many of the antients. Pliny tells us of the hatred of this creature and the baſiliſk; and Solinus adds, that if put into the hole, where a poiſonous ſerpent inhabits, the creature generally periſhes by the bite of the ſerpent, and the ſerpent is deſtroyed by the ſmell of it. If this be the caſe, there needs no anointing with the ſpittle impregnated with *lignum colubrinum*; and the whole matter of the enmity between theſe creatures and the ſerpent kind, ſeems rather reducible to hunger than any other provocation, the fleſh of ſerpents being a very delicious food where they can be got at; but the rattle ſnake muſt needs be an overmatch for any of theſe creatures, as it ſwallows larger animals whole.

LIGNUM *nephriticum*. See NEPHRITIC, *Cycl.*

LIGULA, a word uſed by medical writers in very different ſenſes. Some expreſs by it the clavicle, others the glottis; others uſe it as the name of a meaſure, for things either liquid or dry, being a quarter of a cyathus, equal to a forty-eighth part of a pint with us; others finally uſe it for a weight, leſs than half an ounce by two ſcruples, or ten ſcruples.

LIGULA *marina*, a name given by ſome botanical writers to a plant of the fucus or ſea wrack kind, called by others *fucus in ligulas diviſus*. It uſually grows in places always covered by the ſea, not on the banks, which are dry at the ebbing of the tides; and is for the moſt part compoſed of a ſort of long cords or ſtrings, of an oval rather than a round figure, ſeldom exceeding a fifth of an inch in diameter, but often two or three feet long, and not unfrequently divided into two, at ſeveral diſtances, one above another. The ſtalk is ſolid, and not hollow, as in the *fucus chordam referens*, or the ſtringy fucus of Mr. Ray; at leaſt the ſtalk of this plant is full of a thick and tough viſcous matter, like that found in the bladders, at the extremities of the branches of the common fucus, at the time when the ſeeds are ready to fall. This gluey matter is of a whitiſh green, and the colour of the plant itſelf is a deep olive; there is no rib or nerve to be ſeen in any part, but its texture is very cloſe and compact. The indefatigable Mr. Reaumur diſcovered irregular flowers in this plant; they are each compoſed of a number of ſhort and ſlender filaments, iſſuing out of a little hole, which ſerve them as a cup. Theſe filaments are diſpoſed in a circular order upon the ſtalk; and reſemble, in miniature, the common radiated flowers of the hawk weed, and the like plants; but their diameter is not more than the twentieth part of an inch. Notwithſtanding the ſmallneſs of theſe flowers,

flowers, they are however eaſily diſtinguiſhed becauſe they are green, whereas the ſtalk is olive coloured.

Theſe flowers are diſperſed over the whole plant, and ſometimes ſtand in a ſort of cluſters, a great number of them being placed cloſe together, and afterwards there being a little ſpace, and then another ſuch parcel. What is peculiar in this plant, and differs from the other ſea fucuſes, is, that as in them only a few of the flowers produce ſeeds, in this almoſt all the flowers do it; ſeeds being found ſucceeding thoſe flowers, which ſtand far off from the extremities, as well as thoſe which ſtand near them; and thoſe parts of the plant where the ſeeds are produced do not ſwell any more than the reſt. The viſcous matter lodged only at the extremities of the leaves of the common fucuſes, which ſerves for the nouriſhing the ſeeds, is, as before obſerved, in this lodged all along the center of the ſtalk; and conſequently the ſtalk, or leaf, which ever it may beſt be called, is furniſhed with matter for the nouriſhment of ſeeds all the way down. When the flowers are fallen, it is eaſy to diſcover multitudes of ſmall round holes in the ſtalk, each of which has been the cup of a flower, and underneath each hole there is now to be diſtinguiſhed a little round body, which is a capſule, containing the ſeeds; this capſule being divided, there are ſeen a number of minute round ſeeds ſticking to its ſides. Mem. Acad. Par. 1712.

LIGULATED *floſcules*, *ligulati floſculi*, in botany, a term uſed by authors to expreſs a part of the floſcules, or ſmall ſeparate flowers, which together form the whole head or flower of the compound flowered plants. The *ligulated floſcules* generally ſtand on the edge, and have a flat ſtrait end turned downwards, and armed with three teeth, but not divided into any ſegments.

LIGURINUS, in zoology, a name uſed by many authors for the bird more commonly known by the name of *ſpinus*, and called in England the *ſiſkin*. See SPINUS.

LIGURIUS, in Jewiſh antiquity, a precious ſtone on the high prieſt's breaſt plate. It is called *leſchem* in Hebrew. Theophraſtus and Pliny deſcribe the *ligurius* to be a ſtone like a carbuncle, of a brightneſs ſparkling like fire. Epiphanius and Jerom took it for a kind of hyacinth. Some have aſſerted that it is the ſame as *lyncurius*, or the lynx-ſtone, formed, as is ſaid, of the lynx's urine [a], which is congealed into a ſhining ſtone, as ſoon as it comes out of this creature's body. But this is fabulous, as Pliny himſelf obſerves who relates it. The *ligurius* was the firſt ſtone in the third row upon the high prieſt's pectoral, and the name of God was inſcribed upon it [b]. [—[a] *Ælian* de Animal. l. 4. c. 17. *Plin.* l. 8. c. 38. & l. 37. c. 3. [b] *Calm.* Dict. Bibl.—] See LYNCURIUS *lapis*.

LIGUSTICUM, or LEVISTICUM, *lovage*, in botany, the name of a genus of umbelliferous plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular order round a cup, which finally becomes a fruit compoſed of two oblong ſeeds, gibboſe and ſtriated on one ſide with foliaceous rims, and ſmooth and flat on the other.

The ſpecies of *liguſticum* enumerated by Mr. Tournefort are theſe. 1. The *liguſticum*, which is commonly called the *ſeſeli* of the ſhops. 2. The narrow leaved *liguſticum* or *ſeſeli*. 3. The pyrenean *liguſticum* with very large and thin leaves. 4. The ſmooth hemlock leaved *liguſticum*. 5. The alpine *liguſticum* with long multifid leaves. 6. The Scotch *liguſticum* with apium leaves. 7. The *liguſticum* with leaves like fennel giant. 8. The ſhining pyrenean *liguſticum* with fennel leaves. *Tourn.* Inſt. p. 323.

The root of this plant is eſteemed a powerful alexipharmic and ſudorific; it is recommended in malignant fevers, in palſies and apoplexies, and in all diſorders of the head. The ſeeds are warm and carminative, and are given with ſucceſs in colics, and againſt indigeſtions and flatuſes.

LIGUSTICUM *marmor*, in natural hiſtory, a name by which ſome authors have called the *carrara marble*, the *marmor lunenſe* of the antients. It is a fine white marble, harder than the parian or ſtatuary kind, and uſed for tables, chimneys, &c. as the other for carving. *Aldrovand.* Muſ. Met. 748. See LUNENSE *marmor*.

LIGUSTRUM, *privet*, in botany, the name of a genus of trees, the characters of which are theſe. The flower conſiſts of one leaf, and is of a funnel like ſhape; the piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower: this, finally, becomes a round ſucculent fruit, or berry, and contains uſually four ſeeds, gibboſe on one ſide and flat on the other. *Tourn.* Inſt. p. 596.

The ſpecies of *privet* enumerated by Mr. Tournefort are theſe. 1. The common *privet*. 2. The *privet* with leaves variegated with yellow; and 3. The American bay leaved *privet*, with yellow flowers and white berries.

In the Linnæan ſyſtem of botany, the characters of this genus are, that the plants of it have a ſmall tubular perianthium compoſed of one leaf, with its extremity erect, and divided by four notches; the flower conſiſts of a ſingle petal, which is tubular, and of the ſame length with the perianthium, its extremities expanded, divided into four ſegments of a ſomewhat oval figure; the ſtamina are two ſimple filaments placed oppoſite to one another, and terminated by erect antheræ, of the length of the flower. The piſtillum is compoſed of a roundiſh germ, a ſingle and very ſhort ſtyle, and a thick bifid and obtuſe ſtigma. The fruit is a ſmooth round berry, containing only one cell. The ſeeds are four in number in each berry, and are convex on one ſide, and angular on the other. *Linnæi* Gen. Plant. p. 2. See PRIVET.

LILAC, in botany, the name of a genus of trees, the characters of which are theſe. The flower conſiſts of one leaf, and is of the funnel ſhaped kind, and uſually divided into four ſegments at the edge. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower: this, finally, becomes a compreſſed or flatted fruit of the ſhape of a tongue, which opens into two parts, and is divided by an intermediate ſeptum into two cells, containing flat and marginated ſeeds. *Tourn.* Inſt. p. 607.

The ſpecies of *lilac* enumerated by Mr. Tournefort are theſe. 1. The common blue flowered *lilac*, called by many the *blue ſyringa*, or pipe tree. 2. The *lilac* with ſilvery white flowers. 3. The *lilac* with deep purple flowers. 4. The privet leaved *lilac*, commonly called the *Perſian jaſmine*; and 5. The *lilac* with jagged leaves.

Theſe are frequently cultivated in gardens; and ſome growing, with good management, to eighteen or twenty feet high, are with their large tufts of flowers very ornamental.

The common way of propagating theſe ſhrubs is by ſuckers, which they always produce in very great abundance; theſe ſhould be taken off from the old plants in October, and carefully planted in a nurſery, where after they have ſtood about three years, they will be fit to plant where they are to remain, after which they require no farther care than the digging about their roots once a year, and taking away their ſuckers, which are not only very unſightly but ſtarve the plant. *Miller*'s Gardners Dict.

They will grow almoſt any where, but they are obſerved to flower beſt in a dry ſoil, as indeed do moſt other ſhrubs, though they grow faſteſt in a wet one.

LILI, the name of one of the favourite remedies of Paracelſus, the baſis of which is antimony, but he has not given us the proceſs to prepare it.

LILIAGO, in botany, a name uſed by Cordus and ſome other authors for the phalangium or ſpiderwort. *Ger.* Emac. Ind. 2.

LILIACEOUS, in botany, a term uſed to expreſs the flowers of ſome plants, which approach to thoſe of the lilly in ſhape. The characters of a *liliaceous* flower are theſe; it is compoſed of ſix leaves, or elſe of three leaves divided into ſix, but this is more rarely the caſe; the piſtil, or cup of this flower always becomes finally a ſeed veſſel divided into three cells.

Of this ſort are the flowers of the tulip, hyacinth, aſphodel, ephemerum, and the like; many of which, though they leſs reſemble the lilly flowers than the others, yet are to be diſtinguiſhed by this title, becauſe they leave behind them the *liliaceous* ſeed veſſel, which is long, and divided into three cells. *Tourn.* Inſt. p. 343.

LILIASTRUM, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the liliaceous kind, and is compoſed of ſix petals, and of the ſhape of the lilly flower. The piſtil ariſes from the center of the flower, and finally becomes an oblong fruit, divided into three cells, and containing angular ſeeds. To this, it is to be added, that the root is compoſed of ſeveral long fleſhy bodies hanging from one common head.

The ſpecies of *liliaſtrum* enumerated by Mr. Tournefort are theſe. 1. The greater alpine *liliaſtrum*; and 2. The leſſer alpine *liliaſtrum*, called the *phalangium allobrogicum*, and large flowered *phalangium*. *Tourn.* Inſt. p. 369.

LILIO-ASPHODELUS, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the liliaceous kind, but conſiſts only of one leaf, and is tubular at the bottom, and divided into ſix large ſegments toward the top. The piſtil ariſes from the bottom of the flower, and becomes at length a ſeed veſſel of a ſomewhat oval ſhape, but three cornered; this is divided into three cells, each of which contains a number of roundiſh ſeeds: to this, it may be added, that the root is large and fleſhy. See Tab. 1. of Botany, Claſs 9.

The ſpecies of *lilio-aſphodelus* enumerated by Mr. Tournefort are theſe. 1. The common yellow flowered *lilly-aſphodel*. 2. The ſmaller white flowered *lilly-aſphodel*. 3. The crimſon flowered *lilly-aſphodel*. 4. The ſmaller red *lilly-aſphodel*. 5. The American *lilly-aſphodel*, with white umbellated flowers, each having purple ribs. 6. The aloe leaved American *lilly-aſphodel*, with very large ſweet ſcented flowers diſpoſed in umbells. 7. The American *lilly-aſphodel*, with leaves like the ſquill, and large purple flowers in umbells. 8. The bifoliate American *lilly-aſphodel* with a ſingle purple flower. *Tourn.* Inſt. p. 344.

LILIO-HYACINTHUS, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the liliaceous kind, being compoſed of ſix petals, and reſembling in ſhape the hyacinth flowers. The piſtil finally becomes a fruit of a globoſe, but pointed form, and uſually

ſome-

ſomewhat three cornered, and divided into three cells, which contain roundiſh ſeeds. To this, it is to be added, that the root is of a bulbous ſhape, and made up of fleſhy ſcales in the manner of that of the lilly. *Tourn.* Inſt. p. 371. The ſpecies of *lilio-hyacinthus* enumerated by Mr. Tournefort are theſe. 1. The common blue flowered *lilly-hyacinth*, commonly called the lilly leaved ſtarry hyacinth. 2. The white flowered *lilly-hyacinth*; and 3. The *lilly-hyacinth* with reddiſh flowers. *Tourn.* Inſt. p. 371.

LILIO-NARCISSUS, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the liliaceous kind, and is compoſed of ſix leaves, diſpoſed in the form of thoſe of the common lilly. The cup, or embryo, afterwards becomes a fruit, in all reſpects, like that of the *narciſſus*. To this, it is to be added, that the root is bulbous and truncated in the common way; in which it differs from the lilly, as it does from the *narciſſus*, in the having a ſix leaved flower.

The ſpecies of *lilio-narciſſus* enumerated by Mr. Tournefort are theſe. 1. The broad leaved red flowered Indian *lilio-narciſſus*. 2. The deep purple flowered Indian *lilio-narciſſus*. 3. The largeſt ſpherical Indian *lilio-narciſſus*, with a number of red liliaceous flowers. 4. The Indian *lilio-narciſſus* with white flowers, red on the outſide. 5. The red flowered *lilio-narciſſus* of Japan. 6. The dwarf many flowered Indian *lilio-narciſſus*. 7. The dwarf African many flowered *lilio-narciſſus*. 8. The many flowered *lilio-narciſſus*, as with fleſh coloured flowers, with pale yellow bottoms. 9. The broad leaved *lilio-narciſſus* of Ceylon, with ſnow white flowers, with a purple ſtreak at the back of every petal. 10. The broadeſt leaved *lilio-narciſſus* with more white ſcentleſs flowers. 11. The lilly of the valley leaved American *lilio-narciſſus*, with flowers yellow on the inſide and ſcarlet on the out. 12. The Carolina *lilio-narciſſus*, with a ſingle pale whitiſh red flower. 13. The dwarf white ſingle flowered Indian *lilio-narciſſus*. 14. The Indian *lilio-narciſſus*, with gold yellow flowers ſtreaked with a ſilvery white, with two large bending leaves, and a hollow ſtalk like that of the onion. 15. The yellow ſpring *lilio-narciſſus*. 16. The great yellow autumnal *lilio-narciſſus*. 17. The yellow double autumnal *lilio-narciſſus*. 18. The leſſer yellow autumnal *lilio-narciſſus*. 19. The autumnal *lilio-narciſſus* with a duſky yellow flower. 20. The ſmall yellow ſweet ſcented *lilio-narciſſus*. *Tourn.* Inſt. p. 388.

LILIUM, the *lilly*, in botany, the name of a large genus of plants, the characters of which are theſe. The flower is of a ſort of bell faſhioned ſhape, but is compoſed of ſix leaves, which are more or leſs expanded and bent back. The piſtil ſtands in the center of the flower, and finally becomes an oblong and trigonal fruit, which is divided into three cells, and contains a number of marginated ſeeds, arranged in a double order one on another. To this, it is to be added, that the root is of a bulbous form, and is compoſed of a number of fleſhy ſcales affixed to an axis.

The ſpecies of *lilly* enumerated by Mr. Tournefort are theſe. 1. The common white *lilly*. 2. The double white *lilly* with ſcentleſs flowers. 3. The white *lilly* with depending flowers. 4. The large purpliſh yellow *lilly*. 5. The great white *lilly*. 6. The double flowered purpliſh yellow *lilly*. 7. The common white *lilly* with yellow edges to the leaves. 8. The *lilly* with leaves variegated with yellow ſpots. 9. The *lilly* with the flower variegated with purple lines. 10. The white Syrian *lilly*. 11. The leſſer purpliſh yellow *lilly*. 12. The ſmall double flowered purple *lilly*. 13. The pale purple flowered *lilly*. 14. The many flowered bloody *lilly*. 15. The great broad leaved bulbiferous bloody *lilly*. 16. The narrow leaved bulbiferous bloody *lilly*. 17. The ſmall creeping bulbiferous bloody *lilly*. 18. The hairy bulbiferous *lily*. 19. The mountain *lilly* with red reflex flowers. 20. The double red mountain *lilly* with reflex flowers. 21. The mountain *lilly* with white reflex flowers. 22. The mountain *lilly* with reflex flowers, of a pale purple, ſpotted with a deeper red. 23. The mountain *lilly* with reflex freſh coloured flowers. 24. The mountain *lilly* with reflex flowers, and a longer ſpike. 25. The hairy *lilly* with reflex flowers. 26. The *lilly* with plain purple flowers. 27. The *lilly* with duſky browniſh reflex flowers. 28. The *lilly* with reflex variegated flowers. 29. The *lilly* with white reflex flowers not ſpotted. 30. The *lilly* with double white reflex flowers not ſpotted. 31. The *lilly* with reflex white ſpotted flowers. 32. The ſcarlet Conſtantinople *lilly*. 33. The Conſtantinople *lilly* with plain white flowers. 34. The Conſtantinople *lilly* with yellow flowers. 35. The Conſtantinople *lilly* with pale red flowers. 36. The many flowered Conſtantinople *lilly* with deep red flowers. 37. The late flowering Conſtantinople *lilly*. 38. The double flowered Conſtantinople *lilly*. 39. The purpliſh bloody *lilly* with reflex flowers. 40. The pyramidal muſk *lilly*. 41. The narrow leaved red *lilly*. 42. The red flowered *lilly* with ſhort graſſy leaves. 43. The narrow leaved ſweet ſcented red *lilly*. 44. The narrow leaved yellow *lilly*. 45. The narrow leaved *lilly* with pale whitiſh yellow flowers. 46. The yellow flowered *lilly* with black ſpots in the flowers. *Tourn.* Inſt. p. 369, 370. See LILLY.

LILIUM *convallium*. *Lilly of the valley*, in botany, the name of a genus of plants; the characters of which are, that the flower is compoſed of only one leaf, formed into the ſhape of a bell, ſhort, divided into ſeveral ſegments at the edge, and incloſed in no cup; from the bottom of this flower there riſes a piſtil, which ripens into a ſoft and uſually globular fruit, full of ſeeds, laid cloſely together.

The ſpecies of *lilly of the valley* are theſe. 1. The common white kind. 2. One which has its flowers produced from little follicles. 3. The ſingle flowered kind. 4. The narrow leaved kind. 5. The great broad leaved kind. 6. The double flowered variegated broad leaved one; and 7. The red flowered one.

The plant commonly called *one blade*, and by Caſpar Bauhine *lilium convallium minus*, is uſually eſteemed a ſpecies of this genus, but improperly; it being one of the ſmilaxes. *Tourn.* Inſt. p. 77. See SMILAX.

The name *lilly* is very improperly given to this genus of plants, as they have not the leaſt affinity to the *lilly*.

The flowers of *lilly of the valley* are cephalic and nervine, and preſcribed for vertigoes, apoplexies, palſies, *&c.*

LILIUM *lapideum*, a name given by the writers, in natural hiſtory, to a foſſile body found in ſome parts of Germany; which plainly ſhews, that it was once a ſpecies of ſtar fiſh; though the animal be not, at this time, known in its recent ſtate. Klein, who has well conſidered this body, in compliance to the vulgarly received names of things, call this the *entrochus ramoſus*, or *branched entrochus*; and the reſemblance ſome of its parts have to the common entrochi, ſhews plainly that their origin has been the ſame, and that they are fragments either of this ſpecies or of the magellanic ſtar fiſh. The recent fiſh not being found from which the *lilium lapideum* is formed is no peculiar fate, but is common to it, and to the *cornua ammonis*, and many other animal remains.

LILLO, in ichthyology, a name given by the Rhodians to the *labrus*. See LABRUS.

LILLY, *lilium*, in botany. See the article LILIUM.

All the ſorts of *lillies* and martagons are propagated by ſowing their ſeeds; and if the ſeeds are carefully ſaved from good flowers, the martagons very frequently afford very beautiful varieties.

The manner of ſowing them is this: ſome ſquare boxes ſhould be provided of about ſix inches deep, with holes bored in the bottoms to let out the wet; theſe muſt be filled with freſh light ſandy earth, and the ſeeds muſt be ſown on them pretty thick in the beginning of Auguſt; ſoon after they are ripe, and covered over about half an inch deep with light ſifted earth of the ſame kind. They ſhould be then placed where they may have the morning ſun; and, if the weather prove dry, they muſt be watered at times, and the weeds carefully picked out. In the month of October, the boxes are to be removed to a place where they may have as much ſun as poſſible, and be ſecured from the north and north eaſt winds. In ſpring the young plants will appear, and the boxes are then to be removed into their former ſituation; they ſhould be watered at times during the ſummer; and in Auguſt the ſmalleſt roots are to be emptied out of theſe boxes, and ſtrewed over a bed of light earth, and covered with about half an inch depth of light earth ſifted over them; they muſt here be watered and ſhaded at times, and defended from the ſeverity of the winter, by a light covering of ſtraw, or peas haulm, in the hardeſt weather. In February the ſurface of the bed ſhould be cleared, and a little light earth ſifted over it. When the leaves are decayed, the earth ſhould be a little ſtirred over the roots, and in the month of September following a little more light earth ſifted on. In the September, of the following year, the roots muſt be tranſplanted to the places where they are to remain, and ſet at eight inches diſtance, the roots being placed four inches below the ſurface: this ſhould be done in moiſt weather. They will now require the ſame care as in the preceding winters; and the ſecond after they are tranſplanted, the ſtrongeſt roots will begin to flower. The fine ones ſhould then be removed at the proper ſeaſon into flower beds, and planted at great diſtances from one another, that they may flower ſtrong.

The roots of the *white lilly* are emollient, maturating, and greatly ſuppurative. They are uſed externally in cataplaſms for theſe purpoſes with ſucceſs. The common form of applying them is boiled and bruiſed; but ſome prefer the roaſting them till tender, and then beating them to a paſte with oil, in which form they are ſaid to be excellent againſt burns. Gerard recommends them internally in dropſies.

Water LILLY. See NYMPHÆA.

LIMANDA, in zoology, a name by which ſome authors have called the flat fiſh, which we in Engliſh call the *dab*, the *paſſer aſper* of authors. *Geſner* de Piſc. p. 781.

LIMANDE, in ichthyology, a name given by the French to the *paſſer aſper*, a rough plaice, called in Engliſh a *dab*. This French name is evidently arrived from the Latin *limanda*, uſed by Geſner and Bellonius as the name of this fiſh.

LIMARIA, in ichthyology, a name given by Gaza and ſome other writers to the thynnus or tunny fiſh, called the Spaniſh mackrel. See the article THYNNUS.

LIMAX *marinus*, in zoology, a name given by ſome to the *lipparis*, or as it is commonly termed in Engliſh the ſea ſnail, caught in plenty at the mouths of rivers in Yorkſhire and ſome other places. *Ray*'s Ichthyogr. Append. p. 17.

LIMB (*Cycl.*)—*Motions of the* LIMBS. It cannot but have been obſerved, by every one, that it is much more natural and eaſy to make certain motions with both hands, or both feet at once, in the two contrary or oppoſite directions, than in the ſame direction. We may trace in the air, for inſtance, two ſpiral lines with our two hands, with much more eaſe, in the contrary directions, than if we attempt to do them the ſame way; and it will be eaſy to find that the caſe is exactly the ſame with the feet, if we attempt to do the ſame thing with them when ſitting; and the very ſame difficulty on one hand and facility on the other will be found, if we attempt the ſame motion with one hand only, and with the oppoſite foot at the ſame time: yet it is extremely difficult, and almoſt impoſſible, to make theſe motions in a contrary direction, at the ſame time with the arm and leg of the ſame ſide.

We muſt therefore alſo reſolve into this principle, the power which we have by a ſort of natural mechaniſm, and that without any acquired habitude, of eaſily making with one hand, or even with both hands at once, exactly the counter action to that motion, which the other hand naturally and moſt eaſily is found to make, and the contrary of which it cannot itſelf make without difficulty, and repeated trials and cuſtom. It is owing to this, that we can with the left hand eaſily make the very contrary ſtrokes with the pen, that we are accuſtomed to make with the right; if we ſuffer that left hand to move, without giving our particular attention to what it is doing, as in the playing on ſome inſtruments of muſic, the fingers being after practice left as it were to themſelves, ſucceed more happily than when the attention is more engaged in what they are doing. The letters or figures thus made by counter ſtrokes from the unforced action of the left hand, though they appear ſtrange and confuſed at firſt ſight, yet if held up againſt a looking-glaſs, they will be found ſufficiently determinate and expreſs.

In the ſame manner that the counter actions to thoſe, which ſeem in ſome degree natural to our peculiar *limbs*, are with difficulty performed, there are a great many motions, which we continually do by the mere natural diſpoſition of our *limbs* freely, without art and without exerciſe; nay, even without cuſtom, either of which, with either hand or foot is equally eaſy, and yet we are not without great difficulty able to do both, when in contrary directions one to another. Of this nature is the attempt to make two different motions with the hands, in right lines, the one of which ſhall be perpendicular to the other; the moving one hand, or one foot, perpendicularly up or perpendicularly down, at the ſame inſtant that the other hand or foot is moving, directly from right to left, or from left to right, is, according to this principle, very difficult; eſpecially to make them both perfectly, regularly, and tolerably quick, as is eaſily found by any one, in attempting to rub the body upwards and downwards with one hand, and tranſverſly, or from ſide to ſide with the other; and much more plainly, if it be attempted to make theſe contrary motions in the air, without touching any body, or touching only very lightly, and performing the motion quickly. This is no where more obvious than in thoſe, who are learning to play upon the trumpet marine, a ſtring inſtrument, with a remarkably long neck, where the running up and down the hand to make the notes is found extremely aukward, while the other is employed in an exactly contrary motion ſideways, in directing the bow.

This difficulty of making motions, at the ſame time, contrary to one another with two *limbs*, either of which motions ſingly would be no difficulty to either, is not peculiar to the arms; if we ſit down and try the experiment with the feet the ſucceſs is found the ſame, and even the moving differently the like fingers or toes of the different hands or feet, is found of proportionate difficulty. Nor is the difficulty of theſe motions peculiar to the perpendicular or tranſverſe ones; the making circles, or ſpiral or ſerpentine lines, with the two hands, or two feet, at the ſame time, in the ſame contrary directions, being equally difficult: yet it is equally true, that though it is ſo extremely difficult, and almoſt impoſſible, to make theſe motions in contrary directions at the ſame time, yet they are all motions, which we ſeparately make, with great facility, and with great quickneſs. We, in the ſame manner, are not able, by any means, to direct our two eyes to two different objects, placed in contrary ſituations at the ſame time; but in this the difficulty, though great in the ſtructure of our eyes, is not univerſal to all creatures. The chamæleon being able to do this, and to look before and behind, or in any other ever ſo different directions, both at the ſame time. Mr. Winſlow was led by a great number of obſervations of this kind, diligently to examine the diſpoſitions of the nerves, and their different origins in the brain, the cerebellum, the medulla oblongata, and the ſpinal marrow. The firſt thing on which this accurate anatomiſt made his obſervation, was the crucial interlacement of the nerves in the medulla oblongata, firſt diſcovered by Mr. Petit, and accurately deſcribed and figured by him; and the obſervations of the ſame author, of different perſons, who, within his own knowledge, had become paralytic in the *limbs* on the contrary ſide of their body to the affected part of the brain alſo. The being able determinately to bring on the like ſymptoms in brutes, from injuries to the contrary ſides of the brain, and the regular croſſing of the filaments which paſs tranſverſely on the medullary arch, commonly called the callous body of the brain, and of other of the nervous fibres, ſeemed to promiſe to give ſome light into the explication of the difficulty of theſe contrary motions being performed at the ſame time. When this accurate obſerver had ſufficiently informed himſelf of theſe croſſings of the nerves, and the other reciprocal communications of the ſeveral parts of the brain, or its two lateral halves, as well by the two large tranſverſe cords, as by the thick tranſverſe fibres of the ſmall inferior, and triangular ſurface of the arch; he beſtowed his particular obſervation on the ſtructure of the ſpinal marrow. This he carefully examined by the microſcope, and beſide the tranſverſe fibres, which make the communication between the two columns of this marrow, and which Mr. Petit had before nicely deſcribed, there appeared to Mr. Winſlow, in the thickneſs of each of theſe columns, a long train very diſtinct, and made up of a leſs white and more cloudy matter than the reſt; or a medullary cord, which had not been before obſerved by any body, any more than the ſmall cords and tranſverſe fibres of the ſummit of the arch of the brain, or the croſſing of its tranſverſe fibres.

By theſe ſeveral croſſings, and reciprocal communications of the medullary filaments, which are, as it were, the roots of the nerves of each half, or each ſeveral ſide of the human body; it ſeems not impoſſible to explain the reaſon of the before obſerved difficulty of making the contrary motions with the two oppoſite *limbs* at the ſame time; eſpecially when it is obſerved, that the two ſmall parcels of medullary filaments, which compoſe the primitive trunks of every pair of nerves that are propagated from the ſpinal marrow, have their paſſage through the lateral apertures of the vertebræ, and before that ſeem to proceed partly from the neighbouring column or moiety of the ſpinal marrow, and partly from the other column or moiety, by means of the croſſing beforementioned; and conſequently, that by this reciprocal croſſing, or interlacing, one of the primitive parcels or bundles of filaments of each primitive trunk of the nerves of one ſide of the body, muſt communicate with the fellow parcel or bundle of filaments of the nerves of the other ſide.

Every body almoſt knows that the motion of the muſcles, and ſenſation by the touch, are performed by means of the nerves and their filaments; but no one has ever yet diſcovered the true means: this however is certain, that when we would put in motion, at one time, the two legs, or the two arms, or the fingers or toes of each hand or foot; at that time the croſſed filaments of the primitive trunks of the nerves, which go to their correſpondent muſcles on each ſide, immediately come mutually into contact, and conſent with one another; and their ſo meeting, in the time of their motion, communicates certain impreſſions reciprocally to the ſeveral nerves, which from them are propagated to the two different ſides of the body, and continue them to act in concert on the ſeveral muſcles of both the arms or legs at the ſame time, and communicate to both that principle of motion, which we meant to give alone to one. Mem. Acad. Scien. Par. 1739.

LIMB *of a flower*, among botaniſts. See PETAL.

LIMBERS, in artillery, a ſort of advanced train joined to the carriage of a cannon, upon a march. It is compoſed of two ſhafts wide enough to receive a horſe betwixt them, which is called the *fillet horſe*; theſe ſhafts are joined by two bars of wood, and a bolt of iron at one end, and have a pair of ſmall wheels; upon the axle-tree riſes a ſtrong iron ſpike, upon which the train of the carriage is put. But when a gun is upon action, the *limbers* are run out behind her.

LIMBER *holes*, in a ſhip, little holes cut through her floor timbers, ſerving to let the water to the well of the pump, which otherwiſe would lie between thoſe timbers, where the keel rope runs.

LIME (*Cycl.*)—*Lime* affords a great variety of figures in its ſalts. The moſt perfect concretions among them ſeem to be double pointed figures, thick toward one end and growing thin toward the other; ſome are flat, and of a quadrilateral figure, and others flat and very thin but hexangular; ſome are of the ſhape of a wedge, being cut off taper near one end, and blunt at the other. *Soda*, or pot-aſh, made of the plant *kali*, is very elegant and various in its ſhoots. Some are beautiful priſms, with the angles cut off near each end; others are oblong, and leſs regularly formed, ſome ſquare and very thin; others oblong, with a tendency to a rhomboidal ſhape, and ſome roundiſh. Theſe are a few, out

of a great number of experiments, made by the accurate Lewenhoek, and ſince repeated by other obſervers. The reſt with the figures of theſe ſhoots are publiſhed at large in the Philoſophical Tranſactions.

Lime makes the greateſt improvement upon light ſandy lands, or upon a dry gravel: but a cold clay ſeldom is much benefited by it. If it be mixed with dung, or with mud, drawn from the bottom of the rivers, it makes an excellent mixture, eſpecially where the ſoil is very ſandy; and in Weſtmoreland they procure fine crops of barley from their ſandy lands, by manuring them with *lime* and cow-dung mixed together. The nature of *lime* on land is like that of chalk, it works downwards, as the farmers expreſs it; it is therefore beſt to treat it in the ſame manner, laying it upon a lay the year before it is to be plowed up. *Lime* is reckoned to make corn grow with a thin huſk; but it is not a laſting manure, ſeldom holding for more than five crops. When *lime* is uſed to land, which lies upon a deſcent, it ſhould be mixed with dung, and laid principally on the higher part of the land; the conſequence of which, will be, that the rain will waſh out the virtue of the *lime* and dung together, and carry the whole to the lower parts as it runs down. Dung and *lime* mixed together will do better for any land, than either of them alone.

Lime is made of chalk, or of any ſtone, that is not too cold, or ſandy, as free ſtone, and the like. All the ſoft ſtones that are of a tolerably cloſe texture, will burn to good *lime*, as will alſo marble, ſlate, ſea ſhells, corals, and flints; but this laſt kind of ſtone is more difficult to be burnt to *lime* than the others, except in a reverberatory kiln, for they are apt to run to glaſs. The harder the ſtones of which *lime* is made are, the better the *lime* is; and when it is made of chalk, that is much better, which is made of the hard ſtony kind, than that which is made from the ſoft; but the harder the ſtones are, the more fire is required to burn them: both ſorts may be burnt with wood, coals, turff, or fern, which makes a very fierce fire. The kilns uſed for chalk, or ſtone, they commonly make in a large pit, which is dug either round or ſquare, according as they have convenience; and is of ſuch a ſize, as will be proper for the quantities they intend to burn. They are wideſt at the top, and narrower, by degrees, as they come nearer the bottom. The inſide of this pit is lined with a wall built of *lime*-ſtone; at the outſide, near the bottom, they have a hole, or door, by which they take out the aſhes, and above that ſome have an iron grate, which comes cloſe to the wall all about it; but others arch it over with ſtone, or large pieces of chalk; and upon this they lay a layer of ſtone, or of whatever elſe they burn in the pit; upon this they place a layer of wood, or coals, and ſo on, layer over layer, to the top of the pit; only they obſerve, that the outermoſt layer be always of the fuel, not of the ſtone. When the kiln is thus filled they give fire at the hole underneath, and the *lime* is finiſhed in a different time, according to the nature of the ſubſtance. That made of chalk, is commonly burnt into *lime* in twenty-four hours; but *lime*-ſtone generally takes ſixty hours in burning. Ten buſhels of ſea coal, or one hundred of faggots, three feet long, will burn forty buſhels of chalk, and this will yield thirty buſhels of unſlaked *lime*. Where chalk is ſcarce, they work up the chalk rubbiſh into a ſort of ſtiff paſte with water, and make it into a ſort of bricks, which they dry in the air, and then burn them into *lime* in the common way; but this is not quite ſo good as the other. Hot *lime* taken out of the kiln, and mixed into a very ſoft paſte with water, and then mixed with ſand, makes a kind of mortar, very much ſuperior to the common ſort. *Mortimer*'s Huſbandry.

All *lime* is a very good manure, but that made of ſtone is much better than what is made of chalk. The common allowance is a buſhel to a pole ſquare, or a hundred and ſixty buſhels to an acre.

This they cover with earth, and ſo leave it till the rains fall and ſlake it, and after that they ſpread it as evenly as poſſible upon the ground. They always find that if it be carried hot out of the kiln, and laid upon the land to cool, it does much better than in any other way.

The improvement it makes upon land is owing chiefly to its heat, and the ſalt it contains. It is in much the ſame manner that coal aſhes, and the ſoot of coal become uſeful upon the like ſort of lands; but the farmers always find that a mixture of good earth and *lime*, that has lain a conſiderable time together, is better for this purpoſe than freſh *lime* alone. *Moreton*'s Northampt. p. 481.

In the late diſtemper among the horned cattle, ſome were buried with *lime*, two buſhels to each cow. The effect ſeemed to be a ſtrong ſcent ariſing through the ground, though the carcaſs was ten feet under ground. It was difficult to keep the dogs from ſcratching, and endeavouring to tear up the ground to get at the fleſh. Whereas, when the carcaſſes were buried without *lime*, though but eight feet under ground, the dogs never attempted any ſuch thing. Hence it was thought beſt to bury without *lime*, as it is probable it might ſend up and ſpread malignant particles through the air. That *lime* renders animal ſalts more volatile and pungent, appears in the proceſs of ſpirit of ſal ammoniac with quick *lime*. See Phil. Tranſ. N° 480. p. 224, 225.

Bird-LIME. See BIRD-*lime*.

LIME *galls*, in natural hiſtory, a ſort of *galls* or vegetable protuberances, formed on the edges of the leaves of the *lime* tree in ſpring time; they are very common in the plantations of *limes*, and are irregularly ſhaped, but uſually oblong and rugged, and of a reddiſh colour, they occupy only the edges of the leaves, and are of a red colour, ſometimes very beautiful. As theſe are very plentiful, Mr. Reaumur was of opinion, that they might be of ſervice in the dying trade; he made trial by rubbing them on ſome parts of his linnen, and found that they gave a very beautiful red colour, which did not come out in the firſt waſhings afterwards. It is extremely probable, that there wants only inquiry to prove that we have many valuable productions of this kind, which, though diſregarded at preſent, might prove of great uſe in the ſeveral mechanical arts as well as in medicine.

Theſe *galls* of the *lime* leaves are formed by a worm, which inhabits them during its term of life, being found in them of all ſizes, from the moſt minute to that of the full growth, which is about half an inch in length; but when its period of life, as a worm, draws near, it deſerts this habitation, and goes elſewhere to paſs into its chryſalis ſtate. This alſo is the caſe with the worms that inhabit many *galls*, which are frequently found to contain them in the worm ſtate, but never in that of the chryſalis, which they always paſs into elſewhere. *Reaumur*'s Hiſt. Inſ. Vol. 6. p. 188.

Beſide theſe *galls* of the leaves of the *lime* tree, they have ſometimes another appearance not leſs ſingular, and this is alſo owing to an inſect; though many curious obſervers have miſſed the finding it there. In this ſtate the whole leaf of the *lime* tree reſembles a common ſpoon, being ſunk into a hollow in the middle, and in its pedicle making the handle. The edge of the leaf in this caſe is always tumid, and forms a rib or ridge, running round the whole circumference in the ſhape of a cord: this is uſually found during the time that the leaf is growing to its ſize, and to this is owing the whole figure it aſſumes afterward; for the leaf being unable to extend itſelf farther toward the circumference by reaſon of this ring, naturally forms a ſort of hollow or baſin in its ſucceeding growth. The protuberance, in this caſe, ſurrounding the leaf is a kind of *gall*, and owes its origin in the manner of all the other excreſcences of that kind to an inſect. This, however, has been ſought for in vain by many, who enquired after it too late; but Mr. Reaumur ſearching the leaves in the beginning of May, found in every protuberance of this kind, ſeveral ſmall worms of a white colour, and conſiderable length, though not exceeding a horſe hair in thickneſs. The reaſon that theſe are not found in the ſame place afterwards, probably, is, that they either go out of it, as the inhabitants of many other *galls* do, in order to paſs into their chryſalis ſtate, or elſe that this life in the worm ſtate, and the duration of that in the chryſalis, are both very ſhort, and that they are generally eſcaped in the form of flies before the time that they are ſought for in the leaves. See Tab. of Inſects, N° 27. and *Reaumur*'s Hiſt. Inſ. Vol. 6. p. 189.

LIME *phoſphorus*, a kind of phoſphorus, invented by Mr. Homberg, and made of ſal armoniac and *lime*. The method of making it is this: Take of ſal armoniac one part, of *lime* ſlaked in the air two parts, mix theſe well together, and fill a ſmall crucible with them; ſet this in a ſmall fire of fuſion, and as ſoon as the crucible is red hot, the mixture will melt, and ſhould be ſtirred with an iron rod to prevent its running over. When the matter is entirely fuſed, pour it into a braſs mortar, and when cold it will appear of a grey colour, and as if vitrified; if now it be ſtruck upon with any hard body, it appears as on fire in the whole extent of the ſtroke; but the matter being brittle, it is proper for the experiment's ſake, to dip little bars of iron or copper into the melted matter in the crucible; for thus they will be enamelled as it were with the matter, and theſe bars being ſtruck upon will give the ſame fire, and the experiment may be ſeveral times repeated before all the matter falls off. Theſe bars muſt be kept in a dry place. *Shaw*'s Lectures, p. 406.

LIME *tree*. The ſeveral ſpecies of the *tilia*, or *lime tree*, are all eaſily propagated by layers, which in one year will take good root, and ſhould then be removed to the nurſery, planting them at four feet diſtance in rows, and the plants two feet aſunder in each row. The beſt ſeaſon for removing them is Michaelmas. They ſhould remain four or five years in the nurſery, and ſhould afterwards be removed to the places where they are to remain. The ſoil they love beſt is a ſtrong fat loam, in which they will grow very faſt. *Miller*'s Gardners Dict. See TILIA.

LIME *water*. The general opinion of *lime* acting as a cauſtic, and conſuming the bodies it was made to act upon, by means of the great quantity of particles of fire it contained, long denied any preparation of it a place among internal medicines; at length, water poured upon it was found to take in a part of its virtues, and to be a valuable medicine, and very ſafely to be given internally in large quantities.

All *lime* is not equally good for the making this water, but the ſeveral kinds differ according to the ſubſtances they are made from. In Holland they at this time make *lime* of ſea

ſhells, which they find in vaſt abundance on their ſea ſhores. This was alſo a practice in the time of Dioſcorides; but the *lime* thus made is not fit for making *lime water*. The water made from it does not keep long, and is leſs ſtyptic, and ſweetiſh to the taſte, and is greatly inferior to the water made with *lime* burnt from ſtones. The newer the *lime* is, the leſs it has been expoſed to the air, and the drier it has been kept, and finally, the more it has held together without crumbling, or mouldering to powder, the better it is for the making *lime water*. Hot water has alſo been found to make it better than cold, and rain water much better than any other kind. The ſame *lime* will ſerve twice to make the medicinal water; but if it be tried a third time, the water will be found to be quite inſipid: if after twice uſing it be calcined again, the fire will give it the ſame qualities, and it will again make the *lime water* as ſtrong as the firſt. It has this inconvenience, however made, that it will not mix with any other liquor. It ferments with all kinds of ſyrups, and will not bear the leaſt mixture of any thing in the leaſt acid without becoming turbid, and depoſiting a ſediment. Mem. Acad. Par. 1700.

Experience has ſhewn *lime water* to be an excellent medicine in many caſes. In the gravel and ſtone, particularly. And it has alſo been found very ſerviceable in the gout, in habitual relaxations of the bowels, and in other caſes of relaxation. In ſome kinds of the ſcurvy likewiſe it is of uſe; and is often applied, with ſucceſs, externally, to ulcers, *&c.*

Fabricius ab Aquapendente aſſures us, he cured a ſchirrhus ſpleen, and the dropſy, by a continued uſe of ſponges dipped in common *lime water*, and placed near the part affected. *Boyle*'s Works Abr. Vol. 1. p. 80.

LIMITS, (*Cycl.*) in mathematics, is ſometimes uſed, in general, for quantities, one of which is greater, and the other leſs than another quantity. Thus, in the quantities, a, x, b, if a be leſs than x and b be greater than x, a and b are ſaid to be *limits* of x. The word occurs in this ſenſe, when we ſpeak of the *limits* of the roots of equations.

Sometimes a quantity is ſaid to be a *limit* between two others, when it is greater than the one and leſs than the other. So a ratio is ſaid to be a *limit* between two other ratios, when it is greater than the one and leſs than the other.

But *limit* is often uſed in a more reſtricted ſenſe; thus, when a variable quantity approaches continually to ſome determinate quantity, and may come nearer to it than to have any given difference, but can never go beyond it; then is the determinate quantity ſaid to be the *limit* of the variable quantity.

Hence, the circle may be ſaid to be the *limit* of its circumſcribed, and inſcribed polygons; becauſe theſe, by increaſing the number of their ſides, can be made to differ from the circle leſs than by any ſpace that can be propoſed, how ſmall ſoever.

The *limit* of a variable ratio, is ſome determinate ratio, to which the variable ratio, may continually approach, and come nearer to it than to have any given difference, but can never go beyond it. Hence, the ratio of the ordinate to the ſub-tangent of a curve, is ſaid to be the *limit* of the variable ratio of the differences of the ordinates, to the differences of the abſciſſæ.

The word *limit*, in this ſenſe, ſignifies the ſame as what Sir Iſaac Newton calls a firſt, or prime, and a laſt, or ultimate ratio.

There are two caſes of a variable quantity, or variable ratio, tending to ſuch a *limit*, as we have been deſcribing.

In the firſt caſe, the variable quantity, or ratio, will not only approach to its *limit* nearer than any given difference, but will actually arrive at its *limit*.

In the ſecond caſe, the variable quantity, or ratio, will only approach its *limit* within leſs than any given difference, but will never actually arrive at it.

Sir Iſaac Newton, to avoid the harſhneſs of the hypotheſis, of indiviſibles, and the tediouſneſs of demonſtrations, according to the method of the antients, by deductions *ad abſurdum*, has premiſed ſeveral lemmata, in the firſt ſection of the firſt book of his principles, relating to the firſt and laſt ſums, and ratio's of naſcent and evaneſcent quantities; that is, to the *limits* of ſums, and ratio's. This doctrine chiefly depends on the firſt of thoſe lemmata; the words of which are, *Quantitates ut & quantitatum rationes, quæ ad æqualitatem tempore quovis finito conſtanter tendunt, & ante finem temporis illius propius ad invicem accedunt quam pro data quavis differentia, fiunt ultimo æquales.*

The learned gentlemen, who have written in defence of Sir Iſaac, againſt the author of the Analyſt, are not agreed among themſelves, as to the preciſe meaning of this lemma. One of theſe gentlemen [a] ſays, that the genuine meaning of this propoſition is, that thoſe quantities are to be eſteemed ultimately equal, and thoſe ratio's ultimately the ſame, which are perpetually to each other, in ſuch a manner, that any difference, how minute ſoever, being given, a finite time may be aſſigned, before the end of which, the difference of thoſe quantities, or ratio's, ſhall become leſs than that given difference. [—[a] See Preſ. State of the rep. of Letters for Oct. 1735, and for Oct. 1736.—]

What Sir Iſaac Newton intends, we ſhould underſtand by the ultimate equality of magnitudes, and the ultimate identity of ratio's propoſed in this lemma, will be beſt known from the demonſtration annexed to it. By that it appears, Sir Iſaac Newton did not mean, that any point of time was aſſignable, wherein theſe varying magnitudes would become actually equal, or the ratios really the ſame; but only that no difference whatever could be named, which they ſhould not paſs. The ordinate of any diameter of an hyperbola, is always leſs than the ſame continued to the aſymptote; yet the demonſtration of this lemma can be applied, without changing a ſingle word, to prove their ultimate equality. The ſame is evident from the lemma immediately following, where parallelograms are inſcribed, and others circumſcribed to a curvilinear ſpace. Here the firſt lemma is applied to prove, that by multiplying the number, and diminiſhing the breadth of theſe parallelograms *in infinitum*, that is, perpetually and without end, the inſcribed and circumſcribed figures become ultimately equal to the curvilinear ſpace, and to each other; whereas, it is evident, that no point of time can be aſſigned, wherein they are actually equal; to ſuppoſe this were to aſſert, that the variation, aſcribed to theſe figures, though endleſs, could be brought to a period, and be perfectly accompliſhed; and thus we ſhould return to the unintelligible language of indiviſibles. The excellence of this method conſiſts in making the ſame advantage of this endleſs approximation towards equality, as by the uſe of indiviſibles, without being involved in the abſurdities of that doctrine. In ſhort, the difference between theſe two may be thus explained.

There are but three ways in nature of comparing ſpaces: one is by ſhewing them to conſiſt of ſuch, as by impoſition on each other will appear to occupy the ſame place: another is by ſhewing their proportion to ſome third; and this method can only be directly applied to the like ſpaces as the former; for this proportion muſt be finally determined by ſhewing, when the multiples of ſuch ſpaces are equal, and when they differ: the third method to be uſed, where theſe other two fail, is by deſcribing upon the ſpaces in queſtion ſuch figures, as may be compared by the former methods; and thence deducing the relation between thoſe ſpaces, by that indirect manner of proof, commonly called *deductio ad abſurdum*; and this is as concluſive a demonſtration, as any other, it being indubitable, that thoſe things are equal, which have no difference. Thus Euclid and Archimedes demonſtrate all they have written, concerning the compariſon and menſuration of curvilinear ſpaces. The method advanced by Sir Iſaac Newton for the ſame purpoſe, differs from theirs, only by applying this indirect form of proof to ſome general propoſitions, and from thence deducing the reſt by a direct form of reaſoning. Whoever compares the fourth of Sir Iſaac Newton's lemmas with the firſt, will ſee, that the proof of the curvilinear ſpaces, there conſidered, having the proportion named, depends wholly upon this, that if otherwiſe the figure inſcribed within one of them, could not approach, by ſome certain diſtance, to the magnitude of that ſpace: and this is preciſely the form of reaſoning, whereby Euclid proves the proportion between different circles. As this method of reaſoning is very diffuſely ſet out in the writings of the antients; and Sir Iſaac Newton has here expreſſed himſelf with that brevity, that the turn of his argument may poſſibly eſcape the unwary; the reading the antients, muſt be the beſt introduction to the knowledge of his method. The impoſſible attempt of comparing curvilinear ſpaces, without having any recourſe to the fore-mentioned indirect method of arguing, produced the abſurdity of indiviſibles.

As the magnitudes, called in this lemma, ultimately equal, may never abſolutely exiſt under that equality; ſo the varying magnitudes holding to each other the variable ratios, here conſidered, may never exiſt under that, which is here called their ultimate ratio. Of this Sir Iſaac Newton gives an inſtance, from lines increaſing together by equal additions, and having from the firſt a given difference. For the ultimate ratio of theſe lines, in the ſenſe of this lemma, as Sir Iſaac Newton himſelf obſerves, will be the ratio of equality, though theſe lines can never have this ratio; ſince no point of time can be aſſigned, when one does not exceed the other.

In like manner, the quantities called by Sir Iſaac Newton vaniſhing, may never ſubſiſt under that proportion here eſteemed their ultimate.

In the caſe of drawing tangents to curves, where the ordinate bears the ſame proportion to the ſubtangent, as that wherewith the difference of the ordinates, to the difference of abſciſſæ, vaniſh; theſe lines muſt not be conceived, by the name of an evaneſcent, or any other appellation, ever to ſubſiſt under that proportion: for ſhould we conceive theſe lines, in any manner, to ſubſiſt under this proportion, though at the inſtant of their vaniſhing, we ſhall fall into the unintelligible notion of indiviſibles, by endeavouring to repreſent, to the imagination, ſome inconceivable kind of exiſtence of theſe lines between their having a real magnitude, and becoming abſolutely nothing. Sir Iſaac Newton

ton was himſelf apprehenſive, that this miſtake might be made; for as he thought fit (in compliance with the bad taſte which then prevailed) to continue the uſe of ſome looſe and indiſtinct expreſſions reſembling thoſe of indiviſibles, for which he has himſelf apologized, he expreſsly cautions us againſt miſinterpreting him in this manner, when he ſays: *Si quando dixero quantitates quam minimas, vel evaneſcentes, vel ultimas, cave intelligas quantitates magnitudine determinatas, ſed cogita ſemper diminuendas ſine limite.* Thus expreſsly has he declared to us, that vaniſhing quantities, or whatever other leſs accurate appellation he names them by, are to be conſidered as indeterminate quantities bearing to each other under their different magnitudes, different proportions; which the quantities themſelves can never obtain, and the *limit* of theſe proportions, is that, for the ſake of which theſe quantities are conſidered: inſomuch, that ſince theſe quantities have different proportions, while they obtain the name of vaniſhing quantities, the term ultimate is neceſſarily added to denote that proportion, which is the *limit* of an endleſs number of varying ones. The like remark is neceſſary, when theſe quantities are conſidered in the other light, as ariſing before the imagination: for then the proportion intended muſt be ſpecified, by calling it the firſt, or prime proportion of theſe quantities. And as this additional epithet is neceſſary to expreſs the proportion intended, ſo it is abſurd to apply it to the quantities themſelves; as Sir Iſaac Newton ſays, there are *rationes primæ quantitatum naſcentium*, but not *quantitates primæ naſcentes*. Phil. Tranſ. N° 342. p. 205. So that according to the author we have been quoting, all the examples given by Sir Iſaac in the before-mentioned ſection, are to be underſtood of ſuch *limits* or ultimate ratios, as are never attained to by the quantities and ratios limited, but to which theſe may approach indefinitely, that is, ſo as to differ leſs than by a given quantity.

On the other hand, a learned gentleman, who aſſumed the name of *Philalethes Cantabrigienſis* [a], thinks that Sir Iſaac means, by the words of the lemma, and proves, in his demonſtration, not that the quantities or ratios, are barely to be conſidered as ultimately, becoming equal, or are to be eſteemed as ultimately equal; though, in reality, they can never have that proportion to each other; but that they do at laſt become actually, perfectly, and abſolutely equal. [— [a] Preſ. State of the Rep. of Letters for Nov. 1735. p. 371.—]

He alſo diſtinguiſhes, as above, between quantities and ratios which arrive at their *limits*, and thoſe which do not.

And it is inſiſted on, that every one of the examples given in the *lemmata* of this firſt ſection of the firſt book of Sir Iſaac's principles, are of ſuch quantities and ratios as actually arrive at their reſpective *limits*; nor is there an inſtance there given of a quantity, or ratio, which never arrives at its *limit*, except one at the latter end of the ſcholium of this ſection (and that by way of illuſtration of a particular objection only) of two quantities, having a given difference, and being equally increaſed, *ad infinitum*, and whoſe ratio, it is admitted, never arrives at its *limit*. But decreaſing quantities may really, and, in fact, be diminiſhed *ad infinitum*: for they may vaniſh and come to nothing. The ratio therefore of theſe, ſays he, may arrive at its *limit*, though that of the others cannot.

Neither are theſe learned gentlemen agreed as to the ſenſe of the word *vaniſhing* or *evaneſcent*, in the ſcholium of this firſt ſection of Sir Iſaac's principles.

The queſtion is, whether the quantities that vaniſh, are underſtood to ſpend ſome finite time in vaniſhing, or to vaniſh in an inſtant, or point of time; and conſequently, whether they bear to one another an infinite number of different ſucceſſive ratios during the vaniſhing, or one ratio only, at the point, or inſtant, of their evaneſcence.

This laſt is the ſenſe in which *Philalethes* takes the word evaneſcent or vaniſhing; and the diſpute, on this head, as he obſerves [a], is of no other conſequence, than to determine, whether the ſenſe in which he uſes the word be agreeable to Sir Iſaac Newton's. For, if the quantities vaniſh in an inſtant, and I take the only ratio with which they vaniſh; or they ſpend a finite time in vaniſhing, and I take the laſt of the ratios, which they ſucceſſively bear to one another during that time; ſtill the ratio, taken in either of theſe caſes, will be one and the ſame. [— [a] Preſ. State of Rep. of Lett. for Nov. 1735, p. 383, 384.—]

We cannot pretend to give the whole detail of this controverſy: but muſt refer the curious to the preſent ſtate of the republic of letters for 1735. We ſhall only obſerve, that this diſquiſition is partly critical and partly ſcientifical. The critical enquiry is into the ſenſe of Sir Iſaac, ſo far as it may be determined from his own words, and here we cannot help thinking that this is ſomewhat doubtful. The other enquiry is about the true or ſcientifical notion, upon which this doctrine ought to be founded. With reſpect to which we ſhall only aſk two queſtions, which every reader may reſolve for himſelf, to wit, whether the conception or notion he has of the ratio or proportion of evaneſcent quantities, at the point or inſtance of their evaneſcence, be more clear and diſtinct than the notion of infiniteſimals? And whether the notion of inſcribed or circumſcribed polygons to any curve, attaining their laſt form, and thereby coinciding with their curvilinear *limit*, be more clear and diſtinct than the notion of polygons of an infinite number of ſides, in the method of infiniteſimals?

Before we leave this ſubject, it may be proper to give the ſentiments of an eminent mathematician [c] about the doctrine of *limits*, or of prime and ultimate ratios, and to ſhew the connection of this doctrine with that of fluxions. [—[c] Mr. *Maclaurin*, in his Treat. of Fluxions, Art. 502.—]

Sir Iſaac Newton conſiders the ſimultaneous increments of flowing quantities as finite, and then inveſtigates the ratio which is the *limit* of the various proportions which thoſe increments bear to each other, while he ſuppoſes them to decreaſe together till they vaniſh; which ratio is the ſame with the ratio of the fluxions. In order to diſcover this *limit*, he firſt determines the ratio of the increments in general, and reduces it to the moſt ſimple terms, ſo as that (generally ſpeaking) a part at leaſt of each term may be independent of the value of the increments themſelves; then by ſuppoſing the increments to decreaſe till they vaniſh, the *limit* readily appears.

For example, let a be an invariable quantity, x a flowing quantity, and o any increment of x; then the ſimultaneous increments of xx and ax will be $2xo+oo$ and ao, which are in the ſame ratio to each other, as $2x+o$ is to a. This ratio of $2x+o$ to a, continually decreaſes while o decreaſes, and is always greater than the ratio of $2x$ to a, while o is any real increment; but it is manifeſt, that it continually approaches to the ratio of $2x$ to a as its *limit*; whence it follows, that the fluxion of xx is to the fluxion of ax as $2x$ is to a. If x be ſuppoſed to flow uniformly, ax will likewiſe flow uniformly, but xx with a motion continually accelerated: the motion with which ax flows, may be meaſured by ao; but the motion with which xx flows, is not to be meaſured by its increment $2xo+oo$, but by the part $2xo$ only, which is generated in conſequence of that motion; and the part oo is to be rejected, becauſe it is generated in conſequence only of the acceleration of the motion with which the variable ſquare flows, while o the increment of its ſide is generated: and the ratio of $2xo$ to ao is that of $2x$ to a, which was found to be the *limit* of the ratio of the increments $2xo+oo$ and ao. See the article FLUXION.

It is objected againſt Sir Iſaac Newton's method of inveſtigating this *limit*, that he firſt ſuppoſes that there are increments, that when it is ſaid *let the increments vaniſh*, the former ſuppoſition is deſtroyed, and yet a conſequence of this ſuppoſition, *i. e.* an expreſſion got by virtue thereof, is retained. But the ſuppoſitions that are made in this method of inveſtigating the *limit*, are not ſo contradictory as this objection ſeems to import. He firſt ſuppoſes that there are increments generated, and repreſents their ratio by that of two quantities, one of which is given ſo as not to vary with the increments. If he had afterwards ſuppoſed that no increments had been generated, this indeed had been a ſuppoſition directly contradictory to the former. But when he ſuppoſes thoſe increments to be diminiſhed till they vaniſh, this ſuppoſition ſurely cannot be ſaid to be ſo contradictory to the former, as to hinder us from knowing what was the ratio of thoſe increments, at any term of the time while they had a real exiſtence; how this ratio varied, and to what *limit* it approached, while the increments were continually diminiſhed. On the contrary, this is a very conciſe and juſt method of diſcovering the *limit* which is required.

It is to be obſerved, that the limiting, prime, or ultimate ratio of increments, ſtrictly ſpeaking, is not the ratio of any real increments whatſoever. But as the tangent of an arch is the right line that *limits* the poſition of all the ſecants that can paſs through the point of contact, though ſtrictly ſpeaking it be no ſecant; ſo a ratio may *limit* the variable ratios of the increments, though it cannot be ſaid to be the ratio of any real increments. The ratio of the generating motions may be likewiſe ſaid to be the laſt, or ultimate ratio of the increments, while they are ſuppoſed to be diminiſhed till they vaniſh, for a like reaſon.

LIMITANEI, among the Romans, an appellation given to the ſoldiers who were ſtationed on the frontiers of the empire. *Pitiſc.* Lex. Ant. in voc.

LIMITOTROPHI, among the Romans, the ſame with *limitanei*. See LIMITANEI, ſupr.

LIMMA, λεῖμμα, *reſiduum*, in the antient muſic, is the difference of the diateſſaron and the ditonus. It is expreſſed by $\frac{256}{243}$.

Euclid demonſtrates it to be leſs than the hemitone [a]. Boethius calls the *limma*, *hemitonium minus* [b]. —[a] *Wallis*'s Append. Ptolem. Harm. p. 169, 170. [b] Ibid. p. 170.—]

The *limma* here defined is that of Ptolemy. Modern muſicians have applied this name to ſeveral other intervals, ariſing from the ſubſtraction of ſemi-tones from the tone major. Thus the difference between the ſemi-tone minor and the tone major is $\frac{9}{8} : \frac{25}{24} = \frac{27}{25}$ is by Mr. Euler called *limma majus*; and the difference between the ſemi-tone major and tone major he calls *limma minus* [a]. This laſt is expreſſed by

by $\frac{135}{128} = \frac{9}{8} : \frac{16}{15}$. The octave is nearly equal to nine greater *limmas*, and to thirteen leſſer [b]. [[a] *Euler*, Tentam. Nov. Theor. Muſic. p. 107, 108. [b] Ibid. p. 108.]

LIMNITIS, a word uſed by the antients to expreſs the concretion round reeds, or water plants, by ſome called *adarce*, or ſomewhat analogous to that.

LIMOCINCTI, among the Romans, a kind of prieſts, who officiated at public ſacrifices, and were dreſſed with a garment called *limus*. See LIMUS.

LIMODORUM, *birds neſt*, in botany, the name of a genus of plants; the characters of which are theſe. The flower is of the polypetalous anomalous kind, reſembling the orchis flowers. The cup finally becomes a fruit, which is pervious by three feneſtræ, and furniſhed with a valve to each. The ſeeds are ſmall, and reſemble duſt.

There is only one known ſpecies of *limodorum*, which is the plant called by many *orchis abortiva*, and *birds neſt*. This plant differs from the orchis by fibroſe roots, and from the helleborine in its having a ſpear, or heel, to the flower; as it does from the twy blade, by having its leaves placed alternately on the ſtalks. *Tourn.* Inſt. p. 437.

LIMON, the *lemon tree*, in botany, the name of a genus of trees, the characters of which are theſe. The flowers and leaves are altogether like thoſe of the citron, but the fruit is of an oval figure, and has but a thin fleſhy ſubſtance, divided into many cells, containing juice, and callous ſeeds. To this it is to be added, that there is a peculiar, and appropriated general appearance in the *lemon tree*, by which the gardners, and other perſons converſant in theſe things, readily diſtinguiſh it from the orange and the citron.

The ſpecies of *lemon*, enumerated by Mr. Tournefort, are theſe. 1. The common *lemon*. 2. The little ball *lemon*. 3. The incomparable *lemon*. 4. The ſweet *lemon*. 5. The Liſbon ſweet *lemon*. 6. The pear-ſhaped *lemon*. 7. The ſpataphora *lemon*. 8. The ſhardonian *lemon*. 9. The barbadore *lemon*. 10. The ſweet *lemon*. 11. The ſharp *lemon*. 12. The citron-like *lemon*. 13. The citron *lemon* with one fruit including another. 14. Racemous fruited *lemon*. *Tourn.* Inſt. p. 621.

LIMONIATES, a name given by ſome authors to the emerald. *Plin.* lib. 37. cap. 10.

LIMONIUM, *ſea lavender*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the caryophyllous kind, being compoſed of ſeveral petals arranged in a circular form, and ariſing out of a tubular cup. From the ſame cup there alſo ariſes a piſtil, which finally becomes a ſingle oblong ſeed, which remains involved in the cup. This is the general ſtate of the flowers of this genus of plants; but ſome of them, inſtead of their caryophyllous flower, have a one-leaved funnel-faſhioned one, which is ever, however, ſo divided into ſegments at the end, that it reſembles the flowers of the common kinds.

The ſpecies of *limonium*, enumerated by Mr. Tournefort, are theſe. 1. The common large *limonium*. 2. The late flowering large French *limonium*. 3. The ſmaller *limonium* with olive-like leaves. 4. The little daiſy leaved *limonium*. 5. The little daiſy leaved *limonium* with fennel-like branches. 6. The leſſer *limonium* with heart-faſhioned leaves. 7. The ſmalleſt *limonium*. 8. The little *limonium* with crooked tortuous branches. 9. The ceterach leaved *limonium*. 10. The hairy ſhrub *limonium*. 11. The ſmooth ſhrub *limonium*. 12. The procumbent *limonium* with reticulated ſtalks. 13. The Sicilian heart-faſhioned leaved *limonium*. 14. The little annual *limonium* with echioide, or bullated leaves. 15. The Portugal *limonium* with ſpear pointed leaves. 16. The Portugal *limonium* with leaves like the auriculas. 17. The Portugal hairy leaved *limonium*. 18. The *limonium* with curled appendages to the ſtalks. 19. The *limonium* with ſea purſelain leaves. 20. The woody gall bearing *limonium*. 21. The Spaniſh plantain leaved *limonium* with bullated leaves. 22. The Spaniſh plantain leaved *limonium* with ſmooth leaves. 23. The Spaniſh *limonium* with divided leaves. 24. The *limonium* with leaves like ſtatice, and conglomerated heads. 25. The articulated blueiſh green Spaniſh *limonium*. *Tourn.* Inſt. p. 341, 342.

The common *ſea lavender* is an aſtringent, and is given with good ſucceſs againſt diarrhœas, dyſenteries, profluvia of the menſes, and hæmorrhages of all kinds. The roots and leaves are the parts moſt uſed.

LIMONIUM *gall*, in natural hiſtory, the name of a ſpecies of *gall*, or vegetable protuberance, ſerving for the lodging of an inſect, affording a very beautiful appearance on the plant, and very common in the eaſtern parts of the world. The *galls* of all kinds are produced by the worm of a winged inſect, hatched from an egg depoſited there by the parent animal, that the young progeny may find food, and a defence from injuries, as ſoon as hatched. It is a general obſervation, however, that theſe protuberances on vegetables are the effect of the eggs depoſited by the various ſpecies of flies, but this of the *limonium* is ſingular, in that it is produced from a butterfly egg, and is inhabited by a true caterpillar. The butterfly depoſits her eggs on ſeveral parts of the leaves and ſtalks of this plant, and the young caterpillar, as ſoon as hatched, eats its way through the ſurface; and continuing to eat when within, his depredations occaſion an abundant derivation of juices to the part, by means of which a gall, or protuberance, is formed, which is ſuſtained by a pedicle, and in all reſpects reſembles a fruit. This is of a roundiſh figure, and by degrees grows to the ſize of a nutmeg. It is compoſed of ſeveral coats, or cruſts; the exterior ones are ſoft and ſpungy, but the interior are harder, and more woody than the galls of the oak. As the generality of other caterpillars feed on the ſubſtance of the leaves of trees and plants, this eats only the inſide of its lodgment; and nature ſo readily ſupplies this defect by new matter, that the cavity, in which it is lodged, is never found to be very great.

In the generality of *galls*, their being whole in every part is a proof, that the inſect to which they ſerve for a habitation is yet in them; and when there is a hole ſeen on any ſide, it is a proof that they are empty, the creature having made its eſcape that way. But this does not hold good in this inſtance; for though a fly may have a power of making a hole for itſelf to get out at, a butterfly has no organs with which to perform ſuch a work; and conſequently the caterpillar, while it has the proper organs, muſt do it, and make the hole ready for the creature to come out at. If one of theſe *galls* be opened before there is any hole on its ſurface, the caterpillar is ſure to be found alive, and in an eating ſtate within; but when the time of its transformation approaches, it ceaſes to eat, and the laſt uſe of its teeth is the gnawing a hole through its habitation, out at which it may eſcape when in its winged ſtate. As ſoon as it has finiſhed this aperture, it retreats back into its cell, and there ſpins a web, in which it changes into a butterfly. The creature always has the caution to place that part of the chryſalis, in which the head of the butterfly is, cloſe to the aperture; and the creature then, as it makes its way out of the chryſalis, at the ſame time gets into the paſſage through the ſhell of its habitation, and finally gets out of it before its wings are unfolded, or expanded, as it would be impoſſible for it to paſs through ſo ſmall an aperture with its wings hardened, and of their full ſize. This ſeems the only known inſtance of a gall formed by a genuine caterpillar. The inhabitants of the willow *galls*, though uſually eſteemed ſmooth caterpillars, being not ſo, but the worms of a four winged fly. *Reaumur*, Hiſt. Inſect. Vol. 6. p. 227.

LIMOSA, in zoology, the name of a long legged water bird, common in Italy, and called by ſome *glottis*, *totano*, and *pluvialis major*. It is but a ſmall bird, its uſual weight being about ſeven ounces. Its beak is black, but ſomewhat reddiſh near the angle of the under jaw. The upper part of its head, neck, ſhoulders, wings, and the forepart of its back, is variegated with brown and grey; the middle of the head feathers are black, and their ends whitiſh. Its rump, and its whole breaſt, belly, and throat, are white; the long wing feathers are brown; the tail feathers are variegated with brown and grey. Its legs are very long, and are naked for two fingers breadth above the knee. *Ray*'s Ornitholog. p. 221.

LIMOSA, in ichthyology, a name given by Salvian to the common mackrel, and in his figures to the *thynnus*, or tunny fiſh, called the *Spaniſh mackrel*.

LIMOSELLA, in botany, the name given by Linnæus to a genus of plants, called by Dillenius, and others, *plantaginella*; the characters of which are theſe. The perianthium is erect, one leaved, lightly divided into five ſegments at the edge, and remaining after the flower is fallen. The flower conſiſts of one petal, which is ſmall, erect, acute, and lightly divided into five ſegments at the end. The ſtamina are four erect filaments. The antheræ are ſimple. The germen of the piſtil is oblong and obtuſe. The ſtyle is ſingle, and of the length of the ſtamina, and the ſtigma is globular. The fruit is an oval capſule, affixed to the baſe of the cup, compoſed of two valves, and including two cells, in which are a great number of ſmall ſeeds of an oval figure. *Linnæi* Gen. Pl. p. 300. *Dillen.* Hort. Elth. p. 6.

LIMPET, *patella*, in conchyliology. See Tab. of Shells, N° 1, 2. and the article PATELLA.

The manner of the *limpet*'s faſtening itſelf to the rocks has not been well underſtood till the time of Mr. Reaumur, though the fact was ſo well known, as to become in ſome places a proverbial compariſon.

The ſhell of the *limpet* approaches to the figure of a cone; the baſe of this cone is occupied by a large muſcle, which alone has nearly as much fleſh in it as the whole body of the fiſh. This muſcle is not covered by the ſhell, but ſerves the creature equally to move forward, or to fix itſelf by at pleaſure. When it is in a ſtate of reſt, which is the common caſe, it applies this muſcle every way round to the ſurface of ſome ſtone, and holds itſelf by that means fixed very firmly to it, inſomuch that it is impoſſible to take it off with the hands; and thoſe who would remove them are forced to uſe a knife for that purpoſe, and the removing the fiſh this way is not eaſy; for every where that the

blade of the knife attempts to enter, the fish fixes its muscle with double force to the stone. Mr. Reaumur, to try the force of the adhesion of this fish, tied lines with weights at their ends to the shells, when placed in an horizontal direction on the stone, and found that thirty pound was the least weight that would tear them off, and that they would resist that for several minutes. It might be naturally supposed, that the cause of this strong adhesion was the animal's thrusting the fibres of this muscle into every small pore of the stone, and there keeping them forcibly inflated: but were this the case, the adhesion must cease with the life of the animal; but it does not so, for if a *limpet* be cut into several portions through the shell and body, yet every portion, thus separated, will adhere with its due proportion of force to the stone. Neither can this force be resolved on the principles of the adhesion of two polished marbles, or that of the leather to the stone in the common sport of children; for in both these cases, whatever perpendicular force the adhesion can bear, the least force applied horizontally makes them slip, or slide off from one another. But this is not the case in the adhesion of this fish, it equally resisting horizontal and perpendicular force.

The true cause of this adhesion is a viscous juice, a sort of glue thrown out by this muscle, which, though imperceptible to the eye, is able to produce these great effects. This is easily perceived by the touch, however; for if immediately after the removing a *limpet* from a stone, the finger be applied to the place, it is fastened very strongly to it by means of the glue left there. If any wet, however, have touched the stone, after the fish was removed, there is no viscosity perceived on it, the whole substance of the glue being immediately dissolved, and its effects wholly taken off by it. This is a consideration which may lead us to observe the great care of nature over all her works, manifested eminently in this little fish. It was necessary that it should have a power of fixing itself to stones, *&c.* to prevent its being washed away by every wave: this power is given it by means of a certain glue, which holds it very firmly; but if this glue was not capable of being resolved, and its force destroyed by some power in the animal, it must needs perish for want of food, when once fixed to a barren spot. Water is therefore made a solvent for this glue; the close adhesion of the outer rim of the great circular muscle prevents the external water from acting upon it, else it must always be destroyed as soon as discharged, and so be of no use; but the under surface of the body of the animal is all over covered with small tubercles, containing water, at least many of them do so. When the creature then has a mind to unfix itself for motion, it only discharges a quantity of this water, and the whole cement dissolves before it, and sets the creature free. Those tubercles which do not contain water, probably contain the viscous matter, or glue, whence it may be conveyed by proper vessels to the circumference; so that when the animal has a mind to fix itself to a stone, it needs only squeeze the one set of these tubercles; and when it would unloose itself, the other.

The water contained in these tubercles is particularly necessary in some circumstances, in which, tho' the creature could, at pleasure, open the outer verge of the muscle, to admit sea water, it would not do; for it often fixes itself to rocks left dry at the ebb, and from these nothing but the water contained in itself could set it free. The glue it is provided with is but in a certain limited proportion; for after removing the same *limpet* three or four times, it is found no longer able to fix itself with any degree of firmness, till nature, after a proper time, has supplied the dissipated viscosity. This viscous humidity allotted to this animal, for the fixing itself to the rocks, is not peculiar to it; the *urtica marina* has the same, and the horns of the sea urchins, by which they fix themselves, are endued with a power of discharging a liquor of the same kind, which serves them to the same purpose. Mem. Acad. Par. 1711. See URTICA MARINA, and *Sea* URCHIN.

LIMUS, among the Romans, a garment reaching to the ground, and worn by the priests, who on that account were called *limocincti*. *Pitisc.*

LINARIA, *toad flax*, in botany, the name of a genus of plants; the characters of which are these. The flower is composed of only one leaf, and is personated before, and runs into a heel behind. The forepart has two lips; the upper of which is divided into two or more segments, the lower always into three. The pistil arises from the cup, and is fixed in the manner of a nail into the hinder part of the flower: this finally becomes a fruit, or capsule, of a roundish figure, divided into two cells by an intermediate septum, and containing seeds, in some species flatted, in others angular, or roundish, and fixed to a placenta.

The species of *toad flax*, enumerated by Mr. Tournefort, are these. 1. The great purple flowered broad leaved Portugal *toad flax*. 2. The great broad leaved Dalmatian *toad flax* with very large flowers. 3. The broad leaved trifoliate Sicilian *toad flax*. 4. The lesser three-leaved yellow flowered *toad flax*. 5. The three-leaved blue flowered *toad flax*. 6. The daisy leaved *toad flax*. 7. The white flowered daisy leaved *codflax*. 8. The Portugal *toad flax* with large hairy daisy-like leaves. 9. The common smooth ivy leaved *toad flax*, called by many *cymbalaria*. 10. The Alpine hairy *cymbalaria*. 11. The hairy moneywort leaved corn *toad flax*, called by most authors *elatine*, or round leaved *fluellin*. 12. The hairy yellow flowered moneywort leaved corn *toad flax* with auriculated leaves, called by authors the angular leaved *elatine*, or *fluellin*. 13. The blue flowered hairy auriculated leaved corn *toad flax*. 14. The hairy perennial stone *toad flax* with yellow flowers. 15. The common small field *toad flax*, called by authors the *lesser snapdragon*. 16. The mother of thyme leaved stone *toad flax*, called by authors *stone snapdragon*. 17. The hairy chickweed leaved stone *toad flax*. 18. The hairy knotgrass leaved stone *toad flax*. 19. The hairy moneywort white flowered Spanish *toad flax* with white flowers. 20. The hairy broad leaved trifoliate Spanish *toad flax*. 21. The Portugal sea *toad flax* with milkwort leaves. 22. The smallest hairy auriculated leaved *toad flax* with extremely small yellow flowers. 23. The broad leaved small procumbent *toad flax* with a pale yellow flower, with a gold coloured mouth. 24. The broad leaved trifoliate *toad flax* with a great purple flower, with a yellow opening. 25. The violet coloured annual *toad flax* with the lower leaves roundish. 26. The dwarf Portugal *toad flax* with flowers wanting the palate. 27. The common yellow *toad flax* with larger flowers. 28. The common yellow *toad flax* with smaller flowers. 29. The pale flowered *toad flax* with the deep yellow mouth. 30. The taller pale flowered *toad flax* with a deep yellow mouth. 31. The whitish flowered *toad flax* with a purple mouth. 32. The upright sweet *toad flax* with a dusky blue flower, with a yellow mouth. 33. The small creeping scentless *toad flax*. 34. The great purple sweet scented *toad flax*. 35. The great white sweet scented *toad flax*. 36. The broader leaved sweet purple *toad flax*. 37. The narrowest leaved sweet *toad flax*. 38. The narrow leaved hoary *toad flax*. 39. The narrow leaved rust coloured *toad flax*. 40. The yellow flowered mountain *toad flax* with dyers weed leaves. 41. The least flowered yellow *toad flax*. 42. The American *toad flax* with small yellow flowers. 43. The blue flowered field *toad flax*. 44. The violet coloured field *toad flax*. 45. The four-leaved yellow flowered *toad flax*. 46. The small procumbent yellow *toad flax*. 47. The small flowered yellow dwarf *toad flax* with thick fleshy leaves. 48. The greyish fleshy leaved Spanish *toad flax*. 49. The blue flowered creeping *toad flax*. 50. The snow-white flowered creeping *toad flax*. 51. The low four-leaved purple *toad flax*. 52. The mollugo leaved many stalked Sicilian *toad flax*. 53. The narrow leaved annual *toad flax* with large yellow flowers. 54. The best hairy clammy leaved sea *toad flax* with yellow flowers. 55. The narrow leaved hairy, and clammy Spanish *toad flax*. 56. The thyme leaved stone *toad flax*. 57. The narrow leaved annual *toad flax* with white flowers, with very long heels. *Tourn.* Inst. p. 169, 170.

There are some other plants improperly ranked among the *linariæ* by many authors. Of these are the *osyris frutescens baccifera*, or shrubby berry-bearing osyris, which is a species of *cassia*. The great leafy headed yellow *toad flax* of Caspar Bauhine, which is a species of *fleabane*. The bastard golden *toad flax*, and the white flowered mountain *toad flax*, which are species of *alchymilla*.

LINARIA, in zoology, the name of the *linnet*, a genus of birds, of which there are several species. The general characters of the genus are these. The birds of it are somewhat smaller than the chaffinch; their general colour is a greyish brown; their tail is a little forked, the outer feathers of it having white extremities; and they all sing very sweetly. We have in England four species of this bird. 1. The common brown *linnet*, well known to every one. 2. The *linaria rubra major*, or greater red headed *linnet*. This has a fine red head, a grey neck, a dusky reddish brown back, and its breast and belly are somewhat reddish. The female of this species, however, has no redness on its head, or breast, but has somewhat of a greenish cast among the brown of her back, and is yellowish on the breast, with some brownish spots. 3. The *linaria rubra minor*, or lesser red headed *linnet*. This is smaller than the former, and on the back is of the same colour with the common *linnet*. The back part of its head is red, as is also its breast, but the lower part of its belly is whitish. In this species the female, as well as the male, has a red head, and both have their beaks much sharper, and their feet and legs blacker than in the larger kind. This also is a gregarious bird; the larger kind commonly flies single. 4. The last species is the *linaria montana*, or mountain *linnet*. This is the largest of all the *linnets*. Its beak is very small; its head and back are of the same colour with those of the common *linnet*, and the feathers of its breast and belly are black in the middle, and edged with a whitish colour. The rump is of a fine and beautiful red, and is the only part of the bird which is so. This is common in Derbyshire, but seems not so frequent in other places. *Ray's* Ornitholog. p. 192. See LINNET.

LINCH-*pin*, a term given by carters to the *pin* which keeps the wheel on the axle-tree. See CART.

LINE (*Cycl.*)—A *line* in geometry, is to be conceived as the termination or limit of a ſurface, and not as a part of that ſurface, however ſmall. Hobbes, and ſome others, who have taken it in the latter ſenſe, have fallen into many abſurdities.

LINES *of the third order*. Sir Iſaac Newton [a] enumerated ſeventy-two *lines* of the third order, and Mr. Stirling [b] found four more; ſince that Mr. Stone [c] has found two others which had eſcaped Sir Iſaac and Mr. Stirling. The two ſpecies added are to be reckoned among the hyperbolico-parabolical curves. [—[a] Enumer. Lin. Tert. Ordin. [b] Linea Tert. Ordin. Neutonianæ Oxon. 1717, 8vo. [c] Phil. Tranſ. N° 456. Sect. 6.—]

Angling LINE. The beſt materials for making theſe *lines* are fine and even horſe hairs: the hair ſhould be round and twiſted even, for that greatly ſtrengthens it; and all the hairs ſhould be of an equal bigneſs, or as nearly ſo as may be. They ſhould be laid in the water about a quarter of an hour after twiſting, that it may be ſeen which will ſhrink: they are then to be twiſted over again. In this laſt twiſting ſome intermingle ſilk among them, but that is not ſo well. *Lines* made entirely of ſilk are not bad; but thoſe of ſilk and hair mixed are never found to do well. The beſt colours for a *line* are ſorrel, white, and grey, the two laſt are beſt for angling in clear waters. The former in muddy ones. The pale watery green is alſo a very good colour, and may be made thus: boil in a quart of alum water a large handful of marygold flowers; there will ariſe a ſcum, which muſt be taken off; then add to this liquor copperas and verdigreaſe, of each half a pound, beat to powder together, boil theſe up together: then put the hair into this liquor, and let it lie ten or twelve hours; it will obtain a watery blueiſh green colour, which will not waſh out afterwards.

LINES, among fowlers, is uſed to expreſs the ſtrings by which they catch birds. The large and ſmall land birds are equally eaſy to be taken by them, and ſometimes the water fowl.

Theſe *lines* are made of long and ſmall cords, knotted in different places, and containing in length as many fathom as the places where they are to be laid require. Plovers, and the larger wild fowl, are very conveniently taken by them: when theſe ſtrings are to be uſed, they muſt be limed with the ſtrongeſt bird lime that can be got, and then coming to their haunts before the evening flights, that is before ſun-ſet, or for the morning flights, at leaſt two hours before day, the ſportſman is to carry a parcel of ſmall ſticks, each about two feet long, and ſharpened at both ends, but having a little ſlit in one end like a fork. The plain end of each ſtick is to be ſtuck into the ground, in ſuch a manner, that the ſtick ſtanding aſlant its upper or forked end may be about a foot and half from the ſurface. The limed ſtrings are then to be carried along all theſe ſticks, in different rows, ſome higher than others. Every row of the ſticks is thus to be filled, and the whole haunt covered with the *lines*. The plover, and other birds that fly low, when they come to their haunts, fly directly in among theſe ſtrings, and are taken in great numbers; the whole flight coming in at once, and covering all the place, ſo that thoſe which are not yet alighted, have no opportunity of ſeeing the diſtreſs of their companions. There is no need for the ſportſman to be conſtantly upon the watch for the taking of the bird; for when once they are taken they cannot looſen themſelves, ſo that he may come and take them up at his own time. The water fowl may be eaſily taken, in the ſame manner, by obſerving their haunts, and ſtretching theſe *lines*, in ſeveral rows, acroſs the brook, or river, ſome higher and ſome lower, the loweſt lying almoſt at the edge of the water. Theſe muſt never be uſed in moon light nights on the occaſion, for the ſhadow of the ſtrings in the water will then fright them away.

LINES, in heraldry, the figures uſed in armories to divide the ſhield into different parts, and to compoſe different figures.

They are of different forms, and were it not for this, many arms would be one and the ſame, for a chief wavey differs from a plain chief, by the *lines* which compoſe them, and the heralds ſhew particular reaſons for all theſe different forms of *lines*.

Theſe *lines*, according to their forms and names, give denomination to the pieces or figures which they form, except the ſtrait or plain *lines*.

The crooked *lines* are theſe: firſt the ingraled and inverted; theſe when repreſented together are ſomewhat known the one from the other, being oppoſite to one another, both being made as it were of ſemi-circles. The ingraled with the points upward, the inverted with the points downward. But this is not a ſufficient diſtinction; for ſuppoſe the ſpace between them which they form be a feſs; then the whole is only ingraled, not inverted; for the feſs ingraled muſt have the points on both ſides turned toward the field, and the convex or gibboſe parts toward the feſs itſelf, and ſo of a bend, cheveron, and other proper figures of heraldry; and if theſe be inverted, then the convex parts of the *lines* are toward the field; but theſe *lines* are better diſtinguiſhed when placed by way of bordure, with the letters within a bordure ingraled or inverted.

Theſe two *lines* are more hard to be diſtinguiſhed, when the field is divided into two equal parts, of different colours, as parted per pale, parted per feſs, &c. here we know not whether the *line* be ingraled or inverted, except we follow this rule, that the form of the *line* muſt be applied to the colour firſt named. The French terms for theſe two *lines* are for the ingraled, *engrele*, and for the inverted, *canele*; and the Latin writers expreſs ingraled by *ingrediatus*, *imbricatus*, and *ſtriatus*, and the inverted by the words *invertus* and *canaliculatus*. *Leigh*'s Heraldry.

The wavey, or waved *line*, is ſuch an one as is formed in repreſentation of the waves of the ſea, as parted per feſs wavey in arms and other waved *lines*, as the wavey bars all expreſs that the perſon got his honours by ſea ſervice. Nebulee is another name of a *line* in heraldry; it expreſſes a clouded *line*, the French called it *nuance*, and the Latins *nebuloſa linea*; this alſo has been given to perſons, who have been eminently ſkilled in navigation. *Neſbit*'s Heraldry, p. 22.

Crenele, or imbattled *lines*, repreſent the battlements of a houſe, and are ſaid to repreſent in heraldry the ſkill in architecture, for which the firſt of the family was famous; they were alſo given ſometimes for eminent ſervices, in aſſaulting or defending caſtles in time of war, and ſometimes only as emblems of a houſe, to expreſs the perſon who bore them, being of a noble houſe or family; for of old none were ſuffered to embattle their houſes but perſons of great diſtinction. Cambden ſpeaking of Tunſtall's ſeat in England, mentions it as a ſingular mark of favour, that the king had given him leave to embattle his houſe. The term crenele, however, is properly uſed for a figure only, when one ſide of it is embattled; for when both ſides are formed of embattled *lines*, it is called *bretеſſe*, or as ſome expreſs it *contre bretеſſe*.

The Latin writers in heraldry uſe for the word *crenelee*, the terms *pinnatus* and *pinnis aſperatus*, according to Uredus in his blazons, and Sylveſter petra ſancta in his *murales pinnalee*.

There is another *line* of this kind in heraldry, which Leigh calls the battled embattled *line*; this has one degree of embattling above another. When the upper points in this kind of *line* are repreſented ſharp, it is called campagne, as if the *lines* ending in points, repreſented baſtions, or the outer works of cities and camps; and when the upper points are rounded, it is called crenele embattled arrondi.

The indented *line* is notched ſo at the edges that it repreſents the teeth of a ſaw, and has its name from the Latin *dens*, a tooth, or from the law term indenture, a ſort of deed, the top of which is always notched like the teeth of a ſaw.

The daunzette is another *line*, very much reſembling the indented *line*, but that it is always much ſmaller; it is therefore ſaid by the heralds to be the ſame in quality but not in quantity. The daunzette differs alſo from the indented *line*, in that it always conſiſts but of a few teeth, though never leſs than three; according to Mr. Holmes, in his office of armory, whereas the indented *line* has always a great many teeth. The French expreſs our indented *line* by the terms danche or dentille; and the daunzette, when it has but very few teeth, and thoſe very long, by the term *vivere*, which Meneſtrier takes to be the letter M, with its legs extended from ſide to ſide of the ſhield, becauſe many who carry a partition, or feſs, after that form, have the family name, beginning with that letter. The Latin writers expreſs the term indented, by *dentatus*, *indentatus*, and *denticulatus*, and when the teeth are very long, as in the daunzette, they call them *dentes decumani*.

There are yet two other *lines* mentioned by heraldry writers; the firſt is the patee or dovetail *line*, ſo called from its reſemblance to a ſort of joint uſed by our carpenters, in which one part goes alternately all the way down between two others; this is called by Morgan the inclave, or labelled line, becauſe the points as they proceed from the ordinary, ſuch as a chief or feſs, repreſent not amiſs the points, or rather the ends of labels. The other *line* is called urdee or champagne by Freſne; and by Upton, vair, becauſe its points are formed like pieces of the furr called by heralds vair. *Neſbit*'s Heraldry, p. 23.

The two laſt of theſe are in very little uſe, the others are the common *lines* of arms, and are called the attributes or accidents of armorial figures which they form; and if any other *lines* are found in the figures or engravings of arms, which are not reducible to the one or other of theſe, they are called irregular, and by the French heralds *clatte*. The knowledge and uſe of theſe forms of *lines* are neceſſary in the ſcience of heraldry, to diſtinguiſh and difference many armorial bearings.

Lateral LINE, *linea lateralis*, in ichthyology, a name given by naturaliſts to a *line* or ſtreak, with which many kinds of fiſh are marked, paſſing along their ſides. Few fiſh are without this *line*; but it is very variouſly formed in the ſeveral kinds, and makes a very conſiderable article in their deſcription,

tion, if not in the diſtinction of the ſpecies. In ſome ſpecies it is made of a ſeries of little points, or holes, as appears to the eye; of this nature is the *linea* in eels, &c. In ſome others it is formed of a ſort of duct, running along the center of a great number of ſcales. This is its ſtructure in the generality of fiſhes. *Artedi*'s Ichthyology.

This *line*, in various kinds of fiſh, varies alſo in regard to number, ſituation, figure, and other properties. In regard to number, there is no *line* obſerved in the ſyngnathi and petromyza, in almoſt all other fiſh there is one on each ſide; and finally, in ſome there are as it were two lines on each ſide: an inſtance of this we have in the ammodytæ. In regard to the ſituation, the differences are theſe. 1. In ſome it is near the back, as in the clupea, ſalmons, pearch, and the like. 2. In others it is placed nearer the belly, and runs parallel with it, as in the cyprini. 3. In ſome it is placed in the center of each ſide between the back and the belly, as in the caraſſius. 4. In ſome it is placed againſt the interſtices of the muſcles, or the ſpina dorſalis, as in the muræna; and 5. In ſome it is placed above the interſtices, as in the ammodytæ, &c. It has been ſuppoſed, by many, that this *linea lateralis* was always parallel to the interſtices of the muſcles, but this is evinced to be an erroneous opinion, by the obſervation of the pearch and mackrel. In regard to the differences of figure, this *line* is in ſome ſtrait, as in the coregones, ſalmons, &c. 2. In others it is crooked, as in the cyprini, the pearch, &c. and in the generality of fiſh is ſmooth to the touch, but in ſome it is rough and accelerated, as in the trachurus and pleuronecti. *Artedi* Ichthyolog.

LINES, in muſic, is uſed for thoſe ſtrokes drawn horizontally on a piece of paper, on and between which, the characters and notes of muſic are diſpoſed. Their number is commonly five, when another is added for one, two or more notes, it is called a *leger line*. See LEGER.

Some ſay that it is to Guido Aretine that we owe their invention: they are very commodious, and greatly aſſiſt the imagination in diſtinguiſhing the low notes from the high. Upon their firſt introduction, the *lines* only were uſed, and the ſpaces between them intirely neglected. *Broſſard.*

Originally there were as many *lines* drawn for a ſong, as it required notes aſcending; but at length the notes being placed in the intervals of the *lines*, theſe were reduced to four; ſo that there were nine places or degrees for nine different ſounds, which was their extent: at laſt they raiſed the number to five, of which the loweſt is reckoned firſt; and hereon they placed the characters for eleven different ſounds, including the ſpaces above the fifth and below the firſt; and at the ſame time they had the liberty, at pleaſure, to add more *lines* if the ſong ran to a greater compaſs.

LINE *of the banquet* in the manege. See BANQUET.

Knave LINE, in a ſhip. See KNAVE.

LINE *of equated bodies*. See EQUATED *bodies*.

Indented LINE, in fortification. See INDENTED *line*.

Labelled LINE. See LABELLED *line*.

LINE *of a volt*, in the manege. See SQUARE and VOLT.

LINEA *nubeloſa*. See NUBELOSA *linea*.

LINEAR *leaf*, among botaniſts. See LEAF.

LINEATORES, in the hippodrome at Conſtantinople, were the ſame with the *deſignatores* in the circus at Rome. See HIPPODROMUS, CIRCUS, DESIGNATOR, *Cycl.*

LING, in ichthyology, the Engliſh name for a kind of fiſh, which is a ſpecies of the *aſellus*, according to the generality of authors, and is generally called *aſellus longus*. According to the new Artedian ſyſtem, it is a ſpecies of the *gadi*, and is diſtinguiſhed by the expreſſive name of the *gadus*, with two fins on the back, with a bearded mouth, and with the upper jaw longeſt. See ASELLUS and GADUS.

Ling is eſteemed, both freſh and cured for the table. It is a long bodied fiſh, more approaching to the *merlucius* or hake, than to any other ſpecies. It is covered with very ſmall ſcales which adhere cloſely to the ſkin. The back and ſides are of a blueiſh or greeniſh brown, and the belly white. Its head is flat and large, and its ſnout conſiderably long. The upper jaw is longer than the under, and both are furniſhed with ſeveral rows of ſhort teeth, and the lower with one range of longer. And in the palate there are a large number of ſmall teeth, among which there are four or five large and long ones intermixed. The mouth opens very wide, and in the angle of the lower jaw has a ſingle ſhort beard. It has two fins upon the back, one near the head; the other not far behind it, and reaching down almoſt to the tail. The gill fins are ſmall, the belly fins are placed high, and the tail is not forked. See Tab. of Fiſhes, N° 28. and *Ray*'s Ichthyog. p. 175.

LINGUA *avis*, *birds tongue*, in the materia medica, the ſeed of the aſh tree, or aſhen keys. *Ger.* Emac. Ind. 2.

LINGUÆ *ſecundum par*, a name given by Caſſerius to a pair of muſcles of the tongue, called by the generality of authors *ſtyloglosſus*. See STYLOGLOSSUS.

LINGUA *cervina*, *hart's tongue*, in botany, the name of a genus of plants; the characters of which are theſe. The leaves reſemble the *tongue* of an animal in ſhape, or are, at leaſt, vulgarly ſuppoſed to do ſo; they are uſually plain and ſimple, but ſometimes they are jagged, and in ſome ſpecies they are compoſed of many ſegments affixed to a middle rib. The flowers are not diſcovered, but the ſeeds grow on the under part of the leaf, in ſeveral long, ſulcated and ſeemingly bivalve furrows; theſe are filled with oblong capſules, each of which is furniſhed with an elaſtic ring, by the contraction of which they are burſt when the ſeeds are ripened.

The ſpecies of *hart's tongue* enumerated by Mr. Tournefort are theſe. 1. The common *hart's tongue*. 2. The great *hart's tongue* with undulated leaves, auriculated at their baſes. 3. The *hart's tongue* with the middle rib of the leaf terminating in a prickle. 4. The *hart's tongue* with leaves corniculated, and divided into many ſegments at their ſummits. 5. The narrow leaved ſhining *hart's tongue* with leaves not ſerrated. 6. The ſmalleſt *hart's tongue* with undulated leaves. 7. The narrow leaved great *hart's tongue* with down, hiding the ſegments of the leaves. 8. The oak leaved *hart's tongue*. 9. The Virginian *hart's tongue* with leaves bending down, and taking root from their ſummits. 10. The ſmooth but rigid *hart's tongue*. 11. The broad leaved *hart's tongue* with ſcaly pedicles. 12. The ſhining *hart's tongue* with jointed pedicles. 13. The narrow leaved reticulated *hart's tongue*. 14. The ilex leaved climbing *hart's tongue*. 15. The moſſy *hart's tongue* with yellow hairs and ſcales. 16. The leſſer hairy *hart's tongue*. 17. The ſhort and thick leaved *hart's tongue*. 18. The ſmalleſt, creeping, hairy *hart's tongue*. 19. The largeſt leaved *hart's tongue*. 20. The *hart's tongue* covered on its underſide with a fine gold coloured powder. 21. The long and very narrow leaved *hart's tongue*. 22. The *hart's tongue* with ſharp pointed leaves, duſty at the tops and on their edges. 23. The round dented not branched *hart's tongue*. 24. The *hart's tongue* with long, broad, and ſerrated leaves. 25. The climbing *hart's tongue* with ſcaly ſtalks. 26. The *hart's tongue* with long, narrow, and undulated leaves. 27. The great hairy reddiſh *hart's tongue*. 28. The *hart's tongue* with green ſpotted creeping roots. 29. The hairy *hart's tongue* with broad and roundiſh leaves. 30. The double leaved *hart's tongue*. 31. The narrow leaved *hart's tongue* with hairy ſtalks and ribs. 32. The climbing *hart's tongue* with bay-like ſerrated leaves. 33. The *hart's tongue* with multifid leaves. 34. The larger *hart's tongue* with leaves divided into two or three large ſegments. 35. The great branched *hart's tongue* with multifid and curled leaves. 36. The ſmaller branched *hart's tongue* with multifid and curled leaves. 37. The branched *hart's tongue* with leaves turning round at the ends. 38. The large *hart's tongue* with the appearance of ſmall leaves growing at the extremities of the ſegments. 39. The many pointed ſcaled *hart's tongue*. 40. The multifid *hart's tongue* with jagged tops. 41. The *hart's tongue* with leaves growing on a middle rib. 42. The branched, rough, and undulated *hart's tongue*. 43. The great knotty branched *hart's tongue*. 44. The great climbing and creeping American *hart's tongue*. 45. The great, branched, climbing, citron leaved *hart's tongue*. 46. The ſmaller climbing branched citron leaved *hart's tongue*. 47. The branched *hart's tongue* with pointed and ſerrated leaves. 48. The oak leaved branched *hart's tongue*. 49. The branched *hart's tongue* with black ſpots on the leaves. 50. The climbing branched *hart's tongue* with narrow undulated leaves. 51. The branched *hart's tongue* with ſerrated ſword like leaves. 52. The branched *hart's tongue* with leaves duſty at the edges. 53. The broad leaved branched *hart's tongue* with the edges ſurrounded with a thin membrane. 54. The golden branched *hart's tongue*. 55. The branched *hart's tongue* with black duſty tubercles. 56. The ſmall, knotty branched *hart's tongue*. 57. The *hart's tongue* with ſinuated leaves, divided into three ſegments at their ends. 58. The cinquefoil branched *hart's tongue* with ſcaly pedicles and ſharp pointed leaves. 59. The trefoil *hart's tongue* with narrow and ſerrated leaves. *Tourn.* Inſt. p. 585. See PUFF *ball*.

LINGUADO, in zoology, the name of a Weſt-Indian fiſh, in ſhape reſembling a ſoal. Its mouth is furniſhed with very ſharp teeth, but has no tongue. It has large gills, with two ſmall fins annext near their bottoms to the under part, or belly. It is of a pale ſtone colour, and is cloathed on the back with very ſmall ſcales. Its tail is almoſt ſquare in ſhape, and made of a very thin fin. It lives in ſhallow water, and keeps cloſe upon the ſand. It, upon the whole, very much approaches to our ſoal, but principally differs in that the fins under its gills terminate in a ſmall filament. *Marggrave*'s Hiſt. Braſ. p. 71.

LINGUATULA, in zoology, the name of a ſpecies of fiſh, ſomewhat reſembling the ſoal, but ſmaller and ſhorter, and much inferior to it in taſte. It is common in the Mediterranean, and brought to market at Rome, Venice, and elſewhere, and is called by other authors *cynogloſſus*, and *citharus flavus*, or *citharus aſper*. *Willughby*, Hiſt. Piſc. p. 101. See the article CYNOGLOSSUS.

LINGUIFORM *leaf*, among botaniſts. See LEAF.

LINGULA, in zoology, the name of an extremely ſmall fiſh of the ſoal kind. It is known from the reſt of this genus not only by its ſmallneſs, but by a ridge of ſmall ſcales which

which run along the line over the ſpine, and are much more elevated and diſtinguiſhable, both to the eye and touch, than thoſe of the reſt of the body. It is a well taſted fiſh, and much firmer in its fleſh than the ſoal, but is very ſcarce, and is of little value, becauſe of its thinneſs. It is caught in the Mediterranean. *Geſner.* p. 786.

LINGULACA, in zoology, a name by which ſeveral authors, particularly ſome of the older naturaliſts, have called the *ſoal fiſh*. *Willughby*, Hiſt. Piſc. p. 100.

LINIFICUS *lapis*, a name given by ſome authors to a ſtone, which was ſaid to cure the epilepſy when taken internally. It ſeems to have been a name given by ſome fanciful writers to the *alumen plumoſum*.

LINIMENTUM *album*, a form of medicine differing in nothing from the *unguentum album*, but in that it is a little ſofter: they are both preſcribed in the late London Pharmacopœia, and both made of the ſame ingredients. The preſcription for this is as follows. Take oil olive three ounces, ſperma ceti ſix drams, white wax two drams; melt all together over a gentle fire, ſtirring it till it is perfectly cold. *Pemberton*'s London Diſp. p. 372.

LINIMENTUM *ſaponaceum*, the ſoap *liniment*, a form of medicine preſcribed in the late London Pharmacopœia, and meant to ſupply the place of the ointment well known by the name of *opodeldoch*. It is made thus. Take ſpirit of roſemary a pint, hard Spaniſh ſoap three ounces, camphor one ounce; digeſt the ſoap with the roſemary ſpirit till it is diſſolved, and then add the camphor. When this is melted, the whole is finiſhed. *Pemberton*'s London Diſp. p. 372.

LINIMENTUM *volatile*, a form of medicine preſcribed in the late London Diſpenſatory, and ordered to be made of oil of almonds an ounce, ſpirit of ſal armoniac, made without lime, two drams; theſe are to be ſhook together in a wide mouthed vial, till they are perfectly mixed. *Pemberton*'s London Diſp. p. 374.

LINKIO, in botany, a kind of water plant among the Chineſe, the fruit of which is of a triangular pyramidical form, prominent every way with a green thick rind, that grows reddiſh towards the apex, and, when the fruit is dried, grows black. The internal ſubſtance is exceeding white, its taſte like that of a cheſnut, three or four of which it equals in bulk. The plant is found in ſtanding waters, and has very ſlender leaves, that ſpread themſelves over a large extent on the ſurface of the water, and the fruit lies concealed under water in great numbers. Vid. *Hofm.* Univ. Lex. in voc.

LINNÆA, in botany, the name of a genus of plants, given by Gronovius in honour to his friend Linnæus, the characters of which are theſe. The cup is a double perianthium. The perianthium of the fruit conſiſts of four leaves, two of theſe which ſtand oppoſite to one another are ſmall and acute, and the other two are elliptic, hollow, acute, and hairy: theſe embrace the germen, and remain after the flower is fallen. The perianthium of the flower ſtands upon the germen, and is narrow, erect, and acute, and compoſed of one leaf divided into five ſegments. The flower is monopetalous, of a turbinated form; it is twice as large as the cup, and is lightly divided into five ſegments at the edge. The ſtamina are four ſubulated filaments, inſerted in the baſe of the flower; two of theſe are very ſhort, but the two longer are not ſo long as the flower. The antheræ are of a compreſſed figure, and can turn round upon the ſtamina. The germen of the piſtil is roundiſh, and is placed within the cup. The ſtyle is ſtrait and ſlender, and is of the length of the flower; it always bends toward one ſide, and is terminated by a globoſe ſtigma. The fruit is a dry oval berry of two cells, and is covered with the hairy and glutinous cup of the flower. The ſeeds are ſingle and roundiſh. *Linnæi* Gen. Pl. p. 299.

LINNET, *linaria*, in zoology. See LINARIA.

It is remarkable of this bird, that when it builds in hedges, and when in furz buſhes on heaths, in both which places the neſts are very common, they are made of different materials. When they build in hedges, they uſe the ſlender filaments of the roots of trees, and the down of feathers and thiſtles; but when they build in heaths, they uſe moſs, principally, for the outer part, finiſhing it within with ſuch things as the place will afford. Theſe birds will have young ones three or four times a year, eſpecially if they are taken away before they are able to leave the neſts.

When they are intended to be taught to whiſtle tunes, or to imitate the notes of any other bird, they are to be taken from the old one when they are not more than four days old; for at this time they have no idea of the note of the old ones, and will readily be taught to modulate their voice like any thing that is moſt familiar to their ears, and within the compaſs of their throats. There requires more care in the feeding them when they are taken thus young, than when they are left in the neſt till nearly fledged, but they will be reared very well upon a food half bread, and half rape-ſeed, boiled and bruiſed: this muſt be given them ſeveral times a day. It muſt be made freſh every day, and given them ſufficiently moiſt, but not in the extreme. If it be in the leaſt ſour, it gripes and kills them; and if too ſtiff, it is as miſchievous by binding them up.

They muſt be hung up as ſoon as taken from the neſt, under the bird whoſe note they are intended to learn; or if they are to be taught to whiſtle tunes, it muſt be done by giving them leſſons at the time of feeding, for they will profit more while young in a few days, than in a long time afterwards, and will take in the whole method of their notes before they are able to crack hard ſeeds. Some have attempted to learn them to ſpeak, in the manner of the parrot or other birds, and they will arrive at ſome ſort of perfection in it with great pains.

LINOZOSTIS, in botany, a name given by the antient Greek writers to two plants very different from one another; the one is the *mercurialis*, or Engliſh mercury, a plant common in uncultivated places, and eaten by many boiled in the manner of aſparagus; the other the *epilinum*, or dodder, growing upon the plants of flax.

Theophraſtus, Dioſcorides, and the antient Greeks, uſe the word in the firſt ſenſe, and the modern Greeks in the latter. The Latin authors call this *linozoſtis*, or *epilinum*, ſometimes *angina lini*, and *podagra lini*, looking on it as a diſeaſe which choaks the plant it grows on, and cauſes gouty tumors on the ſtalks.

Dodder, or *cuſcuta*, is a paraſitical plant never taking root in the ground, but always growing upon the ſtalk of ſome other herb. When it grows on thyme it is called *epithymum*; when on the nettle *epurtica*; and ſo on of all the other plants. Aviſenna calls it *keſuth*, or *keſluth*, and Theophraſtus *caſuta*. It ſeems indeed that Dioſcorides confounded the *cuſcuta*, or dodder growing upon the thyme, with the thyme itſelf; for he compares the ſeed of alypum to that of epithymum, and it is found to be very like that of thyme.

LINSEED *(Cycl.)—Linſeed*, from which the oil has been expreſſed, boiled in milk, and applied warm in a cloth to herniæ, is much recommended in the Satyr. Sileſiac. Specim. 4. Obſ. 4.

LINSPINS, are ſmall pins of iron which keep the wheel of a cannon, or waggon, on the axletree; for when the end of the axletree is put through the nave, the *linſpin* is put in to keep the wheel from falling off.

LINT, in ſurgery, is the ſcraping of fine linnen uſed by ſurgeons in dreſſing wounds. It is made into various forms, which acquire different names according to the difference of their figures.

Lint made up in an oval, or orbicular form, is called a *pledgit*; if in a cylindrical form, or in the ſhape of a date or olive ſtone, it is called a *doſſil*. See DOSSIL.

Theſe different forms of *lint* are required for many purpoſes, as 1°. to ſtop blood in freſh wounds, by filling them up with dry *lint* before the application of a bandage: though if ſcraped *lint* be not at hand, a piece of fine linnen may be torn into ſmall rags, and applied in the ſame manner. In very large hæmorrhages the *lint*, or rags, ſhould be firſt dipt in ſome ſtyptic liquor, alcohol, or oil of turpentine, or ſprinkled with a ſtyptic powder. 2°. To agglutinate and heal wounds; to which end *lint* is very ſerviceable, if ſpread with ſome digeſtive ointment, or balſam, or dipt in ſome vulnerary liquor. 3°. In drying up wounds and ulcers, and forwarding the formation of a cicatrix. 4°. In keeping the lips of wounds at a proper diſtance, that they may not haſtily unite, before the bottom is well digeſted and healed. 5°. They are highly neceſſary to preſerve wounds from the injuries of the air.

Small portions of *lint* tied round with a thread are chiefly uſed in dreſſing wounds and ulcers of the deeper kind. They are always applied to the bottom of ſuch wounds, the remaining cavity being filled up with other portions of *lint*. By this means, the immediate removal of the dreſſings is not only provided for, but the poſſibility of leaving any part of them in the bottom of the wound is prevented.

In very large wounds, and eſpecially in amputations of the limbs, which operations are frequently required in the army and navy, at times when *lint* is very ſcarce, it will be ſufficient to dreſs the bare bone and face of the wound with ſcraped *lint*, filling up the cavity with tow, and covering all with a large compreſs.

Surgeons of former ages formed compreſſes of ſponge, feathers, wool, or cotton, linnen being ſcarce; but *lint* is far preferable to all theſe, and is at preſent univerſally uſed. *Heiſt.* Surg. Introd. Sect. 54.

Incombuſtible LINT. See the article INCOMBUSTIBLE.

LINUM, *flax*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the caryophylleous kind, being compoſed of a number of petals arranged into a circular form, and ariſing out of a many leaved cup of a tubular form. The piſtil ariſes from the ſame cup, and finally becomes a fruit of a ſomewhat globular form, but pointed at the end, and compoſed of a number of capſules, which open inwards, and contain ſeeds of a flatiſh ſhape, and oval figure, rounded at one end, and pointed at the other. See Tab. 1. of Botany, Claſs 8.

The ſpecies of *flax*, enumerated by Mr. Tournefort, are theſe. 1. The common manured *flax*. 2. The broad leaved African *flax* with a larger fruit. 3. The great perennial blue flowered *flax* with large heads. 4. The leſſer perennial blue flowered *flax* with ſmaller heads. 5. The common wild *flax*, reſembling the cultivated kind. 6. The hairy broad leaved blue flowered wild *flax*. 7. The hairy white flowered broad leaved wild *flax*. 8. The ſhrubby *flax* with ſnow-white flowers. 9. The broad leaved yellow flowered wild *flax*. 10. The yellow flowered wild *flax* with roundiſh leaves. 11. The yellow flowered *flax* with flowers at the joints of the ſtalk. 12. The duſky yellow flowered ſhrubby *flax*. 13. The wild yellow tree *flax* of Candy. 14. The ſmall broad leaved annual yellow flowered wild *flax*. 15. The ſmall narrow leaved annual yellow flowered *flax*. 16. The yellow flowered ſea *flax*. 17. The wild blue flowered *flax* with ſharp pointed leaves. 18. The narrow leaved wild *flax* with large white flowers. 19. The narrow leaved wild *flax* with large deep blue flowers. 20. The narrow leaved wild *flax* with very large greyiſh flowers. 21. The narrow leaved wild *flax* with white flowers, variegated with ſtreaks of red. 22. The narrow leaved white flowered procumbent wild *flax*. 23. The leſſer flowered wild *flax* with narrow and thick-ſet leaves. 24. The narrow leaved wild *flax* with fewer leaves. 25. The narrow leaved wild *flax* with fewer leaves and white flowers. 26. The leaſt wild *flax* with very ſmall flowers, called by ſome the leaſt ſmooth ſpring *chickweed*. 27. The rough leaved *flax* with yellow umbellated flowers. 28. The yellow Portugal *flax* with ſpiked flowers. 29. The narrow leaved ſhrubby *flax* with rigid and prickly leaves. 30. The capillacious leaved Portugal *flax*. And 31. The larix leaved alpine *flax*. *Tourn.* Inſt. p. 340. See FLAX.

LINUM *carpaſium*, *carpaſian flax*, or *linnen*, a term often occurring in the old writers, and uſed by different authors in very different ſenſes.

The firſt uſe we find made of the word, is for the expreſſing a kind of *flax* which was finer and ſmaller, as well as brighter and more gloſſy than any other. Pliny uſes the word in this ſenſe, and tells us that ſuch *flax* was principally brought from Spain; and that both it, and the *linnen* made of it, were, at his time, called by the name *carpaſian:* from this it became a cuſtom to call all very fine *flax*, or fine *linnen*, *carpaſian linnen*, and the word ſignified no more than delicate, or fine.

The modern Greeks uſe the word in this ſenſe, and Suidas expreſſes the fineſt *linnen* veils by the term *carpaſian*. The author of the *Periplus maris Erythræi*, who was cotemporary with Pliny, calls the *flax*, of which the Indian *linnens* were made, *carpaſos*; but none of the older Greeks have the word. This author is not, however, to be appealed to for aſcertaining the purity of the language of the antients; for it is plain, that he has taken in many words which are not good Greek, nor ever were uſed by any author of credit, but are the mere technical terms of the tradeſmen and merchants of that time.

Pauſanias uſes the word *carpaſium linum* in a very different ſenſe from all theſe; for with him it is made to expreſs the *flax* made of the ſtone aſbeſtos, and the *linnen* made of this, which was thrown into the fire to be cleaned. Solinus uſes the word alſo in the ſame ſenſe: he ſays, that in Caryſtos there was found that kind of *flax* which remained unhurt in the fire; and Hieronymus Mercurialis thinks that the *carbaſus* of the antient Romans was a word properly uſed only to ſignify the *carpaſian flax* of Pauſanias, which was not to be deſtroyed by the fire, and was the true *linum incombuſtibile*, or threads of the aſbeſtos ſtone, or *linnen* made of that material. This, however, is not the ſenſe of the word in later times, for we find it evidently uſed for all *linnen* manufactures of whatever kind.

Caryſtium LINUM, in natural hiſtory, a name given by Pauſanias to the aſbeſtos, a woolly ſtone of which clothes and paper were made, which, on being heated red-hot in the fire, were cleaned, but not conſumed or injured by it. It was found plentifully, in this author's time, near Caryſtus, a town in the Negropont, and thence obtained its name. See ASBESTOS.

LINUM *catharticum*, *Purging flax*, in medicine, makes a common purge among the country people. It is almoſt as rough as that of *gratiola*. See GRATIOLA.

It is a ſpecies of wild *flax*, and is taken in infuſion in ale. A dram of the powder of the dried herb, or of the freſh leaves bruiſed and formed into a bolus, will anſwer the purpoſe.

It is greatly recommended by ſome in dropſies; and to prevent its griping, they mix aniſe, or ſome other of the carminative ſeeds with it. It is given in moſt chronic caſes, where people's conſtitutions are ſtrong enough to bear it, and often with great ſucceſs.

LION, *leo*, in the Linnæan ſyſtem of zoology, makes a diſtinct genus of quadrupeds, the characters of which are, to have two paps placed on the belly, and feet adapted to climbing. *Linnæi* Syſt. Nat. p. 35.

The head of the *lion* appears very large, in proportion to its body, and is the moſt fleſhy of the heads of all the known animals. Its jaw bones alſo are remarkably large. The breaſt alſo appears very large, but this is only owing to the great quantity of long hair that covers it, for the ſternum is ſmaller than that of moſt animals of the ſame ſize. The tail, which is very long, appears alſo of the ſame thickneſs all the way, but this is wholly owing to the growth of the hair. The tail itſelf is largeſt at the baſe, and thence goes taper to the point; but the hair being very ſhort near its baſe, and continuing to grow longer all the way, as that decreaſes in thickneſs, is ſo exactly proportioned in this growth, that it always gives the whole tail this regular appearance. See Tab. of Quadrupeds, N° 1.

The long hair that grows about the neck and breaſt, and makes what is called the mane of the *lion*, only differs from the hair of the reſt of the body in length, having no greater thickneſs, or rigidity, like that of the manes of other animals. The claws of the *lion* have no caſes, as Pliny pretends that they have, for the animal to withdraw them into in walking; but Plutarch, Solinus, and ſome others, are much more in the right, in ſaying that the *lion* draws them up backwards when he walks, and places them cloſely among the articulations of the toes.

It is certain that the laſt joint but one of every toe in this creature has a peculiarly eaſy joint for motion, and by means of this the laſt joint, with the claw that is affixed to it, are very readily drawn up, and hid upon the foot, and placed wholly out of the way of being hurt in walking. This creature, therefore, does not put the extremities of its toes to the ground in walking, but the termination of each toe, as to its touching the earth, is the joint of the laſt piece with the laſt but one. This drawing up of the laſt joint of every toe, by means of which each claw is hid between the toe it belongs to, and the next, is the effect of a ligament, which in its natural ſtate is ſo ſhortened, as to keep them in this poſition; and it is only by the action of a very ſtrong muſcle, that this joint can be pulled downward, when the claws are to be uſed, the ligament beforementioned always drawing them naturally into their firſt poſition again, as ſoon as the force of that muſcle is over.

The *lion* has fourteen teeth in each jaw, four inciſores, four canine, and ſix molares. The inciſores are ſmall, the canine are unequal in ſize, two being very large, and two very ſmall; the large ones are an inch and half long, and are the only ones that the antients allowed to be canine teeth. The molares alſo are irregular in ſize, the anterior ones being very ſmall, the others large, and terminated by three or four points, forming a ſort of flower de luce.

Ariſtotle, Ælian, and others, ſay that the neck of the *lion* is all compoſed of one unjointed bone. It appears indeed very rigid in this creature, but this does not proceed from ſo ſtrange a cauſe, but is found owing to this, that the ſpinoſe apophyſes of the vertebræ of the neck are long, and faſtened together by extremely ſtrong and rigid ligaments.

The tongue of the *lion* is very rough and rigid, being covered with a great number of prominences of a hard matter, reſembling that of a cat's claws, and theſe are much in the ſhape of thoſe claws, and nearly of the ſame ſize, the baſe of each being a round fleſhy prominence on the ſurface of the tongue.

The eyes of the *lion* are clear and bright, even after the creature is dead. The common obſervation that this creature ſleeps with its eyes open, is founded on this, that it has a very thick membrane lodged in the greater canthus of the eye, which it can extend over the whole eye upon occaſion, as birds do their *membrana nictitans*, and thus will have no occaſion to ſhut its eye-lids, in order to exclude the light. It is very remarkable, that the common cat has all the ſingular ſtructure of the ſeveral parts as the *lion* has, its claws, feet, tongue, and eyes, being of the ſame kind, and its internal parts bearing as ſtrong a reſemblance.

The heart of the *lion* is greatly larger than that of any other creature of the ſame ſize, being ſix inches long, and four in diameter, in the largeſt part, and terminating in a very ſharp point. The brain is as remarkably ſmall; and the compariſon of this with the great quantity of brain in a calf, and purſuing the obſervation through ſeveral other creatures, as to the proportion of brain they have, it does not appear that a ſmall quantity of brain is a mark of folly, but uſually of great ſubtlety, and of a cruel diſpoſition. Memoires pour l'Hiſtoire des Anim. p. 5.

The French, when they had once a ſick *lion*, attempted to recover him from his ſickneſs by ſuch foods as nature never intended him, that is, by the tender and pure fleſh of young animals, without any of the external coat. They gave him young lambs flead alive for this purpoſe; but nature not having given this animal the ſubtlety to flea his food, and the hair, wool, feathers, *&c.* being as neceſſary to theſe beaſts of prey with the fleſh, as that fleſh itſelf, the new food bred too much blood, and proved a worſe diſeaſe than that he had before, ſo that he ſoon died. *Pitfield*'s Hiſt. Anim.

LION-*puceron*, in natural hiſtory, the name given by Mr. Reaumur to a genus of worms which deſtroy the *pucerons* in the ſame manner that the *formica leo* does the ants,

Theſe little inſects are a prey alſo to a ſort of worm hatched from the egg of a two winged fly. This has no legs, and is of ſeveral colours. See the article VER-*puceron*.

Though theſe *lion-pucerons* be all hexapodes, yet they are of different origin; ſome being produced from the eggs of a four winged fly, others from thoſe of a beetle. As the *formica leo* has two horns, the extremities of which ſerve him by way of mouths, our *lion-puceron* has the ſame kind alſo; but as the former of theſe inſects can only move backwards, and is forced to make ſnares for his prey, not being able to hunt it; this creature runs very nimbly in the common way, and ſeizes its prey, without having recourſe to ſuch ſtratagems.

The body of the *lion-puceron* is longer than that of the *formica leo*, and is flat; the breaſt is the thickeſt and broadeſt part of it, and from this it gradually tapers off to a point at the tail. It has two legs fixed to the breaſt, the other four to the anterior rings of the body, and when it moves, the poſterior end of the body ſerves it in the place of a ſeventh leg, for it always bends it downward, and draws it along the ſurface it walks upon. The back of this creature is not ſmooth or gloſſy, but is every where rough, and full of wrinkles, and ſeems as if every ring of it was compoſed of ſeveral other ſmaller rings.

This is the general deſcription of the creature, treating of it in a general way, theſe characters ſuiting all the kinds of it. There are others, however, by which the whole claſs may be divided into three principal kinds.

The moſt common ſpecies is diſtinguiſhed by a peculiar character, which is, that it is hairy at the ſides, or, to ſpeak more determinately, every ring of the body has on each ſide, juſt in that part where the back and the belly meet, a fleſhy tubercle, or protuberance, which carries a tuft of ten or twelve hairs. There are of this kind of ſeveral ſizes and colours, and the moſt frequent are of a cheſnut, or yellowiſh hue on the back, and white on the belly.

Theſe are much more voracious devourers of the *pucerons*, than the worms which feed on them. A ſmall *puceron*, ſeized by one of them, is eaten in an inſtant, and the very largeſt is not the work of half a minute for them. Theſe creatures are very ſmall when firſt produced from the egg, and yet they immediately begin to feed. They are ſo ravenous of food alſo, that whenever they can they catch and eat one another. But as the *pucerons*, among which they live, are eaſier to be caught, they uſually eſcape one another's fury pretty well; unleſs where there is a ſcarcity of the *pucerons*, or when they offend one another.

Mr. Reaumur put twenty of theſe creatures together into a box, where they had no other food, and where they could not eſcape one another, and theſe were very ſoon reduced to three or four. It is eaſy to conceive that a creature, which feeds ſo very faſt, muſt ſoon arrive at its full growth; and this is the caſe with theſe animals, for within five or ſix days of their being hatched from the egg, they are ready for their final transformation, or the putting on the form of the animals to whoſe eggs they owed their origin. In order to this, the creature leaves the place where he has hitherto fed, and ſeeks the folds of a leaf, or ſome other ſuch convenient receptacle, where it ſpins a web of very fine ſilk, every way ſurrounding its body with it, and under this cover paſſes the ſtate of a nymph or chryſalis. The ſilk of this web is not only very ſtrong, but the threads are very cloſely laid together, ſo that it is much firmer than the webs of any of the caterpillar kind. It is of a roundiſh figure, and is ſomewhat ſmaller than a pea.

This round figure is owing to the form into which they roll up their body, which ſerves as a mould for it; and the orifice, out of which the ſilky matter is produced, is at the extremity of the poſterior part of the body. The creature continues in this ſtate about three weeks, if it be in the beginning of the ſummer that it goes into it; but if toward autumn, it remains in it all the following winter; and is afterwards, in ſpring, ſeen to come out in the form of a very beautiful fly, of a remarkably large ſize, in proportion to the creature it is produced from, and the web out of which it comes. It is a very long bodied one, and much reſembles the libella or dragon fly, only that its wings are larger in proportion to its body: theſe wings are of a moſt delicately fine ſtructure, the fineſt gawſe being coarſe and thick in compariſon to them. Theſe, when the creature is at reſt, are placed in an angle over the body, and form a ſort of canopy or tent for it, but they are ſo perfectly tranſparent that the body is eaſily ſeen through them. The body and breaſt are all green, and that of a very beautiful tinge; but the moſt remarkable beauty of this creature is its eyes; theſe are large and prominent, and are of a fine gold colour, and of greater luſtre than the moſt highly poliſhed metal.

The eggs of this fly are a very ſingular object, and cannot have eſcaped the eye of any perſon who is converſant among the inſects which live on trees; though of the many who have ſeen them, perhaps few or none ever found what they really were. It is common to ſee on the leaves, and pedicles of the leaves of the plum tree, and ſeveral other trees, as alſo on their young branches, a number of long and ſlender filaments, running out to about an inch in length, and being of the thickneſs of a hair; ten or twelve of theſe are uſually ſeen placed near one another, and a vaſt number of theſe cluſters are often found on the ſame tree. The end of each of theſe filaments is terminated by a ſort of ſwelling or tubercle of the ſhape of an egg. People who have obſerved theſe, have generally ſuppoſed them to be of vegetable origin, and that they were a ſort of paraſitical plants, growing out of others, as the miſletoe, moſſes, *&c.* from the oak and other trees. They very much reſemble in figure thoſe ſpecies of mouldineſs, which Malpighi and others have figured under the ſhape of little muſhrooms, only they are much larger than thoſe little plants, and bear the heat of the ſun and other accidents uninjured, which would deſtroy the tender plants of that kind. There is a time, when theſe egg-like balls, which terminate every one of theſe filaments, are found open at their ends, and in this ſtate they very much reſemble flowers, and they are in this ſtate figured by ſome authors under the name of flowers of a ſingular kind, found on the leaves of the willow. All this, however, is wholly erroneous, and the purſuing the hiſtory of our *lion pucerons*, ſhews their true origin to be from the fly of that creature. What theſe authors took for flowers of the willow were only the eggs of this fly, out of which the young animals had been hatched, and had made their eſcape. The leaves and branches on which theſe eggs are found, are uſually ſeen covered over with the *pucerons*; and the creature providing a place where her young ſhall find nouriſhment as ſoon as hatched, places her eggs in the midſt of theſe harmleſs and defenceleſs animals, fixing each on a ſlender pedicle, yet ſufficiently ſtrong to ſupport its weight. If theſe eggs be nicely examined, a worm may be diſcovered in them while yet whole; but the moſt certain way of judging of them, is, to put ſeveral of them into a box, in which caſe every one of them is found at a proper time to hatch, and to give an inſect; which, when viewed by the microſcope, appears plainly to be a *lion puceron* in all its parts, and requiring only increaſe in ſize, without any change of ſhape, to be one of thoſe we have already deſcribed, as feeding ſo voraciouſly on the *pucerons*. *Reaumur's* Hiſt. Inſ. Vol. 6. p. 142.

The manner in which the parent fly places her eggs in this ſingular way on the trees, is a ſubject that greatly excited the curioſity of Mr. Reaumur. He often watched the animals in vain, in order to ſee them employed in it; and, in fine, ſhut up ſeveral of them in boxes. The conſequence of which was, that they fixed their eggs on long pedicles, to the ſides of the box, in the ſame manner, that they before had to the ſides of the branches, or leaves of trees; but he never could find them employed about it. The manner in which he ſuppoſes it done, however, appears very rational, and is as follows:

The egg is ſuppoſed, while in the body of the inſect, to be covered with a tough glutinous matter, capable of drying very ſuddenly in the air. The creature, when the egg begins to come forth, applies the extremity of it to ſome ſolid body, as a leaf, or ſtalk of a plant, and then drawing herſelf away, there follows a thread or filament of this viſcous matter, which is faſtened at one end to the leaf, and at the other to the egg in her body. When ſhe has drawn this out, to an inch in length, ſhe ſtops a moment, and the whole will harden into a ſolid matter; and, on her next motion, will draw out the egg from her body, and will become a pedicle to it. In this condition it will remain till the egg is hatched, and then the young inſect needs only to deſcend downward on the leaf, on which the pedicle is fixed, and it will find itſelf in the midſt of plenty of food.

Mr. Piſtorius found a number of theſe eggs on a cherry; he diſtinguiſhed them very plainly to be eggs, and preſerved them till they hatched. The young ones died with him for want of nouriſhment; but, by his figures of them engraved from the microſcope, it appears very plainly, that they were the very inſect we have deſcribed under the name of the *lion puceron*.

The ſecond kind of theſe inſects differs from the firſt in no other particular, but that it has no tufts of hairs on its ſides, and in that it is not of a yellow or brown colour as thoſe of the firſt kind are, but of a duſky grey. This after it has lived its proper time in this ſtate, becomes alſo a chryſalis of a round figure, and of the ſize of a pea, enveloped in a web of ſilk of its own ſpinning. After the creature has remained a month in this ſtate, it comes forth in the form of a four winged fly; which, however, is very different from that produced by the firſt kind. Its body is oblong, but leſs long than that of the former; and its wings are extremely different, being as remarkably opake in this, as they are remarkably tranſparent in the other; the outer wings are of a browniſh red, and the inner ones of a yellowiſh colour; the outer ones are conſiderably the moſt opake and thick, and indeed they not a little reſemble the upper wings of the graſhoppers. *Reaumur's* Hiſt. Inſect. Vol. 6. p. 139.

The third kind of theſe inſects is very different from the other two. It is conſiderably ſmaller and thicker bodied, the others being both very flat. This feeds on the *pucerons* in the manner of the others, but it is ſo voracious, that

it

it will ſeize on almoſt any thing. Mr. Reaumur tried it with a hexapode worm of a beetle, which it immediately ſeized upon, though three times as big as itſelf, and ſoon ſucked it abſolutely dry, leaving nothing but ſkin. It is very ſingular alſo in its way of living, as it does not remain naked in the manner of the other kinds, but has always a ſort of houſe or cave over it, in the manner of the common moth found in cloth. This caſe of the *lion puceron* is ſo large, that it ſeems a great burthen for the creature to carry; it covers it all over from the neck to the extremity of the body, and even reaches far beyond it. This caſe is made up of ſeveral coloured filaments, reſembling a ſort of down. Some of theſe are white, others brown, and others yellowiſh. This caſe is made of the ſkins and down of the *pucerons* which the creature has eaten, and if theſe were not in the way it would have made one of any thing elſe. Nature has made this animal tender, and rendered a covering neceſſary, and the creature always prepares itſelf one, out of whatever materials it finds moſt ready.

Mr. Reaumur took the covering off from one of them, and put it naked into a box, where there was a web of a ſilk worm. The creature immediately made itſelf a covering of the fragments, into which it broke the threads of ſilk; and another, in the ſame manner, made itſelf one of ſome ſcraped paper. There is no great ſkill employed in the fabric of this, but the things are coarſely laid together, and hang to one another, and to the inequalities of the body. The manner in which the creature forms it, is only by taking the particles of which it is compoſed ſeverally between its horns, and throwing them over its head, ſo that they may fall on ſome part of the back. This ſpecies, like the two before deſcribed, ſpins itſelf a round web, and after lying about a month in the chryſalis ſtate, it comes forth in form of a four winged fly; and is ſo like the beautiful fly produced from the firſt ſpecies, that it is ſcarce to be known from it, unleſs by its being ſmaller.

Theſe are the *puceron lions* which finally change into flies; but beſide theſe, we have another kind, which have alſo ſix legs, and which finally become beetles: theſe are the worms of a large claſs of ſmall beetles, one of which is extremely common among us, and known to children by the name of the cow lady: as this is yellow, ſpotted with black, there are others which are blue, brown, reddiſh, and of other colours, but all ſpotted in that manner. *Reaumur*'s Hiſt. Inſ. Vol. 6. p. 152.

The worms of all theſe are *puceron lions*; they are oblong and flat, their hinder extremity terminates in a point, and their breaſt is the largeſt part. Their legs are all faſtened near the head; and they have at the extremity of the head two hooks, in the manner of other worms of the fly kind. They are uſually of a rounded figure, in their common ſituation on the leaves of the trees; and as they are hereafter to become beetles, of ſeveral different kinds, they are themſelves of different colours, ſome yellowiſh, ſome greeniſh, and ſome grey, theſe laſt are uſually ſpotted with ſeveral browniſh or black ſpots.

The parents of theſe lay their eggs indifferently on any part of the tree; and the young ones, as ſoon as hatched, are to crawl over the leaves and branches, till they find ſome place where the *pucerons* are; and then they fix their habitation there, till they have eaten all up, or till they have lived their appointed time.

When the period of their change is near, they forbear eating, and ſoon after they faſten themſelves by the hinder part to a leaf; and there, without ſpinning a web, wait for their final transformation, which is made in a caſe or ſhell, formed of their own ſkin dried and hardened. After they have drawn their bodies as ſhort as can be, they remain about a fortnight in this ſtate, and then come out in the form of a lady-bird, or ſome other ſmall beetle of that form. The female of which afterwards lays a number of oblong eggs of the colour of amber; from theſe are ſoon hatched the creatures we have been deſcribing; which, as ſoon as well out of the egg, travels about the tree or plant in ſearch of the cluſters of the *pucerons*.

Ant-LION, *Formica* LEO. See FORMICA *leo*.

LIONS *tail*, in botany. See LEONURUS.

LIONESS, *leæna*, a female *lion*. See LION.

The *lioneſs* has no mane, or long hairs upon the neck and breaſt, which ſo remarkably characterizes the *lion*. The noſe alſo is longer in the *lioneſs*, and the head more flatted in the upper part. The claws alſo are much ſmaller than thoſe of the male *lion*. This creature, when full grown, is about three feet high, from the fore feet to the ridge of the back, and about five feet long from the end of the noſe to the inſertion of the tail, which is about two feet and a half long. The claws are of a fibroſe texture, the fibres being very hard in themſelves, but eaſily ſeparable from one another. In other particulars the *lioneſs* very little differs from the *lion*. See Tab. of Quadrupeds, N° 2. and the article LION.

LIONINE, or LIONADE, in the hiſtory of the coins current in Ireland, a name given to certain coins, imported privately from France and other places. There were beſide theſe many others of the ſame ſort, impreſſed with eagles, roſes, and the like, and called by names ſignifying thoſe impreſſions. They were a very baſe and poor ſort of money. The penny *lionade*, or *lionine*, not coming up to the value of the half-penny of the coin of the kingdom. They were diſcountenanced in the year 1300; and good money being ſtruck there, it was made death, and confiſcation of goods to import any of them; and the run of them was thus ſtopped. *Simon*'s Iriſh coins.

LIP (*Cycl.*)—*Wounded* LIPS. Wounds of the *lips* are made either with ſharp or with blunt inſtruments, or elſe with bullets. Thoſe of the firſt ſort, whether longitudinal, or tranſverſe, are generally to be cured by the dry ſuture. The patient, while under cure, muſt avoid talking and chewing; his diet therefore muſt be ſpoon meat. But in caſes where the wound is very large the bloody ſuture is ſometimes neceſſary. In wounds of the *lips* made by blunt inſtruments, by falls, or by bullets, the ſhattered parts muſt be brought to digeſtion; and the *lips* of the wound, after being cleaned, brought together, either by means of ſticking plaiſters, or by the ſuture uſed in the hare *lip*. *Heiſter* Surg. 81.

LIP *of a horſe*, in the manege, is the ſkin that covers the ſides of his mouth, and ſurrounds his jaws. A horſe is ſaid to arm or guard himſelf with his *lips*, when his *lips* are ſo thick, that they cover their bars, and keep off the preſſure of the curb.

LIPA, a word uſed frequently by Hippocrates to expreſs any thing fat or oily. He calls certain ſtools, which have a fatty appearance by this name. Theſe are eſteemed a ſign of great colliquation; he alſo applies it to a ſort of fatty ſubſtance, often ſeen ſwimming on the ſurface of the urine like a ſpider's web; this the ſame great author gives as a ſign of a conſumption.

LIPARÆUS *lapis*, in the natural hiſtory of the antients, the name of a ſtone uſually found in Lipara, one of the Æolian Iſlands, and brought thence in the time of the Greeks among the pumices, of which that place always afforded them a large quantity.

It was a ſmall ſtone, about the bigneſs of a filbert, of an irregular and uncertain ſhape, and porous and friable conſtitution, like that of the pumices, but more eaſily falling to pieces on rubbing between the fingers, than even the ſofteſt of them; the colour was a duſky grey, and the whole external ſurface plainly ſhewed that it had ſuffered changes by the means of fire. The antients had theſe ſtones in great eſteem; and Pliny has recorded an idle tradition concerning them, which ſeems to have been then generally believed. This was that all ſorts of wild beaſts were got together by the burning of it. The ſtone, at preſent, however, is ſo little regarded, that the writers on ſuch ſubjects have even forgot to name it; and Wormius, the only one of the late naturaliſts, who ſeems to have had the ſtone, and given it a place in his muſæum, and a deſcription in his hiſtory of it, yet has not honoured it with any particular name, and ſeems not to have known that it ever had any. They are ſometimes brought to us, to this day, among the pumices from the burning mountains, but are not regarded. *Hill*'s Theophraſtus, p. 36.

LIPARIS, in zoology, the name of a fiſh of the general order of the anguilliformes, or eel ſhaped, and moſt approaching to the alauda, of any ſpecies. Its head is ſhaped ſomewhat like that of a rabbet. Its mouth is ſmall, and its jaws rough, but deſtitute of teeth. It has a broad back fin reaching from near the head to the tail. It is covered with ſmall ſcales, and has two pair of belly fins, the one placed under the gills, the other lower down, and another from the anus to the tail which is forked. It ſeems one lump of fat within, not only the inteſtines being loaded with fat, but it in a manner ſupplying the place of fleſh under the ſkin. It is brought to the table among other ſmall fiſh, but is of an inſipid taſte, and generally either offends the ſtomach, or urges to ſtool. It is caught in the Mediterranean and other ſeas. *Rondelet* de Piſc.

The name is originally Greek, and is formed of the adjective λιπαρὸς fat.

LIPARIS is alſo uſed by ſome for the fiſh, called by authors the *gunnellus*, and by the people of Cornwall the butter fiſh. *Ray*'s Ichthyog. p. 115. See the article GUNNELLUS.

LIPARIS, in botany, a name given by ſome authors to the pinguicula, butterwort, or Yorkſhire ſanicle.

LIPARIS *noſtras*, in zoology, the name of a ſmall fiſh common on the coaſts of Yorkſhire and ſome other parts of England, and called in Engliſh the *ſnail*, and *limax marinus* by ſome authors. It is about five fingers long. On its back and ſides it is of a bright brown, and on the belly of a fine white. Theſe are its colours, when freſh taken, for when it has been kept ten or twelve hours, the whole ſurface of the body, except the fins, becomes of a paler and bright brown. The head is thick, and not flat, but rounded. It has no teeth, but its jaws are both rough like files. The apertures of the gills are ſmall holes, ſcarce large enough to admit a pea; and over the root of the firſt pair of fins there is a ſort of valve which the fiſh opens and contracts at pleaſure; and under the throat there is a round ſpot, exactly reſembling the impreſſion of a ſeal; this is of a blueiſh white, and has twelve ſmaller ſpots of the ſame colour ſurrounding

ſt. The tail has much the appearance of that of an eel. The whole fiſh, head as well as body is very ſoft and unctuous, and eaſily melts into a ſort of oily liquor. It is caught principally at the mouths of great rivers where they open into the ſea. *Ray*'s Ichthyogr. Append. p. 17.

LIPOTHYMIA, (*Cycl.*) in medicine, the name of a diſeaſe uſually confounded with the ſyncope, but really different from it in many particulars.

The *lipothymia* is a very conſiderable abolition of the vital and animal faculties, at leaſt to appearance: and the ſyncope is a plenary or total abolition of them, as far as appears to us at the time. It is eaſy to ſee, however, that theſe are only two different ſtages of the ſame diſtemperature. The *lipothymy* is ſometimes an idiopathic, ſometimes a ſymptomatic diſeaſe, and moſt frequently attends the ſcurvy, malignant fevers, and other diſorders: the ſyncope is idiopathic, and attacks perſons in health as well as thoſe that are diſeaſed. The *lipothymy* is always eaſily diſtinguiſhed from a convulſed ſtate of the body, by this, that the limbs are all flaccid in it. The ſyncope differs from death only in degree; and the body being flaccid in this, and growing rigid under the laſt convulſions in death, is the only diſtinction of them in extreme caſes.

Signs of it. The *lipothymia* is uſually preceded by a remarkable anxiety about the heart, and this is ſucceeded by an immediate loſs of life and motion for a time: the ſenſes, the animal motions, and even the pulſe, ſeeming all to be loſt for a time; and the heart flutters weakly, or trembles, and reſpiration is ſcarce ſenſible. In the ſyncope, the reſpiration as well as the pulſe ſeem wholly impeded, and the patient appears wholly dead; the face looks as pale as in a corpſe, and the limbs are wholly flaccid, and without motion. The extremities grow cold, and the eyes are either ſhut, or turgid, and inflamed; the mouth is ſometimes ſhut, but not clenched firmly together as in convulſions, and ſometimes it continues frightfully open; and as ſoon as the patient comes to himſelf he uſually ſighs ſeveral times, and reſpiration ſeems very much laboured.

Perſons ſubject to it. The idiopathic *lipothymy* is a very uncommon complaint, and the perſons ſubject to it are thoſe of a tender and ſenſible diſpoſition, who are eaſily affected by the ſeveral paſſions, and particularly by fear, or ſuch as have been before frequently ſubject to it in diſeaſes, or are of a melancholic habit. People who uſe inceſſant ſtudy for a long time on many occaſions, alſo ſometimes fall into it, women with child are alſo ſubject to it from the preſſure of the breaſt from the abdomen; and unmarried women, when they faint at meals, give too much cauſe to ſuſpect this to be the caſe with them. Some people who are paſſionate, and ſuppreſs violent fits of it while at their meals, fall into faintings alſo.

The ſymptomatic *lipothymy* is a very common diſorder, and ariſes from a great number of different cauſes. Women who have ſuppreſſions of the menſes are very frequently ſubject to it. People fatigued with violent emetics alſo often fall into it, as do alſo perſons exhauſted by violent hæmorrhages, by profuſe ſweats, diarrhœas, violent pains of any kind, and by want of food. People, on the contrary, who are very voracious, and load the ſtomach with great quantities of food as often fall into it; and women after hard child birth, or too great a flux of the lochia are very ſubject to it. People who have taken poiſons, and ſuch as have taken violently cooling medicines alſo ſometimes are ſubject to it; and thoſe, who in fevers, ſuddenly cool themſelves, and check their ſweats, or who once load the ſtomach with great quantities of food immediately after recovering from illneſſes. The approach of epidemical malignant fevers is often preſaged by faintings; and finally, people are ſometimes ſubject to them from omitting any cuſtomary evacuations.

Prognoſtics in it. An idiopathic *lipothymy*, which happens in healthy, but very tender and ſenſible, or melancholic perſons, and has had a fright, or ſome other paſſion for its origin, is a thing of no great conſequence for the preſent; but it is apt to grow upon people if not taken care of, and they will be perhaps always ſubject to it afterwards. *Lipothymies*, when ſymptomatic, are of much more conſequence. In chronic diſeaſes they are leſs dangerous ſymptoms than in acute ones if attended with faintings in the beginning; for theſe often prove dangerous. In other ſtages of acute diſeaſes, faintings are always bad ſymptoms; but when they are owing to the ſuppreſſion of ſome habitual excretion, during the courſe of the diſeaſe, they are of leſs danger than when they appear without ſuch cauſes. All faintings that attend other diſeaſes are however to be regarded only as ſymptoms, not treated diſtinctly; and when the diſtemper which occaſioned them goes off, they naturally follow it. Syncopes that often return upon a perſon, and continue for a long time, frequently leave fevers behind them. Syncopes from hæmorrhages are often dangerous, eſpecially in perſons not accuſtomed to them, and to ſuch as are of a timid diſpoſition; whence women in childbed, who are ſubject to faint, are to be carefully watched, for they ſometimes die in theſe fits.

Method of cure. In idiopathic *lipothymies* ſtimulating glyſters, the ſprinkling of cold water upon the face, and the penetrating ſmells, ſuch as thoſe of the volatile ſalts, ſpirit of hartſhorn and Hungary water, all tend to recover the loſt motion. To theſe are to be added undreſſing, or looſening the clothes, lying down in a warm bed, frictions, ſternutatory powders, and the laying a little pepper, or a ſmall morſel of ſome pungent volatile ſalt upon the tongue. After the patient is, by this means, brought to himſelf, a glaſs of warm wine, with ſome tincture of ſaffron, is very proper to recruit the ſtrength; and if there be danger of a fever coming on, that is to be guarded againſt, by giving powders of nitre, crabs eyes, diaphoretic antimony, and a little cinnabar. In caſes where faintings happen from an over repletion of the ſtomach, or from a weakneſs of the primæ viæ, with crudities lodged there, and attended with eructations, the uſe of digeſtive medicines is proper; and vomits ſhould be now and then given with them. When the faintings happen from the violence of emetic medicines, burnt wine, with the ſpices, is to be taken occaſionally in the day time, and a moderate doſe of the theriaca at night. When faintings have been brought on by violent paſſions, a vomit ſhould always be given; and when the operation of that is over, the nitrous and abſorbent medicines ſhould be given for a day or two, to prevent a fever, which often attends faintings from ſuch cauſes. When they happen to people exhauſted by repeated hæmorrhages, or by diarrhœas, profuſe ſweats, or other evacuations, the analeptics are the proper medicines to carry them off, and reſtorative electuaries, with coral and the like, are to be given; and the frequent eating of jellies, and other rich foods of that kind, recommended by way of prevention. The crudities of the primæ viæ muſt be cleared off by digeſtives and purging medicines; the mind muſt be unbent from ſtudy, and kept free from the violence of all paſſions; the neceſſary and habitual excretions muſt be, by all means promoted; and the patients ſhould always have ſalts, and volatile ſpirits about them, to uſe on occaſion of being threatened with a fit. Finally, moderate exerciſe is always to be adviſed. In the time of the fits ſtimulating glyſters are never to be given, before it has continued a quarter of an hour; and in general, where there remains any ſign of life, they are not neceſſary; and during the time of the fit, an internal medicine muſt be given with the greateſt caution; for they are apt to paſs into the aſpera arteria. People, juſt recovered out of a fainting fit, are not to be ſuffered to ſleep, if they ever ſo much deſire it; and after the paroxyſm is thoroughly over, a chearfulneſs of temper will do more towards a thorough cure, and the prevention of returns, than all the medicines in the world. If a fever comes on immediately after the fainting, then the uſe of a glaſs of wine, ſo beneficial on all other occaſions of this kind, is not to be allowed, but recourſe is immediately to be had to antifebrific medicines. Vomits are very proper in faintings occaſioned by paſſion or terror, in the time of eating a hearty meal, or immediately after it; for it is much better that the food ſhould be thrown up undigeſted, than remain ſo in the ſtomach.

Many people are ſubject to faintings after bleeding; in this caſe the arm ſhould be but gently tied up, and they ſhould never be blooded after a full meal, nor get up immediately after the bleeding is over.

It is very obſervable, that in faintings ariſing from a preſent cauſe, as in the juſt mentioned article of bleeding, the patient has at firſt ſome power of motion, though on a confuſed principle, and will often, before he faints, violently attempt to prevent the ſurgeon from tying up the arm; but in thoſe faintings, which are preſages of future miſchief, the patient always falls down at once to the ground, and has no power of motion, or ſenſe of it, in its approach. *Junker*'s Conſp. Med. p. 673, ſeq.

LIPPIA, in botany, the name of a genus of plants, the characters of which are theſe. The perianthium is roundiſh, flatted, and perpendicular, and on each ſide is enlarged by a ſmall margin, its tranſverſe diameter being greater than its length. This cup remains till the ſeed is ripened. The flower conſiſts of one petal, and is open and bellied, and its edge is divided into four ſegments, which are rounded at the ends, and the upper and lower ones larger than the ſide ones; the upper ſegment alſo bends back. The ſtamina are four filaments, two of which are longer than the others, but they are all ſhorter than the flower. The antheræ are ſimple. The germen of the piſtil is of an oval figure. The ſtyle is of the ſame length with the ſtamina, and ſtands in the ſame direction. The ſtigma is marginated. The fruit is a bivalve capſule of a compreſſed figure, and the ſeeds are contained two in its ſingle cell: theſe uſually alſo grow together. Many of the fructifications of this plant are uſually collected into a head. *Linnæi* Gen. Pl. p. 299.

LIPTOTES, in rhetoric, a figure, wherein, by denying the contrary of what we intend, more is ſignified than we would ſeem to expreſs: thus in the following verſe of Virgil,

Quid prodeſt, quod me ipſe animo non ſpernis, Amynta?

See *Voſs*, Rhet. l. 4. p. 183.

LIPYRIA, a name given by ſome medical writers to a dangerous ſpecies of fever, in which the outſide of the fleſh is cold, while the inſide is very hot.

LIQUAMEN *pyriticum*, in natural hiſtory, a name given by ſome authors to the liquid matter remaining in the pans in which the common vitriol is made; after which no more of that ſalt will ſhoot. It is otherwiſe called *liquamen of vitriol*. See VITRIOL.

LIQUAMUMIA, a term invented by ſome of the diſpenſatory writers to ſignify human fat.

LIQUID (*Cycl.*)—See FLUIDS, *Cycl.* and *Suppl.*

LIQUID *alum*. We have a ſort of *liquid alum* found with us. It is very well known, that the ſame ſtone will often produce vitriol, alum, and ſulphur. This is practiſed in the countries where theſe ſubſtances are prepared in greateſt abundance. The ſtones are firſt burnt, and the ſulphur melted from them; they are then expoſed to the air till they moulder in pieces, and then the vitriol is produced from them; and after all this is ſeparated, they afford *alum* on a ſecond burning and expoſing to the air. The ſame ſtones, which are of the marcaſite kind, as are uſed in Germany for this purpoſe, are found in our coal countries, as about Newcaſtle, and elſewhere; and nature with us ſometimes performs that which art does with them. When there have been ſubterraneous fires in any part of theſe countries, it is not uncommon to find *liquid alum* in the places where they have raged. It is a milky thick liquor, and is found lodged in cavities of the ſtrata of ſtone, when the ſulphur and ſal armoniac have been ſublimed away. The acid aluminous part of the matter will alſo take wing with a great degree of heat, leaving in the place of the liquor only a dry ſtyptic, and hard ſtony matter. The liquor itſelf is of a very ſtyptic taſte, and will yield one half its weight of pure cryſtalline *alum* on evaporation. Philoſ. Tranſ. N° 130.

LIQUOR (*Cycl.*) — *Fermented* LIQUORS. See the article FERMENTED *liquors*.

Teſt LIQUOR, among the dealers in brandy. See the articles SPIRIT and TEST *liquors*.

LIQUOR *mineralis anodynus*, the name given by Hoffman to a *liquor* of his own invention, famous at this time in Germany, and ſuppoſed by Burggrave to be made in this manner. Take oil of vitriol and Indian nitre, of each four ounces, diſtil the ſpirit gradually from this by a retort; pour two ounces of this ſpirit cautiouſly and ſucceſſively into fifteen ounces of ſpirit of wine highly rectified; diſtil this, and there comes over a very fragrant ſpirit. This is to be again diſtilled, to render it perfectly pure, adding firſt to it a ſmall quantity of oil of cloves, and a quantity of water, equal to that of the ſpirit; after this, as ſoon as the watery vapours begin to ariſe, the whole proceſs is to be ſtopped, and the ſpirit kept alone in a bottle well ſtopt. This has great virtues, as an anodyne, diaphoretic, antiſeptic, and carminative. It is not certain, that it is exactly the ſame with Hoffman's, that author having never publiſhed his manner of making it, but it appears the ſame to the ſmell and taſte, and has the ſame virtues.

LIQUORICE, *glycyrrhiza*, in botany. See GLYCYRRHIZA. This is a plant propagated in many parts of England to very great advantage. It delights in a rich light ſandy ſoil, which ſhould be three feet deep at leaſt; for the greateſt advantage conſiſts in the length of the roots. The greateſt quantities of it propagated in England are about Pontefract in Yorkſhire, and about Godalmin in Surry, though there is no inconſiderable quantity propagated in the gardens about London.

The ground deſigned for *liquorice* muſt be well dug, and dunged the year before, that the dung may be thoroughly rotted in it, and juſt before it is planted, the earth is to be dug three ſpades deep; and laid very light. The plants to be ſet ſhould be taken from the ſides or heads of the old roots, and each muſt have a very good bud, or eye, otherwiſe they are very ſubject to miſcarry; they ſhould alſo be about ten inches long, and perfectly ſound. The beſt ſeaſon for planting them is the end of February, or the beginning of March, and this muſt be done in the following manner. The rows muſt be marked by a line drawn acroſs the bed, at two feet diſtance, and the plants muſt be ſet in theſe by making a hole of their full depth, and ſomething more, that the eye of the root may be an inch below the ſurface: they muſt alſo be ſet at two feet diſtance from each other in each row. When this is done, the ground may be ſowed over with onions, which not rooting deep, will do the *liquorice* roots no injury for the firſt year. In October, when the ſtalks of the *liquorice* are dead, a little very rotten dung ſhould be ſpread over the ſurface of the ground. Three years after the time of planting, the *liquorice* will be fit to take up for uſe; and this ſhould be done juſt when the ſtalks are dead off; for if taken up ſooner, the roots are very apt to ſhrink greatly in their weight. The roots about London look browner than thoſe which have been propagated in a leſs rich ſoil, but then they are much larger, and grow quicker to their ſize. *Miller*'s Gardners Dict.

LIRIODENDRUM, in botany, a name given by Linnæus to a genus of plants called *tulipifera* by Cateſby, and others, and by us the *tulip tree*. The characters are theſe: the perianthium conſiſts of three oblong and concave leaves, which ſtand expanded, and reſemble petals, and fall with the flower. The flower conſiſts of ſix or nine petals, which are oblong, erect, and obtuſe, narrower at the baſe than in any other part, and all of the ſame ſize. The ſtamina are a great number of filaments, ſhorter than the flower, erect, and very ſlender, and affixed to the receptacle of the fructification. The antheræ are ſlender, and grow to the inſides of the ſtamina. The germina are numerous, and are ranged into the form of a cone. The ſtyles are ſhort, and the ſtigmata are ſimple. There is properly no fruit, but the ſeeds are laid together in an imbricated manner, ſo as to reſemble a ſtrobilus: theſe are numerous, pointed, and compreſſed at the baſe, and ending in a pointed ſcale. *Linnæi* Gen. Pl. p. 254. *Cateſby*, p. 48.

LISSA, or *Thynnus* LYSSA, in zoology, a name by which ſome authors have called the fiſh more uſually called *gliſſa*, a large ſea fiſh of the tunny kind. *Bellon.* de Piſc. p. 118.

LISTENING, in the manege, as when we ſay a horſe goes a *liſtening* pace. See ECOUTE.

LITCHI, in botany, the name of an Oriental fruit very common in China, and greatly eſteemed by the Chineſe. They ſay it is of the exact middle temperature between hot and cold, and that, beyond all other vegetables, it gives vigour and ſtrength to the body: they alſo commend it for the gravel, when properly prepared. This is a fruit that muſt be nicely watched, to find the time of its ripening, and when that comes it muſt be gathered, for it ſoon decays.

LITE, the name of a plaiſter much commended by the antients; it conſiſted of verdigreaſe, wax, and reſin. Whatever virtues this plaiſter poſſeſſed, might be probably found in the melilot plaiſter of the ſhops in general, till the late reformation made by the London Pharmacopœa, the colour being generally given by our wholeſale dealers with verdigreaſe, not with the juice of the herb from which it took its name.

LITERÆ *communicatoriæ*, in church hiſtory, letters granted by the biſhop to penitents, when the time of their penance was finiſhed, by which they were again received into the communion of the faithful. *Hofm.* Lex. in voc.

LITHAGOGI, an epithet given by ſome medical writers to ſuch medicines as work by urine, and are ſuppoſed to have the virtue of expelling the ſtone.

LITHANTHRAX, in natural hiſtory, is uſed as the name of the common pit coal. Among the learned, it is one of the claſs of opake inflammable foſſils, and is diſtinguiſhed from the reſt by being of a gloſſy hue, ſoft, friable, not fuſible, but eaſily inflammable, and leaving, after burning, a large reſiduum of whitiſh aſhes. We have three ſpecies of this foſſil in common uſe for our fuel in different parts of the kingdom. 1. A hard duſky black coal. This is in common uſe with us, under the name of Scotch coal (though that name is not reſtrained to this ſpecies alone, but the following is indiſcriminately known among the dealers by the ſame appellation) this is uſually of a rough and duſty ſurface, and is leſs gloſſy, when freſh broken, than any other coal. It burns briſkly, and turns wholly to aſhes, not leaving any cinders. There is a vaſt deal of this dug about Limington in Hampſhire, whence it is often called by the dealers Limington coal. 2. A hard gloſſy coal. This is ſometimes ſold in London with the former, under the name of Scotch coal, but it is more determinately known in many parts of the kingdom by the name of Welch coal. It is diſtinguiſhed from the others by its great hardneſs, and gloſſy black, where freſh broken, and is much eſteemed for burning with leſs ſmoak than any other kind; and in ſome parts of this kingdom, and generally in Wales, they uſe it to make malt, without any previous burning. The third is our common coal, too well known to need any deſcription, but diſtinguiſhed from all the others by its ſhattery friable ſtructure, and its great gloſs when freſh broken. *Hill*'s Hiſt. of Foſſ. p. 418. See COAL.

LITHARGE (*Cycl.*)—This preparation of lead is of great uſe in the roaſting the ſtubborn ores of gold, ſilver, and copper; for it melts all kinds of ſtones and earth into glaſs, ſooner than the metals; and by this means the metal, which is heavier, will fall through the glaſs, which is a thin and light ſubſtance, and will be collected under it into a regulus, with only a few duſty ſcoriæ adhering to it. But if it be copper that is thus ſeparated, a ſmall portion of it is always deſtroyed; and if gold or ſilver, a like ſmall portion is always lodged and detained in the ſcoriæ.

But as the *litharge* penetrates through all ſorts of veſſels, and while melting riſes into a ſcum, that often runs over their edges, the aſſayers never uſe it alone, but always mix with it ſuch ſubſtances as may give it a clammyneſs, ſuch as flints, ſand, clay, or the like: they mix two parts of *litharge* with one part of any of theſe ſubſtances, and add ſome nitre, or common ſalt, that the whole may run the more eaſily. They ſhut up the veſſels, which muſt be made very thick and ſolid, with a ſmall cover or lid, cut cloſe, and placing this in a wind furnace, they keep it in fuſion a quarter of an hour, looking at times into the aſh-hole, to ſee if the glaſs have not eſcaped through the veſſel, and run down thither. Very often it is found ſweating through the ſides of the veſſel, like water, and falling in drops into the aſh-

aſh-hole; and in this caſe, there is no way to preſerve the remainder, but to take the veſſel out of the fire.

When the whole is cool, the veſſel muſt be broke, and at the bottom there will be found a ſmall quantity of a regulus of lead, revived by means of the ſalt; in the middle the glaſs of lead, which muſt be kept for uſe; and at the top a ſaline cruſt, which is to be thrown away.

LITHIDIA, in natural hiſtory, the name of a large claſs of foſſils, including the flint and pebble kinds.

The *lithidia* are defined to be ſtones of a debaſed cryſtalline matter, covered by, and ſurrounded with an opake cruſt, and frequently of great beauty, and conſiderable brightneſs within, though of but a ſlight degree of tranſparence, approaching to the nature of the ſemipellucid gems, and like them found in not very large maſſes.

The bodies of this claſs are divided into two general orders, and under thoſe into three genera. The firſt order of the *lithidia* contains thoſe compoſed of a cryſtalline matter, but ſlightly debaſed, and that ever by one and the ſame earth, though diffuſed through them in different degrees, and always free from veins. The ſecond order is of thoſe of a more debaſed cryſtalline matter, blended with different portions of differently coloured earths.

Of the firſt of theſe orders there is only one genus, which is that of the common flint. See the article SILEX.

Of the ſecond order there are two genera. 1. The *homochroa*, which are of one plain and ſimple colour; and 2. the *calculi*, which are compoſed of cruſts of ſeveral different colours. Both theſe genera are compriſed under the common Engliſh name of *pebbles*. *Hill*'s Hiſt. of Foſſ. p. 505. See HOMOCHROA and PEBBLES.

LITHOBOLIA, λιθοβολια, in antiquity, a feſtival celebrated by the Træzenians in memory of Lamia and Auxeſia, two virgins, that coming from Crete to Træzene, in a time of tumult and ſedition, became a ſacrifice to the fury of the people, by whom they were ſtoned to death. *Potter*, Archæol. Græc. l. 2. c. 20. Tom. I. p. 412.

LITHOBOLIA, or *lapidation*, was alſo a common puniſhment inflicted by the primitive Greeks upon ſuch as were taken in adultery. *Potter*, l. 1. c. 25. Tom. I. p. 135.

LITHODÆMON, or LAPIS *dæmonum*, a name given by ſome authors to jet. See GAGATES.

LITHODENDRON, a name by which, according to Dioſcorides, many of the antients expreſs the common red coral. *Dale*'s Pharm. p. 54.

LITHOGENESIA, a term uſed by ſome authors to expreſs the formation and origin of ſtones. See STONE.

Henkell has thrown together ſome very ingenious thoughts on this abſtruſe ſubject, in a treatiſe publiſhed in the year 1734, where he builds no opinions on any other baſis than that of facts, obſervations of nature, and experiments.

He had lived twenty years in the neighbourhood of the mines in Miſnia, and had in that time perhaps ſeen more of the entrails of the earth opened, than any other man who ever viewed it with a philoſophic eye; and loving chemiſtry, had made experiments greatly more numerous than thoſe of any other writer on this ſubject: this may give ſome weight to his opinions, which differ greatly from thoſe of the generality of writers, and with which he modeſtly acknowledges himſelf not to be perfectly ſatisfied, as to all the operations of nature in this abſtruſe and hidden myſtery.

He ſuppoſes that the earth was at firſt every where ſoft on the ſurface, and that this ſoft matter, by degrees, hardened, and formed ſtones of ſeveral kinds. He ſeems to imagine, that the ſurface of the earth was a ſecond time all reduced to this ſoft ſtate by the univerſal deluge at the time of Noah, and that this matter, afterwards hardening into ſtones of various kinds, included the ſhells of ſea fiſhes, and other animal remains of the produce of the ſeas, in flints, in limeſtone, or in whatever other ſubſtance the matter among which they lay, chanced to harden. Thus may the ſea ſhells, found ſingly in the middle of hard flints, or lodged in vaſt numbers in the ſtrata of earth, limeſtone, or marble, be accounted for.

Waters of other kinds we are very ſenſible may carry particles of ſtony matter, and lodge them ſo in other bodies, as to form compleat hard and ſolid ſtones: this is frequently done at this day in the common petrifactions of wood, and in the ſtones generated in the bladders of animals. If this be allowed a property common to ſeveral fluids, and to water in ſeveral ſtates, there is no reaſon why it ſhould be denied to have exiſted in that of the univerſal deluge; and if that be acknowledged to have had a power of forming ſtones of various kinds, there is no wonder that ſtones of various kinds ſhould be found in the ſtrata, and on the ſurface of this earth, which was all covered by that water; or that the ſtones formed in that immenſe body of water ſhould ſhew, as they do in many inſtances, the ſeveral cruſts or coats laid one upon another, by the ſucceſſive applications of the matter of which they were formed.

If we conſider alſo the immenſe quantity of animal and vegetable bodies; ſome entire, others only ſeparated into parts which muſt have been mixed with, floating among, or lying upon the bottom of this immenſe bed of water, and that ſtones were continually forming out of this water at this time, we cannot wonder that theſe ſtones ſhould take up theſe parts of plants or animals, or concrete about them, or that we ſhould find ſhells and teeth of fiſhes, or pieces of wood, or leaves of plants preſerved in them.

Nor is water alone the agent that may have made theſe changes in the once ſoft parts of the earth's ſurface; we can by fire reduce the pooreſt earths into a ſort of glaſs, a hard tranſparent body, not a little reſembling the nature of flint or the other ſemi-pellucid ſtones. Fire is of power to do great things in the bowels of the earth, and the way to learn what changes it may there make in ſtones, is to try its effect upon the ſeveral different kinds of ſtones and earths here. By experiments of this kind we learn, that of the ſeveral ſpecies of ſtones in their preſent ſtate ſome are reduced to a friable maſs, and finally to powder by the force of fire, others are hardened by it, others are melted, and become a kind of glaſs: and by experiments, on the other foſſile ſubſtances, it appears, that the original matter of all ſtones has been earth, either of the nature of chalk, marl, or clay; and that many of them have been greatly altered by receiving metallic or other mineral matter into their earthy matter, at the time of their formation; and all ſeem to have owed their change into their hard ſtate, either to fire alone, or to ſaline, oily, metallic or ſaline ſulphureous matters, either conjunctly with the force of this agent, or alone. *Henkell*'s Lithogeneſia.

Thoſe ſtones, which were formed in their preſent ſtate, immediately out of fluids, have been produced either by congelation, a rude coalition, or cryſtallization; and that all the gems have been once fluid, is plain, from their imperfections in certain inſtances, as from their containing grains of ſand, or the like extraneous ſubſtances, firmly embodied in them. If theſe, the hardeſt of all ſtones, have been once fluid, there is no reaſon to diſpute, but that all the other kinds may have been ſo, which are leſs hard and leſs perfect.

LITHOLABON, a name given by ſome chirurgical writers to an inſtrument uſed in the operation of lithotomy, it is a forceps intended for taking hold of the ſtone.

LITHOMANTIA, λιθομαντεια, in antiquity, a ſpecies of divination performed with ſtones. Sometimes the ſtone, called *ſiderites*, was uſed: this they waſhed in ſpring-water in the night by candle-light; the perſon that conſulted it, was to be purified from all manner of pollution, and to have his face covered: this done, he repeated divers prayers, and placed certain characters in an appointed order; and then the ſtone moved of itſelf, and in a ſoft, gentle, murmur, (or as ſome ſay) in a voice like that of a child, returned an anſwer. By a ſtone of this nature, Helena is reported to have foretold the deſtruction of Troy. *Potter*, Archæol. Græc. l. 2. c. 18. T. 1. p. 351.

LITHOMARGA, (*Cycl.*) *Stone marle*, a name given by ſome authors to a ſparry ſubſtance highly debaſed by earth, which is found in great plenty in the caves of the Hart's foreſt in Germany, and uſed there in medicine, under the name of the *unicornu foſſile*, or foſſile unicorn's horn, from its ſometimes emulating that figure. *Hill*'s Hiſt. of Foſſ. p. 360.

LITHONTRIPTICON *Tulpii*, the name of a famous diuretic medicine, invented by Tulpius, and given with great ſucceſs in caſes of the ſtone, but requiring great judgment and caution in the adminiſtring it.

The preparation is this: take a dram of cantharides without their wings, and a dram of leſſer cardamoms without their huſks, powder them fine, and pour upon them an ounce of rectified ſpirit of wine, and half an ounce of ſpirit of nitre: ſet them to infuſe, without heat, for five or ſix days, ſtirring them from time to time. The vial muſt not be ſtopped cloſe; becauſe, if it be, the continual fermentation will burſt it. The doſe is from fourteen to fifteen, or twenty drops, in a glaſs of wine and water, it is to be taken in a morning, an hour after the eating a meſs of broth, and may be repeated for three or four days.

It is remarkable, that this mixture never ceaſes fermenting for many years; but if it be too faſt corked will break the glaſs; if but ſlightly ſtopped, it only throws out the cork with an exploſion. Mem. Acad. Par. 1709. p. 358. Edit. Par.

LITHOPAEDION, a word uſed by ſome medical writers to expreſs a recent calculous concretion in the bladder.

The ſtone, in this ſtate, is ſuppoſed to be more eaſily worked upon by medicines, than when of longer ſtanding; but the cruſtated ſtructure of theſe ſtones, when examined plainly, ſhews that they arrive at their bigneſs only by ſlow degrees, and therefore, that there is properly no ſuch thing as a recent calculous concretion capable of giving pain.

LITHOPHYTON, *Coral*, in botany, the name of a genus of ſea plants, the characters of which are theſe. They are of a ſort of horney texture, or of a middle degree of hardneſs between that of ſtone and wood, and have uſually a ſort of bark, either compoſed of fibres, and reſembling the bark of trees, or elſe merely cruſtaceous, and reſembling a tartarous cruſt. See Tab. 1. of Botany, Claſs 17.

The ſpecies of *lithophyton*, enumerated by Mr. Tournefort, are

are theſe. 1. The white ſea *lithophyton* called ſhrubby coralline. 2. The purple ſea *lithophyton*, called purple ſhrubby coralline. 3. The yellow punctated *lithophyton*. 4. The white knotty *lithophyton*. 5. The *lithophyton* with a white verrucoſe coat. 6. The grey rugoſe *lithophyton*. 7. The ſmall white rugoſe *lithophyton*. 8. The pale yellow *lithophyton* with a ſmooth bark. 9. The great, grey American *lithophyton* with a punctated bark. 10. The ſmaller yellow American *lithophyton* with a punctated bark. 11. The great black American *lithophyton* beſet with tubercles pointing upwards. 12. The ſmall white American *lithophyton* beſet with erect tubercles. 13. The white American *lithophyton* reſembling the leaves of polypody. 14. The American *lithophyton* with compreſſed branches reſembling pods. 15. The black woody coral *lithophyton*. 16. The black, hairy, or briſtly *lithophyton*. 17. The white, hairy, or briſtly *lithophyton*. 18. The larger black, hairy, briſtly *lithophyton*. 19. The circumvoluted black ſetaceous *lithophyton*. 20. The *lithophyton* variegated with yellow and roſe colours. 21. The *lithophyton* variegated with white and roſe colour. 22. The great purple reticulated *lithophyton*. 23. The ſmaller purple reticulated *lithophyton*. 24. The great yellow reticulated *lithophyton*. 25. The great reticulated *lithophyton*, yellow on one part and white on the other. 26. The tall tamariſk like erect *lithophyton*. 27. The knotty and reticulated *lithophyton*. 28. The prickly ferulaceous *lithophyton*.

The nature and origin of *coral* has been as much diſputed as any one point in natural knowledge. The moderns can neither agree with the antients about it, nor with one another; and there are, at this time, among the men of eminence in thoſe ſtudies, ſome who will have it to be of vegetable, ſome of mineral origin, and others only the caſes of ſome of the animal kingdom.

It were eaſy to overthrow all that has been advanced toward the proving it to belong to the animal kingdom. Its being of mineral origin, has gained much more ground, however, and the excellent and truly great Dr. Woodward, has ſtood up as a very vigorous champion for this opinion.

It may not be improper to obſerve, that it was of abſolute neceſſity, to this gentleman's ſyſtem, of the ſolution of all foſſils at the deluge, that *coral* ſhould be proved to be one; becauſe, he gives it as a certainty, that all the foſſile *corals* have been in a ſtate of ſolution; which, according to his own ſyſtem, had they ever been vegetable bodies they could not have been. But if his ſyſtem be juſt, in this point, there are abundant proofs in the foſſile world, whatever he might think to the contrary, of *coral*'s being a vegetable; for there are unqueſtionable authorities in the bodies themſelves for proving, that they never have been in a ſtate of ſolution; and muſt have been, therefore, according to his ſyſtem, a vegetable body; for we frequently find numbers of *corals* in our clay and chalk pits, which have upon them the very ſhells of the balani marini, which had affixed themſelves to them while they were growing in the ſea, and yet remain on them in their natural poſtures.

It might be poſſibly objected, that ſhells being affixed to *coral*, could be no proof of its not having been once diſſolved, and having concreted again: ſince, if it concreted in a fluid, where theſe ſhells were ſuſpended in great abundance, they might have been affixed to it by being waſhed againſt it, during that ſecond concretion. But, in this caſe, the ſhells muſt have been lodged in, as well as upon the *corals*; which is never found to be the caſe; and they would alſo have been laid on it in any poſture that happened readieſt; whereas thoſe found remaining on the foſſile *corals* are ever found in their natural poſitions, and living poſture. Nor are we to imagine, that the foſſile *corals* have been in a ſtate of ſolution, becauſe they are often of a ſtony hardneſs, or have matter very different from the coralline in their conſtitution; for we find this frequently the caſe in foſſile wood, ſome of which is almoſt wholly formed of ſtony matter, and a vaſt deal wholly of that of the pyrites; yet this being a vegetable body, beyond contradiction, cannot have been in a ſtate of ſolution, according to the Woodwardian ſyſtem. *Hill*'s Theophr. p. 97.

To this, it may be added, that after that gentleman has been at all poſſible pains, to prove the marine *corals* truly of foſſile origin, and formed, by an appoſition of particles, not by vegetation; yet a chemical analyſis of them, obliges him to own, that they have ſomething of a vegetable matter in them. And how are we to ſuppoſe that this vegetable matter comes there? When we can be informed how any thing of a vegetable matter can be produced, otherwiſe than from ſeeds; we may ſuppoſe, according to this gentleman's ſyſtem, that *corals* are formed by a mere appoſition of particles waſhed out of the neighbouring rocks; but till then we certainly have a much more rational account of their ſeveral elegant figures, in the concluding, that like all other ſubſtances, which are compoſed of vegetable matter, they are vegetables.

One of the moſt remarkable ſpecies of the ſmall *lithophyta*, we have any where an account of, is that deſcribed by Mr. Lewenhoek, though without any particular name in the Philoſophical Tranſactions.

The firſt notice this gentleman took of this water plant was accidental; for ſtanding by the ſide of a canal, whoſe water was very clear, he obſerved ſomething glitter in it as it paſſed along; examining this with the beſt diligence by the naked eye, could give no farther idea of its figure, but that of its being an aſſemblage of ſmall fibres. On taking up ſome of this water from the canal into a glaſs tube, there was perceived ſome few of theſe floating branches of matter, which ſtuck to the ſides of the glaſs, and could not be removed from thence, though the water was ſhook about them. On viewing theſe with a microſcope, they are always found very beautifully divaricated, and repreſent, in figure, either ſome of the large and branched *lithophyta*, which grow to rocks in the ſea, or the boughs of a tree, with numbers of ramoſe twigs upon them. They grow in the very ſame manner from the ſides of the tube that theſe ſea plants do, from ſtones and other things under the water. The part which ſeems in the place of a root is a ſmall roundiſh flatted particle, applied firmly againſt the ſides of the glaſs; from this ariſes the main ſtem, and that again divides into a great number of finer branches. Phil. Tranſ. N° 286. p. 1430.

Theſe plants do not faſten themſelves to the glaſs on the inſtant of the waters being received into it; but ſometimes, when firſt taken up, there appear nothing of them, and on the ſtanding twenty or thirty hours of the water in the glaſs, the ſmall particle attaches itſelf to ſome part of the ſides, and from this the reſt of the plant grows in its due form and order.

When theſe plants have arrived at a certain ſize, they do not increaſe any farther; but there is an appearance at their extremities, very much reſembling the flowers of ſome plants, and which might very naturally be miſtaken for the proper flowers of theſe: they appear like little roſes, compoſed of four round bodies, each reſembling the petals or leaves of flowers; theſe alſo reſemble flowers, in this particular, that they ſoon decay and fall off. But it would be a very great error to ſuppoſe them ſuch, for they are in reality no part of the plant, but only a ſort of ſmall animals, which find this a proper place for their reſiding, and conſtantly fix themſelves thus to the extremities of the twigs of theſe plants, where they propagate their ſpecies, and then periſh.

It is not uncommon to ſee a ſmall round body endued with animal motion, fall from one of what appear the petals of this flower, and go where it pleaſes. It is not only on the ſummits, or twigs of theſe tips, that theſe animals live; they are alſo found very frequently on their ſides, and even on the main trunk; and they in the ſame manner propagate their ſpecies; but it is only on theſe ſummits of the branches, that they are ſo diſtinctly viſible.

It is remarkable, that the ſucceſſive growth of this plant, from its firſt appearance, is ſo very ſudden, that it is ſcarce poſſible to find it in a time of increaſe, but it is uſually found at its full growth as ſoon it is obſerved at all. All the ramifications of it are ſo extremely minute, and fine, that it requires a good microſcope to ſee them, with any degree of preciſion, but toward the top it always divides itſelf it into ſome extreme branches, which are ſo very ſlender, that they even eſcape the microſcope itſelf; theſe, however, are terminated, at their ſummits, by the ſame animalcules, four in a cluſter, and reſembling flowers.

The weight of theſe animals bends down the branch they adhere to, ſo that they often appear out of the line of the reſt of the boughs, but they are known to belong to the plant; though the branches to which they are attached, are wholly inviſible, becauſe they never remove their places; and if the whole little plant be ſhook, by putting the water in a ſlight motion, theſe flowers, as they appear to be, are always moved in the ſame manner as the reſt of the branches are, and never can be ſeparated from them, unleſs by ſuch a motion of the water, as will wholly deſtroy the plant. Theſe branches are in a continual vibration while in the water; and it is a very pleaſant ſight to obſerve the motion of the cluſters of animals at the ends, as well of the viſible as of the inviſible branches. But the way to come at a perfect view of the whole plant, with all its ramifications, is to pour all the water gently out of the glaſs, and the whole plant will then be laid ſideways along the glaſs, and all its ramifications diſtinctly traced. The whole plant, though it appear bright and glittering in ſome lights, yet it is in general of the colour of a branch of the oak.

The ingenious obſerver of theſe plants, ſeems in ſome doubt, as to their being in reality of vegetable origin; he was apt to ſuppoſe them mere combinations of particles, hanging one to another, in chains, like filings of iron, by means of a magnet: but as there is, in this caſe, no ſuch external force to put them in this arrangement; and as the whole growth and appearance of them reſembles very exactly that of a larger *lithophyton*, there is no doubt of their being in reality ſmall plants of the ſame genus with the larger.

The antients extolled *coral* as a cordial and alexipharmic; alſo as a cooling and aſtringent medicine. They uſed it externally, as well as internally: we uſe it only internally, and that as an aſtringent and abſorbent in diarrhœas, the fluor albus, and hæmorrhages, but in none of theſe caſes alone,

alone, being always prescribed with other medicines of the same intention.

Dispensary writers have given us receipts for a great many preparations of *coral*, as magisteries, tinctures, syrups, salts, &c. none of which enter the present practice.

LITHOPHYTON *terrestre*, a name given by Mr. Marchant to a species of plant, approaching to the mushroom kind, and resembling that fungous production, compared by some authors to the clusters of the Æthiopian pepper.

Mr. Marchant's curious observations on this little regarded subject, give many valuable hints towards the explaining the vegetation of great numbers of the other plants, whose fructification is less obvious to the eyes, and may lead to a knowledge of many of the fructifications of sea plants; which all our enquires, on other foundations, have as yet left us unacquainted with.

This gentleman having cut down a maple in his garden, found after some months a number of little tubercles, of a fungous substance on the stump; they somewhat approached to the figure of an olive, with its stalk, and were then of a brown colour.

The outside of these tubercles was porous, and they appeared somewhat spongy though rigid, and on squeezing a little there issued out of the pores a small quantity of an aqueous humidity; the inside, when it was cut open, appeared composed of fine and closely compacted fibres.

These plants, as they may properly be called, stood the whole winter, and in the following spring were found to be grown to their full size, which was about an inch and half long, and half an inch thick; they stood in clusters, of near twenty together, and resembled a set of irregular and ill proportioned fingers, and when pressed were found to be much harder than while young. Mem. Acad. Par. 1711.

The pores on their surface, which still continued visible, and were very different from any known plant of the mushroom kind, gave the observer hopes of a discovery of something new in the fructification, and the stump of the tree being now perfectly dry, and unable to furnish any more nourishment to them, he cut them all off, with part of the stump, and carried them to his closet for observation.

Each plant was nearly circular in figure, and terminated in a roundish or pointed end, and had at several distances two or three circular lines, by means of which it resembled a toe or finger with its joints. The outer skin was now become wrinkled, and the pores were all surrounded with a sort of rosaceous rim, and within them there often appeared a number of fine slender filaments, having the appearance of stamina.

On cutting the plants vertically, these pores were all found to correspond with certain round cavities within the plant, which were lined with a black matter. These cavities were formed in a white fibrous matter; all the fibres of which took their origin at the center, and tended to the circumference, and of these was the whole inner substance of the plant composed.

Some months after this, on cutting more of these plants, the round cavities, in some of them, were found filled with a black matter, in form of a powder, composed of small granules, and looked as if filled up with very fine gunpowder. The help of a microscope shewed this matter to be composed of small black particles, resembling the seeds of the vanilla pods, only vastly less, and not so shining.

On the whole, Mr. Marchant, notwithstanding the external resemblance of this plant to some of the mushrooms, thinks, that when closely examined, it approaches more to the nature of the marine *lithophytons*.

It grows, as he observes, on hard bodies, without any appearance of roots in the manner of those sea plants. Its bark, or outer covering, seems a sort of coriaceous or tartareous substance, much more resembling the bark of the sea *lithophytons* than that of any land plant; and its pores surrounded with rosaceous rims, and answering to certain cavities containing seeds within the body of the plant, bring it to a near resemblance with the sea *lithophytons*, though they do not at all resemble any known land plant.

The *corals* and other *lithophytons* of the sea have all of them flowers on their surface, surrounded with the same sort of rosaceous rim with the pores of this plant: in the sea plants the flowers are indeed more distinguishable than in this land vegetable, but their seeds are too small for the nicest eye to distinguish; these, however, in the land plant, are large enough to be easily seen; and thus between both kinds, the whole secret of the fructification both of these two, and of multitudes of other plants of the same class, both sea and land ones may be understood. Mem. Acad. Par. 1711.

LITHOPHOSPHORUS *fuhlensis*, in natural history, a name given by some authors to a species of spar, which, when it has been heated over the fire, retains a property of giving light in the dark. This is a quality that seems more or less in degree to be inherent in several sorts of spars. *Woodw.* Cat. Foss. V. 2. p. 11.

The Bononian stone is a fossile of this kind, and several of the green spars of the German mines, have been found to possess this quality in some degree.

The *lithophosphorus* here meant, has the appearance of a common purple spar. There is another kind, of an opake white colour, so common about the edge of the Hart's forest, that it is used as a flux for some of the copper ores, readily burning into lime, and then acting as an alkali, and absorbing their sulphurs; this kind, when moderately heated, shews an elegant light on being put into a dark room, but when it is heated too much it bursts to pieces.

LITHOPTERIS, *stone fern*, in natural history, a name given by Mr. Lhuyd, to some of the fossile plants of the fern kind. See PLANTS *fossile*.

LITHOSPERMUM, *gromwell*, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these. The cup is an oblong erect perianthium, divided into five segments, and remaining after the flower is fallen. The several segments are tapering and hollowed. The flower consists of a single petal of the length of the cup, formed into a cylindric tube, with its edge divided slightly into five erect obtuse segments; the mouth of the flower is perforated. The stamina are five extremely short filaments, the antheræ are oblong, and situated in the opening of the flower. The pistil has four germina, the style is slender, and of the length of the tube of the flower. The stigma is obtuse and bifid. The cup remains to supply the place of a fruit, containing in its bottom four smooth, very hard, and pointed seeds. *Linnæi* Gen. Plant. p. 57.

The characters of this genus, according to Tournefort, are these. The flower consists of one leaf, and is fashioned like a funnel, and divided into segments at the edge. The cup is divided to its very base, and from it there arises a pistil, which is fixed in the manner of a nail in the lower part of the flower, and surrounded with four embryos, which afterwards become so many roundish hard polished bodies, remaining till ripe in the cup, which becomes enlarged for the containing them. *Tourn.* Inst. p. 137.

The species of *gromwell*, enumerated by Mr. Tournefort, are these. 1. The smaller upright *gromwell*. 2. The great creeping broad leaved *gromwell*. 3. The common smaller field *gromwell*. 4. The smaller field *gromwell* with blueish yellow flowers. 5. The small blue flowered marsh or water *gromwell*. 6. The smaller marsh *gromwell* with white flowers. 7. The small alpine woolly *gromwell*.

There have been several plants referred to this genus, by authors, which do not at all belong to it. Of this number are, 1. The Job's tears. See LACRYMA *jobi*. 2. The red rooted field *gromwell*, a species of *bugloss*. See BUGLOSS. 3. The *lithospermum linariæ folio*, a species of *thymelæa*; and another plant of the same name, a species of flax. See FLAX and LINUM.

The seeds of the *common gromwell*, which are hard, white, and of a delicate polish, are recommended as very powerful diuretics, and some have pretended to cure the stone solely by the use of them. The good women have an opinion of them also, as promoters of the menses and of labour.

LITHOSTROTA, among the antients, pavements made up of small pieces of cut marble of different kinds and colour. *Pitisc.* Lex. Ant. in voc.

LITHOSTROTION, in natural history, the name of a species of fossile *coral*, composed of a great number of long and slender columns, sometimes round, sometimes angular, jointed nicely to one another, and of a starry or radiated surface at their tops. These are found in considerable quantities in the northern and western parts of this kingdom, sometimes in single, sometimes in complex specimens. See Tab. of Fossils, Class 7.

LITHOXOS. See COLAPTICE.

LITHOXYLUM, in botany, a term used by Linnæus, to express a heterogeneous substance on sea plants, which has fructifications in impressed points.

LITHUS, a name given by some authors for the magnet.

LITUITES, in natural history, a name given by some authors to a figured fossile, found in the shell of the sea fish, called *lituus*, a concamerated shell of the conic kind, running strait for a great part of its length, and after that twisting into a spiral form.

LINUFAR, in botany, a name used by some of the writers of the middle ages, to express the water lilly. The Arabians gave this genus of plants the name of *nilufar*, and this word *linufar* is only formed of that by transposing some of the letters. See NILUFAR.

LITOTES, Λιτότης, in rhetoric. See LIPTOTES.

LITTER (*Cycl.*)—When a horse comes tired into a stable, fresh *litter* has the virtue always to occasion him immediately to stale. This is known to be a very great advantage to a horse in a tired state; and when the *litter* is old and dirty, it never has any such effect upon him. If the owner knew how refreshing it is to a horse to discharge his urine on his return from labour, they would be more careful in giving him all means and occasions of it than they do. This staling after fatigue prevents those obstructions in the neck of the bladder or urinary passages, which horses are too subject to. The bladder being often inflamed by the long retention of the heated urine in it, and the creature perishing by it. Some of our farmers act wrong in this case of the *litter*, not through carelessness or accident, but by principle; they order the old *litter* to be left a long time in the stables, that

it may be impregnated with more and more of the urine, &c. of the animal, and be made richer for the fields. It is not to be doubted but the manure is greatly improved by this; but the damage done to the horſe by it is greatly over-proportioned to the benefit. The heat which the dung acquires, by thus lying together, ſpoils the feet of the creature, and makes it unfit for any ſervice, and occaſions many diſtempers, which are ignorantly continued and increaſed by the continual addition of heat in the fermenting dung, till at length the horſe periſhes.

LITUITES, a name given to the ſtones formed in the lituus-ſhell. See LITUITUS, infra.

LITUUS, in natural hiſtory, a name given to a genus of ſhells of the claſs of the polythalamii, or thoſe which conſiſt of ſeveral concamerations or chambers, parted from one another by ſhelly diaphragms, and communicating with one another by means of a ſiphunculus, which runs through the whole length of the ſhell. To this general character of the claſs, it is to be added, that the *lituus* is always a conic ſhell, running in a ſtrait line from the mouth, through a great part of the length, and from the end of this ſtrait part to the extremity, twiſting into the ſhape of a cornu ammonis, or ſpiral ſhell of that kind.

It is thus called from its reſembling the inſtrument called *lituus* among the antients. The ſtony matter often found caſt in this ſhell, and reſembling all its lineaments, is called by authors *lituites*, as thoſe ſtones formed in the pecten *pectinites*, and thoſe in the echini marini *echinitæ*. *Breynius* de Polythalamiis.

LIVE, at ſea, is uſed to ſignify the ſame, as being able to endure the ſea, without overſetting or ſuffering any damage; thus, they ſay of a boat, that it will *live* in any ſea; that is, it will endure, or bear with, any ſea.

LIVE *caves*, in mining, a phraſe uſed by many people, to expreſs ſuch caverns in the earth as have but little communication with the external air, and are found to abound with mineral productions. The workers in the lead mines on Mendip hills, diſtinguiſh the numerous caverns in thoſe places into the *live* or *quick caves*, and the *dead caves*; the latter are ſuch as admit the air into them two or three ways, and are barren of any thing valuable; the others have only one paſſage, and that but narrow and winding, and generally lie at great depths. Theſe abound in numerous elegant productions. They almoſt always contain ore in ſome form or other, and uſually abound in elegant ſpars. Mr. Beaumont mentions one of theſe in the Philoſophical Tranſactions, which lay at thirty-five fathom perpendicular depth, in which there was found a fine liver coloured earth, of the nature of bole armenic, which in many places ſhoot up in a wonderful manner into a ſort of ſpires of the height of three or four inches, formed with ridges and furrows, and uſually covered with ſpar at the top; ſometimes all the way down, to the bed of earth. Phil. Tranſ. N° 129.

LIVER (*Cycl.*)—Thoſe things which increaſe or leſſen the proportion of the weight of the heart to the weight of the body, do at the ſame time leſſen or increaſe the proportion of the weight of the *liver* to the weight of the heart. (See HEART.) And conſequently, when an animal grows fat from much food, much ſleep and little exerciſe, its heart leſſens, and its *liver* increaſes; and, on the contrary, when an animal grows lean from little food, little ſleep and much exerciſe, its heart increaſes and its *liver* leſſens. When the weight of the heart is too little for the weight of the body, the *liver* enlarges beyond its juſt magnitude, and preſſes too much on the contiguous parts, particularly on the ſtomach, inteſtines, and diaphragm, and by the preſſure leſſens the capacities of the ſtomach, inteſtines, and thorax; whence the appetite grows leſs, the periſtaltic motion leſs, and reſpiration more difficult and uneaſy. Dr. *Robinſon*'s Diſſ. on the Food, &c. of Hum. Bod.

The weight of the *liver* in proportion to the quantity of blood, is leſs at a medium in wild beaſts than in tame, and in round fiſh than in flat fiſh. Ibid. p. 111.

In moſt chronical diſeaſes the *liver* is larger than in health, as has been found by diſſections. And it ſeems probable, that the weight of the heart, and quantity of blood, in thoſe diſtempers, are both leſs than in health; moſt chronical diſeaſes ariſing from too much food and too little exerciſe, leſſen the weight of the heart and quantity of blood, but increaſe the *liver*. Hence, when this part is grown too large by intemperance and inactivity, it may be leſſened and brought to a healthful magnitude by temperance and exerciſe. It may indeed alſo be emptied by art, but nothing can prevent its filling again, and conſequently ſecure good and conſtant health, but an exact diet and exerciſe. Thus purging and vomiting may leſſen the *liver*, but cannot prevent its increaſing again, ſo long as perſons live too fully and uſe too little exerciſe. Ibid. p. 119.

Each lobule of the *liver* conſiſts of an external, friable, yelloviſh-red cortical ſubſtance, and of an internal ſoft, pulpous, medullary part. The medullary ſubſtance is the pulpy extremities of the biliary ducts, proceeding from the cortical part. See Mr. *Ferren* in Hiſt. de l'Acad. des Scienc. 1733.

The blood in the hepatic artery has bile ſecreted from it, and its remaining blood is conveyed by veins into the vena portarum, where a ſecond ſecretion is made from it. Beſides, the ſecretion of bile made from the hepatic artery and vena portarum, Mr. Ferren has ſeen biliary ducts coming from the left ligament of the *liver*, the diaphragm coats of the gall bladder, and part of the vena cava; all which are viſible upon injecting coloured liquors into the trunks of the hepatic ducts. The bile is equally bitter and ſtrong in the ſmalleſt biliary canals, as in the larger trunks. The thick yellow bile, ſometimes found in the trunks, being the cyſtic bile, remounting from the common into the hepatic duct, on which account the hepatic is often larger than the common duct. The lymphatic veſſels may be traced to the extreme branches of the vena portarum, and to the biliary ducts, by injecting liquors into the larger trunks of the external lymphatics. *Ferren* ubi ſupra.

The *liver* in fiſhes, is generally very large in proportion to the reſt of the body, and is generally placed in the left ſide of the abdomen; but this is not the caſe in all. In figure and proportion it differs greatly in the different kinds; it is in ſome ſimple, and undivided, as in the pleuronecti, petromyza, ſalmons, &c. In ſome it is divided into two lobes, as in pearch and moſt of the cartilaginous kinds. As alſo in the torpedo, the ſquali, the lamiæ, the perilophus, the paſtinacha of authors, the clupeæ, the eels, the ſtromateus of Rondeletius, the dolphins, and ſome of the ligyri. In ſome it is divided into three lobes, as in the cyprini, ſome of the gadi, the ſcorpæna, the rays, the ſquatina, the tunny, the gaſteroſteus, and the faber, or Solen doree. *Artedi* Ichthyol.

In regard to proportion, it is in ſome fiſh much ſhorter than the abdomen; as in pearch, clupeæ, oſmari, coregones, ſalmons, eſoces, and the greater part of fiſhes. In ſome it is nearly of the ſame length with the abdomen, as in the gaſteroſteus, &c. The gall bladder, which is an appendage to the *liver*, is never wanting in any kind of fiſh, but it is very differently ſituated in the different kinds.

In the cartilaginous fiſhes, it is immerſed in the ſubſtance of the *liver*; in other fiſh, it ſometimes adheres cloſely to the lower part of it, as in the eſoces, cyprini, pearch, and the greater part of fiſhes. In others it is hung to the *liver* by a long neck, as in the muræna, conger and ammodytes.

Abſceſs in the LIVER. Abſceſſes in the *liver* have been uſually accounted mortal, and wholly beyond the reach of remedy; we have, however, in the hiſtory of the academy of Paris, an account of a very remarkable one, perfectly cured by Mr. Souiller, a ſurgeon of Montpelier, in the following manner. The patient was a young gentleman of about fourteen, who had contracted a violent fever, by putting his feet while very hot into ſome cold water. The conſequence of this fever was a large tumor in the middle of the epigaſtric region, which raiſed the xiphoide cartilage, and puſhed it two inches out of its place, and terminated below, two inches under the navel. The common means failing to do any ſervice, the patient was ſent to Montpelier, where the beforementioned ſurgeon opened the tumor; on this the *liver* was found abſceſſed in its anterior or convex part, and a cavity was found there capable of receiving half a hen's egg, and there iſſued out of it on a gentle preſſure a thick and bloody, ſometimes a yelloviſh bitter and inflammable matter. This laſt was true bile, and both with this and with the other diſcharge, there always came away ſmall portions of the ſubſtance of the *liver*, and the ſmall extremities of numbers of veſſels might be perceived, ſome ſanguineous, ſome bilious.

The great buſineſs for the ſurgeon, in this caſe, was the getting the matter out of the abſceſs, the preventing its remaining in the ſubſtance of the *liver*, or being again received into the blood. For this purpoſe, Mr. Souiller invented a particular canula, made very ſoft at the end, where it was to be paſſed into the *liver*, and having there ſix lateral holes capable of receiving the matter. This canula was of ſilver, and under its other end there was placed a thin plate of lead, to receive the matter which was diſcharged through it, which would otherwiſe have excoriated any part on which it fell. The abſceſs, which was, by this means, always kept perfectly clean, ſoon began to heal; the fever went off by degrees, the patient every day grew into a better ſtate; and finally, the wound was cicatrized, and all perfectly cured in a very ſhort time. Hiſt. Acad. Par. 1730.

One thing obſervable in the courſe of the cure, was the refutation of a common opinion, that the bile is neither bitter nor coloured, till it gets into the gall bladder; for, in this caſe, it was diſcharged yellow and bitter from the wounded veſſels of the *liver*.

LIVER, in antiquity, was much uſed in divination. See the article HEPATOSCOPIA.

LIVER-*wort*. See the article LICHEN.

LIVERYMEN, (*Cycl.*) in natural hiſtory, a name given by authors to a ſort of caterpillars, remarkable for their variety of colours. Theſe are of that claſs of caterpillars, which live in communities, and build themſelves neſts to defend them from the injuries of the weather. Theſe may be ranked among the proceſſionary kinds, always following one ano-

another with great order in their marches; but what is moſt ſurpriſing, is, to ſee them ſtraggle very far from their neſts, and this often, by ſeveral repeated windings and turnings without loſing their way. Their art, in doing this, deſerves notice, and is the ſame by which Theſeus got out of the labyrinth of Crete. Phil. Tranſ. N° 470. p. 459.

Theſe creatures ſpin all the way that they go. The firſt ſpins a thread as he crawls along, the ſecond follows him in the ſame tract, and a third follows that, and ſo on, all ſpinning as they go; and their threads being all laid cloſe together, by means of their all purſuing the ſame track, they at length furniſh a fine ſhining track all the way they have gone. Theſe make a ſort of path, and ſeveral of theſe paths are ſeen running ſeveral ways from the neſt, which is the common center of them all. By means of theſe paths the creatures are able, at pleaſure, to run back directly to the neſt through all the ways they have gone from it.

If any one of theſe congeries of threads be broken in any part, all the caterpillars that are beyond that part, will be found at a terrible loſs, and running about in different directions, when they come to the place, without any knowledge of the true road to the neſt, till they are led by ſome one, who happens to find the way to the other broken end of the path, and by drawing his threads acroſs the breach, unites the path again; as ſoon as this is done, all the reſt go on the ſame road, and arrive at the neſt.

Theſe, and ſome other caterpillars, have very ſingular taſtes as to food. They firſt of all prey upon the ſhell of the egg out of which they were hatched, and ſome not content with this ſmall quantity of a food they judge ſo delicious, will eat the ſhells of other eggs of the ſame ſpecies that lie near them, and are not yet hatched. Other caterpillars are very fond of their own ſkins, eating up their own exuviæ as a very delicious food. They ſeize upon theſe as food the moment they are thrown off; and this is the more ſingular, as it is well known that the caterpillar, when it has newly thrown off its ſkin, is very feeble, and is not in a condition to eat for ſome time, till its neceſſary organs are hardened in this new ſtate. Yet theſe ſpecies not only immediately devour their tough ſkin, but even the hard parts of their former covering, as the ſkull, ſcales, legs, &c. nay, ſome are obſerved to ſeize firſt of all upon theſe hard parts, and to eat them up before they touch any other. Phil. Tranſ. N° 470. p. 461.

LIVIA, in zoology, a name given by ſome authors to a particular ſpecies of pigeon called *pelæas* by the Greeks. It is very like the common pigeon in ſhape, but is ſomewhat ſmaller, its legs are red, and its beak white, except that it is a little purpliſh about the noſtrils.

It is all over grey, but that the ends of its tail feathers are black, and there is a purpliſh and greeniſh variegation about the ſides and ſhoulders. And its wing feathers have ſome white variegations, as has alſo the lower part of the neck. It is ſuppoſed, by Mr. Ray, and ſome others, to be the ſame with the *faſſarollo* of the Italians, or COLUMBA *rupicola*. *Geſner* de Avib. See the article SASSAROLLO.

LIVONICA *terra*, in the materia medica, a kind of fine bole uſed in the ſhops of Germany and Italy, of which there are two ſpecies, the yellow and the red. The diſtinguiſhing characters of which are theſe.

The yellow livonian earth is a pure and perfectly fine bole, of a ſhattery friable texture conſiderably heavy, and of a dull duſky yellow, which has uſually ſome faint bluſh of reddiſhneſs in it. It is of a ſmooth ſurface, and does not ſtain the hands; it adheres firmly to the tongue, and melts freely in the mouth, leaving no grittineſs between the teeth, and ferments not at all with acid menſtrua.

The red livonian earth is an impure bole, of a looſe texture, and of a pale red. It is of a ſmooth ſurface, breaks eaſily between the fingers, and does not at all ſtain the hands. It melts freely in the mouth, has a very ſtrongly aſtringent taſte, but leaves a grittineſs between the teeth, and does not ferment with acid menſtrua.

Theſe earths are both dug out of the ſame pit, in the place from whence they have their name, and in ſome other parts of the world. They are generally brought to us made up into little cakes, and ſealed with the impreſſion of a church, and an eſcutheon with two croſs keys. In Spain and Portugal they are much uſed, ſometimes ſingly, ſometimes mixed together, and are good in fevers and in fluxes of all kinds. The red is the more powerful aſtringent. *Hill*'s Hiſt. of Foſſ. p. 12.

The Spaniards and Portugueze make alſo a light kind of earthen ware of them.

LIXIVIAL *ſalts*. See the artice SALT.

LIXIVIUM (*Cycl.*)—LIXIVIUM *martis*, a new form of medicine introduced into practiſe in the late London Diſpenſatory. The manner of preparing it is to ſet the matter remaining in the retort after the ſubliming the *flores martis*, in a damp place, where by means of the moiſture of the air it will run into a liquor. *Pemberton*'s Lond. Diſp. p. 216. See the article FLORES *martiales*.

LIXIVIUM *ſaponarium*, *ſoap lees*, a liquor now much uſed in medicine in caſes of the ſtone; and when intended for this uſe, is to be made ſomething leſs ſtrong than for the ſoap boiler's uſe, and ſhould be prepared in the following manner. Take Ruſſia pot-aſh, and quick-lime, of each an equal quantity; throw water on them by ſmall quantities till the lime is ſlaked; then throw on more water, and ſtir the whole together, that the ſalt of the aſhes may be diſſolved: after ſome time pour the liquor filtered through paper, if needful, into another veſſel. A true ſtandard wine pint of this liquor meaſured with the greateſt exactneſs, ought to weigh juſt ſixteen ounces. If it be found on trial to be heavier than this; for every dram it exceeds that weight, an ounce and a half of water is to be added to each pint: but if it be lighter than this, it muſt be either boiled to this ſtandard, or elſe poured upon freſh lime and aſhes.

The makers of ſoft ſoap with us prepare their *lees* ſo much ſtronger than this, that to be reduced to this ſtandard, it requires to be diluted with an equal quantity of fair water. *Pemberton*'s Lond. Diſp. p. 183.

LIXIVIUM *tartari*, the name given in the London Diſpenſatory to the liquor called, by moſt authors, oil of tartar per deliquium. This is made of tartar which is to be calcined to a whiteneſs, and then ſet in a damp place, where it will liquify by the moiſture of the air. The liquor thus procured is more pure, than if the calcined tartar were diſſolved directly in water. *Pemberton*'s Lond. Diſp. p. 181.

LIZARD, in zoology. See LACERTUS.

Devil-LIZARD, or *Fly-catching* LIZARD. See MABOUJAS.

LIZIERE, the ſame with *berme*, *foreland*, or *relais*. See the article BERME, *Cycl.*

When this ſpace is covered with a parapet, it is called a *fauſſe-braye*, or low wall. See FAUSSE-BRAYE, *Cycl.*

LLECH, the welch name for a kind of monumental ſtone found in that country. See PILLAR.

LOACH, in ichthyology, the Engliſh name of a fiſh, called alſo the *groundling*, and by the Germans the *ſmorle* or *ſmorling*. It is a ſpecies of the cobitis, and is diſtinguiſhed by Artedi, by the name of the ſmooth ſpotted cobitis with the cylindric body. See COBITIS.

LOAD (*Cycl.*)—LOAD, in mining, is uſed, eſpecially in the tin mines, for a vein of ore. See TIN.

It is to be obſerved, that mines in general are veins or cavities within the earth, whoſe ſides receding from or approaching to each other, make them of unequal breadths in different places, ſometimes forming large ſpaces, which are called *holes*; theſe holes are filled like the reſt with ſubſtances; which, whether metallic, or of any other nature, are called *loads*. When the ſubſtances forming theſe *loads* are reducible to metal, the *loads* are by the Engliſh miners ſaid to be alive, otherwiſe they are termed dead *loads*.

In Cornwal and Devonſhire the *loads* all hold their courſe from eaſtward to weſtward, though in other parts of England they frequently run from north to ſouth. The miners report, that the ſides of the *load* never bear in a perpendicular, but always overhang either to the north or ſouth. The mines ſeem to have been ſo many channels, through which the waters paſs within the earth, and like rivers they have their ſmall branches opening into them, in all directions; theſe are by the miners termed the feeders of the *load*. Moſt mines have ſtreams of water running through them, and when they are found dry, it ſeems owing to the water having changed its courſe, which it ſeems ſometimes to have been compelled to by the *load*'s having filled up the courſe, and ſometimes to have fallen into other more eaſy channels. Phil. Tranſ. N° 401. p. 404.

The *load* is frequently intercepted by the croſſing of a vein of earth, or ſtone, or ſome other metalline ſubſtance, in which caſe it generally happens, that one part of the *load* is moved to a conſiderable diſtance on one ſide. This tranſient *load* is, by the miners, termed a *flooking*; and the part of the *load* which is moved, is by them ſaid to be heaved. This heaving of the *load* would be an inexpreſſible loſs to the miner, did not experience teach him, that as the *loads* always run on the ſides of the hills, ſo the part heaved is always moved toward the deſcent of the hill; ſo that the miner working toward the aſcent of the hill, and meeting a flooking, conſiders himſelf as working in the heaved part; wherefore, cutting through the flooking, he works upon its back up the aſcent of the hill, till he recovers the load, and *vice verſa*.

Sometimes, though not univerſally, the mine is lined with an intermediate ſubſtance between the *load* and itſelf. This is properly ſpeaking the wall of the *load*; though, in the common acceptation of that term, it ſignifies either ſuch intermediate ſubſtance, or the ſide of the mine where the *load* immediately unites itſelf to it. The ſprings in theſe parts are always hard, as they abound in ſtony or other mineral particles. From theſe particles, which are ſuſtained in large quantities in all theſe places, we frequently find the paſſages quite choaked up; the ſtony matter ſeparated from the water of the ſpring, gradually concreting to the walls of the mine, till it has in time blocked up the whole cavity, with a maſs of ſpar, of a coarſe texture and irregular figure; at other times this ſtony matter concretes more diſtinctly; in which caſe it ſeems to be governed in its formation by a

plaſtic

plaſtic power, or peculiar modus of attraction, by which the particles before ſuſpended in the water are brought together under a peculiar form. This power in general ſo exerts itſelf over the harder particles of matter ſuſtained in the water, as to arrange them into the form of an hexangular pyramid, terminating an hexangular column of four, five, or more times its length. Thus is the common rock cryſtal formed; and when this power is unmoleſted, the columns of this body are carried to a great ſize.

Theſe cryſtals are of different tranſparences and colours, as the pure matter, of which they are compoſed, is more or leſs diſengaged from the mixture of foreign particles; or as thoſe, or other ſubſtances, are found capable of imparting their tinctures, or other qualities to them: but when the plaſtic particles are more numerous, there ſeems reaſon to believe that theſe very plaſtic particles, before they are fixed, are ſubject to the controul and direction of any fixed plaſtic particle, within the verge of whoſe activity they happen to move. Notwithſtanding which, after they are once fixed, they exert their own plaſtic powers, and, in conjunction with the firſt plaſtic principle, govern the future concretion in ſuch manner, as to form a ſeemingly irregular cryſtal, though compoſed of two more regular cryſtals.

Theſe cryſtalline concretions exert a ſtrong attraction on many metallic ſubſtances, ſo as frequently to contain lead, copper, and other metals, in very conſiderable quantities, embodied in them.

The waters of mines are, beſide cryſtal, impregnated alſo with a great quantity of ſulphureo-ſaline particles, and theſe are in ſome of a vitriolic, and in others of an arſenical nature. The firſt of theſe, when pure, concrete into white cubes, reſembling grains of ſilver; while the other, or arſenical ſulphur, concretes into yellow cubes, reſembling grains of pure gold. Both theſe concretions, whether ſingle, or in large confuſed cluſters, are called by the miners *mundick*. The ſulphureo-ſaline principle of concretion ſeems of the ſame nature with the plaſtic power in the formation of cryſtals; and theſe bodies, like the others, are in the ſame manner found ſometimes ſimple, ſometimes compound. On the ſides of theſe the concretion may always be obſerved forming itſelf into threads, which in three ſides run in different directions, but are always ſimilar in the oppoſite ſides. Philoſ. Tranſ. N° 401, p. 403.

LOAD is alſo uſed for nine diſhes of ore, each diſh being about half a hundred weight. *Houghton*'s compl. Miner in the Explan. of the Terms.

Maſter LOAD, among miners. See MASTER *load*.

LOADSTONE (*Cycl.*)—*Armed* LOADSTONE, one that is capped, caſed, or ſet in iron or ſteel, in order to make it take up a greater weight, and alſo to diſtinguiſh its poles readily.

The armour of a *loadſtone*, in figure of a right angled parallelogram, conſiſts of two thin pieces of ſteel or iron, in figure of a ſquare, having a thickneſs proportional to the goodneſs of the ſtone; for if a weak ſtone has a ſtrong armour, it will produce no effect; and if the armour of a ſtrong *loadſtone* be too thin, it will not produce ſuch an effect, as if the armour were thicker. A convenient thickneſs for the armour is found by filing it thinner and thinner, until you find its effect to be the greateſt poſſible.

The armour of a ſpherical *loadſtone* conſiſts of two ſteel ſhells faſtened to one another by a joint, and muſt cover a good part of the convexity of the ſtone. This muſt be alſo filed away by degrees, until the effect of the *loadſtone* is found greateſt.

It is very wonderful, that the armour of a *loadſtone* will ſo much augment its effect, that good ſtones, after they are armed, will lift up above one hundred and fifty times more than before. And even indifferent ones, that weigh only three ounces unarmed, will, when armed, lift more than ſeven pounds.

LOAM, (*Cycl.*) in natural hiſtory, the name of a claſs of foſſile bodies, the characters of which are theſe. They are compound earths compoſed of diſſimilar particles, hard, ſtiff, denſe, harſh, and rough to the touch, not eaſily ductile while moiſt, readily diffuſible in water, and uſually compoſed of ſand and a tough viſcid clay.

Of this claſs there are two genera. 1. The *thrauſtomicthes*; and 2. the *gliſchromicthes*. The firſt are compoſed of ſand and a leſs viſcid clay, and are of a friable or crumbly texture. The ſecond are compoſed of ſand and a more viſcid clay, and are of a more tough and viſcid texture. *Hill*'s Hiſt. of Foſſ. See the articles THRAUSTOMICTHES and GLISCHROMICTHES.

LOBLOLLY, a ſea-faring diſh, otherwiſe called *burgoo*. See the article BURGOO.

LOBS, in mining, are ſteps that aſcend or deſcend within the mines, as ſtairs up to and down from a chamber. *Houghton*'s compl. Miner in the Explan. of the Terms.

LOBUS *echinatus*, in the materia medica, a name by which ſome authors have called the *bonduch*, or Bezoar nut. *Ger. Emac.* p. 1554.

LOCH, (*Cycl.*) in the materia medica, a name given by Aviſenna, and others, to the gum lac. They call it alſo *keikem* and *kenkem*, and are too apt to confound it with the cancamum, ſandarach, and other gums, with which they made their ſeveral ſorts of varniſh. See CANCAMUM.

LOCHE, or *ſea* LOCHE, a name uſed in ſome parts of England for the muſtela, called in other places, particularly in Cornwall, the *whiſtle fiſh*. *Willughby*'s Hiſt. Piſc. p. 121. See MUSTELA.

LOCHIA (*Cycl.*)—The flux of the *lochia*, or of blood and humors from the uterus, about the time of parturition, is of two kinds; the one called *legitimate*, which happens after the excluſion of the fœtus, at its proper time; the other *abortive*, which attends miſcarriages, and does not indeed follow them, but either precedes, or happens immediately in the act of abortion, and that uſually in a very violent and terrible manner. The legitimate is alſo often too copious.

Signs of it. The legitimate *lochial* flux is an excretion of blood from the genitals for eight, ten, twelve, or fourteen days after child-birth, and ſometimes for a longer time than that. During the firſt days, pure blood, grumous, and coagulated, is diſcharged, or at leaſt a fluid coloured with blood; after the fourth or fifth day, this diſcharge is attended with a diſagreeable, and ſometimes with a plainly fœtid ſmell; in the ſucceeding days the humor becomes leſs bloody, and more and more yellowiſh, and after this it gradually becomes pale and watery, till it loſes all colour and ſmell: all this while alſo the flux becomes more and more moderate in quantity, till at length it wholly ceaſes of itſelf. This is the natural ſtate of this flux; but if the ſecundines are too long retained, or if a part of them be torn off and left in the uterus, then the flux frequently exceeds its due bounds, and many pains and ſpaſtic motions are felt about the uterus, and throughout the abdomen.

In the *lochial* fluxes attending abortions, the blood uſually flows out gently and moderately before the act, then it comes on, during the excluſion of the fœtus, with great violence. Sometimes alſo, when violent paſſions of the mind have preceded, it comes on with all this violence at the firſt attack, before the fœtus is excluded: this is followed by the fœtus, or falſe conception, which ever is in the uterus, and this is attended uſually with faintings, and with violent pains in the belly. Perſons ſubject to frequent abortions, have leſs trouble and pain with them than others, and the *lochial* flux is with them in leſs quantity.

The too great flux of the *lochia* is a thing of dangerous conſequence, and the perſons principally ſubject to it are thoſe of plethoric habits, and ſuch as are ſubject to violent paſſions; ſuch as are uſed to much wine, or other ſtrong liquors, and to high ſeaſoned foods, as alſo ſuch as have omitted bleeding at the proper times during their being with child, and ſuch as have been accuſtomed to too copious fluxes of the menſes. In caſes of abortions, thoſe are moſt of all ſubject to immoderate fluxes of them, who have not been duly treated, or properly purged and cleanſed, after a former lying in. The principal occaſions of large fluxes of the *lochia* after child-birth, are either a plethoric habit, or the uſe of violent medicines to promote delivery, or the retention of part of the ſecundines in the uterus.

Prognoſticks from it. The flux of the *lochia*, when moderate and regular, is of the utmoſt benefit to the perſon, and the ſuppreſſion of it is ever attended with danger. This is, of all other fluxes of blood, the moſt ſubject to exceed the uſual quantity; and in abortions, after the third month of pregnancy, is uſually greater than in parturitions at the full time. When this flux is immoderately great, the patient's ſtrength is conſumed by it in a very little time; and when it is not thus violent for a continuance, but returns, after ſhort intervals, with violent effects, it is a ſign that the womb is not properly cleanſed, and the perſon is afterwards frequently either barren, or ſubject to repeated abortions. In caſes of a threatned abortion, when there has once been a copious diſcharge of blood, there ſhould be no attempt made to retain the fœtus in its place.

Method of treating. When the flux of the *lochia* is moderate, it requires no aſſiſtance from the phyſician, but nature is to be left to her own courſe; if they flow too immoderately, the ſame means are to be uſed as in caſes of violent fluxes of the menſes. The medicines which have power to quiet the violent emotions of the blood are to be often repeated, ſuch are nitre, the alkaline abſorbents, as crabs eyes, and the like, and a little cinnabar: if theſe are inſufficient, recourſe is to be had to the milder aſtringents, ſuch as the *crocus martis antimonialis*, and tincture of ſalt of ſteel, and the decoction, or extract of the common yarrow. The abortive flux of the *lochia* is to be treated in the ſame manner with the too violent one attending parturition at the full time. The abortion is always to be haſtened, and the fœtus, mole, or whatever, to be taken out as ſoon as poſſible, when the flux becomes violent, leſt the patient faint and periſh under it. The way to prevent an immoderate flux of the *lochia* in parturition, is to bleed often during the time of pregnancy, and if neceſſary, this may be done even juſt before delivery. The proper ligatures on the belly, after the excluſion of the fœtus, are alſo of great ſervice in

this view, and the keeping perfectly quiet, and avoiding much talking, are greatly conducive to it. The return of abortions is principally guarded againſt by a ſufficient cleanſing of the womb at the time, and by bleeding in the arm about that time of pregnancy, at which the abortion happened before.

Child-bearing women are to be conſidered after parturition, as wounded perſons, in whom fevers are very eaſily brought on, and every thing that makes any commotion in the blood is to be carefully avoided by them. Aſtringent medicines are to be avoided as much as poſſible in theſe caſes; and where they are found abſolutely neceſſary, the milder only are to be given, and attemperating medicines muſt always be given between; and if this is neglected, inflammatory fevers, hectics, and often dropſies, are the conſequence. *Junker*. Conſpect. Med. p. 60, ſeq.

Suppreſſions of the LOCHIA. Theſe are either plenary or partial. In the plenary ſuppreſſion there is no blood diſcharged at all, or if there was a beginning of a proper diſcharge, it ſtops during the firſt day. In the partial ſuppreſſion, or as it is called by ſome writers, the imminution of the *lochia*, they keep their period of eight, ten, or twelve days, but are in ſo ſmall a quantity, as to be ſcarce allowable under the name of a flux of this kind. In the judging of this imminution, it is neceſſary to conſider the natural ſtate and conſtitution of the patient; and if in the time of her not being pregnant, ſhe have been uſed to but ſmall diſcharges by the menſtrual flux, there is not to be expected a large flux of the *lochia*; if the perſon has had children before, enquiry is alſo to be made into the quantity diſcharged at thoſe times, and from that is to be determined what is to be expected. The perſons ſubject to ſuppreſſions of the *lochia* are principally thoſe of a plethoric habit, and whoſe veins are ſmall; thoſe who are of a timid diſpoſition, and eaſily ſubject to fear, ſorrow, and the like paſſions. Theſe are principally the natural cauſes of a ſuppreſſion of the *lochia*, but to theſe are to be joined many accidental and adventitious ones; ſuch as the ſudden cooling of the body, the giving very forcing medicines to forward the delivery, and the improper uſe of hot medicines. Theſe are often given to promote the *lochia*, when they are judged not to flow in ſufficient quantity, and they often produce a plenary ſuppreſſion of them, inſtead of a cure. Myrrh, ſaffron, and the volatile ſalts, when given injudiciouſly, are of this tribe. Sometimes alſo ſuppreſſions of them are brought on by violent paſſions, and by the repeated and forcible efforts the perſon has been obliged to make during a hard labour.

Prognoſticks from it. There is no kind of hæmorrhage, the ſuppreſſion of which is attended with ſuch great, or ſuch imminent danger, as this of the *lochia*. The natural ſuppreſſions are uſually either from an over quantity of blood, with a ſpiſſitude of it, or from a turgeſcence and violent emotion of it. In the firſt caſe, the ſymptoms which ſucceed are leſs violent, in the latter they are more terrible. Of the firſt kind are inquietude, toſſing and turning about, anxiety, and ſtraitneſs of the præcordia, pains of the head, and want of appetite. In the latter caſe, fevers of the inflammatory kind often immediately enſue, and ſometimes miliary and purple fevers, with great malignity; ſome alſo immediately fall into deliriums of the moſt violent kinds, and into quinſeys. Theſe are the ſudden effects of theſe ſuppreſſions; but beſide theſe, there are often left coagulations, or grumes of blood in the uterus; theſe prevent future conception, or prevent the fœtus, when conceived, from receiving due nouriſhment, and bring on, by that means, abortion; and when this is not the caſe, they ſubject the patient to various hyſteric and convulſive diſorders, and frequent faintings.

Method of cure. When the ſuppreſſion is but partial, and the *lochia* do flow, though in too ſmall a quantity; in this caſe the more gently ſtimulating medicines are to be given, and even theſe only in very ſmall doſes. The tincture of myrrh and ſaffron, and eſſence of amber, may in this caſe be mixt and given, twenty, or twenty-five drops at a doſe twice a day: theſe often have a very ſpeedy and happy effect. When the ſuppreſſion is plenary, and eſpecially when it has already held the patient ſome days, it is vain to expect to bring on a regular diſcharge of them at once by ſtimulating medicines; the cauſes of the ſuppreſſion are then to be enquired into, and the febrile emotions of the blood allayed by febrifuges, and by nitrous medicines; and when the blood is reſtored to its proper ſtate, they will again begin to flow regularly. The common method of bleeding to bring them on again, is ſeldom attended with much ſucceſs; when indeed the patient has omitted bleeding at proper times during pregnancy, this ſometimes proves ſerviceable; but rarely when the blood is faulty in quality, rather than in quantity. The generality of the world are afraid of nitre in theſe caſes, leſt it ſhould bring on diarrhœas, but it is only an immoderate uſe of it, that is liable to this objection; for given in doſes of four, five, or ſix grains, it will rather prevent, than occaſion a diarrhœa in theſe caſes. *Junker*'s Conſp. Med. p. 80. See DELIVERY.

LOCHIAL *fevers*, a term uſed by medical writers to expreſs ſuch fevers as ariſe from ſuppreſſions, or imminutions of the *lochial* diſcharges in lying-in-women, or from any other irregularities during the time of that diſcharge. *Junker*'s Conſp. Med. p. 252.

LOCKER, in a ſhip, a kind of box or cheſt made along the ſide of a ſhip, to put or ſtow any thing in.

LOCKMAN, in the Iſle of Man, the officer who executes the orders of the government, much like our under ſheriff. *King*'s Deſcript. Iſl. Man, p. 26.

LOCKS, in the manege, in French called *entravons*, are pieces of leather two fingers broad, turned round, and ſtuffed on the inſide, to prevent their hurting the paſtern of a horſe, round which they are clapped. An *entrave* is compoſed of two *entravons* joined by an iron chain, ſeven or eight inches long.

LOCKSPIT, among miners, is the ſmall cut, or trench made with a ſpade of about a foot wide, to mark out the firſt lines of a work.

LOCRIAN, in antient muſic, the ſeventh ſpecies of the diapaſon. It was alſo called *hypodorian*, and *common*. See the article DIAPASON.

LOCUS, (*Cycl.*) among antient muſicians, was uſed to ſignify the interval between one degree of acuteneſs, or gravity of ſound, and another. The Greeks uſed the word τοπος in the ſame ſenſe, for the ſpace through which the voice moved. *Wallis*'s Append. ad Ptolem. Harmon. p. 153. *Ariſtoxenus*, p. 3, 8, 9, 10. Edit. Meibom. See MOTION.

This motion the Greeks diſtinguiſhed into two kinds; one continued, συνεχη, the other disjunct, διαστηματικη. Inſtances of the firſt kind are in ſpeaking; of the ſecond in ſinging; and this they called melodic motion, or what was adapted to ſinging. Ptolemy in like manner divides ſounds of unequal pitch, ψοφους ανισοτονους, into continued and diſcrete, and ſays the firſt kind are improper, and the ſecond proper, for harmony.

Ariſtides Quintilianus [a] interpoſes a third kind of motion between the two here mentioned, ſuch as that of a perſon reciting a poem.—[[a] Id. p. 6. Edit. Meibom.]

LOCUS, the *locuſt tree*, in botany, is uſed by ſome for the tree whoſe juices afford us the gum anime of the ſhops. *Dale*'s Pharm. p. 338.

LOCUS, in rhetoric, a topic, or head, whence arguments are brought to prove the queſtion in hand. Some of theſe are called *loci communes*, or common topics, as being common to all ſorts of arguments; thus, whether a thing be poſſible or impoſſible, more or leſs than ſomething elſe, &c. *Voſſ.* Rhet. l. 1. p. 12.

Beſide theſe, three others are mentioned by rhetoricians *juſtum*, *utile*, & *honeſtum*; to which ſome add *jucundum*; but Voſſius will have this laſt to be comprehended under *utile*. Id. ibid. p. 32, ſeq.

LOCUST, *locuſta*, a genus of inſects comprehending the *locuſt*, ſimply ſo called, the ſeveral ſpecies of other *locuſts* and graſhoppers, with the crickets of the houſe and field.

Willughby obſerves, that in theſe animals there are always more males than females, which is contrary to the order of nature in other inſects, where the females are much the moſt numerous; and Swammerdam obſerves, that it is only the males that make a noiſe, which he ſays they do by a ſwift vibration of their wings, either againſt one another, or againſt their legs. See Tab. of Inſects, N° 3. ſeq.

The nympha, or worm of the *locuſt*, ſcarce at all differs from the creature in its perfect ſtate. It moves and eats in the nymph ſtate, and all the viſible difference is, that the wings are not expanded as in the perfect *locuſt*, but are gathered up in a ſmall compaſs, and form four little buttons on the ſhoulders. Swammerdam obſerves, that the want of attention to this particular in former writers, had been the occaſion of a very unneceſſary multiplication of names; as Aldrovand, Johnſon, Mouffet, and others, have deſcribed theſe *locuſts* in the nymph ſtate under the names of *bruchi*, *attebali*, and *aſelli*, ſuppoſing them to be ſo many diſtinct ſpecies of animals. It is obſerved, that toward the end of ſummer the males are very tender of the females, three or four of them being frequently ſeen gathered about one of that ſex, and ſeeming to do her all the kind offices in their power, fluttering about with their wings, and rubbing her with their fore legs. The males are always more briſk and nimble than the females; and among all the kinds of *locuſts*, there are a great many naturally imperfect; particularly many have only one hinder leg, yet theſe hop almoſt as well as the reſt. *Swammerd.* Bibl. Natur. *Ray*'s Hiſt. Inſ. p. 60.

We have in England but very few inſects of this kind. The ſpecies mentioned by Mr. Ray are theſe. 1. The common ſmall green *graſhopper*. This has articulated antennæ, very flexile, and nearly half an inch long; its belly is green; its outer wings brown, and its inner ones membranaceous, tranſparent, and reticulated. Its back is divided into eight or nine rings, and is of a browniſh colour. The hinder legs are very long, and ſtrong. There is a great variety in the colour of this ſpecies, ſome have more, ſome leſs green, and ſome have a little yellow about them. 2. The larger

grey

grey winged *graſhopper*. This is diſtinguiſhed by having grey wings ſpotted with black. 3. The ſmall brown *graſhopper* with a long rhomboidal head. The antennæ in this ſpecies are very ſhort. 4. The great green *graſhopper*. This is accurately deſcribed by Joan. de Muralto in the German Ephemerides, and Mr. Ray has taken the whole into his hiſtory. The antennæ are long and ſlender, the eyes black and prominent, and the breaſt is remarkably high and narrow. 5. The great Spaniſh *locuſt* of a browniſh grey with ſpotted wings. This is about three inches long, and is the ſpecies lately found in England. 6. The great African *locuſt* with ſtriated ſhoulders. This differs from the former only in theſe ſtreaks. 7. The great African *locuſt*. This is four inches long, and is of a green colour. Under the ſhoulders there are only ſmall rudiments of wings, and it has two ſtrong yellow forceps's under the tail, which terminate in black points. Thoſe ſpecies of this genus commonly called crickets, ſee under the article GRYLLUS. Ephem. Germ. Anno 12. Obſ. 16. *Ray*'s Hiſt. Inſ. p. 64. See alſo CICADA and HARVEST-*fly*.

The country of the Coſſacks or Ukrain is, in dry ſummers, much infeſted with ſwarms of *locuſts* driven thither by an eaſt or ſouth eaſt wind. The number of theſe inſects is ſo great, that they darken the air, and devour all the corn of the country. They lay their eggs in autumn and then die. It is ſaid that each of theſe creatures lays two, or three hundred eggs, which hatching the enſuing ſpring, produce ſuch a number of *locuſts*, that they do far more miſchief than before, unleſs the rains fall, which kill both the eggs and the inſects, or unleſs a ſtrong north or north weſt wind ariſes, which drives all into the Euxine Sea. The hogs of the country are fond of theſe eggs, and devour great quantities of them. In the night, when theſe inſects reſt on the ground, they cover it to the height of three or four inches. If a wheel paſs over them they emit an intolerable ſtench. Phil. Tranſ. N° 8. p. 137. where Monſieur Beauplan's deſcription of Poland, and Thevenot's Voyages, Part I. are referred to.

Water LOCUST, *locuſta aquatica*, the name given by authors to a ſpecies of water inſect, ſomewhat reſembling the *locuſt* kind in ſhape. It is about three inches long, its tail an inch and quarter, and its legs are of different lengths; the anterior pair being the ſhorteſt of all. Its body is ſlender, and its fore-legs are always carried ſtrait forward, ſo as to reach beyond the head in the form of antennæ. Theſe, as well as the other legs, end each in two claws. The eyes are ſmall and not very prominent, and the upper wings are cruſtaceous, the under ones membranaceous, thin, and tranſparent. The middle joint of the leg is ſuch, that the creature can only move them upwards, not downwards, and there runs an acute tongue or proboſcis under the belly, as is the caſe in the water ſcorpion and notonecta. *Ray*'s Hiſt. Inſ. p. 59.

LOCUSTA *pulex*, a name given by Swammerdam to a genus of inſects, deſcribed ſince by Mr. Ray, under the name *cicadula*. See CICADULA.

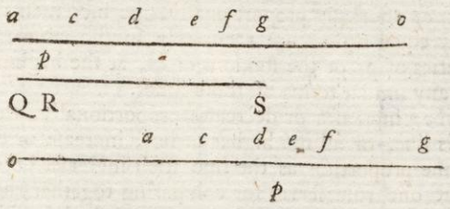
LOCUSTELLA, in zoology, the name of a ſmall bird of the lark kind. It is ſmaller than the common wren, and of a browniſh yellow colour ſpotted with black; its tail is long and brown, and its belly and thighs are variegated with oblong ſtreaks of a blackiſh brown; its legs are very long, ſlender, and brown. It feeds on flies, and makes the ſame ſort of noiſe that the graſhopper does, only much louder; and uſually, as it ſings, ſits on the ſummit of ſome prickly ſhrub, and vibrates its wings about very briſkly. *Johnſon* de Avibus.

LOESELIA, in botany, the name of a genus of plants, called alſo *royenia* by Houſton. The characters are theſe: the perianthium is one leaved, and tubular; it is ſhort, and divided into four ſegments, and remains after the flower is fallen. The flower conſiſts of one irregular petal. It is formed into a tube of the length of the cup, and its verge is divided into five equal ſegments, all bending toward one ſide, and of an oval figure. The ſtamina are four filaments of the length of the flower. Two of theſe are ſhorter than the others. The antheræ are ſimple, and the germen of the piſtil is oval. The ſtyle is ſimple, the ſtigma thick, the capſule is of an oval figure, divided into three cells, and containing a number of ſeeds of an angular figure. *Linnæi* Gen. Pl. p. 306. *Houſton* A. A.

LOG (*Cycl.*)—LOG, in the Jewiſh antiquities, a meaſure which held a quarter of a *cab*, and conſequently five ſixths of a pint. There is mention of a *log*, 2 Kings vi. 25. under the name of a *fourth part of a cab*. But in Leviticus the word *log* is often met with, and ſignifies that meaſure of oil, which lepers were to offer at the temple after they were cured of their diſeaſe.[—*Calmet*. Dict. Bibl. Levit. xiv. 12, 24.—]

Dr. Arbuthnot ſays, that the *log* was a meaſure of liquids, the 72^{d} part of the *Bath* or *Ephah*, and 12th part of the Hin, according to all the accounts of the Jewiſh writers. *Arbuth*. Tables of antient coins, *&c.*

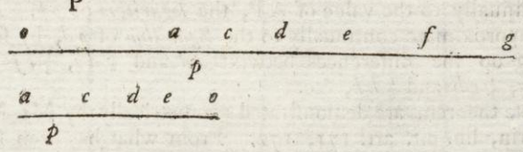
LOG-*book*, at ſea, a book ruled and columned like the *log-board*. It is uſed by ſome to enter the *log-board*'s account in every day at noon, with the obſervations then made; and from hence it is corrected and entered into the journals.



LOG-*wood*, the wood of a tree called by Ray *arbor ſiliquoſa floribus papilionaceis*. It is deſcribed by Breynius under the name of *criſta pavonis coronillæ folio ſecunda*, and *erythroxylum indicum ſpinoſiſſimum coluteæ foliis, floribus luteis, ſiliquis maximis*. It grows both in the Eaſt and Weſt-Indies, but no where ſo plentifully as on the coaſt of Campeche. See CAMPECHE, *Cycl.*

Beſide its uſe among dyers, it is found to be an excellent aſtringent, and is given, with ſucceſs, in form of extract in diarrhœas.

LOGARITHM (*Cycl.*)—*Logarithms* are not only of great uſe for facilitating computations in arithmetic and trigonometry, but have been found of extenſive ſervice in the higher geometry, particularly in the method of fluxions. The nature and geneſis of *logarithms* is explained in the Cyclopædia, after the manner made uſe of in moſt elementary treatiſes; but it may be proper to add ſomething more on this ſubject from Mr. Mac Laurin's Treatiſe of fluxions, who has explained the nature and geneſis of *logarithms*, agreeably to the notion of their firſt inventor Lord Napier.



Logarithms, and the quantities to which they correſpond, may be ſuppoſed to be generated by the motion of a point. If this point moves over equal ſpaces in equal times, the line deſcribed by it increaſes equally.

Again, a line decreaſes proportionally when the point that moves over it deſcribes ſuch parts in equal times as are always in the ſame conſtant ratio to the lines from which they are ſubducted, or to the diſtances of that point at the beginning of thoſe times, from a given term in the line. In like manner, a line may increaſe proportionally, if in equal times the moving point deſcribes ſpaces proportional to its diſtances from a certain term, at the beginning of each time. Thus, in the firſt caſe, let *ac* be to *ao*, *cd* to *co*, *de* to *do*,

ef to *eo*, *fg* to *fo*, always in the ſame ratio of QR to QS; and ſuppoſe the point *p* ſets out from *a*, deſcribing *ac*, *cd*, *de*, *ef*, *fg*, in equal parts of the time; and let the ſpace deſcribed by *p* in any given time, be always in the ſame ratio to the diſtance of *p* from *o* at the beginning of that time, then will the right line *ao* decreaſe proportionally.

In like manner the line *oa*, increaſes proportionally, if the point *p* in equal times deſcribes ſpaces *ac*, *cd*, *de*, *ef*, *fg*, &c. ſo that *ac* is to *ao*, *cd* to *co*, *de* to *do*, &c. in a conſtant ratio.

If we now ſuppoſe a point P deſcribing the line AB with an uniform motion, while the point *p* deſcribes a line increaſing or decreaſing proportionally, the line AP deſcribed by P with this uniform motion, in the ſame time that *oa* by increaſing or decreaſing proportionally becomes equal to *op*, is the *logarithm* of *op*. Thus AC, AD, AE, *&c.* are the *logarithms* of *oc*, *od*, *oe*, &c. reſpectively; and *oa* is the quantity whoſe *logarithm* is ſuppoſed equal to nothing.

We have here abſtracted from numbers, that the doctrine may be the more general; but it is plain, that if AC, AD, AE, *&c.* be ſuppoſed 1, 2, 3, *&c.* in arithmetic progreſſion; *oc*, *od*, *oe*, &c. will be in geometric progreſſion, and that the *logarithm* of *oa*, which may be taken for unity, is nothing.

Lord Napier, in his firſt ſcheme of *logarithms*, ſuppoſes, that while *op* increaſes or decreaſes proportionally, the uniform motion of the point P, by which the *logarithm* of *op* is generated, is equal to the velocity of *p* at *a*; that is, at the term of time, when the *logarithms* begin to be generated. Hence *logarithms* formed after this model are called *Napier*'s *logarithms*, and ſometimes *natural logarithms*.

When a ratio is given, the point *p*, deſcribes the difference of the terms of the ratio in the ſame time. When a ratio is duplicate of another ratio, the point *p* deſcribes the difference of the terms in a double time. When a ratio is triplicate of another, it deſcribes the difference of the terms in a triple time; and ſo on. Alſo when a ratio is compounded of two or more ratio's, the point *p* deſcribes the difference of the terms of that ratio, in a time equal to the ſum of the times, in which it deſcribes the differences of the terms of the ſimple ratios of which it is compounded. And

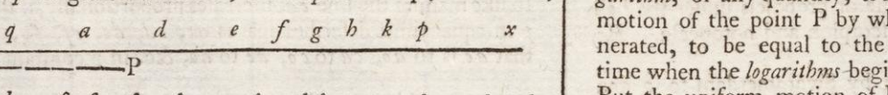
what is here ſaid of the times of the motion of p when op increaſes proportionally, is to be applied to the ſpaces deſcribed by P, in thoſe times; with its uniform motion.

Hence the chief properties of *logarithms* are deduced. They are the meaſures of ratios. The exceſs of the *logarithm* of the antecedent above the *logarithm* of the conſequent meaſures the ratio of thoſe terms. The meaſure of the ratio of a greater quantity to a leſſer is poſitive, as this ratio compounded with any other ratio increaſes it. The ratio of equality compounded with any other ratio, neither increaſes nor diminiſhes it; and its meaſure is nothing. The meaſure of the ratio of a leſſer quantity to a greater is negative, as this ratio compounded with any other ratio diminiſhes it. The ratio of any quantity A to unity, compounded with the ratio of unity to A, produces the ratio of A to A, or the ratio of equality; and the meaſures of thoſe two ratios deſtroy each other when added together; ſo that when the one is conſidered as poſitive, the other is to be conſidered as negative.

When op increaſes proportionally, the motion of p is perpetually accelerated; and, on the contrary, when op decreaſes proportionally, the motion of p is perpetually retarded.

If the velocity of the point p be always as the diſtance op, then will this line increaſe or decreaſe in the manner ſuppoſed by Lord Napier; and the velocity of the point p being the fluxion of the line op, will always vary in the ſame ratio as this quantity itſelf. See *Mac Laurin*'s Fluxions, Art. 151—160.

The fluxion of any quantity is to the fluxion of its *logarithm*, as the quantity itſelf is to unity.



Hence, the fluxion of the *logarithm* of x will be $\frac{\dot{x}}{x}$. For $x : 1 :: \dot{x} : \frac{\dot{x}}{x}$ = the fluxion of the *logarithm* required.

When op increaſes proportionally, the increments generated in any equal times, are accurately in the ſame ratio as the velocities of p, or the fluxions of op, at the beginning, end, or at any ſimilar terms of thoſe times.

When op increaſes or decreaſes proportionally, the fluxions of this line, of all the higher orders, increaſe or decreaſe in the ſame proportion as the line itſelf increaſes or decreaſes; ſo that one rule ſerves for comparing together thoſe of any kind at different terms of the time. And in this caſe we never arrive at any conſtant or invariable fluxion.

If the *logarithms* of two quantities be always to each other in any invariable ratio, the fluxions of thoſe quantities ſhall be in a ratio that is compounded of the ratio of the quantities themſelves, and of the invariable ratio of their *logarithms*.

Let op be greater than oa; $ad : ap :: oa : op$; and let oa,

ad, de, ef, fg, &c. be continued in proportion: then by adding together ad, $\frac{1}{2}de$, $\frac{1}{3}ef$, $\frac{1}{4}fg$, &c. we approximate continually to the value of A P, the *logarithm* of op. And we approximate continually to the *logarithm* of od, by ſumming up the differences betwixt ad and $\frac{1}{2}de$, $\frac{1}{3}ef$ and $\frac{1}{4}fg$, $\frac{1}{5}gh$ and $\frac{1}{6}hk$, &c.

Theſe theorems are demonſtrated geometrically by Mr. Mac Laurin, lib. cit. art. 171, 172. From what has been ſaid, it follows, that if $oa : od :: op : ox$, then the *logarithm* of ox will be equal to the ſum of the *logarithms* of op and od, that is, to the ſum of $ad + \frac{1}{2}de + \frac{1}{3}ef + \frac{1}{4}fg + \frac{1}{5}gh + \frac{1}{6}hk$, &c. and $ad - \frac{1}{2}de + \frac{1}{3}ef - \frac{1}{4}fg + \frac{1}{5}gh - \frac{1}{6}hk$, &c. which ſum is $2ad + \frac{2}{3}ef + \frac{2}{5}gh +$ &c.

Let $aq = ad$; then the *logarithm* of ox will meaſure the ratio of od to oq. But od and oq have half their ſum equal to oa, and half their difference equal to ad, which are the two firſt terms of the geometric progreſſion oa, ad, de, ef, fg, gh, hk, &c. Hence, if $oa = 1$, and $ad = x$, de, ef, fg, &c. will be reſpectively, x^2, x^3, x^4, &c. and the ratio of $1+x$ to $1-x$ will be equal to that of od to oq. But the *logarithm* of this ratio is $2ad + \frac{2}{3}ef + \frac{2}{5}gh +$, &c. therefore the *logarithm* of $\frac{1+x}{1-x} = 2x + \frac{1}{3}x^3 + \frac{1}{5}x^5 + \frac{1}{7}x^7 +$ &c. agreeably to what has been ſhewn by Dr. Halley and others.

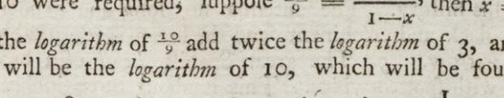
To find, for example, the *logarithm* of 2. From this expreſſion of the *logarithm* of $\frac{1+x}{1-x}$. Then $\frac{1+x}{1-x} = 2$, or $1+x = 2-2x$, and $3x = 1$ or $x = \frac{1}{3}$, that is in decimals.

x	= 0.33333333	And x	= 0.33333333
x^3	= 3703703	$\frac{1}{3}x^3$	= 1234568
x^5	= 411522	$\frac{1}{5}x^5$	= 82304
x^7	= 45725	$\frac{1}{7}x^7$	= 6532
x^9	= 5081	$\frac{1}{9}x^9$	= 720
x^{11}	= 564	$\frac{1}{11}x^{11}$	= 51
x^{13}	= 63	$\frac{1}{13}x^{13}$	= 5
x^{15}	= 7	Sum	0.34657513
		Multiply by	2
			0.69315026 Napier's.

Logarithm of 2.

To find the *log.* of 3, find firſt the *logarithm* of $\frac{1}{2} = \frac{1+x}{1-x}$ where $x = \frac{1}{3}$. To the *logarithm* of $\frac{1}{2}$ add the *logarithm* of 2, and the ſum will be the *logarithm* of 3. If the *logarithm* of 10 were required, ſuppoſe $\frac{10}{9} = \frac{1+x}{1-x}$, then $x = \frac{1}{19}$. To the *logarithm* of $\frac{10}{9}$ add twice the *logarithm* of 3, and the ſum will be the *logarithm* of 10, which will be found to be 2.30258509, &c. and its reciprocal or $\frac{1}{2.30258, \&c.}$ will be = 0.43429448, &c.

Now to convert any of Napiers's or of the natural *logarithms* into Briggs, where the *logarithm* of 10 is unity, ſay, as Napier's *logarithm* of 10 is to 1, ſo is any other of Napier's *logarithms* to Brigg's *logarithm* of the ſame number. Hence, Briggs's *logarithm* will be equal to Napier's divided by 2.30258509, &c. or which comes to the ſame thing, multiplied by its reciprocal, 0.43429448, &c. And *vice verſa*, Briggs's *logarithm* being given, to find Napier's correſponding, multiply Briggs's by 2.30258509, &c.

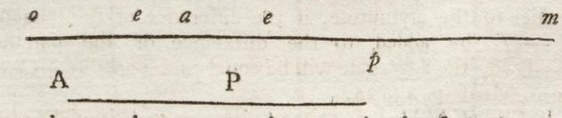


In general, to find Briggs's *logarithm* of any number n. Let $\frac{1+x}{1-x} = n$, and conſequently $x = \frac{n-1}{n+1}$. Multiply x by 0.86858896, &c. (= 2 × 0.43429, &c.) and then continually multiply this product by xx, and divide the reſulting products, reſpectively, by the terms of the progreſſion 1, 3, 5, 7, &c. The ſum of theſe quotients will be Briggs's *logarithm* required.

The firſt *logarithms* being once found, we may thence form the *logarithm* of any prime number. For inſtance, let it be required to find the *logarithm* of 19. Take two integers, one immediately greater, the other leſs than 19, that is, 18 and 20. Theſe not being primes, their *logarithms* may be found from thoſe of their factors, 2, 3, and 5; thus $l.20 = 2l.2 + l.5$. and $l.18 = 2l.3 + l.2$. But the ſquare of the mean number 19 always exceeds the rectangle of the two above and below it by 1. (Since in general, $nn = \overline{n+1} \times \overline{n-1} + 1 = nn - 1 + 1$). Find therefore the *logarithm* of $\frac{361}{360} = \frac{1+}{1-x}$, where $x = \frac{1}{721}$. To this *logarithm* add the *logarithm* of $360 = l.18 + l.20$, the ſum will be $l.361$, half of which is the *logarithm* of 19. See *Cotes*'s Harm. Menſ. Prop. 2.

As to the various compendia ariſing in the practice of conſtructing a table of *logarithms*, we refer to Gardiner's, and to Sherwin's Tables.

We have already obſerved, that Napier's, or the natural *logarithm*, of any quantity, is found by ſuppoſing the uniform motion of the point P by which the *logarithm* of op is generated, to be equal to the velocity of p, at the term of time when the *logarithms* begin to be generated.

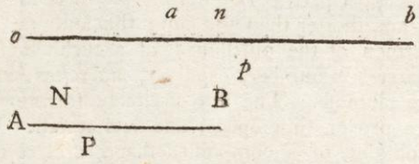


But the uniform motion of P may be ſuppoſed equal to the motion of p at any other term, as when it comes to e, in which caſe the conſtant velocity of P is to the velocity with which p ſets out from a, when the *logarithm* begins to be generated, as oe is to oa. Thus we may have as many *logarithms* as we pleaſe; and the line oe is what Mr. Cotes calls the *modulus* of the ſyſtem.

The meaſures of a given ratio in the different ſyſtems are in the ſame proportion as the lines oe, e being always the term where the velocity of p becomes equal to the conſtant velocity of P. Hence, the *logarithm* of any quantity in Napier's firſt ſyſtem, becomes equal to the *logarithm* of the ſame quantity in any other ſyſtem whoſe modulus is oe, by multiplying by the number which expreſſes the ratio of oe to oa; and the modulus of any ſyſtem is to the modulus of any other ſyſtem, as the *logarithm* of any given quantity in the firſt is to its *logarithm* in the ſecond. Thus in Napier's firſt ſcheme, in the ſame time that op from being equal to oa becomes equal to ten times oa, the point P deſcribes a line, the ratio of which to oa is that of 2.30258509, &c. to unity. But it was found convenient that the *logarithm* of 10 ſhould be 1; and the motion of P was ſuppoſed to be ſo far diminiſhed, that the ſpace deſcribed by it in that time might be equal only to oa; that is, its velocity, in this caſe, was ſuppoſed leſs than its velocity in the former, in the ſame ratio, as 1 is leſs than 2.30258, &c. If oe be taken leſs than oa in the ſame ratio, the velocity of P ſhall be equal, in this caſe, to the velocity of p at e; and oe will be the modulus of this ſyſtem, which will therefore be expreſſed by 0.43429448, &c. $= \frac{1}{2.30258509 \&c.}$ oa being unity. *Mac Laur.* Lib. cit. Art. 174.

When a ratio is given, its meaſure is always as the modulus of the ſyſtem. It is therefore the ſame invariable ratio that is always meaſured by the modulus of the ſyſtem, which

is called by Mr. Cotes *ratio modularis*. This ratio is that of *om* to *oe*, if *op* by increasing proportionally, from being

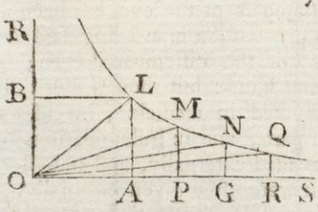


equal to *oe*, becomes equal to *om*, in the same time that P, by its uniform motion, describes a line equal to the modulus *oe*. Ibid. Art. 175, 753.

This *ratio modularis* is found to be that of 2,718281828459, &c. to 1; or of 1 to 0.367879441171, &c. *Cotes*, Harm. Mensur. p. 7.

If a *logarithm* z be given, the number corresponding, if z be a natural *logarithm*, will be expressed by this series, $1 + z + \frac{1}{2} z^2 + \frac{1}{6} z^3 + \frac{1}{24} z^4 + \frac{1}{120} z^5 + \frac{1}{720} z^6 +$, &c. or generally, if the modulus be M, by this, $1 + \frac{z}{M} + \frac{z^2}{2M^2} + \frac{z^3}{6M^3} +$, &c. which when $z = M$ is chang'd into $1 + 1 + \frac{1}{2} + \frac{1}{6} + \frac{1}{24} + \frac{1}{120} +$, &c. or $1 + \frac{1}{1} + \frac{1}{1.2} + \frac{1}{1.2.3} + \frac{1}{1.2.3.4} + \frac{1}{1.2.3.4.5} + \frac{1}{1.2.3.4.5.6} +$, &c. = 2.7182818, &c. the ratio of which to 1 is the ratio modulans. See *Mac Laurin*, Flux. Art. 753. *Cotes*, Harm. Mensur. p. 6, 7.

We have said, that, in Lord Napier's first system, the constant velocity of P, by which the *logarithm* AP is generated, is equal to the velocity with which *p* sets out from *a*. Therefore, if we suppose AP and *ap* to be diminished continually,

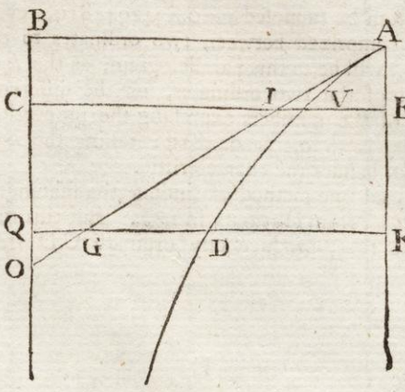


AP being always the *logarithm* of *op*, their ratio shall continually approach to a ratio of equality as its limit. (See LIMIT.) And, *oa* being supposed to represent unity, if *ap* be very small compared with *oa*, it may be supposed in approximations to be the *logarithm* of *op*, in this system; and any very small fraction may be supposed to be the *logarithm* of the sum of unity and that fraction added together. From this it follows, that if a series of mean proportionals be interposed between *oa* and any given line *ob*, and the number of all the terms, exclusive of *oa*, be *x*; and *on* being the second term of the series, *an* be to *ab* as unity is to the number *q*: then, by increasing continually the number of mean proportionals betwixt *oa* and *ob*, the ratio of *x* to *q* shall approach continually to the ratio of AB (the *logarithm* of *ob*) to *ab*, as its limit. For the number *x* is to unity as AB is to AN (the *logarithm* of *on*;) and unity is to *q* as *an* (which approaches continually to AN) is to *ab*. Therefore the ratio of *x* to *q* approaches continually to that of AB to *ab*. For instance, if *ob* be double of *oa*, the ratio of *x* to *q* approaches continually to the ratio of the natural *logarithm* of 2 to unity, which is nearly that of 7 to 10. *Mac Laurin*, lib. cit. Art. 179. and *De Moivre* Doctr. of Chances, Probl. 5.

Hyperbolic LOGARITHMS are the same as natural *logarithms*, or those of Napier's first scheme.

The reason of the appellation is the analogy hyperbolic spaces have to *logarithms*. Thus,

It is known, that if on the asymptote OS of an hyperbola



LMN, the abscissæ OA, OP, OG, OR, &c. be taken in geometric progression, the corresponding sectors LOM, LON, LOQ, &c. or the segments LAPM, LAGN, LARQ, &c. will be in arithmetical progression. Hence, the segments or sectors will be the *logarithms* of their corresponding abscissæ, OP, OG, OR, &c. And the sector LOM, or the segment LAPM measures the ratio OP to OA. The modulus of this system of *logarithms* is the parallelograms OALB, which being supposed unity, these *logarithms* coincide with Napier's.

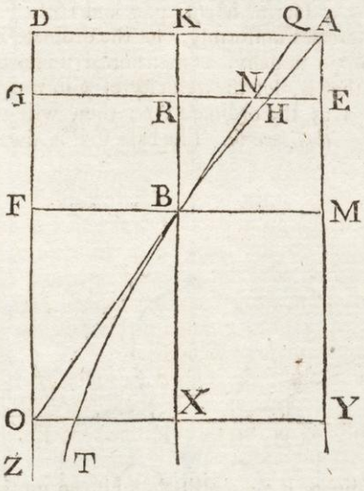
Hyperbolic sectors measure ratios as circular sectors or arches measure angles. See *Mac Laurin*, l. c. Art. 177. *L'Hopital* Sect. Coniq. Art. 221.

LOGARITHMIC (*Cycl.*)—LOGARITHMIC *curve*. This curve was called *logarithmic* or *logistic* by Huygens: though others had considered it before him, none had named it. He has given us several curious properties relating to it, at the end of his treatise of the cause of gravity, but without demonstrations. These have been since supplied by Guido Grandi. See *Huyg.* Oper. Vol. 2. Amstel. 1728.

These properties are,

1. The spaces comprehended between two ordinates, are as the difference of those ordinates. Thus let AVD be a *logarithmic*, and its ordinates AB, VC, DQ; let the two last continued meet AK, a parallel to the asymptote BO, in E and K, then will the spaces ABCV, ABQD be to each other as EV to KD.

2. If AO be a tangent in A, intersecting CE and KQ in I, G; the spaces AVE, ADK, will be to each other as VI and DG.



3. The space ABQD; is to the infinite space beyond QD, and lying between the curve and its asymptote, as KD to DQ.

The accurate author observes, that when he says the infinite space has a certain proportion to a finite one, he means that this infinite, or indefinite space, may approach so near to a given space, having that certain proportion to another, that the difference may become less than any assigned quantity.

4. The subtangent is constant.

5. This subtangent may be found by approximation, and is to the portion of the asymptote intercepted between ordinates in the ratio of 2 to 1, as 43429, &c. to 30103, or nearly as 13 to 9. That is, as the modulus of Briggs's system, to the *logarithm* of 2. See LOGARITHM.

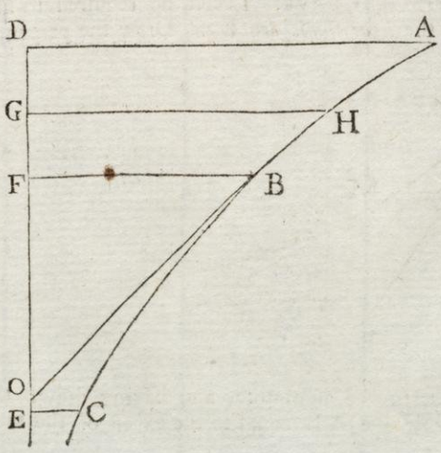
6. If there be three ordinates, as AD, GH, BF, and if from the extremity B of the least, there be drawn a parallel to the asymptote BK, cutting the other two ordinates in R, K; as also a tangent BQ, cutting them in N, Q; the trilinear spaces ABK, HBR, will be to each other as the portions of the ordinates intercepted between the curve and the tangent, that is, as AQ, HN.

7. The infinite space between the curve and its asymptote, lying beyond any ordinate BF is double of the triangle BFO, formed by that ordinate, the subtangent and tangent. In which sense this is to be understood. See above N° 3.

8. The space comprehended between two ordinates is equal to the rectangle under the subtangent and the difference of the ordinates. Thus the space ABFD is equal to the rectangle under FO, AK, or to BMXY.

9. The solid formed by the revolution of the infinite space lying beyond any ordinate, about the asymptote, is to a cone of the height of the subtangent, with a base equal to the circle described with that ordinate as radius, as 3 to 2. Thus the solid formed by the revolution of the indefinite space FBTZ, about FZ is to the cone formed by the revolution of the triangle FBO, as 3 to 2.

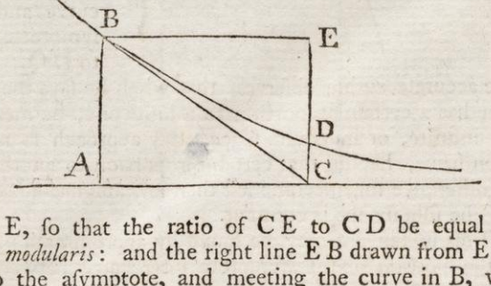
10. The solid formed by the revolution of the same infinite space about the ordinate FB, is sextuple of the cone formed by the triangle FBO, revolving about FB.



11. The distance of the center of gravity of this infinite plain space from the ordinate BF, is the length of the subtangent FO.

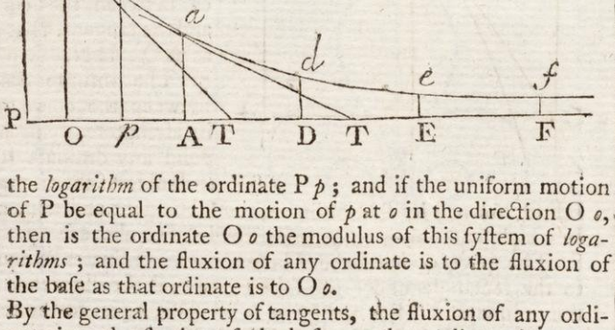
12. The distance of this center from the asymptote is one fourth of the ordinate.

13. The distance of the center of gravity of the first of the before-mentioned solids, from its base, is one half of the sub-tangent.



14. The distance of the center of gravity of the other solid, from its infinite base, is one eighth of its axis.

15. If there be two segments of an hyperbola, comprized between ordinates to one of its asymptotes, and if the ordinates of the one be to each other, as the ordinates AD, HG of the *logarithmic*; and if the ordinates of the other, be as BF, to CE; then will the hyperbolic spaces be to each other, as DG to FE. And these hyperbolic

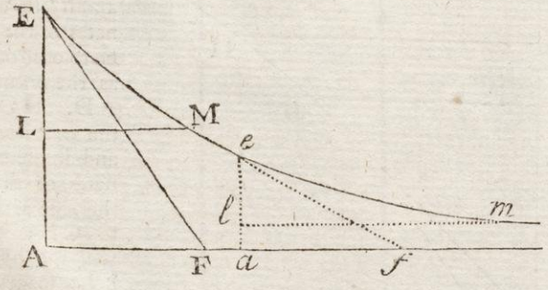


perbolic ſpaces are ⊕ the parallelogram of the hyperbola, as the lines DG, FE are to the ſubtangent FO. So that if this parallelogram be ſuppoſed = 0.4342944819, every hyperbolic ſpace comprized between two ordinates to one of the aſymptotes, will be to this parallelogram, as the *logarithm* of the ratio of the two ordinates, or the difference of the *logarithms* of the numbers expreſſing the proportions of thoſe ordinates, is to 0.4342944819; taking the *logarithms* of 10 figures beſides the characteriſtic.

We have mentioned one method of finding the ſubtangent of a given *logarithmic* from Huygens in n° 4. But this may be otherwiſe done thus, produce any ordinate CD from

C to E, ſo that the ratio of CE to CD be equal to the *ratio modularis*: and the right line EB drawn from E parallel to the aſymptote, and meeting the curve in B, will be equal to the ſub-tangent. The *ratio modularis* is 2.7182818, &c. to 1, or 1 to 0.3678794, &c. for which may be ſubſtituted the approximations 11 to 4, 87 to 32, &c. greater than the true, and 8 to 3, 19 to 7, 106 to 39, &c. leſs than the true ratio. See *Cotes*, Harm. Menſ. p. 7 and 16.

While the baſe OP increaſes uniformly, let the ordinate P*p* increaſe or decreaſe proportionally, as mentioned under the head LOGARITHM; that is, let the velocity of *p* in the direction O*o*, be always as the ordinate P*p*; then will the point *p* deſcribe the *logarithmic curve*. The baſe OP is always



the *logarithm* of the ordinate P*p*; and if the uniform motion of P be equal to the motion of *p* at *o* in the direction O*o*, then is the ordinate O*o* the modulus of this ſyſtem of *logarithms*; and the fluxion of any ordinate is to the fluxion of the baſe as that ordinate is to O*o*.

By the general property of tangents, the fluxion of any ordinate is to the fluxion of the baſe, as that ordinate is to the ſub-tangent. Hence the ſub-tangent OT, or AT, will be equal to O*o*. The ſub-tangent will therefore be conſtant. In any other *logarithmic curve*, the ſub-tangent will always be equal to that ordinate, whoſe fluxion is equal to the fluxion of the baſe, that is, the modulus always expreſſes the ſub-tangent of the *logarithmic curve*. See the article LOGARITHM.

The ſub-tangent of the *logarithmic* expreſſing the modulus of that ſyſtem of *logarithms*, the ſubtangent will be the *logarithm* of the ratio modularis, that is, of the ratio of two ordinates raiſed at the extremities of the ſub-tangent; and as the *ratio modularis* is the ſame in all ſyſtems of *logarithms*, ſo the ratio of the two ordinates placed at the extremities of their reſpective ſub-tangents, is the ſame in all *logarithmic curves* whatſoever.

When the *logarithmic curve* is ſuppoſed to be deſcribed, exponential quantities are eaſily determined by it. Let the ordinate A*a*, be expreſſed by A; let OP be to OA as any quantity expreſſed by *x* is to 1: then the ordinate P*p* may be expreſſed by A^x, an exponential quantity of the firſt degree when *x* is variable. See EXPONENTIAL, *Cycl.*

To rectify the logarithmic CURVE. Let it be required to find the length of the *logarithmic* arc E*e*. Draw the perpendi-

lars ELA, *ela*, to the aſymptote, and having drawn the tangents EF, *ef*, take AL equal to the exceſs of the tangent above the ſub-tangent AF; and *al*, equal to the exceſs of the tangent *ef* above *af*; then having drawn LM, *lm* parallel to the aſymptote, if the difference of the tangents EF—*ef*, be added to the difference of the parallels *lm*—LM, the aggregate will be equal to the arc E*e*. *Cotes*, Harm. Menſ. p. 23, 24.

LOGISTIC (*Cycl.*)—LOGISTICA, in geometry, is uſed to ſignify the *logarithmic curve*. Huygens introduced this term in his treatiſe of the cauſe of gravity, at the end of which he gives us ſeveral curious properties of this curve. See LOGARITHMIC *curve*.

LOGOGRAPHI, Λογογράφοι, among the antients, were the ſecretaries of the logiſtæ, and kept an account of the public revenues. See LOGISTÆ, *Cycl.*

LOGOTHETA, an officer under the emperors of the eaſt, who kept an account of the various branches of public and private expence.

There were ſeveral kinds of them, diſtinguiſhed by the particular branch they ſuperintended, as the *logotheta τῦ δρόμε*, or poſt-maſter general, *logotheta τῶν οἰκειακῶν*, or maſter of the houſhold, &c. Vid. du *Cange*, Gloſſ. Lat. T. 2. in voc.

LOLIUM, *Darnell*, in the Linnæan ſyſtem of botany, makes a diſtinct genus of plants. The diſtinguiſhing characters of which are, that the calyx is a glume containing ſeveral flowers, univalve, oblong, ſtrait, pointed, and very rigid, containing the flowers gathered in a ſort of ſpike placed cloſely againſt the ſtalk. The flower is compoſed of two valves; the inferior is narrow, and pointed, rolled up, and of the length of the cup; the upper valve is ſhorter, ſtrait, obtuſe, and hollow in its upper part. The ſtamina are three filaments, very ſlender, and ſhorter than the cup; the antheræ are oblong. The germen of the piſtillum is of a turbinated form, the ſtyles are two in number, capillary, and reflex, and the ſtigmata are plumoſe. The flower cloſely ſurrounds the ſeed, and at a proper time opens, and lets it fall. The ſeed is ſingle, oblong, of a compreſſed ſhape, and convex on one ſide, and flat and furrowed on the other. *Linnæi* Gen. Plant. p. 16.

The antients uſe the word *lolium*, as the name of a diſeaſed ſtate of corn of any kind, and have given accounts of ſeveral ſorts of diſeaſed appearances, to all of which they indifferently gave this name. When the corn was deſtroyed by the great and unnatural increaſe of the root, they called it *polypode lolium*. This never produced good ears, but often a great number of ſtraggling and uſeleſs branches. Another kind of *lolium* was owing to the ſeeds in the ear being ſtinted in growth, never arriving at their natural ſize, and becoming of a greyiſh colour. Another kind was, when the ſeeds in the ear were larger and harder than they naturally ought to be, and of a black colour; and another kind was, when the grains grew large, and oblong, and were crooked, and marked with a white ſpot in the middle, but black in all the other parts. The Germans are ſubject to this diſtemperature of their grain, and they call it *mutter korn*.

Theſe diſtempered ſtates of the corn, when they affect a great quantity of it in the fields, and are gathered and ground along with the natural and ſound corn, for the uſe of the common people, are the cauſe of epilepſies, and many other terrible diſeaſes raging violently among them, and carrying off great numbers.

The antients were well acquainted with the pernicious nature of this ſort of corn; and Ariſtotle, Theophraſtus, Pliny, and many others, the moſt eminent hiſtorians, naturaliſts, and poets, give accounts of diſeaſes brought on by eating it. The cauſing diſtempers of the eyes has been attributed to this, even to a proverb; a man being ſaid *lolia victitare*, to feed on *lolium*, or this diſtempered corn; inſtead of, in plain words, being blind: but though thus hurtful in food, this *lolium* was uſed in medicine, in caſes of pains in the head and other parts, and in inflammations and ulcers; in theſe caſes it was uſed externally, and in hyſteric complaints a few grains of it were often given internally.

LOMBAIRE *externe*, in anatomy, a name given by Winſlow, and ſome other of the French writers, to a muſcle, called by the earlier authors the *primus dorſi*, and now generally known by the name *quadratus lumborum*. The French call this the external lumbal muſcle, in diſtinction from the *pſoas magnus*, which they call the *lombaire interne*.

LOMBAIRE *interne*, in anatomy, a name given by Winſlow, and ſome other French writers, to the muſcle generally called *pſoas magnus*.

LOMENTUM, a word uſed by the old writers on medicine, to expreſs a meal made of beans, or bread made of this meal, and uſed as a waſh. See DETERSORIUM.

Others have applied it to the French chalk, or morochthus, uſed by the ſcowerers of cloaths, which is brought over in large cakes, reſembling loaves or cakes of bread.

LOMWIA, in zoology, the name of a web footed water fowl common on the Engliſh ſhores, and called in different places the *guillem*, *guillemot*, *ſea hen*, *kiddow*, and *ſkout*: the laſt name, however, is ſomewhat equivocal, as the Scotch call the common *razor bill* by this name.

The *lomwia*, or kiddow, is much like the razor bill, but

it

it is larger, being of the full ſize of the common duck. Its head, neck, wings, back, and tail, as alſo the upper part of its throat are of a mixed colour, between brown, black, and grey. Its breaſt, belly, and lower part of its throat are white, and its wings are variegated with a mixture of white; its bill is ſtrait, black, and ſharp, and is three fingers breadth long, and rounded. Its legs are placed far behind, and it has no hinder toes. It is very plentiful on the Corniſh ſhore, and builds on the naked rocks there. *Ray*'s Ornithol. p. 244.

LONCHITIS, *ſpleenwort*, in botany, the name of a genus of plants, the characters of which are theſe. The flowers have not been diſcovered, but the ſeeds grow on the back part of the leaves. The leaves reſemble thoſe of the ferns in ſhape, but differ in that the pinnules are auriculated near their baſes. See Tab. 1. of Botany, Claſs 16.

The ſpecies of *lonchitis*, enumerated by Mr. Tournefort, are theſe. 1. The great rough *lonchitis*. 2. The tall globuliferous *lonchitis*, called by many the berry bearing *maiden-hair*. 3. The prickly *lonchitis* with broad pinnules, called the prickly auriculated male fern. 4. The great prickly *lonchitis*. 5. The leſſer prickly *lonchitis*. 6. The ſea *lonchitis*, called the dwarf ſea fern. 7. The climbing Braſilian *lonchitis*, with elegantly jagged pinnules. 8. The great ſmooth *lonchitis*. 9. The ſmaller ſmooth *lonchitis*. 10. The ſerrated *lonchitis*. 11. The *lonchitis* with leaves duſty near the middle rib. 12. The branched *lonchitis* duſty near the edge. 13. The branched *lonchitis* with long, and in part auriculated pinnules. 14. The broad leaved *lonchitis*, divided into broad, obtuſe, and lightly crenated pinnules. 15. The leſſer round dented *lonchitis*. 16. The ſlender branched *lonchitis*, with prickly pedicles. 17. The broad leaved *lonchitis* with black ſhining ſtalks. 18. The betony leaved *lonchitis*. 19. The water *lonchitis* formed of a thin membrane. 20. The *lonchitis* with long and narrow leaves, duſty at the edges. 21. The *lonchitis* with long narrow leaves, foliaceous at their bottoms. 22. The branched, duſty *lonchitis*, with black pedicles. 23. The great *lonchitis* with leaves divided in their upper part. 24. The ſmall *lonchitis* with leaves divided at their upper part. 25. The jagged *lonchitis* with roundiſh auricles. 26. The branched *lonchitis* with ſquammoſe ſtalks. 27. The heart faſhioned leaved *lonchitis*. 28. The little branched *lonchitis*. 29. The pointed leaved *lonchitis* with round auricles. 30. The *lonchitis* divided into roundiſh auricles. 31. The radiated *lonchitis* with the appearance of maiden-hair, called the radiated *maiden-hair*, and American branched *maiden-hair*. *Tourn.* Inſt. p. 538.

The general character of the *lonchitis*, according to Linnæus, is, that the fructifications are diſpoſed in lines of a lunulated figure, which are placed in the under part of the ſinus's of the leaves.

LONCHOTON, a word uſed by ſome chemical writers to expreſs the beſt and pureſt kinds of native vitriol, of the green or blueiſh green kinds.

LONG, (*Cycl.*) in muſic. See CHARACTER, *Cycl.* and LONGA, *Supplem.*

LONG-*jointed*, in the manege. A horſe is ſaid to be *long-jointed*, whoſe paſtern is ſlender and pliant. *Long-jointed* horſes are wont to have wind galls.

LONGA, *long*, in the Italian muſic, is a character marked thus , containing four ſemi-breves, in common tune, and conſequently eight minims, unleſs tied to a breve; for its content in ſuch caſe [a], ſee LIGATURE.[—[a] *Broſſ.* Muſ. Dict. in voc.—]

LONGANON, a name given by ſome authors to the inteſtinum rectum.

LONGINA, in botany, a name uſed by ſome authors for the lonchitis or ſpleen-wort. *Ger.* Emac. Ind. 2.

LONICERA, in botany, a name given by Plumier and others to a genus of plants, called by Linnæus *loranthus*. The characters are theſe: the perianthium is the margin of the fruit, and is hollow and undivided; beſide this, there is another perianthium, proper to the flower, which ſtands upon the germen of the piſtil, and is in the ſame manner hollow and undivided. The flower conſiſts of one leaf, and is of a ſexangular figure, divided at the edge into ſix ſlender and nearly equal ſegments, which bend back at their points. The ſtamina are ſix ſubulated filaments, three of which are ſomewhat longer than the others, but all nearly of the ſame length with the flower. The germen of the piſtil is roundiſh. The ſtyle is ſimple, and of the length of the ſtamina. The ſtigma is obtuſe. The fruit is a roundiſh berry, having only one cell, and contains ſix ſeeds, convex on one ſide and angular on the other. *Linnæi* Gen. Pl. 151. *Plumier* Gen. 37. *Vaillant* 30.

LONKETT, a term uſed by ſome chemical writers to expreſs ſpirit of turpentine.

LOOF (*Cycl.*)—LOOF-*hook*, in a ſhip, a tackle with two hooks to it, one of which is to hitch into the crengle of the main and fore-ſail, and the other is to hitch into a certain ſtrap, which is ſpliced into the cheſs-tree, and ſo down the ſail. Its uſe is to ſuccour the tackles in a large ſail, that all the ſtreſs may not bear upon the tack. Sometimes alſo it is uſed when the tack is to be ſeized the furer.

LOOF-*pieces*, in a man of war, are thoſe guns which lie at the *loof* of the ſhip.

LOOF-*tackle*, or LUFF-*tackle*, in a ſhip, a ſmall *tackle*, ſerving to lift all ſmall weights in or out of the ſhip.

LOOL, in metallurgy, a veſſel made to receive the waſhings of ores of metals. The heavier or more metalline part of the ores remaining in the trough in which they are waſhed; the lighter, and more earthy, running off with the water, but ſettling in the *lool*. *Ray*'s Engliſh words, p. 121.

LOOME, at ſea. If a ſhip appears big, when ſeen at a diſtance, they ſay ſhe *looms*, or appears a great ſail.

LOOME-*gale*, at ſea, a gentle, eaſy gale or wind, in which a ſhip can carry her top-ſails *a-trip*. See TRIP.

LOON, in zoology, a name given to the *columbus major*, or great diver. See DIVER.

LOOP (*Cycl.*)—LOOP, in the iron works, is a part of a ſow or block of caſt iron broken or melted off from the reſt, and prepared for the forge or hammer. The uſual method is, to break off the *loop* of about three quarters of a hundred weight. This *loop* they take up with their ſlingling tongs, and beat it with iron ſledges upon an iron plate near the fire, that ſo it may not fall to pieces, but be in a condition to be carried under the hammer. It is then placed under the hammer, and a little water being drawn to make the hammer move but ſoftly, it is beat very gently, and by this means the droſs and foulneſs are forced off, and after this they draw more and more water by degrees, and beat it more and more till they bring it to a four ſquare maſs, of about two feet long, which they call a bloom. *Ray*'s Engliſh words, p. 128.

LOOPING, in metallurgy, a word uſed by the miners of ſome counties of England, to expreſs the running together of the matter of an ore into a maſs, in the roaſting, or firſt burning, intended only to calcine it ſo far as to make it fit for powdering. This accident, which gives the miners ſome trouble, is generally owing to the continuing the fire too long in this proceſs. *Ray*'s Engliſh words, p. 125.

LOPHIA, in anatomy, a term for the upper part of the *cervix*, or back part of the human neck.

LOPHIUS, in ichthyology, the name of a genus of fiſhes of the branchioſtegous kind. The characters of which are theſe. There is no branchioſtege membrane. The figure of the body is monſtrous and depreſſed, the head very large; there are ſeveral pinnules, which ſurround the ſides of the fiſh from the head to the tail. We at preſent know only one ſpecies of this genus, which is the *lophius* or *cirrhoſa* of Artedi, or the *rana piſcatrix* of authors. *Artedi* Gen. Piſ. 41. *Linnæi* Syſt. Nat. p. 52. See the article RANA *piſcatrix*.

LOPPA, a word uſed by the chemical writers, to expreſs the metallic maſs, which reſults from a cementatory calcination, either with or without regulus.

LOPPING, among gardners, the cutting in a proper and artful manner the branches of trees, ſo as to make them grow more beautiful or more durable.

It is obſervable, that moſt old trees are hollow within, and this is in general owing to their wrong management, the tops being ſuffered to grow too large before they are lopped. This is a very common error in regard to the aſh, elm, horn beam, &c. and is owing to peoples perſuading themſelves, that by this means they ſhall have more great wood; but, they do not conſider, that the cutting off large tops, deſtroys or decays the tree, ſo that it decays more in the body than it grows in the head. And though the horn beams, and elm will bear large tops when the outſide is little more than a ſhell; yet this is not at all the caſe with the aſh, which ſhould therefore always be cut down as ſoon as it begins to decay. *Miller*'s Gardners Dict.

The *lopping* of young trees, that is of ſuch as are ten or twelve years old, will preſerve them much longer, and will occaſion the ſhoots to grow more into wood in one year, than they do in old tops in two or three. The taking off of large boughs in a careleſs manner deſtroys many a tree; they ſhould therefore always be lopped with great care, and the wound covered with ſome loam to keep it from rotting, and preventing the wet from entering and getting into the body of the tree.

All ſorts of reſinous trees, or ſuch as abound with a milky juice, ſhould be lopped but very ſparingly, for they are very ſubject to decay when cut. The beſt ſeaſon for the *lopping* theſe is the end of Auguſt, when they will not bleed very much, and the wounds will heal before the hard weather.

Whatever ſhape a tree is intended to be of, it muſt be thrown into it by *lopping* while young, for the branches being then ſmall, full of juice, heal eaſily, and never endanger the tree. When a tree is intended for timber it muſt be left to grow to its own height, and its top is never to be cut off on any account, Thoſe trees which have large piths, as the aſh, elm, willow, poplar, and the like, muſt never have their heads cut off, if intended to ſtand long, for the wet gets into the ſoft part of the tree, and begins to hollow, and rot it

where cut off, and ſoon ſpreads to the very root, ſo that the whole is but a ſhell or caſe of a tree. If a tree grow top heavy, and be in danger of breaking down, then ſome think it neceſſary to take off the top to preſerve it; but this may be much better done only by thinning the top, that is cutting off the ſmall branches that grow from the main boughs of the head, and leaving them bare, ſo as to let the wind have a free paſſage through them. This is a very good practice for young trees, which are intended to be ſpreading ones; and if they are intended to be tall and ſlender ones, the beſt method to be taken with them, while young, is rubbing off the buds as faſt as they appear in the ſpring, and taking off the ſide ſhoots as they grow, leaving only here and there one; when any new ſhoots break out, ſome of them may be ſaved, and the others cut off in their place, always obſerving to cut off the largeſt, and leave the youngeſt; the whole intent being to leave ſome check there for the ſap, to prevent its all running up to the head, which would endanger the breaking of the body in ſome weak place. When the trunk ſeems ſtrong and robuſt, the fewer of theſe ſhoots need be left: the great care, in this caſe, is to be employed about the head. The leading ſtalk, or branch, muſt be carried up all the way ſtrait and ſingle, and not ſuffered to fork or ſplit till it come to the head, and the quantity of boughs left there muſt be ſuch as will not leave the whole top heavy. When the tree is grown to its proper height, the head is to be ſuffered to break out in its natural way, and the ſide branches are to be kept cut off as they ſhoot, or at any proper diſtances of time. *Mortimer*'s Huſbandry, Vol. 2. p. 81, ſeq.

If the ſide boughs are found ſtill breaking out, and the top is able to ſuſtain itſelf, the boughs that put out in ſpring ſhould be lopped very cloſe in ſummer, a little after Midſummer; this will cauſe the bark to ſhoot over them, and they will not be liable to grow again. This is the only method of making a tree grow with a fine ſtrait and handſome body.

The generality of the world are againſt pruning timber trees at all, and where they naturally grow ſtrait and regular it is much better let alone. But all the common faults in ſhape may be regulated by this *lopping* them while young, and it can be attended with no ill conſequence to the timber; for the cut not lying near the timber pith cannot affect it, when grown up, and ſquared in the working for beams or other uſes, or to be quartered; for all the defects occaſioned by ſuch wounds, are in the ſuperficial parts, and all the four quarters are perfectly ſound within.

As to the large foreſt trees they ſhould not be lopped at all, except in caſes of great neceſſity, and then the large boughs muſt not be cut, but only the ſide branches, and even theſe muſt be cut off cloſe, that the bark may ſoon cover the wound, and yet a little ſlanting, that the water may run off, not lodge upon the cut part.

If there is a neceſſity of cutting off a large bough, as by its being broken or cankered, let it be cut off ſlanting at about four feet diſtance from the body of the tree, and that if poſſible near ſome place where there is a young ſhoot from it, which may receive the ſap, and grow up in its place. No ſtump muſt be left ſtanding out farther than this, becauſe they are wounded parts which never can heal, and which will always be letting in the water, and will ſerve as pipes to convey that water to the heart of the body of the tree, and by degrees will utterly ſpoil it. All that grow upright, whether they be large or ſmall branches, muſt in cutting be taken off ſlanting, never evenly for the ſame reaſon; thoſe boughs that bear from the head are to be cut with the ſlope on the lower ſide, and on any occaſion that great wounds are given to a tree, they ſhould be covered with a mixture of clay and horſe dung, which will make them heal much ſooner than they otherwiſe would do. Ibid. Vol. 2. p. 84.

LORARII, among the Romans, officers whoſe buſineſs it was, with whips and ſcourges, to compel the gladiators to engage.

The *lorarii* alſo puniſhed ſlaves who diſobeyed their maſters. *Pitiſc.* Lex. Ant. in voc.

LORD (*Cycl.*)—Lords *of the admiralty*, a name frequently uſed for the commiſſioners for executing the office of *lord* high admiral.

Lords *of ſeſſion*, in Scotland. See Session.

LORDOSIS, in the medical writings, a name given to a diſtempered ſtate of the ſpine, in which it is bent inwards, or toward the anterior parts. It is uſed in oppoſition to gibbous, or hump backed.

LORICA, a name given by ſome chemical writers to a peculiar lute made for the coating over veſſels, which are to bear a very vehement fire.

This is ordered to be made of the powdered glaſs of broken retorts mixed up into a paſte with potters clay by means of warm water: the retort, or other veſſel, to be loricated, is to be covered a third of an inch thick with this matter, and if it cracks in the drying, which muſt be done gradually before it is to be uſed, the cracks muſt be filled up with ſome of the ſame paſte, and this muſt be left to dry as the former. Collect. Chym. Leyd. See farther under Lorication.

LORICATION, or Coating, in chemiſtry, is the covering a glaſs or earthen veſſel with a *coat* or *cruſt* of a matter able to reſiſt the fire; to prevent its breaking in the performing an operation, that requires great violence of fire.

Either when veſſels are expoſed to a fire too ſtrong for their ſtructure, or on the throwing on of freſh cold fuel into the fire where they ſtand, it frequently happens that they crack and burſt; for the preventing of which the operator has recourſe to this method of *coating* or *loricating* his veſſels; it is performed in the following manner: take a quantity of waſhed clay, with an admixture of pure ſand, powder of calcined flints, or broken crucibles; and inſtead of pure water, moiſten it with freſh blood that has not yet been coagulated, diluted with twice or three times its quantity of water; make the clay with this into a thin paſte, and work into it ſome cow's hair, or other hair not too long, or too ſtiff, and a little powdered and ſifted glaſs, if you have it at hand; ſmear over the veſſel intended to be uſed with this paſte, by means of a pencil, and ſet it to dry; when dry beſmear it again, and repeat the operation, till the veſſel have a cruſt of a third, or a quarter of an inch at leaſt thick, of this matter, and let it be thoroughly dry before it is uſed.

To keep blood in a proper ſtate for this uſe, it muſt, when juſt let out from the animal, be well ſtirred about with a ſtick, for ſome time; at leaſt till it is quite cold, and being thus prepared, it will keep for ſome days without coagulating and fit for uſe.

This compoſition, with an admixture of bole, worked into a paſte with the whites of eggs diluted with water, makes alſo the proper lute for cloſing the junctures of other chemical veſſels, in the diſtilling ſtrong ſpirits. *Cramer*, Art of Aſſay. p. 74.

LORIMERS, one of the companies of London, that make bits for bridles, ſpurs, and ſuch like ſmall iron ware. They are mentioned Stat. 1 Rich. 2. c. 12.

The word ſeems derived from the Latin *lorum*, a thong.

LORIPES, in zoology, the name uſed by ſome authors for the *himantopus*, a bird of the water kind, remarkable for the length and weakneſs of its legs. *Ray*'s Ornithol. p. 220. See the article Himantopus.

LORUS, a name by which ſome of the chemical writers have called mercury.

LOT (*Cycl.*)—Lot, or Loth, in mining, is the thirteenth diſh, meaſure, or part of the miner's ore, which the bar-maſter takes up for the king, or the farmer. *Houghton*'s compl. miner. in the explan. of the terms.

LOTA, in zoology, the name of a ſpecies of the *muſtela fluviatilis*, or eel pout, differing from the ordinary kind, in that it has no hairs or excreſcences on the upper jaw. The tail is flat, and like the point of a broad ſword, whereas that of the common kind is more rounded, and that it is covered with eaſily diſtinguiſhable ſcales. *Rondelet.*

LOTION (*Cycl.*)—Lotio *ſaponacea*, the ſaponaceous *lotion*, the name of a form of medicine preſcribed in the late London Pharmacopœia, being properly ſoap in a liquid form. It is ordered to be made thus: take damaſk roſe water three quarters of a pint, oil of olives a quarter of a pint, ley of tartar half an ounce in meaſure; rub the ley and oil together till they are mixed, and then gradually add the water. *Pemberton*'s Lond. Diſp. p. 348.

LOTOMETRA, in botany, a name given by many of the antients to the *nymphæa indica*, or *ægyptiaca*, called alſo the *faba ægyptiaca*; and originally the *nilufar*, an abbreviation of *nilnufar*; *nufar* ſignifying a water lilly, and the prefix *nil* expreſſing its growing particularly in the river Nile.

Neophytus tells us, that this *lotometra* has leaves of a middle form, between thoſe of the common *nymphæa* which are roundiſh, and thoſe of the *arum* which are oblong and pointed, and are cordated at the baſe, and this is the very figure of the leaves of the *faba ægyptiaca*, as we ſee it in all paintings, &c.

LOTUS, in botany, the name of a genus of plants. The characters of which are theſe. The flower is of the papilionaceous kind. Its piſtil ariſes from the cup, and finally becomes a pod, ſometimes divided by tranſverſe ſepta into ſeveral cells, and furniſhed with roundiſh ſeeds. To this it is to be added, that the leaves ſtand three at a joint, and are furniſhed at the ſtalk with two other foliaceous wings.

The ſpecies of *lotus*, enumerated by Mr. Tournefort, are theſe. 1. The ſmall ſmooth hand cinquefoil *lotus*, called the ſmaller ſmooth horned *lotus*. 2. The ſmall ſmooth cinquefoil *lotus* with longer and narrower leaves. 3. The leſſer hairy horned *lotus*. 4. The ſmall five leaved hairy *lotus* with very ſlender pods. 5. The five leaved *lotus* with a large ſhining yellow flower. 6. The hoary and white large cinquefoil *lotus*. 7. The great cinquefoil *lotus*. 8. The ſhrubby cinquefoil *lotus* with very narrow ſmooth leaves. 9. The Spaniſh *lotus* with ſpotted leaves. 10. The ſilvery ſhrubby *lotus* of Crete, with long, ſtrait, propendent pods. 11. The yellow flowered Cretic *lotus* with long, erect pods. 12. The hairy, white, cinquefoil *lotus*. 13. The low white hæmorrhoidal, podded *lotus*. 14. The talleſt hairy *lotus* with glomerated flowers. 15. The large hard ſtalked yellow meadow *lotus*. 16. The ſmaller, and ſofter ſtalked

ſtalked yellow meadow *lotus*. 17. The yellow, podded, ſea *lotus*, with a thick, fleſhy, and ſmooth leaf. 18. The red *lotus* with angulated pods. 19. The cinquefoil *lotus* with a horned pod. 20. The *lotus* with the ornithopodium pods. 21. The cinquefoil *lotus* with crooked pods, reſembling the toes of a raven's foot. 22. The great yellow Portugal *lotus*. 23. The yellow Sicilian *lotus* with articulated pods. *Tourn.* Inſt. p. 402. See Tab. 1. of Botany, Claſs 10. The fruit of the *lotus* was, by the antients, imagined to be endowed with the virtue of making ſtrangers forget their native country. *Pitiſc.* Lex. Ant. in voc.

LOTUS *glycycalamus*, a name given by the antient Greeks to an Egyptian plant according to ſome, and according to others, to a rare plant, found only in few places, and only met with by accident, by people who made long and uncommon voyages. The whole account given of it, by the earlieſt writers, is no more than that it was of a very ſweet and pleaſant taſte. Myrepſus uſes the term frequently, and his interpreters underſtand him to mean the *caſſia fiſtula* by it. But we have accounts from Homer, that the followers of Ulyſſes were detained by eating the *lotus glycycalamus*; and it is not at all probable, that the *caſſia fiſtula* could be the thing meant by the word in this place; neither will the words of the author allow it to be any thing of this kind. The *caſſia fiſtula* is the fruit of a tree; but this *glycycalamus* we find in Homer himſelf was an herbaceous plant. Quintilian [a] calls it expreſsly a kind of graſs, *gramen*; and from the other accounts of its growing in form of reeds, and in wet places; it ſeems very probable, that it was the ſugar cane that they called by this name.[—[a] *Quintill.* l. 5. c. 8.—]

LOVAGE, in botany. See LIGUSTICUM.

LOVE-APPLE is the Engliſh name for the fruit of the *lycopersicon*, a plant cultivated in gardens with us, for the ſingularity of its appearance. The Portugueſe call it *tomato*, and eat the fruit, either raw or ſtewed, as do alſo the Jew families in England. See LYCOPERSICON.

LOUF, in the ſea language. See LOOF.

LOUS, Λως, in chronology, the Macedonian name for the Athenian month *ecatombæon*, which was the firſt of their year, and anſwered to the latter part of our June and the beginning of July. See the articles ECATOMBÆON and MONTH.

LOUSE. This animal affords to the microſcopic obſerver of the works of the creation, a very delicate and beautiful ſtructure of parts. See Tab. of microſcopical Objects, Claſs 1. This creature has ſo tranſparent a ſhell, or ſkin, that we are able to diſcover more of what paſſes within its body, than in moſt other living creatures. It has naturally three diviſions, the head, the breaſt, and the tail part. In the head appear two fine black eyes, with a horn that has five joints, and is ſurrounded with hairs ſtanding before each eye; and from the end of the noſe, or ſnout, there is a pointed projecting part, which ſerves as a ſheath or caſe to a piercer, or ſucker, which the creature thruſts into the ſkin to draw out the blood and humours which are its deſtined food, for it has no mouth that opens in the common way. This piercer, or ſucker, is judged to be ſeven hundred times ſmaller than a hair, and is contained in another caſe within the firſt, and can be thruſt out or drawn in at pleaſure. *Baker*'s Microſcope, p. 177.

The breaſt is very beautifully marked in the middle, the ſkin is tranſparent, and full of little pits, and from the under part of it proceed ſix legs, each having five joints, and their ſkin all the way reſembling ſhagreen, except at the ends where it is ſmoother. Each leg is terminated by two claws, which are hooked, and are of an unequal length and ſize; theſe it uſes as we would a thumb and a middle finger, and there are hairs between theſe claws as well as all over the legs. *Lewenhoek*'s Arcan. Natur. T. 2. p. 74.

On the back of the tail part there may be diſcovered ſome ring like diviſions, abundance of hairs, and a ſort of marks, which will look like the ſtrokes of a rod on a child that has been whipped; the ſkin of the belly ſeems like ſhagreen, and toward the lower end is very clear, and full of pits: at the extremity of the tail there are two ſemi-circular parts, covered all over with hairs, which ſerve to conceal the anus.

When the *louſe* moves its legs, the motion of the muſcles, which all unite in an oblong dark ſpot in the middle of the breaſt, may be diſtinguiſhed perfectly, and ſo may the motion of the muſcles of the head when it moves its horns. We may likewiſe ſee the various ramifications of the veins and arteries, which are white, with the pulſe regularly beating in the arteries. But the moſt ſurprizing of all the ſights is the periſtaltic motion of the guts, which is continued from the ſtomach down to the anus. Philoſ. Tranſ. N° 102.

If one of theſe creatures, when hungry, be placed on the back of the hand, it will thruſt its ſucker into the ſkin, and the blood it ſucks may be ſeen paſſing in a fine ſtream to the fore part of the head; where falling into a roundiſh cavity, it paſſes again in a fine ſtream to another circular receptacle in the middle of the head; from thence it runs through a ſmaller veſſel to the breaſt, and then to a gut which reaches to the hinder part of the body, where in a curve it turns again a little upward. In the breaſt and the gut the blood is moved, without intermiſſion, with a great force, eſpecially in the gut; and that with ſo ſtrong a propulſion downward, and ſuch a contraction of the gut as is very ſurpriſing. *Power*'s Mic. Obſ. 9.

In the upper part of the crooked aſcending gut beforementioned the propelled blood ſtands ſtill, and ſeems to undergo a ſeparation; ſome of it becoming clear and wateriſh, while other little black particles paſs downward to the anus.

If a *louſe* be placed on its back two bloody darkiſh ſpots appear; the larger in the middle of the body, the leſſer toward the tail. In the larger ſpot, a white film or bladder contracts and dilates upwards and downwards from the head toward the tail, the motions of which are followed by a pulſation of the dark bloody ſpot, in or over which the white bladder ſeems to lie. This motion of the ſyſtole and diaſtole is beſt ſeen when the creature begins to grow weak; and on pricking the white bladder, which ſeems to be the heart, the creature always inſtantly dies. The lower dark ſpot is ſuppoſed to be the excrements in the guts. *Lewenhoek*'s Arcan. Nat. T. 2. p. 77.

Lice have been ſuppoſed to be hermaphrodites, but this is erroneous; for Mr. Lewenhoek diſcovered that the males have ſtings in their tails, which the females have not. And he ſuppoſes the ſmarting pain theſe creatures ſometimes give to be owing to their ſtinging with theſe ſtings, when made uneaſy by preſſure or otherwiſe. And this accurate obſerver ſays, that he felt little or no pain from their ſuckers, though ſix of them were feeding on his hand at once.

The ſame accurate obſerver determining to know their true hiſtory and manner of breeding, put two females into a black ſtocking which he wore night and day. He found, on examination, that in ſix days one of them had laid above fifty eggs; and upon diſſecting it, he found as many yet remaining in the ovary; whence, he concludes, that in twelve days it would have laid an hundred eggs. Theſe eggs naturally hatch in ſix days, and would then probably have produced fifty males and as many females; and theſe females coming to their full growth in eighteen days, might each of them be ſuppoſed after twelve days more to lay a hundred eggs; which eggs, in ſix days more, might produce a young brood of five thouſand; ſo that in eight weeks one *louſe* may ſee five thouſand of its own deſcendants. A *louſe* may be eaſily diſſected in a ſmall drop of water upon a ſlip of glaſs; and thus placed before the microſcope, it is common to find five or ſix eggs of a ſize ready to be laid, and ſixty or ſeventy others of different bigneſſes. In the male the penis is very remarkably diſtinct, as are alſo the teſtes, of which he ſeems to have a double pair, as is alſo the ſting the ſtructure of which merits a peculiar attention. *Lewenhoek*'s Arcan. Natur. p. 78.

Many animals, both of the quadruped and flying kinds, are ſubject to *lice*; but theſe are of peculiar ſpecies on each animal, and are not at all like thoſe which infeſt the human body. Nay, even inſects are infeſted with vermin, which feed on them and torment them. Several kinds of beetles are very ſubject to *lice*, but particularly that kind, called thence the louſy beetle. The *lice* on this are very numerous, but will not be ſhook off. The ear-wig is often infeſted with *lice* juſt at the ſetting on of its head; theſe are white, and ſhining like mites, but they are much ſmaller; they are round backed, flat bellied, and have long legs, particularly the foremoſt pair. Snails of all kinds, but eſpecially the large naked kinds, are very ſubject to *lice*, which are continually ſeen running about them, and devouring them. Numbers of little red *lice*, with a very ſmall head, and in ſhape reſembling a tortoiſe, are often ſeen about the legs of ſpiders, and they never leave the ſpider while he lives, but if he be killed they almoſt inſtantly forſake him. A ſort of whitiſh *lice* are very common on humble bees; they are alſo found on ants; and many ſorts of fiſhes are not leſs ſubject to them than the land animals. Kircher ſays, that he has found *lice* alſo on flies. *Baker*'s Microſcope, p. 182.

Senior Redi, who has more accurately examined theſe creatures than any other author, has engraved ſeveral ſpecies found on different animals. He calls thoſe found on beaſts *lice*, and thoſe found on birds fleas. He is of opinion that every ſpecies of birds has its peculiar ſort of flea, different from thoſe of other birds; and has obſerved that they are hatched white, but that they gradually acquire a colour, like that of the feathers they live among; yet they uſually remain tranſparent enough for a good microſcope to diſcover the motion of their inteſtines. The kinds he has obſerved are theſe: on the hawk three different ſorts; on the large pigeon, the turtle dove, the hen, the ſtarling, the crane, the magpye, the heron, the leſſer heron, the ſwan, the turky duck, the ſea mew, the ſmall ſwan, the teal, the caſtrel, the peacock, the capon, and the crow, on each one ſort; on the moorhen three ſorts; on the wild gooſe two ſorts; and on the crane, beſide the common one, a white ſort, marked as it were with Arabic characters. Men, he obſerves, are ſubject to two kinds, the common *louſe*, and that called the crab-*louſe*. He alſo found peculiar ſorts on the

the goat, the camel, the aſs, the African ram, the ſtag, which has, like many of the birds, two kinds, and on the lion and the tyger. The ſame author has obſerved, that the ſize of theſe creatures is not at all proportioned to that of the animal they are to inhabit, for the ſtarling has them as large as the ſwan. *Redi*, Gen. Inſ. p. 312.

It is obſervable, that ſome ſort of conſtitutions are more apt to breed *lice* than others; and that in certain places, of different degrees of heat, they are very certain to be deſtroyed upon people, who in other climates are over-run with them. It is an obſervation of Oviedo, that the Spaniſh ſailors, who are generally much afflicted with *lice*, always looſe them in a certain degree in their voyage to the Indies, and have them again on their coming to the ſame degree at their return; this is not only true of the Spaniards, but of all other people who make the ſame voyage; for though they ſet out ever ſo *louſy*, they have not one of theſe creatures to be found after they come to the tropic. And in the Indies there is no ſuch thing as a *louſe* about the body, though the people be ever ſo naſty. The ſailors continue free from theſe creatures till their return; but in going back they uſually begin to be *louſy*, after they come to about the latitude of Maderas. The extreme ſweats, which the working people naturally fall into between this latitude and the Indies, drown and deſtroy the *lice*, and are of the ſame effect as the rubbing over the *louſy* heads of children with butter and oil. The ſweat in and about the Indies is not rank as in Europe, and therefore it is not apt to breed *lice*; but when the people return into latitudes where they ſweat rank again, their naſtineſs ſubjects them to the ſame viſitations of theſe vermin which it uſed to have.

The people in general, in the Indies, are very ſubject to *lice* in their heads, though free from them in their bodies. The reaſon of this is, that their heads ſweat leſs than their body, and they take no care to comb and clean them. The Spaniſh negroes waſh their heads thoroughly once every week with ſoap, to prevent their being louſy. This makes them eſcape much better than the other negroes who are ſlaves there, for the *lice* grow ſo numerous in their heads, that they often eat large holes in this part.

Mr. de la Hire has given a curious account of the creature which he found on the common fly. Having occaſion to view a living fly by the microſcope; he obſerved on its head, back, and ſhoulders, a great number of ſmall animals crawling very nimbly about, and often climbing up the hairs, which grow at the origin of the fly's legs. He, with a fine needle, took up one of theſe and placed it before the microſcope, uſed to view the animalcules in fluids. It had eight legs, four on each ſide; they were not placed very diſtant from one another, but the four toward the head were ſeparated by a ſmall ſpace from the four toward the tail. The feet were of a particular ſtructure, being compoſed of ſeveral fingers, as it were, and fitted for taking faſt hold of any thing; the two neareſt the head were alſo more remarkable in this particular than thoſe near the tail; the extremities of the legs, for a little way above the feet, were dry and void of fleſh, like the legs of birds, but above this part they appeared plump and fleſhy. It had two ſmall horns upon its head, formed of ſeveral hairs arranged cloſely together; and there were ſome other cluſters of hairs by the ſide of theſe horns, but they had not the ſame figure; and toward the origin of the hinder legs there were two other ſuch cluſters of hairs, which took their origin at the middle of the back. The whole creature was of a bright yellowiſh red; and the legs, and all the body, except a large ſpot in the center, were perfectly tranſparent. In ſize, the author believes it was about $\frac{1}{4000}^{th}$ part of the bigneſs of the head of the fly; he obſerves, that it is rarely that flies are found infeſted with them. Mem. Acad. Par. 1693.

Wood LOUSE. See MILLEPEDES.

LOW *bell*, in birding, a name given to a *bell*, by means of which they take birds in the night in open champaign countries, and among ſtubble in October. The method is to go out about nine o'clock at night in a ſtill evening, when the air is mild and the moon does not ſhine.

The *low bell* is to be of a deep and hollow ſound, and of ſuch a ſize, that a man may conveniently carry it in one hand. The perſon who carries it is to make it toll all the way he goes, as nearly as may be, in that manner in which the *bell* on the neck of a ſheep tolls, as it goes on while it feeds. There muſt alſo be a box made like a large lanthorn, about a foot ſquare, and lined with tin, but with one ſide open. Two or three great lights are to be ſet in this, and the box is to be fixed to the perſon's breaſt, with the open ſide forwards, ſo that the light may be caſt forward to a great diſtance; it will ſpread as it goes out of the box, and will diſtinctly ſhew the perſon who carries it whatever there is in the large ſpace of ground which it extends over, and conſequently all the birds that rooſt upon the ground. Two perſons muſt follow him who carries the box and *bell*, one on each ſide, ſo as not to be within the reach of the light to ſhew themſelves. Each of theſe is to have a hand net of about three or four feet ſquare, faſtened to a long ſtick or pole; and on which ever ſide any bird is ſeen at rooſt, the perſon who is neareſt is to lay his net over it, and take it with as little noiſe as poſſible. When the net is over the bird, the perſon who laid it, is not to be in a hurry to take the bird, but muſt ſtay till he who carries the light is got beyond it, that the motions may not be diſcovered. The blaze of the light, and the noiſe of the *bell*, terrify and amaze the birds, in ſuch a manner, that they remain ſtill to be taken; but the people who are about the work muſt keep the ſtricteſt quiet and ſtillneſs that may be.

Some people are fond of going on this ſcheme alone. The perſon then fixes the light box to his breaſt, and carries the *bell* in one hand and the net in the other; the net, in this caſe, may be ſomewhat ſmaller, and the handle ſhorter. When more than one are out at a time, it is always proper to carry a gun. It is no uncommon thing to ſpy a hare when on this expedition; and, in that caſe, it is better to ſhoot her, than to truſt to the taking her in the net, for ſhe will very eaſily eſcape from that. Some tye the *bell* to their girdle, and carry the light in their left hand and the net in the right; the light is not to be ſo large in this caſe, and the other way is therefore rather the better.

LOW, in the manege—To *carry* LOW. See CARRY.

LOW-*water*. See WATER.

LOW *wines*. See *low* WINES.

LOWERING (*Cycl.*)—LOWERING, in the diſtillers buſineſs, a term uſed to expreſs the debaſing the ſtrength of any ſpirituous liquor by mixing water with it. The ſtandard and marketable price of theſe liquors is fixed, in regard to a certain ſtrength in them called proof; this is that ſtrength, which makes them, when ſhook in a vial, or poured from on high into a glaſs, retain a froth or crown of bubbles for ſome time. In this ſtate ſpirits conſiſt of about half pure, or totally inflammable ſpirit and half water; and if any foreign or home ſpirit is to be expoſed to ſale, and is found to have that proof wanting, ſcarce any one will buy it, till it has been diſtilled again and brought to that ſtrength; and if it is above that ſtrength, the proprietor uſually adds water to it to bring it down to that ſtandard. This addition of water, to debaſe the ſtrength, is what is called *lowering* it. People well acquainted with the goods, will indeed buy ſpirits at any ſtrength, only *lowering* a ſample to the proof ſtrength, and by that judging of the ſtrength of the whole; but the generality of buyers will not enter into this, but muſt have it all *lowered* for them. *Shaw*'s Eſſay on Diſtillery.

There is another kind of *lowering* in practice among the retailers of ſpirituous liquors to the vulgar, this is the reducing it under the ſtandard of proof. They buy it proof, and afterwards increaſe their profit upon it, by *lowering* it with water one eighth part. The quantity of ſpirit is what they generally allow themſelves for the addition of water; and whoever has the art of doing this, without deſtroying the bubble proof, as this is eaſily done by means of ſome addition, that gives a greater tenacity to the parts of the ſpirit, will deceive all that judge by this proof alone; that is, very nearly all who are concerned in the ſpirit trade. Such an additional quantity of water as one eighth, makes the ſpirit taſte ſofter and cooler, and will make many prefer it to the ſtronger ſpirit which is hoter and more fiery; but unleſs the ſpirit, thus *lowered*, were tolerably clean, or the proof be ſome other way preſerved, the addition of the water lets looſe ſome of the coarſe oil, which makes the liquor milky, and leaves a very nauceous taſte in the mouth. *Shaw*'s Eſſay on Diſtillery.

The way to judge of ſpirits not being thus *lowered*, or debaſed in its ſtrength, is to examine it by the eye and tongue; and in buying a quantity of proof goods, ſuch ſhould always be choſen as are clean, thin, and light, and have a good crown of froth which goes off in large bubbles, ſuch as taſte ſoft and uniform, and are not high flavoured, of an alkaline guſt, nor acrid and fiery, but ſoon quit the tongue.

LOXIA, in zoology, the name of a bird, called in Engliſh the *croſs bill*, and in ſome places the *ſhell apple*, ſuppoſed to be the Tragon of the antients.

It is about the ſize of the green finch, and much of the ſame ſhape. Its beak is very hard, thick, ſtrong, and black; and contrary to the cuſtom of nature, in all other birds, both parts of it are crooked, and that contrary ways: the upper chap being bent into a point downwards, and the lower one hooked and brought upwards to one as ſharp, ſo that the ends ſtand acroſs. They do not always obſerve the ſame ſide of falling over: the upper one ſometimes lying on the right, ſometimes on the left ſide of the under. One would think this croſs ſtructure of the beak, but a bad one for feeding with, yet the bird is very voracious; it feeds on ſeeds, which it picks up with great dexterity; in particular, it is fond of the kernels of the apple, and to get at them, ſplits an apple in two with one ſtroke of its odly faſhioned beak, by which it does infinite miſchief in orchards. Its back and head are variegated with black and green; the middle of every feather being of the former of thoſe colours, and the edges of the latter; there is alſo a mixture of grey about the head; the rump is green, the upper part of the throat is grey, the breaſt green, and the belly white; the wings and tail are variegated with black and green. See Tab. of Birds, N° 36.

It is common in Germany, Sweden, and ſome other countries, and ſometimes in autumn, comes over to us in vaſt abundance, doing great miſchief to the orchards in the weſt of England. It ſings very ſweetly, and, as it is ſaid, only in winter. *Ray*'s Ornitholog. p. 181.

In the Linnæan ſyſtem of zoology, *loxia* is uſed for the name of a genus of birds of the paſſeres kind; the diſtinguiſhing characters of which are, that the tongue is plain, equal, and whole; the beak large, thick, and ſhort, and crooked and convex both ways.

Of this genus are the *coccothrauſtes*, *loxia*, or *croſs-bill*, &c. *Linnæus*'s Syſt. Naturæ. p. 48.

LOYAL, in the manege. A horſe is ſaid to be *loyal*, that freely bends all his force in obeying, and performing any manege he is put to; and does not defend himſelf, or reſiſt, notwithſtanding his being ill treated.

A *loyal* mouth is an excellent mouth, of the nature of ſuch as we call mouths, with a full reſt upon the hand.

LOZENGES (*Cycl.*)—LOZENGES, among jewellers, are common to brilliant and roſe diamonds. In the former they are formed by the meeting of the ſkill and ſtar facets on the bezil; in the latter, by the meeting of the facets in the horizontal ribs of the crown. *Jeffries* on Diamonds. See the article FACETS, *&c.*

LUBI, in botany, a name by which many authors have called the *coconut-tree*, or *palma nucifera medica* of other writers. *Camell.* Syll. p. 43.

LUCAR, among the Romans, an appellation given to the money expended upon plays and public ſhews. *Pitiſc.*

LUCERNA, in zoology, the name of a fiſh caught in the Mediterranean and ſome other ſeas, of the cuculus kind, and very nearly approaching to the ſhape and figure of the hirundo. Its tail is but ſlightly forked, and what diſtinguiſhes it principally from the hirundo, is, that its ſide lines near the tail divide into two, whereas in that fiſh they continue ſingle. Its ſcales are very ſmall, and it has a furrow on the back, edged by twenty-five ſpines on each ſide. The gill fins are of a remarkable ſize, and look like wings. It feeds on ſhrimps and other ſmall animals. See Tab. of Fiſhes, N° 47. and *Willughby*'s Hiſt. Piſc. p. 281.

LUCERNE, in huſbandry, the name of a plant frequently cultivated by our farmers in the manner of clover. It is the ſame plant which the antients were ſo fond of under the name of *medica*, and in the culture of which they beſtowed ſuch great care and pains. See MEDICA.

Its leaves grow three at a joint, like thoſe of the clover; its flowers are blue, and its pods of a ſcrew like ſhape, containing ſeeds like thoſe of the broad clover, but larger, and more kidney ſhaped.

The ſtalks grow erect, and after mowing, they immediately grow up again from the parts where they were cut off. The roots are longer than thoſe of the ſaint foin, and are not ſingle, but ſometimes they run perpendicularly in three or four places from the crown.

It is the only plant in the world, whoſe hay is preferable to the ſaint foin for the fattening of cattle; but its virtues, in that reſpect, are ſo great, that they are not to be credited by any that have not tried the plant. It is the ſweeteſt graſs in the world, but muſt be given to cattle with caution, and in ſmall quantities, otherwiſe they will ſwell and incur diſeaſes from it.

The antients were at the greateſt pains to plant this properly, they choſe the fatteſt and beſt land they had for it, and this they dunged and laid out in beds as we do for the choiceſt garden plants. They ſowed it in the end of April, firſt carefully preparing the ground by breaking the clods, they then raked the earth over the ſeeds to cover them lightly, and when it was come up they carefully kept the beds clear of weeds. They ſowed it very thick, and let the firſt crop of it ſtand till the ſeed was in part ſhattered out, that they might be ſure of more plants in the beds; after this, they cut it as young as they pleaſed, and it uſually yielded them four or five crops or more in a year. A land well planted with it, would, with proper management, laſt ten years, and produce largely all the time. It is computed that Engliſh gardiners make forty pounds of an acre of aſparagus, or many other garden plants, with half the labour and expence, that was beſtowed upon an acre of the Roman *medica*. This was a piece of huſbandry only practiſed while that great empire was in its glory; at preſent they have very little *medica* or *lucerne* in Italy, and what they have is manured in a leſs troubleſome manner.

In the ſouth of France there is annually a great quantity of it raiſed. They ſow it alone in March, or in the end of September, chooſing for this purpoſe dry and ſandy lands, but ſuch as lie low.

They prepare theſe by ploughing and harrowing them very fine, and the ſpring and autumn being rainy, they have no occaſion to water the plants, while young, as the Romans did. The ſummers in that part of the world are much drier than in Italy, and by that means the graſs is burnt up, and other weeds much deſtroyed, ſo that the crop does not want that vaſt expence in weeding that the Roman *medica* did, by this means the expence alſo is greatly abated.

The colder countries are leſs calculated for the raiſing of *lucerne*; becauſe being more wet, and leſs hot, the ground ſooner hardens on the ſurface, and common graſs ſooner grows into turf, and covers it, and this is the great deſtruction of *lucerne*. In Swiſſerland they cultivate ſmall parcels of it in their vineyards, that they may have it for their cattle, when ſick, but it uſually ſtands but about two years, and muſt then be replanted; and, in France, about Paris, they find it ſucceed ſo ill, that they are now plowing it up, and ſowing ſaint foin in its place as a plant, that much better keeps the graſs under.

From the ſucceſs of *lucerne*, in other countries, there appears very little proſpect of bringing it into uſe in England, where the ſeaſons are more rainy, and the ſun weaker. Our poor land will not produce crops of it ſufficient to pay the expences of the farmer, and our rich land will produce graſs ſo faſt among it, that it will be ſoon choaked up and deſtroyed.

It has been carefully tried to plant *lucerne*, in a meadow breaſt, plowed and ſown firſt with carrots. When, by this means, the graſs was entirely deſtroyed, the *lucerne* was ſown, and flouriſhed for two years; but after that the graſs grew among it, and wholly choaked it up; and if it be tried in our gardens, it is always found to decline, as the graſs grows up amongſt it, which is the ſooner, the richer the land is.

The poor whitiſh ſoil, ſo common in many parts of England, has been tried for *lucerne*, as the natural graſs grows of itſelf, but poorly here: it was hoped the great inconvenience of *lucerne* in England might be obviated by this means; but the *lucerne* will not come to any perfection on this poor land; and though it continues ſeveral years, is always ſo weak and low, that the crops will ſcarce pay the expence of mowing; and by all the trials that have been made in England, all our land ſeems either too rich, too poor, or too cold, for the raiſing this valuable plant, in the way of the common huſbandry.

The advantage of the new horſe-hoeing huſbandry is very evident in the caſe of this plant, for by it all the before-named inconveniences are remedied, and thoſe very peculiarities of our ſoil and climate, which prevented its ſucceſs with us, become the means of that ſucceſs.

Mr. Tull ſpeaks experimentally of the ſucceſs of a great number of old plants of this *lucerne* in ſeveral lands, as well poor as rich ones; and ſeems convinced, that many thouſands of acres of Engliſh land are capable of producing, by this management, fine crops of it, and that for an age together. The greater degree of moiſture, and leſs heat, of this climate, are all of the utmoſt advantage to this plant, when horſe-hoed, as that ſufficiently prevents the growth of the turf which would deſtroy it.

In the drier ſummers in Italy and the ſouth of France, the *lucerne* yields only four or five crops inſtead of ſix or ſeven; but in the drieſt ſummers in England, it would ſucceed the beſt of all, and give the moſt numerous crops. The horſe-hoeing prevents the turf, and makes the land imbibe the dews, and retain them for the nouriſhment of the plants; and *lucerne*, in ſheltered places, will grow by this means, even in our winter, plants of it having been ſeen at Chriſtmas of fourteen inches high. Our winters need not be feared in regard to the *lucerne*, for at Neuf Chatell it is found to ſtand all the winters very well; yet there the roſemary plants all die if left out in the winter. This is a proof that the winters are more ſevere than ours, for it is not one winter in forty that hurts this ſhrub with us.

In the year 1708, the *lucerne* in Languedoc ſuffered by the ſeverity of the winter, but this was ſo ſharp, that the olive trees, and even the walnut trees were alſo killed by it: as no ſuch froſts come among us, as to kill our walnut trees, we need not fear a crop of this plant, for much of it ſurvived even there, when thoſe trees periſhed.

In Languedoc the *lucerne* never arrives at any great height, except where it has the advantage of the plow; and in Wiltſhire there have been lands ſown with it, where it grew but poorly and low; but after the ſame grounds had been plowed, and after corn laid down with ſaint foin, the *lucerne* plants that were left grew up to a vaſt height, and were very vigorous, this ſhews the advantage of the plow; and all this advantage will be regularly given by horſe-hoeing, without the deſtruction of any of the plants. *Tull*'s Horſe-hoeing Huſbandry, p. 93. ſeq.

Though the common method of huſbandry will not raiſe *lucerne* to advantage; yet the horſe-hoeing huſbandry will raiſe it annually, increaſing in value to the owner, and make one of the moſt profitable articles of his buſineſs of it.

The ſoil to plant it on muſt be either a hot gravel, or a very rich and dry land, or ſome other rich and dry land that has not an under ſtratum of clay, and is not too near ſprings of water. The natural poorneſs of gravel may be made up by dung and the benefit of the hoe, and the natural richneſs of the other lands being increaſed by hoeing and cleanſing them from graſs, the *lucerne* will thrive with leſs heat; for what is wanted in one of theſe qualities muſt be

be made up in the other. The beſt ſeaſon for planting it in England is early in the ſpring, the earlier the better, for then there is always moiſture enough in the earth to make it grow, and not ſo much heat as would dry up its tender roots, and kill it after the firſt ſhooting. About a pound and half of ſeed will be ſufficient for an acre; and if this be ſown in February, though ſome of the young plants will be deſtroyed by the froſts in March, yet there will be enough left of them for the making as thick a crop as is neceſſary. The planting it in autumn might do very well in hotter countries, but with us the long winters would kill a great part of the tender plants, and greatly ſtunt and injure thoſe which they did not kill. The number of *lucerne* plants ſhould be leſs than thoſe of ſaint foin to an acre, becauſe they grow much larger in this way of management, and each occupies a greater ſpace of ground, and produces a larger quantity of hay. The quick growth of this plant requires that it ſhould have large ſupplies of nouriſhment, and good room to grow in, and it is better in all things of this kind to err in ſetting the plants too far diſtant than in ſetting them too near.

The moſt fatal diſeaſe incident to *lucerne* is ſtarving; for this reaſon good culture is neceſſary to it, and the often turning the earth with the hoe all about it. By this means, a plant, that in the common way of ſowing, would not have been more than four or five inches high will be three feet, and will ſpread every way, ſo as to produce a quantity of hay, more like the cutting of a ſhrub than a plant.

The plants ſhould ſtand at five inches diſtance in ſingle rows, and the intervals between theſe rows muſt be left wide enough for the uſe of the hoe plow.

The rows of *lucerne* plants muſt not be thinned till they are grown up to ſome height; for while young they are ſubject to be eaten by the fly, like turnips; and if this deſtroyer ſhould ſeize them, after they are reduced to only a competent number, the crop would be rendered much too thin. The hoe plow is the only inſtrument that can bring this plant to perfection, and it muſt be frequently had in proportion to the number of crops it produces; but then it muſt be ſtill ſome years, leſt the plowed ground injure the hay that is made upon it; and when it is come to a turf, and the *lucerne* wants renewing, the four coultered plow is the only inſtrument that can prepare the turf to be killed, and cure the *lucerne*. This plow muſt be uſed in the following manner: turn its furrows toward one row, and from the next; that is, plow round one row, and that will finiſh two intervals; and ſo of the reſt. The next plowing muſt be towards thoſe rows from which they were turned the firſt time, and care muſt be taken that the firſt furrows do not lie long enough on the rows to kill the plants, which will be much longer in winter than in ſummer.

Lucerne is to be made into hay in the ſame manner as ſaint foin; but this is to be obſerved, that it is always to be cut juſt before it comes to flower. The richeſt *lucerne* hay of any is that cut while the ſtalks are ſingle, without any collateral branches, and in this caſe there uſually is not ſo much as the bud of a flower to be ſeen on the plants.

Lucerne can never be expected to ſucceed well any where, let the ſoil be ever ſo good, unleſs it be kept clean from natural graſs. *Tull*'s Huſbandry, p. 102.

LUCERNE, in ichthyology, a name given by the Venetians to the fiſh commonly called the *uranoſcope*. It is a ſpecies of Trachinus, with many beards on the lower jaw.

LUCIDA (*Cycl.*)—LUCIDA *hydræ*, in aſtronomy. See COR *hydræ*, *Cycl.*

LUCIOLA, in botany, a name uſed by ſome authors for the ophiogloſſum, or adder's tongue. *Ger.* Emac. Ind. 2.

LUCIOPERCA, the *pike pearch*, a fiſh caught in the Danube and other large rivers, and in the lakes of Germany, and eſteemed a very good one for the table. Others have called it by the names *ſchilus* and *nagumulus*. It is a fiſh that grows to a very conſiderable ſize, being frequently caught from two feet to three or four in length. It is of a longer ſhape than the river pearch, and grows narrower toward the tail; its ſnout is alſo more pointed and longer, and its back much leſs prominent than that of the common pearch. Its figure, upon the whole, more approaches to that of the pike than of the pearch; its belly is however broad and flat; and on the anterior part of the back, toward the head, there is a furrow in the middle. The ſcales are ranged very cloſely together, and are fimbriated round their edges. The breaſt has no ſcales. The ſides are of the ſame colour with thoſe of the common pearch, a yelloviſh brown, and its belly and fins are red, but leſs ſo than in the common pearch. *Ray*'s Ichthyog. p. 292.

LUCIUS, in zoology, the name of the common river fiſh, called in Engliſh the *jack*, or *pike*, and by ſome the *pickerel*. It is a well known fiſh, and very frequent in our ponds, lakes, and rivers, and grows to a very great ſize, often weighing from fifteen to thirty pounds. It is a very voracious fiſh, feeding on others, and often ſeizing ſuch as are but little leſs than itſelf. It is often found in ponds where the owners never intended it ſhould come, and devours multitudes of ſmall fiſh. It is ſaid that it will be produced in theſe places from the ſpawn eaten by herons, and voided in them. *Ray*'s Ichthyog. p. 236.

Many authors have treated of the common *pike* under the names of three ſpecies; theſe are diſtinguiſhed by the different times of ſpawning, and have no real characters to diſtinguiſh them by; though they are called by three names, as if ſo many diſtinct ſorts of fiſh. The firſt is the *giadda*, that is the *lucius glacialis* or *ice-pike*. This is common in the lakes of Sweden, and ſpawns in the ſpring time under the ice. The ſecond is called the *blomſter-giadda*, that is the *flower pike*. It has this name from its time of ſpawning, which is at a more advanced ſeaſon, when the flowers begin to open in the fields. The third is called *fro-giadda*, or the *ſeed pike*. This ſpawns much later in the ſeaſon, as in Auguſt and September, and is thus called from the plants being in ſeed at that time. But the fiſh is the ſame ſpecies, under all theſe differences of time of ſpawning, and the diſtinctions therefore idle and unneceſſary. *Artedi*'s Ichthyol.

LUCIUS *marinus*, the *ſea pike*, a name given by ſome authors to the fiſh more uſually called the *merlucius*, and in Engliſh the *hake*. *Willughby*'s Hiſt. Piſc. p. 174. See the article MERLUCIUS.

LUCIUS *marinus*, is alſo uſed by many authors for the *ſudis*, called alſo by ſome *ſphyræna*. *Aldrovand.* de Piſc. p. 102. See the article SUDIS.

LUCIUS *terreſtris*, the *land pike*, in zoology, the name of a very ſingular ſpecies of American lizard, which has the ſhape, ſcales, &c. of the pike fiſh. In the place of the fins of that fiſh it has four legs, but theſe are ſo weak and ſlender that it makes no uſe of them in walking, but crawls along upon the ground in the manner of a ſnake, and draws its legs after it. It grows to about fifteen inches long, with a proportionable thickneſs. It is all over covered with ſmall, ſtrong, and gloſſy ſcales, of a ſilvery grey. In the night they retire into holes and caverns, and make a very diſagreeable and loud noiſe, much louder than the croaking of frogs. They ſeldom ſtir out of their holes, unleſs in the duſk of the evening; and if they are ever met with in the day time, their ſtrange motion ſurprizes all who ſee them. *Rochefort*'s Hiſt. Inſ. Antill.

LUCULLEUM *marmor*, in the natural hiſtory of the antients, the name of a hard ſtony kind of marble, of a good fine black, and capable of an elegant poliſh, but little regarded from its want of variegations. When freſh broken, it is ſeen to be full of ſmall, but very bright ſhining particles, appearing like ſo many ſmall ſpangles of talc.

It had its name from the Roman conſul Lucullus, who firſt brought it into uſe in that city. It is common in Italy, Germany, and France. We have much of it imported, and our artificers call it the *namur* marble, the Spaniards call it marble of *buga*. *Hill*'s Hiſt. of Foſſ. p. 466.

LUDUS (*Cycl.*)—LUDUS *helmontii*, in natural hiſtory, an opake foſſile of an irregular ſhape, but of a very regular and ſingular internal ſtructure. It is of an earthy hue, and always divided into ſeparate maſſes, by a number of veins of a different colour, and purer matter than the reſt. Theſe maſſes, into which it is divided, are ſometimes ſmall and pretty regularly figured; in which caſe, they are called *tali* or *ludi*, dice; but they are more frequently of no regular ſhape at all. There are others of them cruſtated or compoſed of many coats, diſpoſed one over another about a central nucleus. In theſe the *ſepta*, or dividing veins, are very thin and fine, in the others thicker.

It is only theſe *ſepta* that are uſed in medicine, being given in nephritic complaints with ſucceſs. The doſe is from a ſcruple to a dram.

LUDWIGIA, in the Linnæan ſyſtem of botany, the name of a genus of plants, the diſtinguiſhing characters of which are theſe. The cup is a perianthium compoſed of one leaf, divided into four ſegments, ſituated on the germen of the piſtil, and remaining after the flower is fallen; the ſegments of the cup are pointed, ſpread very wide, and of the ſame length with the petals of the flower. The flower is compoſed of four petals all of the ſame ſize, ſpread wide open, flat, and cordated. The ſtamina are four erect, pointed, ſhort filaments. The antheræ are ſimple, erect, and oblong. The germen of the piſtil is ſquare, and is cloathed with the baſis of the cup under the receptacle of the flower. The ſtyle is cylindric, and of the length of the ſtamina, and the ſtigma is ſomewhat ſquared and headed. The fruit is an obtuſe, ſquare capſule, covered with, and crowned by the cup; it contains four cells, and opens four ways. The ſeeds are numerous and ſmall. *Linnæi* Gen. Plant. p. 49.

LUG-*a-leaf*, a name uſed in ſome parts of England for a ſmall fiſh of the turbot kind, or rather a middle kind, between that and the plaiſe. The ſame with the *ſoaggio*. *Willughby*'s Hiſt. Piſc. p. 95. See the article SOAGGIO.

LUGGS, the Engliſh name for a peculiar ſpecies of inſect, found in great plenty on the ſhores of Cornwal. It is of the nature of the *ſcolopendra*, and is called by Mr. Ray *vermis ſcolopendroides*. It grows to twelve inches long, and has inſtead of legs nineteen pair of ſtiff briſtles, theſe all ſtand toward the head part of the creature. The tail being

of at leaſt five inches long when full grown, and having no mark of them. Its body is rounded, and much reſembles the body of the common earth worm, and is of a fleſh colour, or pale red; it has no forceps.

LUGMON, in natural hiſtory, a name given by the people of the Philippine Iſlands to a ſpecies of turtle; the female of which has a tuft of red feathers, of a pale blood colour on her breaſt, which have greatly the appearance of a wound, given by nature, but ſo much reſembling a real wound, that any body would at firſt ſight be deceived.

LUJULA, *wood ſorrel*, in medicine. See SORREL.

LULANIS, in botany, a name given by ſome of the antient Greeks to a plant, uſed very frequently for a yellow colour in dying, and by the ladies for tinging their hair yellow, the favourite colours of thoſe times. Neophytus explaining this word, ſays, that it ſignified the ſame with iſatis, glaſtum, or woad; and ſeveral others have been of that opinion, though very abſurdly, ſince the glaſtum or woad dies a blue colour not a yellow; and by no means anſwers the deſcription of the *lulanis*, which is the ſame with the *lutum* or *lutea herba* of the Romans, and with the *geniſtella tinctoria* or dyers wood of theſe times. See the article LUTUM.

LUMELLA, in the glaſs trade, the round hole in the floor of the tower of the leer, which is directly over the working furnace, and by which the flame is let into the tower. *Neri*'s Art of Glaſs, p. 243.

LUMINOUS (*Cycl.*)—*Luminous* emanations have been obſerved from human bodies, as alſo from thoſe of brutes. The light ariſing from currying a horſe, or from rubbing a cat's back are known to moſt. Inſtances of a like kind have been known on combing a woman's head. Bartholin [a] gives us an account, which he entitles *mulier ſplendens*, of a lady in Italy, whoſe body would ſhine, whenever ſlightly touched with a piece of linnen. Theſe effluvia of animal bodies have many properties in common with thoſe produced from glaſs; ſuch as their being lucid, their ſnapping, and their not being excited without ſome degree of friction, to which may be added electricity; as a cat's back has been found ſtrongly electrical when ſtroaked [b].—[[a] Cant. 3. Hiſt. 70. [b] Phil. Tranſ. N° 476. p. 444, ſeq.—] See ELECTRICITY.

Human bodies not only appear *luminous*, but even the exhalations from them adhering to their cloathing will cauſe it to ſhine likewiſe [c].—[[c] Ibid. & p. 477.]

LUMME, in zoology, the name of a water fowl of the colymbus kind, called by authors *colymbus arcticus*, and common about Iceland and ſome parts of Norway, and ſcarce known in any other part of the world.

It is a beautful bird of the ſize of a duck. It has a black and ſharp beak of two inches long, and its head and neck are covered with grey feathers, running each way to a ſharp edge, and making the appearance of a hood or friar's cawl. Its back and wings are black, variegated with ſquare ſpecks of white, and juſt under the neck there is a large black ſquare ſpot. This runs down the back alſo to five inches in length, and is about two inches broad, and beautifully variegated with black, white, and grey. Its belly is white, its legs are ſhort, and its feet webbed. The people where it is common, hold it as ſacred, in ſome meaſure, and are afraid of killing it in ſome places; but the icelanders make it their principal food, and are very dextrous at catching it with ſnares. *Ray*'s Ornithol. p. 259.

LUMP *fiſh*. See the article LUMPUS.

LUMP *of fleſh*, in the manege. See BOUILLON.

LUMPEN, in ichthyology, the name of a long bodied fiſh of the muſtela kind, common in the markets at Antwerp.

It is of a long and round body, growing gradually ſlenderer to the tail. Its colour is a greeniſh yellow, with black broad lines on the back placed tranſverſely; and it has a little redneſs at the end of its tail. *Willughby*'s Hiſt. Piſc. p. 120.

It has alſo a number of duſky ſpots all over the body, except under the longitudinal mark, which runs along each ſide from the gills to the tail. It has either no ſcales, or ſuch as are too ſmall to be perceptible; its mouth is large, and furniſhed with one row of teeth in each jaw; its tongue is broad, ſoft, and roundiſh, and the iris of the eyes is yellow. The apertures of its gills are ſmall, its back fin runs ſingly the whole length of the back, and turning round the tail, comes up to the anus; near which there is another aperture, out of which may be preſſed an aqueous liquor.

The *lumpen* is the *galea piſcis*, or *muſtela altera* of Geſner and others. It is a ſpecies of the *blenni* diſtinguiſhed by Artedi, by the name of the *blennus*, with fins like cirri under its neck, and tranſverſe ſtreaks on the back. The cirri are bifid.

LUMPUS, in zoology, the name of a thick and ſhort ſea fiſh, called in Engliſh the *lump fiſh*, and *ſea own*, and by the Scotch the *cock paddle*.

It is a thick and very ill ſhaped fiſh. Its belly is broad and flat, and its back riſes to a ridge. Its colour is a mixture of blackiſh and red; its belly is red. It has no ſcales, but is covered with a tough ſkin, which is full of ſharp tubercles; and on each ſide it has three rows of prickles or crooked thorns. It has two fins on the back, the firſt thick, cartilaginous, or rather fleſhy, and having no rays or nerves; and another below it ſupported by nine rays. Its mouth is large, and its jaws are furniſhed with vaſt numbers of ſmall teeth. It is caught in many parts of the Engliſh ſeas, and is common in the fiſhmongers ſhops in London, but it is not much eſteemed. See Tab. of Fiſhes, N° 32. and *Willughby*'s Hiſt. Piſc. p. 208.

LUNA (*Cycl.*)—LUNA *marina*, in zoology, a name by which Geſner has called a peculiar ſpecies of *ſtar fiſh*, called alſo the *ſea ſun*. See SOLEIL *de mer*.

LUNA *piſcis*, in zoology, a name by which ſome have called the *mola*, which we uſually call in Engliſh the *ſun fiſh*. *Willughby*'s Hiſt. Piſc. p. 15. See the article MOLA.

Lac LUNÆ. See the article LAC *lunæ*.

LUNÆTRIA, a term invented by ſome affected writers, on medicine for a fever, which they ſay is curable in one period of the moon.

LUNAR (*Cycl.*)—LUNAR *cycle*, in chronology. See CYCLE *of the moon*, Cycl.

LUNARE *os*, in anatomy, is the ſecond bone in the firſt row of the carpus. It has its name from the Latin *luna*, the moon, becauſe one of its ſides is in form of a creſcent.

The articular ſides in this bone are four in number. One convex for the baſis of the radius, one ſemi-lunar for the os ſcaphoides, one almoſt triangular for the os cuneiforme, and one hollow; which, with the hollow ſide of the os ſcaphoides, forms a cotyloide cavity for the head of the os magnum. The convex ſide, together with that of the os ſcaphoides, forms an oblong convexity, anſwering to the oblong concavity in the baſis of the radius, the outer and inner ſurfaces are ſmall and rough. This bone would ſomewhat more properly be named *os ſemi-lunare*, than *lunare*, &c. *Winſlow*'s Anatomy, p. 83.

LUNARIA, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of four leaves, and is of the cruciform kind. The piſtil ariſes from the cup, and finally becomes a very remarkable ſeed veſſel, extremely broad, thin, and flat and divided by an intermediate membrane into two cells, which uſually contain kidney ſhaped and marginated ſeeds. See Tab. 1. of Botany, Claſs 8.

The ſpecies of *lunaria*, enumerated by Mr. Tournefort, are theſe. 1. The common larger round podded *lunaria*. 2. The white flowered round podded perennial larger *lunaria*. 3. The larger *lunaria* with long ſhaped pods. 4. The purple flowered long podded larger *lunaria*. 5. The wall flower leaved *lunaria* with large and long pods. 6. The wall flower leaved *lunaria* with long ſhaped ſmaller pods. 7. The *lunaria* with long crooked pods. *Tourn.* Inſt. p. 218.

This plant is famous in ſome parts of the kingdom for its medicinal virtues, though it has not the fortune to be received in the ſhops. The people in the northern countries dry the whole plant in an oven, and give as much as will lie on a ſhilling for a doſe, twice a day, in hæmorrhages of all kinds, particularly in the too abundant flowing of the menſes, and this with great ſucceſs. The Welſh, among whom it is not uncommon, Dr. Needham informs us, make an ointment of it, which they uſe externally, and pretend it cures dyſenteries. *Dale* Pharm.

LUNARIA, in natural hiſtory, is alſo uſed by ſome authors for the Selenites.

LUNARIS *cochlea*, in natural hiſtory, the name of a genus of ſhells of the ſnail kind, the diſtinguiſhing character of which is their having a perfectly round mouth. Theſe are univalve, umbilicated ſhells, with a depreſſed clavicle, and a ſurface ſometimes ſmooth, but more frequently ſtriated, furrowed, laciniated, or covered with tubercles.

The *cochleæ*, or ſnails in general, are divided into three genera, which are founded on the differences in the ſhape of the mouth. The firſt genus has the mouth round, the ſecond has it ſemi-circular, and the third oval. The firſt is, the genus charactered by the term *cochlea lunaris*.

This genus of *cochleæ* may be very aptly divided into three ſections. 1. The ſmooth *cochleæ lunares*. 2. The ſulcated ones, and 3. The rough or ſcabrous ones. Yet, it is to be obſerved, that this method of diſtinction, which was inſtituted by Rumphius, is, though very obvious, yet very ſlightly founded, as it takes in only the varieties of the ſuperficies, not any eſſential characters. The name *limax* ſeems to have been given the ſnail from the Latin *limus* mud, for it is uſually bred among mud. They have all an operculum or covering for the mouth. This entirely ſtops up the aperture of the ſhell, when the fiſh draws its body into it; and this operculum, when found looſe, and ſeparate, as many kinds of it frequently are, is called by many *umbilicus veneris*, as if it were a peculiar ſpecies of ſhell. No ſnail has leſs than two volutæ or turns, in the ſhell, and many have as far as ten. It is ſaid, that Archimedes took the invention of the ſcrew, ſo famous ever ſince his time, and ſtill called after his name from the form of this ſhell; and it is generally allowed, that architects have taken the hint of their winding flights of ſtairs from it. *Rumph.* p. 29. *Liſter* de Conch. Hiſt. Nat. Eclaire, P. 2. p. 251.

The ſmall ſpecies of crab, called *bernard the hermit*, often lodges itſelf in a ſhell of one of theſe animals, after the creature

creature to whom it belonged is dead. One ſpecies of this genus is called the *rotunda* from its round ſhape. This is ſo large as to contain two quarts of water, and from an old practice of uſing this ſpecies by way of an oil jar in families, it obtained the name of *olearia*. There is a peculiar ſpecies called the dauphin ſnail, which is elegantly furniſhed with rows of points of a jagged form on all its ſpires; and the ſhell called the *eperon* is another ſpecies of this genus, the volutæ of which are in the ſame manner furniſhed with points; but in this ſpecies they are ſmoother and ſharper than in the dauphin ſnail. Rondeletius has given the name *echinophora* to one, which is all over covered with rough tubercles. And there is one ſpecies of this ſhell brought from America, which is very large, and of a fine pearly coat within. The workmen in toys take much of what they uſe from it, and what we imagine the inſide of the nacre, or mother of pearl, is often no other than the inner coat of this ſnail.

The ſpecies of this genus are the following. 1. The faſciated and tuberous *lunar* ſnail. 2. The great American *burgau*. This is often ſeen in the cabinets of the curious, with its outer ſurface eaten off, and then when it has been poliſhed it looks all over pearly, and makes a very elegant appearance. 3. The ſerpent ſkin *lunar* ſnail, ſo called from the colours and ſpots. 4. The green ſnail. 5. The *olearia* or large umbilicated *lunar cochlea*. 6. The *lunar* ſnail, with an exerted clavicle. 7. The ribband ſnail. This, however, is but a variety of the former ſpecies. 8. The furrowed *lunar* ſnail. 9. The parrot *lunar* ſnail. 10. The roaſted cheſnut ſnail. 11. The variegated ſnail. 12. The *lunar* ſnail with a depreſſed apex, of a variegated green colour. 13. The ſmall ſmaragdine ſnail. 14. The goat's eye ſnail; there is a Chineſe ſpecies of this ſnail, with green and white lines very beautiful. 15. The violet ſnail of Columna. 16. The wide lipped *lunar* ſnail variegated with yellow and white. 17. The rough and furrowed ſnail, called the *os aureum*, or golden mouth. 18. The rough and furrowed ſnail, called the ſilver mouth, or *os argenteum*. 19. The dauphin ſnail. 20. The granulated and umbilicated ſnail. 21. The depreſſed ſnail with tubercles on each ſide. 22. The ſpur ſnail, with prickles diſpoſed in two ranges. Hiſt. Nat. Eclair, p. 2. p. 251.

LUNDA, in zoology, a name by which Wormius, Hoier, and ſome others, have called the bird, commonly known by the name of *anas arctica Cluſii*. See DUCK.

LUNDRESS, in our old writers, a ſterling ſilver-penny; which had its name from being coined only at London, and not at the country mints. *Lownds*'s Eſſay upon Coins, p. 17.

LUNE, *Lunula* (*Cycl.*)—The quadrature of the *lunula* is generally aſcribed to Hippocrates of Chios; but Proclus tells us expreſsly, that it was found by Œnopidas of Chios. See Mr. *Heinius* in Mem. de l'Acad. de Berlin, Tom. 2. p. 410. who has given us a diſſertation about this Œnopidas.

LUNENSE *marmor*, in the natural hiſtory of the antients, the name of that ſpecies, of white marble now known among us, by the name of the *Carrara marble*, and diſtinguiſhed from the ſtatuary kind, by its greater hardneſs and leſs ſplendour. It was ever greatly eſteemed in building and ornamental works, and is ſo ſtill. It is of a very cloſe and fine texture, of a very pure white, and much more tranſparent than any other of the white marbles. It has always been found in great quantities in Italy, and is ſo to this day. *Hill*'s Hiſt. of Foſſ. p. 463.

LUNETTE (*Cycl.*)—LUNETTE, in the manege. A half horſe-ſhoe, or ſuch a ſhoe as wants the ſpunge, *i. e.* that part of the branch which runs towards the quarters of the foot, has this name given it.

LUNETTE is alſo the name of two ſmall pieces of felt made round and hollow, to clap upon the eyes of a vicious horſe that is apt to bite, and ſtrike with his fore feet, or that will not ſuffer his rider to mount him.

LUNGS (*Cycl.*)—From the experiments made on living animals by Dr. Houſton [a], Dr. Hoadley [b], and Mr. Bremond [c], the *lungs* ſeem to act independent of the thorax, continuing to be dilated and contracted after they are expoſed to the air.[—[a] Phil. Tranſ. N° 441. Sect. 4. [b] Lectures on Reſpiration. [c] Mem. de l'Acad. des Sciences, 1739.—]

An artificial inflation of the *lungs* of a dead or dying animal will put the heart in motion, and continue it ſo for ſome time. And we have an inſtance of the ſucceſsful application of this experiment to the reſcuing the life of a perſon ſuffocated by the means of a coal pit. See Medic. Eſſ. Edinb. Vol. 5. And Phil. Tranſ. N°. 475. Sect. 11.

In the medical Eſſays Edinb. we read of an ulcer in the *lungs*, piercing through the diaphragm into the liver. See Vol. 1. Art. 26.

Dropſy of the LUNGS. See the article HYDROPS *pulmonum*.

LUNGS *wounded*. There is always reaſon to apprehend that the *lungs* are wounded, when the patient voids a great quantity of frothy blood by the mouth, accompanied with a cough after receiving a wound in the thorax, eſpecially when the blood that is voided at the wound, is very florid, and the patient makes a particular noiſe when he draws his breath. The office of a ſurgeon, in this caſe, is to clear the cavity of the thorax from extravaſated blood, and to heal the external wound when that may be done with ſafety: but as no application can be made to the internal wound, that muſt be left to nature. Whenever the divided veſſels contract themſelves, and the blood ſtops of itſelf, the patient will recover; the perſons who have recovered from theſe wounds, are afterwards externally ſubject to conſumptions, and ulcers of the *lungs*. Sometimes in caſes of this kind, the wounded part of the *lungs* puſhes itſelf forward, and ſticks pretty firmly in the orifice of the external wound. In this caſe, if it is forced back again, it will diſcharge a great quantity of blood into the cavity of the thorax: therefore it is better to let it remain in the ſituation nature has thrown it into, for by this means it will admit of the immediate application of proper dreſſings, and you may ſafely encourage it to adhere to the lips of the external wound: but if a wounded portion of the *lungs* ſhould be puſhed out of the thorax, beyond the limits of the external wound, a fine piece of linnen is to be wrapped round this part, and a ligature muſt be then made above the linnen, and all that is below the ligature taken off with a fine knife, and the ſound part of the *lungs* muſt then be returned into the body, keeping one end of the ligature conſtantly hanging out at the external wound; the wound is then to be kept open with a tent, and the ligature at length may be ſafely drawn out. The wound is then to be healed in the ordinary way. And during the courſe of the cure, the patient muſt take internally vulnerary decoctions, and lucatellus balſam. By this treatment wounds of this dangerous kind are ſometimes cured, but when they are not, it is a ſatisfaction to know that all has been done, that could be done in ſo deſperate a caſe. *Heiſter*. Surg. 73.

LUNGS *of inſects*. In the fly claſs the ſtigmata are extremely numerous, and the tracheæ which they terminate are branched and divaricated all over the body in an amazing manner, as if every part and particle of the bodies of theſe little animals had occaſion for its particular air veſſels; beſide theſe, however, flies are provided with proper *lungs*. They have two, and thoſe ſo very large, that they frequently take up half, and ſometimes two thirds of the body of the animal. *Reaumur*'s Hiſt. Inſ. Vol. 4. p. 267.

Theſe are two bladders placed ſideways one by the other, alike in ſhape and ſize; and having their origin at the junction of the corcelet and body, and in many flies whoſe bodies are compoſed of five rings, extending to the third, and ſometimes reaching the fourth. The ſize and figure of each of theſe bladders is ſuch, as is neceſſary, to fill almoſt entirely that cavity of the body in which it is lodged. They each of them touch the ſides of this cavity, the part when they join one another is flat, and this commiſſure forms a line running ſtrait down the body; they are, however, in this part, though ſo cloſely in contact, yet not at all joined to one another; this commiſſure, however, does not reach quite up to the back or quite down to the belly, there is a ſmall cavity left between each, which was very neceſſary in both places; the one to give paſſage to the great artery, the other to the excrements. Ibid. p. 268.

LUNG-*wort*, *Pulmonaria*, in botany. See PULMONARIA.

LUNULA, in geometry. See LUNE, *Cycl.* & *Suppl.*

LUNULA, the *half moon*, among the Romans, an ornament the patricians wore on their ſhoes.

LUNULA was alſo an ornament in form of a moon worn by the ladies.

LUNULARIA, a name given by Micheli to certain ſpecies of the marchantia, a kind of lichen. Theſe have the male cup divided into four ſegments, and thoſe turning their edges over the flower; whereas the marchantia, as he calls them, have eight or ten ſegments, and thoſe plain. *Micheli* Nov. Gen. Pl. 55.

LUNULATED *leaf*, among botaniſts. See LEAF.

LUPIA, in ſurgery, a name given by ſome authors to that ſort of ſwelling, called by others *talpa* and *teſtudo*. This is an encyſted tumor, more diſtinguiſhed by its ſituation than by its nature, ſince of whatever kind it be, whether aſteatomatous, or atheromatous, &c. if ſituated under the ſcalp, it is called by theſe names. *Heiſter*'s Surgery, p. 324.

LUPINASTER, in botany, the name given by Buxbaum to a new genus of plants, from their near approach to the characters of the lupine. The flowers are like thoſe of the other papilionaceous plants; the leaves are digitated as in the lupines. The flowers are collected into a head, ſuſtained on a long pedicle, iſſuing from the alæ of the leaves. The pods are flat, and the ſeeds kidney ſhaped. The ſtalks are ſix or eight inches high, the leaves long, of a blueiſh green; ſharply ſerrated, and elegantly ſtriated; they grow ſix, ſeven, or eight on a pedicle, which comes out of a yellowiſh membrane ſurrounding the ſtalk. The flowers are of a blueiſh purple, and ariſe out of cups, divided into ſeveral ſegments. The pods are long and depreſſed, and the ſeeds black and kidney ſhaped. It grows in great plenty about the banks of the Volga. Act. Petrop. Vol. 2. p. 346.

LUPINE, in botany. See LUPINUS, infra.

LUPINUS, the *lupine*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the

the papilionaceous kind. The piſtil ariſes from the cup, and finally becomes a pod, containing in ſome ſpecies roundiſh, and in others flatted ſeeds. The leaves of the *lupine* are alſo of a fan-like ſhape, or grow in the ſhape of fingers, all from the extremity of the ſtalks.

The ſpecies of *lupine* enumerated by Mr. Tournefort are theſe. 1. The common white garden *lupine*. 2. The great hairy blue flowered *lupine*. 3. The broad leaved hairy purple flowered *lupine*, called the wild *lupine* by old authors. 4. The broad leaved and hairy wild *lupine* with white flowers, in all things greatly reſembling the cultivated kind. 5. The white flowered hairy, low, broad leaved *lupine*. 6. The American trifoliate tree *lupine* with white flowers, and variegated fruit. 7. The broad leaved duſky flowered Portugal *lupine*. 8. The great *lupine* with fleſh coloured flowers. 9. The purple flowered wild *lupine*, with large, round, variegated ſeeds. 10. The purple flowered wild *lupine*, with ſmaller, round, variegated ſeeds. 11. The reddiſh flowered wild *lupine*. 12. The wild *lupine* with roſe coloured flowers. 13. The tall narrow leaved blue flowered *lupine*. 14. The little blue flowered *lupine*. 15. The little perennial creeping, blue flowered Virginian *lupine*. 16. The little Indian *lupine*, and 17. The wild, yellow flowered *lupine*. *Tourn.* Inſt. p. 392.

There are ſeveral ſpecies of this plant propagated in gardens, where they make a very agreeable appearance. But the kind moſt frequent with us is the leſſer purple or blue flowered kind. This is propagated by ſowing the ſeeds in a common flower border, where they require no care, but will come up and thrive of themſelves, they ſhould be ſown in April, in May, and in June, that there may be a ſucceſſion of them in flower for a conſiderable time. They ſhould always be ſown where they are to remain, for it gives leſs trouble, and they are plants which but very badly bear tranſplanting. *Miller*'s Gardners Dict.

LUPULUS, *hop*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the apetalous kind, being compoſed only of a number of ſtamina placed in a cup. Theſe flowers are barren, and the embryo fruits are found on other ſpecies of *hops*, on which there are no flowers. Theſe finally become a ſquammoſe fruit, compoſed of many leaves affixed to an axis, and containing many ſeeds, covered with a hand.

The ſpecies of *hop*, enumerated by Mr. Tournefort, are theſe. 1. The common male *hop*. 2. The common female *hop*. *Tourn.* Inſt. p. 535.

The flowers of the *hop*, beſide their uſe in brewing, are recommended as of great uſe in medicine, in the intention of anodynes and diſcutients. They are given in powder in diſeaſes of the liver and ſpleen, in the jaundice, and in obſtructions of the menſes, they alſo powerfully promote urine; and uſed externally in the way of a cataplaſm, they are of ſervice in tumors and contuſions. *Strother*, Pharm.

It is generally ſaid, that the *lupulus*, or *hop*, was, the *bryon* of the antient Greeks. Theſe authors have indeed deſcribed the *bryon*, βρυον, to be a climbing plant, with long branches, twiſting itſelf round every thing that comes in its way, and growing up to a great height; but this is all they have ſaid that gives the leaſt countenance to the opinion of their meaning the *lupulus* or *hop* by it, and this may as well agree with any other of the climbing plants as the *hop*. All that gave birth to this error, was, the writing in abbreviation, the word *bryon* being only a compendious way of writing *bryonia*, and it is very certain that the white *bryony* is the only plant ever meant by this word: the later Greek writers have indeed omitted the abbreviation, and have conſtantly written *bryonia* at length, which our tranſlators from the Greek render *lupulus*. See BRYON and HOPS.

LUPUS, the *wolf*, in zoology (*Cycl.*)—This is a beaſt of prey, but wholly of the dog kind, and the largeſt and fierceſt of that race of animals. It is extremely like the domeſtic dog in ſhape, and if the head did not differ a little in figure, one would be apt to declare it the very ſame animal. It has a very fierce look about the face, its eyes are glaring and ſavage, and its teeth, and the opening of its mouth fierce and frightful. The antients had an opinion, that the neck of the *wolf* was all of one ſolid bone; but, on the contrary, this creature is able to turn and twiſt about better than the dog kind. *Ray*'s Syn. Quad. p. 171.

The *wolf*, as well as all the other beaſts of prey, can endure hunger a long time, though very voracious when it meets with food. The *wolf* differs from the dog in his note, for inſtead of the barking of the dog this creature only howls; his ears which ſtand erect, and his buſhy tail make him alſo greatly reſemble the fox.

LUPUS, in botany, a name ſaid to be given by Pliny to the common hops: this is, however, an error, for tho' the word ſtands in moſt of the copies of that author *lupus*, the true meaning is doubtleſs *lupulus*, the hop. Pliny has coupled it with a word that expreſſes its climbing upon willows, calling it *lupus ſalictarius*. We find in all the old writers the *upulus*, which is the proper name of the hop before the initial, *l*, was added, joined with the word *ſalictarius*, but no where mention of *lupus ſalictarius*, unleſs in Pliny.

LUPUS, in ornithology, a name given by ſome authors to the *monedula* or *jackdaw*, from his voracious appetite and habit of ſtealing. *Aldrovand.* de Avibus.

LUPUS, in the hiſtory of inſects, the name of a *fly* called alſo in Engliſh the *wolf fly*. It has this name from its ravenous and devouring diſpoſition. It feeds on flies, or whatever other inſects come in its way, and is eaſily known by being of a very large ſize, and having long and ſtrong legs, and an oblong and conſiderable thick black body.

LUPUS is alſo the name given by authors to a peculiar claſs of ſpiders, from the manner of their taking their prey, which is by open hunting and running down, and not by means of webs as the common ſpiders do theirs. Theſe are diſtinguiſhed into two kinds, the one properly the *lupus*, or *wolf ſpider*, the other the *crab ſpider*.

All the ſpiders of the *lupus* kind have four large eyes and four ſmall ones. Their hinder pair of legs are longer than any of the others; and they uſually live upon the ground, ſeldom climbing into trees. Of the firſt kind, or the *lupi*, properly ſo called, there are four principal ſpecies. 1. The black ſpider. This is of a middle ſize, the male and female are both black, the head is ſmall, and the legs are beautifully ſpotted. 2. The brown ſpider with oblique ſtreaks upon the body. This is of a middle ſize, and has a black head. 3. The plain yellowiſh ſpider, with a long ſhaped pointed body. This is a very large ſpider, and its legs are long and robuſt; it lives among buſhes. 4. The livid ſpider with a long pointed body undulated with white. This is a very large ſpecies, and lives among trees and under hedges. *Ray*'s Hiſt. Inſ. p. 36.

Of the cancriform, or crab ſpiders, which are leſs properly called *lupi*, there are two principal kinds. The diſtinguiſhing character of the crab ſpiders, is, their having the hinder pair of legs the ſhorteſt of all, or at the utmoſt, not exceeding the third pair in length. The ſpecies are theſe. 1. The ſlow moving crab ſpider, with a blue body and very ſmall purple eyes. This is of a middling ſize, and when in motion, has much of the appearance of a ſmall crab. The ſmall nimble crab ſpider, of a yellowiſh colour, but with a brown tip of the body. This is a very ſmall ſpider, and is of a brown colour, when viewed in the ſhade, but gilded when turned to the ſun.

LUPUS *aureus*, the *gold coloured wolf*, in zoology, the name by which Latin authors call the creature known in Engliſh by the name of the *jackall*.

LUPUS *cervarius*, in zoology, a name by which many authors have called the *lynx*, from its feeding on deer. See the article LYNX. See JACKALL.

LUPUS *marinus*, the *ſea wolf*, a voracious ſea fiſh, caught ſometimes in our ſeas, but more frequently in the Mediterranean, and very fierce and voracious. Its head is larger in proportion to its ſize, than that of the ſhark, and rounder. This, as alſo the back, ſides, and fins, are all of a blueiſh colour. The belly is white, the ſkin is ſmooth and ſoft, but his teeth ſo remarkably hard and ſtrong, that if he bites againſt an anchor of a ſhip, or other iron ſubſtance, they make a loud noiſe, and leave their marks in the iron. In the rim of his under jaw he has ten ſharp and round teeth diſpoſed in two rows, and twelve grinders on each ſide behind theſe, diſpoſed in the ſame manner in two rows. The upper jaw has twelve ſharp and round teeth before, and there are three orders or rows of grinders in his palate; the middle one conſiſting of twelve teeth, as the others, but having them larger than the human teeth, and running farther toward the jaw; and in the upper jaw he has two rough and ſharp bones; to which a rough part near the root of the tongue anſwers; and this like thoſe is beſet with ſharp teeth. *Willughby*'s Hiſt. Piſc. p. 130.

It has two fins like wings, ſituated juſt under the gills; each of two hands breadth long, and one long fin running from the head to the tail of four or five fingers broad, and another reaching from the anus to the tail.

LURE (*Cycl.*)—There are three things to be conſidered before the *lure* be ſhewn to a hawk newly reclaimed; the firſt is, that ſhe be bold and familiar in company, and not afraid of dogs or horſes; the ſecond is, that ſhe be very ſharp ſet and hungry, having regard to the hour of the morning and evening when ſhe is to be *lured*; and thirdly, ſhe muſt be clean within, and the *lure* muſt be well garniſhed on all ſides with meat, and when it is intended to give her the length of a leaſh, the falconer muſt abſcond himſelf: ſhe muſt alſo be unhooded, and a bit or two given her on the *lure* as ſhe ſits on the fiſt: after this the *lure* is to be taken from her and hid, then thrown upon the ground ſo near her that ſhe may catch it within the length of her leaſh, and as ſoon as ſhe has ſeized it, the falconer is then to uſe his voice, and then to feed her on the ground with the warm thigh of a pullet.

After this, by degrees, another perſon is to hold the hawk while the falconer holds the *lure*, and ſhe is to be taught to come to it for food. This is to be done at greater and

greater diſtances; and finally, when ſhe is accuſtomed to it alone it is to be done in company, taking great care that nothing fright her; and when ſhe is perfect in it on foot, ſhe is to be *lured* on horſeback.

LUSCINIA, the *nightingale*. See PHILOMELA.

LUSHBURGHS, or LUXENBURGHS, in our old writers, a baſe ſort of foreign coin, made of the likeneſs of Engliſh money, and brought into England in the time of Ed. 3. to deceive the king and his people: on account of which it was made treaſon, for any one willingly to bring any ſuch money into the realm, as knowing it to be falſe. Stat. 23 Ed. 3. 3 Inſt. 1. *Terms of Law.*

LUST, at ſea. If a ſhip *heel* either to ſtar-board or port the ſeamen ſay ſhe hath a *luſt* that way; and they ſay ſo, though it be occaſioned only by the ſhooting of her ballaſt, or by the unequal ſtowing of things in her hold; though it is more properly ſaid of a ſhip, when ſhe is inclined to heel any way upon the account of her mold or make.

LUSTRE, an appellation given to a branched candleſtic, when made of glaſs. See the articles BRANCH and JESSE.

LUSTRATION (*Cycl.*)—The manner of the Macedonians purifying their army by *luſtration* was this; at the time of their feſtival Xanthica, they divided a bitch into two halves, one of which, together with the entrails, was placed upon the right hand, the other upon the left; between theſe the army marched in this order: after the arms of the Macedonian kings, came the firſt line of the army, conſiſting of horſe; theſe were followed by the king, and his children, after whom went the life guards; then followed the reſt of the army: this done, the army was divided into two parts, one of which being ſet in array againſt the other, there followed a ſhort encounter, in imitation of a fight. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 417.

LUSTRICUS *dies*, among the antients, the day on which young children underwent the ceremony of *luſtration*, and received their names. Some will have it to have been the ninth day after their birth in males, and the eighth in females; but others make it the fifth day after their birth, and ſome the laſt day of the week. The ceremony was performed among the Greeks after this manner: the midwives, having firſt purified themſelves by waſhing their hands, ran round the fire-hearth with the infant in their arms, thereby, as it were, entering it into the family, and putting it under the protection of the houſhold gods, to whom the hearth ſerved inſtead of an altar; hence it had the name of *amphidromia*. See AMPHIDROMIA, *Cycl.*

It was celebrated as a feſtival with great expreſſions of joy; and they received gifts from their friends on this occaſion. If the child was a male, their door was decked with an olive garland; if a female, with wool, to ſignify the work women were to be employed about. *Potter*, Archæol. Græc. l. 4. c. 14. T. 2. p. 328. *Hofm.* Lex. in voc.

LUSTRUM (*Cycl.*)—The *cenſus* was accompanied always by a *luſtration* of the people, ſo the word, *luſtrum*, has conſtantly been taken by the antients and moderns for a term of five years: yet, if we enquire into the real ſtate of the caſe, we ſhall find no good ground for fixing ſo preciſe a ſignification to it; but, on the contrary, that the *cenſus* and *luſtrum* were, for the moſt part, held irregularly and uncertainly, at very different and various intervals of time, as the particular exigencies of the ſtate required. *Middlet.* of Rom. Sen. p. 107.

LUTATION, in chemiſtry, is uſed for the cementing of chemical veſſels cloſe together.

LUTEA, in natural hiſtory, the name of a ſpecies of fly found frequently near waters after rain; it is of a duniſh yellow colour, the wings are long, and the eyes large and prominent; the tail is thick, and has two hairs of a conſiderable length, growing at the head, ſo that it is of the biſetæ kind.

LUTEA is alſo a name by which ſome authors have called the *emberiza flava*, or *yellow hammer*. See the article YELLOW *Hammer*.

LUTEOLA, *dyers weed*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the polypetalous anomolaus kind, conſiſting of ſeveral irregularly ſized petals. The piſtil ariſes from the cup, and finally becomes a fruit, or ſeed veſſel, of a ſomewhat orbicular ſhape, terminating in three points, and containing roundiſh ſeeds.

The ſpecies of *luteola*, enumerated by Mr. Tournefort, are theſe. 1. The common or willow leaved *luteola*. 2. The little Portugal *luteola* with curled leaves. 3. The dwarf Pyrenean *luteola* with toad flax leaves. *Tourn.* Inſt. p. 423.

LUTEOLA, in zoology, a name given by many to a ſmall bird, called by others *aſelus*, and by others *regulus non criſtatis*; but this laſt is a name that has occaſioned ſome confuſion, as many have erroneouſly called our common wren the *regulus*, and as it has no creſt imagined it to be the bird meant by this name.

It is, excepting the creſted wren, the ſmalleſt of all European birds, and it very little exceeds that in ſize. Its head, neck, and back, are of a greeniſh brown; the rump is greener than the reſt. It has a yellow line on each ſide, extended from the noſtrils, beyond the eyes, to the hinder part of the head. The breaſt, throat, and belly, are yellow, with a very faint caſt of green. The wings and tail are brown, and all their feathers are tipped with green at their ends: the under part of the wings has much of a very fine green. The beak is extremely ſlender, and half an inch long. The mouth yellow within. It makes a loud noiſe, like that of the graſshopper, and is principally found among willows: it is continually creeping, and ſinging among the branches of trees. It builds with ſtraw and feathers, and lays five eggs, which are white, and ſpotted with red. There is a conſiderable variation in the colours of theſe birds; ſome of them being much greener on the back, and much whiter on the belly, than others. *Ray*'s Ornitholog. p. 164.

LUTRA, in zoology, the name given by authors to the otter, called by the Greeks, from his loving the water, ἔνυδρις, *enhydris*. See Tab. 1. of Quadruped, N° 19.

The otter is ſmaller than the beaver, and has a longer and more ſlender body. Its tail is alſo longer than that of the beaver, and is all over covered with hair; and its legs are very ſhort in proportion to the ſize of its body. The feet have all five toes each, which are naturally expanded, and are connected by a membrane like the toes of web-footed fowl; and are all ſo equally diſtant, that there is no diſtinction of any in the place of the great toe in other animals. The head and face exactly reſemble the beaver, and the ears are ſmall, and placed under the eyes, near the upper jaw, as in the beaver. The hair is ſhort, and of a cheſnut brown, but paler under the belly. The tail has ſhorter hair than that of the body, but longer than that of the legs. *Ray*'s Syn. Quad. p. 187.

In the Linnæan ſyſtem of zoology, the *lutra* makes a diſtinct genus of animals. The diſtinction of which, from thoſe quadrupeds to which it moſt approaches, is its feet being adapted to ſwimming. He makes two ſpecies of the *lutra*; the common otter, which he calls *lutra digitis equalibus*, and the *lutra pollice digitis breviore*. The firſt, the otter with all its toes of equal length; the ſecond, the otter with the great toe ſhorter than the reſt. *Linnæi*, Syſt. Nat. p. 36.

LUTTA, in botany, the name of a ſpecies of momordica. See MOMORDICA.

LUTUM, in botany, a name given by the antient Roman authors to a plant ſince called *luteola*, or dyers weed, and by authors of later date *carniola*, and *cymene*. It is uſed at this time to dye things yellow, and was ſo by the antient Greeks, who expreſsly mention the dying woollen cloaths with it. The Roman courtezans had alſo a way of dying their hair yellow with it, and hence the old verſe,

Sus immunda luto, *gaudet meretricula* luto.

This laſt *lutum* evidently means the yellow herb *lutea*, or *luteola*. Vitruvius calls it *lutea herba*, as does alſo Pliny; but Macer, and Paulus Ægineta, with ſeveral others, miſtaking it to be the ſame plant with the *iſatis*, or woad, call it *gioſda*, or *gueſda*. This is a common name of that plant, but can never belong to the *lutea*, unleſs blue and yellow can be proved to be the ſame colour; the woad *iſatis*, or *gueſda*, dying blue, not yellow. Neophytus is in the ſame error, and ſays that *iſatis* is the plant which the Romans called *lutea*. It is ſtrange alſo how this error, of confounding two plants ſo different in their nature and properties, has made its way to this time in the world. So far as the confuſion of names will carry it, we call the *luteola* in England ſometimes *dyers weed*, which is a very indeterminate name, and more uſually *wold*, or *woad*, the very names of the *iſatis*; and the Burgundians call it *guad*, the very name by which they call *woad*; though both they, and we, perfectly well know that they are different plants, and dye different colours. There is this alſo yet to be obſerved, that as we confound the herb *luteola*, and the *geniſta tinctoria*, together, under the name *dyers weed*; ſo others have done it under the names of *lutum*, *carniola*, &c. and it is plain that theſe words, as alſo the *cymene*, and *æcomene* of the Greeks, ſometimes expreſs the one, and ſometimes the other of thoſe plants. See LUTEOLA.

LUXATION (*Cycl.*)—LUXATION *of the ancle*. See the article ANCLE.

LUXATION *of the humerus*. Heiſter is of opinion, that the ſurgeon's hand and a napkin, with ſtrong and dextrous aſſiſtants to make the extenſion, and hold the patient firm, will of themſelves be generally ſufficient for the buſineſs. He ſeems to have no great opinion of the ambe of Hippocrates, nor of ſeveral other contrivances for this purpoſe. Vid. *Heiſt.* Surg. Vol. 1. p. 160, 163. See AMBE.

LUZZO *marino*, in ichthyology, a name given by the Italians to the fiſh called by the antient Greek writers, and many of the modern Latin authors, *ſphyræna*; and by Pliny, Varro, and ſome other of the old Roman authors, *ſudis*. Gaza has called it the *malleolus*, and the French, at this time, call it *ſpet*. It ſeems to belong to the genus of the *ſcombri*.

ſcombri. Salvian has given a figure of it, but it is an imperfect one; for he has omitted the firſt fin of the back. See the articles SPHYRÆNA and SUDIS.

LYCÆA, Λυκαια, in antiquity, an Arcadian feſtival reſembling the Roman *lupercalia*, in which the conqueror was rewarded with a ſuit of brazen armour. *Potter*, Archæol. Græc. lib. 2. c. 20. Tom. I. p. 412. See the article LUPERCALIA, *Cycl.*

LYCHNIS, *catch fly*, in botany, the name of a very large genus of plants, the characters of which are theſe. The flower is of the caryophylleous kind, being compoſed of ſeveral petals, diſpoſed in an orbicular form, and ariſing out of a tubular cup; and being uſually bifid, and ſurrounded with a ſort of circle of two or three ſmall leaves. The piſtil ariſes from the cup, and finally becomes a fruit, which terminates in a conic point, and is enveloped in the cup. This opens at the end when ripe, and is ſeen to contain ſometimes roundiſh, ſometimes angular, and ſometimes kidney-ſhaped ſeeds, affixed to a placenta. See Tab. 1. of Botany, Claſs 8.

The ſpecies of *lychnis*, enumerated by Mr. Tournefort, are theſe. 1. The great hairy ſcarlet *lychnis*, called the Conſtantinople *lychnis*. 2. The great hairy *lychnis* with fleſh coloured flowers. 3. The great hairy *lychnis* with ſaffron coloured flowers. 4. The great hairy *lychnis* with white flowers. 5. The great hairy *lychnis* with variegated flowers. 6. The great hairy *lychnis* with red lead coloured flowers. 7. The ſmooth ſoft leaved purpliſh red flowered *lychnis*. 8. The leſſer ſcarlet flowered Conſtantinople *lychnis*. 9. The pale red flowered garden *campion*. 10. The deep red flowered garden *campion*. 11. The crimſon flowered garden *campion*. 12. The white flowered garden *campion*. 13. The garden *campion* with flowers red within, and white without. 14. The garden *campion* with fleſh coloured ſpotted flowers. 15. The garden *campion* with fleſh coloured flowers, not ſpotted. 16. The double garden *campion*. 17. The Helvetian mountain *lychnis* with flowers in umbells. 18. The common white flowered ſingle wild *lychnis*. 19. The double flowered white *lychnis*. 20. The wild white *lychnis* with long and ſmooth leaves. 21. The white wild ſea *campion* with fleſhy leaves. 22. The green flowered proliferous wild *lychnis*. 23. The green flowered ocymaſtrum leaved wild *lychnis*. 24. The ſingle wild purple marſh *lychnis*. 25. The wild double red flowered *lychnis*. 26. The early procumbent purple *lychnis* with roundiſh leaves. 27. The larger *corn cockle*. 28. The *corn cockle* with yellow flowers, commonly called *yellow nigella*. 29. The red perfoliate leaved corn *lychnis*. 30. The perfoliate leaved corn *lychnis* with fleſh coloured flowers. 31. The perfoliate leaved corn *lychnis* with white flowers. 32. The common wild white *lychnis*, called *white ben*. 33. The double flowered *white ben*. 34. The wild *ben* with greeniſh purple flowers. 35. The narrower and more pointed leaved wild *ben*. 36. The ſmooth leaved purple flowered wild *lychnis*, or ſpatling poppy. 37. The alpine *ben* with roundiſh leaves and purple flowers. 38. The creeping ſea *lychnis*. 39. The ſhrubby myrtle leaved *lychnis*, reſembling the *white ben*. 40. The double flowered ſhrubby white *lychnis*. 41. The night flowering *campion*. 42. The ſweet ſcented narrow leaved night flowering *campion*. 43. The white flowered broad leaved viſcous mountain *lychnis*. 44. The *lychnis* called *the little white ocymoides*. 45. The ſmooth broad leaved purple viſcous *lychnis*. 46. The double flowered graſſy leaved *lychnis*. 47. The white flowered, broad leaved ſmooth viſcous *lychnis*. 48. The viſcous *lychnis* with flowers, purple on the outſide, and white within. 49. The viſcous *lychnis* with flowers, purple on the outſide, and white within, with ſmooth ſtalks and cups, and with the flowers diſpoſed in umbells. 50. The duſty leaved *lychnis* with narrow petals, purple on the outſide, and white within. 51. The clammy *lychnis* with ſlightly hoary leaves. 52. The viſcous hairy *lychnis* with fleſh coloured flowers. 53. The viſcous *lychnis* with larger moſſy barren flowers. 54. The viſcous *lychnis* with ſmaller moſſy fruitful flowers. 55. The leſſer moſſy leaved *lychnis*. 56. The auricula-like *lychnis*. 57. The larger woolly wild *lychnis*. 58. The ſmaller woolly wild *lychnis*. 59. The *lychnis*, commonly called *ſoap wort*. 60. The double flowered *ſoap wort*. 61. The meadow *lychnis* with jagged flowers. 62. The pale red jagged flowered meadow *lychnis*. 63. The jagged meadow *lychnis* with white flowers. 64. The jagged flowered meadow *lychnis* with large double purple flowers. 65. The jagged flowered meadow *lychnis* with large double white flowers. 66. The jagged flowered meadow *lychnis* with ſmall double flowers. 67. The wild broad leaved *lychnis* with turgid and ſtriated flower cups. 68. The narrow leaved wild *lychnis* with ſtriated turgid cups. 69. The procumbent Sicilian *lychnis* with extremely large turgid and ſtriated flower cups. 70. The wild *lychnis* with many leaves growing from every joint. 71. The red flowered narrow leaved viſcous wild *lychnis*. 72. The white flowered narrow leaved viſcous wild *lychnis*. 73. The broader leaved viſcous red flowered wild *lychnis*. 74. The narrow leaved hairy cretic *lychnis*. 75. The knot-graſs leaved mountain *lychnis*, called by many *ocymoides montanum*. 76. The dwarf graſſy leaved mountain *lychnis*, or *lychnis* flowered alpine moſs. 77. The dwarf graſſy leaved mountain *lychnis* with ſnow white flowers. 78. The procumbent ſea *lychnis* with very narrow and long leaves. 79. The long and hairy leaved *lychnis* with five petals, not bifid, in each flower. 80. The little hairy night flowering *lychnis*. 81. The daiſy leaved mountain *lychnis* with very ſmall pale red flowers. 82. The ſmalleſt moſſy flowered mountain *lychnis*. 83. The ſmooth leaved *lychnis* with very hard flower cups. 84. The wild hairy perennial *lychnis* with leaves like the Engliſh ſcurvy graſs, and very large flowers like the ſoap wort. 85. The little hairy annual *lychnis* with a ſmall fleſh coloured flower. 86. The round fruited *lychnis* with fleſh coloured flowers, ſtanding on long weak foot-ſtalks. 87. The red flowered ſmooth annual *lychnis* with oblong pyramidal capſules. 88. The wild white *lychnis* with a bending ſpike of flowers. 89. The little hairy *lychnis* with variegated flowers. 90. The fading flowered wild *lychnis*. 91. The night flowering *lychnis* with very ſmall flowers. 92. The little *lychnis* with red flowers and long narrow cups. 93. The little *lychnis*, called by many the *ſaxifrage* of the antients. 94. The little dwarf alpine ſtone *lychnis*. 95. The tall *lychnis* with numerous ſmall flowers, and toad flax leaves. 96. The flax leaved many flowered alpine *lychnis* with very large roots. 97. The ſmalleſt annual *lychnis* with fleſh coloured flowers, marked with purple lines. 98. The daiſy leaved annual Portugal *lychnis* with purple flowers. 99. The daiſy leaved annual Portugal *lychnis* with fleſh coloured flowers. 100. The lavender leaved *lychnis*. 101. The fleſhy leaved duſty ſea *lychnis*. 102. The willow leaved annual Spaniſh ſea *lychnis*. 103. The many flowered kali leaved Spaniſh *lychnis*. 104. The leaſt Pyrenean umbelliferous *lychnis*. 105. The naked ſtalked holoſteum leaved umbelliferous ſtone *lychnis*. 106. The Spaniſh *lychnis* with red valerian leaves and purple flowers. 107. The narrow leaved ſea *lychnis*. 108. The Portugal marſh *lychnis* with ſtriated cups. 109. The ſtinking viſcous Portugal mountain *lychnis*. 110. The capillaceous leaved Spaniſh *lychnis*. 111. The dwarf juniper leaved rock *lychnis*. 112. The little narrow leaved ſtone horned *lychnis*. 113. The fatty leaved ſea *lychnis*. 114. The upright ſpeedwell leaved *lychnis*.

The *lychniſes* differ from the *caryophylli*, or pinks, in that their flower cup is ſimple, not ſquammoſe at the bottom, as in the pink, and in the corona, which occupies the middle of the flower, and have angular kidney ſhaped ſeeds. *Tourn.* Inſt. p. 334, ſeq.

There are ſeveral ſpecies of this plant, which, for the beauty of their flowers, are cultivated in our gardens; they are very hardy plants, and are eaſily propagated either by parting the roots, or by ſeed.

The roots ſhould be parted in the latter end of Auguſt, or beginning of September, and planted in a light dry ſoil.

If they are to be raiſed from ſeed, they ſhould be ſown in March upon a bed of light freſh earth, and in May the young plants ſhould be removed into another bed of the like earth, at about ſix inches diſtance from each other, and watered and ſhaded till they have taken root; after which they will require no farther care, but to be kept clear from weeds; and at the end of the September following they may be removed, for the laſt time, into the borders where they are to ſtand, and they will flower in the June and July following; when, if they are ſuffered to ripen their ſeeds, they will ſow themſelves, and come up without any further trouble. *Miller*'s Gardners Dictionary.

LYCHNITES *marmor*, in the natural hiſtory of the antients, a name given by many to the Parian marble, of which the fineſt ſtatues among the antients were formed.

Varro imagines that it had this name from λυχνος, a lamp, becauſe, as he ſuppoſes, it was cut by candle-light in the quarries; but it ſeems much more probable, that it had it from the verb λυχνευειν, to ſhine, or be bright, from its remarkable ſplendor.

LYCIUM, in the materia medica, the name of a fruit called by the French *baye d'Avignon*, the Avignon berry, and by many authors the *pyxacantha*. The ſhrub which produces it, is the *lycium ſive pyracantha* of Gerrard. The fruit is about the ſize of a grain of wheat, and is not round, but of an angular form when dried, ſometimes of three, ſometimes of four angles, and ſometimes dented in at one end like a heart. It is of a yellowiſh green colour, and of a bitter and aſtringent taſte. It ſhould be choſen freſh dried, and large. There was formerly a rob, or inſpiſſated juice made from theſe berries, much in uſe in medicine; but this was generally adulterated with a rob made of the berries of the woodbind, privet, ſloe, or other ſhrub, and is now quite out of uſe. The dyers in France and Holland uſe it for a yellow; and the Dutch have another uſe for it, which is, that they boil it in alum water, and mixing it with whiting, form it into twiſted ſticks, which they ſell to the painters in water colours, under the name of *ſtil de grain*. *Lemery*, Dict. de Drog.

LYCODONTES, in natural hiſtory, the name given by Dr. Hill to thoſe foſſile bodies, called by the generality of authors *bufonitæ*. They have had this laſt name from an erroneous opinion of their being generated in the toad, but being now known to be the teeth of the *lupus piſcis*, or *wolf fiſh*, it is proper that they ſhould be called by another name. See Tab. of Foſſils, Claſs 8.

Many authors have taken theſe for mere ſtones, and the generality of writers have ranked them among the gems; but as they appear, on compariſon, to be the very ſame in ſhape and form, with the teeth of the recent jaws of this fiſh, and have been ſeveral times found yet remaining in the foſſile jaws, bedded in the ſtrata of ſtone; they certainly are the grinders, or *dentes molares*, of this fiſh, and not improbably ſome of them of other fiſh alſo.

The *lycodontes* are all of the ſame general figure, though of many varieties in the different degrees. The more common kind is rounded, riſing to an orbicular prominence at the top, and is hollowed within. Of theſe many reſemble a ſmall acorn cup, and their hollow is found commonly filled up with the matter of the ſtratum in which it is immerſed: this alſo is uſually the caſe in regard to the other kinds, but they are all ſometimes found alſo with their hollows empty. Another ſort of them are of an oblong figure, but rounded in the ſame manner with the others at the top. Theſe have by ſome been ſuppoſed to reſemble a ſmall boat in ſhape; and of theſe ſome are found of an equal diameter all the way, others are larger in the middle than elſewhere, and others at one end; ſome of them are alſo found remarkably raiſed in the middle, and ſome emulating a conic form. They are generally pretty deeply hollowed, but ſome are very little ſo, and ſome ſcarce at all; and ſome have been found hollowed at the top, as well as at the bottom. Many of them have an outer circle of a different colour from the reſt, and this is ſometimes ſtriated with very fine lines; ſome are found very long in proportion to their breadth, and in ſome degree reſembling the bodies called *ſiliquaſtra*; and finally, there are ſome perfectly round, but theſe are more rare.

The *lycodontes* are naturally of a fine poliſh, and are worn in rings for the ſake of their imaginary virtues, without any addition to this from the workman. Some of them have been found, however, a little rough and uneven, and ſome few ſtriated.

They are of various ſizes, from that of a pin's head, to ſuch as meaſure between two and three inches round, and are of a great variety of colours; ſome being black, others blueiſh, others brown; many of a light cheſnut colour, many of a liver colour, ſome of a reddiſh black, and ſome few whitiſh. They are moſt frequently of one ſimple colour in each, but ſometimes they are very beautifully mottled and variegated. The yellowiſh ones are often found irregularly variegated with black. Some of them are edged round with a circle of a different colour, and others have a beautiful ſpot in the center, ſurrounded with a number of circular lines; theſe are of all others the moſt elegant.

They are found in many parts of England, but more plentifully in Germany, and moſt of all ſo in the iſland of Malta. With us they are uſually bedded in ſtone; in Germany they are not unfrequently found bedded in a blue clay, and in Malta in the medicinal earth of that iſland, in which they lie in various cluſters, and are commonly called *ſerpents eyes*. *Hill*'s Hiſt. of Foſſ. p. 644.

LYCOGALA, in botany, a name by which Micheli has called ſeveral of the ſpecies of mucor, a kind of fungus conſiſting of ſmall bladders, with ſeeds on their inner ſurface affixed to capillary filaments. See MUCOR.

LYCOIDES, a term uſed by medical writers to expreſs the diſorders which ariſe in the human body by a long retention of the ſeed. Theſe are ſometimes madneſs, and very often dangerous quinſies and ſwellings, and inflammations about the neck and throat. If we conſider the natural tendency of the diſorders of this kind to affect the neck, and the remarkable ſwelling of the necks of bucks, and ſome other animals, at ruting time, it may give ſome rational hints towards underſtanding the alteration of the voice in boys who arrive at puberty.

Blancard derives the word *lycoides* from λυκος, *lupus*, and ειδος, *forma*, from a ſuppoſition that wolves are ſubject to this diſorder.

LYCOPERDON, *puff-ball*, in botany, the name of a genus of plants, the characters of which are theſe. The whole plant, while young, is of the fleſhy ſubſtance of the muſhrooms, but when ripe, it becomes hollow, and full of an extremely ſubtile powder.

The ſpecies of *lycoperdon*, enumerated by Mr. Tournefort, are theſe. 1. The great alpine *lycoperdon* with a lacerated bark. 2. The ſmaller *lycoperdon* with a lacerated bark. 3. The common orbicular *lycoperdon*. 4. The ſemi-orbicular *lycoperdon*. 5. The ſmall ſpherical cluſter *lycoperdon*. 6. The ſmall oval cluſter *lycoperdon*. 7. The ſmalleſt *lycoperdon* ſtanding on a pedicle. 8. The *lycoperdon* with a long ſcabrous pedicle. 9. The *lycoperdon* with a long tumid pedicle. 10. The greyiſh white pear faſhioned *lycoperdon*. 11. The white rough pear faſhioned *lycoperdon*. 12. The aſh coloured pear faſhioned *lycoperdon*. 13. The Virginian pear faſhioned *lycoperdon* with a ſpungy bottom. 14. The trifid Virginian *lycoperdon*. 15. The ſmooth, oblong and inwardly marginated *lycoperdon*. 16. The white ſphærical *lycoperdon*, variegated with brown ſcales. 17. The rough and warty ſphæric *lycoperdon*. 18. The blood red ſphæric *lycoperdon*. 19. The ſnow white ſphærical *lycoperdon*, with numbers of ſmall flat faces on the ſurface. 20. The white globular *lycoperdon* with a broad ſeſſile baſe. 21. The ſtinking oval *lycoperdon* placed croſswiſe, and without a baſe. 22. The ſmall warty *lycoperdon*. 23. The *lycoperdon* of the form of a chemical receiver. 24. The finger faſhioned *lycoperdon*. 25. The white club faſhioned *lycoperdon*. 26. The mortar faſhioned *lycoperdon*. 27. The ſtellated bladder *lycoperdon*. *Tourn.* Inſt. p. 563.

LYCOPERSICON, *woolf's peach*, or *love apple*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of a rotated form, and divided into ſeveral ſegments at the edge. The piſtil ariſes from the cup, and is fixed in the manner of a nail into the middle of the flower: this finally becomes a large, fleſhy, ſoft fruit, of a roundiſh figure, divided into ſeveral cells, and uſually containing flat ſeeds. The ſpecies of *lycoperſicon*, enumerated by Mr. Tournefort, are theſe. 1. The common *lycoperſicon*, called *mala aurea*. 2. The *lycoperſicon* with red fruit not ſtriated. 3. The yellow fruited *lycoperſicon*. 4. The white fruited *lycoperſicon*. 5. The pale fleſh colour fruited *lycoperſicon*. 6. The yellow cherry fruited *lycoperſicon*. 7. The red cherry fruited *lycoperſicon*. 8. The hard ſtriated fruited *lycoperſicon*, called by ſome *mala Æthiopica*. 9. The ſhrubby American *lycoperſicon* with large ſinuated leaves. *Tourn.* Inſt. p. 150.

The firſt ſpecies of this plant is cultivated in many of our gardens, and its fruit is eaten by the Spaniards and Italians, and by the Jew-families in England, as we do cucumbers, with oil and vinegar, or elſe ſtewed in ſoops. They are propagated by ſowing their ſeeds in March on a moderate hot-bed. When they come up, they are to be tranſplanted into another hot-bed of about the ſame temperature, where they are to be ſet at three inches diſtance. In this place they muſt be watered and ſhaded, and muſt have as much freſh air as may be; and in May they are to be tranſplanted into pots, or borders, and the branches, when they grow long, muſt be ſupported with ſticks, otherwiſe the fruit, when it grows large, will break them. They require frequent watering, and in Auguſt ripen their fruit, which grows to a large ſize, and makes a very pretty figure. But they ſhould not be planted near habitations, for the leaves and ſtalks, when rubbed by the clothes in people's paſſing by, yield a very ſtrong and very offenſive ſmell. *Miller*'s Gard. Dict.

LYCOPHTHALMUS, *the wolf's eye-ſtone*, a name given by ſome authors to ſuch pieces of agate, or any other ſemi-pellucid ſtone, as chance to have circular ſpots in them, reſembling in colour the eye of that animal.

LYCOPODIOIDES, in botany, the name of a genus of moſſes, the characters of which are theſe. It produces its ſeeds in ſpikes, in the manner of the *lycopodium*, or wolf's claw moſs, but that in two ways; for ſome of the capſules incloſe a powder, which ſeems only a farina; others ſeem to contain true ſeeds; theſe always ſtand to the number of three in each capſule. It differs from the *lycopodium* alſo, in its general appearance and manner of growth, the leaves being all placed in the ſame plane, and expanded in the manner of fins, with an intermediate ſeries of ſmall leaves, which cover the upper ſide of the middle rib, or ſtalk. Of theſe moſſes there are two orders; the firſt comprehends ſuch as are creeping, or procumbent.

Of theſe the following are all the known ſpecies. 1. The creeping ſcaly, or imbricated *lycopodioides*. This is found in ſhady and rocky places, but is not met with in England. It is the moſs called by many authors *muſcus denticulatus minor*, or the ſmall toothed moſs. Some have ſaid that they found it in England, but they all ſeem to have miſtaken ſome other ſpecies of moſs for it. 2. The creeping pinnated *lycopodioides* with birds foot leaves. This grows in Malabar, and the iſland of Ceylon. 3. The creeping denticulated *lycopodioides* with ſpikes ſtanding on ſlender pedicles. This is called *muſcus denticulatus*, and *muſcus denticulatus major*, by authors, and has been ſaid alſo to grow in England, but erroneouſly. It is frequent on the high mountains in Swiſſerland. 4. The creeping denticulated *lycopodioides* with footleſs ſpikes. This is found in ſhady places in Penſylvania, and other parts of North America. *Dillen*, Hiſt. Muſc. p. 469.

The ſecond order of the *lycopodioides* comprehends thoſe which are erect, or have ſome erect, and ſome procumbent, or creeping branches, with erect ſhoots riſing from them. Of this order the following are all the known ſpecies.

1. The ſhrubby *lycopodioides* with looſe and naked ſpikes. The leaves of this ſtand out in the manner of ſmall ſpines. It is a native of the Eaſt-Indies. 2. The larger upright fern-

fern-like *lycopodioides* with dentated leaves, and cylindric and very much branched ſtalks. This grows on the continent, as well as in the iſlands of America, in wet places. 3. The upright acacia leaved fern *lycopodioides* with ſulcated ſtalks. This is an Eaſt-Indian moſs, and is found in Malabar, and other parts. 4. The ſmall upright fern-like *lycopodioides* with denticulated leaves. This alſo is an oriental moſs, and is commonly brought from China. 5. The ſpleenwort-like *lycopodioides*, or *lycopodioides* with auriculated leaves. This alſo is found in the Eaſt-Indies. 6. The forked yew leaved *lycopodioides*. This is found in ſome parts of America. 7. The ſmaller forked ſtiff *lycopodioides* with denticulated leaves. This was found by Plumier in the iſland of St. Domingo. 8. The ſcaly *lycopodioides* with curled points. This is a native of the Eaſt-Indies. Id. Ibid. p. 473. See Tab. of Moſſes, N° 15.

LYCOPODIUM, in botany, the name of a genus of moſſes, the characters of which are theſe. It produces capſules in the alæ of certain leaves, which are very unlike the capſules of the other moſſes, having neither calypha, operculum, nor pedicle. Theſe do not ſtand as thoſe of the *felago*, in all the alæ of the leaves, but are collected together into a ſort of ſpike of a ſcaly ſtructure, and one capſule ſtands under every ſcale, or leaf. Theſe capſules are of the ſhape of a kidney, and when ripe, they ſeparate longitudinally into two parts, and throw out a powder, conſiſting of round globules. It has been ſuppoſed by many, that this powder is the farina of the flower; but as there are no ſeeds found in any other part of the plant for it to impregnate, it ſeems a much more probable opinion, that this powder, as well as that of the capſules of all the other moſſes, is the true and genuine ſeed of the plant. In moſt of the ſpecies of this plant, the ſpikes are compoſed of leaves of a different figure from thoſe of the reſt of the plant, and are therefore called ſcales; but in ſome they are made of leaves of the ſame figure with thoſe of the other parts of the moſs. See Tab. 2. of Botany, N° 14.

The firſt order of the *lycopodia*, according to Dillenius, conſiſts of thoſe which have their ſpikes ſupported on pedicles; and of theſe the firſt ſeries are diſtinguiſhed by the appellation of *juliferæ*, from their ſpikes reſembling the juli, or catkins of ſome trees, and being not of the ſame leaves with the reſt of the plant. Of theſe the following are all the known ſpecies. 1. The common *wolf's claw moſs*, or hairy rambling *lycopodium*. This has ſtalks of a vaſt length, and grows on heaths in many parts of England. 2. The creeping ſavin-like *lycopodium*, called by ſome cypreſs moſs, or heath cypreſs. This is very common in Yorkſhire, and ſome other parts of England, but not met with any where about London. 3. The long and round double forked *lycopodium* with finger'd arbor vitæ leaves. This creeps on the ground, and is found in many parts of North America. 4. The tall double ſquare forked *lycopodium*. This alſo is found in ſome parts of America. 5. The croſs broad leaved *lycopodium* with ſlender forked ſpikes. This is an Eaſt-Indian moſs, found in Malabar, and in the iſland of Ceylon. 6. The creeping pinnated *lycopodium* with long pedicles and ſpikes. This is the only ſpecies of the *lycopodia* whoſe ſpikes ſtand on pedicles, that has its leaves placed in the ſame plane. The whole, or compound leaves, are not more than an inch in length, and the pedicles of the ſpikes much longer. This was found by Mr. Cateſby in damp places in Carolina.

The ſecond ſeries of the *lycopodia* comprehends thoſe whoſe ſpikes conſiſt of leaves, the ſame with thoſe of the other part of the plant. Of this ſeries there are only two known ſpecies. 1. The ſhort creeping bag *lycopodium*, with ſingle erect clubs or ſpikes. This was firſt found by Mr. Ray on Hampſtead-heath, but has ſince been met with in many other parts of England. 2. The fox-tail *lycopodium* ſending roots from the ends of its branches.

The ſecond order of the *lycopodia* comprehends thoſe which have ſpikes not placed on pedicles. Of theſe there are only three known ſpecies. 1. The juniper leaved *lycopodium* with ſingle footleſs ſpikes. This is found on the Welch mountains. 2. The fine leaved curled ſhrub *lycopodium* with ſhort drooping clubs. This grows in the iſland of St. Helena and in the Indies. 3. The ſharp, ſquare ſpiked hoary, rock *lycopodium*. This grows on the rocks in Maryland and Penſylvania.

LYCOPSIS, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is a perianthium, divided into five broad, oblong, acute, and open ſegments, and remaining after the flower is fallen. The flower conſiſts of a ſingle petal in form of a cylindric and crooked tube; the rim of which is ſlightly divided into five ſegments, and is obtuſe. The opening is covered with five convex and prominent ſcales, converging one towards another. The ſtamina are five extremely ſmall filaments, placed at the bending of the tube of the flower. The antheræ are ſmall and covered. The piſtil has four germina. The ſtyle is ſlender, and of the length of the ſtamina; and the ſtigma is obtuſe and bifid. The cup is very large, and contains four oblong ſeeds. *Linnæi* Gen. Pl. p. 61.

LYCOPUS, *water hore hound*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of the labiated kind; but, in ſome degree, reſembles the bell faſhioned flowers; for the upper lip is ſcarce at all to be diſtinguiſhed from the lower, ſo that the flower appears at firſt ſight a tubular one, divided ſimply into four ſegments. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the lower part of the flower. It is ſurrounded by four embryos, which afterwards become as many ſeeds of a roundiſh form, and are contained in an open capſule, which was before the cup of the flower. *Tourn.* Inſt. p. 190.

The ſpecies of *lycopus* enumerated by Mr. Tournefort are theſe. 1. The ſmooth water *lycopus*. 2. The hairy water *lycopus*. 3. The cut leaved Canada *lycopus* with ſmooth leaves. 4. The water *lycopus*, with leaves very deeply divided into ſegments.

In the Linnæan ſyſtem of botany, the characters of this genus of plants are, that the cup is a monophyllous, or one leaved perianthium, tubulated and marked with five notches at the end, the ſegments all narrow and acute. The flower is compoſed of a ſingle petal in form of a cylindric tube, of the length of the cup, the margin of which is indented by four notches, and is obtuſe and ſpread open. The ſegments are all nearly equal in length, but the upper ſomewhat broader and rimmed round the edge, and the under narrower. The ſtamina are two filaments ſomething longer than the flower, and bent towards its upper ſegment: the antheræ are very ſmall. The piſtil has a quadrifid germen. The ſtyle is thread like ſtrait, and of the ſame length with the ſtamina. The ſtigma is bifid and bent backward. It has properly no fruit, the cup remaining after the flower is fallen, and containing in its bottom the ſeeds which are roundiſh, and four in number from each flower. *Linnæi* Gen. Pl. p. 7.

LYCOSTAPHYLÆ, *wolfs grapes*, in botany, a name given by ſome of the Greek writers to the *pomum amoris*, a kind of eſculent nightſhade, which we have much more properly called *lycoperſicon*, the *wolfs peach*; its fruit being as large as a peach, and in nothing reſembling a grape. Some of the Latin authors we find have called this *morella*; and ſome who have not underſtood this ſynonymous uſe of the word, have miſtaken the writers to have meant the muſhroom we call morell, when they preſcribe this plant in fevers. The ſeeds of this plant are, however, what are uſually preſcribed in this caſe, and there is no danger therefore of their ſubſtituting the morell muſhroom for it, if they will ſtick to the letter of the text; the ſeeds of that morella being too ſmall to be gathered in ſuch quantities as are preſcribed.

Æmilius Macer tells us, that the nightſhades, in general, were called by the name *morella* in his time: his words are *herbam quam Græci ſtrychnum dixere, Latini morellam dicunt.* The name *morella* ſeems to be formed upon the word *morion*, a name given both by the Greeks and Latins to one of the ſleepy nightſhades, and to the male mandrake, of Dioſcorides, which the ſhepherds were fond of eating; but which brought on ſleepy diſorders, if taken too largely.

LYCOSTOMUS, in zoology, the name of a fiſh caught in the Baltic, but not very frequently, and approaching ſomewhat to the nature of the herring or pilchard. It is uſually of five or ſix inches long, and ſo fat and fleſhy, that its body is not flat, as all the herring kind have theirs, but rounded. Its ſcales are very ſmall and looſe, eaſily falling off on rubbing. Its belly is white. Its ſides of a ſilvery brightneſs, and its back blackiſh. Its head is ſmall and pointed, and its upper jaw is longer than the lower, which is alſo ſharp, and falls into the upper as into a box. Its mouth is wide, and both the upper and lower jaw are furniſhed with ſharp but ſmall teeth. *Schonefeld* Hiſt. Piſc.

The name *lycoſtomus* is given by Ælian, and many other of the Greek authors to the *anchovy*, called by others the *encraulus* and *encrauſicholus*, and by the late writers *encraſicolus*. Artedi proves it to be only a ſpecies of the herring or clupea, and diſtinguiſhes it from the reſt by the name of the *clupea*, with the upper jaw longeſt.

LYCURGIA, Λυκουργία, in antiquity, a feſtival celebrated by the Spartans in memory of Lycurgus, whom they honoured with a temple, and an anniverſary ſacrifice. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 413.

LYDIAN, (*Cycl.*) in antient muſic, the ſecond ſpecies of the diapaſon. See DIAPASON.

LYDIUM *marmor*, a name given by the antients, not only to the black marble, uſed as a touch-ſtone to the trial of gold, &c. but alſo to another very different one brought from the ſame place; the ground of which was red, and the veins, which were very numerous, and uſually beautifully diſpoſed, were white. This was an elegant marble, and was uſed in moſt of the public buildings for pavements, and covering the inner ſide of the walls.

LYDIUS *lapis*, in the natural hiſtory of the antients, the name of the ſtone uſed by way of touch-ſtone for the trial of gold and ſilver, and called alſo by ſome *heraclius lapis*, both which names are alſo applied by the antients to the load-ſtone, and hence have ariſen no ſmall miſunderſtandings of their works. Pliny has obſerved, that both the load-

load-ſtone and touch-ſtone were, at times, called *lydius* and *heraclius lapis*; but Salmaſius cenſures him on this occaſion, and declares, that the load-ſtone never was called by the latter of theſe names: in this, however, that great critic errs; and Pliny, however often wrong, is there right; the antient Greeks having called it ſo, as appears from Theophraſtus, *&c.* *Hill*'s Theophr. p. 111.

The true *lapis lydius*, or touch-ſtone, was antiently found only in the river Tmolus, but afterwards it was diſcovered in many other places, and is now very common in many of the rivers of Germany. The antients give us very remarkable and circumſtantial accounts of the uſes they made of it, and it is plain they were able to diſcern the alloys in gold, by means of it, with a very great exactneſs. We at preſent uſe ſeveral different ſtones under this name, and for the ſame purpoſe; in Italy a green marble, called *verdello*, is what is moſt frequently uſed; and with us, very frequently, ſmall pieces of the *baſaltes*, the ſame with that vaſt maſs of black marble, called the *giant's cauſeway* in Ireland. See BASALTES and GIANT's *cauſeway*.

LYGDINUM *marmor*, in the natural hiſtory of the antients, the name of a ſort of alabaſter, which may properly be diſtinguiſhed by the name of the white kind. It is a very elegant and beautiful ſtone, of a whiteneſs greatly ſuperior both to the Parian marble ſo famed of old, and to the carrara of the moderns; and in ſplendor greatly ſurpaſſing all the marble claſs. It is of a looſe, rough, and ſhattery texture; and when broken, is ſeen to be compoſed of a multitude of broad, flat, and large particles, of a very bright, and perfectly white marble ſpar. It is always found pure and free from veins, and is moderately hard in the maſs, but eaſily crumbles in ſmall pieces; it is however eaſily cut, and takes a very high and elegant poliſh. It is found in immenſe ſtrata in Ægypt and Arabia, and is not uncommon in Italy. It is ſeldom found in large blocks, the ſtrata being from the nature of the ſtone ſubject to very frequent perpendicular fiſſures. And the antients give us the ſame account of it, and uſed it for making vaſes and other ornamental furniture. *Hill*'s Hiſt. of Foſſ. p. 490.

LYGDUS *lapis*, in natural hiſtory, a name given by ſome of the antients to the ſpecies of alabaſter, which others of them called *marmor lygdinum*, by which name it was moſt uſually known. See LYGDINUM *marmor*.

LYGON, in botany. See AGNUS *caſtus*.

LYGUS, in botany, is uſed for *agnus caſtus*. *Lemeri* Tr. des Drog. p. 19. See AGNUS *caſtus*.

LYING-*in-women*. The diſorders that attend *lying-in-women* are principally theſe. The ſuppreſſion, or immoderate flux of the lochia; the manner of curing which, ſee under the article LOCHIA. Inflammatory fevers are too common in theſe caſes, and uſually ariſe either from a retention of part of the ſecundines, a ſuppreſſion of the lochia, or taking cold; or finally, from violent paſſions of the mind, ſuch as anger, fear, joy, or the like. Theſe fevers very often prove fatal, if not carefully treated. The beſt method in them, is to give the ſaline medicines joined to the abſorbents, partly ſaturated with acids, and the uſual attemperating powders of nitre, and the like. The diſcuſſion of the cauſe is at the ſame time to be attempted by the mild alexipharmics, among which the cortex elutherii holds a principal place, and during the uſe of theſe, the patient is to be kept in a gentle breathing ſweat, during the courſe of the cure; the bowels muſt alſo be kept gently open, by means of mild ſuppoſitories, emollient glyſters, or the gentle laxative medicines in ſmall doſes. The miliary fever often alſo attends *lying-in-women*, the method of cure in which ſee under the article PURPUREA *febris*, and not unfrequently they fall into the *febris popularis*, diſtinguiſhed from the other by the broadneſs of the ſpots. This uſually goes off by the uſe of attemperating and abſorbent medicines, and a gently diaphoretic regimen; and finally, after about fourteen days, it is proper to carry off the remaining ſordes by ſome gentle doſes of rhubarb.

A bilious diarrhœa is often alſo a complaint at theſe times. This is eaſily brought on by violent paſſions, or by drinking cold liquors, or ſuch as are fæculent and fermenting; and ſometimes it ſucceeds a natural ſuppreſſion of a flux of blood. This often proves a very terrible and fatal ſymptom, being attended with violent pains, and an inflammation of the inteſtines, attended with an inflammatory fever, eſpecially when it continues longer than three or four days. In caſe of this ſymptom the method is to give abſorbent powders, ſuch as mother of pearl and the like; and after the matter has been corrected by this, and the other teſtaceous powders, as coral and crabs eyes, the bitter extracts of gentian, *&c.* are to be given to ſtrengthen the parts, and in the intermediate days ſmall doſes of rhubarb, and if it be neceſſary of opiates, or other anodynes carefully corrected. Aſtringents and an improper uſe of opium are very dangerous, and it is always proper to drink a large quantity of warm diluting liquors: if it be found neceſſary to give nitre, it muſt be mixed in ſmall quantities with theſe liquors.

Flatulencies are alſo very common to women in child-bed, from improper diſcharges of the *lochia*; theſe are cured by giving internally the common abſorbents with calx of antimony, oil of ſweet almonds, aniſated ſpirit of ſal armoniac, eſſence of orange peel; and, in people of hot habits, nitrous medicines, and the *ſpiritus nitri dulcis*, with carminative broths, with a ſmall quantity of ſaffron boiled in them.

After Pains are the greateſt of all the complaints of *lying-in-women*, and withal the moſt common; theſe ſometimes ariſe from difficult labour; ſometimes from ſome part of the ſecundines being left, or from blood coagulated in the uterus; they alſo frequently ariſe from the improper evacuation of the lochia, whether they be too much, or too little in the quantity; alſo from cold; from neglecting the proper binding or ligature of the abdomen after delivery; and finally, from the infant's ſucking too violently while the mother is weak.

Theſe pains are greatly mitigated by the carminative, aromatic and nervous medicines; ſuch are the tincture of orange peels, zedoary, angelica root, and camomile flowers. Caſtor is to be particularly avoided in this caſe. Candied nutmegs are a very good medicine in it, and carminative broths; with the diſtilled waters of penny royal, baum, cinnamon, and the like. Externally fomentations may be uſed at the ſame time, made of decoctions of roſemary, mint, elder flowers, and bay berries; and the common carminative clyſters are often of the utmoſt ſervice; and finally, the carminative oils, as that of caraway, and the like, may be rubbed on the pit of the ſtomach.

Theſe pains ſeldom happen to women in their firſt *lying* in; but they are not wholly exempt from them, for ſingular inſtances happen of their violence in thoſe caſes

Swelling of the belly. This is another very common complaint with women after their *lying* in; and uſually is owing to the neglecting the proper ligatures about the abdomen after delivery. The cure for this is to be found in carminatives and reſolvents, which firſt of all cleanſe the womb from all its foulneſſes, and afterwards reſtore it to its due tone. Bryony and hellebore roots in various forms, as alſo the leaves of betony, origanum and chervil ſerve to this purpoſe; and Stahl's or Becker's pills are of the moſt ſingular ſervice, but all theſe things are to be uſed for ſome time.

Swelling of the pudenda. This is a ſymptom that uſually takes its riſe from difficult delivery; and beſide the pain, and other inconveniences attending it, uſually brings on a dyſury. The proper remedies are ointments of elder and of marſhmallows, with the camphorated white ointment, commonly called by the good women ſimply unguentum. Bags of camomile flowers, with linſeed, and a little camphor, boiled in milk, and then lightly ſqueezed, are alſo of great ſervice. When the dyſury continues after the ſwelling is taken down, it is then to be treated in the common way. When there is any actual wound in the parts, the liquor of myrrh, or oil of eggs, and other balſams are to be uſed, but all fatty ſubſtances are to be carefully avoided, as they uſually occaſion tumors.

Proper treatment of lying-in-women. As ſoon as ever they are delivered, they are to be put immediately into a warm bed, and the belly wound round with a broad ſwathe or roller; they are then to be kept with the utmoſt care from external cold; for the ſweats, on the one hand, and the lochia on the other, make them extremely ſuſceptible of miſchief that way; and the conſequence is a ſuppreſſion of the lochia with fevers of a very dangerous kind, tumors of the abdomen, and many other terrible complaints. They are then to be kept extremely quiet, and if they are not in danger of fainting they are to be ſuffered to ſleep as ſoon as poſſible; but if there be any ſuſpicion of fainting, they muſt be kept awake three or four hours after delivery. Their ſtrength is then to be reſtored by broths of tender meats, as chicken, or the like, and by caudles. And the uſe of jellies, as of hartſhorn, and the like, is to be freely indulged. After the fourth day, when the painful buſineſs of the milk is over, they may be indulged with good wine, drank alone, in moderate quantities. The heat of the room is to be all the time preſerved as equally as may be; and they are to be allowed to drink as much warm liquors as they pleaſe, but they muſt not touch any cold ones. The ſeveral excretions are carefully to be regarded, and eſpecially the lochia. Great care muſt be taken that this diſcharge is not rendered too great by means of hot medicines, or a too hot regimen, nor ſuppreſſed by a cold regimen, or by the cold air. A gentle ſweating is to be encouraged, and promoted during the whole time; and even, if this become very conſiderable, in people of corpulent habits, it is not to be checked. Coſtiveneſs, during the two or three firſt days, is not to be regarded, for the vital principle is at that time ſo much engaged in the ſecretions of the lochia and milk, that it is no wonder if the bowels are leſs ſtimulated. No means are to be uſed to irritate the bowels in this time, nor ſhould the ſtomach be loaded with ſolid foods. After theſe firſt days are over, if the coſtiveneſs remains, it is proper to give glyſters at times, to make the patient take lubricating foods, and now and then ſwallow a little oil of ſweet almonds. All paſſions of the mind are to be avoided in the moſt careful manner, and all occaſions of them kept from the

the patient. Fear is often known to ſtop the lochia, and anger to bring on hæmorrhages of a dangerous kind, and ſometimes fevers and bilious diarrhœas, and both often throw the patient into faintings. The light is to be kept out of the room in a great meaſure; for it often happens, that the ſight is much impaired, and the eyes weakened in tender perſons; and ſometimes noiſes and ringing in the ears, ſometimes deafneſs is brought on.

Talking much is very improper in theſe caſes, as it eaſily throws the blood into commotions; and it is to be carefully obſerved, that when the exceſſive flux of the lochia has rendered the patients very weak, and often ſubject to faintings, they are by no means to be indulged in that ſleepineſs which uſually grows upon them at this time; for they ſometimes die in ſuch ſleeps. Bags of carminative ingredients are very properly applied to the abdomen, during the firſt days of *lying in*, for they greatly prevent flatulencies; and it is a very good cuſtom, of ſome people, to apply cloths wetted in wine to the pudenda, when ſwelled, or otherwiſe injured in delivery. In young people, eſpecially thoſe of plethoric habits, all hot things are to be avoided, and wine is to be uſed with great caution and circumſpection. If the blood is on any occaſion thrown into commotions, abſorbents, and nitrous medicines are proper: when the perſon is of a weak conſtitution, ſhe is not to be ſuffered to get out of bed until the firſt nine days are over, and not to leave her room until a month, or until five or ſix weeks are over, and then it is proper to give a doſe or two of ſome gentle purge. *Junker*'s Conſp. Med. p. 727, ſeq. See the articles DELIVERY, MOLA and LOCHIA.

LYLAC, in botany. See the article LILAC.

LYMPHÆA, among the Romans, a kind of grotto's, or artificial caves, ſo called from *lympha*, water; becauſe they were furniſhed with a great many tubes, canals, and ſecret paſſages, through which the water ſuddenly guſhed upon the ſpectators, while buſy in admiring the great variety and beautiful arrangement of ſhells, with which the grotto was adorned. *Pitiſc.* in voc.

LYNCIS *lapis*, in natural hiſtory, the name given by moſt of the writers of the middle age to the belemnites. See the article BELEMNITES.

LYNCURIUS *lapis*, in the natural hiſtory of the antients, the name of a ſtone about which there have been various diſputes among the later writers. Theophraſtus has left us this account of it; that it was hard, and uſed for engraving ſeals on, and was of a very ſolid texture like the gems; that it had an attractive power like amber, and was pellucid, and of a flame colour.

The firſt, and moſt generally received opinion about this ſtone is, that it was what we call the *belemnites*, or thunderbolt. This is the opinion of Woodward, *&c.* but from the account we find of it in Theophraſtus, this opinion is very plainly erroneous. A belemnites could never be called a proper ſtone for engraving ſeals on; nor is it by any means of a ſolid texture, as the ſtones or gems, but compoſed of a number of thin cruſts, made up of tranſverſe ſtriæ, and no harder than ſpar, being eaſily cut, or ſcraped with a knife: this therefore muſt be allowed an erroneous opinion.

The few who diſſent from this opinion, of the belemnites being the *lapis lyncurius* of the antients, of which number are Geſner, Geoffroy, *&c.* hold, that amber is the ſubſtance which was called by the antients by that name. But we find this could never be the caſe, becauſe Theophraſtus, in the account we have quoted from him of the *lyncurius*, compares it in ſome degree to amber, and obſerves, that it had an attractive power like that of amber. It is not to be ſuppoſed that any author could intend to compare a thing to itſelf, and conſequently Theophraſtus plainly aſſures us, that the *lapis lyncurius* was not amber.

All that the antients have ſaid about it, determines that it was really one of the gems, and that it was of a flame colour; and this deſcription agrees perfectly with the gem we call the hyacynth, and this doubtleſs was the ſtone they knew by that name; ſince it is plain, by the antique heads we ſee cut in it, that it was in common uſe among them; and it is plain from all their writings, that they did not know it by any other name: what they called the hyacinth being a very different ſtone, and one to which that name much more properly belonged, being a bluer amethyſt than the common kind, and ſomewhat reſembling the colour of the hyacinth flower. The antients have ſpoken of three or four kinds of it, that is, three or four varieties in degree of colour; and we alſo, at this time, are acquainted with the very ſame varieties. What they called the male and female *lyncurius*, were plainly our deeper and paler hyacinth; and the fine *lyncurius*, deſcribed by Pliny, our hyacintha la bella. *Hill*'s Theophraſt. p. 75. See the article HYACINTH.

LYNX, in zoology, the name of a very fierce beaſt of prey called in Engliſh the *ounce*, and by many Latin authors the *lupus cervarius*, or dear wolf, from its loving to feed on deer. See Tab. of Quadrupeds, N° 4.

Pliny ſeems to diſtinguiſh the *lynx* from the *lupus cervarius*, but there ſeems not the leaſt reaſon for it. The principal colours of this creature are a whitiſh, and a purpliſh yellow, variegated with numerous very beautiful round ſpots like eyes, in the manner of the *leopard*; theſe are uſually black. Sometimes it is ſeen alſo of a plain fox colour on the back, and full of black ſpots, and grey on the belly, and inner part of the legs, with the like ſpots as on the back and ſides, but larger, of a ſomewhat paler colour, and fewer in number.

The hairs of this creature, as well ſuch as appeared reddiſh, as thoſe which were grey, when nicely examined, are all found to be truly of three colours in each ſingle hair; the middle part being of a reddiſh tawney, the bottom grey, and the top white; but thoſe which compoſe the black ſpots are only of two colours, there being no white at their ends.

This creature's eyes are extremely bright and vivid, and ſhew plainly that it has a very piercing ſight. Its ears are like thoſe of a cat, but have this peculiarity, which diſtinguiſhes the creature from all the animals of the ſame claſs; they have a fine pencil of black hairs growing out at their extremities, very ſmooth, and of a deep black like velvet, and two fingers long. Its tongue is rough like that of the lion. The *lynx* is found wild in Italy and Germany, but the greater number are in Aſia, and theſe are much finer coloured than the Europæan. They all differ conſiderably from one another, at times, in the number and diſpoſition of their ſpots. *Ray*'s Syn. Quad. p. 166.

LYRA, (*Cycl.*) in ichthyology, the name of a fiſh of the cuculus, or gurnard kind, of which there are two ſpecies. The one the *tibicen*. See the article TIBICEN.

The other the *lyra cornuta*, or horned harp fiſh. This laſt is a fiſh of an octagonal form, covered all over with bony ſcales: theſe are of a rhomboidal figure, and each has in its middle a ſharp and ſtrong prickle bending backwards. There are in reality only ſix orders, or ranges of theſe ſcales, but to a ſlight obſerver they appear eight, two being larger than the reſt, and appearing double. It is of a red colour, and its head is very large. Its ſnout divides toward the extremity into two long horns, on which are placed two perpendicular ſpines, and a third above makes an acute angle with theſe. It has one very long fin on the back, and another anſwering to it behind the anus; alſo two large ones at the gills, and two ſmaller on the belly. It has only two filaments, called fingers, behind its gill-fins. Its mouth is large, but has no teeth, and there are ſeveral beards on its under jaw; two of which are longer than the reſt, and are branched. It is caught in the Mediterranean, and brought to market at Rome. It is a ſcarce fiſh in other places, and at Montpelier was once ſhewed to Mr. Ray for the *remora*. See Tab. of Fiſhes, N° 45. *Geſner* de Piſc. p. 610.

LYRA is alſo the name of a beautiful ſea ſhell of the genus of the *concha globoſa*, or dolium. There are three ſpecies of the *lyra*, or harp ſhell. 1. The common *lyra*, which has thirteen roſe coloured ribs running along its body. 2. The eleven ribbed *lyra*. And 3. the noble harp, or *lyra nobilis*. This is a moſt elegantly variegated ſhell; its ground colour is a deep brown, and its variegations very elegant and black.

LYRATUM *folium*, among Botaniſts. See LEAF.

LYRODI, among the antients, a kind of muſicians who played on the lyre, and ſung at the ſame time. See the article LYRE, *Cycl.*

LYRODI was alſo an appellation given to ſuch as made it their employment, to ſing lyric poems compoſed by others. *Pitiſc.* in voc.

LYSANDRIA, λυσανδρια, in antiquity, a Samian feſtival celebrated with ſacrifices and games, in honour of Lyſander the Lacedæmonian admiral. It was antiently called *herea*, which name was aboliſhed by a decree of the Samians. *Potter*, Archæol. Græc. l. 2. c. 20. Tom. I. p. 413.

LYSIMACHIA, *willow herb*, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe. The cup is an erect perianthium divided into five ſegments, and remaining after the flower is fallen. The flower conſiſts of a ſingle petal, which forms no tube, but is divided into five oval oblong ſegments at the edge. The ſtamina are five tapering filaments cohering together at their baſe: theſe are but of half the length of the flower. The antheræ are pointed; the germen of the piſtil is roundiſh; the ſtyle is ſlender, and of the length of the ſtamina; the ſtigma is obtuſe. The fruit is a globoſe capſule, containing only one cavity, which has ten valves. The ſeeds are very numerous, and of an angular figure. The receptacle is globoſe, very large, and dotted. *Linnæi*, Genera Plant. p. 65.

The characters of *lyſimachia*, according to Tournefort, are theſe. The flower conſiſts of one leaf, and is rotated, and divided into ſegments at the edge. The piſtil ariſes from the cup, and is fixed into the lower part of the flower, in the manner of a nail, and afterwards ripens into a ſhell, or fruit, nearly of a globular figure, and opening

at

at the end, is ſeen to contain many ſeeds affixed to a placenta.

It is to be obſerved, that the word *willow herb* with us is the name of ſeveral different genera of plants, as is alſo the *lyſimachia* with many authors. It is here reſtrained to the yellow *willow herb* alone; but takes in alſo what our authors have erroneouſly accounted a diſtinct genus of plants, and called *nummularia*, or money wort, from the roundneſs of the leaves of the common kind, which reſemble pieces of money.

The ſpecies of *lyſimachia*, thus aſcertained, are theſe. 1. The common great yellow *willow herb*. 2. The yellow *lyſimachia* with leaves growing three at a joint. 3. The yellow *lyſimachia* with leaves four at a joint. 4. The yellow *lyſimachia* with leaves five at a joint. 5. The great five leaved *lyſimachia* of America with double yellow flowers. 6. The leſſer yellow *willow herb* with leaves ſpotted with black. 7. The three leaved yellow *lyſimachia* with ſpiked flowers. 8. The two leaved yellow *lyſimachia* with globular tufts of flowers. 9. The white flowered ſpiked willow leaved *lyſimachia*, called by ſome authors *ephemerum*. 10. The procumbent ſpreading ſmall round leaved *lyſimachia*, called *nummularia lutea*, or yellow moneywort. 11. The round leaved ſpreading procumbent *lyſimachia* with purple flowers, called *purple moneywort*. 12. The low ſpreading yellow *lyſimachia* with roundiſh, but pointed leaves, commonly called *anagallis lutea nemorum*, yellow pimpernel of the woods. And 13. the ſmall annual knotgraſs leaved *lyſimachia*, called *linum ſtellatum minimum* by Caſpar Bauhine.

Authors have called alſo ſeveral other plants by this name, which properly belong to other genera.

Of the number of theſe are the *lyſimachia lutea corniculata*, or horned yellow *willow herb*, which is a ſpecies of onagra. 2. The ſpecies of ſiliquoſe, or podded *willow herbs*, which are properly chamerions. 3. The purple ſpiked *willow herb*, which is a ſpecies of ſalicaria. 4. The blue ſpiked *willow herb*, which is a kind of veronica. 5. The headed *willow herb*, which is a ſpecies of caſſia. *Tourn.* Inſt. p. 141.

LYSIMACHIA *worm*, in natural hiſtory, a name given to an inſect found very frequently feeding on the leaves of the *lyſimachia*, or willow herb. It has uſually been eſteemed a caterpillar, but is properly one of the fauſſe chenilles, having a rounded head, and twenty two legs. This creature changes its ſkin ſeveral times, and finally changes its colour with it. It is at firſt of a blueiſh grey, but on its laſt change in the worm ſtate, it becomes of a yellowiſh green. When it has lived a week, or thereabout, after this laſt change, it becomes a chryſalis, from which there afterwards comes out a four winged fly. *Reaumur*'s Hiſt. Inſect. Vol. 9. p. 18.

LYSSA, a word uſed by medical authors to expreſs that ſpecies of madneſs which is peculiar to dogs and wolves, but is communicated by their bite to man and other animals. Hence perſons, labouring under the diſmal effects of ſuch a bite, are called alſo *lyſſodecti*.

LYTHRUM, in botany, a name by which Linnæus calls a genus of plants, named by Tournefort, and other Authors, *ſalicaria*. *Linnæi* Gen. Pl. p. 208. See SALICARIA.
